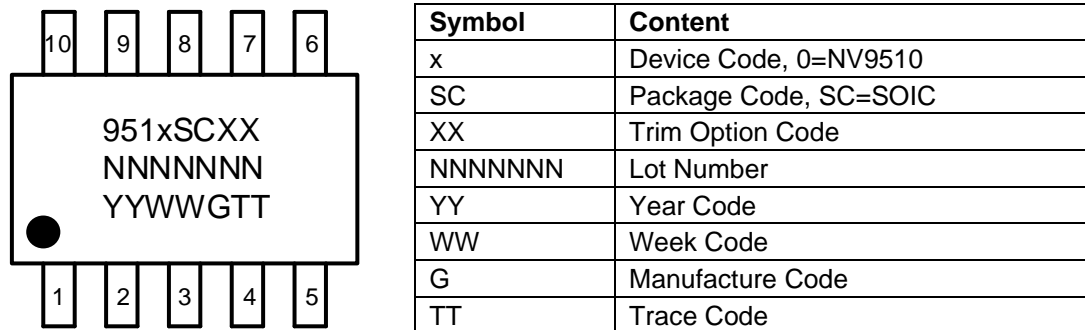

Figure 3. Pin Configuration (Top View)

Pin Names and Descriptions

Pin No.	Name	Description
1	VDD	Power Supply. IC operation current is supplied through this pin. Typically, this pin is connected to external V _{DD} capacitor. The device starts to operate when V _{DD} exceeds V _{DD_ON} .
2	FB	Feedback. Input for the internal PWM comparator.
3	SD	Shut Down. Typically, this pin is connected to a NTC thermistor. The device enters the fault mode if the voltage on this pin is pulled below the fault thresholds.
4	GND	Ground.
5	DMAG	Demagnetization Sense. This pin is used to detect resonant valleys for QR switching. It also detects the output voltage information, as well as the input voltage information for Brown-in & Brown-out protection.
6	CS	Current Sense. This pin detects the power FET current cycle by cycle when connected to a current-sense resistor.
7	DRV	Gate Drive Output. This pin is connected to the gate to drive power FET
8	VREG	LDO Output. Typically, this pin is connected to an external capacitor.
9	NC	Not Connect.
10	HV	High Voltage Startup. This pin is the input for the high voltage startup. It can connect to X-cap for X-cap discharge function(option).

9. Specifications

9.1 Absolute Maximum Ratings⁽¹⁾

Stresses exceeding the absolute maximum ratings may damage the device. The device may not function or be operable above the recommended operating conditions and stressing the parts to these levels is not recommended. In addition, extended exposure to stresses above the recommended operating conditions may affect device reliability. The absolute maximum ratings are stress ratings only.

Symbol	Parameter		Min.	Max.	Unit
V _{HV}	HV Pin Input Voltage		-0.3	700	V
V _{AUX}	AUX Pin Input Voltage		-0.3	30	V
V _{ST}	ST Pin Input Voltage		-0.3	30	V
V _{VDD}	VDD DC Supply Voltage		-0.3	80	V
V _{DRV}	DRV Pin Output Voltage		-0.3	12	V
V _{CS}	CS Pin Input Voltage		-0.3	5.5	V
V _{FB}	FB Pin Input Voltage		-0.3	5.5	V
V _{DMAG}	DMAG Pin Input Voltage		-0.3	5.5	V
V _{SD}	SD Pin Input Voltage		-0.3	5.5	V
V _{REG}	VREG Pin Output Voltage		-0.3	13.5	V
θ _{JA}	Thermal Resistance (Junction-to-Ambient) SOIC-10			158.3	°C/W
θ _{JC}	Thermal Resistance (Junction-to-Case) SOIC-10			95.6	°C/W
T _J	Operating Junction Temperature		-40	150	°C
T _{STG}	Storage Temperature Range		-40	150	°C
T _L	Lead Temperature (Soldering) 10 Seconds			260	°C
ESD	Electrostatic Discharge Capability	Human Body Mode, ANSI/ESDA/JEDEC JS-001-2017 (Including All Pin)		2.0	kV
		Charge Device Mode, ANSI/ESDA/JEDEC JS-001-2018		2.0	kV

Notes (1):

- Stress beyond those listed under absolute maximum ratings may cause permanent damage to the device.

