CMOS SERIAL E^2PROM

S-29UXX0A Series

The S-29UXX0A Series is low power 1K/2K/4K-bit E^2PROM with a low operating voltage range. They are organized as 64-word × 16-bit, 128-word × 16-bit and 256-word × 16-bit, respectively. Each is capable of sequential read, at which time addresses are automatically incremented in 16-bit blocks. The instruction code is compatible with the NM93CSXX Series.

■ Features

- Low power consumption
  - Standby : 2.0 μA Max. (VCC = 3.6 V)
  - Operating : 0.6 mA Max. (VCC = 3.6 V)
  - 0.4 mA Max. (VCC = 2.7 V)
- Low operating voltage range
  - Read : 0.9 to 3.6 V
  - Write : 1.8 to 3.6 V
- Sequential read capable
- Endurance : 10^5 cycles/word
- Data retention : 10 years
- S-29U130A : 1K bits NM93CS46 instruction code compatible
- S-29U220A : 2K bits NM93CS56 instruction code compatible
- S-29U330A : 4K bits NM93CS66 instruction code compatible

■ Pin Assignment

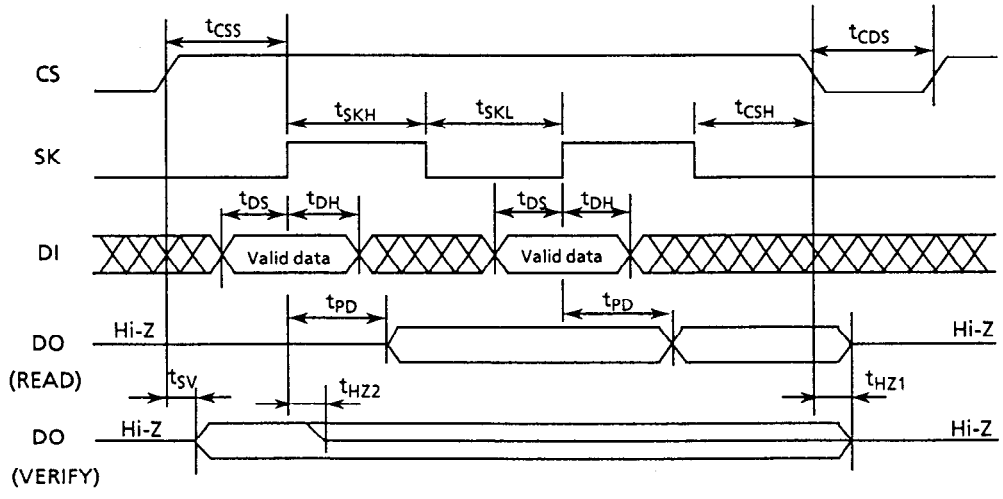

Figure 3 Timing Chart

■ Operation

Instructions (in the order of start-bit, instruction, address, and data) are latched to DI in synchronization with the rising edge of SK after CS goes high. A start-bit can only be recognized when the high of DI is latched to the rising edge of SK when CS goes from low to high, it is impossible for it to be recognized as long as DI is low, even if there are SK pulses after CS goes high. Any SK pulses input while DI is low are called "dummy clocks." Dummy clocks can be used to adjust the number of clock cycles needed by the serial IC to match those sent out by the CPU. Instruction input finishes when CS goes low, where it must be between commands during t_{CDS}.

All input, including DI and SK signals, is ignored while CS is low, which is stand-by mode.

1. Read

The READ instruction reads data from a specified address. After A0 is latched at the rising edge of SK, DO output changes from a high-impedance state (Hi-Z) to low level output. Data is continuously output in synchronization with the rise of SK.

When all of the data (D0) in the specified address has been read, the data in the next address can be read with the input of another SK clock. Thus, it is possible for all of the data addresses to be read through the continuous input of SK clocks as long as CS is high.

The last address (An ··· A1 A0 = 1 ··· 11) rolls over to the top address (An ··· A0 = 0 ··· 00).

