

### HIGH FREQUENCY & HIGH DRIVE SYNCHRONOUS PWM CONTROLLER

PRELIMINARY DATA SHEET

#### DESCRIPTION

The NX2210/2211 family of controller ICs are synchronous Buck controller IC designed for step down DC to DC converter applications. They are optimized to convert bus voltages from 2V to 25V to outputs as low as 0.8V voltage. Both devices offer an Enable pin that can be used to program the converter's start voltage using an external divider from bus voltage. The NX2211 operates at fixed 600kHz while 2210 has ability to program switching frequency from 200kHz to 1MHz, making it ideal for applications requiring ceramic output capacitor. The NX2211 has an added Power Good function. Both devices have less than 50 nS of dead band which increases efficiency at higher frequencies.

Other features of the device are: Internal digital soft start; Vcc undervoltage lock out; Output undervoltage protection with digital filter and shutdown capability via the enable pin.

- <1ohm Driver keeps High Capacitance Synchronous MOSFET off during SW node transition
- Bus voltage operation from 2V to 25V
- Power Good indicator available for NX2211
- Fixed 600kHz for NX2211 and adjustable frequency up to 1MHz for NX2210
- Internal Digital Soft Start Function
- Less than 50 nS adaptive deadband
- Enable pin allows BUS voltage UVLO programmability
- Short protection with feedback UVLO

#### APPLICATIONS

- Graphic Card on board converters
- Memory Vddq Supply
- On board DC to DC such as 12V to 3.3V, 2.5V or 1.8V
- ADSL Modem

#### TYPICAL APPLICATION

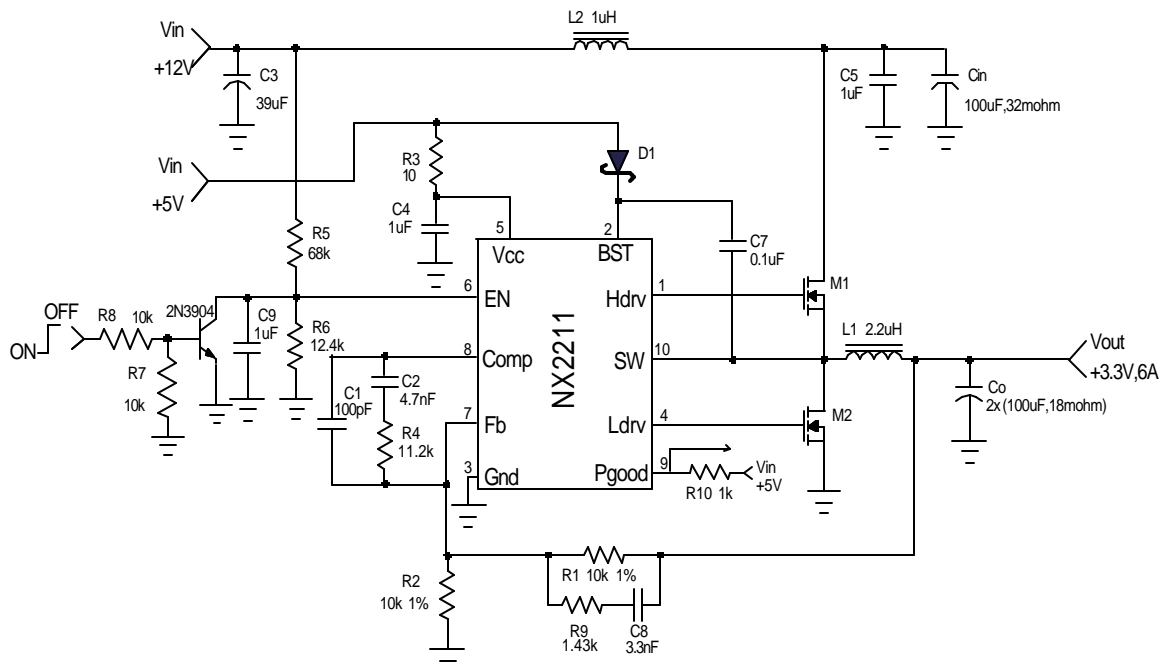

Figure1 - Typical application of 2211

#### ORDERING INFORMATION

Device	Temperature	Package	Frequency
NX2210CMTR	0 to 70°C	MLPD-10L	200kHz to 1MHz
NX2211CMTR	0 to 70°C	MLPD-10L	600kHz

## ABSOLUTE MAXIMUM RATINGS(NOTE1)

Vcc to GND & BST to SW voltage .....	6.5V
BST to GND Voltage .....	35V
Storage Temperature Range .....	-65°C to 150°C
Operating Junction Temperature Range .....	-40°C to 125°C

## PACKAGE INFORMATION

NOTE1: Stresses above those listed in "ABSOLUTE MAXIMUM RATINGS", may cause permanent damage to the device. This is a stress only rating and operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied.

