

A Reverse-current Blocking, 15 mΩ, 4 A Integrated Power Switch with Analog Current Monitor Output

General Description

Operating from a 2.5 V to 5.5 V power supply, the SLG59M1714V is a 15 mΩ, 4 A single-channel integrated power switch with back-to-back reverse-current blocking when the power switch is disabled. With a fixed V_{OUT} slew rate of 2.8 V/ms, inrush current is internally limited. Incorporating two-stage current protection as well as thermal protection and fault signaling, the SLG59M1714V is designed for all 0.8 V to 5.5 V power rail applications. Fully specified over the -40 °C to 85 °C temperature range, the SLG59M1714V is packaged in a space-efficient, low thermal resistance 1.6 mm x 2.5 mm STQFN package.

Features

- Low $R_{DS(ON)}$ nFET Block: 15 mΩ
- Back-to-back Reverse-current Blocking (when OFF)
- Maximum Continuous Switch Current: Up to 4 A
- Supply Voltage: $2.5\text{ V} \leq V_{DD} \leq 5.5\text{ V}$
- Wide Input Voltage Range: $0.8\text{ V} \leq V_{IN} \leq V_{DD}$
- Fixed V_{OUT} Slew Rate: 2.8 V/ms
- Two-stage Overcurrent Protection:
 - Resistor-adjustable Active Current Limit
 - Fixed 0.5 A Short-circuit Current Limit
- Thermal Shutdown Protection
- Analog MOSFET Current Monitor Output: 100 μA/A
- Open-drain FAULT Signaling
- Operating Temperature: -40 °C to 85 °C
- Low θ_{JA} , 16-pin 1.6 mm x 2.5 mm STQFN
 - Pb-Free / Halogen-Free / RoHS compliant

Pin Configuration

16-pin FC-STQFN (Top View)

Applications

- Notebook Power Rail Switching
- Tablet Power Rail Switching
- Smartphone Power Rail Switching

Block Diagram

Pin Description

Pin #	Pin Name	Type	Pin Description
1	VDD	Power	With an internal 1.9V UVLO threshold, VDD supplies the power for the operation of the power switch and internal control circuitry where its range is $2.5\text{ V} \leq V_{DD} \leq 5.5\text{ V}$. Bypass the VDD pin to GND with a 0.1 μF (or larger) capacitor
2	$\overline{\text{FAULT}}$	Output	An open drain output, $\overline{\text{FAULT}}$ is asserted within 8ms when a current-limit or an over-temperature condition is detected. $\overline{\text{FAULT}}$ is deasserted within 8 ms when the fault condition is removed. Connect an external 10-k Ω resistor from the FAULT pin to local system logic supply.
3-7	VIN	MOSFET	Drain terminal of Power MOSFET (Pins 3-7 fused together). Connect a 10- μF (or larger) low-ESR capacitor from this pin to ground. Capacitors used at VIN should be rated at 10 V or higher.
8-12	VOUT	MOSFET	Source terminal of Power MOSFET (Pins 8-12 fused together). Connect a low-ESR capacitor from this pin to ground and consult the Electrical Characteristics table for recommended C_{LOAD} range. Capacitors used at VOUT should be rated at 10 V or higher.
13	IOUT	Output	MOSFET Load Current Monitor Output. As an analog output current, this signal when applied to a ground-reference resistor generates a voltage proportional to the current through the n-channel MOSFET. The IOUT transfer characteristic is typically 100 $\mu\text{A}/\text{A}$ with a voltage compliance range of $0.5\text{ V} \leq V_{IOUT} \leq V_{DD} - 1\text{ V}$. Optimal IOUT linearity is exhibited for $0.5\text{ A} \leq I_{DS} \leq 4\text{ A}$. Bypass the IOUT pin to GND with a 0.01 μF capacitor.
14	RSET	Input	A 1%-tolerance, metal-film resistor between 10 k Ω and 80 k Ω sets the IPS's active current limit. A 40 k Ω resistor sets the SLG59M1714V's active current limit to 2 A and a 80 k Ω resistor sets the active current limit to 1 A.
15	GND	GND	Ground
16	ON	Input	A low-to-high transition on this pin closes the power switch. ON is an asserted-HIGH, level-sensitive CMOS input with $V_{IL} < 0.3\text{ V}$ and $V_{IH} > 0.85\text{ V}$. Connect this pin to the output of a general-purpose output (GPO) from a microcontroller or other application processor. While there is an internal pull down circuit to ground ($\sim 4\text{ M}\Omega$), do not allow this pin to be open-circuited.

