

## SONET/SDH PRECISION CLOCK MULTIPLIER IC

### Features

- Ultra-low-jitter clock output with jitter generation as low as 0.3 pSRMS
- No external components (other than a resistor and standard bypassing)
- Input clock ranges at 19, 39, 78, 155, 311, and 622 MHz
- Output clock ranges at 19, 155, or 622 MHz
- Digital hold for loss of input clock
- Support for forward and reverse FEC clock scaling
- Selectable loop bandwidth
- Loss-of-signal alarm output
- Low power
- Small size (9x9 mm)

### Applications

- SONET/SDH line/port cards
- Optical modules
- Core switches
- Digital cross connects
- Terabit routers

### Description

The Si5320 is a precision clock multiplier designed to exceed the requirements of high-speed communication systems, including OC-192/OC-48 and 10 GbE. This device phase locks to an input clock in the 19, 39, 78, 155, 311, or 622 MHz frequency range and generates a frequency-multiplied clock output that can be configured for operation in the 19, 155, or 622 MHz range. Silicon Laboratories' DSPLL™ technology delivers all PLL functionality with unparalleled performance while eliminating external loop filter components, providing programmable loop parameters, and simplifying design. FEC rates are supported with selectable 255/238 or 238/255 scaling of the clock multiplication ratios. The Si5320 establishes a new standard in performance and integration for ultra-low-jitter clock generation. It operates from a single 3.3 V supply.

## 1. Electrical Specifications

**Table 1. Recommended Operating Conditions**

Parameter	Symbol	Test Condition	Min <sup>1</sup>	Typ	Max <sup>1</sup>	Unit
Ambient Temperature	T <sub>A</sub>		-20 <sup>2</sup>	25	85	°C
Si5320 Supply Voltage <sup>3</sup> When Using 3.3 V Supply	V <sub>DD33</sub>		3.135	3.3	3.465	V

**Notes:**

1. All minimum and maximum specifications are guaranteed and apply across the recommended operating conditions. Typical values apply at nominal supply voltages and an operating temperature of 25 °C unless otherwise stated.
2. The Si5320 is guaranteed by design to operate at -40° C. All electrical specifications are guaranteed for an ambient temperature of -20 to 85° C.
3. The Si5320 specifications are guaranteed when using the recommended application circuit (including component tolerance) of Figure 5 on page 15. 3.3 V operation uses an on-chip voltage regulator and is recommended.

A. Operation with Single-Ended Clock Input

Note: When using single-ended clock sources, the unused clock input on the Si5320 must be ac-coupled to ground.

B. Operation with Differential Clock Input

Note: Transmission line termination, when required, must be provided externally.

**Figure 1. CLKIN Voltage Characteristics**

Differential Output Voltage Swing (CLKOUT)	$V_{OD}$	100 $\Omega$ Load Line-to-Line	816	906	1100	mV <sub>PP</sub>
Output Common Mode Voltage (CLKOUT)	$V_{OCM}$	100 $\Omega$ Load Line-to-Line	1.4	1.8	2.2	V
Output Short to GND (CLKOUT)	$I_{SC(-)}$		-60	—	—	mA
Output Short to $V_{DD25}$ (CLKOUT)	$I_{SC(+)}$		—	15	—	mA
Input Voltage Low (LVTTL Inputs)	$V_{IL}$		—	—	0.8	V
Input Voltage High (LVTTL Inputs)	$V_{IH}$		2.0	—	—	V
Input Low Current (LVTTL Inputs)	$I_{IL}$		—	—	50	$\mu\text{A}$
Input High Current (LVTTL Inputs)	$I_{IH}$		—	—	50	$\mu\text{A}$
Internal Pulldowns (All LVTTL Inputs)	$I_{pd}$		—	—	50	$\mu\text{A}$
Input Impedance (LVTTL Inputs)	$R_{IN}$		50	—	—	k $\Omega$
Output Voltage Low (LVTTL Outputs)	$V_{OL}$	$I_O = .5\text{ mA}$	—	—	0.4	V
Output Voltage High (LVTTL Outputs)	$V_{OH}$	$I_O = .5\text{ mA}$	2.0	—	—	V

**Notes:**

1. The Si5320 device provides weak 1.5 V internal biasing that enables ac-coupled operation.
2. Clock inputs may be driven differentially or single-endedly. When driven single-endedly, the unused input should be ac coupled to ground.
3. Transmission line termination, when required, must be provided externally.
4. Although the Si5320 device can operate with input clock swings as high as 1500 mV<sub>PP</sub>, Silicon Laboratories recommends maintaining the input clock amplitude below 500 mV<sub>PP</sub> for optimal performance.

<b>Notes:</b>						
1. Higher PLL bandwidth settings provide smaller clock output wander with temperature gradient.						
2. For reliable device operation, temperature gradients should be limited to 10 °C/min.						
3. Telcordia GR-1244-CORE requirements specify maximum phase transient slope during clock rearrangement in terms of nanoseconds per millisecond. The equivalent ps/μs unit is used here since the maximum phase transient magnitude for the Si5320 (t <sub>PT_MTIE</sub> ) never reaches one nanosecond.						