9.2 Recommended Operating Conditions⁽²⁾

The Recommended Operating Conditions table defines the conditions for actual device operation. Recommended operating conditions are specified to ensure optimal performance. Elevation does not recommend exceeding them or designing to Absolute Maximum Ratings.

Symbol	Parameter	Min.	Typ.	Max.	Unit
V _{HV}	HV Pin Supply Voltage	-0.3		450	V
V _{VDD}	VDD Pin Supply Voltage	-0.3		75	V
V _{CS}	CS Pin Supply Voltage	-0.3		5	V
V _{FB}	FB Pin Supply Voltage	-0.3		5	V
V _{DMAG}	DMAG Pin Supply Voltage	-0.3		5	V
V _{SD}	SD Pin Supply Voltage	-0.3		5	V

Notes (2):

- Functional operation of the device at these or any other conditions beyond those indicated under recommended operating conditions is not implied, exposure to absolute maximum rated conditions of extended periods may affect device reliability. All voltage values are with respect to the normal operation ambient temperature range is from -40°C to +125°C unless otherwise noted.

9.3 Electrical Specifications

10. Function Description

The following functional description contains additional information regarding the IC operating modes and pin functionality.

Basic Operation

NV9510 family ICs are offline Flyback controllers which operate in quasi-resonant (QR) mode and significantly enhance system efficiency and power density. It regulates the output based on the load condition through opto-coupler feedback circuitry.

The QR resonant frequency is determined by the the transformer magnetizing inductance (L_m) and the primary side effective capacitance ($C_{oss-eff}$).

$$C_{oss-eff} = C_{oss-FET} + C_{parasitic} + C_{transformer} \quad (\text{Equation 1})$$

$$t_{resonance} = 2\pi\sqrt{L_m \times C_{oss-eff}} \quad (\text{Equation 2})$$

For the heavy load condition (e.g. 50%~100% of full load), the blanking time for the valley detection is fixed such that the switching time is between $1/f_{S_BNK_MAX_LL(HL)}$ and $1/f_{S_BNK_MAX_LL(HL)} + t_{resonance}$ as shown in Figure 19. The primary side peak current is modulated by the feedback voltage. For the medium load condition (e.g.25%~50% of full load), the blanking time is modulated as a function of load current such that the upper limit of the blanking frequency varies from $f_{S_BNK_MAX_LL(HL)}$ as load decreases. The blanking frequency reduction stop point is f_{S_TMO} . For the light load condition (e.g.5%~25%), the blanking time is fixed such that the switching time is between $1/f_{S_TMO}$ and $1/f_{S_TMO} + t_{resonance}$ and the primary side peak current is modulated by the function of V_{CS_MIN} modulation, as shown in Figure .

NV9510 family ICs also have ability to operate in CCM. When the device enters CCM, the maximum blanking frequency is limited at $f_{S_BNK_MAX_CCM}$.

Figure 17 Frequency Fold-Back Operation

Burst Mode

As shown in Figure 18, when feedback voltage V_{FB} drops below $V_{FB_BST_ENT}$ at light load, the PWM output shuts off and the output voltage drops at a rate depending on the load current level. Thereafter, feedback voltage V_{FB} rises. Once V_{FB} exceeds $V_{FB_BST_EXT}$, NV9510 family products resume switching and the switch peak currents is limited by V_{CS_MIN} . If more power is delivered to the load than required, V_{FB} voltage will decrease. Once V_{FB} voltage is pulled below $V_{FB_BST_ENT}$, switching stops again. In this manner, the burst mode operation alternately enables and disables switching of the FET to regulate the output and in the meanwhile reduce the switching losses.

Figure 18 Burst Mode Operation

Deep Green Mode

NV9510 family ICs enter the deep green mode if V_{FB} voltage stays below $V_{FB_BST_ENT}$ for more than t_{D_DPGN} (480 μ s). In the deep green mode, the IC operating current is reduced to I_{DD_DPGN} (300 μ A) to minimize power consumption. IC resumes switching with normal operating current I_{DD_OP} once V_{FB} voltage rises above $V_{FB_BST_EXT}$.

Valley Detection

NV9510 family valley detection is achieved by monitoring V_{DMAG} voltage, which is the divided auxiliary winding voltage by R_{DMAG1} and R_{DMAG2} as shown in Figure . One ceramic capacitor (C_{DMAG}) less than 10 pF is recommended to filter out the noise if PCB noise coupling is observed.

