

General Description

PSoC® 6 MCU is a high-performance, ultra-low-power and secure MCU platform, purpose-built for IoT applications. The PSoC 63 with BLE product family, based on the PSoC 6 MCU platform, is a combination of a dual core microcontroller with low-power flash technology, digital programmable logic, high-performance analog-to-digital and standard communication and timing peripherals. The PSoC 63 family provides wireless connectivity with BLE 5.0 compliance.

Features

32-bit Dual-Core CPU Subsystem

- 150-MHz Arm® Cortex®-M4F CPU with single-cycle multiply (Floating Point and Memory Protection Unit)
- 100-MHz Cortex-M0+ CPU with single-cycle multiply and MPU
- User-selectable core logic operation at either 1.1 V or 0.9 V
- 8-KB Instruction Caches for both CPU cores
- Active CPU current slope with 1.1-V core operation
 - Cortex-M4: 40 µA/MHz
 - Cortex-M0+: 20 µA/MHz
- Active CPU current slope with 0.9-V core operation
 - Cortex-M4: 22 µA/MHz
 - Cortex-M0+: 15 µA/MHz
- Two DMA controllers with 16 channels each

Flash Memory Subsystem

- 1-MB Application Flash, 32-KB emulated EEPROM area, and 32-KB Supervisory Flash
- 288-KB SRAM with power and data retention control
- One-Time-Programmable (OTP) 1-Kb eFuse memory for validation and security

Bluetooth Low Energy (Bluetooth Smart) BT 5.0 Subsystem

- 2.4-GHz RF transceiver with 50-W antenna drive
- Digital PHY
- Link Layer engine supporting master and slave modes
- Programmable output power: up to 4 dBm
- RX sensitivity: -95 dBm
- RSSI: 4-dB resolution
- 5.7 mA TX (0 dBm) and 6.7 mA RX (2 Mbps) current with 3.3-V battery and internal SIMO Buck converter
- Link Layer engine supports four connections simultaneously
- Supports 2 Mbps LE data rate

Low-Power 1.7-V to 3.6-V Operation

- Six power modes for fine-grained power management
- Deep Sleep mode current of 7 µA with 64-KB SRAM retention
- On-chip Single-In Multiple Out (SIMO) DC-DC Buck converter, <1 µA quiescent current
- Backup domain with 64 bytes of memory and Real-Time Clock

Flexible Clocking Options

- On-chip crystal oscillators (4 to 35 MHz, and 32 kHz)
- Phase-locked Loop (PLL) for multiplying clock frequencies
- 8 MHz Internal Main Oscillator (IMO) with ±2% accuracy
- Ultra-low-power 32-kHz Internal Low-speed Oscillator (ILO)
- Frequency Locked Loop (FLL) for multiplying IMO frequency

QSPI Interface (QSPI)/Serial Memory Interface (SMIF)

- Execute-In-Place (XIP) from external Quad SPI Flash
- On-the-fly encryption and decryption
- 4-KB cache for greater XIP performance with lower power
- Supports single, dual, quad, dual-quad, and octal interfaces w/ throughput up to 640 Mbps

Serial Communication

- Nine run-time configurable serial communication blocks (SCBs)
 - Eight SCBs: configurable as SPI, I²C, or UARTs
 - One Deep Sleep SCB: configurable as SPI or I²C
- USB Full-Speed Dual-role Host and Device interface

Audio Subsystem

- Two PDM channels and one I²S channel with TDM mode

Programmable Analog

- 12-bit 1-Msps SAR ADC with differential and single-ended modes and 16-channel sequencer with result averaging
- Two low-power comparators available in Deep Sleep and Hibernate modes
- Built-in temp sensor connected to ADC
- One 12-bit voltage mode DAC with < 5-µs settling time
- Two opamps with low-power operation modes

Up to 78 Programmable GPIOs

- Two Smart I/O ports (16 I/Os) enable Boolean operations on GPIO pins; available during Deep Sleep
- Programmable drive modes, strengths, and slew rates
- Six overvoltage-tolerant (OVT) pins

Capacitive Sensing

- Cypress CapSense Sigma-Delta (CSD) provides best-in-class SNR, liquid tolerance, and proximity sensing
- Enables dynamic usage of both self and mutual sensing
- Automatic hardware tuning (SmartSense™)

Security Built into Platform Architecture

- ROM-based root of trust via uninterruptible Secure Boot
- Step-wise authentication of execution images
- Secure execution of code in execute-only mode for protected routines
- All Debug and Test ingress paths can be disabled
- Up to eight Protection Contexts

Cryptography Accelerators

- Hardware acceleration for symmetric and asymmetric cryptographic methods and hash functions
- True Random Number Generator (TRNG) function

Programmable Digital

- 12 programmable logic blocks, each with 8 Macrocells and an 8-bit data path (called universal digital blocks or UDBs)
- Usable as drag-and-drop Boolean primitives (gates, registers), or as Verilog programmable blocks
- Cypress-provided peripheral component library using UDBs to implement functions such as Communication peripherals (for example, LIN, UART, SPI, I²C, S/PDIF and other protocols), Waveform Generators, Pseudo-Random Sequence (PRS) generation, and many other functions.)

Energy Profiler

- Block that provides history of time spent in different power modes
- Allows software energy profiling to observe and optimize energy consumption

Packages

- 116-BGA and 104-MCSP packages with PSoC 6 and BLE Radio
- 104-MCSP package with BLE Radio and USB
- 124-BGA package in the process of qualification
- 68-QFN package

PSoC Creator

PSoC Creator is a free Windows-based Integrated Design Environment (IDE). It enables you to design hardware and firmware systems concurrently, based on PSoC 6 MCU. As shown below, with PSoC Creator, you can:

1. Explore the library of 200+ Components in PSoC Creator
2. Drag and drop Component icons to complete your hardware system design in the main design workspace
3. Configure Components using the Component Configuration Tools and the Component datasheets
4. Co-design your application firmware and hardware in the PSoC Creator IDE or build project for 3rd party IDE
5. Prototype your solution with the PSoC 6 Pioneer Kits. If a design change is needed, PSoC Creator and Components enable you to make changes on the fly without the need for hardware revisions.

Figure 1. PSoC Creator Schematic Entry and Components

ModusToolbox™ IDE and the PSoC 6 SDK

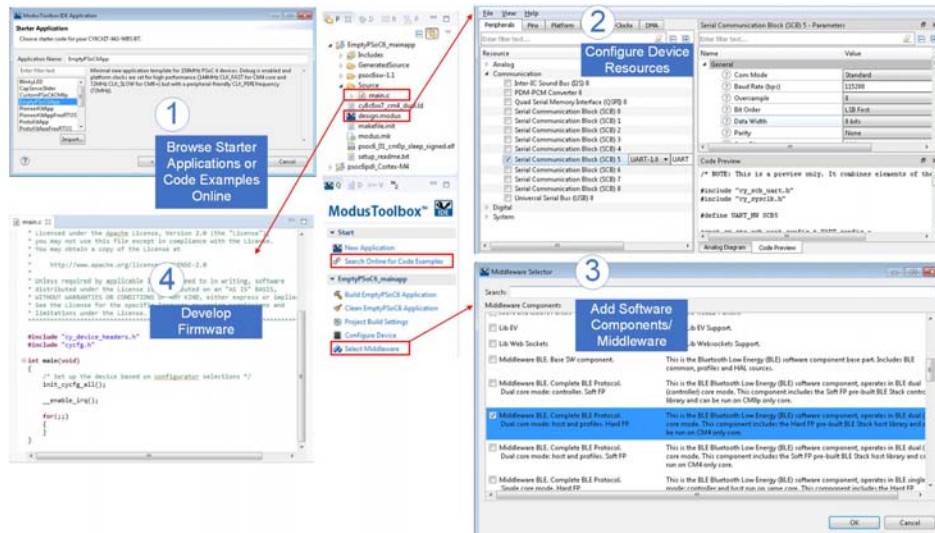

ModusToolbox is an Eclipse-based development environment on Windows, macOS, and Linux platforms that includes the ModusToolbox IDE and the PSoC 6 SDK. The ModusToolbox IDE brings together several device resources, middleware, and firmware to build an application. Using ModusToolbox, you can enable and configure device resources and middleware libraries, write C/assembly source code, and program and debug the device.