**Table 5. Absolute Maximum Ratings**

Parameter	Symbol	Value	Unit

## 2. Functional Description

The Si5320 is a high-performance precision clock multiplication and clock generation device. This device accepts a clock input in the 19, 38, 77, 155, 311, or 622 MHz range, attenuates significant amounts of jitter, and multiplies the input clock frequency to generate a clock output in the 19, 155, or 622 MHz range. Additional optional scaling by a factor of either 255/238 (15/14) or 238/255 (14/15) is provided for compatibility with systems that provide or require clocks that are scaled for forward error correction (FEC) rates. Typical applications for the Si5320 in SONET/SDH systems would be the generation and/or cleaning of 19.44, 155.52, or 622.08 MHz clocks from 19.44, 38.88, 77.76, 155.52, 311.04, or 622.08 MHz clock sources.

The Si5320 employs Silicon Laboratories DSPLL™ technology to provide excellent jitter performance while minimizing the external component count and maximizing flexibility and ease-of-use. The Si5320's DSPLL phase locks to the input clock signal, attenuates jitter, and multiplies the clock frequency to generate the device's SONET/SDH-compliant clock output. The DSPLL loop bandwidth is user-selectable, allowing the Si5320's jitter performance to be optimized for different applications. The Si5320 can produce a clock output with jitter generation as low as 0.3 ps<sub>RMS</sub> (see Table 4), making the device an ideal solution for clock multiplication in SONET/SDH (including OC-48 and OC-192) and Gigabit Ethernet systems.

The Si5320 monitors the clock input signal for loss-of-signal, and provides a loss-of-signal (LOS) alarm when missing pulses are detected. The Si5320 provides a digital hold capability to continue generation of a stable output clock when the input reference is lost.

### 2.1. DSPLL™

The Si5320's phase-locked loop (PLL) uses Silicon Laboratories' DSPLL technology to eliminate jitter, noise, and the need for external loop filter components found in traditional PLL implementations. This is achieved by using a digital signal processing (DSP) algorithm to replace the loop filter commonly found in analog PLL designs. This algorithm processes the phase detector error term and generates a digital control value to adjust the frequency of the voltage-controlled oscillator (VCO). The technology produces low phase noise clocks with less jitter than is generated using traditional methods. See Figure 4 for an example phase noise plot. In addition, because external loop filter components are not required, sensitive noise entry points are eliminated, making the DSPLL less susceptible to board-level noise sources.

This digital technology also allows for highly-stable and consistent operation over all process, temperature, and voltage variations. The benefits are smaller, lower power, cleaner, more reliable, and easier-to-use clock circuits.

#### 2.1.1. Selectable Loop Filter Bandwidth

The digital nature of the DSPLL loop filter allows control of the loop filter parameters without the need to change external components. The Si5320 provides the user with up to eight user-selectable loop bandwidth settings for different system requirements. The base loop bandwidth is selected using the BWSEL[1:0] along with DBLBW = 0 pins. When DBLBW is driven high, the bandwidth selected on the BWSEL[1:0] pins is doubled. (See Table 7.)

When DBLBW is asserted, the Si5320 shows improved jitter generation performance. DBLBW function is defined only when hitless recovery and FEC scaling are disabled. Therefore, when DBLBW is high, the user must also drive FXDDELAY high and FEC[1:0] to 00 for proper operation.

## 2.2. Clock Input and Output Rate Selection

The Si5320 provides a 1/32x, 1/16x, 1/8x, 1/4x, 1/2x, 1x, 2x, 4x, 8x, 16x, or 32x clock frequency multiplication function with an option for additional frequency scaling by a factor of 255/238 or 238/255 for FEC rate compatibility. Output rates vary in accordance with the input clock rate. The multiplication factor is configured by selecting the input and output clock frequency ranges for the device.

The Si5320 accepts an input clock in the 19, 38, 77, 155, 311, or 622 MHz frequency range. The input frequency range is selected using the INFRQSEL[2:0] pins. The INFRQSEL[2:0] settings and associated output clock rates are given in Table 8.

The Si5320's DSPLL phase locks to the clock input signal to generate an internal VCO frequency that is a multiple of the input clock frequency. The internal VCO frequency is divided down to produce a clock output in the 19, 155, or 622 MHz frequency range. The clock output range is selected using the Frequency Select (FRQSEL[1:0]) pins. The FRQSEL[1:0] settings and associated output clock rates are given in Table 9.

The Si5320 clock input frequencies are variable within the range specified in Table 3 on page 7. The output rates scale accordingly. When a 19.44 MHz input clock is used with no FEC scaling enabled, the clock output frequency is 19.44, 155.52, or 622.08 MHz.