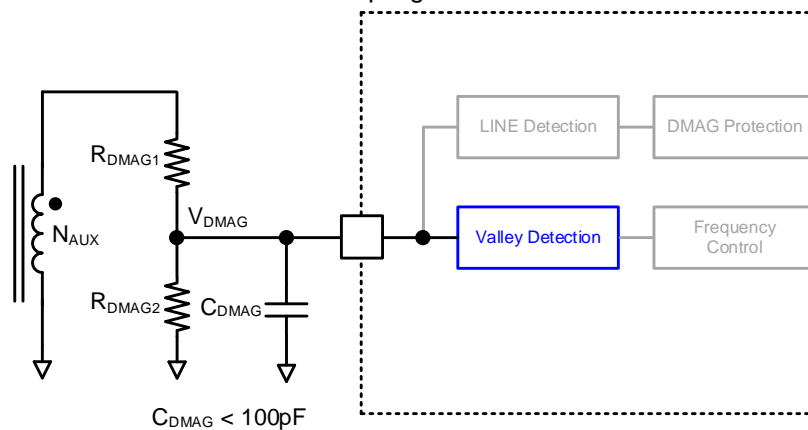

Figure 19 Valley Detection Circuit

Inherent Frequency Jitter

In Flyback application, the DC ripple (ΔV_{DC}) of bulk capacitor at the low line application is larger than at the high line application as shown in Figure . This large DC ripple will result in switching frequency variation for a valley switched converter. The frequency variation scatters EMI noise over the nearby frequency band, allowing compliance with EMI requirement easily. Therefore, the EMI performance at the low line application is easy to comply with EMI limitation naturally. However, at the high line application, the DC ripple is relatively small and consequently the EMI performance may suffer. To maintain good EMI performance across over the universal input, a frequency jitter is implemented in the NV9510 family products.

Figure 20 Inherent Frequency Jitter

Output Voltage Detection

Figure shows the DMAG voltage ($V_{DMAG-S/H}$) is sampled at the end of t_{DMAG_BNK} to avoid sampling error. The DMAG voltage should be set based on the transformer turn ratio, the voltage divider resistors R_{DMAG2} & R_{DMAG1} and the specified IC parameter DMAG sampling normalization ratio, $Ratio_{DMAG}$ (0.16).

$$Ratio_{DMAG} = \frac{V_{DMAG-S/H}}{V_O} = \frac{N_A}{N_S} \times \frac{R_{DMAG2}}{R_{DMAG1} + R_{DMAG2}} = 0.16 \quad \text{(Equation 3)}$$

Figure 21 Output Voltage Detection

Line Voltage Detection

As illustrated in Figure , NV9510 family products indirectly senses the line voltage through DMAG pin during FET turn-on period. During the FET conduction time, the line voltage detector clamps DMAG pin voltage at 0V. The auxiliary winding voltage, V_{AUX} , is proportional to the input bulk capacitor voltage, V_{BLK} . So current I_{DMAG} flowing out of DMAG pin is expressed as:

$$I_{DMAG} = \frac{V_{BLK}}{R_{DMAG1}} \times \frac{N_A}{N_P} \quad \text{(Equation 4)}$$

I_{DMAG} current, reflecting the line voltage information, is used for the brown-in and brown-out protection.

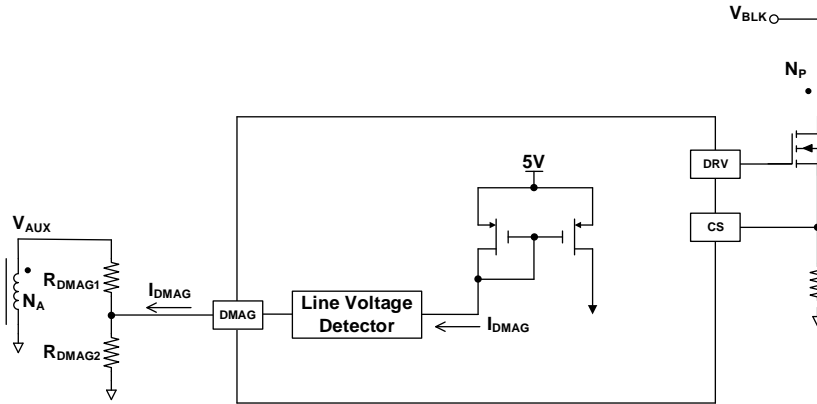

Figure 22 Line Voltage Detection Circuit

LPS Function

The NV9510 family products incorporates built-in power limit (PL) and current limit (CC) circuits to limit output power in the event of the protocol IC becoming malfunction. As Figure 23 shows, when output voltage is equal and lower than 11V, the LPS is controlled by CC; when higher than 11V, the LPS is controlled by PL and CC or CC only. The LPS can be adjusted by current sense resistance, it is recommended to have 10~15% margin.

