STV7710

Vaccum fluorescent display (VFD) driver

Features

- 96 outputs VFD driver
- 90 V absolute maximum supply
- 3.3V/5V compatible logic
- -40/30mA source/sink output MOS
- -50/50mA source/sink output diode
- 1-bit data bus (40 MHz)
- BCD process
- Packaging: die form

Description

STV7710 is a driver for vacuum fluorescent display (VFD) designed in the ST proprietary BCD high voltage technology. Using a 1 bit wide data bus, it can control 96 high current & high voltage outputs. The STV7710 is supplied with a separated 70V power output supply. All command inputs are CMOS and 3.3V logic levels compatible.

4.3 Description

STV7710 includes all the logic and power circuits necessary to drive electrodes of a vacuum fluorescent display (VFD). Binary values of each pixel of the displayed line are loaded into the shift register DATA_A/B data bus. Data is shifted at each low to high transition of the *CLK* clock. After 96 shifts, the data is available at the output of the shift register. This output can be used to cascade several Ics to drive higher resolution displays.

The forward /reverse (F/$\overline{R}$) input is used to select the direction of the shift register. Data input/output status is set according to the selected direction (refer to *Table 6*).

The maximum frequency of the shift clock is 40MHz.

When the STB signal is high, data are transferred from the shift register to the latch and power output stages.

All the output data are kept memorized and held in the latch stage when the latch input STB is set at low level.

Vsssub and Vsslog must be connected as close as possible to the logical reference ground of the application. Also, make sure that TEST input pin is connected to ground (*Figure 8*).

STV7710 is supplied with a 5 V power supply. All the logic inputs can be driven either by 5 V CMOS logic, or by 3.3 V CMOS logic.