Table 7. Loop Bandwidth Settings

Loop Bandwidth	BWSEL1	BWSEL0	DBLBW*
12800 Hz	1	1	1
6400 Hz	1	1	0
6400 Hz	0	0	1
3200 Hz	0	0	0
3200 Hz	0	1	1
1600 Hz	0	1	0
1600 Hz	1	0	1
800 Hz	1	0	0

\*Note: When DBLBW = 1, FXDDELAY must be asserted and FEC scaling must be disabled.

Table 8. Nominal Clock Input Frequencies

Input Clock Frequency Range	INFRQSEL2	INFRQSEL1	INFRQSEL0
Reserved	1	1	1
622 MHz	1	1	0
311 MHz	1	0	1
155 MHz	1	0	0
77 MHz	0	1	1
38 MHz	0	1	0
19 MHz	0	0	1

FEC Frequency Scaling	FEC1	FEC0
1/1	0	0
255/238	0	1
238/255	1	0
Reserved	1	1

### 2.2.1. FEC Rate Conversion

The Si5320 provides a 1/32x, 1/16x, 1/8x, 1/4x, 1/2x, 1x, 2x, 4x, 8x, 16x, or 32x clock frequency multiplication function with an option for additional frequency scaling by a factor of 255/238 or 238/255 for FEC rate compatibility. The multiplication factor is configured by selecting the input and output clock frequency ranges for the device. The additional frequency scaling by a factor of either 255/238 or 238/255 for FEC compatibility is selected using the FEC[1:0] control inputs. (See Table 10.)

For example, a 622.08 MHz output clock (a non-FEC rate) can be generated from a 19.44 MHz input clock (a non-FEC rate) by setting INFRQSEL[2:0] = 001 (19.44 MHz range), setting FRQSEL [1:0] = 11 (32x multiplication), and setting FEC[1:0] = 00 (no FEC scaling).

A 666.51 MHz output clock (a FEC rate) can be generated from a 19.44 MHz input clock (a non-FEC rate) by setting INFRQSEL[2:0] = 001 (19.44 MHz range), setting FRQSEL [1:0] = 11 (32x multiplication), and setting FEC[1:0] = 01 (255/238 FEC scaling). Finally, a 622.08 MHz output clock (a non-FEC rate) can be generated from a 20.83 MHz input clock (a FEC rate) by setting INFRQSEL[2:0] = 001 (19.44 MHz range), setting FRQSEL [1:0] = 11 (32x multiplication), and setting FEC[1:0] = 10 (238/255 FEC scaling).

### 2.3. PLL Performance

The Si5320 PLL is designed to provide extremely low jitter generation, high jitter tolerance, and a well-controlled jitter transfer function with low peaking and a high degree of jitter attenuation.

#### 2.3.1. Jitter Generation

Jitter generation is defined as the amount of jitter produced at the output of the device with a jitter free input clock. Generated jitter arises from sources within the VCO and other PLL components. Jitter generation is also a function of the PLL bandwidth setting. Higher loop bandwidth settings may result in lower jitter generation, but may also result in less attenuation of jitter on the input clock signal.

#### 2.3.2. Jitter Transfer

Jitter transfer is defined as the ratio of output signal jitter to input signal jitter for a specified jitter frequency. The jitter transfer characteristic determines the amount of input clock jitter that passes to the outputs. The DSPLL technology used in the Si5320 provides tightly-controlled jitter transfer curves because the PLL gain parameters are determined by digital circuits that do not vary over supply voltage, process, and temperature. In a system application, a well-controlled transfer curve

minimizes the output clock jitter variation from board to board, providing more consistent system level jitter performance.

The jitter transfer characteristic is a function of the BWSEL[1:0] setting. (See Table 7.) Lower bandwidth selection settings result in more jitter attenuation of the incoming clock but may result in higher jitter generation. Table 4 on page 9 gives the 3 dB bandwidth and peaking values for specified BWSEL settings. Figure 6 shows the jitter transfer curve mask.

**Figure 6. PLL Jitter Transfer Mask/Template**

### 2.3.3. Jitter Tolerance

Jitter tolerance for the Si5320 is defined as the maximum peak-to-peak sinusoidal jitter that can be present on the incoming clock. The tolerance is a function of the jitter frequency, because tolerance improves for lower input jitter frequency. See Figure 7.

**Figure 7. Jitter Tolerance Mask/Template**

### 2.4. Digital Hold of the PLL

When no valid input clock is available, the Si5320 digitally holds the internal oscillator to its last frequency value. This provides a stable clock to the system until an input clock is again valid. This clock maintains very stable operation in the presence of constant voltage and temperature. The frequency accuracy specifications for digital hold mode are given in Table 4 on page 9.

### 2.5. Hitless Recovery from Digital Hold

When the Si5320 device is locked to a valid input clock, a loss of the input clock causes the device to automatically switch to digital hold mode. When the input clock signal returns, the device performs a “hitless” transition from digital hold mode back to the selected input clock. That is, the device performs “phase build-out” to absorb the phase difference between the internal VCO clock operating in digital hold mode and the new/returned input clock. The maximum phase step size seen at the clock output during this transition and the maximum slope for this phase step are given in Table 4 on page 9.

