

2-WIRE CMOS SERIAL E²PROM**S-24C01B/02B/04B**

The S-24C01B/02B/04B is a 2-wired, low power and wide range operation 1k bit, 2k bit, 4k bit E²PROM organized as 128 words × 8 bits, 256 words × 8 bits, and 512 words × 8 bits in each.

Page write and sequential read are available.

■ Features

- Low power consumption Standby : 1.0 μA Max. (V_{CC}=5.5 V)
 Operating : 0.8 mA Max. (V_{CC}=5.5 V)
 0.3 mA Max. (V_{CC}=3.3 V)
- Wide operating voltage range : 2.0 to 5.5
- Page write : 8 bytes / page (S-24C01B/02B)
 16 bytes / page (S-24C04B)
- Sequential read
- Operating Frequency : 400 kHz (V_{CC}=5 V±10 %)
- Endurance : 10⁶ cycles/word
- Data retention : 10 years
- Write protection S-24C01B : 100%
 S-24C02B/04B : 50%
- S-24C01B : 1k bit
- S-24C02B : 2k bit
- S-24C04B : 4k bit

■ Package

Package name	Drawing code		
	Package	Tape	Reel
8-Pin DIP	DP008-A	–	–
8-Pin SOP(JEDEC)	FJ008-A	FJ008-D	FJ008-D
8-Pin MSOP	FN008-A	FN008-A	FN008-A

Remark For details, please refer to “Product Code Structure”.

Caution This product is intended to use in general electronic devices such as consumer electronics, office equipment, and communications devices. Before using the product in medical equipment or automobile equipment including car audio, keyless entry and engine control unit, contact to SII is indispensable.

■ Pin Functions

1. SDA (Serial Data Input/Output) Pin

The SDA pin is used for bilateral transmission of serial data. It consists of a signal input pin and an Nch open-drain transistor output pin.

Usually pull up the SDA line via resistance to the V_{CC} , and use it with other open-drain or open-collector output devices connected in a wired OR configuration.

2. SCL (Serial Clock Input) Pin

The SCL pin is used for serial clock input. It is capable of processing signals at the rising and falling edges of the SCL clock input signal. Make sure the rising time and falling time conform to the specifications.

3. WP Pin

The WP pin is used for write protection. When there is no need for write protection, connect the pin to the GND; when there is a need for write protection, connect the pin to the V_{CC} .

Remark Please refer to the Application Note “**TIPS, TRICKS AND TRAPS WHEN USING THE S-24C/24CS SERIES**” for equivalent circuit of each pin.

DISCONTINUED PRODUCT

■ Operation

1. Start Condition

When the SCL line is “H” the SDA line changes from “H” to “L”. This allows the device to go to the start condition.

All operations begin from the start condition.

2. Stop Condition

When the SCL line is “H” the SDA line changes from “L” to “H”. This allows the device to go to the stop condition.

When the device receives the stop condition signal during a read sequence, the read operation is interrupted, and the device goes to standby mode.

When the device receives the stop condition signal during write sequence, the retrieval of write data is halted, and the E²PROM initiates rewrite.

Figure 8 Start/Stop Condition

3. Data Transmission

Changing the SDA line while the SCL line is “L” allows the data to be transmitted. A start or stop condition is recognized when the SDA line changes while the SCL line is “H”.

Figure 9 Data Transmission Timing

4. Acknowledgment

The unit of data transmission is 8 bits. By turning the SDA line “L” the slave device mounted on the system bus which receives the data during the 9th clock cycle outputs the acknowledgment signal verifying the data reception. When the E²PROM is rewriting, the device does not output the acknowledgment signal.

Figure 10 Acknowledge Output Timing

5. Device Addressing

To perform data communications, the master device mounted on the system outputs the start condition signal to the slave device. Next, the master device outputs 7-bit length device address and a 1-bit length read/write instruction code onto the SDA bus.

Upper 4 bits of the device address are called the "Device Code", and set to "1010". Successive 3 bits are "don't care" bits.