Ordering Information

Part Number	Type	Production Flow
SLG59M1714V	STQFN 16L	Industrial, -40 °C to 85 °C
SLG59M1714VTR	STQFN 16L (Tape and Reel)	Industrial, -40 °C to 85 °C

Absolute Maximum Ratings

Parameter	Description	Conditions	Min.	Typ.	Max.	Unit
V_{DD}	Power Supply Pin to GND		--	--	7	V
V_{IN} to GND	Power Switch Input Voltage to GND		-0.3	--	7	V

Timing Diagram - Basic Operation including Active Current Limit Protection

Timing Diagram - Active Current Limit & Thermal Protection Operation

SLG59M1714V Power-Up/Power-Down Sequence Considerations

To ensure glitch-free power-up under all conditions, apply V_{DD} first, followed by V_{IN} after V_{DD} exceeds 1.9 V. Then allow V_{IN} to reach 90% of its max value before toggling the ON pin from Low-to-High. Likewise, power-down in reverse order.

If V_{DD} and V_{IN} need to be powered up simultaneously, glitching can be minimized by having a suitable load capacitor. A 10 μF C_{LOAD} will prevent glitches for rise times of V_{DD} and V_{IN} less than 2 ms.

If the ON pin is toggled HIGH before V_{DD} and V_{IN} have reached their steady-state values, the IPS timing parameters may differ from datasheet specifications.

SLG59M1714V Current Limiting Operation

The SLG59M1714V has two types of current limiting triggered by the output V_{OUT} voltage.

1. Standard Current Limiting Mode (with Thermal Shutdown Protection)

When the V_{OUT} voltage > 250 mV, the output current is initially limited to the Active Current Limit (I_{ACL}) specification listed in the Electrical Characteristics table. The ACL monitor's response time is very fast and is triggered within a few microseconds to sudden (transient) changes in load current. When a load current overload is detected, the ACL monitor increases the FET resistance to keep the current from exceeding the power switch's I_{ACL} threshold. During active current-limit operation, V_{OUT} is also reduced by $I_{ACL} \times R_{DS(on)_{ACL}}$. This observed behavior is illustrated in the timing diagrams on Pages 9 and 10.

When a current-limit event is detected, the $\overline{\text{FAULT}}$ signal becomes asserted in approximately $T_{\overline{\text{FAULT}}_{LOW}}$ and the SLG59M1714V operates in constant current mode with the output current set by R_{SET} (see R_{SET} -Current Limit Table). The SLG59M1714V continues to operate in constant current mode indefinitely until a) the current-limit event has elapsed or b) the SLG59M1714V's internal thermal shutdown threshold is reached. When a current-limit event has elapsed or been removed, its $\overline{\text{FAULT}}$ signal will be deasserted after approximately $T_{\overline{\text{FAULT}}_{HIGH}}$.

Once thermal shutdown has been triggered, the IC's $\overline{\text{FAULT}}$ signal will remain asserted. As the die cools, the MOSFET will be turned back on when the die temperature falls to $\sim 100^\circ\text{C}$; in this case, the $\overline{\text{FAULT}}$ signal will be deasserted in approximately $T_{\overline{\text{FAULT}}_{HIGH}}$. If the current-limiting condition has not elapsed or been removed, die temperature will increase and the SLG59M1714V's thermal shutdown operation will repeat indefinitely.

2. Short Circuit Current Limiting Mode (with Thermal Shutdown Protection)

The SLG59M1714V's short-circuit current-limit monitor includes two operating modes depending upon the state of the IC's ON pin:

a) Before ON low-to-high transition

When the V_{OUT} voltage < 0.25 V (which is the case with a hard short, such as a solder bridge on the power rail), the power switch's internal Short-circuit Current Limit (SCL) monitor limits the FET current to approximately 500 mA (the I_{SCL} threshold). The SLG59M1714V's short-circuit current limit (SCL) protection scheme is disabled automatically once V_{OUT} rises above 0.3 V. While the internal Thermal Shutdown Protection circuit remains enabled and since the I_{SCL} threshold is much lower than the I_{ACL} threshold, thermal shutdown protection may become activated only at higher ambient temperatures.

b) After ON low-to-high transition

If a short-circuit or a very large load current transient occurs after an ON low-to-high transition, the SLG59M1714V's internal SCL circuit will be triggered if V_{OUT} falls by 0.2 V. The response time of this fast turn-off detection is ~ 1 μs .