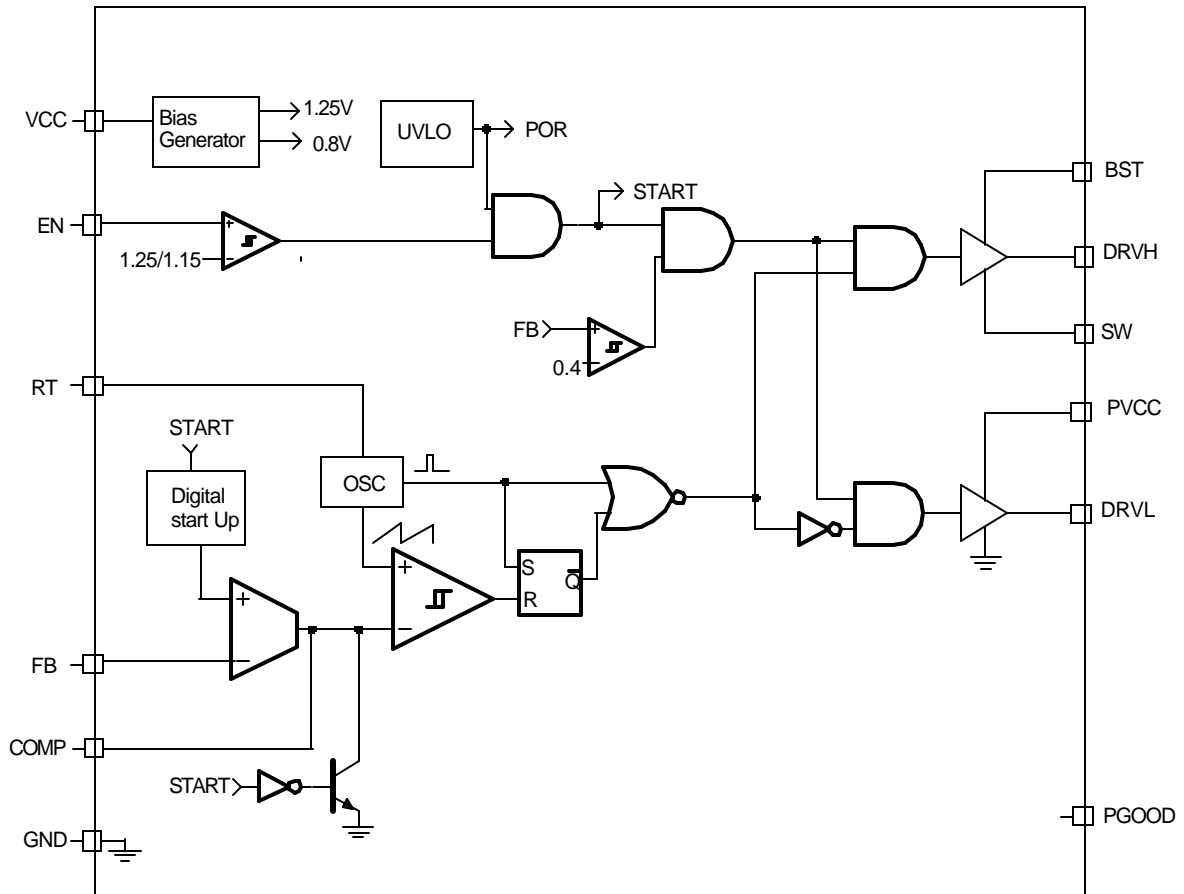

NOTE2: PAD is NC.

NOTE3: PAD is NC.

### PIN DESCRIPTIONS

PIN #		PIN SYMBOL	PIN DESCRIPTION
2210	2211		
1	1	HDRV	High side MOSFET gate driver.
2	2	BST	This pin supplies voltage to the high side driver. A high frequency ceramic capacitor of 0.1 to 1 uF must be connected from this pin to SW pin.
3	3	Gnd	Power and analog ground pin. Connect this pin directly to ground plane using a via.
4	4	LDRV	Low side MOSFET gate driver.
5	5	Vcc	Voltage supply for the internal circuit as well as the low side MOSFET gate driver. A 1uF high frequency ceramic capacitor must be connected from this pin to ground plane using a via.
6		Rt	Add resistor to this pin for adjustable frequency which is from 20kHz to 1MHz
7	6	EN	Pull up this pin to Vcc for normal operation. Pulling this pin down below 1.25V shuts down the controller and resets the soft start. This pin can also be used as a UVLO detector for the bus voltage via a resistor divider.
8	7	FB	FB pin is the error amplifier inverting input. This pin is also connected to the output UVLO comparator. When this pin falls below 0.4V, both HDRV and LDRV outputs are latched off.
9	8	COMP	This pin is the output of the error amplifier and together with FB pin is used to compensate the voltage control feedback loop. This pin is also used as a shut down pin.
10	10	SW	This pin is connected to the source of the high side MOSFET and provides return path for the high side driver.
	9	PGood	This is an open drain output and it is pulled low if the output voltage is not within the above specification. If not used it may be left floating.

