SK10/100E445
4-Bit Serial/Parallel Converter

Description

The SK10/100E445 is an integrated 4-bit serial-to-parallel data converter. The device is designed to operate for NRZ data rates of up to 2.0 Gb/s. The chip generates a divide by 4 and a divide by 8 clock for both 4-bit conversion and a two chip 8-bit conversion function. The conversion sequence was chosen to convert the first serial bit to Q0, the second to Q1, etc.

Two selectable serial inputs provide a loopback capability for testing purposes when the device is used in conjunction with the R446 parallel to serial converter.

The start bit for conversion can be moved using the SYNC input. A single pulse applied asynchronously for at least two input clock cycles shifts the start bit for conversion from Qn to Qn–1. For each additional shift required, an additional pulse must be applied to the SYNC input. Asserting the SYNC input will force the internal clock dividers to "swallow" a clock pulse, effectively shifting a bit from the Qn to the Qn–1 output (see Timing Diagram B).

The MODE input is used to select the conversion mode of the device. With the MODE input LOW, or open, the device will function as a 4-bit converter. When the mode input is driven HIGH, the data on the output will change on every eighth clock cycle, thus allowing for an 8-bit conversion scheme using two E445's. When cascaded in an 8-bit conversion scheme, the devices will not operate at the 2.0 Gb/s data rate of a single device. Refer to the applications section of this data sheet for more information on cascading the E445.

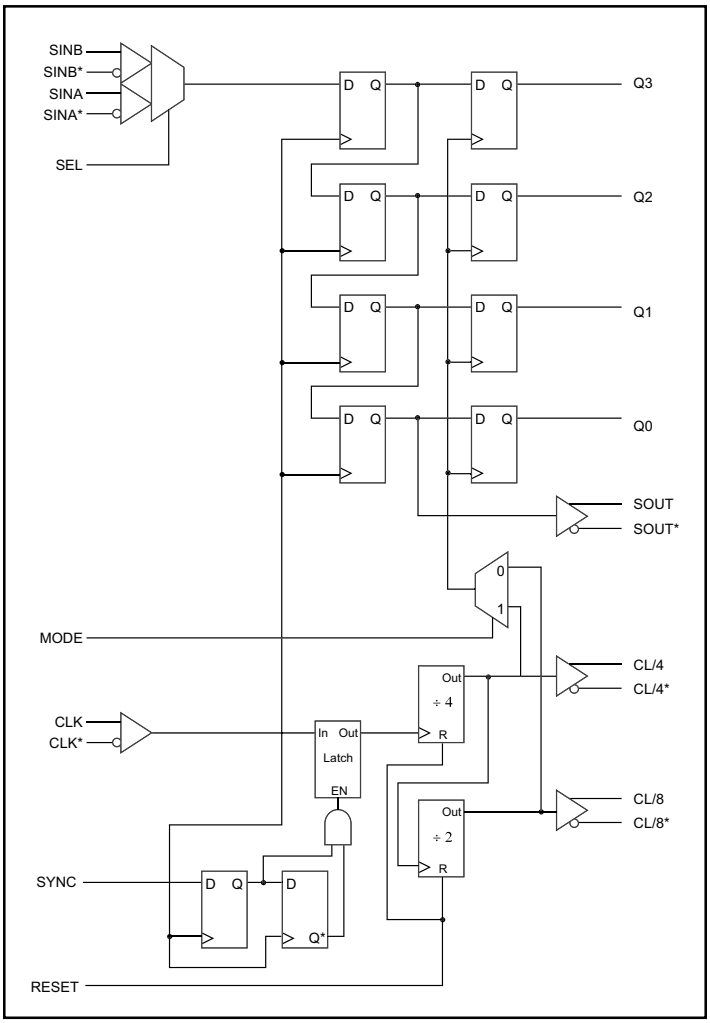
For lower data rate applications, a V_{BB} reference voltage is supplied for single-ended inputs. When operating at clock rates above 500 MHz, differential input signals are recommended. For single-ended inputs, the V_{BB} pin is tied to the inverting differential input and bypassed via a 0.01 µF capacitor. The V_{BB} provides the switching reference for the input differential amplifier. The V_{BB} can also be used to AC couple an input signal.

Upon power-up, the internal flip-flops will attain a random state. To synchronize multiple E445's in a system, the master reset must be asserted.