When the comparison results match, the slave device outputs the acknowledgment signal during the 9th clock cycle.

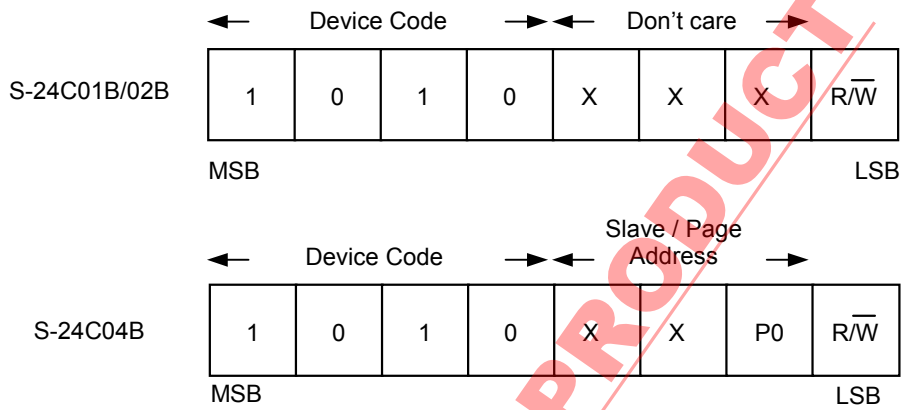

Figure 11 Device Address

In the S-24C04B, 7th bit becomes "P0". "P0" is a page address bit and is equivalent to an additional uppermost bit of the word address. Accordingly, when P0="0", the former half area corresponding to 2 k bits (addresses from 000h to 0FFh) in the entire memory are selected; when P0="1", the latter half area corresponding to 2 k bits (addresses from 100h to 1FFh) in all areas of the memory are selected.

DISCONTINUED PRODUCT

6. Write

6.1 Byte Write

When the E²PROM receives a 7-bit length device address and a 1-bit read/write instruction code “0”, following the start condition signal, it outputs the acknowledgment signal. Next, when the E²PROM receives an 8-bit length word address, it outputs the acknowledgment signal.

After the E²PROM receives 8-bit write data and outputs the acknowledgment signal, it receives the stop condition signal. Next, the E²PROM at the specified memory address starts to rewrite.

When the E²PROM is rewriting, all operations are prohibited and the acknowledgment signal is not output.

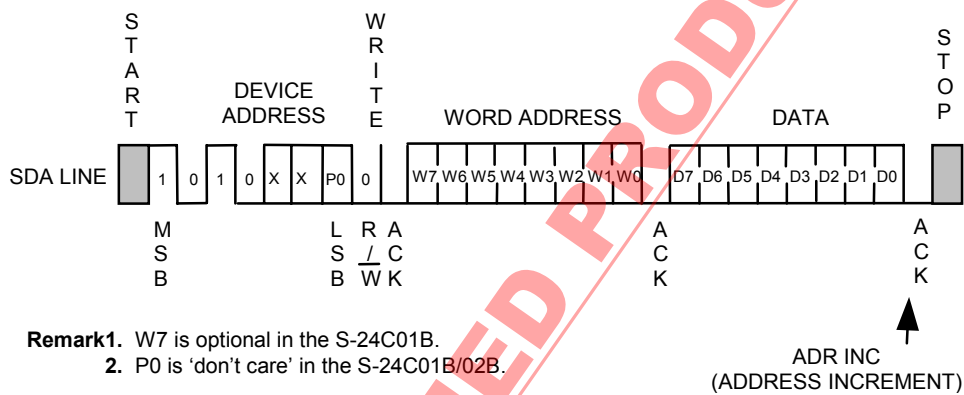

Figure 12 Byte Write

6.3 Acknowledgment Polling

Acknowledgment polling is used to know when the rewriting of the E²PROM is finished.

After the E²PROM receives the stop condition signal and once it starts to rewrite, all operations are prohibited. Also, the E²PROM cannot respond to the signal transmitted by the master device.

