

Dual Output DC-DC & Linear Regulator IC

The 34710 is a dual-output power regulator IC integrating switching regulator, linear regulator, supervisory and power supply sequencing circuitry. With a wide operating input voltage range of 13 V to 32 V, the 34710 is applicable to many commercial and industrial applications using embedded MCUs.

A mode-selected 5.0 V or 3.3 V DC-DC switching regulator is provided for board-level I/O and user circuitry up to 700 mA. A linear regulator provides mode-selected core supply voltages of either 3.3V, 2.5V, 1.8V, or 1.5V at currents up to 500 mA.

The supervisor circuitry ensures that the regulator outputs follow a predetermined power-up and power-down sequence.

Features

- Efficient 5.0 V/3.3 V Buck Regulator
- Low Noise LDO Regulator (mode-selected 3.3V, 2.5V, 1.8V, or 1.5V)
- On-Chip Thermal Shutdown Circuitry
- Supervisory Functions (Power-ON Reset and Error Reset Circuitry)
- Sequenced I/O and Core Voltages
- Pb-Free Packaging Designated by Suffix Code EW

FUNCTIONAL DESCRIPTION

INTRODUCTION

V_{I/O} Switching Regulator

The V_{I/O} switching regulator output voltage is determined by the Mode digital input terminals. The 34710's Mode terminals select the output voltage. For example, if Mode2, Mode1, and Mode0 are set to 0, 0, 0 (respectively) then V_{I/O} will be set to 5.0 V; if Mode2, Mode1, and Mode0 are all left floating (i.e., Open, Open, and Open), then the voltage for V_{I/O} will be set to 3.3 V. [Table 2](#) provides the truth table for setting the various combination of regulator outputs via the Mode pins.

The topology of the regulator is a hysteretic buck regulator operating from the internal ~200 kHz oscillator.

V_{CORE} Linear Regulator

The V_{CORE} linear LDO (low drop-out) regulator can produce either a +3.3 V, 2.5 V, 1.8 V, or 1.5 V output voltage at currents up to 500 mA. The input to the V_{CORE} regulator is a terminal that may be connected to the V_{I/O} regulator output or to an external power supply. Note, the minimum input voltage level must be equal to or greater than the

selected V_{CORE} voltage + 0.8 V. (i.e., 0.8V is the LDO regulator drop out voltage.)

The Mode terminals select the output voltage as depicted in [Table 2](#).

FUNCTIONAL TERMINAL DESCRIPTION

Power Supply Input (B+)

Main supply voltage for the V_{I/O} Switching Regulator and general chip bias circuitry.

Core Voltage Regulator Input (Lin B+)

Supply voltage for the V_{CORE} Regulator. May be provided by the V_{I/O} regulator output or from an independent supply.

Mode Control (MODE 0,1,2)

Mode select terminals to select the V_{I/O} and V_{CORE} output voltages per table 2. Pull to ground for low state, float for high state.

Switching Capacitors 1 and 2 (CP1/CP2)

Terminals for the Charge Pump capacitor.

Boost Voltage (VB)

The Boost Voltage is an output terminal used for the charge pump boost voltage and is a connection point for the Charge Pump bulk capacitor. It provides a gate drive for the V_{I/O} Switch FET.

Reset ($\overline{\text{RST}}$)

Reset is an output terminal for supervisory functions. This terminal is in high state during normal operation and low state

during fault conditions. This terminal has no input function and requires an external pull-up resistor.

The $\overline{\text{RST}}$ terminal is an open drain output driver to prevent oscillations during the transition. It is recommended to connect a 0.1 uF capacitor between the CT pin and $\overline{\text{RST}}$ pin. Note: error conditions must be present for a minimum time, t_{FILTER}, before the 34710 responds to them. Once all error conditions have been cleared, $\overline{\text{RST}}$ is held low for an additional time of t_{DELAY}.

Reset Delay Capacitor (CT)

This terminal is the external delay. It is used with a capacitor to ground to delay $\overline{\text{RST}}$ turn-on time and to $\overline{\text{RST}}$ to prevent $\overline{\text{RST}}$ oscillations during chip power-on.

V_{I/O} Switching Regulator Feedback (VFB)

This terminal is the feedback input for the V_{I/O} Switching Regulator and the output of the regulator application.

V_{I/O} Switching Regulator output (VSWITCH)

This terminal is the Switching output for the V_{I/O} Buck Regulator. It has internal high side FET.

