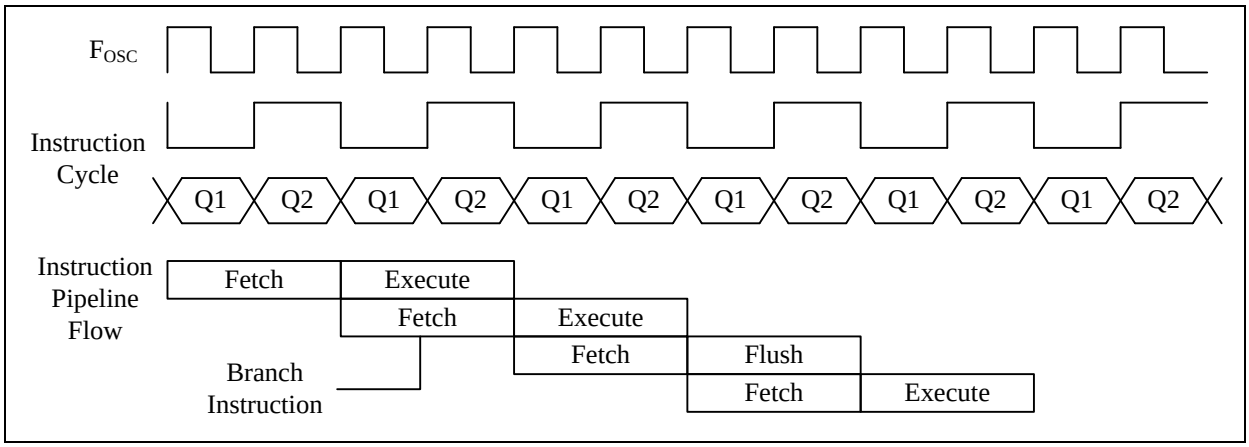
FUNCTIONAL DESCRIPTION

1. CPU Core

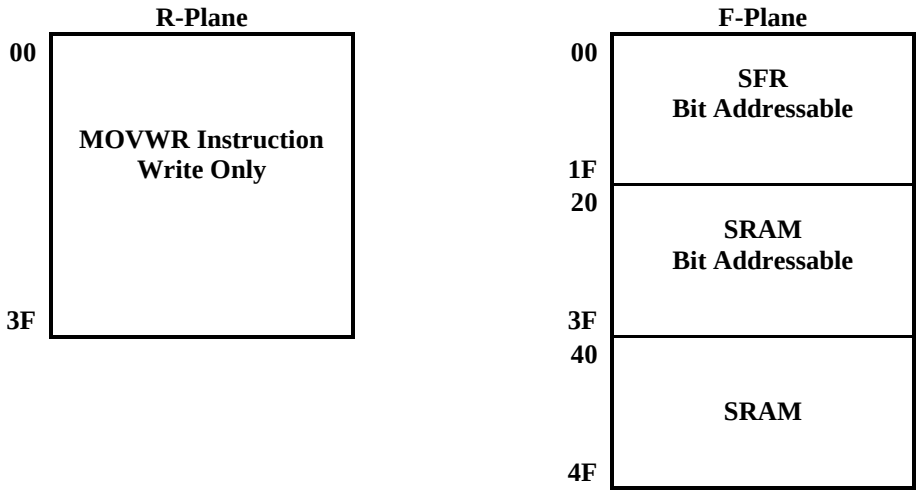
1.1 Clock Scheme and Instruction Cycle

The system clock is internally divided by two to generate Q1 state and Q2 state for each instruction cycle. The Programming Counter (PC) is updated at Q1 and the instruction is fetched from program ROM and latched into the instruction register in Q2. It is then decoded and executed during the following Q1-Q2 cycle. Branch instructions take two cycles since the fetch instruction is 'flushed' from the pipeline, while the new instruction is being fetched and then executed.



1.2 Addressing Mode

There are two Data Memory Planes in CPU, R-Plane and F-Plane. The registers in R-Plane are write-only. The "MOVWR" instruction copies the W-register's content to R-Plane registers by direct addressing mode. The lower locations of F-Plane are reserved for the SFR. Above the SFR is General Purpose Data Memory, implemented as static RAM. F-Plane can be addressed directly or indirectly. Indirect Addressing is made by INDF register. The INDF register is not a physical register. Addressing INDF actually addresses the register whose address is contained in the FSR register (FSR is a pointer). The first half of F-Plane is bit-addressable, while the second half of F-Plane is not bit-addressable.



