

## Advanced 4/3-Phase PWM Controller for CPU Core Power

### General Description

The RT8867A is an advanced 4/3-phase synchronous buck controller with 3 integrated MOSFET drivers. It integrates an 8-bit DAC that supports Intel VR11.x CPUs power application.

The IC adopts state-of-the-art dynamic phase control capability by PS1/2/3 pins and achieves high efficiency over a wide load range. It uses lossless  $R_{DS(ON)}$  current sensing to achieve phase current balance. Other features include adjustable operating frequency, adjustable soft-start, short circuit protection, adjustable over current protection, over voltage protection, under voltage protection, power good indication, VR\_HOT indication and VR\_SHDN indication.

The RT8867A is available in a small footprint with WQFN-48L 6x6 package.

### Ordering Information

RT8867A□□

- Package Type  
QW : WQFN-48L 6x6 (W-Type)
- Lead Plating System  
Z : ECO (Ecological Element with Halogen Free and Pb free)

Note :

Richtek products are :

- ▶ RoHS compliant and compatible with the current requirements of IPC/JEDEC J-STD-020.
- ▶ Suitable for use in SnPb or Pb-free soldering processes.

### Marking Information

RT8867A ZQW YMDNN 	RT8867AZQW : Product Number YMDNN : Date Code
--	--

### Features

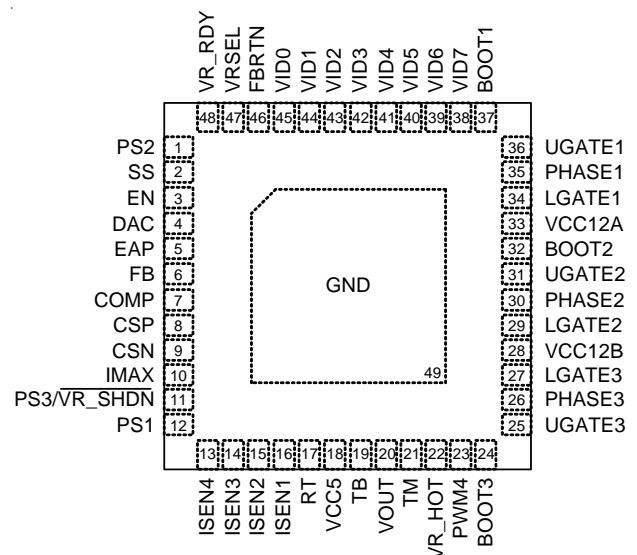

- 12V Power Supply Voltage
- 4/3-Phase Power Conversion
- Integrated 3 MOSFET Drivers with Internal Bootstrap Diode
- Dynamic Phase Control Capability
- 8-bit DAC Supports Intel VR11.x CPUs
- Lossless  $R_{DS(ON)}$  Current Sensing for Current Balance
- Adjustable Frequency : 50kHz to 1MHz
- Adjustable Over Current Protection
- Adjustable Soft-Start
- VR\_RDY, VR\_HOT and VR\_SHDN Indications
- Small 48-Lead WQFN Package
- RoHS Compliant and Halogen Free

### Applications

- Desktop CPU Core Power
- Middle/High End Graphic Cards
- Low Voltage, High Current DC/DC Converters