The PSoC 6 SDK is the software development kit for the PSoC 6 MCU. The SDK makes it easier to develop firmware for supported devices without the need to understand the intricacies of the device resources.

For additional detail on using the Cypress tools, refer to [AN221774: Getting Started with PSoC 6 MCU](#) and the documentation and help integrated into ModusToolbox. As Figure 1 shows, with the ModusToolbox IDE, you can:

1. Create a new application based on a list of starter applications, filtered by kit or device, or browse the collection of code examples online.
2. Configure device resources in *design.modus* to build your hardware system design in the workspace.
3. Add software components or middleware.
4. Develop your application firmware.

Blocks and Functionality

Figure 3 shows the block diagram.

There are five major subsystems: CPU subsystem, BLE subsystem, system resources, peripheral blocks, and I/O subsystem.

Figure 3. Block Diagram

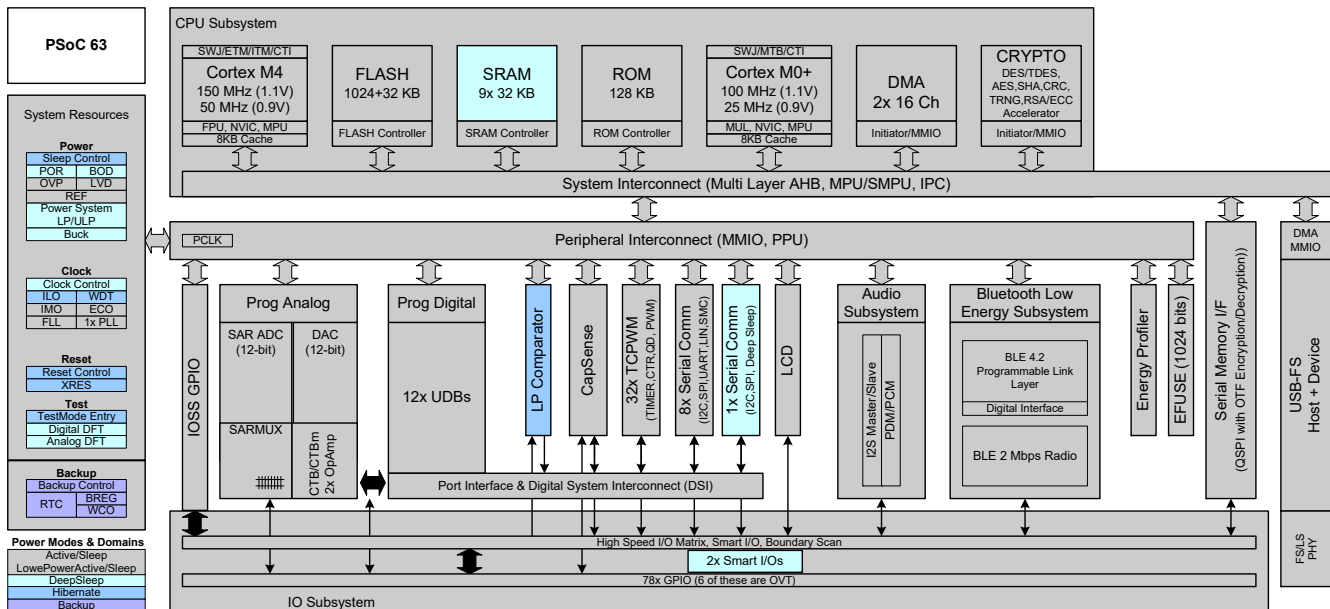

Figure 3 shows the subsystems of the chip and gives a very simplified view of their inter-connections (Multi-layer AHB is used in practice). The color-coding shows the lowest power mode where the particular block is still functional (for example, LP Comparator is functional in Deep Sleep mode).

The PSoC 6 devices include extensive support for programming, testing, debugging, and tracing both hardware and firmware.

Complete debug-on-chip functionality enables full device debugging in the final system using the standard production device. It does not require special interfaces, debugging pods, simulators, or emulators. Only the standard programming connections are required to fully support debug.

The ModusToolbox Integrated Development Environment (IDE) provides fully integrated programming and debug support for these devices. The SWJ (SWD and JTAG) interface is fully compatible with industry-standard third party probes. With the ability to disable debug features, with very robust flash protection, and by allowing customer-proprietary functionality to be implemented in on-chip programmable blocks, PSoC 6 provides a very high level of security.

There are three debug access ports, one each for CM4 and CM0+, and a system port. They are enabled by default. Each can be disabled and enabled independently.

Additionally, all device interfaces can be permanently disabled (device security) for applications concerned about attacks due to a maliciously reprogrammed device or attempts to defeat security by starting and interrupting flash programming sequences. All programming, debug, and test interfaces are disabled when maximum device security is enabled. The security level is a trade-off the customer can make.

Functional Description

The following sections provide an overview of the features, capabilities and operation of each functional block identified in the block diagram in [Figure 3](#). For more detailed information, refer to the following three references.

- Peripheral Driver Library (PDL) Application Programming Interface (API) Reference Manual.

PDL provides low-level drivers for each resource in the device, and supports the entire PSoC 6 MCU portfolio. PDL is an element of the PSoC 6 SDK, which is installed as part of [ModusToolbox](#). With ModusToolbox installed, you can access the PDL API reference manual either from the Documentation tab of the Quick Panel, or you can navigate directly to it at `<install_directory>\ModusToolbox_<version>\libraries\psoc6sw-<version>\docs`. Using PDL should be the primary means of interacting with the PSoC 6 MCU hardware.

- Architecture Technical Reference Manual (TRM)

The architecture TRM provides the detailed description of each resource in the device. This is the next reference to use if it is necessary to understand the operation of the hardware below the software provided by PDL. It describes the architecture and functionality of each resource and explains the operation of each resource in all modes. It provides specific guidance regarding the use of associated registers.

- Register Technical Reference Manual

The register TRM provides the complete list of all registers in the device. It includes the breakdown of all register fields, their possible settings, read/write accessibility, and default states. All registers that have a reasonable use in typical applications have functions to access them from within PDL. Note that ModusToolbox and PDL may provide software default conditions for some registers that are different from and override the hardware defaults.

CPU and Memory Subsystem

PSoC 63 has multiple bus masters, as [Figure 3](#) shows. They are: two CPUs, two DMA controllers, and a Crypto block. Generally, in , all memory and peripherals can be accessed and shared by all bus masters through multi-layer Arm AMBA high-performance bus (AHB) arbitration. Accesses between Cores can be synchronized using an inter-processor communication (IPC) block.

CPU

There are two Arm Cortex CPUs:

The Cortex-M4 (CM4) CPU has single-cycle multiply, a floating-point unit (FPU), and a memory protection unit (MPU). It can run at up to 150 MHz. This is the main CPU, designed for a short interrupt response time, high code density, and high throughput.

CM4 implements a version of the Thumb instruction set based on Thumb-2 technology (defined in the *Armv7-M Architecture Reference Manual*).

The Cortex-M0+ (CM0+) CPU has single-cycle multiply, and an MPU. It can run at up to 100 MHz; however, for CM4 speeds above 100 MHz, CM0+ and bus peripherals are limited to half

the speed of CM4. Thus, for CM4 running at 150 MHz, CM0+ and peripherals are limited to 75 MHz.

CM0+ is the secondary CPU; it is used to implement system calls and device-level security, safety, and protection features. CM0+ provides a secure, uninterruptible boot function. This guarantees that post boot, system integrity is checked and memory and peripheral access privileges are enforced.

CM0+ implements the Armv6-M Thumb instruction set (defined in the *Armv6-M Architecture Reference Manual*).

These CPUs have the following power draw, at $V_{DD} = 3.3\text{ V}$ and using the internal buck regulator:

Table 1. Active Current Slope at $V_{DD} = 3.3\text{ V}$ Using the Internal Buck Regulator

		System Power Mode	
		ULP	LP
CPU	Cortex-M0+	15 $\mu\text{A}/\text{MHz}$	20 $\mu\text{A}/\text{MHz}$
	Cortex-M4	22 $\mu\text{A}/\text{MHz}$	40 $\mu\text{A}/\text{MHz}$

These CPUs can be selectively placed in their Sleep and Deep Sleep power modes as defined by Arm.