Features

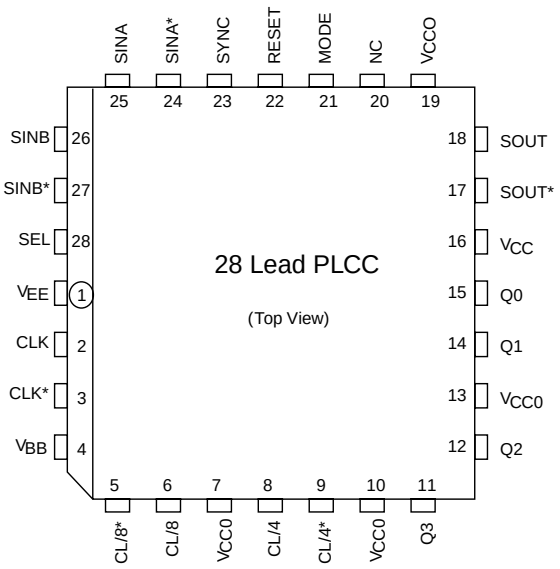
- On-Chip Clock ÷ 4 and ÷8
- 2.0 Gb/s Data Rate Capability
- Differential Clock and Serial Inputs
- V_{BB} Output for Single-Ended Input Applications
- Asynchronous Data Synchronization
- Mode Select to Expand to 8-Bits
- Internal 75 kΩ Input Pulldown Resistors
- ESD Protection of >4000V
- Extended 100E VEE Range of –4.2V to –5.46V
- Fully Compatible with MC10/100E445
- Available in 28-Pin PLCC Package

Functional Block Diagram



PIN Description

Pinout



Pin Names

Pin	Function
SinA, SINA*	Differential Serial Data Input A
SINB, SINB*	Differential Serial Data Input B
SEL	Serial Input Selector Pin
Q0 - Q3	Parallel Data Outputs
CLK, CLK*	Differential Clock Inputs
CL/4, CL/4*	Differential ÷4Clock Output
CL/8, CL/8*	Differential ÷8Clock Output
MODE	Conversion Mode 4-Bit/8Bit
SYNCH	Conversion Synchronizing Input

Function Table

Mode	Conversion	SEL	Serial Input
L	4-Bit	H	A
H	8-Bit	L	B

Application Information

The SK10/100E445 is an integrated 4-bit serial-to-parallel data converter. The chip is designed to work with the E446 device to provide both transmission and receiving of a high speed serial data path. The E445 can convert up to a 2.0 GB/s NRZ data stream into 4-bit parallel data. The device also provides a divide by four clock output to be used to synchronize the parallel data with the rest of the system.

The E445 features multiplexed dual serial inputs to provide test loop capability when used in conjunction with the E446. Figure 1 illustrates the loop test architecture. The architecture allows for the electrical testing of the link without requiring actual transmission over the serial data path medium. The SINA serial input of the E446 has an extra buffer delay and should be used as the loopback serial input.

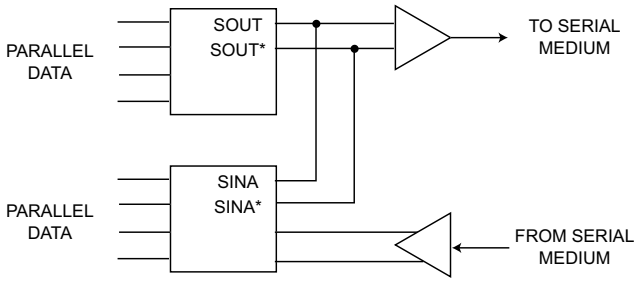


Figure 1. Loopback Test Architecture

The E445 features a differential serial output and a divide by 8 clock output to facilitate the cascading of two devices to build a 1:8 demultiplexer. Figure 2 illustrates the architecture for a 1:8 demultiplexer using two E445's; the timing diagram for this configuration can be found in Figure 6. Notice the serial outputs (SOUT of the lower order converter feed the serial inputs of the higher order device. This feedthrough of the serial inputs bounds the upper end of the frequency of operation. The clock to serial output propagation delay plus the setup time of the serial input pins must fit into a single clock period for the cascade architecture to function properly. Using the worst case values for these two parameters from the datasheet, TPD CLK to SOUT = 1150 ps and tS for SIN = –100 ps, yields a minimum period of 1050 ps or a clock frequency of 950 MHz.