1.3 Programming Counter (PC) and Stack

The Programming Counter is 10-bit wide capable of addressing a 1K x 14 OTP ROM. As a program instruction is executed, the PC will contain the address of the next program instruction to be executed. The PC value is normally increased by one except the followings. The Reset Vector (000h) and the Interrupt Vector (001h) are provided for PC initialization and Interrupt. For CALL/GOTO instructions, PC loads 10 bits address from instruction word. For RET/RETI/RETLW instructions, PC retrieves its content from the top level STACK. For the other instructions updating PC [7:0], the PC [9:8] keeps unchanged. The STACK is 10-bit wide and 5-level in depth. The CALL instruction and hardware interrupt will push STACK level in order. While the RET/RETI/RETLW instruction pops the STACK level in order.

1.4 ALU and Working (W) Register

The ALU is 8-bit wide and capable of addition, subtraction, shift and logical operations. In two-operand instructions, typically one operand is the W register, which is an 8-bit non-addressable register used for ALU operations. The other operand is either a file register or an immediate constant. In single operand instructions, the operand is either W register or a file register. Depending on the instruction executed, the ALU may affect the values of Carry (C), Digit Carry (DC), and Zero (Z) Flags in the STATUS register. The C and DC flags operate as a /Borrow and /Digit Borrow, respectively, in subtraction.

Note: /Borrow represents inverted of Borrow register.

/Digit Borrow represents inverted of Digit Borrow register.

1.5 STATUS Register

This register contains the arithmetic status of ALU and the reset status. The STATUS register can be the destination for any instruction, as with any other register. If the STATUS register is the destination for an instruction that affects the Z, DC or C bits, then the write to these three bits is disabled. These bits are set or cleared according to the device logic. It is recommended, therefore, that only BCF, BSF and MOVWF instructions are used to alter the STATUS register because these instructions do not affect those bits.

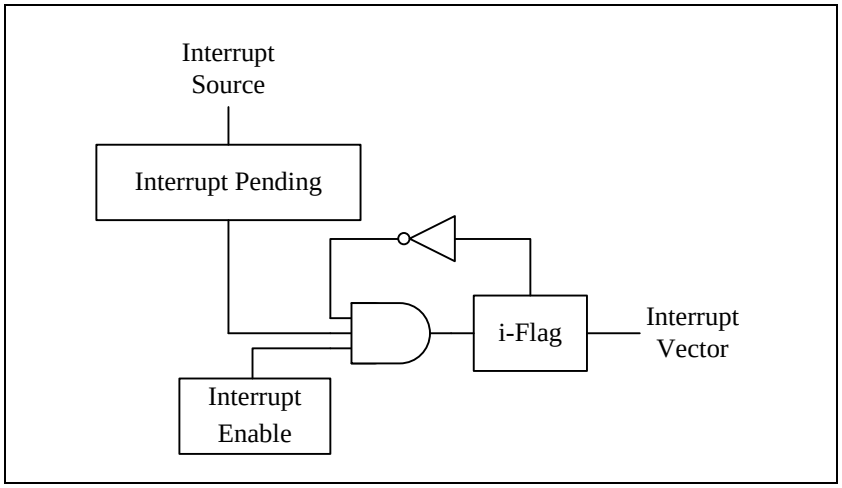
1.6 Interrupt

The TM57PE11A has 1 level, 1 vector and 4 interrupt sources. Each interrupt source has its own enable control bit. An interrupt event will set its individual pending flag; no matter its interrupt enable control bit is 0 or 1. Because TM57PE11A has only 1 vector, there is not an interrupt priority register. The interrupt priority is determined by F/W.

If the corresponding interrupt enable bit has been set (INTE), it would trigger CPU to service the interrupt. CPU accepts interrupt in the end of current executed instruction cycle. In the mean while, A "CALL 001" instruction is inserted to CPU, and i-flag is set to prevent recursive interrupt nesting.

The i-flag is cleared in the instruction after the "RETI" instruction. That is, at least one instruction in main program is executed before service the pending interrupt. The interrupt event is level triggered. F/W must clear the interrupt event register while serving the interrupt routine.



