# LLC Resonance Power Transformer SRX Series

Conformity to RoHS Directive

## Development Concept

Compliant with worldwide safety standards, this is a small and thin transformer with the advantages of effective use of low-loss ferrite material.

### ■ MATERIAL

Optimized materials and core shapes have been developed. The necessary power can be transmitted with a small number of windings.

While optimizing materials, TDK has further improved its proprietary core shape to develop a new-type ECO core.

The transformer has been downsized considerably, and its temperature increase has also been curbed.

### ■ MANUFACTURING METHOD

Since the ECO Series supports automatic winding, the product is of a high quality and can be manufactured stably.

It is designed to support automatic winding, which enables a remarkable reduction in the loss generated to achieve a proficient in manual winding until stable production.

In addition, the characteristic variations of the winding wire and creepage tape have largely been removed, stabilizing the transformer's characteristics.

### ■ OPTIMIZATION DESIGN

Using design tools developed with TDK's comprehensive know-how, high-precision design has been achieved in a short period of time.

1) For optimization design and high-quality stable production, customers can use a specification request form.

If you provide the necessary information in the form, you will receive the optimization design in a short time.

2) TDK recommends design with a standard core gap (AL-value) for optimization and shorter trial and mass production lead time.

Design is simple as each shape retains its GAP, AL-value, and K parameters beforehand.

### ■ ENVIRONMENT

The SRX series is RoHS directive-compliant product.

- Ferrite cores, bobbins, cases, etc. are not sold individually.
- Conformity to RoHS Directive: This means that, in conformity with EU Directive 2002/95/EC, lead, cadmium, mercury, hexavalent chromium, and specific bromine-based flame retardants, PBB and PBDE, have not been used, except for exempted applications.
- All specifications are subject to change without notice.

# LLC Resonance Power Transformer

## SRX Series

Conformity to RoHS Directive

TDK now provides a characteristically thin resonance LLC resonance power transformer. In order to develop this transformer, TDK made effective use of low loss performance (which is a feature of the PC47 family), optimized the structure of the core and the bobbin, and utilized its proprietary automatic winding industrial method.

### FEATURES

- A low height (8 to 31.5mm in height) is achieved.
- Large power is achieved in a small shape.
- The automatic winding industrial method is adopted.
- It is a product conforming to RoHS directive.

### APPLICATIONS

AV equipment, digital consumer electronic

### PRODUCT IDENTIFICATION

## Design Reference for LLC Resonant Power Transformers

### LLC RESONANT CONVERTER

The LLC resonant converter features low noise and high efficiency and is a circuit system suitable for relatively large power requirements. The LLC resonant converter is of SRC (Series Resonant Converter) type.

SFM (Frequency modulation control) is generally used for control of the converter.

The converter is driven by a half bridge and, because the usage rate of the core is high, low-loss core materials are recommended for the downsizing of the converter.

In addition, because its input voltage range is narrower than that of a PWM-system power supply, it is recommended that PFC be used at the front stage to stabilize input voltage. Even when PFC is not used, increasing the ratio of resonance inductance to excitation inductance can stabilize input voltage to some extent. Under such circumstances, however, optimized design and efficiency will be difficult to achieve.

It therefore follows that there are difficulties facing global design of this system.

Figure 1 Basic circuit (1) (with a resonance inductor separated)

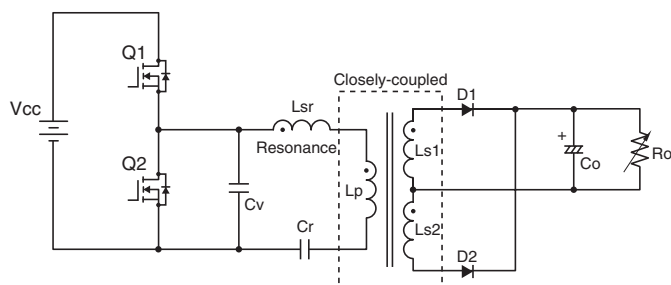

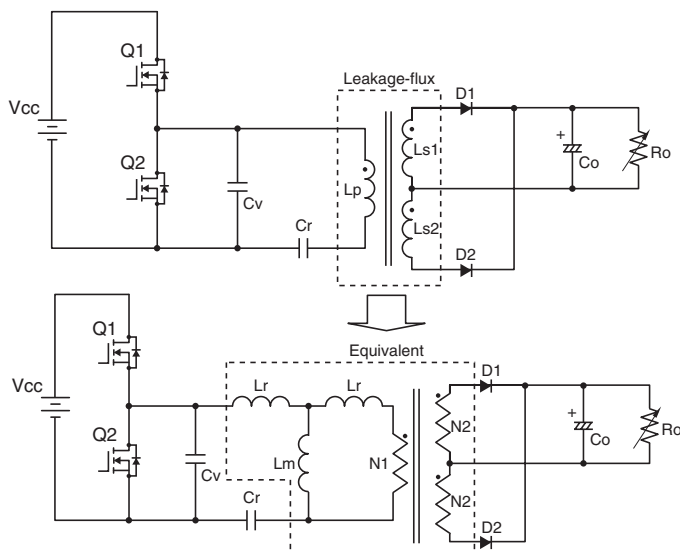

Figure 2 Basic circuit (2) (with a resonance inductor one type)