## APPLICATION INFORMATION

### Symbol Used In Application Information:

- $V_{IN}$  - Input voltage
- $V_{OUT}$  - Output voltage
- $I_{OUT}$  - Output current
- $\Delta V_{RIPPLE}$  - Output voltage ripple
- $F_s$  - Working frequency
- $\Delta I_{RIPPLE}$  - Inductor current ripple

### Design Example

The following is typical application for NX2211, the schematic is figure 2.

- $V_{IN} = 12V$
- $V_{OUT} = 3.3V$
- $F_s = 600kHz$
- $I_{OUT} = 6A$
- $\Delta V_{RIPPLE} \leq 30mV$
- $\Delta V_{DROOP} \leq 100mV @ 6A \text{ step}$

### Output Inductor Selection

The selection of inductor value is based on inductor ripple current, power rating, working frequency and efficiency. Larger inductor value normally means smaller ripple current. However if the inductance is chosen too large, it brings slow response and lower efficiency. Usually the ripple current ranges from 20% to 40% of the output current. This is a design freedom which can be decided by design engineer according to various application requirements. The inductor value can be calculated by using the following equations:

$$L_{OUT} = \frac{V_{IN} - V_{OUT}}{\Delta I_{RIPPLE}} \times \frac{V_{OUT}}{V_{IN}} \times \frac{1}{F_s} \quad \dots(1)$$

$$I_{RIPPLE} = k \times I_{OUTPUT}$$

where k is between 0.2 to 0.4.

Select k=0.3, then

$$L_{OUT} = \frac{12V - 3.3V}{0.3 \times 6A} \times \frac{3.3V}{12V} \times \frac{1}{600kHz}$$

$$L_{OUT} = 2.2\mu H$$

Choose inductor from COILCRAFT DO5022P-222 with L=2.2uH is a good choice.

Current Ripple is recalculated as

$$\Delta I_{RIPPLE} = \frac{V_{IN} - V_{OUT}}{L_{OUT}} \times \frac{V_{OUT}}{V_{IN}} \times \frac{1}{F_s}$$

$$= \frac{12V - 3.3V}{2.2\mu H} \times \frac{3.3V}{12V} \times \frac{1}{600kHz} = 1.8A \quad \dots(2)$$

### Output Capacitor Selection

Output capacitor is basically decided by the amount of the output voltage ripple allowed during steady state(DC) load condition as well as specification for the load transient. The optimum design may require a couple of iterations to satisfy both condition.

#### Based on DC Load Condition

The amount of voltage ripple during the DC load condition is determined by equation(3).

$$\Delta V_{RIPPLE} = ESR \times \Delta I_{RIPPLE} + \frac{\Delta I_{RIPPLE}}{8 \times F_s \times C_{OUT}} \quad \dots(3)$$

Where ESR is the output capacitors' equivalent series resistance,  $C_{OUT}$  is the value of output capacitors.

Typically when large value capacitors are selected such as Aluminum Electrolytic, POSCAP and OSCON types are used, the amount of the output voltage ripple is dominated by the first term in equation(3) and the second term can be neglected.

For this example, POSCAP are chosen as output capacitors, the ESR and inductor current typically determines the output voltage ripple.

$$ESR_{desire} = \frac{\Delta V_{RIPPLE}}{\Delta I_{RIPPLE}} = \frac{30mV}{1.8A} = 16.7m\Omega \quad \dots(4)$$

If low ESR is required, for most applications, multiple capacitors in parallel are better than a big capacitor. For example, for 30mV output ripple, POSCAP 6TPE100MI with 18mΩ are chosen.

$$N = \frac{ESR_E \times \Delta I_{RIPPLE}}{\Delta V_{RIPPLE}} \quad \dots(5)$$

Number of Capacitor is calculated as

$$N = \frac{18m\Omega \times 1.8A}{30mV}$$

$$N = 1.08$$

The number of capacitor has to be round up to a integer. Choose N =2.