Each CPU has an 8-KB instruction cache with 4-way set associativity. Both CPUs have nested vectored interrupt controllers (NVIC) for rapid and deterministic interrupt response, and wakeup interrupt controllers (WIC) for CPU wakeup from Deep Sleep power mode.

These CPUs have extensive debug support. has a debug access port (DAP) that acts as the interface for device programming and debug. An external programmer or debugger (the "host") communicates with the DAP through the device serial wire debug (SWD) or Joint Test Action Group (JTAG) interface pins. Through the DAP (and subject to device security restrictions), the host can access the device memory and peripherals as well as the registers in both CPUs.

Each CPU offers debug and trace features as follows:

- CM4 supports six hardware breakpoints and four watchpoints, 4-bit embedded trace macrocell (ETM), serial wire viewer (SWV), and printf()-style debugging through the single wire output (SWO) pin.

- CM0+ supports four hardware breakpoints and two watchpoints, and a micro trace buffer (MTB) with 4 KB dedicated RAM.

PSoC 63 also has an Embedded Cross Trigger for synchronized debugging and tracing of both CPUs.

Interrupts

PSoC 63 with BLE has 147 system and peripheral interrupt sources and supports interrupts and system exception on both CPUs. CM4 has 147 interrupt request lines (IRQ), with the interrupt source 'n' directly connected to IRQn. CM0+ has 32 interrupts IRQ[31:0] with configurable mapping of one system interrupt source to any of the IRQ[31:0].

Each interrupt supports configurable priority levels (eight levels for CM4 and four levels for CM0+). One system interrupt can be mapped to each of the CPU's non-maskable interrupt (NMI). Up to 41 interrupt sources are capable of waking the device from Deep Sleep power mode using the WIC. Refer to the technical reference manual for details.

DMA Controllers

There are two DMA controllers with 16 channels each. They support independent accesses to peripherals using the AHB Multi-layer bus. The descriptors for DMA channels can be in SRAM or flash. Therefore, the number of descriptors are limited only by the size of the memory. Each descriptor can transfer data in two nested loops with configurable address increments to the source and destination. The size of data transfer per descriptor varies based on the type of DMA channel. Refer to the technical reference manual for detail.

Cryptography Accelerator (Crypto)

This subsystem consists of hardware implementation and acceleration of cryptographic functions and random number generators.

The Crypto subsystem supports the following:

- Encryption/Decryption Functions
 - Data Encryption Standard (DES)
 - Triple DES (3DES)
 - Advanced Encryption Standard (AES) (128-, 192-, 256-bit)
 - Elliptic Curve Cryptography (ECC)
 - RSA cryptography functions
- Hashing functions
 - Secure Hash Algorithm (SHA)
 - SHA1
 - SHA224/256/384/512
- Message authentication functions (MAC)
 - Hashed message authentication code (HMAC)
 - Cipher-based message authentication code (CMAC)
- 32-bit cyclic redundancy code (CRC) generator
- Random number generators
 - Pseudo random number generator (PRNG)
 - True random number generator (TRNG)

Protection Units

PSoC 63 with BLE has multiple types of protection units to control erroneous or unauthorized access to memory and peripheral registers. CM4 and CM0+ have Arm MPUs for protection at the bus master level. Other bus masters use additional MPUs. Shared memory protection units (SMPUs) help implement memory protection for memory/ resources that are shared among multiple bus masters. Peripheral protection units (PPU) are similar to SMPUs but are designed for protecting the peripheral register space.

Protection units support memory and peripheral access attributes including address range, read/write, code/data, privilege level, secure/non-secure, and protection context.

Protection units are configured at secure boot to control access privileges and rights for bus masters and peripherals.

Up to eight protection contexts (secure boot is in protection context 0) allow access privileges for memory and system resources to be set by the secure boot process per protection context by bus master and code privilege level. Multiple protection contexts are supported on a single CPU.

Memory

PSoC 63 with BLE contains flash, SRAM, ROM, and eFuse memory blocks.

■ Flash

Up to 1 MB of application flash is provided, with two additional 32-KB flash sectors. The application flash is organized into 256-KB sectors. The first 32-KB flash sector is typically used for EEPROM emulation, or equivalent data storage. The second 32-KB region is the supervisory flash (SFlash). Data stored in SFlash includes device trim values, [Flash Boot](#) executable code, and encryption keys. After the device transitions into secure mode, SFlash can no longer be changed.

The flash has 128-bit-wide accesses to reduce power. Write operations can be performed at the row level. A row, also referred to as a page, is 512 bytes. Read operations are supported in both System Low Power and Ultra-Low Power modes, however write operations may not be performed in System Ultra-Low Power mode.

■ SRAM

There is 288 KB of SRAM memory, which can be fully retained or retained in increments of user-designated 32 KB blocks.

■ ROM

The 128-KB ROM, also referred to as the supervisory ROM (SROM), provides code ([ROM Boot](#)) for several system functions. The PSoC 6 MCU ROM contains device initialization, flash write, security, eFuse programming, and other system-level routines. ROM code is executed only by the CM0+ CPU, in protection context 0. A system function can be initiated by either CPU, or through the DAP. This causes an NMI interrupt in CM0+, which causes CM0+ to execute the system function.

■ eFuse

One-time-programmable eFuse consists of 1024 bits, of which 512 are reserved for system use. The remaining bits are available for storing security key information, hash values, unique IDs or other similar user-defined content. Each fuse is individually programmed; once programmed (or “blown”), its state cannot be changed. Blowing a fuse transitions it from the default state of 0 to 1. To program an eFuse, V_{DDIO0} must be at $2.5\text{ V} \pm 5\%$, with a current draw of 14 mA (max).

Boot Code

Two blocks of code, [ROM Boot](#) and [Flash Boot](#), are pre-programmed into the device and work together to provide device startup and configuration, basic security features, life-cycle stage management and other system functions.

■ ROM Boot

On a device reset, the boot code in ROM is the first code to execute. This code performs the following:

- Integrity checks of flash boot code
- Device trim setting (calibration)
- Setting the device protection units
- Setting device access restrictions for secure life-cycle states

ROM cannot be changed and acts as the Root of Trust in a secure system. ROM code will guarantee secure boot if authentication of application flash is required.

Flash Boot

Flash boot is firmware stored in SFlash that ensures that only a validated application may run on the device. It also ensures that the firmware image has not been modified, such as by a malicious third party.

Flash boot:

- Is validated by ROM Boot
- Runs after ROM Boot and before the user application
- Verifies the integrity of the user application
- Enables system calls
- Configures the Debug Access Port
- Launches the user application in the CM4

If the user application cannot be validated, then flash boot ensures that the device is transitioned into a safe state.

Memory Map

Both CPUs have a fixed address map, with shared access to memory and peripherals. The 32-bit (4 GB) address space is divided into the regions shown in [Table 2](#). Note that code can be executed from the code and SRAM regions.

Table 2. Address Map for CM4 and CM0+

Address Range	Name	Use
0x0000 0000 – 0x1FFF FFFF	Code	Program code region. Data can also be placed here. It includes the exception vector table, which starts at address 0.
0x2000 0000 – 0x3FFF FFFF	SRAM	Data region. Code can also be executed from this region. Note that CM4 bit-band in this region is not supported.
0x4000 0000 – 0x5FFF FFFF	Peripheral	All peripheral registers. Code cannot be executed from this region. Note that CM4 bit-band in this region is not supported.
0x6000 0000 – 0x9FFF FFFF	External RAM	Code can be executed from this region.
0xA000 0000 – 0xDFFF FFFF	External device	Not used.
0xE000 0000 – 0xE00F FFFF	Private peripheral Bus	Provides access to peripheral registers within the CPU core.
0xE010 0A000 – 0xFFFF FFFF	Device	Device-specific system registers.