2. Chip Operation Mode

2.1 Reset

The TM57PE11A can be RESET in four ways.

- Power-On-Reset
- Low Voltage Reset (LVR)
- External Pin Reset (PA7)
- Watchdog Reset (WDT)

After Power-On-Reset, all system and peripheral control registers are then set to their default hardware Reset values. The clock source, LVR level and chip operation mode are selected by the SYSCFG register value. The Low Voltage Reset features static reset when supply voltage is below a threshold level. There are two threshold levels can be selected. The LVR's operation mode is defined by the SYSCFG register.

There are two voltage selections for the LVR threshold level, one is higher level which is suitable for application with VDD is more than 3.3V, while another one is suitable for application with VDD is less than 3.3V. See the following LVR Selection Table; user must also consider the lowest operating voltage of operating frequency.

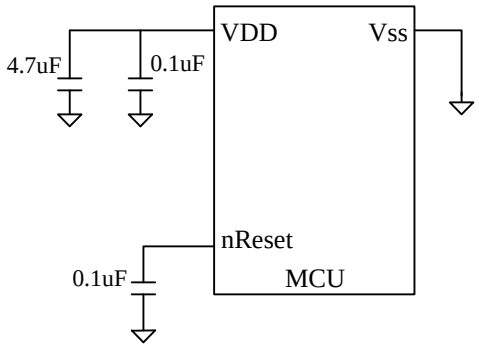
LVR Selection Table:

LVR Threshold Level	Consider the operating voltage to choose LVR
LVR2.9	5.5V > V_{DD} > 3.3V
LVR2.0	V_{DD} is wide voltage range

The External Pin Reset and Watchdog Reset can be disabled or enabled by the SYSCFG register. These two resets also set all the control registers to their default reset value. The TO/PD flag is not affected by these resets.

2.2 External Reset Circuit

External reset pin is low level active. The system is running when reset pin is high level voltage input. The reset pin receives the low voltage and the system is reset. The external reset can reset the system during power on duration, and good external reset circuit can protect the system to avoid working at unusual power condition.



2.3 System Configuration Register (SYSCFG)

The System Configuration Register (SYSCFG) is located at ROM address 3FCh. The SYSCFG determines the option for initial condition of MCU. It is written by PROM Writer only. User can select clock source, LVR threshold voltage and chip operation mode by SYSCFG register. The default value of SYSCFG is 3FFFh. The 13th bit of SYSCFG is code protection selection bit. If this bit is 0, the data in PROM will be protected, when user reads PROM.