SLG59M1714V FAULT Operation

As previously stated in the Pin Description section, the open-drain $\overline{\text{FAULT}}$ output is asserted when an active-current limit (ACL) or thermal shutdown fault condition is detected. This output becomes asserted in $T_{\overline{\text{FAULT}}_{LOW}}$ upon the detection of a fault condition and becomes deasserted $T_{\overline{\text{FAULT}}_{HIGH}}$ once the fault condition is removed. If the ON pin is toggled HIGH-to-LOW while the $\overline{\text{FAULT}}$ output is low, the $\overline{\text{FAULT}}$ output is deasserted without delay.

SLG59M1714V Reverse-blocking Operation

The SLG59M1714V's back-to-back FET configuration effectively blocks any reverse-current flow from VOUT to VIN when $V_{DD} = 0\text{ V}$ and switch OFF (ON = LOW). In this condition, leakage current from VOUT to VIN is less than $I_{REVERSE}$. In the event V_{DD} is active with ON = LOW, the SLG59M1714V's VOUT discharge circuit would be active; hence, there would also be a current path from VOUT to GND.

Setting the SLG59M1714V Output Current Limit with R_{SET}

The current-limit operation of the SLG59M1714V begins by choosing the appropriate $\pm 1\%$ -tolerance R_{SET} value for the application. The recommended range for R_{SET} is:

$$13.3\text{ k}\Omega \leq R_{SET} \leq 80\text{ k}\Omega$$

which corresponds to an output constant current limit in the following range:

$$1\text{ A} \leq I_{ACL} \leq 6\text{ A}$$

Table 1: Setting Current Limit Threshold vs. R_{SET}

Constant Current Limit	R_{SET}
1 A	80 k Ω
2 A	40 k Ω
4 A	20 k Ω
6 A	13.3 k Ω

Since the behavior of the SLG59M1714V's Current Limit – R_{SET} characteristic is approximately linear, an interpolation of the R_{SET} values shown applies for current-limit values in between those shown in Table 1.

Power Dissipation

The junction temperature of the SLG59M1714V depends on different factors such as board layout, ambient temperature, and other environmental factors. The primary contributor to the increase in the junction temperature of the SLG59M1714V is the power dissipation of its power MOSFET. Its power dissipation and the junction temperature in nominal operating mode can be calculated using the following equations:

$$PD = R_{DS_{ON}} \times I_{DS}^2$$

where:

PD = Power dissipation, in Watts (W)

$R_{DS_{ON}}$ = Power MOSFET ON resistance, in Ohms (Ω)

I_{DS} = Output current, in Amps (A)

and

$$T_J = PD \times \Theta_{JA} + T_A$$

Power Dissipation (continued)

where:

T_J = Junction temperature, in Celsius degrees ($^{\circ}\text{C}$)

Θ_{JA} = Package thermal resistance, in Celsius degrees per Watt ($^{\circ}\text{C}/\text{W}$)

T_A = Ambient temperature, in Celsius degrees ($^{\circ}\text{C}$)

During active current-limit operation, the SLG59M1714V's power dissipation can be calculated by taking into account the voltage drop across the power switch ($V_{IN} - V_{OUT}$) and the magnitude of the output current in active current-limit operation (I_{ACL}):

$$PD = (V_{IN} - V_{OUT}) \times I_{ACL} \text{ or}$$

$$PD = (V_{IN} - (R_{LOAD} \times I_{ACL})) \times I_{ACL}$$

where:

PD = Power dissipation, in Watts (W)

V_{IN} = Input Voltage, in Volts (V)

R_{LOAD} = Load Resistance, in Ohms (Ω)

I_{ACL} = Output limited current, in Amps (A)

$V_{OUT} = R_{LOAD} \times I_{ACL}$