SUPERVISORY FUNCTIONS

Supervisory Circuitry

The supervisory circuitry provides control of the $\overline{\text{RST}}$ line, an open drain signal, based on system operating conditions monitored by the 34710. $V_{\text{I/O}}$, V_{CORE} , $V_{\text{B+}}$, and thermal shutdown (TSD) detectors in various parts of the chip are monitored for error conditions. $V_{\text{I/O}}$, V_{CORE} , $V_{\text{B+}}$, and thermal shutdown have both positive- and negative-going thresholds for triggering the reset function.

The supervisor circuitry also ensures that the regulator outputs follow a predetermined power-up and power-down sequence. Specifically, the sequencing ensures that $V_{\text{I/O}}$ is never less than 0.9 V below V_{CORE} . This means that $V_{\text{CORE}} - V_{\text{I/O}}$ will be clamped at 0.5 V, and that the V_{CORE} regulator

operation will be suppressed during startup and shutdown to ensure that $V_{\text{CORE}} - V_{\text{I/O}} = 0.9 \text{ V}$.

VB Charge Pump

The high-side MOSFET in the switching regulator (buck converter) requires a gate drive supply voltage that is biased higher than the B+ voltage, and this boosted voltage is provided by the internal charge pump and stored in a capacitor between the VB pin and the B+ pin. The charge pump operates directly from the B+ supply, and uses an internal oscillator operating at 200 kHz.

Internal Oscillator

The internal oscillator provides a 200 kHz square wave signal for charge pump operation and for the buck converter.

TYPICAL APPLICATIONS

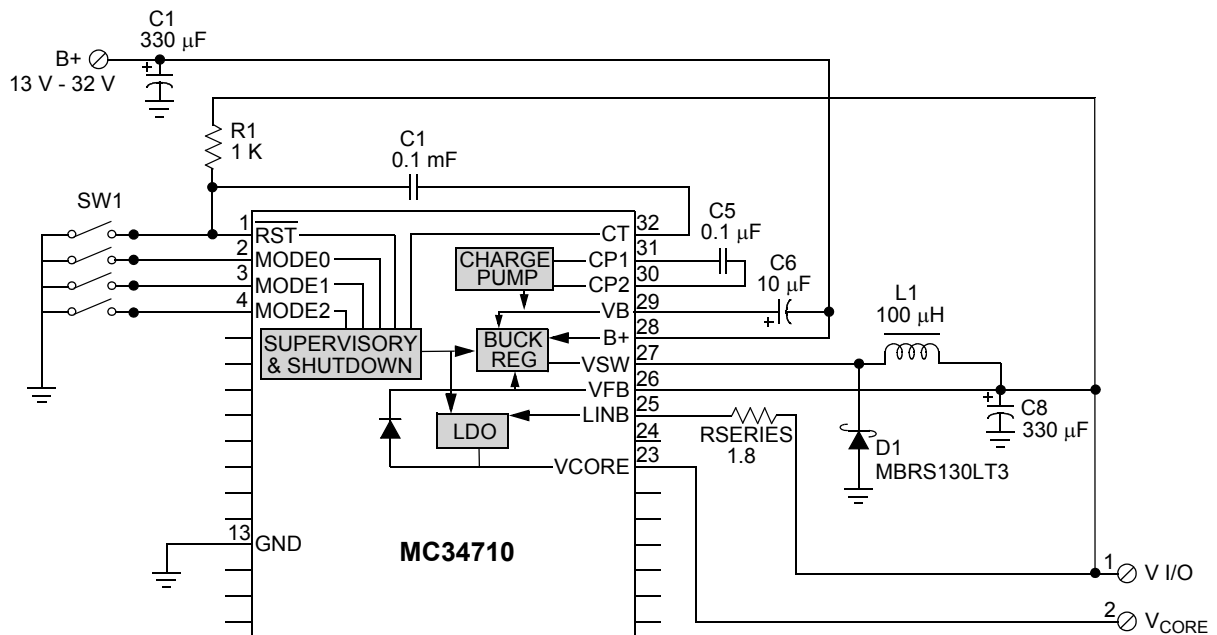

Figure 4. Typical Application Diagram

The MC34710 provides both a buck converter and an LDO regulator in one IC. Figure 4 above shows a typical application schematic for the MC34710. L1 is the buck converter's inductor. The buck inductor is a key component and must not only present the required reactance, but do so at a dc resistance of less than 20 milliohms in order to preserve the converter's efficiency. Also important to the converter's efficiency is the utilization of a low Vf Schottky diode for D1.