The device memory map shown in [Table 3](#) applies to both CPUs. That is, the CPUs share access to all PSoC 6 MCU memory and peripheral registers. Note that code can be executed from the Code, SRAM, and external RAM regions.

Table 3. Internal Memory Address Map for CM4 and CM0+

Address Range	Memory Type	Size
0x0000 0000 – 0x0001 FFFF	ROM	128 KB
0x0800 0000 – 0x0804 7FFF	SRAM	Up to 288 KB
0x1000 0000 – 0x100F FFFF	Application flash	Up to 1 MB
0x1400 0000 – 0x1400 7FFF	EEPROM emulation flash	32 KB
0x1600 0000 – 0x1600 7FFF	Supervisory flash	32 KB
0x1800 0000 - 0x1FFF FFFF	External memory execute in place region	Up to 128 MB

Note that the SRAM is located in the Code region for both CPUs (see [Table 2](#)). There is no physical memory located in the CPUs' SRAM region.

System Resources

Power System

The power system provides assurance that voltage levels are as required for each respective mode and will either delay mode entry (on power-on reset (POR), for example) until voltage levels are as required for proper function or generate resets (brown-out detect (BOD)) when the power supply drops below specified levels. The design guarantees safe chip operation between power supply voltage dropping below specified levels (for example, below 1.7 V) and the reset occurring. There are no voltage sequencing requirements.

The V_{DD} supply (1.7 to 3.6 V) powers an on-chip buck regulator or an LDO, selectable by the user. In addition, both the buck and the LDO offer a selectable (0.9 or 1.1 V) core operating voltage (V_{CCD}). The selection lets users choose between two system power modes:

- System Low Power (LP) operates V_{CCD} at 1.1 V and offers high performance, with no restrictions on any of the device configurations.
- System Ultra Low Power (ULP) operates V_{CCD} at 0.9 V for exceptional low power results, but imposes limitations on maximum clock speeds.

An additional backup domain adds an “always on” functionality using a separate power domain supplied by a backup supply (V_{BACKUP}) such as a battery or supercapacitor. It includes a real-time clock (RTC) with alarm feature, supported by a 32.768-kHz watch crystal oscillator (WCO), and power-management IC (PMIC) control. Pin 5 of Port 0 (P0.5) can be assigned as an enable signal for an external PMIC. RTC alarms can be used as a trigger for the PMIC enable signal.

Power Modes

PSoC 6 MCU can operate in four system and three CPU power modes. These modes are intended to minimize the average power consumption in an application. For more details on power modes and other power-saving configuration options, see the application note, [AN219528: PSoC 6 MCU Low-Power Modes and Power Reduction Techniques](#) and the [Architecture TRM, Power Modes chapter](#).

Power modes supported by PSoC 6 MCUs, in the order of decreasing power consumption, are:

- System Low Power (LP) – All peripherals and CPU power modes are available at maximum speed
- System Ultra Low Power (ULP) – All peripherals and CPU power modes are available, but with limited speed
- CPU Active – CPU is executing code in system LP or ULP mode
- CPU Sleep – CPU code execution is halted in system LP or ULP mode
- CPU Deep Sleep – CPU code execution is halted and system Deep Sleep is requested in system LP or ULP mode
- System Deep Sleep – Only low-frequency peripherals are available after both CPUs enter CPU Deep Sleep mode
- System Hibernate – Device and I/O states are frozen and the device resets on wakeup

CPU Active, Sleep, and Deep Sleep are standard Arm-defined power modes supported by the Arm CPU instruction set architecture (ISA). LP, ULP, Deep Sleep and Hibernate modes are additional low-power modes supported by PSoC 6 MCU. Hibernate mode is the lowest power mode in the PSoC 6 MCU and on wakeup, the CPU and all peripherals go through a reset.

Clock System

The PSoC 63 with BLE clock system consists of the following (see Figure 3):

- IMO
- ILO/PILO
- Watch crystal oscillator (WCO)
- External MHz crystal oscillator (ECO)
- External clock input
- One PLL
- One FLL

Clocks may be buffered and brought out to a pin on a smart I/O port.

IMO Clock Source

The IMO is the primary source of internal clocking. It is trimmed during testing to achieve the specified accuracy. The IMO default frequency is 8 MHz. IMO tolerance is $\pm 2\%$ and its current consumption is less than 10 μA .

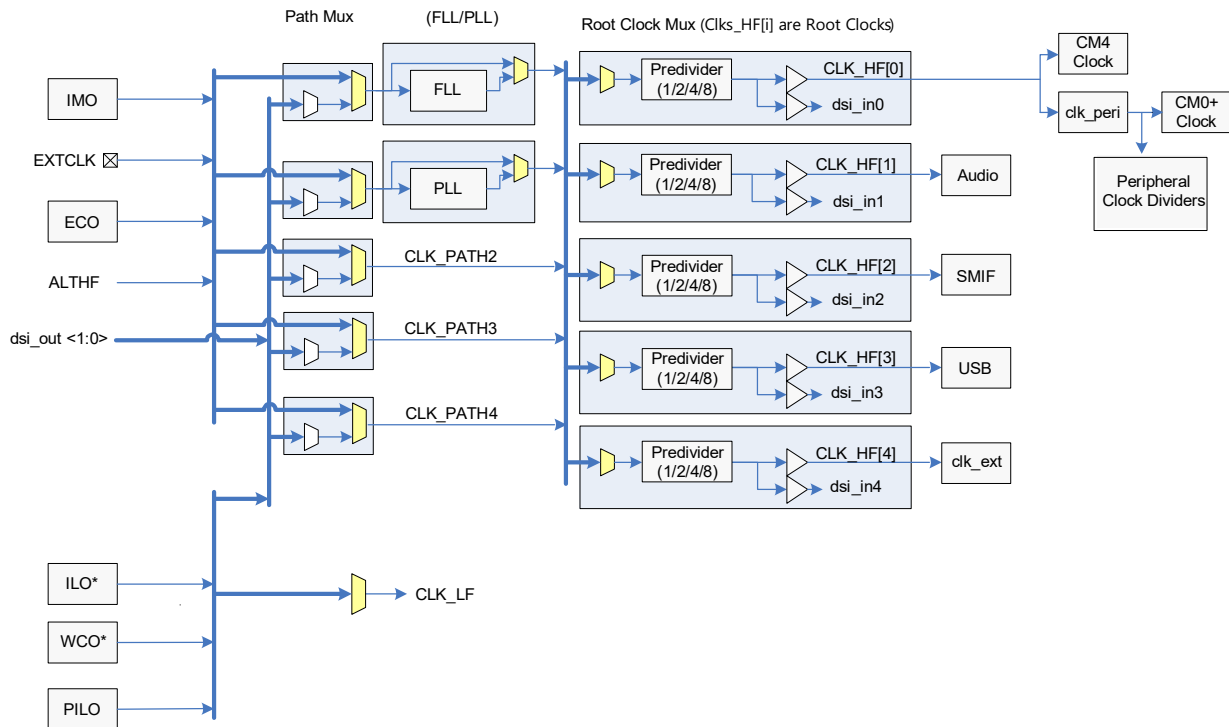

ILO Clock Source

The ILO is a very low power oscillator, nominally 32 kHz, which operates in all power modes. The ILO can be calibrated against a higher accuracy clock for better accuracy.

Precision ILO (PILO)

PILO is an additional source that can provide a more accurate 32.768-kHz clock than ILO when periodically calibrated using a high-accuracy clock such as the ECO. The PILO works in Deep Sleep and higher modes. It does not work in Hibernate mode.

Figure 4. Clocking Diagram

Watchdog Timer

A watchdog timer is implemented in the clock block running from the ILO; this allows watchdog operation during Deep Sleep and Hibernate modes, and generates a watchdog reset if not serviced before the timeout occurs. The watchdog reset is recorded in the Reset Cause register.

Clock Dividers

Integer and fractional clock dividers are provided for peripheral use and timing purposes. There are:

- Eight 8-bit clock dividers
- Sixteen 16-bit integer clock dividers
- Four 16.5-bit fractional clock dividers
- One 24.5-bit fractional clock divider

Trigger Routing

PSoC 6 MCU contains a trigger multiplexer block. This is a collection of digital multiplexers and switches that are used for routing trigger signals between peripheral blocks and between GPIOs and peripheral blocks.