### Pin Configurations

**Functional Pin Description**

Pin No.	Pin Name	Pin Function
1	PS2	Dynamic Phase Control Threshold Input 2. Connect this pin to GND by a resistor to set dynamic phase control threshold.
2	SS	Soft-Start Ramp Slope Set Pin. Connect this pin to FBRTN by a capacitor to adjust soft-start slew rate.
3	EN	Chip Enable Pin. Pull this pin higher than 0.8V to enable the PWM controller.
4	DAC	DAC Output Pin. Connect a resistor from this pin to EAP pin for setting the load line slope.
5	EAP	Non-inverting Input of Error-Amplifier Pin. Connect a resistor from this pin to DAC pin to set the load line slope.
6	FB	Inverting Input of Error Amplifier Pin.
7	COMP	Compensation Pin. Output of error amplifier and input of PWM comparator.
8, 9	CSP, CSN	Input of Current Sensing Amplifier. The sensed current is for droop control and over current protection.
10	IMAX	Output Current Indication. Connect a resistor from this pin to GND to set the over current protection threshold.
11	PS3/ $\overline{\text{VR\_SHDN}}$	Multi Function Pin. Dynamic phase control threshold input 3 & $\overline{\text{VR\_SHDN}}$ indication. Connect this pin to a resistive voltage divider to set dynamic phase control threshold.
12	PS1	Dynamic Phase Control Threshold Input 1. Connect this pin to GND by a resistor to set dynamic phase control threshold.
13, 14, 15, 16	ISN4, ISN3, ISN2, ISN1	Phase Current Sense Pins for Phase 4, Phase 3, Phase 2 and Phase 1. Per phase current signal is sensed via the voltage across low side MOSFETs $R_{\text{DS(ON)}}$ for current balance.
17	RT	Switching Frequency Set Pin. Connect this pin to GND by a resistor to adjust switching frequency.
18	VCC5	Internal 5V Regulator Output.
19	TB	Transient Boost Pin. This pin along with the VOUT pin sets the transient boost function.
20	VOUT	Positive Voltage Sensing Pin. This pin is the positive node of the differential voltage sensing and along with TB pin sets the transient boost function.
21	TM	Thermal Monitoring Input Pin. Connect a resistive voltage divider with NTC to detect temperature.
22	VR_HOT	Thermal Monitoring Output Pin. Connect a resistor to VTT for VR_HOT signal assertion.
23	PWM4	PWM Output for Phase 4.
24, 32, 37	BOOT3, BOOT2, BOOT1	Bootstrap Power Pins for Phase 3, Phase 2 and Phase 1. This pin powers the high side MOSFETs drivers. Connect this pin to the junction of the bootstrap capacitor with the cathode of the bootstrap diode.
25, 31, 36	UGATE3, UGATE2, UGATE1	Upper Gate Drivers for Phase 3, Phase 2 and Phase 1. This pin drives the gate of the high side MOSFETs.

Pin No.	Pin Name	Pin Function
26, 30, 35	PHASE3, PHASE2, PHASE1	Switch Nodes of High Side Driver 3, Driver2 and Driver1. Connect this pin to high side MOSFETs sources together with the low side MOSFETs drains and inductor.
27, 29, 34	LGATE3, LGATE2, LGATE1	Lower Gate Drivers for Phase 3, Phase 2 and Phase 1. This pin drives the gate of low side MOSFETs.
28	VCC12B	Supply Input Pin. This pin supplies current for phase 2 and phase 3 gate drivers.
33	VCC12A	Supply Input Pin. This pin supplies current for phase 1 gate driver and control circuits.
38 to 45	VID7 to VID0	Voltage Identification Input for DAC.
46	FBRTN	Return Ground Pin. This pin is negative node of the differential remote voltage sensing.
47	VRSEL	Load Line Adjustment Enable Pin. Connect this pin to VTT to disable load line adjustment function or connect this pin to GND to enable load line adjustment function.
48	VR_RDY	VR Ready Indication.
49 (Exposed pad)	GND	The exposed pad must be soldered to a large PCB and connected to GND for maximum power dissipation.

## Function Block Diagram

**Absolute Maximum Ratings** (Note 1)

- Supply Input Voltage (VCC12A, VCC12B) ----- -0.3V to 15V
- BOOTx to GND
  - DC ----- -0.3V to 30V
  - < 20ns ----- -0.3V to 42V
- PHASEx to GND
  - DC ----- -2V to 15V
  - < 20ns ----- -5V to 30V
- UGATEx to GND ----- (V<sub>PHASE</sub> - 0.3V) to (V<sub>BOOT</sub> + 0.3V)
- < 20ns ----- (V<sub>PHASE</sub> - 5V) to (V<sub>BOOT</sub> + 5V)
- LGATEx to GND ----- (GND - 0.3V) to (V<sub>CC</sub> + 0.3V)
- < 20ns ----- (GND - 5V) to (V<sub>CC</sub> + 5V)
- Power Dissipation, P<sub>D</sub> @ T<sub>A</sub> = 25°C
  - WQFN-48L 6x6 ----- 2.857W
- Package Thermal Resistance (Note 2)
  - WQFN-48L 6x6, θ<sub>JA</sub> ----- 35°C/W
  - WQFN-48L 6x6, θ<sub>JC</sub> ----- 6°C/W
- Junction Temperature ----- 150°C
- Lead Temperature (Soldering, 10 sec.) ----- 260°C
- Storage Temperature Range ----- -65°C to 150°C
- ESD Susceptibility (Note 3)
  - HBM (Human Body Model) ----- 2kV

**Recommended Operating Conditions** (Note 4)

- Supply Input Voltage (VCC12A, VCC12B) ----- 10.8V to 13.2V
- Junction Temperature Range ----- -40°C to 125°C
- Ambient Temperature Range ----- -40°C to 85°C

**Electrical Characteristics**

(V<sub>CC12x</sub> = 12V, T<sub>A</sub> = 25°C, unless otherwise specified)

### Application Information

The RT8867A is an advanced 4/3 phase synchronous buck controller with 3 integrated MOSFET drivers. It integrates an 8-bit DAC that supports Intel VR11.x VID table.

