

#### LOW NOISE, MULTI-MODE, QUAD-BAND, QUADRATURE MODULATOR AND PA DRIVER

**RoHS Compliant & Pb-Free Product** 

### Typical Applications

- EDGE/GSM (GSM850/900) Handsets
- EDGE/GSM (DCS/PCS) Handsets
- W-CDMA Handsets/Data Cards

### **Product Description**

The RF2705 is a low noise, multi-mode, guad-band direct I/Q to RF modulator and PA driver designed for handset applications where multiple modes of operation are required. Frequency doublers, dividers and LO buffers are included to support a variety of LO generation options. Dynamic power control is supported through a single analog input giving 90dB of power control range for the W-CDMA mode and 40dB of power control in the other two modes. Three sets of RF outputs are provided: high band and low band low noise EDGE/GMSK outputs, as well as one wideband W-CDMA output. The device is designed for 2.7V to 3.3V operation, and is assembled in a plastic, 24-pin, 4mmx4mm QFN.

#### **Optimum Technology Matching® Applied**

 W-CDMA/GSM/EDGE Multimode Handsets and Data Cards

#### Package Style: QFN, 24-Pin, 4x4

#### Features

- W-CDMA High/Mid/Low Power Modes
- Quad-Band Direct Quadrature Modulator
- Variable Gain PA Drivers
- GMSK Bypass Amplifiers
- LO Frequency Doubler and Divider
- Baseband Filtering

 Note 1: In low power mode it is recommended that the IQ level be reduced to 0.4V<sub>P-P</sub> If IQ level is >0.4V<sub>P-P</sub> this mode should be used for W-CDMA TX power levels below -20dBm (measured at antenna).

Pin	Function	Description	Interface Schematic
1	VCC2	Supply for LO buffers, frequency doubler and dividers.	Modulator and VGA
2	LO HB P	High band local oscillator input (1800MHz). In "low band $F_{LO}/2$ " modes the signal (LOHBP-LOHBN) undergoes a frequency division of 2 to provide the low band LO signal for the modu- lator. In "high band $F_{LO}x1$ " modes the signal (LOHBP-LOHBN) is used as the high band LO signal for the modulator. In "high band bypass" a modulated DCS1800/PCS1900 signal (LOHBP-LOHBN) is switched into the RF signal path. The modulator is disabled and the signal is routed to the RFOutHb outputs through a differential PA driver amplifier. The LOHBP input is AC-coupled internally. The noise performance, carrier suppression at low output powers and sideband suppression all vary with LO power. The optimum LO power is between -3dBm and +3dBm. The device will work with LO powers as low as -20dBm however this is at the expense of higher phase noise in the LO circuitry and poorer sideband suppression. The input impedance should be externally matched to 50Ω. The port can be driven either differentially or single ended. The port impedance does not vary significantly between active and power down modes. The RF2705 is intended for use with the RF6002. This performs the GSM GMSK modulation within a Frac-N synthesizer loop. The 8PSK EDGE and W-CDMA signal modulations are performed in the RF2705 and uses the RF6002's synthesizers to generate the LO signals. The LO signal for EDGE900 mode is derived by frequency division by 2 of the RF6002's DCS1800 VCO. This helps protect the system against PA pulling.	
3	LO HB N	The complementary LO input for both LOHBP LO signals. In any of the modes the LOHB input may be driven either single ended or differentially. If the LO is driven single ended then the PCB board designer can ground this pin. It is recommended that if this pin is grounded that it is kept isolated from the GND1 pin and the die flag ground. All connections to any other ground should be made through a ground plane. Poor routing of this ground signal can significantly degrade the LO leakage performance.	See pin 2.

Pin	Function	Description	Interface Schematic
4	LO LB P	Low band local oscillator input (900MHz). In "wideband $F_{LO}x^2$ " and "high band $F_{LO}x^2$ " modes the signal (LOLBP-LOLBN) is doubled in frequency to provide the LO signal for the modulator. In "Low band $F_{LO}x^1$ " modes the signal (LOLBP-LOLBN) is used as the LO signal for the modulator. In "Low band Bypass" a modulated GSM900 signal (LOLBP-LOLBN) is switched into the RF signal path. The modulator is disabled and the signal is routed to the RFOutLb outputs through a differential PA driver amplifier. This LOLBP input is AC-coupled internally. The noise performance, carrier suppression at low output powers and sideband suppression performance are functions of LO power. The optimum LO power is between -3dBm and +3dBm. The device will work with LO powers as low as -20dBm however this is at the expense of higher noise performance at high output powers and poorer side- band suppression. The input impedance should be externally matched to 50 $\Omega$ . The port impedance does not vary significantly between active and powered modes. The RF2705 is intended for use with the RF6002 which performs the GSM GMSK modulation within a Frac-N synthesizer loop. The 8PSK EDGE and W-CDMA signal modulations are performed in the RF2705 and uses the RF6002's synthesizers to generate the LO signals. The LO signal for DCS1800 mode is derived by frequency doubling RF6002's GSM900 VCO. This helps protect the system against PA pull- ing.	
5	LO LB N	The complementary LO input for both LOLBP LO signals. In any of the modes the LOLB input may be driven either single ended or differentially. If the LO is driven single ended then the PCB board designer can ground this pin. It is recommended that if this pin is grounded that it is kept isolated from the GND1 pin and the die flag ground. All connections to any other ground should be made through a ground plane. Poor routing of this GndLO signal can significantly degrade the LO leakage performance.	See pin 4.
6	MODE C	Chip enable control pin. See the Logic Truth table. CMOS Logic inputs: Logic $0=0V$ to $0.4V$ ; Logic $1=1.4V$ to $V_{CC}$ .	
7	MODE D	Mode control pin. See the Logic Truth table. CMOS Logic inputs: Logic $0=0V$ to $0.4V$ ; Logic $1=1.4V$ to $V_{CC}$ .	See pin 6.