The clock frequency is significantly lower than that of a single converter. To increase this frequency, some games can be played with the clock input of the higher order E445. By delaying the clock feeding the second E445 relative to the clock of the first E445, the frequency of operation can be increased. The delay between the two clocks can be increased until the minimum delay of clock to serial out would potentially cause a serial bit to be swallowed (Figure 3).

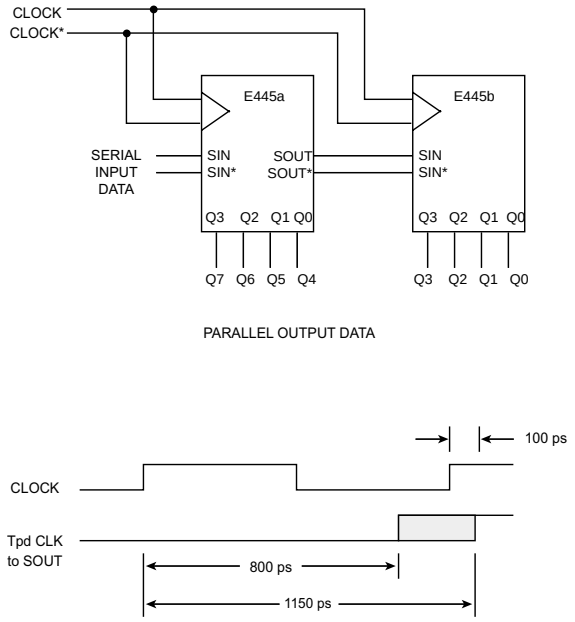

Figure 2. Cascaded 1:8 Converter Architecture

With a minimum delay of 800 ps on this output, the clock for the lower order E445 cannot be delayed more than 800 ps relative to the clock of the first E445 without potentially missing a bit of information. Because the setup time on the serial input pin is negative, coincident excursions on the data and clock inputs of the E445 will result in correct operation.

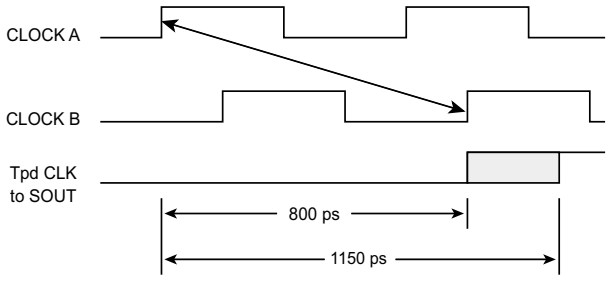

Figure 3. Cascade Frequency Limitation

Application Information (continued)

Perhaps the easiest way to delay the second clock relative to the first is to take advantage of the differential clock inputs on the E445. By connecting the clock for the second E445 to the complimentary clock input pin, the device will clock a half a clock period after the first E445 (Figure 5). Utilizing this simple technique will raise the potential conversion frequency up to 1.4 GHz. The divide by eight clock of the second E445 should be used to synchronize the parallel data to the rest of the system as the parallel data of the two E445's will no longer by synchronized. This skew problem between the outputs can be worked around as the parallel information will be static for eight more clock pulses.