#### Supply Voltage and POR

There are three supply voltage pins built in the RT8867A : VCC12A/VCC12B and VCC5. VCC12A/VCC12B are power input pins that receive an external 12V voltage for the embedded driver logic operation. VCC5 is a power output pin which is the output of an internal 5V LDO regulator. The 5V LDO regulator regulates VCC12A to generate a 5V voltage source for internal gate logic and external circuit biasing, e.g., OCP biasing. Since the VCC5 voltage is regulated, the variation of VCC5 (2%) will be much smaller than Platform ATX 5V (5% to 7%). The maximum supply current of VCC5 is 10mA, which is designed only for controller circuit biasing. The recommended configuration of the RT8867A supply voltages is as follows: Platform ATX 12V to the VCC12A/ VCC12B pins, and decoupling capacitors on the VCC12A/ VCC12B and VCC5 pins (minimum 0.1μF). The initialization of the RT8867A requires all the voltage on VCC12A/VCC12B and VCC5 to be ready. Since VCC5 is regulated internally from VCC12A, the VCC5 voltage will be ready (>4.6V) after VCC12A reaches about 7V, so there is no power sequence problem between VCC12A/VCC12B and VCC5. After VCC5 > 4.6V and VCC12A/VCC12B > 9.6V, the internal Power-On-Reset (POR) signal goes high. This POR signal indicates the power supply voltages are all ready. When POR = high and EN = high, the RT8867A initiates soft-start sequence. When POR = low, the RT8867A will try to turn off both high side and low side MOSFETs to prevent catastrophic failure.

Figure 1. Circuit for Power Ready Detection

#### Switching Frequency

The switching frequency of the RT8867A is set by an external resistor connected from the RT pin to GND. The frequency follows the graph in Figure 2.

Figure 2. Switching Frequency vs. R<sub>RT</sub> Resistance

#### Soft-Start

The V<sub>OUT</sub> soft-start slew rate is set by a capacitor from the SS pin to FBRTN. Before power on reset (POR = low), the SS pin is held at GND. After power on reset (POR = high, EN = high) and an extra delay of 1600μs (T<sub>1</sub>), the controller initiates ramping up. V<sub>OUT</sub> will always trace V<sub>EAP</sub> during normal operation of the RT8867A, where V<sub>EAP</sub> is the positive input of the error amplifier, which can be described as V<sub>EAP</sub> = V<sub>DAC</sub> - V<sub>DROOP</sub>. (The definition of V<sub>DROOP</sub> will be described later in the Load Line section). The first ramping up duration of V<sub>OUT</sub> (T<sub>2</sub>) ramps V<sub>OUT</sub> to V<sub>BOOT</sub>.

After V<sub>OUT</sub> ramps to V<sub>BOOT</sub>, the RT8867A stays in this state for 800μs (T<sub>3</sub>), waiting for a valid VID code sent by the CPU. After receiving the valid VID code, V<sub>OUT</sub> continues ramping up or down to the voltage specified by VID code. After V<sub>OUT</sub> ramps to V<sub>EAP</sub> = V<sub>DAC</sub> - V<sub>DROOP</sub>, the RT8867A stays in this state for 1600μs (T<sub>5</sub>) and then asserts VR\_RDY = high. The ramping slew rate of T<sub>2</sub> and T<sub>4</sub> is controlled by the external capacitor connected to SS pin. The voltage of the SS pin will always be V<sub>EAP</sub> + 0.7V, where the mentioned 0.7V is the typical turn-on threshold of an internal power switch. Before VR\_RDY = high, the

slew rate of  $V_{EAP}$  is limited to  $80\mu A/C_{SS}$ . When  $VR\_RDY = \text{high}$ , the slew rate of  $V_{EAP}$  is limited to  $160\mu A/C_{SS}$ , which is 2 times faster than the soft-start slew rate for dynamic VID feature. The soft-start waveform is shown in Figure 4.

Figure 3. Circuit for Soft-Start and Voltage Control Loop

Figure 4. Soft-Start Waveforms

$T1$  is the delay time from power on reset state to the beginning of  $V_{OUT}$  rising.  $T2$  is the soft-start time from  $V_{OUT} = 0$  to  $V_{OUT} = V_{BOOT}$ .  $T3$  is the dwelling time for  $V_{OUT} = V_{BOOT}$ .  $T4$  is the soft-start time from  $V_{OUT} = V_{BOOT}$  to  $V_{OUT} = V_{DAC}$ .