Note that a 0.1µF capacitor is connected between CT and the reset pins; this prevents any possibility of oscillations occurring on the reset line during transitions by allowing the CT terminal to discharge to ground potential via the RST pin, and then charge when RST returns to a logic high. The capacitor between the CP1 and CP2 pins is the charge pump's "bucket capacitor", and sequentially charges and discharges to pump up the reservoir capacitor connected to the VB pin. Note that the reservoir capacitor's cathode is connected to B+ rather than ground. Also note that the charge pump is intended only to provide gate-drive potential for the buck regulator's internal power MOSFET, and therefore connecting external loads to the VB pin is not recommended.

The IC's internal V_{CORE} LDO regulator can provide up to 500 mA of current as long as the operating junction

temperature is maintained below 105 degrees C. The heat-generating power dissipation of the LDO is primarily a function of the Volt x Amp product across the LINB+ and V_{CORE} terminals. Therefore, if the LINB+ voltage is >> than the selected V_{CORE} voltage + 0.8 V, it is recommended to use a power resistor in series with the LINB+ input to drop the voltage and dissipate the heat externally from the IC. For example, if the output of the buck regulator (V I/O on the schematic) is used as the input to LINB+, and the mode switches are set such that V I/O = 5 V and V_{CORE} = 3.3 V, then a series resistance of 1.8 ohms at the LINB+ pin would provide an external voltage drop at 500 mA while still leaving the minimum required headroom of 0.8 V. Conversely, if the mode switches are set such that V I/O = 3.3 V and V_{CORE} = 2.5 V, then no series resistance would be required, even at the maximum output current of 500 mA.

Designing a power supply circuit with the MC34710, like all dc-dc converter ICs, requires special attention not only to component selection, but also to component placement (i.e., printed circuit board layout). The MC34710 has a nominal switching frequency of 200 kHz, and therefore pcb traces between the buck converter discrete component terminals and the IC should be kept as short and wide as possible to keep the parasitic inductance low. Likewise, keeping these

pcb traces short and wide helps prevent the converter's high di/dt switching transients from causing EMI/RFI.

Figure 5. Typical PCB Layout

Figure 5 shows a typical layout for the pcb traces connecting the IC's switching terminal (VSWITCH) and the power inductor, rectifier, and filter components.

Also, it is recommended to design the component layout so that the switching currents can be immediately sunk into a broad full-plane ground that provides terminations physically right at the corresponding component leads. This helps prevent switching noise from propagating into other sections of the circuitry.

Figure 6. Bottom Copper Layout

Figure 6 illustrates a pcb typical bottom copper layout for the area underneath a buck converter populated on the top of the same section of pcb.

The ground plane is highlighted so the reader may note how the ground plane has been kept as broad and wide as

possible. The square vias in the plane are located to provide an immediate path to ground from the top copper circuitry.

Figure 7. Top Copper Layout

Figure 7 shows the corresponding top copper circuit area with the component placement.

Again, the ground plane and the vias have been highlighted so the reader may note the proximity of these current sink pathways to the key converter components. It is also important to keep the power planes of the switching converter's output spread as broad as possible beneath the passive components, as this helps reduce EMI/RFI and the potential for coupling noise transients into adjacent circuitry.

Figure 8. Output Plane of Buck Converter

Figure 8 shows the output plane of the buck converter highlighted.

This layout provides the lowest possible impedance as well as lowest possible dc resistance for the power routing. Note that the power path and its return should be placed, if possible, on top of each other on different layers or opposite sides of the pcb.

Small ceramic capacitors are placed in parallel with the Aluminum electrolytics so that the overall bulk filtering presents a low ESL to the high di/dt switching currents. Alternatively, special low ESL/ESR switching-grade electrolytics may be used.

An additional feature of the MC34710 is the 32 SOICW-EP exposed pad package. The package allows heat to be conducted from the die down through the exposed metal pad underneath the package and into the copper of the pcb. In order to best take advantage of this feature, a grid array of thru-hole vias should be placed in the area corresponding to the exposed pad, and these vias then should then connect to a large ground plane of copper to dissipate the heat into the ambient environment. An example of these vias can be seen in the previous figures of a typical pcb layout.