If ceramic capacitors are chosen as output ca

capacitors, both terms in equation (3) need to be evaluated to determine the overall ripple. Usually when this type of capacitors are selected, the amount of capacitance per single unit is not sufficient to meet the transient specification, which results in parallel configuration of multiple capacitors .

For example, one 100uF, X5R ceramic capacitor with 2mΩ ESR is used. The amount of output ripple is

$$\Delta V_{\text{RIPPLE}} = 2\text{m}\Omega \times 1.8\text{A} + \frac{1.8\text{A}}{8 \times 600\text{kHz} \times 100\mu\text{F}}$$

$$= 3.6\text{mV} + 3.8\text{mV} = 7.4\text{mV}$$

Although this meets DC ripple spec, however it needs to be studied for transient requirement.

### Based On Transient Requirement

Typically, the output voltage droop during transient is specified as:

$$\Delta V_{\text{DROOP}} < \Delta V_{\text{TRAN}} \text{ @ step load } \Delta I_{\text{STEP}}$$

During the transient, the voltage droop during the transient is composed of two sections. One Section is dependent on the ESR of capacitor, the other section is a function of the inductor, output capacitance as well as input, output voltage. For example, for the overshoot, when load from high load to light load with a  $\Delta I_{\text{STEP}}$  transient load, if assuming the bandwidth of system is high enough, the overshoot can be estimated as the following equation.

$$\Delta V_{\text{overshoot}} = \text{ESR} \times \Delta I_{\text{step}} + \frac{V_{\text{OUT}}}{2 \times L \times C_{\text{OUT}}} \times \tau^2 \quad \dots(6)$$

where  $\tau$  is the a function of capacitor, etc.

$$\tau = \begin{cases} 0 & \text{if } L \leq L_{\text{crit}} \\ \frac{L \times \Delta I_{\text{step}}}{V_{\text{OUT}}} - \text{ESR} \times C_{\text{OUT}} & \text{if } L \geq L_{\text{crit}} \end{cases} \quad \dots(7)$$

where

$$L_{\text{crit}} = \frac{\text{ESR} \times C_{\text{OUT}} \times V_{\text{OUT}}}{\Delta I_{\text{step}}} = \frac{\text{ESR}_E \times C_E \times V_{\text{OUT}}}{\Delta I_{\text{step}}} \quad \dots(8)$$

where  $\text{ESR}_E$  and  $C_E$  represents ESR and capacitance of each capacitor if multiple capacitors are used in parallel.

The above equation shows that if the selected output inductor is smaller than the critical inductance, the voltage droop or overshoot is only dependent on the ESR

of output capacitor. For low frequency capacitor such as electrolytic capacitor, the product of ESR and capacitance is high and  $L \leq L_{\text{crit}}$  is true. In that case, the transient spec is dependent on the ESR of capacitor.

In most cases, the output capacitors are multiple capacitors in parallel. The number of capacitors can be calculated by the following

$$N = \frac{\text{ESR}_E \times \Delta I_{\text{step}}}{\Delta V_{\text{tran}}} + \frac{V_{\text{OUT}}}{2 \times L \times C_E \times \Delta V_{\text{tran}}} \times \tau^2 \quad \dots(9)$$

where

$$\tau = \begin{cases} 0 & \text{if } L \leq L_{\text{crit}} \\ \frac{L \times \Delta I_{\text{step}}}{V_{\text{OUT}}} - \text{ESR}_E \times C_E & \text{if } L \geq L_{\text{crit}} \end{cases} \quad \dots(10)$$

For example, assume voltage droop during transient is 100mV for 6A load step.

If the POSCAP 6TPE100MI(100uF, 18mΩ ) is used, the critical inductance is given as

$$L_{\text{crit}} = \frac{\text{ESR}_E \times C_E \times V_{\text{OUT}}}{\Delta I_{\text{step}}}$$

$$\frac{18\text{m}\Omega \times 100\mu\text{F} \times 3.3\text{V}}{6\text{A}} = 0.99\mu\text{H}$$

The selected inductor is 2.2uH which is bigger than critical inductance. In that case, the output voltage transient not only dependent on the ESR, but also capacitance.

number of capacitors is

$$\tau = \frac{L \times \Delta I_{\text{step}}}{V_{\text{OUT}}} - \text{ESR}_E \times C_E$$

$$= \frac{2.2\mu\text{H} \times 6\text{A}}{3.3\text{V}} - 18\text{m}\Omega \times 100\mu\text{F} = 2.2\mu\text{s}$$

$$N = \frac{\text{ESR}_E \times \Delta I_{\text{step}}}{\Delta V_{\text{tran}}} + \frac{V_{\text{OUT}}}{2 \times L \times C_E \times \Delta V_{\text{tran}}} \times \tau^2$$

$$= \frac{18\text{m}\Omega \times 6\text{A}}{100\text{mV}} + \frac{3.3\text{V}}{2 \times 2.2\mu\text{H} \times 100\mu\text{F} \times 100\text{mV}} \times (2.2\mu\text{s})^2$$

$$= 1.4$$

The number of capacitors has to satisfied both ripple and transient requirement. Overall, we can choose N=2.