$T5$  is the  $VR\_RDY$  delay time.

$$T1 = 1600\mu s + 0.7V \times C_{SS}/80\mu A.$$

$$T2 = V_{BOOT} \times C_{SS}/80\mu A.$$

$$T3 \approx 800\mu s.$$

$$T4 \approx |V_{DAC} - V_{BOOT}| \times C_{SS}/80\mu A.$$

$$T5 \approx 1600\mu s.$$

**Dynamic VID**

The RT8867A can accept VID input changing while the controller is running. This allows the output voltage ( $V_{OUT}$ ) to change while the DC/DC converter is running and supplying current to the load. This is commonly referred to as VID On-The-Fly (OTF). A VID OTF can occur under either light or heavy load conditions. The CPU changes the VID inputs in multiple steps from the start code to the finish code. This change can be positive or negative. Theoretically,  $V_{OUT}$  should follow  $V_{DAC}$  which is a staircase waveform, but in real application, the bandwidth of the converter is finite while the staircase waveform needs infinite bandwidth to follow. Thus, undesired  $V_{OUT}$  overshoot (when  $V_{DAC}$  changes up) or undershoot (when  $V_{DAC}$  changes down) is often observed in this type of design.

However, for the RT8867A, as mentioned before in the soft-start section,  $V_{DAC}$  slew rate is limited by  $I_{SS2}/C_{SS}$  when  $VR\_RDY = \text{high}$ . This slew rate limiter works as a low-pass filter of  $V_{DAC}$  and makes the bandwidth of  $V_{DAC}$  waveform finite. By smoothing the  $V_{DAC}$  staircase waveform,  $V_{OUT}$  will no longer overshoot or undershoot. On the other hand,  $C_{SS}$  will increase the settling time of  $V_{OUT}$  during VID OTF. In most cases, a 5nF to 30nF ceramic capacitor will be suitable for  $C_{SS}$ .

**Output Voltage Differential Sensing**

The RT8867A uses a high gain low offset error amplifier for differential sensing. The CPU voltage is sensed between the FB and FBRTN pins. A resistor ( $R_{FB}$ ) connects FB pin with the positive remote sense pin of the CPU ( $V_{CC\_SNS}$ ), while the FBRTN pin connects directly to the negative remote sense pin of the CPU ( $V_{SS\_SNS}$ ). The error amplifier compares  $V_{EAP} (= V_{DAC} - V_{DROOP})$  with the  $V_{FB}$  to regulate the output voltage.

**Transient Boost**

In steady state, the voltage of  $V_{OUT}$  is controlled to be very close to  $V_{EAP}$ , however a load step transient from light load to heavy load could cause  $V_{OUT}$  to be lower than  $V_{EAP}$  by several tens of mV. In conventional buck converter design (without non-linear control) for CPU VR application, due to limited control bandwidth, it is hard for the VR to prevent  $V_{OUT}$  undershoot during quick load transient from light load to heavy load. Hence, the RT8867A builds in a

state-of-the-art transient boost function which detects load transient by monitoring  $V_{OUT}$ . If  $V_{OUT}$  suddenly drops below " $V_{TB}$ " the transient boost signal rises up and the RT8867A turns on all high side MOSFETs and turns off all low side MOSFETs. The voltage difference " $V_{OUT} - V_{TB}$ " is set by following equation :

$$V_{OUT} - V_{TB} = 10\mu A \times R_{TB}$$

Sensitivity of the transient boost can be adjusted by varying the values of  $C_{FB}$  and  $R_{FB}$ . Smaller  $R_{FB}$  and/or larger  $C_{FB}$  will make transient boost easier to be triggered. Figure 5 shows the circuit and typical waveforms.

Figure 5. (a) Transient Boost Circuit

Figure 5. (b) Typical Waveforms

**Output Current Sensing**

The RT8867A provides a low input offset Current Sense Amplifier (CSA) to monitor the output current. The output current of CSA ( $I_X$ ) is used for load line control, dynamic phase control and over current protection. In this average inductor current sensing topology,  $R_S$  and  $C_S$  must be set according to the equation below :

$$R_{equ} = R_X // R_{NTC}$$

$$\frac{L}{DCR} = \frac{R_S \times C_S}{N + \frac{R_S}{R_{equ}}}$$

Where the constant N is a set maximum operation phase number, not affected by the dynamic phase control machine. Then, the output current of CSA will follow the equation below :

$$I_X = \frac{I_{OUT} \times DCR}{N \times R_{CSN}}$$

Figure 6 is the current sense circuit.