This feature can be disabled by asserting the FXDDELAY pin. When the FXDDELAY pin is high, the output clock is phase and frequency locked with a known phase relationship to the input clock. Consequently, any abrupt phase change on the input clock propagates through the device, and the output slews at the selected loop bandwidth until the original phase relationship is restored.

**Note:** When the DBLBW is asserted, hitless recovery must also be disabled by driving FXDDELAY high for proper operation.

**Figure 8. Recovery from Digital Hold**

### 2.6. Loss-of-Signal Alarm

The Si5320 has loss-of-signal (LOS) circuitry that constantly monitors the CLKIN input clock for missing pulses. The LOS circuitry sets a LOS output alarm signal when missing pulses are detected.

The LOS circuitry operates as follows. Regardless of the selected input clock frequency range, the LOS circuitry divides down the input clock into the 19 MHz range. The LOS circuitry then over-samples this divided-down input clock to search for extended periods of time without input clock transitions. If the LOS

circuitry detects four consecutive samples of the divided-down input clock that are the same state (i.e., 1111 or 0000), a LOS condition is declared, the Si5320 goes into digital hold mode, and the LOS output alarm signal is set high. The LOS sampling circuitry runs at a frequency of  $f_{O\_622/8}$ , where  $f_{O\_622}$  is the output clock frequency when the FRQSEL[1:0] pins are set to 11. Table 3 on page 7 lists the minimum and maximum transitionless time periods required for declaring a LOS on the input clock ( $t_{LOS}$ ).

Once the LOS alarm is asserted, it is held high until the input clock is validated over a time period designated by the VALTIME pin. When VALTIME is low, the validation time period is about 100 ms. When VALTIME is high, the validation time period is about 13 s. If another LOS condition is detected on the input clock during the validation time (i.e., if another set of 1111 or 0000 samples are detected), the LOS alarm remains asserted, and the validation time starts over. When the LOS alarm is finally released, the Si5320 exits digital hold mode and locks to the input clock. The LOS alarm is automatically set high at power-on and at every low-to-high transition of the RSTN/CAL pin. In these cases, the Si5320 undergoes a self-calibration before releasing the LOS alarm and locking to the input clock.

The Si5320 also provides an output indicating the digital hold status of the device, DH\_ACTV. The Si5320 only enters the digital hold mode upon the loss of the input clock. When this occurs, the LOS alarm will also be active. Therefore, applications that require monitoring of the status of the Si5320 need only monitor the CAL\_ACTV and either the LOS or DH\_ACTV outputs to know the state of the device.

## 2.7. Reset

The Si5320 provides a Reset/Calibration pin, RSTN/CAL, which resets the device and disables the outputs. When the RSTN/CAL pin is driven low, the internal circuitry enters into the reset mode, and all LVTTTL outputs are forced into a high-impedance state. Also, the CLKOUT+ and CLKOUT- pins are forced to a nominal CML logic LOW and HIGH respectively (See Figure 9). This feature is useful for in-circuit test applications. A low-to-high transition on RSTN/CAL initializes all digital logic to a known condition and initiates self-calibration of the DSPLL. Upon completion of self-calibration, the DSPLL begins to lock to the clock input signal.

**Figure 9. CLKOUT± Equivalent Circuit, RSTN/CAL asserted LOW**

## 2.8. PLL Self-Calibration

The Si5320 achieves optimal jitter performance by using self-calibration circuitry to set the VCO center frequency and loop gain parameters within the DSPLL. Internal circuitry generates self calibration automatically on powerup or after a loss of power condition. Self-calibration can also be manually initiated by a low-to-high transition on the RSTN/CAL input.

A self-calibration should be initiated after changing the state of the FEC[1:0] inputs.

Whether manually initiated or automatically initiated at powerup, the self-calibration process requires the presence of a valid input clock.

If the self-calibration is initiated without a valid clock present, the device waits for a valid clock before completing the self-calibration. The Si5320 clock output is set to the lower end of the operating frequency range while the device is waiting for a valid clock. After the clock input is validated, the calibration process runs to completion; the device locks to the clock input, and the clock output shifts to its target frequency. Subsequent losses of the input clock signal do not require re-calibration. If the clock input is lost following self-calibration, the device enters digital hold mode. When the input clock returns, the device re-locks to the input clock without performing a self-calibration. During the calibration process, the output clock frequency is indeterminate and may jump as high as 5% above the final locked value.

## 2.9. Bias Generation Circuitry

The Si5320 makes use of an external resistor to set internal bias currents. The external resistor allows precise generation of bias currents which significantly reduces power consumption and variation as compared with traditional implementations that use an internal resistor. The bias generation circuitry requires a 10 k $\Omega$  (1%) resistor connected between REXT and GND.