Accordingly, the master device transmits the start condition signal and the device address read/write instruction code to the E²PROM (namely, the slave device) to detect the response of the slave device. This allows users to know when the rewriting of the E²PROM is finished.

That is, if the slave device does not output the acknowledgment signal, it means that the E²PROM is rewriting; when the slave device outputs the acknowledgment signal, you can know that rewriting has been completed. It is recommended to use read instruction "1" for the read/write instruction code transmitted by the master device.

6.4 Write Protection

The S-24C01B/02B/04B are capable of protecting the memory. When the WP pin is connected to V_{CC}, writing to all memory area is prohibited in the S-24C01B, writing to 50% of the latter half of memory area is prohibited in the S-24C02B/04B. (prohibited address are 080h to 0FFh in the S-24C02B; 100h to 1FFh in the S-24C04B) Even when writing is prohibited, since the controller inside the IC is operating, the response to the signal transmitted by the master device is not available during the time of writing (t_{WR}).

When the WP pin is connected to GND, the write protection becomes invalid, and writing in all memory area becomes available. However, when there is no need for using write protection, always connect the WP pin to GND. The write protection is valid in the operating voltage range.

DISCONTINUED PRODUCT

7. Read

7.1 Current Address Read

The E²PROM is capable of storing the last accessed memory address during both writing and reading. The memory address is stored as long as the power voltage is more than the retention voltage V_{AH}. Accordingly, when the master device recognizes the position of the address pointer inside the E²PROM, data can be read from the memory address of the current address pointer without assigning a word address. This is called "Current Address Read".

"Current Address Read" is explained for when the address counter inside the E²PROM is an "n" address. When the E²PROM receives a 7-bit length device address and a 1-bit read/write instruction code "1", following the start condition signal, it outputs the acknowledgment signal. However, in the S-24C04B, page address P0 becomes invalid, and the memory address of the current address pointer becomes valid. Next, 8-bit length data at an "n" address is output from the E²PROM, in synchronization with the SCL clock. The address counter is incremented at the falling edge of the SCL clock by which the 8th bit of data is output, and the address counter goes to address n+1. The master device does not output the acknowledgment signal and transmits the stop condition signal to finish reading.

Remark P0 is 'don't care' in the S-24C01B/02B

Figure 14 Current Address Read

For recognition of the address pointer inside the E²PROM, take into consideration the following: The memory address counter inside the E²PROM is automatically incremented for every falling edge of the SCL clock by which the 8th bit of data is output during the time of reading. During the time of writing, upper bits of the memory address (upper 5 bits of the word address in the S-24C01B/02B; upper 4 bits of the word address and page address P0 in the S-24C04B) are left unchanged and are not incremented.

- *1. S-24C01B/02B is the upper 5 bits of the word address.
S-24C04B is the upper 4 bits of the word address and the page address P0.

7.2 Random Read

Random read is a mode used when the data is read from arbitrary memory addresses.

To load a memory address into the address counter inside the E²PROM, first perform a dummy write according to the following procedures:

When the E²PROM receives a 7-bit length device address and a 1-bit read/write instruction code “0”, following the start condition signal, it outputs the acknowledgment signal.

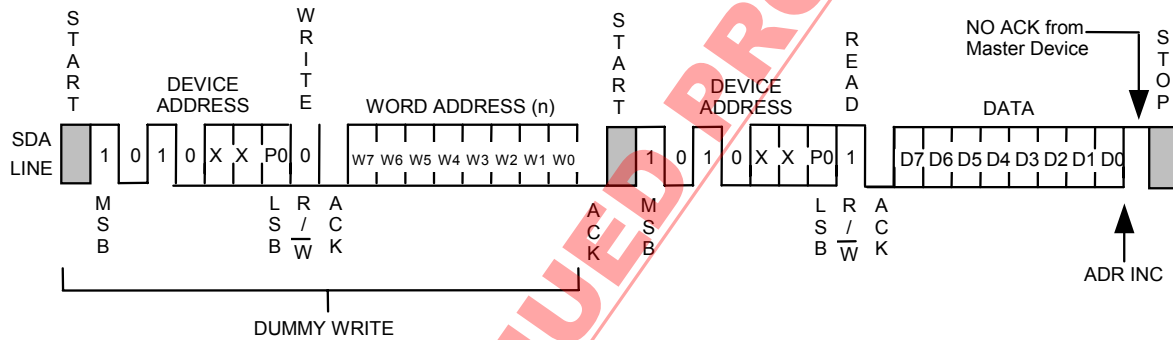

Next, the E²PROM receives an 8-bit length word address and outputs the acknowledgment signal. Last, the memory address is loaded into the address counter of the E²PROM.