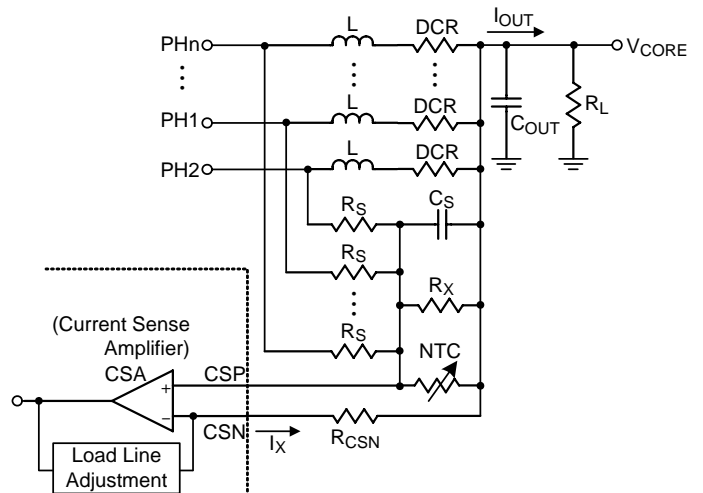

Figure 6. Circuit for Current Sensing

**Load Line**

The RT8867A utilizes inductor DCR current sense technique for load line control function. The sensed output current is proportionally mirrored from the  $I_X$  signal to the  $R_{DROOP}$  resistor to establish the voltage of  $V_{DROOP}$ .  $V_{DROOP}$  subtracted from  $V_{DAC}$  generates  $V_{EAP}$ . The voltage control loop is shown in Figure 3. Because  $I_X$  is a PTC (Positive Temperature Coefficient) current, an NTC (Negative Temperature Coefficient) resistor is needed to connect in parallel with the capacitor  $C_S$ . If the NTC resistor is properly selected to compensate the temperature coefficient of  $I_X$ , the  $V_{DROOP}$  voltage will be proportional to  $I_{OUT}$  without temperature effect. In the RT8867A, the positive input of error amplifier is  $V_{EAP}$  and  $V_{OUT}$  will follow " $V_{DAC} - V_{DROOP}$ ". Thus, the output voltage which decreases linearly with  $I_{OUT}$  is obtained. The load line is defined as :

$$LL(\text{Load Line}) = \frac{\Delta V_{OUT}}{\Delta I_{OUT}} = \frac{\Delta V_{DROOP}}{\Delta I_{OUT}} = \frac{DCR \times R_{DROOP} \times 4}{N \times R_{CSN}}$$

Basically, the resistance of  $R_{DROOP}$  sets the resistance of the load line. The temperature coefficient of  $R_{DROOP}$  compensates the temperature effect of the load line.

Connecting  $VRSEL$  pin to GND enables load line adjustment function. When load line adjustment function is enabled, the current  $I_X$  is decreased by  $10mV/R_{CSN}$ . Note that the minimum output current sensing range is also reduced by  $10mV/R_{CSN}$  when load line adjustment function is enabled.

**Current Balance**

The RT8867A sensed per phase current signal  $I_{SENx}$  via the voltages on the low side MOSFETs switch on resistance ( $R_{DS(ON)}$ ) for current balance as shown in Figure 7, in which  $I_{SENx}$  is defined as :

$$I_{SENx} = \frac{I_{PHASEx} \times R_{DSON} + V_{DC}}{R_{SENx}}$$

Where  $V_{DC}$  is the offset voltage for the current balance circuit.

In Figure 7, the phase current sense signals  $I_{SENx}$  are used to raise or lower the internal sawtooth waveforms (RAMP [1] to RAMP [n]) which are compared with error amplifier output (COMP) to generate a PWM signal. The raised sawtooth waveform will decrease the PWM duty of the corresponding phase current and the lowered sawtooth waveform will increase the PWM duty of the corresponding phase current. Eventually, current flowing through each phase will be balanced.

Figure 7. Circuit for Current Balance

**Dynamic Phase Control Capability**

The RT8867A has the ability to automatically control its phase number according to the total load current. Connect a resistive voltage divider to PS3 pin to define the 3-4 phase transition threshold,  $V_{PS3}$ . Connect a resistor to ground at PS2 pin to set the 2-3 phase transition threshold,  $V_{PS2}$ . Connect a resistor to ground at PS1 pin to set the 1-2 phase transition threshold,  $V_{PS1}$ .