Figure 23 LPS vs. Rcs

HV Startup

During startup, the internal HV startup circuit is enabled and the bulk capacitor voltage supplies the current, I_{HV} , to charge hold-up capacitor C_{VDD} through R_{HV} (100kohm is recommended). When V_{DD} voltage reaches V_{DD_ON} , the HV startup circuit is disabled. The IC starts PWM switching and senses DMAG signal to check the brown-in condition. If the brown-in is not detected, the IC enters the auto-restart mode.

NV9510 integrates X-cap discharge function by connect one resistor from X-cap to HV pin as shown in Figure 24. The removal of line voltage (such as unplug) is detected by X-cap voltage detector. Once unplug detected, a de-bounce timer $t_{HV_LINE_Removal}$ (32ms) starts to make sure the unplug event is valid. After $t_{HV_LINE_Removal}$ (32ms) de-bounce timer, unplug event is confirmed and NV9510 enters protection. The PWM control block will be disabled, a built-in discharge path from X-cap through R_{HV} to HV pin will be enabled, and the discharge timer t_{HV_DIS} will keep 312ms to guarantee X-cap can be fully discharged.

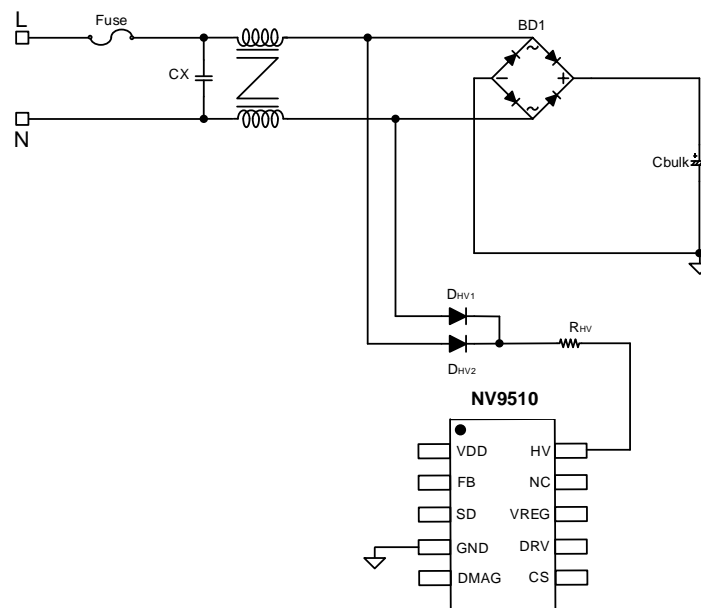

Figure 24 X-cap discharge circuit

Protection Description

NV9510 family products protection functions include VDD over-voltage protection (VDD-OVP), Brown-out protection, DMAG over-voltage protection (DMAG-OVP), DMAG under-voltage protection (DMAG-UVP), IC internal over-temperature protection (OTP), IC external thermal shut-down (SD). The brown-out protection is implemented with auto-restart mode. The VDD-OVP, DMAG-OVP and external SD protection can be configured with auto-restart or latch mode. The DMAG-UVP can be configured with auto-restart or long auto-restart mode.

When the long auto-restart mode protection is triggered, the DRV is turned off for a time period of t_{VDD_LAR} (2.64s). After t_{VDD_LAR} , if VDD rises above V_{DD_ON} , NV9510 family products resume normal operation as shown in Figure .

Figure 25 Auto-Restart Long AR Mode

VDD-OVP

VDD-OVP prevents IC damage from over voltage stress when abnormal system conditions occur. When VDD voltage exceeds V_{DD_OVP} (78.5V) for the debounce time $t_{D_VDD_OVP}$ (32 μ s), the VDD-OVP protection is triggered, the device enters the auto-restart mode or latch mode.