Pin	Function	Description	Interface Schematic
8	Q SIG N	Quadrature Q channel negative baseband input port. Best performance is achieved when the QSIGP and QSIGN are driven differentially with a 1.2V common mode DC voltage. The recommended differential drive level ( $V_{QSIGP}$ - $V_{QSIGN}$ ) is 1.2 $V_{P-P}$ for EDGE, 0.8 $V_{P-P}$ for W-CDMA modulation and 1.0 $V_{P-P}$ for GMSK modulation. This input should be DC-biased at 1.2V. In sleep mode an internal FET switch is opened, the input goes high impedance and the modulator is de-biased. Phase or amplitude errors between the QSIGP and QSIGN signals will result in a common-mode signal which may result in an increase in the even order distortion of the modulation in the output spectrum. DC offsets between the QSIGP and QSIGN signals will result in increased carrier leakage. Small DC offsets may be deliberately applied between the ISIGP/ISIGN and QSIGP/QSIGN inputs to cancel out the LO leakage. The optimum corrective DC offsets will change with mode, frequency and gain control. Common-mode noise on the QSIGP and QSIGN should be kept low as it may degrade the noise performance of the modulator. Phase offsets from quadrature between the I and Q baseband signals results in degraded sideband suppression.	
9	Q SIG P	Quadrature Q channel negative baseband input port. See pin 8.	See pin 8.
10	VREF	Voltage reference decouple. External 10nF decoupling capacitor to ground. The voltage on this pin is typically 1.67V when the chip is enabled. The voltage is 0V when the chip is powered down. The purpose of this decoupling capacitor is to filter out low frequency noise (20MHz) on the gain control lines. Poor positioning of the VREF decoupling capacitor can cause a degra- dation in LO leakage. A voltage of around 2.5V on this pin indicates that the die flag under the chip is not grounded and the chip is not biased correctly.	
11	GC DEC	Gain control voltage decouple with an external 1 nF decoupling capaci- tor to ground. The voltage on this pin is a function of gain control (GC) voltage when the chip is enabled. The voltage is 0V when the chip is powered down. The purpose of this decoupling capacitor is to filter out low frequency noise (20MHz) on the gain control lines. The size capacitor on the GC DEC line will effect the settling time response to a step in gain control voltage. A 1nF capacitor equates to around 200ns settling time and a 0.5nF capacitor equates to a 100ns settling time. There is a trade-off between settling time and noise contributions by the gain control cir- cuitry as gain control is applied. Poor positioning of the VREF decoupling capacitor can cause a degra- dation in LO leakage.	
12	GC	Gain control voltage. Maximum output power at 2.0V. Minimum output power at 0V. When the chip is enabled the input impedance is $10k\Omega$ to $1.67V_{DC}$ . When the chip is powered down a FET switch is opened and the input goes high impedance.	

Pin	Function	Description	Interface Schematic
13	RF OUT LB N	Differential low band PA driver amplifier output. This output is intended for low band (GSM850/900) operation and drives a differential SAW. A bypass mode allows the low band PA driver amplifier's input to be switched between the signal from the modulator and the signal applied at LOLB. This enables a GMSK-modulated signal on the LOLB input to be switched into the RF signal path. The output is an open collector. The outputs are matched off-chip. 	On-Frequency LO Options					
Wideband F <sub>LO</sub> x1 (High Power) Modulator and on-frequency LO enabled	0	0	1	0	LoHbP LoHbN RFOutWb P RFOutWb N	Bands: 1920MHz to 1980MHz Modulation: 3GPP W-CDMA
Wideband F <sub>LO</sub> x1 (Medium Power) Modulator and on-frequency LO enabled	0	0	1	1	LoHbP LoHbN RFOutWb P RFOutWb N	Bands: 1920MHz to 1980MHz Modulation: 3GPP W-CDMA
Wideband F <sub>LO</sub> x1 (Low Power) Modulator and on-frequency LO enabled	0	0	0	1	LoHbP LoHbN RFOutWb P RFOutWb N	Bands: 1920MHz to 1980MHz Modulation: 3GPP W-CDMA
High Band F <sub>LO</sub> x1 Modulator and on-frequency LO enabled	0	1	1	1	LoHbP LoHbN RFOutHb P RFOutHb N	Bands: DCS1800 or PCS1900 Modulation: GMSK, TDMA and 8PSK EDGE
Low Band F <sub>LO</sub> x1 Modulator and on-frequency LO enabled	0	1	0	1	LoLbP LoLbN RFOutLb P RFOutLb N	Bands: GSM900 to GSM850 Modulation: GMSK, TDMA and 8PSK EDGE