It should be considered that the proposed equation is based on ideal case, in reality, the droop or overshoot is typically more than the calculation. The equation gives a good start. For more margin, more capacitors have to be chosen after the test. Typically, for high frequency capacitor such as high quality POSCAP especially ceramic capacitor, 20% to 100% (for ceramic) more capacitors have to be chosen since the ESR of capacitors is so low that the PCB parasitic can affect the results tremendously. More capacitors have to be selected to compensate these parasitic parameters.

### Compensator Design

Due to the double pole generated by LC filter of the power stage, the power system has 180° phase shift, and therefore, is unstable by itself. In order to achieve accurate output voltage and fast transient response, compensator is employed to provide highest possible bandwidth and enough phase margin. Ideally, the Bode plot of the closed loop system has crossover frequency between 1/10 and 1/5 of the switching frequency, phase margin greater than 50° and the gain crossing 0dB with -20dB/decade. Power stage output capacitors usually decide the compensator type. If electrolytic capacitors are chosen as output capacitors, type II compensator can be used to compensate the system, because the zero caused by output capacitor ESR is lower than crossover frequency. Otherwise type III compensator should be chosen.

#### A. Type III compensator design

For low ESR output capacitors, typically such as Sanyo oscap and poscap, the frequency of ESR zero caused by output capacitors is higher than the crossover frequency. In this case, it is necessary to compensate the system with type III compensator. The following figures and equations show how to realize the type III compensator by transconductance amplifier.

$$F_{Z1} = \frac{1}{2 \times p \times R_4 \times C_2} \quad \dots(11)$$

$$F_{Z2} = \frac{1}{2 \times p \times (R_2 + R_3) \times C_3} \quad \dots(12)$$

$$F_{P1} = \frac{1}{2 \times p \times R_3 \times C_3} \quad \dots(13)$$

$$F_{P2} = \frac{1}{2 \times p \times R_4 \times \frac{C_1 \times C_2}{C_1 + C_2}} \quad \dots(14)$$

where  $F_{Z1}, F_{Z2}, F_{P1}$  and  $F_{P2}$  are poles and zeros in the compensator. Their locations are shown in figure 10.

The transfer function of type III compensator for transconductance amplifier is given by:

$$\frac{V_e}{V_{OUT}} = \frac{1 - g_m \times Z_f}{1 + g_m \times Z_{in} + Z_{in} / R_1}$$

For the voltage amplifier, the transfer function of compensator is

$$\frac{V_e}{V_{OUT}} = \frac{-Z_f}{Z_{in}}$$

To achieve the same effect as voltage amplifier, the compensator of transconductance amplifier must satisfy this condition:  $R_4 \gg 2/g_m, R_1 \parallel R_2 \parallel R_3 \gg 1/g_m$  is desirable.

Figure 9 - Type III compensator using transconductance amplifier

Figure 10 - Bode plot of Type III compensator

Design example for type III compensator are in order. The crossover frequency has to be selected as  $F_{LC} < F_O < F_{ESR}$ , and  $F_O \approx 1/10 \sim 1/5 F_s$ .

1. Calculate the location of LC double pole  $F_{LC}$  and ESR zero  $F_{ESR}$ .

$$F_{LC} = \frac{1}{2 \times p \times \sqrt{L_{OUT} \times C_{OUT}}} = \frac{1}{2 \times p \times \sqrt{2.2\mu H \times 200\mu F}} = 7.59\text{kHz}$$

$$F_{ESR} = \frac{1}{2 \times p \times ESR \times C_{OUT}} = \frac{1}{2 \times p \times 9\text{m}\Omega \times 200\mu F} = 88.42\text{kHz}$$

2. Set  $R_2$  equal to  $10.2\text{k}\Omega$ ,

$$R_1 = \frac{R_2 \times V_{REF}}{V_{OUT} - V_{REF}} = \frac{10.2\text{k}\Omega \times 0.8\text{V}}{3.3\text{V} - 0.8\text{V}} = 3.26\text{k}\Omega$$

Choose  $R_1 = 3.24\text{k}\Omega$ .