## 2.10. Differential Input Circuitry

The Si5320 provides a differential input for the clock input, CLKIN. This input is internally biased to a voltage of  $V_{ICM}$  (see Table 2 on page 6) and may be driven by a differential or single-ended driver circuit. For differential transmission lines, the termination resistor is connected externally as shown.

## 2.11. Differential Output Circuitry

The Si5320 utilizes a current mode logic (CML) architecture to drive the differential clock output, CLKOUT.

For single-ended output operation, simply connect to either CLKOUT+ or CLKOUT-, and leave the unused signal unconnected.

## 2.12. Power Supply Connections

The Si5320 incorporates an on-chip voltage regulator. The voltage regulator requires an external

compensation circuit of one resistor and one capacitor to ensure stability over all operating conditions.

Internally, the Si5320  $V_{DD33}$  pins are connected to the on-chip voltage regulator input, and the  $V_{DD33}$  pins also supply power to the device's LVTTTL I/O circuitry. The  $V_{DD25}$  pins supply power to the core DSPLL circuitry and are also used for connection of the external compensation circuit.

The regulator's compensation circuit is in reality a resistor and a capacitor in series between the  $V_{DD25}$  node and ground. (See Figure 5 on page 15.) Typically, the resistor is incorporated into the capacitor's equivalent series resistance (ESR). The target RC time constant for this combination is 15 to 50  $\mu$ s. The capacitor used in the Si5320 evaluation board is a 33  $\mu$ F tantalum capacitor with an ESR of 0.8  $\Omega$ . This gives an RC time constant of 26.4  $\mu$ s. The Venkel part number, TA6R3TCR336KBR, is an example of a capacitor that meets these specs.

To get optimal performance from the Si5320 device, the power supply noise spectrum must comply with the plot in Figure 10. This plot shows the power supply noise tolerance mask for the Si5320. The customer should provide a 3.3 V supply that does not have noise density in excess of the amount shown in the diagram. However, the diagram cannot be used as spur criteria for a power supply that contains single tone noise.

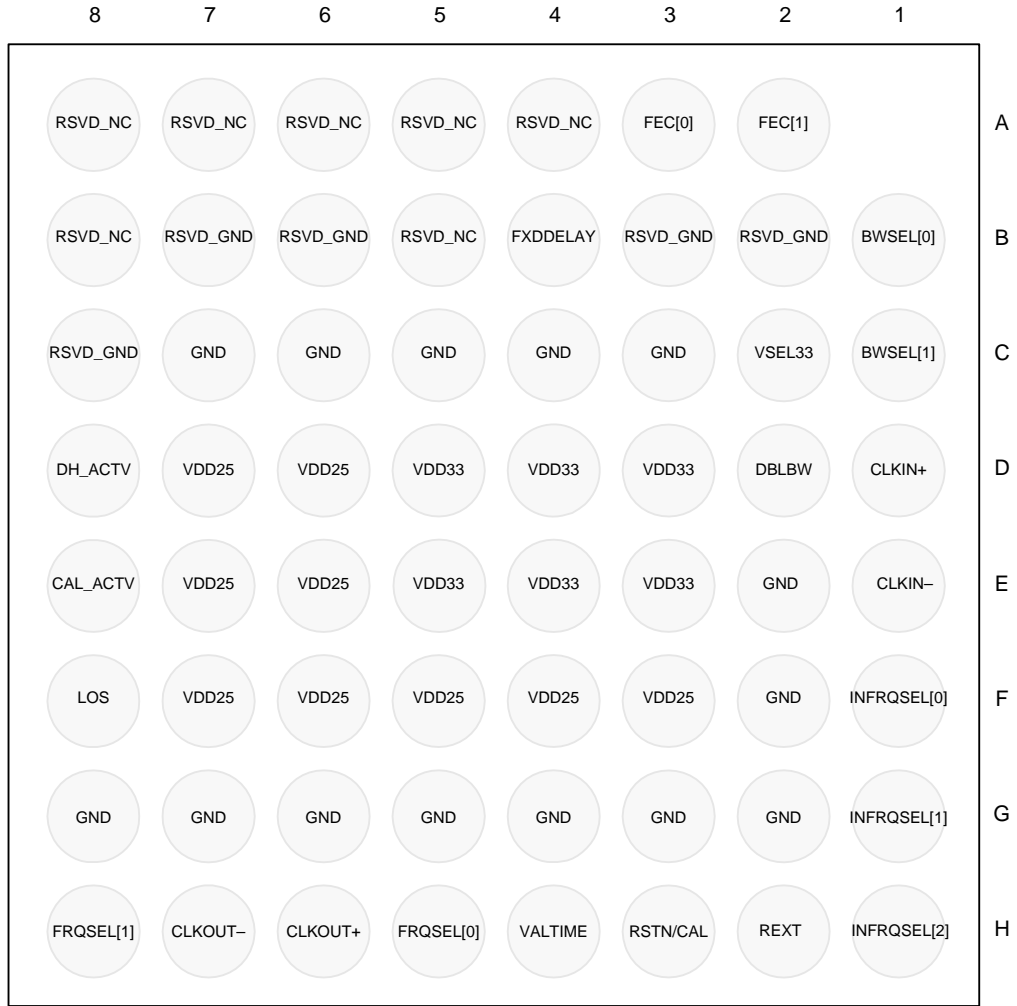

Figure 10. Power Supply Noise Tolerance Mask

## 2.13. Design and Layout Guidelines

Precision clock circuits are susceptible to board noise and EMI. To take precautions against unacceptable levels of board noise and EMI affecting performance of the Si5320, consider the following:

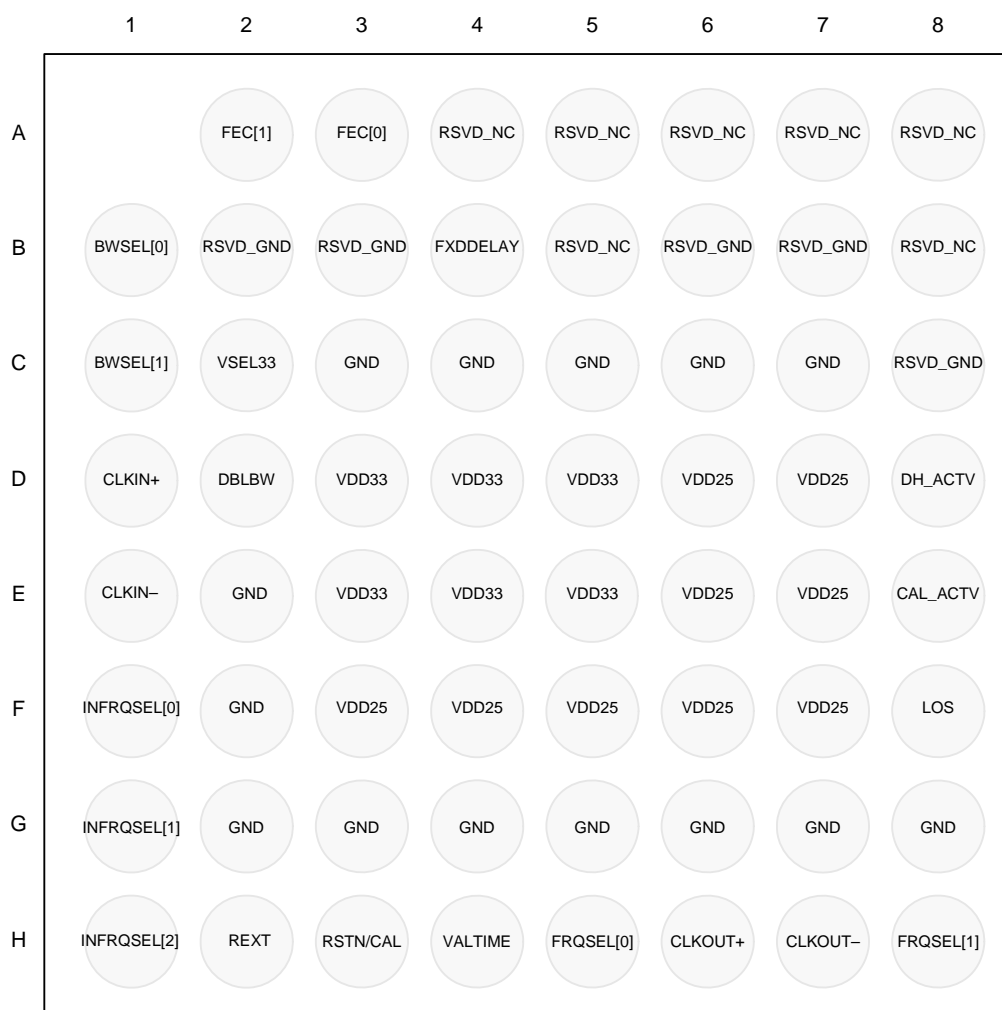

- Power the device from 3.3 V since the internal regulator provides at least 40 dB of isolation to the  $V_{DD25}$  pins (which power the PLL circuitry).
- Use an isolated local plane to connect the  $V_{DD25}$  pins. Avoid running signal traces over or below this plane without a ground plane in between.
- Route all I/O traces between ground planes as much as possible
- Maintain an input clock amplitude in the 200 mV<sub>PP</sub> to 500 mV<sub>PP</sub> differential range.
- Excessive high-frequency harmonics of the input clock should be minimized. The use of filters on the input clock signal can be used to remove high-frequency harmonics.