Reset

PSoC 6 MCU can be reset from a variety of sources:

- Power-on reset (POR) to hold the device in reset while the power supply ramps up to the level required for the device to function properly. POR activates automatically at power-up.
- Brown-out detect (BOD) reset to monitor the digital voltage supply V_{DD} and generate a reset if V_{DD} falls below the minimum required logic operating voltage.
- External reset (XRES) to reset the device using an external input. The XRES pin is active LOW – a logic ‘1’ on the pin has no effect and a logic ‘0’ causes reset. The pin is pulled to logic ‘1’ inside the device. XRES is available as a dedicated pin.
- Watchdog timer (WDT) reset to reset the device if the firmware execution fails to service the watchdog timer within a specified timeout period.
- Software-initiated reset to reset the device on demand using firmware.
- Logic-protection fault can trigger an interrupt to a fault handler or reset the device if unauthorized operating conditions occur; for example, reaching a debug breakpoint while executing privileged code.
- Hibernate wakeup reset to bring the device out of the Hibernate low-power mode.

Reset events are asynchronous and guarantee reversion to a known state. Some of the reset sources are recorded in a register, which is retained through reset and allows software to determine the cause of the reset.

BLE Radio and Subsystem

PSoC 63 with BLE incorporates a Bluetooth Smart subsystem that contains the Physical Layer (PHY) and Link Layer (LL) engines with an embedded security engine. The physical layer consists of the digital PHY and the RF transceiver that transmits and receives GFSK packets at 2 Mbps over a 2.4-GHz ISM band, which is compliant with Bluetooth Smart Bluetooth Specification 5.0. The baseband controller is a composite hardware and firmware implementation that supports both master and slave modes. Key protocol elements, such as HCI and link control, are implemented in firmware. Time-critical functional blocks, such as encryption, CRC, data whitening, and access code correlation, are implemented in hardware (in the LL engine).

The RF transceiver contains an integrated balun, which provides a single-ended RF port pin to drive a 50- Ω antenna via a matching/filtering network. In the receive direction, this block converts the RF signal from the antenna to a digital bit stream after performing GFSK demodulation. In the transmit direction, this block performs GFSK modulation and then converts a digital baseband signal to a radio frequency before transmitting it to air through the antenna.

Key features of BLESS are as follows:

- Master and slave single-mode protocol stack with logical link control and adaptation protocol (L2CAP), attribute (ATT), and security manager (SM) protocols
- API access to generic attribute profile (GATT), generic access profile (GAP), and L2CAP
- L2CAP connection-oriented channel (Bluetooth 4.1 feature)
- GAP features
 - Broadcaster, Observer, Peripheral, and Central roles
 - Security mode 1: Level 1, 2, and 3
 - User-defined advertising data
 - Multiple bond support
- GATT features
 - GATT client and server
 - Supports GATT sub-procedures
 - 32-bit universally unique identifier (UUID) (Bluetooth 4.1 feature)
- Security Manager (SM)
 - Pairing methods: Just works, Passkey Entry, and Out of Band
 - LE Secure Connection Pairing model
 - Authenticated man-in-the-middle (MITM) protection and data signing
- Link Layer (LL)
 - Master and Slave roles
 - 128-bit AES engine
 - Low-duty cycle advertising
 - LE Ping
- Supports all SIG-adopted BLE profiles
- Power levels for Adv (1.28s, 31 bytes, 0 dBm) and Con (300 ms, 0 byte, 0 dBm) are 42 μ W and 70 μ W respectively

Programmable Analog Subsystem

12-bit SAR ADC

The 12-bit, 1-Msps SAR ADC can operate at a maximum clock rate of 18 MHz and requires a minimum of 18 clocks at that frequency to do a 12-bit conversion. One of three internal reference voltages may be used for the ADC reference voltage. The references are, V_{DD} , $V_{DD}/2$, and V_{REF} (nominally 1.2 V and trimmed to $\pm 1\%$). An external reference may also be used, by either driving the VREF pin or routing an external reference to GPIO pin P9.7. These reference options allow ratio-metric readings or absolute readings at the accuracy of the reference used. The input range of the ADC is the full supply voltage between V_{SS} and V_{DDA}/V_{DDIOA} . The SAR ADC may be configured with a mix of single ended and differential signals in the same configuration.

The SAR ADC's sample-and-hold (S/H) aperture is programmable to allow sufficient time for signals with a high impedance to settle sufficiently, if required. System performance will be 65 dB for true 12-bit precision provided appropriate references are used and system noise levels permit it. To improve performance in noisy conditions, an external bypass capacitor for the internal reference amplifier (through the fixed "VREF" pin), may be added.

The SAR is connected to a fixed set of pins through an input sequencer. The sequencer cycles through the selected channels autonomously (sequencer scan) and does so with zero switching overhead (that is, the aggregate sampling bandwidth is equal to 1 Msps whether it is for a single channel or distributed over several channels). The result of each channel is buffered, so that an interrupt may be triggered only when a full scan of all channels is complete. Also, a pair of range registers can be set to detect and cause an interrupt if an input exceeds a minimum and/or maximum value. This allows fast detection of out-of-range values without having to wait for a sequencer scan to be completed and the CPU to read the values and check for out-of-range values in software. The SAR can also be connected, under firmware control, to most other GPIO pins via the Analog Multiplexer Bus (AMUXBUS). The SAR is not available in Deep Sleep and Hibernate modes as it requires a high-speed clock (up to 18 MHz). The SAR operating range is 1.71 to 3.6 V.

Temperature Sensor

An on-chip temperature sensor is part of the SAR sequencer block and may be scanned by the SAR ADC. It consists of a diode, which is biased by a current source that can be disabled to save power. The temperature sensor may be connected directly to the SAR ADC as one of the measurement channels. The ADC digitizes the temperature sensor's output and a Cypress-supplied software function may be used to convert the reading to temperature which includes calibration and linearization.

12-bit Digital-Analog Converter

There is a 12-bit voltage mode DAC on the chip, which can settle in less than 5 μ s. The DAC may be driven by the DMA controllers to generate user-defined waveforms. The DAC output from the chip can either be the resistive ladder output (highly linear near ground) or a buffered output.

Continuous Time Block (CTBm) with Two Opamps

This block consists of two opamps, which have their inputs and outputs connected to fixed pins and have three power modes and a comparator mode. The outputs of these opamps can be used as buffers for the SAR inputs. The non-inverting inputs of these opamps can be connected to either of two pins, thus allowing independent sensors to be used at different times. The pin selection can be made via firmware. The opamps can be set to one of the four power levels; the lowest level allowing operation in Deep Sleep mode in order to preserve lower performance Continuous-Time functionality in Deep Sleep mode. The DAC output can be buffered through an opamp.

Low-Power Comparators

Two low-power comparators are provided, which can operate in all power modes. This allows other analog system resources to be disabled while retaining the ability to monitor external voltage levels during Deep Sleep and Hibernate modes. The comparator outputs are normally synchronized to avoid metastability unless operating in an asynchronous power mode (Hibernate) where the system wake-up circuit is activated by a comparator-switch event.

- Double buffering of compare/capture and period values
- Underflow, overflow, and capture/compare output signals
- Supports interrupt on:
 - Terminal count – Depends on the mode; typically occurs on overflow or underflow
 - Capture/compare – The count is captured to the capture register or the counter value equals the value in the compare register
- Complementary output for PWMs
- Selectable start, reload, stop, count, and capture event signals for each TCPWM with rising edge, falling edge, both edges, and level trigger options. The TCPWM has a Kill input to force outputs to a predetermined state; for example, this is used in motor-drive systems when an overcurrent state is indicated and the PWMs driving the FETs need to be shut off immediately with no time for software intervention.

In this device there are:

- Eight 32-bit TCPWMs
- Twenty-four 16-bit TCPWMs

Serial Communication Blocks (SCB)

PSoC 63 with BLE has 9 SCBs:

- Eight can implement either I²C, UART, or SPI.
- One SCB can operate in Deep Sleep with an external clock, this SCB can be either SPI slave or I²C slave.