the E²PROM receives the write data during byte or page writing. However, data reception is not performed during dummy write.

The memory address is loaded into the memory address counter inside the E²PROM during dummy write. After that, the master device can read the data starting from the arbitrary memory address by transmitting a new start condition signal and performing the same operation as that in the “Current Address Read”.

That is, when the E²PROM receives a 7-bit length device address and a 1-bit read/write instruction code “1”, following the start condition signal, it outputs the acknowledgment signal.

Next, 8-bit length data is output from the E²PROM, in synchronization with the SCL clock. The master device does not output an acknowledgment signal and transmits the stop condition signal to finish reading.

- Remark1. W7 is optional in the S-24C01B.
- 2. P0 is “don't care” in the S-24C01B/02B.

Figure 15 Random Read

7.3 Sequential Read

When the E²PROM receives a 7-bit length device address and a 1-bit read/write instruction code “1” in both current and random read operations, following the start condition signal, it outputs the acknowledgment signal.

When 8-bit length data is output from the E²PROM, in synchronization with the SCL clock, the memory address counter inside the E²PROM is automatically incremented at the falling edge of the SCL clock, by which the 8th data is output.

When the master device transmits the acknowledgment signal, the next memory address data is output.

When the master device transmits the acknowledgment signal, the memory address counter inside the E²PROM is incremented and read data in succession. This is called “Sequential Read”.

When the master device does not output an acknowledgement signal and transmits the stop condition signal, the read operation is finished.

Data can be read in the “Sequential Read” mode in succession. When the memory address counter reaches the last word address, it rolls over to the first memory address.

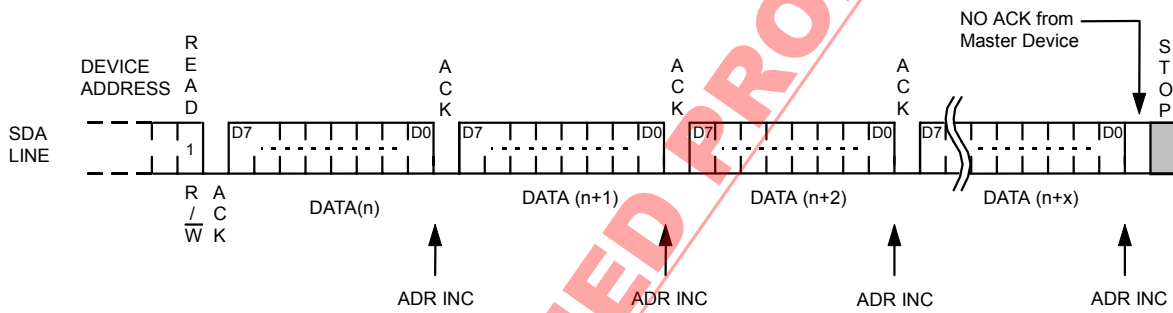

Figure 16 Sequential Read

DISCONTINUED PRODUCT

8. Address Increment Timing

The address increment timing is as follows. During reading operation, the memory address counter is automatically incremented at the falling edge of the SCL clock (the 8th read data is output). During writing operation, the memory address counter is also automatically incremented at the falling edge of the SCL clock when the 8th bit write data is fetched.