Brown-in & Brown-out

The sensed line voltage information is used for the brown-in and brown-out protection. During FET conduction time, when the current, I_{DMAG} , flowing out of DMAG pin is higher than 0.48mA for 4 debounce cycles, the brown-in is enabled. The input bulk capacitor voltage level to enable the brown-in is given as:

$$V_{BLK_Brownin} = 0.48mA \times \frac{R_{DMAG1}}{N_A/N_P} \quad \text{(Equation 5)}$$

When I_{DMAG} is lower than 0.36mA for longer than 16.5ms, the brown-out is triggered. The input bulk capacitor voltage level to trigger the brown-out protection is given as:

$$V_{BLK_Brownout} = 0.36mA \times \frac{R_{DMAG1}}{N_A/N_P} \quad \text{(Equation 6)}$$

IC Internal OTP

The internal temperature-sensing circuit disables the PWM output if the junction temperature exceeds 140°C (T_{OTP}), and the IC enters protection mode.

DMAG-OVP

DMAG-OVP prevents IC damage caused by the output over voltage.

Figure shows the internal circuit of DMAG-OVP. When abnormal system conditions occur and cause DMAG oltage to exceed V_{DMAG_OVP} (3.55V) for more than 4 consecutive switching cycles (N_{DMAG_OVP}), PWM pulses are disabled and the IC enters the auto-restart mode or the latch mode. Usually, DMAG over voltage protection is caused by an open circuit of the secondary side feedback network or a fault condition of the DMAG voltage divider resistors.

For DMAG voltage divider design, R_{DMAG1} is obtained from Equation 5, and R_{DMAG2} is determined by Equation 3. The output over voltage protection level, V_{O_OVP} , can be determined by Equation 7.

$$V_{O_OVP} = \frac{N_S}{N_A} \times \left(1 + \frac{R_{DMAG1}}{R_{DMAG2}}\right) \times V_{DMAG_OVP} \quad (\text{Equation 7})$$

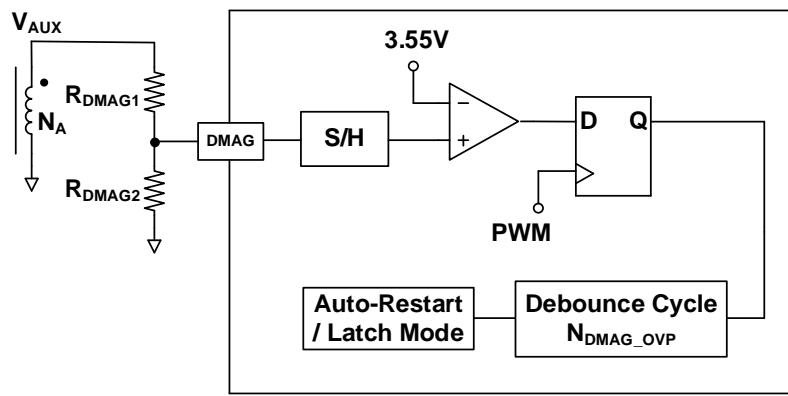

Figure 26 DMAG Over Voltage Protection Circuit

DMAG-UVP

In the event with shorted output, the output voltage will drop and the primary peak current will increase. To prevent operation for a long time under this condition, NV9510 family incorporate the under voltage protection through DMAG pin (DMAG-UVP).

Figure shows the internal circuit for DMAG-UVP. By sampling the auxiliary winding voltage on DMAG pin at the end of the secondary-side rectifier conduction time, the output voltage is indirectly sensed. When DMAG voltage is less than V_{DMAG_UVP} (0.425V) and longer than debounce cycles N_{DMAG_UVP} , DMAG UVP is triggered and the IC enters the auto-restart mode or the long auto-restart mode.

The output under voltage protection level, V_{O_UVP} , can be determined by Equation 8.

$$V_{O_UVP} = \frac{N_S}{N_A} \times \left(1 + \frac{R_{DMAG1}}{R_{DMAG2}}\right) \times V_{DMAG_UVP} \quad (\text{Equation 8})$$

To avoid DMAG-UVP triggering during the startup sequence, startup blanking time $t_{VDMAG_UVP_BNK}$ (32ms) is incorporated for system power on.