## 3. Pin Descriptions: Si5320

Bottom View

**Figure 11. Si5320 Pin Configuration (Bottom View)**

Top View

Figure 12. Si5320 Pin Configuration (Transparent Top View)

Table 11. Si5320 Pin Descriptions

Pin #	Pin Name	I/O	Signal Level	Description
B4	FXDDELAY	I*	LVTTL	<p><b>Fixed Delay Mode.</b></p> <p>Set high to disable hitless recovery from digital hold mode. This configuration is useful in applications that require a known, or constant, input-to-output phase relationship.</p> <p>When this pin is high, hitless switching from digital hold mode back to a valid clock input is disabled. When switching from digital hold mode to a valid clock input with FXDDELAY high, the clock output changes as necessary to re-establish the initial/default input-to-output phase relationship that is established after powerup or reset. The rate of change is determined by the setting of BWSEL[1:0].</p> <p>When this pin is low, hitless switching from digital hold mode back to a valid clock input is enabled. When switching from digital hold mode to a valid clock input with FXDDELAY low, the device enables "phase build out" to absorb the phase difference between the clock output and the clock input so that the phase change at the clock output is minimized. In this case, the input-to-output phase relationship following the transition out of digital hold mode is determined by the phase relationship at the time that switching occurs.</p> <p><b>Note:</b> FXDDELAY should remain at a static high or static low level during normal operation. Transitions on this pin are allowed only when the RSTN/CAL pin is low. FXDDELAY must be set high when DBLBW is set high.</p>
D1 E1	CLKIN+ CLKIN-	I	AC Coupled 200–500 mV <sub>PPD</sub> (See Table 2)	<p><b>System Clock Input.</b></p> <p>Clock input to the DSPLL circuitry. The frequency of the CLKIN signal is multiplied by the DSPLL to generate the CLKOUT clock output. The input-to-output frequency multiplication factor is set by selecting the clock input range and the clock output range. The frequency of the CLKIN clock input can be in the 19, 38, 77, 155, 311, or 622 MHz range (nominally 19.44, 38.88, 77.76, 155.52, 311.04, or 622.08 MHz) as indicated in Table 3 on page 7. The clock input frequency is selected using the INFRQSEL[2:0] pins. The clock output frequency is selected using the FRQSEL[1:0] pins. An additional scaling factor of either 255/238 or 238/255 may be selected for FEC operation using the FEC[1:0] control pins.</p>
<p><b>*Note:</b> The LVTLL inputs on the Si5320 device have an internal pulldown mechanism that causes these inputs to default to a logic low state if the input is not driven from an external source.</p>				

Table 11. Si5320 Pin Descriptions (Continued)

The clock input frequency is selected using the INFRQSEL[2:0] pins. An additional scaling factor of either 255/238 or 238/255 may be selected for FEC operation using the FEC[1:0] control pins as indicated below. 00 = No FEC scaling. 01 = 255/238 FEC scaling for all clock outputs. 10 = 238/255 FEC scaling for all clock inputs. 11 = Reserved. <b>Note:</b> FEC[1:0] must be set to 00 when DBLBW is set high.</p>
<p><b>*Note:</b> The LVTLL inputs on the Si5320 device have an internal pulldown mechanism that causes these inputs to default to a logic low state if the input is not driven from an external source.</p>				

Table 11. Si5320 Pin Descriptions (Continued)

Pin #	Pin Name	I/O	Signal Level	Description
B1 C1	BWSEL[0] BWSEL[1]	I*	LVTTL	<b>Bandwidth Select.</b> BWSEL[1:0] pins set the bandwidth of the loop filter within the DSPLL to 6400, 3200, 1600, or 800 Hz as indicated below. 00 = 3200 Hz 01 = 1600 Hz 10 = 800 Hz 11 = 6400 Hz <b>Note:</b> The loop filter bandwidth will be twice the value indicated when DBLBW is set high.
E8	CAL_ACTV	O	LVTTL	<b>Calibration Mode Active.</b> This output is driven high during the DSPLL self-calibration and the subsequent initial lock acquisition period.
H4	VALTIME	I*	LVTTL	<b>Clock Validation Time for LOS.</b> VALTIME sets the clock validation times for recovery from an LOS alarm condition. When VALTIME is high, the validation time is approximately 13 seconds. When VALTIME is low, the validation time is approximately 100 ms.
B2, B3, B6, B7, C8	RSVD_GND	—	LVTTL	<b>Reserved—GND.</b> This pin must be tied to GND for normal operation.
A4–8, B5, B8	RSVD_NC	—	LVTTL	<b>Reserved—No Connect.</b> This pin must be left unconnected for normal operation.
C2	VSEL33	I*	LVTTL	<b>Select 3.3 V V<sub>DD</sub> Supply.</b> This is an enable pin for the internal regulator. To enable the regulator, connect this pin to the V <sub>DD33</sub> pins.
D3–D5, E3–E5	V <sub>DD33</sub>	V <sub>DD</sub>	Supply	<b>3.3 V Supply.</b> 3.3 V power is applied to the V <sub>DD33</sub> pins. Typical supply bypassing/decoupling for this configuration is indicated in the typical application diagram for 3.3 V supply operation.
D6, D7, E6, E7, F3–F7	V <sub>DD25</sub>	V <sub>DD</sub>	Supply	<b>2.5 V Supply.</b> These pins provide a means of connecting the compensation network for the on-chip regulator.
<b>*Note:</b> The LVTTL inputs on the Si5320 device have an internal pulldown mechanism that causes these inputs to default to a logic low state if the input is not driven from an external source.				