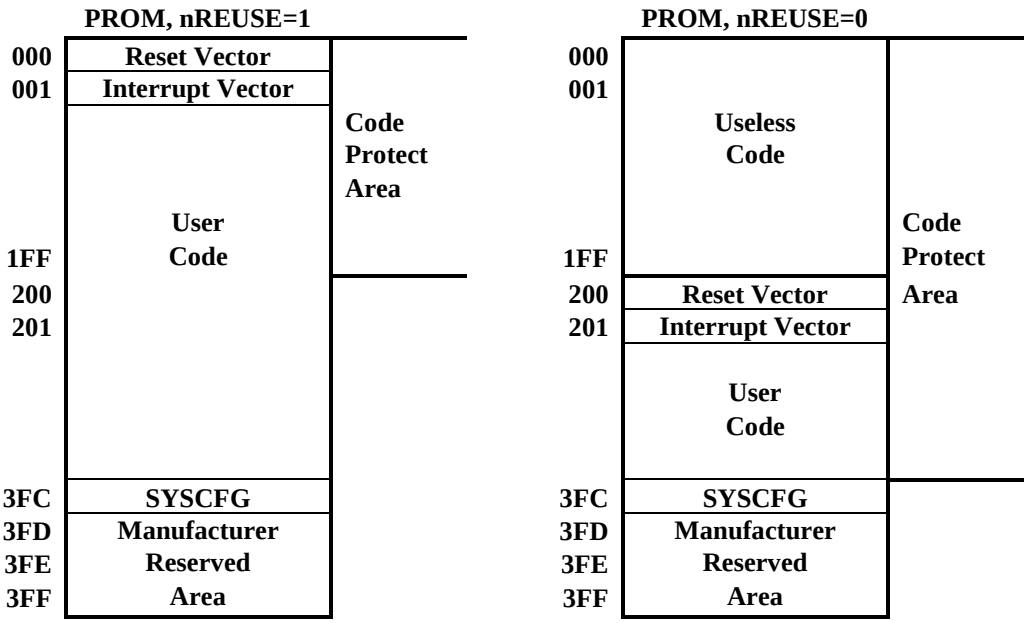
2.4 PROM Re-use ROM

The PROM of this device is 1K words. For some F/W program, the program size could be less than 512 words. To fully utilize the PROM, the device allows users to reuse the PROM. This feature is named as Two Time Programmable (TTP) ROM. While the first half of PROM is occupied by a useless program code and the second half of the PROM remains blank, users can re-write the PROM with the updated program code into the second half of the PROM. In the Re-use mode, the Reset Vector and Interrupt Vector are re-allocated at the beginning of the PROM's second half by the Assembly Compiler. Users simply choose the "REUSE" option in the ICE tool interface, and then the Compiler will move the object code to proper location. That is, the user's program still has reset vector at address 000h, but the compiled object code has reset vector at 200h. In the SYSCFG, if nPROTECT=0 and nREUSE=1, the Code protection area is first half of PROM. This allows the Writer tool to write then verify the Code during the Re-use Code programming. After the Re-use Code being written into the PROM's second half, user should write "nREUSE" control bit to "0". In the mean while, the Code protection area becomes the whole PROM except the Reserved Area.