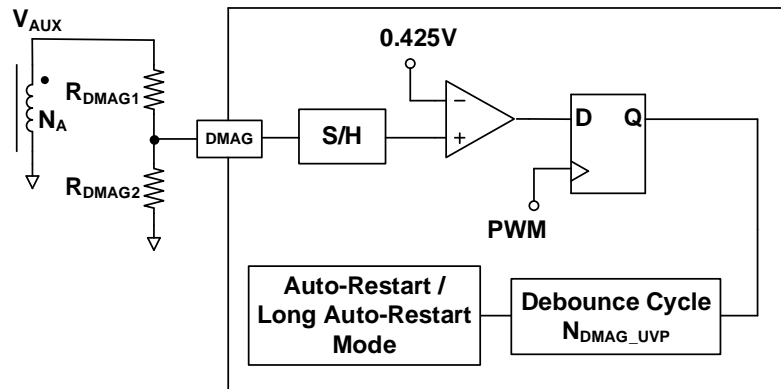

Figure 27 DMAG Under Voltage Protection Circuit

External Thermal Shut-down

During the startup, when VDD voltage reaches V_{DD_ON} , the shut-down trigger level is set at $V_{TH_SD_STR}$ (1.1V). After startup, the trigger level is changed to V_{TH_SD} (1.0V). By pulling down SD pin voltage below threshold voltage V_{TH_SD} (1.0V), the shut-down can be triggered externally and the IC will enter the auto-restart or the latch mode as shown in

Figure . There is an internal constant current source I_{SD} (50 μ A) that is connected to SD pin. So an external OTP function can be implemented by connecting a NTC thermistor between SD pin and ground. The resistance of the NTC thermistor becomes smaller as the ambient temperature increases, therefore the voltage at SD pin will decrease. When the voltage is below the threshold voltage, V_{TH_SD} (1.0V), for debounce time of t_{D_SD} (400 μ s), the OTP protection is triggered. A capacitor may also be placed in parallel with the NTC thermistor to further improve the noise immunity.

Figure 28 External OTP by SD Pin

Cycle by Cycle Current Limit

Under certain operation condition, such as the startup or the overload condition, the feedback control loop can be saturated and is unable to control the primary peak current. To limit the current under such conditions, NV9510 family products incorporate the cycle by cycle current limit protection which forces the DRV switch turn off when CS pin voltage reaches the current limit threshold, V_{CS_LIM} .

Current Sense Short Circuit Protection (CSSP)

NV9510 family has CSSP function. When abnormal system conditions occur, In case after debounce time CS pin voltage is still lower than 0.15V ,DRV switch turn on time will be limited to limit output power.

Secondary Side Rectifier Short Protection (SSSP)

When the secondary-side rectifier is damaged, the primary-side switch current will increase dramatically within the leading-edge blanking time. To limit the switch current during such conditions, NV9510 family products incorporate SSSP function which forces the DRV Switch to turn off when CS pin voltage reaches 1.1V. After 2 switching cycle, the IC will enter the auto-restart mode.

11. Package Outline

STMBOLS	STANDARD	
	MIN.	MAX.
A	-	1.75
A1	0.10	0.25
A2	1.25	-
b	0.30	0.45
c	0.10	0.25
D	4.90 BSC	
E	6.00 BSC	
E1	3.90 BSC	
e	1.00 BSC	
L	0.40	1.27
h	0.25	0.50
θ°	0	8

VARIATIONS (ALL DIMENSIONS SHOW IN MM)

12. Tape and Reel Information

Nominal Hub Width	W1	W2 MAX
12mm	12.8mm +1.6 / -0.4	18.4mm

④① $Ao = 6.50$
 $B_0 = 5.20$
 $Ko = 2.10$
 $Kl = 1.70$

13. 20-Year Limited Product Warranty

The 20-year limited warranty applies to all packaged Navitas GaNFast Power ICs, GaN Controller Co-pak ICs, and Controller ICs in mass production, subject to the terms and conditions of, Navitas' express limited product warranty, available at <https://navitassemi.com/terms-conditions>. The warranted specifications include only the MIN and MAX values only listed in Absolute Maximum Ratings and Electrical Characteristics sections of this datasheet. Typical (TYP) values or other specifications are not warranted.

14. Revision History

Date	Status	Notes
May. 12, 2023	DATASHEET	First publication
May. 25, 2023	DATASHEET	<ol style="list-style-type: none"> 1. Modify part number. 2. Modify block diagram. 3. Add critical specification range.