**Table 11. Si5320 Pin Descriptions (Continued)**

Pin #	Pin Name	I/O	Signal Level	Description
C3–C7, E2, F2, G2–G8	GND	GND	Supply	<b>Ground.</b> Must be connected to system ground. Minimize the ground path impedance for optimal performance of the device.
H2	REXT	I	Analog	<b>External Biasing Resistor.</b> Used by on-chip circuitry to establish bias currents within the device. This pin must be connected to GND through a 10 k $\Omega$ (1%) resistor.
D2	DBLBW	I*	LVTTL	<b>Double Bandwidth</b> Active high input to boost the selected bandwidth 2x. When this pin is high, the loop filter bandwidth selected on BWSEL[1:0] is doubled. When this pin is high, FXDDELAY must also be high and FEC[1:0] must be 00.

**\*Note:** The LVTTL inputs on the Si5320 device have an internal pulldown mechanism that causes these inputs to default to a logic low state if the input is not driven from an external source.

**4. Ordering Guide**

<b>Part Number</b>	<b>Package</b>	<b>Temperature Range</b>
Si5320-G-BC	63-Ball CBGA (Prior Revision) RoHS-5	-20 to 85 °C
Si5320-H-BL	63-Ball PBGA (Current Revision) RoHS-5	-20 to 85 °C
Si5320-H-GL	63-Ball PBGA (Current Revision) RoHS-6	-20 to 85 °C

## 5. Package Outline

Figure 13 illustrates the package details for the Si5320. Table 12 lists the values for the dimensions shown in the illustration.

Figure 13. 63-Ball Plastic Ball Grid Array (PBGA)

Table 12. Package Diagram Dimensions (mm)

Symbol	Min	Nom	Max
A	1.24	1.41	1.58
A1	0.40	0.50	0.60
A2	0.34	0.38	0.42
A3	0.50	0.53	0.56
b	0.50	0.60	0.70
D	9.00 BSC		
E	9.00 BSC		
D1	7.00 BSC		

Symbol	Min	Nom	Max
E1	7.00 BSC		
e	1.00 BSC		
S	0.50 BSC		
aaa	0.10		
bbb	0.10		
ccc	0.12		
ddd	0.15		
eee	0.08		

**Notes:**

1. All dimensions shown are in millimeters (mm) unless otherwise noted.
2. Dimensioning and Tolerancing per ANSI Y14.5M-1994.
3. This drawing conforms to JEDEC outline MO-192, variation AAB-1.
4. Recommended card reflow profile is per the JEDEC/IPC J-STD-020C specification for Small Body Components.

## 6. 9x9 mm PBGA Card Layout

Symbol	Min	Nom	Max
X	0.40	0.45	0.50
C1	7.00		
C2	7.00		
E1	1.00		
E2	1.00		

### Notes:

#### General

1. All dimensions shown are in millimeters (mm) unless otherwise noted.
2. Dimensioning and Tolerancing is per the ANSI Y14.5M-1994 specification.
3. This Land Pattern Design is based on the IPC-7351 guidelines.

#### Solder Mask Design

1. All metal pads are to be non-solder mask defined (NSMD). Clearance between the solder mask and the metal pad is to be 60  $\mu\text{m}$  minimum, all the way around the pad.

#### Stencil Design

1. A stainless steel, laser-cut and electro-polished stencil with trapezoidal walls should be used to assure good solder paste release.
2. The stencil thickness should be 0.125 mm (5 mils).
3. The ratio of stencil aperture to land pad size should be 1:1.

#### Card Assembly

1. A No-Clean, Type-3 solder paste is recommended.
2. The recommended card reflow profile is per the JEDEC/IPC J-STD-020C specification for Small Body Components.

## DOCUMENT CHANGE LIST

### Revision 2.0 to Revision 2.1

- Updated Figure 8, "Recovery from Digital Hold," on page 18.
- Updated Figure 13, "63-Ball Plastic Ball Grid Array (PBGA)," on page 30.
- Updated Table 12, "Package Diagram Dimensions (mm)," on page 30
- Added Figure 4, "Typical Si5320 Phase Noise (CLKIN = 155.52 MHz, CLKOUT = 622.08 MHz, and Loop BW = 800 Hz)," on page 14

### Revision 2.1 to Revision 2.2

- Updated "2.7. Reset" on page 19.
- Updated Table 12, "Package Diagram Dimensions (mm)," on page 30.

### Revision 2.2 to Revision 2.3

- Updated "5. Package Outline" on page 30.

### Revision 2.3 to Revision 2.4

- Updated "4. Ordering Guide" on page 29.
- Updated "5. Package Outline" on page 30.
- Updated "6. 9x9 mm PBGA Card Layout" on page 31.

### Revision 2.4 to Revision 2.5

- Updated Table 6, "Thermal Characteristics," on page 14.