Here, the following equation applies:

$$L_p = L_r + L_m \quad L_r = (1 - k) \times L_p \\ L_m = k \times L_p$$

$L_p$ : Primary inductance

$L_m$ : Excitation inductance

$L_r$ : Leakage inductance

$k$ : Coupling coefficient

### LEAKAGE-FLUX TRANSFORMER FOR LLC POWER SUPPLY

This is a transformer in which leakage inductance has been intentionally increased and the value of the inductance has been standardized. Here, when the secondary side has completely short-circuited, the primary-side inductance is handled as resonance inductance  $LLK$ .

As a structure, the primary and secondary sides are separated from each other by a wall installed in the reel, which decreases the coupling. When the resonance inductance, primary inductance, and coupling coefficient are  $LLK$ ,  $L_p$ , and  $k$ , respectively, the equation shown below applies.  $LLK$  operates as a resonance inductor.

$$LLK = L_p \times (1 - k^2)$$

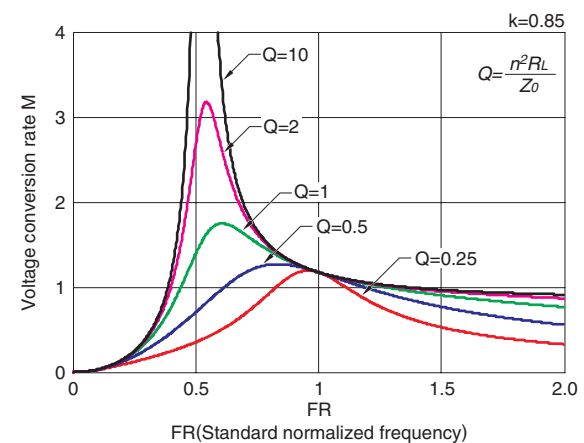

$L_p$  is  $AL$ -value  $\times N_p^2$ .  $AL$ -value is determined according to the core gap, and  $k$  is a parameter determined according to the core gap and a bobbin structure.

### ABOUT TRANSFORMER DESIGN

The stationary operation condition is set so that it is near to CRM (Critical Mode). However, it may be changed to some extent in relation to the input voltage range and output voltage.

Figure 3 shows the voltage conversion rate of a leakage-flux transformer-type LLC circuit, calculated with  $k$  being 0.85 according to a theoretical formula. Initially, FR (normalized frequency) is set so that it is near 1.

Figure 3 LLC resonant circuit normalized frequency characteristics

Here,  $Q$  shows the ratio of load resistance to characteristic impedance; in many cases, it is set in the range of about 0.5 to 1.5 at stationary loading.

When  $k$  is higher, the exciting current can be decreased further. Normally,  $k$  is set at about 0.8 to 0.95. However, when the input voltage range is wide, it is set lower, and when the range is narrow, it is set higher.

The figure below is an example of a transformer designed with the following conditions:  $V_{in}=390V$ ,  $V_o=24V$ ,  $I_o=8A$ , and stationary frequency=100kHz.

Shown below is a design example with the operation point near  $F_s$ .

Conditions:  $AL=410nH/n^2$   $k=0.906$

$V_{in}=390V$ ,  $V_o=24V$ ,  $V_F=0.65V$ ,  $I_o=8A$ ,  $F_s=100kHz$ ,  $Q=0.80$

1. The ratio of turns  $n$  is determined from input voltage  $V_{in}$  and output voltage  $V_o$ .

$$n = \frac{V_m}{2 \times k \times (V_o + V_f)} = \frac{390}{2 \times 0.906 \times 24.65} = 8.732$$

2. Calculation of characteristic impedance  $Z_o$

$$R_L = \frac{V_o}{I_o} = \frac{24}{8} = 3.0 \quad Z_o = \frac{n^2 \times R_L}{Q} = \frac{8.732^2 \times 3.0}{0.80} = 285.9 [\Omega]$$

3. Calculation of  $C_r$  (resonance capacity) and  $L_{LK}$  (resonance inductance)

$$Z_o = \frac{k}{1 - k^2} \sqrt{\frac{L_{LK}}{C_r}}$$

$$C_r = \frac{1}{2 \times \pi \times \frac{1 - k^2}{k} \times F_s \times Z_o} = \frac{1}{2 \times \pi \times 0.1978 \times 100000 \times 285.9} = 28.14 [\text{nF}]$$

$$L_{LK} = \left( \frac{1 - k^2}{k} \right)^2 \times Z_o^2 \times C_r = 0.1978^2 \times 285.9^2 \times 28.14 \times 10^{-9} = 90.0 [\mu\text{H}]$$