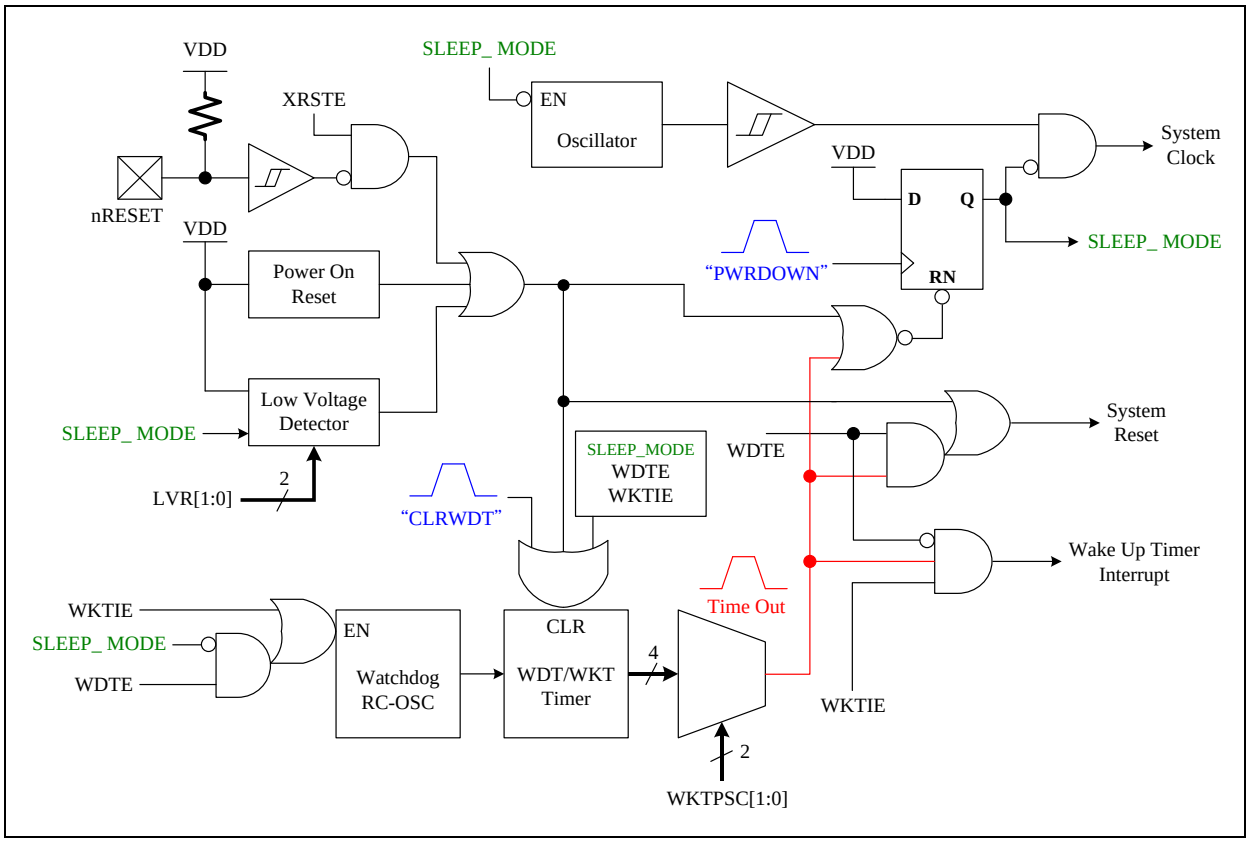
2.5 Power-Down Mode

The Power-down mode is activated by SLEEP instruction. During the Power-down mode, the system clock and peripherals stops to minimize power consumption, while the WDT/WKT Timer is working or not depends on F/W setting. The Power down mode can be terminated by Reset, or enabled Interrupts (External pins and WKT interrupts).

3. Peripheral Functional Block

3.1 Watchdog (WDT) / Wakeup (WKT) Timer

The WDT and WKT share the same internal RC Timer. The overflow period of WDT/WKT can be selected from 13 ms to 131 ms. The WDT/WKT is cleared by the CLRWDT instruction. If the Watchdog Reset is enabled (WDTE=1), the WDT generates the chip reset signal, otherwise, the WKT only generates overflow time out interrupt. The WDT/WKT works in both normal mode and sleep mode. During sleep mode, user can further choose to enable or disable the WDT/WKT by "WKTIE". If WKTIE=0 in sleep mode (no matter WDTE is 1 or 0), the internal RC Timer stops for power saving. In other words, user keeps the WDT/WKT alive in Sleep Mode by setting WKTIE=1. If the WDTE=1 and WKTIE=0, WDT/WKT timer will be cleared and stopped to power saving in sleep mode. If the WDTE=1 and WKTIE=1, WDT/WKT timer keeps counting in sleep/normal mode. Refer to the following table and figure.