3. Set zero  $F_{Z2} = F_{LC}$  and  $F_{P1} = F_{ESR}$ .

4. Calculate  $R_4$  and  $C_3$  with the crossover frequency smaller than  $1/10 \sim 1/5$  of the switching frequency. Set  $F_O = 60\text{kHz}$ .

$$C_3 = \frac{1}{2 \times p \times R_2} \times \left( \frac{1}{F_{Z2}} - \frac{1}{F_{P1}} \right) = \frac{1}{2 \times p \times 10\text{k}\Omega} \times \left( \frac{1}{7.59\text{kHz}} - \frac{1}{88.42\text{kHz}} \right) = 1.9\text{nF}$$

Choose  $C_3 = 2.2\text{nF}$ .

$$R_4 = \frac{V_{OSC}}{V_{IN}} \times \frac{2 \times p \times F_O \times L}{C_3} \times C_{OUT} = \frac{2\text{V}}{12\text{V}} \times \frac{2 \times p \times 60\text{kHz} \times 2.2\mu H}{2.2\text{nF}} \times 200\mu F = 12.6\text{k}\Omega$$

Choose  $R_4 = 12.7\text{k}\Omega$

5. Calculate  $C_2$  with zero  $F_{Z1}$  at 75% of the LC double pole by equation (11).

$$C_2 = \frac{1}{2 \times p \times F_{Z1} \times R_4} = \frac{1}{2 \times p \times 0.75 \times 7.59\text{kHz} \times 12.7\text{k}\Omega} = 2.22\text{nF}$$

Choose  $C_2 = 2.2\text{nF}$

6. Calculate  $C_1$  by equation (14) with pole  $F_{P2}$  at half the switching frequency.

$$C_1 = \frac{1}{2 \times p \times R_4 \times F_{P2}} = \frac{1}{2 \times p \times 12.7\text{k}\Omega \times 150\text{kHz}} = 42\text{pF}$$

Choose  $C_1 = 39\text{pF}$

7. Calculate  $R_3$  by equation (13).

$$R_3 = \frac{1}{2 \times p \times F_{P1} \times C_3} = \frac{1}{2 \times p \times 88.42\text{kHz} \times 2.2\text{nF}} = 818\Omega$$

Choose  $R_3 = 820\Omega$ .

## B. Type II compensator design

If the electrolytic capacitors are chosen as power stage output capacitors, usually the Type II compensator can be used to compensate the system.

Type II compensator can be realized by simple RC circuit without feedback as shown in figure 11. R3 and C1 introduce a zero to cancel the double pole effect. C2 introduces a pole to suppress the switching noise. The following equations show the compensator pole zero location and constant gain.

$$\text{Gain} = g_m \times \frac{R_1}{R_1 + R_2} \times R_3 \quad \dots (15)$$

$$F_z = \frac{1}{2 \times p \times R_3 \times C_1} \quad \dots (16)$$

$$F_p \approx \frac{1}{2 \times p \times R_3 \times C_2} \quad \dots (17)$$

figure 12 - Bode plot of Type II compensator

Figure 11 - Type II compensator with transconductance amplifier

For this type of compensator,  $F_o$  has to satisfy  $F_{LC} < F_{ESR} \ll F_o \leq 1/10 \sim 1/5 F_s$ .

The following uses the same power stage parameters as demoboard design in figure 2 as an example for type II compensator design, except for output capacitor is one POSCAP 220uF with 12mΩ instead.

1. Calculate the location of LC double pole  $F_{LC}$  and ESR zero  $F_{ESR}$ .

$$F_{LC} = \frac{1}{2 \times p \times \sqrt{L_{OUT} \times C_{OUT}}} = \frac{1}{2 \times p \times \sqrt{2.2 \mu H \times 220 \mu F}} = 7.2 \text{ kHz}$$

$$F_{ESR} = \frac{1}{2 \times p \times ESR \times C_{OUT}} = \frac{1}{2 \times p \times 15 \text{ m}\Omega \times 220 \mu F} = 48 \text{ kHz}$$

2. Set  $R_2$  equal to 10kΩ. Using equation 18,

$$R_1 = \frac{10 \text{ k}\Omega \times 0.8 \text{ V}}{3.3 \text{ V} - 0.8 \text{ V}} = 3.2 \text{ k}\Omega$$

3. Set crossover frequency at 1/10~ 1/5 of the switching frequency, here  $F_o = 65 \text{ kHz}$ .

4. Calculate  $R_3$  value by the following equation.

$$R_3 = \frac{V_{OSC}}{V_{in}} \times \frac{2 \times p \times F_o \times L}{R_{ESR}} \times \frac{1}{g_m} \times \frac{R_1 + R_2}{R_1}$$

$$= \frac{2V}{12} \times \frac{2 \times p \times 65kHz \times 2.2\mu H}{15m\Omega} \times \frac{1}{2.5mA/V} \times \frac{3.2k\Omega + 10k\Omega}{3.2k\Omega}$$

$$= 16.5k\Omega$$

Choose  $R_3 = 16.2k\Omega$ .