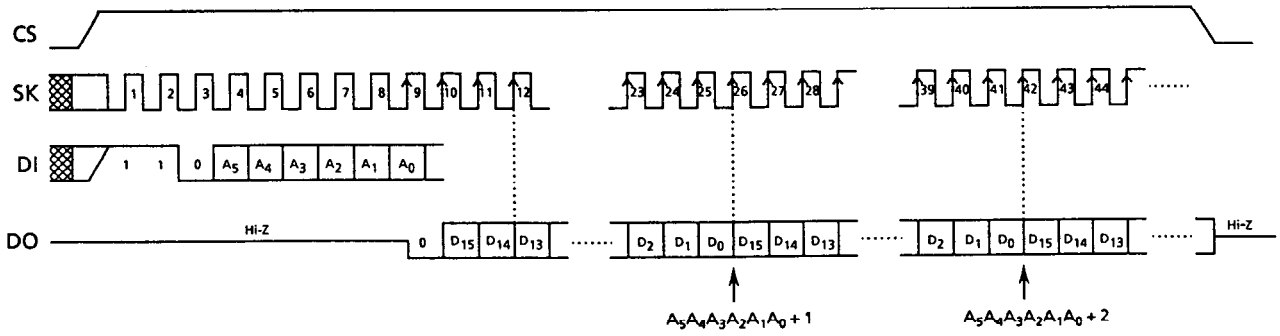

Figure 4 Read Timing (S-29U130A)

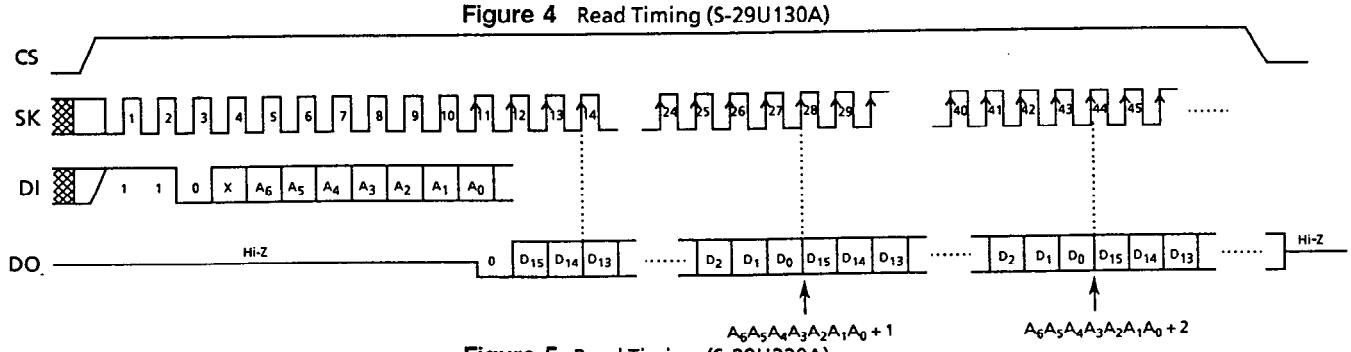

Figure 5 Read Timing (S-29U220A)

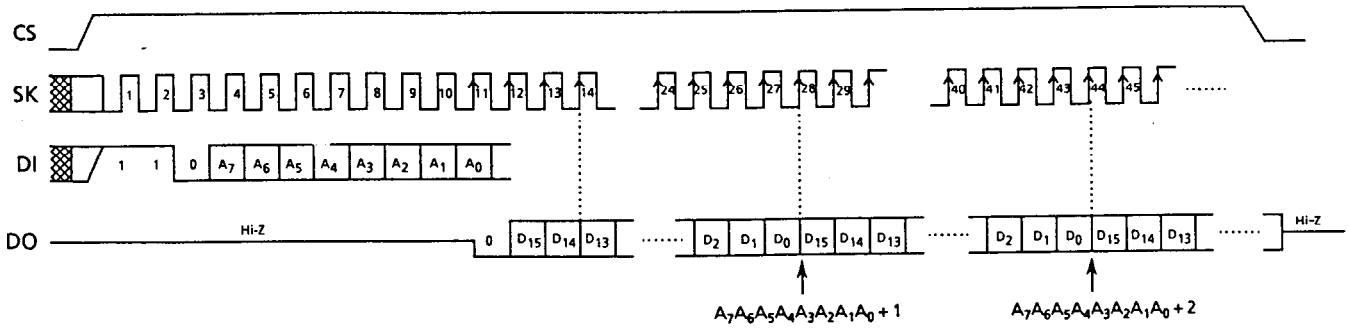

Figure 6 Read Timing (S-29U330A)

2. WRITE (WRITE, ERASE)

There are two write instructions, WRITE and ERASE. Each automatically begins writing to the non-volatile memory when CS goes low at the completion of the specified clock input.

The write operation is completed in 10 ms (t_{PR} Max.), and the typical write period is less than 5 ms. In the S-29UXX0A Series, it is easy to VERIFY the completion of the write operation in order to minimize the write cycle by setting CS to high and checking the DO pin, which is low during the write operation and high after its completion. This VERIFY procedure can be executed over and over again.