### **Application Information**

The baseband inputs of the RF2705 must be driven with balanced signals. Amplitude and phase matching <0.5dB and <0.5 degrees are recommended. Phase or gain imbalances between the complementary input signals will cause additional distortion including some second order baseband distortion.

The RF2705 is designed to be driven with either single-ended or differential LO signals. Driving the chip differentially is beneficial in improving the LO leakage performance. Decreasing the LO drive level will also improve LO leakage, but the output noise performance will be degraded. Driving the LO level too high will degrade linearity.

The ground lines for the LO sections are brought out of the chip independently from the ground to the RF and modulator sections. This is intended to give the board design the independence of isolating the LO signals from the RF output sections.

The RF2705 includes frequency doubler and divider modes that allow the LO to operate at half or twice the frequency depending on the application. This provides some flexibility in improving VCO isolation and LO leakage through frequency translation.

The RF outputs use open collector architecture and may be biased at voltages higher than  $V_{CC}$ . In practice, biasing at a higher voltage may improve the intermodulation performance. The load resistors are selected to provide sufficient output power while maintaining good linearity.

The GC DEC and  $V_{REF}$  output pins should be decoupled to ground. A 10nF capacitor on  $V_{REF}$  and a 1nF capacitor on GC CEC are recommended. The purpose of these capacitors is to filter out low frequency noise (20MHz) in the gain control lines that may cause noise on the RF signal. The capacitor on the GC DEC line will effect the settling time of the step response in power control voltage. A 1nF capacitor equates to around a 200ns settling time; a 0.5nF capacitor equates to a 100ns settling time. There is a trade-off between setting time and phase noise as gain control is applied.

As with any RF circuit, the RF2705 is sensitive to PC board layout. The suggested schematic and board layout is included as a guideline. Proper grounding of the die flag under the chip is essential in achieving acceptable RF performance. A symmetric output structure will maintain signal balance while keeping the RF lines short will reduce losses. Proper routing and bypassing of the supply lines will improve stability and performance, especially under low gain control settings where carrier suppression becomes crucial. The location and value of the bypass capacitor on pin 1 is critical in promoting good carrier suppression and is designated to resonate out the series wire bond and PC board inductance.

### **Application Schematic**

### **Evaluation Board Schematic**

### **PCB Design Requirements**

#### PCB Surface Finish

The PCB surface finish used for RFMD's qualification process is Electroless Nickel, immersion Gold. Typical thickness is 3µinch to 8µinch Gold over 180µinch Nickel.

#### **PCB Land Pattern Recommendation**

PCB land patterns are based on IPC-SM-782 standards when possible. The pad pattern shown has been developed and tested for optimized assembly at RFMD; however, it may require some modifications to address company specific assembly processes. The PCB land pattern has been developed to accommodate lead and package tolerances.

#### **PCB Metal Land Pattern**

Figure 1. PCB Metal Land Pattern (Top View)

#### PCB Solder Mask Pattern

Liquid Photo-Imageable (LPI) solder mask is recommended. The solder mask footprint will match what is shown for the PCB Metal Land Pattern with a 2mil to 3mil expansion to accommodate solder mask registration clearance around all pads. The center-grounding pad shall also have a solder mask clearance. Expansion of the pads to create solder mask clearance can be provided in the master data or requested from the PCB fabrication supplier.

Figure 2. PCB Solder Mask Pattern (Top View)

#### Thermal Pad and Via Design

The PCB land pattern has been designed with a thermal pad that matches the exposed die paddle size on the bottom of the device.

Thermal vias are required in the PCB layout to effectively conduct heat away from the package. The via pattern shown has been designed to address thermal, power dissipation and electrical requirements of the device as well as accommodating routing strategies.

The via pattern used for the RFMD qualification is based on thru-hole vias with 0.203mm to 0.330mm finished hole size on a 0.5mm to 1.2mm grid pattern with 0.025mm plating on via walls. If micro vias are used in a design, it is suggested that the quantity of vias be increased by a 4:1 ratio to achieve similar results.