5. Calculate  $C_1$  by setting compensator zero  $F_z$  at 75% of the LC double pole.

$$C_1 = \frac{1}{2 \times p \times R_3 \times F_z}$$

$$= \frac{1}{2 \times p \times 16.2k\Omega \times 0.75 \times 7.2kHz}$$

$$= 1.8nF$$

Choose  $C_1 = 1.8nF$ .

6. Calculate  $C_2$  by setting compensator pole  $F_p$  at half the swithing frequency.

$$C_2 = \frac{1}{p \times R_3 \times F_s}$$

$$= \frac{1}{p \times 16.2k\Omega \times 600kHz}$$

$$= 33pF$$

Choose  $C_2 = 33pF$ .

## Output Voltage Calculation

Output voltage is set by reference voltage and external voltage divider. The reference voltage is fixed at 0.8V. The divider consists of two ratioed resistors so that the output voltage applied at the Fb pin is 0.8V when the output voltage is at the desired value. The following equation and picture show the relationship between  $V_{OUT}$ ,  $V_{REF}$  and voltage divider.

$$R_1 = \frac{R_2 \times V_{REF}}{V_{OUT} - V_{REF}} \quad \dots(18)$$

where  $R_2$  is part of the compensator, and the value of  $R_1$  value can be set by voltage divider.

Choose  $R_2 = 10k\Omega$ , to set the output voltage at 1.6V, the result of  $R_1$  is  $10k\Omega$ .

Figure 13 - Voltage divider

In general, the minimum output load impedance including the resistor divider should be less than  $5k\Omega$  to prevent overcharge the output voltage by leakage current (e.g. Error Amplifier feedback pin bias current). A minimum load for  $5k\Omega$  less ( $<1/16W$  for most of application) is recommended to put at the output. For example, in this application,

$$V_{out} = 1.6V$$

The power loss is  $1/16W$  less

$$R_{LOAD} = 1.6V \times 1.6V / (1/16W) = 40\Omega$$

Select minimum load is  $1k\Omega$  should be good enough.

## Input Capacitor Selection

Input capacitors are usually a mix of high frequency ceramic capacitors and bulk capacitors. Ceramic capacitors bypass the high frequency noise, and bulk capacitors supply current to the MOSFETs. Usually  $1\mu F$  ceramic capacitor is chosen to decouple the high frequency noise. The bulk input capacitors are decided by voltage rating and RMS current rating. The RMS current in the input capacitors can be calculated as:

$$I_{RMS} = I_{OUT} \times \sqrt{D} \times \sqrt{1-D}$$

$$D = \frac{V_{OUT}}{V_{IN}} \quad \dots(19)$$

$V_{IN} = 12V$ ,  $V_{OUT} = 3.3V$ ,  $I_{OUT} = 6A$ , using equation (19), the result of input RMS current is  $2.68A$ .

For higher efficiency, low ESR capacitors are recommended. One Sanyo OSCON SP series 16SP100M 16V 100uF with 2.89A is chosen as input bulk capacitor.

## Power MOSFETs Selection

The NX2211 requires two N-Channel power MOSFETs. The selection of MOSFETs is based on maximum drain source voltage, gate source voltage, maximum current rating, MOSFET on resistance and power dissipation. The main consideration is the power loss contribution of MOSFETs to the overall converter efficiency. In this design example, one Fairchild FDS6294 ( $V_{DS}=30V, I_D=13A, R_{DS(ON)}=14.4m\Omega, Q_{GATE}=10nC$ ) and one Fairchild FDS6676 ( $V_{DS}=30V, I_D=14.5A, R_{DS(ON)}=8m\Omega, Q_{GATE}=45nC$ ) are used.

There are three factors causing the MOSFET power loss: conduction loss, switching loss and gate driver loss.

Gate driver loss is the loss generated by discharging the gate capacitor and is dissipated in driver circuits. It is proportional to frequency and is defined as:

$$P_{gate} = (Q_{HGATE} \times V_{HGS} + Q_{LGATE} \times V_{LGS}) \times F_s \quad \dots(20)$$

where  $Q_{HGATE}$  is the high side MOSFETs gate charge,  $Q_{LGATE}$  is the low side MOSFETs gate charge,  $V_{HGS}$  is the high side gate source voltage, and  $V_{LGS}$  is the low side gate source voltage.