Because all SK and DI inputs are ignored during the write operation, any input of instruction will also be disregarded. When DO outputs high after completion of the write operation or if it is in the high-impedence state (Hi-Z), the input of instructions is available. Even if the DO pin remains high, it will enter the high-impedence state upon the recognition of a high of DI (start-bit) attached to the rising edge of an SK pulse (see Figure 3).

DI input should be low during the VERIFY procedure.

2.1 WRITE

This instruction writes 16-bit data to a specified address.
After changing CS to high, input a start-bit, op-code (WRITE), address, and 16-bit data. If there is a data overflow of more than 16 bits, only the last 16-bits of the data is considered valid. Changing CS to low will start the WRITE operation. It is not necessary to make the data "1" before initiating the WRITE operation.

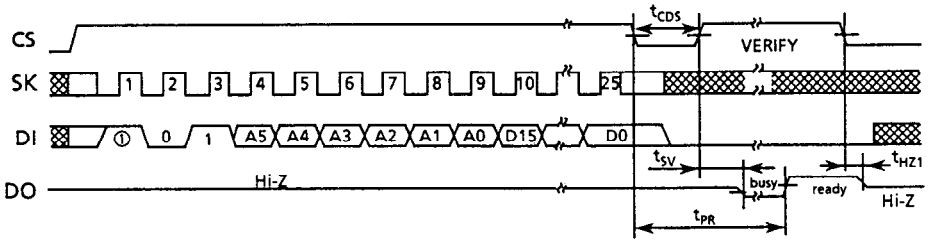

Figure 7 WRITE Timing (S-29U130A)

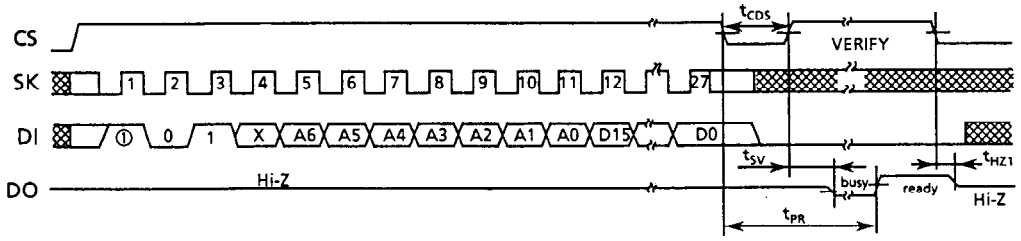

Figure 8 WRITE Timing (S-29U220A)

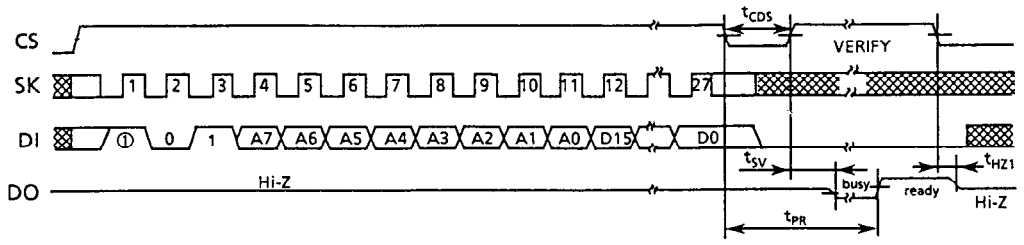

Figure 9 WRITE Timing (S-29U330A)

2.2 ERASE

This command erases 16-bit data in a specified address.
After changing CS to high, input a start-bit, op-code (ERASE), and address. It is not necessary to input data.
Changing CS to low will start the ERASE operation, which changes every bit of the 16 bit data to "1."

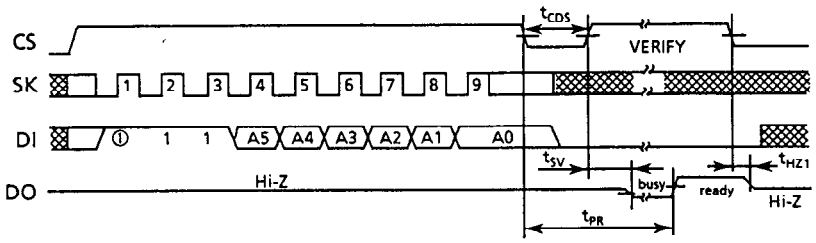

Figure 10 ERASE Timing (S-29U130A)

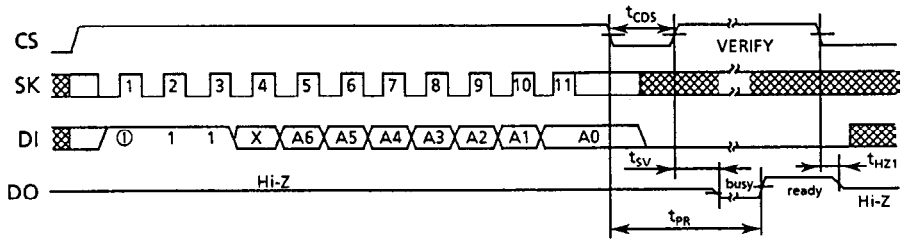

Figure 11 ERASE Timing (S-29U220A)