4. Calculation of transformer parameters

$$L_p = \frac{L_{LK}}{(1 - k^2)} = \frac{90.0}{(1 - 0.906^2)} = 502.3 [\mu\text{H}]$$

$$N_p = \sqrt{\frac{L_p}{A_L}} = \sqrt{\frac{502.3}{0.410}} = 35.0 [\text{Ts}]$$

$$N_s = \frac{N_p}{n} = \frac{35.0}{8.732} = 4.0 [\text{Ts}]$$

Repeating the above calculation several times will optimize each parameter. It is better for  $N_s$  with a smaller number of turns to be near an integer.

Design is complete when the flux, current, etc., calculated with this number of turns are within acceptable values. When they exceed the values, the frequency,  $Q$ , and transformer parameters ( $A_L$ -value and  $k$ ) need to be revised.

Figure 4 shows frequency characteristics illustrated graphically, based on the results of conditions set after the aforementioned calculation results have been further optimized.

Figure 4 Example of LLC resonant circuit frequency characteristics

## OPERATION POINT AND OPERATION WAVEFORM

The operation point and operation waveform are briefly explained here. Figure 5 shows frequency characteristics according to the conditions in Figure 4, above.  $Q=0.80$  and  $Q=20$  are characteristics at stationary loading and at light loading, respectively. In addition,  $F_s$  and  $F_{min}$  are calculated as 102.1kHz and 43.2kHz, respectively.

Figure 5 LLC resonant circuit operation point

When the operation point frequency is  $F_m$ , there are four modes available. Normally, the transformer is operated in modes other than the off-resonance mode. Unless any special request is made, the transformer is designed so that its stationary operation condition is near to Critical Mode. In addition, when  $F_m$  is larger than  $F_s$ , the control-limit voltage is reached, which causes the voltage not to decrease.

Figures 6a and 6b show examples of operation waveforms in each mode when a circuit simulator is used. When CRM is selected, the transformer

Figure 6a Operation waveforms in each mode

$F_m > F_s$ : Continuous Mode (CCM)      $F_m = F_s$ : Critical Mode (CRM)  
 $F_{min} < F_m < F_s$ : Continual Mode (DCM)      $F_m < F_{min}$ : Off-resonance mode

## CRM

Figure 6b Operation waveforms in each mode

**DCM****CCM****FLUX DENSITY AND CORE LOSS**

Because the transformer is a bridge-system circuit, the core is excited in two quadrants. Therefore, low-loss materials that decrease core loss are suitable for transformer downsizing. Shown below is a rough calculation formula of  $B_m$  of the LLC resonant converter. In addition, the variation width of  $B$  is twice this. Core loss needs to be evaluated with this  $\Delta B$ .

$$I_{PMAX} = \frac{V_o \times n}{4 \times k \times L_p \times F_s} \quad B_m = \frac{L_p \times I_{PMAX}}{N_p \times A_e}$$

$$\Delta B = 2 \times B_m$$

$V_o$ : Output voltage  
 $n$ : Ratio of turns  
 $k$ : Coupling coefficient  
 $L_p$ : Primary inductance  
 $N_p$ : Primary number of turns  
 $A_e$ : Effective cross-sectional area  
 $F_s$ : Resonance frequency

Figure 7 shows core loss temperature characteristics in common power ferrite materials and TDK's low-loss materials represented by PC47.

In an environment where the temperature of a core is 80°C or greater, low-loss materials have achieved a low loss of 20% compared with common materials, which contributes to the set's temperature decrease and downsizing.

Figure 7 Example of core loss temperature characteristics

**PRECAUTIONS****About Multi-output Transformers**

In design, the number of turns on the secondary side may be small. Even in such cases, multi-output is possible, but it is difficult when voltage does not correspond with the ratio of turns on the secondary side.

For example, when this winding has been optimally designed with 4Ts at  $V_o=24V$ , note that the second output can have only  $24/4=6V$ -step voltage.

**Narrower Input Voltage Range Compared with the PWM System**

As described earlier, the operation-enabling input voltage range is narrow in principle; therefore, it is recommended that a circuit that improves the input range of PFC, etc., be installed at the front stage of the LLC resonant converter.

**About Multi-transformer Configuration**

When one transformer cannot attain the necessary power because of shape restriction, etc., combining multiple same-shape transformers enables the required power to be obtained. Contact us for more details on transformer design methods that correspond with each wire connection.

**About the Influence of Leakage Flux**

There are often problems with thin resonant transformers. When the transformer has a structure in which metal plates, etc., are arranged close to each other on the upper and lower sides during operation, leakage flux generated from the transformer crosses through the metal and overcurrent loss occurs as a result. This in turn may cause the metal plate or the transformer to generate heat.