According to equation (20),  $P_{GATE}=0.17W$ . This power dissipation should not exceed maximum power dissipation of the driver device.

Conduction loss is simply defined as:

$$\begin{aligned} P_{HCON} &= I_{OUT}^2 \times D \times R_{DS(ON)} \times K \\ P_{LCON} &= I_{OUT}^2 \times (1 - D) \times R_{DS(ON)} \times K \\ P_{TOTAL} &= P_{HCON} + P_{LCON} \end{aligned} \quad \dots(21)$$

where the  $R_{DS(ON)}$  will increase as MOSFET junction temperature increases,  $K$  is  $R_{DS(ON)}$  temperature dependency. As a result,  $R_{DS(ON)}$  should be selected for the worst case, in which  $K$  approximately equals to 1.43 at 125°C according to datasheet. Using equation (21), the result of  $P_{TOTAL}$  is 0.5W. Conduction loss should not exceed package rating or overall system thermal budget.

Switching loss is mainly caused by crossover conduction at the switching transition. The total switching loss can be approximated.

$$P_{SW} = \frac{1}{2} \times V_{IN} \times I_{OUT} \times T_{SW} \times F_s \quad \dots(22)$$

where  $I_{OUT}$  is output current,  $T_{SW}$  is the sum of  $T_R$  and  $T_F$  which can be found in mosfet datasheet, and  $F_s$  is switching frequency. Switching loss  $P_{SW}$  is frequency dependent.

## Soft Start, Enable and shut Down

The NX2211 has a digital start up. It is based on digital counter with 1024 cycles. For NX2211 with 600kHz operation, the start up time is about 1.75ms. For NX2210 with 1MHz operation, the start up time is about 1ms.

The start up of NX2211/2210 can be programmed through resistor divider at Enable pin. For example, if the input bus voltage is 12V and we want NX2211 starts when  $V_{bus}$  is above 8V. We can select

$$R_2 = 1.24k$$

$$R_1 = \frac{(8V - 1.25V) \times R_2}{1.25V} = 6.8k\Omega$$

The NX2211/NX2210 can be turned off by pulling down the ENable pin by extra signal MOSFET or NPN transistor such as 2N3904 as shown in the above Figure. When Enable pin is below 1.15V, the digital soft start is reset to zero. In addition, all the high side is off and output voltage is turned off.

Figure 14 - Enable and Shut down NX2211/NX2210 by pulling down EN pin.

## Feedback Under Voltage Shut Down

NX2211/NX2210 relies on the Feedback Under Voltage Lock Out (FB UVLO) to provide short circuit protection. Basically, NX2211/NX2210 has a comparator compares the feedback voltage with the FB UVLO threshold 0.4V.

During the normal operation, if the output is short, the feedback voltage will be lower than 0.4V and

comparator will change the state. After certain internal delay, both high side and low side driver will be turned off. The output will be latched. The normal operation should be achieved by removing the short and recycle the VCC.

Figure 15 - Operation waveform during short

Figure 16 - Operation waveform with start up at short.

During the start up, the output voltage is discharged to zero by the synchronous FET. FB voltage starts increase from zero when digital start block operates. Before half of the start up time, the Feedback Under Voltage Lock Out comparator is disabled. After half of start up time, the Feedback UVLO comparator is enabled. The FB UVLO threshold is set to be half of voltage at the positive input of error amplifier. With this set up, if the

output is short before soft start, the Feedback UVLO comparator can catch it and turn off the driver. The short circuit operation waveform during normal operation and during the soft start are shown as follows.

The Feedback UVLO can provide certain short circuit protection. However, since feedback does not have accurate information of current, this protection only provides certain level of over current protection. MOSFET should design such that it can survive with high pulse current for a short period of time. A 0.1µF or 1µF capacitor should be added on enable pin to keep enable pin high during short.

### Layout Considerations

The layout is very important when designing high frequency switching converters. Layout will affect noise pickup and can cause a good design to perform with less than expected results.

Start to place the power components, make all the connection in the top layer with wide, copper filled areas. The inductor, output capacitor and the MOSFET should be close to each other as possible. This helps to reduce the EMI radiated by the power traces due to the high switching currents through them. Place input capacitor directly to the drain of the high-side MOSFET, to reduce the ESR replace the single input capacitor with two parallel units. The feedback part of the system should be kept away from the inductor and other noise sources, and be placed close to the IC. In multilayer PCB use one layer as power ground plane and have a control circuit ground (analog ground), to which all signals are referenced.

The goal is to localize the high current path to a separate loop that does not interfere with the more sensitive analog control function. These two grounds must be connected together on the PC board layout at a single point.