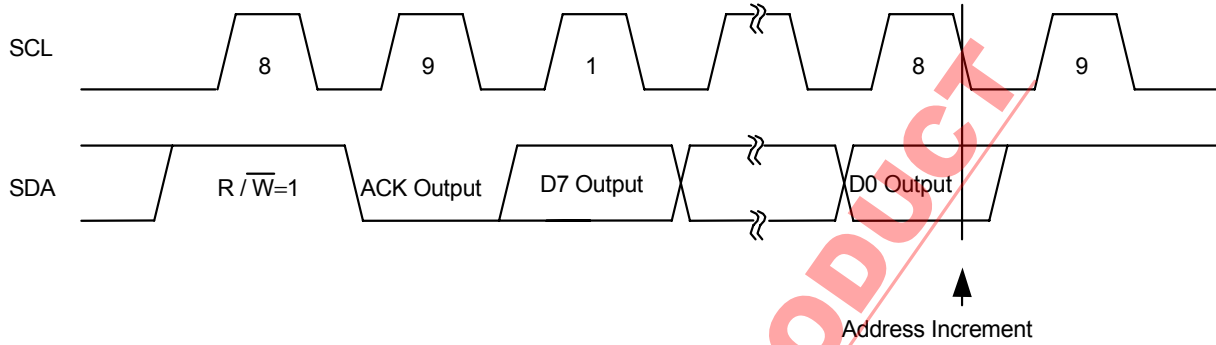

Figure 17 Address Increment Timing in Reading

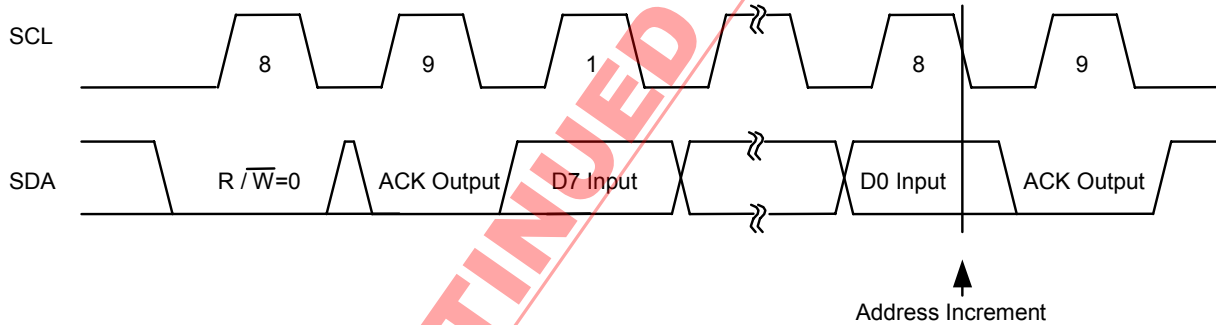

Figure 18 Address Increment Timing in Writing

DISCONTINUED PRODUCT

■ Precautions

- Generally, an E²PROM may cause a malfunction by the operation in low voltage range induced by power ON/OFF. The S-24C01B/02B/04B initialize themselves by the power on clear circuit at power on. Attention should be paid to the followings so as to operate the power on clear circuit correctly, otherwise malfunction may occur.
 1. All input and output pins should be connected to the V_{CC} or the GND level so as not to be floating.
 2. Raise the power voltage up to the operation voltage from 0 V without staying at middle range.
 3. Raising speed of the power voltage should be faster than 40 ms/V.
 4. Power off interval before power on should be longer than 100 ms.
- Do not apply an electrostatic discharge to this IC that exceeds the performance ratings of the built-in electrostatic protection circuit.
- SII claims no responsibility for any and all disputes arising out of or in connection with any infringement of the products including this IC upon patents owned by a third party.

■ I²C Bus License

Purchase of I²C components of Seiko Instruments Inc., conveys a license under the Philips I²C Patent. Rights to use these components in an I²C system, is granted provided that the system conforms to the I²C Standard Specification as defined by Philips.

Please note that a product or a system incorporating this IC may infringe upon the Philips I²C Patent Rights depending upon its configuration. In the event of such infringement Seiko Instruments Inc., shall not bear any responsibility for any matters with regard to and arising from such patent infringement.