I²C Mode: The SCB can implement a full multi-master and slave interface (it is capable of multimaster arbitration). This block can operate at speeds of up to 1 Mbps (Fast Mode Plus). It also supports EzI2C that creates a mailbox address range in the memory of PSoC 63 and effectively reduces the I2C communication to reading from and writing to an array in the memory. The SCB supports a 256-byte FIFO for receive and transmit.

The I²C peripheral is compatible with I²C standard-mode, Fast Mode, and Fast Mode Plus devices as defined in the NXP I²C-bus specification and user manual (UM10204). The I²C bus I/O is implemented with GPIO in open-drain modes.

UART Mode: This is a full-feature UART operating at up to 8 Mbps. It supports automotive single-wire interface (LIN), infrared interface (IrDA), and SmartCard (ISO7816) protocols, all of which are minor variants of the basic UART protocol. In addition, it supports the 9-bit multiprocessor mode that allows the addressing of peripherals connected over common RX and TX lines. Common UART functions such as parity error, break detect, and frame error are supported. A 256-byte FIFO allows much greater CPU service latencies to be tolerated.

SPI Mode: The SPI mode supports full Motorola SPI, TI Secure Simple Pairing (SSP) (essentially adds a start pulse that is used to synchronize SPI Codecs), and National Microwire (half-duplex form of SPI). The SPI block supports an EzSPI mode in which the data interchange is reduced to reading and writing an array in memory. The SPI interface will operate with a 25-MHz SPI Clock.

USB Full-Speed Dual Role Host and Device Interface

PSoC 63 with BLE incorporates a dual-role USB Host and Device interface. The device can have up to eight endpoints. A 512 byte SRAM buffer is provided and DMA is supported.

QSPI Interface Serial Memory Interface (SMIF)

A serial memory interface is provided, running at up to 80 MHz. It supports single, dual, quad, dual-quad and octal SPI configurations, and supports up to four external memory devices. It supports two modes of operation:

- Memory-mapped I/O (MMIO), a command mode interface that provides data access via the SMIF registers and FIFOs
- Execute in Place (XIP), in which AHB reads and writes are directly translated to SPI read and write transfers.

In XIP mode, the external memory is mapped into the PSoC 6 MCU internal address space, enabling code execution directly from the external memory. To improve performance, a 4-KB cache is included. XIP mode also supports AES-128 on-the-fly encryption and decryption, enabling secure storage and access of code and data in the external memory.

GPIO

PSoC 63 with BLE has up to 78 GPIOs. The GPIO block implements the following:

- Eight drive strength modes:
 - Analog input mode (input and output buffers disabled)
 - Input only
 - Weak pull-up with strong pull-down
 - Strong pull-up with weak pull-down
 - Open drain with strong pull-down
 - Open drain with strong pull-up
 - Strong pull-up with strong pull-down
 - Weak pull-up with weak pull-down
- Input threshold select (CMOS or LVTTTL)
- Hold mode for latching previous state (used for retaining the I/O state in Deep Sleep and Hibernate modes)
- Selectable slew rates for dV/dt-related noise control to improve EMI

The pins are organized in logical entities called ports, which are up to 8-pin in width. During power-on and reset, the pins are forced to the disable state so as not to crowbar any inputs and/or cause excess turn-on current. A multiplexing network known as the high-speed I/O matrix (HSIOM) is used to multiplex between various peripheral and analog signals that may connect to an I/O pin. Data output and pin state registers store, respectively, the values to be driven on the pins and the states of the pins themselves.

Every I/O pin can generate an interrupt if so enabled; each I/O port has an interrupt request (IRQ) and interrupt service routine (ISR) vector associated with it. Six GPIO pins are capable of overvoltage-tolerant (OVT) operation where the input voltage may be higher than VDD. (These OVT pins are commonly used for the I²C functionality to allow powering the chip OFF while maintaining a physical connection to an operating I²C bus without affecting its functionality).

GPIO pins can be ganged to source or sink higher values of current. GPIO pins, including OVT pins, may not be pulled up higher than 3.6 V.

Special-Function Peripherals

Audio Subsystem

This subsystem consists of the following hardware blocks:

- One Inter-IC Sound (I²S) interfaces
- Two pulse-density modulation to pulse-code modulation decoder channels

The I²S interface implements two independent hardware FIFO buffers – TX and RX, which can operate in master or slave mode. The following features are supported:

- Multiple data formats – I²S, left-justified, Time Division Multiplexed (TDM) mode A, and TDM mode B
- Programmable channel/word lengths – 8/16/18/20/24/32 bits
- Internal/external clock operation. Up to 192 ksp/s
- Interrupt mask events – trigger, not empty, full, overflow, underflow, watchdog
- Configurable FIFO trigger level with DMA support

The I²S interface is commonly used to connect with audio codecs, simple DACs, and digital microphones.

The PDM-to-PCM decoder implements a single hardware RX FIFO that decodes a stereo or mono 1-bit PDM input stream to PCM data output. The following features are supported:

- Programmable data output word length – 16/18/20/24 bits

- Programmable gain amplifier (PGA) for volume control – from –12 dB to +10.5 dB in 1.5 dB steps
- Configurable PDM clock generation. Range from 384 kHz to 3.072 MHz
- Droop correction and configurable decimation rate for sampling; up to 48 ksp/s
- Programmable high-pass filter gain
- Interrupt mask events – not empty, overflow, trigger, underflow
- Configurable FIFO trigger level with DMA support

The PDM-to-PCM decoder is commonly used to connect to digital PDM microphones. Up to two microphones can be connected to the same PDM Data line.

CapSense Subsystem

CapSense is supported in PSoC 6 MCU through a CapSense sigma-delta (CSD) hardware block. It is designed for high-sensitivity self-capacitance and mutual-capacitance measurements, and is specifically built for user interface solutions.

In addition to CapSense, the CSD hardware block supports three general-purpose functions. These are available when CapSense is not being used. Alternatively, two or more functions can be time-multiplexed in an application under firmware control. The four functions supported by the CSD hardware block are:

- CapSense
- 10-bit ADC
- Programmable current sources (IDAC)
- Comparator

CapSense

Capacitive touch sensors are designed for user interfaces that rely on human body capacitance to detect the presence of a finger on or near a sensor. Cypress CapSense solutions bring elegant, reliable, and simple capacitive touch sensing functions to applications including IoT, industrial, automotive, and home appliances.

The Cypress-proprietary CapSense technology offers the following features:

- Best-in-class signal-to-noise ratio (SNR) and robust sensing under harsh and noisy conditions
- Self-capacitance (CSD) and mutual-capacitance (CSX) sensing methods
- Support for various widgets, including buttons, matrix buttons, sliders, touchpads, and proximity sensors
- High-performance sensing across a variety of materials
- Best-in-class liquid tolerance
- SmartSense™ auto-tuning technology that helps avoid complex manual tuning processes
- Superior immunity against external noise
- Spread-spectrum clocks for low radiated emissions
- Gesture and built-in self-test libraries
- Ultra-low power consumption
- An integrated graphical CapSense tuner for real-time tuning, testing, and debugging

ADC

The CapSense subsystem slope ADC offers the following features:

- Selectable 8- or 10-bit resolution
- Selectable input range: GND to V_{REF} and GND to V_{DDA} on any GPIO input
- Measurement of V_{DDA} against an internal reference without the use of GPIO or external components

IDAC

The CSD block has two programmable current sources, which offer the following features:

- 7-bit resolution
- Sink and source current modes
- A current source programmable from 37.5 nA to 609 μ A
- Two IDACs that can be used in parallel to form one 8-bit IDAC

Comparator

The CapSense subsystem comparator operates in the System Low Power and Ultra-Low Power modes. The inverting input is connected to an internal programmable reference voltage and the non-inverting input can be connected to any GPIO via the AMUXBUS.

CapSense Hardware Subsystem

Figure 6 shows the high-level hardware overview of the CapSense subsystem, which includes a delta sigma converter, internal clock dividers, a shield driver, and two programmable current sources.