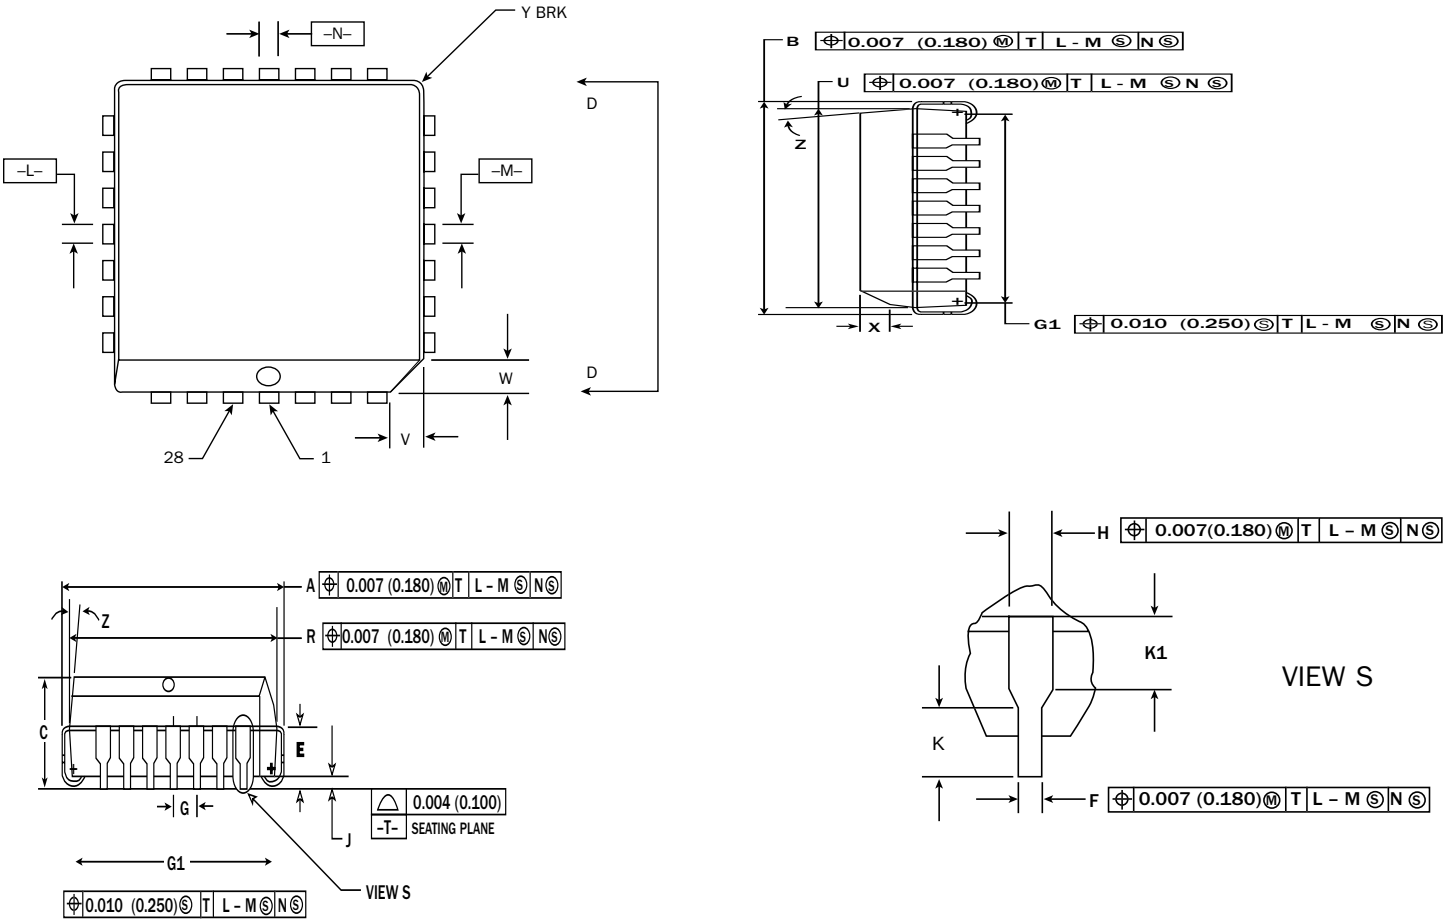
Package Information



NOTES:

1. Datums -L-, -M-, and -N- determined where top of lead shoulder exits plastic body at mold parting line.
2. DIM G1, true position to be measured at Datum -T-, Seating Plane.
3. DIM R and U do not include mold flash. Allowable mold flash is 0.010 (0.250) per side.
4. Dimensioning and tolerancing per ANSI Y14.5M, 1982.
5. Controlling Dimension: Inch.
6. The package top may be smaller than the package bottom by up to 0.012 (0.300). Dimensions R and U are determined at the outermost extremes of the plastic body exclusive of mold flash, tie bar burrs, gate burrs and interlead flash, but including any mismatch between the top and bottom of the plastic body.
7. Dimension H does not include Dambar protrusion or intrusion. The Dambar protrusion(s) shall not cause the H dimension to be greater than 0.037 (0.940). The Dambar intrusion(s) shall not cause the H dimension to be smaller than 0.025 (0.635).