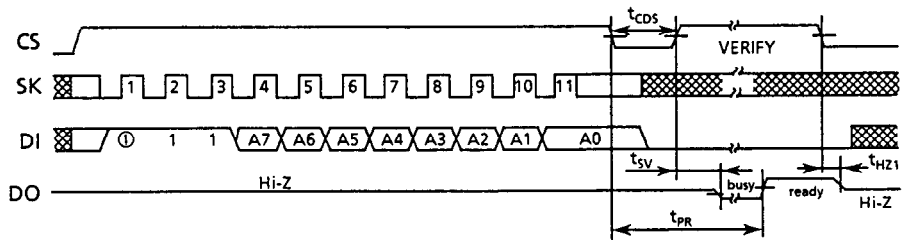

Figure 12 ERASE Timing (S-29U330A)

3. Write enable (EWEN) and Write disable (EWDS)

The EWEN instruction puts the S-29UXX0A Series into write enable mode, which accepts WRITE and ERASE instructions. The EWDS instruction puts the S-29UXX0A Series into write disable mode, which refuses WRITE and ERASE instructions.
The S-29UXX0A Series powers on in write disable mode, which protects data against unexpected, erroneous write operations caused by noise and/or CPU malfunctions. It should be kept in write disable mode except when performing write operations.

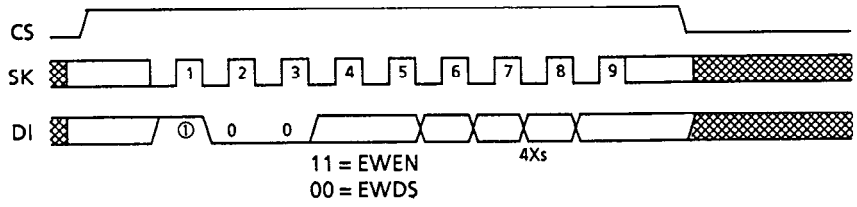

Figure 13 EWEN/EWDS Timing (S-29U130A)

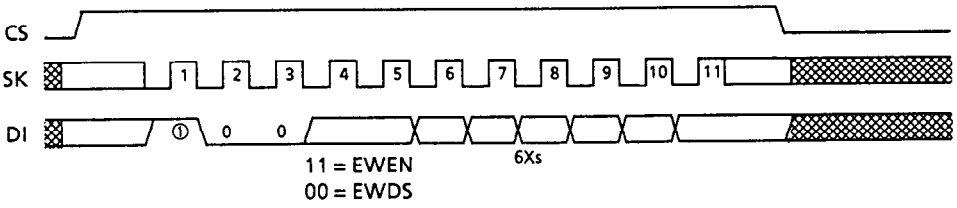

Figure 14 EWEN/EWDS Timing (S-29U220A)

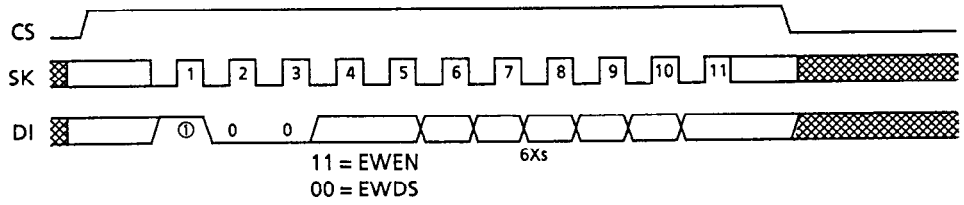

Figure 15 EWEN/EWDS Timing (S-29U330A)

■ Receiving a Start-Bit

Both the recognition of a start-bit and the VERIFY procedure occur when CS is "high". Therefore, only after a write operation, in order to accept the next command by having CS go high, will the DO pin switch from a state of high-impedence to a state of data output; but if it recognizes a start-bit, the DO pin returns to a state of high-impedence.

■ Three-wire Interface (DI-DO direct connection)

Although the normal configuration of a serial interface is a 4-wire interface to CS, SK, DI, and DO, a 3-wire interface is also a possibility by connecting DI and DO. However, since there is a possibility that the DO output from the serial memory IC will interfere with the data output from the CPU with a 3-wire interface, install a resistor between DI and DO in order to give preference to data output from the CPU to DI(See Figure 16).