The voltage at IMAX pin ( $V_{IMAX}$ ) represents total current information, and the RT8867A will compare  $V_{IMAX}$  with  $V_{PS1}$ ,  $V_{PS2}$  and  $V_{PS3} / 5$  to determine the number of operating phases. Figure 8 shows the typical connections of PS1, PS2 and PS3 pins for setting the dynamic phase control thresholds.

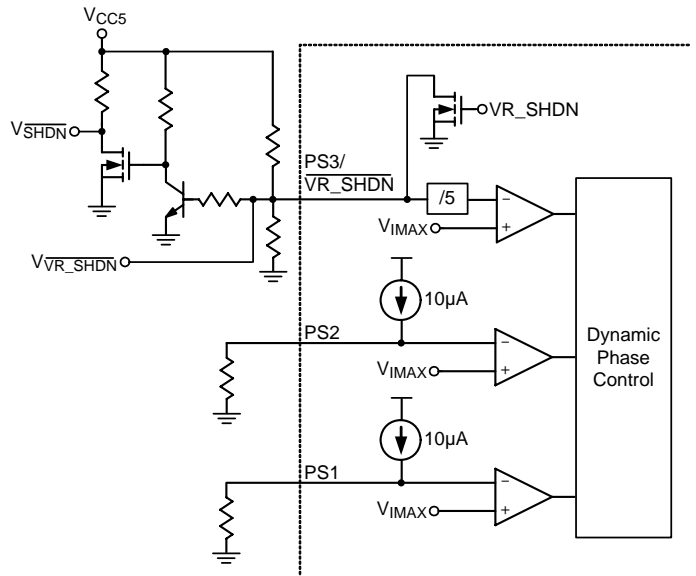

Figure 8. Circuit for Dynamic Phase Control and VR Shutdown

**Table 2. Dynamic Phase Control**

$V_{IMAX}$			Phase Number	
			Max 4 Phase	Max 3 Phase
$V_{PS1} < 0.8V, V_{PS2} < 0.1V$ $V_{IMAX} = \text{Don't Care}$			Forced 1 (1)	Forced 1 (1)
$V_{PS1} > 0.8V, V_{PS2} > 0.1V,$ $V_{IMAX} = \text{Don't Care}$			Forced 4 (1, 2, 3, 4)	Forced 3 (1, 2, 3)
$> V_{PS1}$	$> V_{PS2}$	$> \frac{V_{PS3}}{5}$	4 (1, 2, 3, 4)	3 (1, 2, 3)
$> V_{PS1}$	$> V_{PS2}$	$< \frac{V_{PS3}}{5}$	3 (1, 2, 3)	3 (1, 2, 3)
$> V_{PS1}$	$< V_{PS2}$	$< \frac{V_{PS3}}{5}$	2 (1, 3)	2 (1, 3)
$< V_{PS1}$	$< V_{PS2}$	$< \frac{V_{PS3}}{5}$	1 (1)	1 (1)

After setting the voltages at the PS1 to PS3 pins, the RT8867A will continuously compare  $V_{IMAX}$  and  $V_{PS1}$  to  $V_{PS3}$  after POR. Once the  $V_{IMAX}$  enters each voltage state mentioned in Table 2, the RT8867A will automatically change its operation phase number. See Table 2 for the dynamic phase control mechanism. For Example, If  $V_{PS1} = 0.3V$ ,  $V_{PS2} = 0.5V$ ,  $V_{PS3} = 4V$ , the RT8867A will operate in 4-phase operation when  $V_{IMAX} = 0.9V$ , and 2 phase operation when  $V_{IMAX} = 0.4V$ . There are two states mentioned in Table 2 that the RT8867A will be forced not to change its operating phase number, and the  $V_{IMAX}$  voltage is meaningless for dynamic phase control circuit under these conditions.

### Over Current Protection (OCP)

When  $V_{IMAX}$  is higher than 1.2V, the over current protection is triggered with 100 $\mu s$  delay to prevent false trigger, and the short circuit OCP level is designed at 1.6V with 10 $\mu s$  delay. The controller will turn off all high side / low side MOSFETs to protect CPU. Note that, the OCP level does not change according to different operating phase numbers.

### Over Voltage Protection (OVP)

The over voltage protection monitors the output voltage via the FB pin. Once  $V_{FB}$  exceeds " $V_{EAP} + 390mV$ ", OVP is triggered and latched. The RT8867A will turn on low side MOSFET and turn off high side MOSFET to protect CPU.

### Under Voltage Protection (UVP)

The under-voltage protection monitors the output voltage via the FB pin. Once  $V_{FB}$  is lower than " $V_{EAP} - 300mV$ ", UVP is triggered and latched. The RT8867A will turn off all high side / low side MOSFETs to protect CPU.