The inputs are managed through analog multiplexed buses (AMUXBUS A/B). The input and output of all functions offered by the CSD block can be provided on any GPIO or on a group of GPIOs under software control, with the exception of the comparator output and external capacitors that use dedicated GPIOs.

Self-capacitance is supported by the CSD block using AMUXBUS A, an external modulator capacitor, and a GPIO for each sensor. There is a shield electrode (optional) for self-capacitance sensing. This is supported using AMUXBUS B and an optional external shield tank capacitor (to increase the drive capability of the shield driver) should this be required. Mutual-capacitance is supported by the CSD block using AMUXBUS A, two external integrated capacitors, and a GPIO for transmit and receive electrodes.

The ADC does not require an external component. Any GPIO that can be connected to AMUXBUS A can be an input to the ADC under software control. The ADC can accept V_{DDA} as an input without needing GPIOs (for applications such as battery voltage measurement).

The two programmable current sources (IDACs) in general-purpose mode can be connected to AMUXBUS A or B. They can therefore connect to any GPIO pin. The comparator resides in the delta-sigma converter. The inverting input is connected to V_{REF} , with output on dedicated GPIO. The non-inverting input and output is accessible on any GPIO using AMUXBUS.

The CSD block can operate in active and sleep CPU power modes, and seamlessly transition between LP and ULP system modes. It can be powered down in Deep Sleep and Hibernate modes. Upon wakeup from Hibernate mode, the CSD block requires re-initialization. However, operation can be resumed without re-initialization upon exit from Deep Sleep mode, under firmware control.

Figure 6. CapSense Hardware Subsystem

Figure 7 shows the high-level software overview. Cypress provides a middleware library for each function to enable quick integration. User applications interact only with middleware to implement functions of the CSD block. The middleware interacts with underlying drivers to access hardware as necessary. The CSD driver facilitates time-multiplexing of the CSD hardware if more than one piece of CSD-related middleware is present in a project. It prevents access conflicts in this case.

CapSense middleware has configurator software to enable fast configuration and incorporating it into middleware. It also has a tuner for performance evaluation and real-time tuning of the system. Both can be launched from the ModusToolbox IDE or in standalone mode. The tuner requires the EZ12C communication interface in the application to enable real-time tuning capability. The tuner can update configuration parameters directly in the device as well as in the configurator.

CapSense and ADC middleware use the CSD interrupt to implement non-blocking sensing and A-to-D conversion. Therefore, interrupt service routines are a defined part of the middleware, which must be initialized by the application. For dual-CPU devices, middleware and drivers can operate on either CPU. Cypress recommends using the middleware only in one

CPU. If both CPUs must access the CSD driver, memory access should be managed in the application.

Refer to [AN85951: PSoC 4 and PSoC 6 MCU CapSense Design Guide](#) for more details on CSX sensing, CSD sensing, shield electrode usage and its benefits, and capacitive system design guidelines. Refer to the middleware API reference guide available in the PSoC 6 SDK for more detail on middleware.

The correspondence of power supplies to ports by package type is as follows:

- P0: VBACKUP
- P1: VDDD. Port 1 Pins are Over-Voltage Tolerant (OVT).
- P5, P6, P7, P8: VDDIO1
- P9, P10: VDDA
- P11, P12, P13: VDDIO0

Each Port Pin has multiple alternate functions. These are defined in Table 8.

Note

- The notation for a signal is of the form IPName[x].signal_name[u]:y.
 IPName = Name of the block (such as tcpwm), x = Unique instance of the IP, Signal_name = Name of the signal, u = Signal number where there are more than one signals for a particular signal name, y = Designates copies of the signal name.
 For example, the name tcpwm[0].line_comp[3]:4 indicates that this is instance 0 of a tcpwm block, the signal is line_comp # 3 (complement of the line output) and this is the fourth occurrence (copy) of the signal. Signal copies are provided to allow flexibility in routing and to maximise utilisation of on-chip resources.

Note

- The notation for a signal is of the form IPName[x].signal_name[u]:y.
 IPName = Name of the block (such as tcpwm), x = Unique instance of the IP, Signal_name = Name of the signal, u = Signal number where there are more than one signals for a particular signal name, y = Designates copies of the signal name.
 For example, the name tcpwm[0].line_comp[3]:4 indicates that this is instance 0 of a tcpwm block, the signal is line_comp # 3 (complement of the line output) and this is the fourth occurrence (copy) of the signal. Signal copies are provided to allow flexibility in routing and to maximise utilisation of on-chip resources.

Power Supply Considerations

The power system diagram (see Figure 8) shows the general requirements for power pins. The diagram also shows the radio pins that need to be decoupled. The power scheme allows different VDDIO and VDDA connections. Because no sequencing requirements need to be analyzed and specified, customers may bring up the power supplies in any order and the power system is responsible for ensuring power is good in all domains before allowing operation. VDDD, VDDA, and VDDIO may be separate nets, which are not ohmically connected on

chip. Depending on different package requirements, these may be required to be connected off chip.

The power system will have a buck regulator in addition to an LDO. A Single Input Multiple Output (SIMO) Buck regulator with multiple outputs allows saving an inductor and also providing a high-efficiency supply to the radio (see Figure 8).

Figure 8. Power Connections

Note

2. Applicable for PSoC 6 devices with BLE only.

Figure 8 shows the power supply pins to the PSoC and the connections between the PSoC and the radio. It also shows which pins need bypass capacitors. Refer to [AN218241 - PSoC 6 MCU Hardware Design Considerations](#) for details on the required connections for any given design.

Description of power pins is as follows:

- **VBACKUP** is the supply to the backup domain. The backup domain includes the 32-kHz WCO, RTC, and backup registers. It can generate a wake-up interrupt to the chip via the RTC timers or an external input. It can also generate an output to wakeup external circuitry. It is connected to VDDD when not used as a separate battery backup domain. VBACKUP provides the supply for Port 0.
- **VDDD** is the main digital supply input (1.7 to 3.6 V). It provides the inputs for the internal Regulators and for Port 1.
- **VDDA** is the supply for analog peripherals (1.7 to 3.6 V). It must be connected to VDDIOA on the PCB.
- **VDDIOA** is the supply to for Ports 9 and 10. It must be connected to VDDA on the PCB when present. Ports 9 and 10 are supplied by VDDA when VDDIOA is not present.
- **VDD_NS** is the supply input to the Buck and should be at the same potential as VDDD. The bypass capacitor between VDD_NS and ground should be 10 μ F.
- **VDDIO0** is the Supply for Ports 11 to 13 when present. When not present, these ports are supplied by VDDD.
- **VDDIO1** is the Supply for Ports 5 to 8 when present. When not present, these ports are supplied by VDDA.
- **VDDIOR** is the Supply for Ports 2 to 4 on the 124 BGA only.
- **VDDUSB** is the USB supply and is required to be 2.85 V to 3.6 V for USB operation. In addition, the pin powers Port 14. When USB is not used, this pin can be 1.7 V to 3.6 V for using Port 14 pins as GPIOs

All the pins above may be shorted to VDDD as shown in [Figure 8](#).

- **VBUCK1** is the output 1 of on-chip SIMO regulator and requires a bypass capacitor connection for proper operation. This output can power VCCD when internal regulators are powered down.
- **VCCD** is the internal core regulators' (LDO) output and requires a bypass capacitor connection for proper operation. Used as core supply input when internal regulators are OFF.
- **VRF** is the output 2 of the on-chip SIMO regulator and requires bypass capacitor connection for proper operation. This output can power the VDCDC input.
- **VDCDC** is the BLE radio digital supply input and is typically connected to VRF externally.
- The **VDDR1**, **VDDR2**, and **VDDR3** pins are for the BLE radio analog supply input and are connected to VDCDC externally.
- **VDDR_HVL** is the PSoC 6 MCU to BLE radio interface supply output and requires a bypass capacitor connection for proper operation.
- **DVDD** is the BLE subsystem regulators' (LDO) output and requires a bypass capacitor connection for proper operation.