### Loop Compensation

The RT8867A is a voltage mode controller and requires external compensation. To compensate a typical voltage mode buck converter, there are two ordinary compensation schemes, commonly known as type-II compensator and type-III compensator. The choice of using type-II or type-III compensator lies with the platform designers, and the main concern deals with the position of the capacitor ESR zero and mid-frequency to high frequency gain boost.

Typically, the ESR zero of output capacitor will tend to stabilize the effect of output LC double poles. Hence, the position of the output capacitor ESR zero in frequency domain may influence the design of voltage loop compensation. Figure 9 shows a typical control loop using type-III compensator. Below is the compensator design procedure.

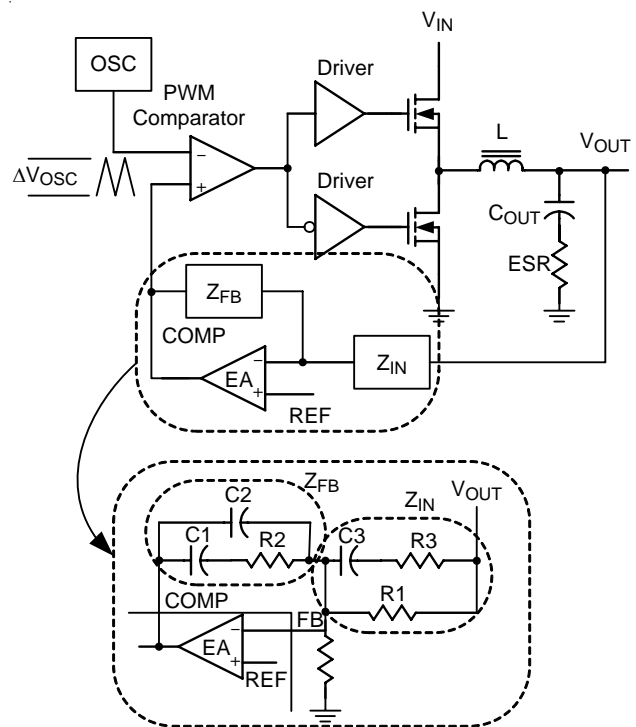

Figure 9. Compensation Circuit

### 1) Modulator Characteristic

The modulator consists of the PWM comparator and power stage. The PWM comparator compares the error amplifier output (COMP) with oscillator (OSC) sawtooth wave to provide a Pulse-Width Modulated (PWM) gate-driving signal. The PWM wave is smoothed out by the output filter,  $L_{OUT}$  and  $C_{OUT}$ . The output voltage ( $V_{OUT}$ ) is sensed and fed to the inverting input of the error amplifier. The modulator transfer function is the small-signal transfer function of  $V_{OUT}/V_{COMP}$  (output voltage over the error amplifier output). This transfer function is dominated by a DC gain, a double pole, and an ESR zero as shown in Figure 10. The DC gain of the modulator is the input voltage ( $V_{IN}$ ) divided by the peak-to-peak oscillator voltage  $V_{OSC}$ . The output LC filter introduces a double pole, 40dB/

decade gain slope above its corner resonant frequency, and a total phase lag of 180 degrees. The resonant frequency of the LC filter is expressed as:

$$f_{LC} = \frac{1}{2\pi \times \sqrt{L_{OUT} \times C_{OUT}}}$$

The ESR zero is contributed by the ESR associated with the output capacitance. Note that this requires the output capacitor to have enough ESR to satisfy stability requirements. The ESR zero of the output capacitor is expressed as the following equation :

$$f_{ESR} = \frac{1}{2\pi \times C_{OUT} \times ESR}$$

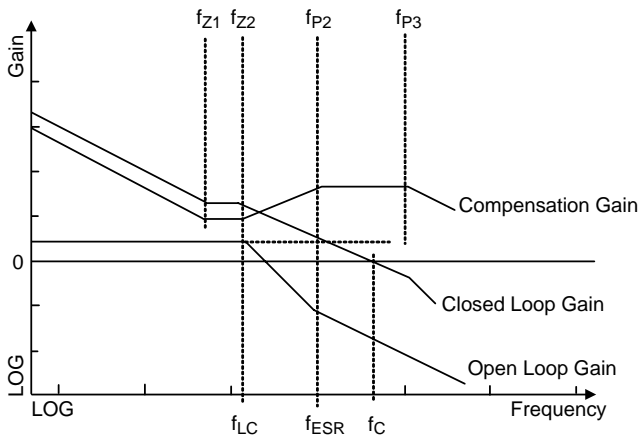

Figure 10. Bode Plot of Loop Gain

**2) Design of the Compensator**

A well-designed compensator regulates the output voltage to the reference voltage  $V_{REF}$  with fast transient response and good stability. In order to achieve fast transient response and accurate output regulation, an adequate compensator design is necessary. The goal of the compensation network is to provide adequate phase margin (usually greater than  $45^\circ$ ) and the highest bandwidth (0dB crossing frequency,  $f_c$ ) possible. It is also recommended to manipulate the loop frequency response such that its gain crosses over 0dB at a slope of  $-20\text{dB/dec}$ . According to Figure 10, the location of poles and zeros are :

$$f_{z1} = \frac{1}{2\pi \times R2 \times C1}$$

$$f_{z2} = \frac{1}{2\pi \times (R1 + R3) \times C3}$$

$$f_{p1} = 0$$

$$f_{p2} = \frac{1}{2\pi \times C3 \times R3}$$

$$f_{p3} = \frac{1}{2\pi \times \frac{C1 \times C2 \times R2}{C1 + C2}}$$

Generally,  $f_{z1}$  and  $f_{z2}$  are designed to cancel the double pole of the modulator. Usually, place  $f_{z1}$  at a fraction of  $f_{LC}$ , and place  $f_{z2}$  at  $f_{LC}$ .  $f_{p2}$  is usually placed at  $f_{ESR}$  to cancel the ESR zero, and  $f_{p3}$  is placed below the switching frequency to cancel high frequency noise.

For a given bandwidth,  $R2$ ,  $f_{z1}$ ,  $f_{z2}$ ,  $f_{p2}$ ,  $f_{p3}$ , then

$$C1 = \frac{1}{2\pi \times R2 \times f_{z1}}$$

$$C3 = \frac{G_{vd@BW}}{2\pi \times f_c \times R2}$$

$$R1 = \frac{1}{2\pi \times f_{z2} \times C3}$$

$$R3 = \frac{1}{2\pi \times f_{p2} \times C3}$$

$$C2 = \frac{1}{2\pi \times f_{p3} \times C1 \times R2 - 1}$$

where  $G_{vd@BW}$  is open loop gain at cross over frequency.

**Thermal Monitoring (VR\_HOT & VR\_SHDN)**

The RT8867A provides thermal monitoring function via sensing the TM pin voltage, and which can set 2 thresholds to indicate ambient temperatures through the voltage divider  $R1$  and  $R_{NTC}$ . The voltage of TM is typically set to be higher than  $0.5 \times VCC5$  when ambient temperature is lower than  $VR\_HOT$  &  $VR\_SHDN$  assertion target. However, when ambient temperature rises, TM voltage will fall, and the  $VR\_HOT$  signal will be set to high if TM voltage drops below  $0.43 \times VCC5$ . Furthermore, if the temperature continues to rise and the TM voltage is lower than  $0.32 \times VCC5$ , the controller will pull the  $VR\_SHDN$  signal to low. Accordingly,  $VR\_HOT$  will be reset when TM voltage rises above  $0.5 \times VCC5$ , but the  $VR\_SHDN$  signal will not recover to high once thermal shutdown occurs.

**Thermal Considerations**

For continuous operation, do not exceed absolute maximum junction temperature. The maximum power dissipation depends on the thermal resistance of the IC package, PCB layout, rate of surrounding airflow, and difference between junction and ambient temperature. The maximum power dissipation can be calculated by the following formula :

$$P_{D(MAX)} = (T_{J(MAX)} - T_A) / \theta_{JA}$$

where  $T_{J(MAX)}$  is the maximum junction temperature,  $T_A$  is the ambient temperature, and  $\theta_{JA}$  is the junction to ambient thermal resistance.

For recommended operating condition specifications of the RT8867A, the maximum junction temperature is 125°C and  $T_A$  is the ambient temperature. The junction to ambient thermal resistance,  $\theta_{JA}$ , is layout dependent. For WQFN-48L 6x6 packages, the thermal resistance,  $\theta_{JA}$ , is 35°C/W on a standard JEDEC 51-7 four-layer thermal test board. The maximum power dissipation at  $T_A = 25^\circ\text{C}$  can be calculated by the following formula :

$$P_{D(MAX)} = (125^\circ\text{C} - 25^\circ\text{C}) / (35^\circ\text{C/W}) = 2.857\text{W for WQFN-48L 6x6 package}$$

The maximum power dissipation depends on the operating ambient temperature for fixed  $T_{J(MAX)}$  and thermal resistance,  $\theta_{JA}$ . For the RT8867A package, the derating curve in Figure 11 allows the designer to see the effect of rising ambient temperature on the maximum power dissipation.