The supply voltage range is 1.71 to 3.6 V with all functions and circuits operating over that range. All grounds must be shorted together on the PCB. Bypass capacitors must be used from VDDD and VDDA to ground and wherever indicated in the diagram. Typical practice for systems in this frequency range is to use a capacitor in the 10- μ F range in parallel with a smaller capacitor (0.1 μ F, for example). Note that these are simply rules of thumb and that, for critical applications, the PCB layout, lead inductance, and the bypass capacitor parasitic should be simulated to design and obtain optimal bypassing. Recommended Buck output capacitor values are 10 μ F for Vrf and 4.7 μ F for VBUCK1. The capacitor connected to Vind2 should be 100 nF. All capacitors should be $\pm 20\%$ or better; the recommended inductor value is 2.2 μ H $\pm 20\%$ (for example, TDK MLP2012H2R2MT0S1).

Note

- Usage above the absolute maximum conditions listed in Table 10 may cause permanent damage to the device. Exposure to absolute maximum conditions for extended periods of time may affect device reliability. The maximum storage temperature is 150 °C in compliance with JEDEC Standard JESD22-A103, High Temperature Storage Life. When used below absolute maximum conditions but above normal operating conditions, the device may not operate to specification.

Note

6. It can take as much as 16 milliseconds to write to flash. During this time, the device should not be reset, or flash operations will be interrupted and cannot be relied on to have completed. Reset sources include the XRES pin, software resets, CPU lockup states and privilege violations, improper power supply levels, and watchdogs. Make certain that these are not inadvertently activated.

Errata

This section describes the errata for the PSoC 6 63 Product Family. Details include errata trigger conditions, scope of impact, available workarounds, and silicon revision applicability. Compare this document to the device's data sheet for a complete functional description. Contact your local Cypress Sales Representative if you have questions.

PSoC 6 63 Errata Summary

Noise is caused in supply and ground traces when multiple outputs switch. The amount of noise is dependent on the number of outputs, the drive strength of the output drivers, the frequency of the switching, and the impact on specific ports. The noise is worse at higher voltages ($V_{DD} = 2.7\text{ V}$ and higher) and should not be an issue with 1.8 V externally regulated (that is, $V_{DD} = 1.8\text{ V} \pm 5\%$) designs.

For cases where there are large numbers of GPIOs switching simultaneously, the following errata conditions are applicable. Note that the exact number cannot be specified as there are too many system-dependent conditions.

This table defines the errata applicability to available PSoC 63 family devices.

Items	CY8C6XX 63	Silicon Revision	Fix Status
[1] Drive mode strength must be limited.	All	*C silicon	Investigation underway. Fix planned by Q2'19
[2] CapSense use is restricted to Ports 6 and 7 with switching restrictions on other ports.	All	*C silicon	Investigation underway. Fix planned by Q2'19
[3] Switching noise can cause ADC errors due to voltage reference noise.	All	*C silicon	Investigation underway. Fix planned by Q2'19
[4] Port Usage restrictions must be applied.	All	*C silicon	Investigation underway. Fix planned by Q2'19

1. Drive mode strength must be limited.	
Problem Definition	<p>There are four Drive mode strengths: DM0, DM1, DM2, and DM3, DM0 being the strongest and DM3 the weakest in order. Usage of DM0 can cause noise in supply and ground lines for simultaneous outputs switching. Drive mode strength must be limited to DM2 for all GPIOs except for the 80 MHz QSPI clock which may use DM1.</p> <p>The V_{OL} and V_{OH} specs are affected as follows (also applies to V_{DDIO}, V_{DDIOA}, and V_{DDA} pins):</p> <p>$V_{DD} < 2.7\text{ V}$: $V_{OL} = 0.5\text{ V} @ I_{OL} = 6\text{ mA}$. $V_{OH} = V_{DD} - 0.5\text{ V}$, $I_{OH} = 6\text{ mA}$.</p> <p>$V_{DD} \geq 2.7\text{ V}$: $V_{OL} = 0.4 @ I_{OL} = 6\text{ mA}$. $V_{OH} = V_{DD} - 0.5\text{ V}$, $I_{OH} = 6\text{ mA}$.</p>
Parameters Affected	Drive mode settings.
Trigger Condition(s)	Simultaneous outputs switching with high drive strength
Scope of Impact	Causes supply and ground noise, which can affect ADC and CapSense operation
Workaround	Follow drive mode strength restrictions. Drive Mode 2 (DM2) should be used for all ports except for the 80-MHz QSPI clock, which should be DM1
Fix Status	Investigation underway. Fix planned by Q2'19.

2. CapSense use is restricted to Ports 6 and 7 with switching restrictions on other ports.	
Problem Definition	GPIO simultaneous switching creates noise which can affect CapSense accuracy in unrestricted use
Parameters Affected	CapSense sensitivity and accuracy
Trigger Condition(s)	Noise caused by GPIO simultaneous output switching during CapSense operation
Scope of Impact	CapSense may produce erroneous results due to noise coupling from switching GPIOs.
Workaround	<p>For CapSense usage, the following restrictions apply:</p> <ul style="list-style-type: none"> a. Limit switching on Port 1 to 1 MHz (no more than 2 outputs) with slow slew rate. b. CapSense pins are restricted to Ports 6 and 7. No other GPIO output activity is allowed on Ports 6 and 7. c. Switching in Ports 5 and 8 is restricted to 1 MHz (no more than 2 outputs) with slow slew rate setting. <p>CapSense must use the SRSS reference.</p>
Fix Status	Investigation underway. Fix planned by Q2'19.

3. Switching noise can cause ADC errors due to voltage reference noise.	
Problem Definition	12-bit SAR ADC Counts are affected by switching noise
Parameters Affected	ADC accuracy
Trigger Condition(s)	Switching noise caused by GPIO simultaneous switching
Scope of Impact	ADC accuracy will be impacted
Workaround	<p>Restrict switching on Ports 9 and 10 (analog input ports). The Programmable Analog Sub-System (PASS), including the SAR ADC, is connected to Ports 9 and 10. With no switching on Ports 9 and 10, the ADC error may be up to 4 LSB counts. Switching in Ports 9 and 10 is restricted to 1 MHz (no more than 2 outputs) with slow slew rate setting and, in this case, the ADC error may be up to 12 counts.</p>
Fix Status	Investigation underway; Fix planned by Q2 19.

4. Port Usage restrictions must be applied.	
Problem Definition	GPIO simultaneous switching causes supply and ground noise that adversely affects other on-chip subsystems).
Parameters Affected	CapSense and ADC results
Trigger Condition(s)	GPIO simultaneous switching with unrestricted strengths and frequency.
Scope of Impact	Incorrect results may cause false sensing or failure to sense for CapSense and inaccurate results for the SAR ADC (may not deliver 12-bit accuracy).
Workaround	<p>Follow Port Usage restrictions:</p> <ul style="list-style-type: none"> a. Switching on Port 0 must be restricted to less than 8 MHz. b. Switching on Port 1 must be restricted to less than 1 MHz with slow rate and no more than 2 outputs. c. Ports 9 and 10 must be restricted to 8 MHz when not using the ADC and the restrictions stated earlier used when the ADC is used. d. Use VREF from System Resource Subsystem (SRSS) for CapSense
Fix Status	Investigation underway. Fix planned by Q2'19.

Revision History

Description Title: PSoC [®] 6 MCU: PSoC 63 with BLE Datasheet Programmable System-on-Chip (PSoC [®]) Document Number: 002-18787				
Revision	ECN	Orig. of Change	Submission Date	Description of Change
*F	6164322	WKA	05/03/2018	Release of production datasheet.
*G	6250376	WKA	07/17/2018	Corrected document number in the revision history table.
*H	6522270	WKA	04/01/2019	Updated Functional Description . Added "Pinouts for 104-MCSP with USB" table in Pinouts . Added package diagram (spec 001-97718 *B). Added a note in Table 4 . Updated Table 11 , Table 24 , and Table 34 in Electrical Specifications . Updated Features, Blocks and Functionality , ILO Clock Source , One-Time-Programmable (OTP) eFuse , Packaging , and Ordering Information . Updated Figure 4 (spec 002-16508 *D to *E) in Packaging . Corrected Unit usage throughout the document. Added Errata . Updated Copyright information in Sales page.