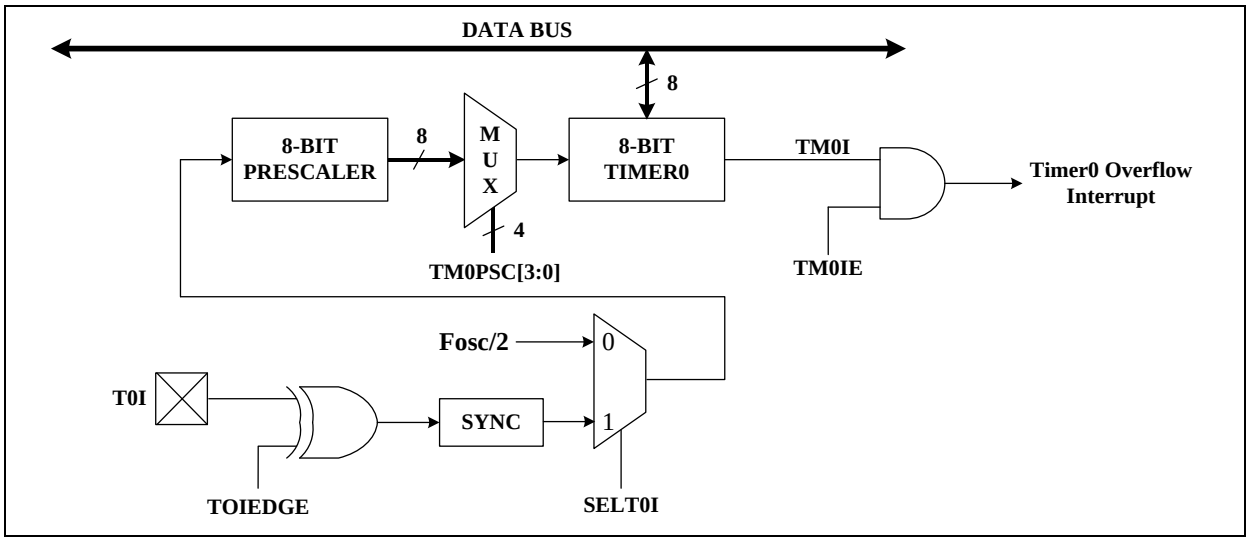


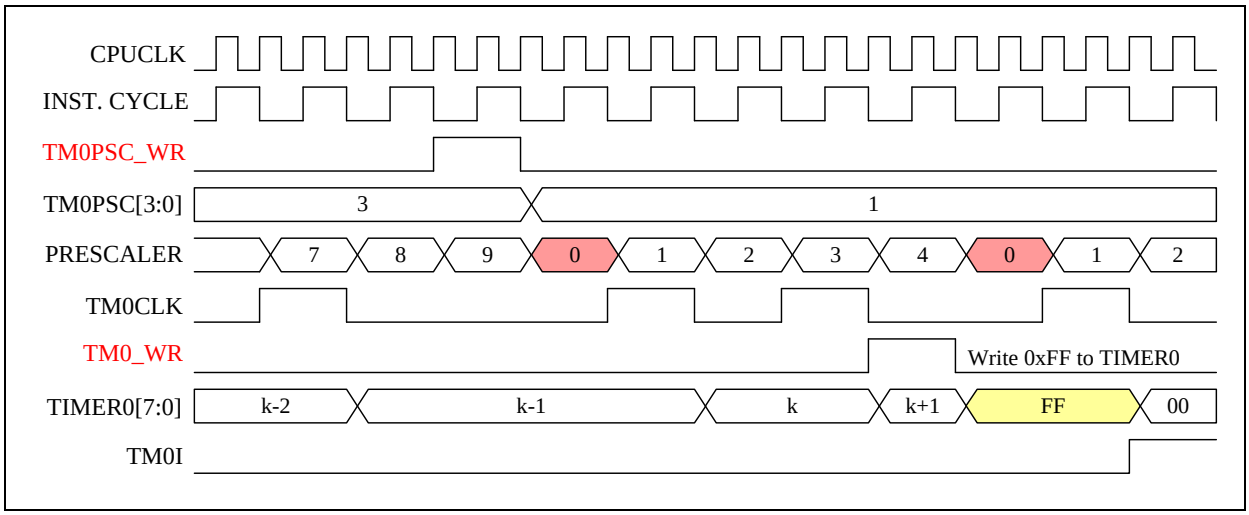
If the user program needs the MCU totally shut down for power conservation in sleep mode, the below setting of control bits should be followed.

Mode	WDTE	WKTIE	Watchdog RC Oscillator
Normal Mode	0	0	Stop
	0	1	Run
	1	0	
	1	1	
Sleep Mode	0	0	Stop
	0	1	Run
	1	0	Stop
	1	1	Run

3.2 Timer0: 8-bit Timer/Counter with Pre-scale (PSC)

The Timer0 is an 8-bit wide register of F-Plane. It can be read or written as any other register of F-Plane. Besides, Timer0 increases itself periodically and automatically rolls over based on the pre-scaled clock source, which can be the instruction cycle or T0I input. The Timer0 increase rate is determined by "Timer0 Pre-Scale" (TM0PSC) register in R-Plane. The Timer0 can generate interrupt flag (TM0I) when it rolls over.





Timer0 interrupt frequency by instruction cycle: (Fosc / 2) / div / 256

Note: The div variable represents the prescale factor by TM0PSC [3:0] select value (1, 2, ~ 128, 256)

When Fosc = 4 MHz, div = TM0PSC [3:0] when select 4'b0000 = 1

(4M/2)/1/256 = 2 M/256 Hz = 7.8125 KHz

Timer0 interrupt frequency by T0I: (T0I) / div / 256

Note: T0I frequency <= Fosc / 4

3.3 System Clock Oscillator

System clock can be operated in two different oscillation modes, which is selected by setting the CLKS in the SYSCFG register. In external RC mode, the external resistor and capacitor determine the oscillation frequency. In the internal RC mode, the on chip oscillator generates 4/8 MHz system clock. When the IRC is 8 MHz, the LVR can only be set to 2.9V (cannot use 2V). In this mode, PCB Layout may have strong effect on the stability of Internal Clock Oscillator. Since power noise degrades the performance of Internal Clock Oscillator, placing power supply bypass capacitors 1 uF and 0.1 uF very close to VDD/VSS pins improves the stability of clock and the overall system.

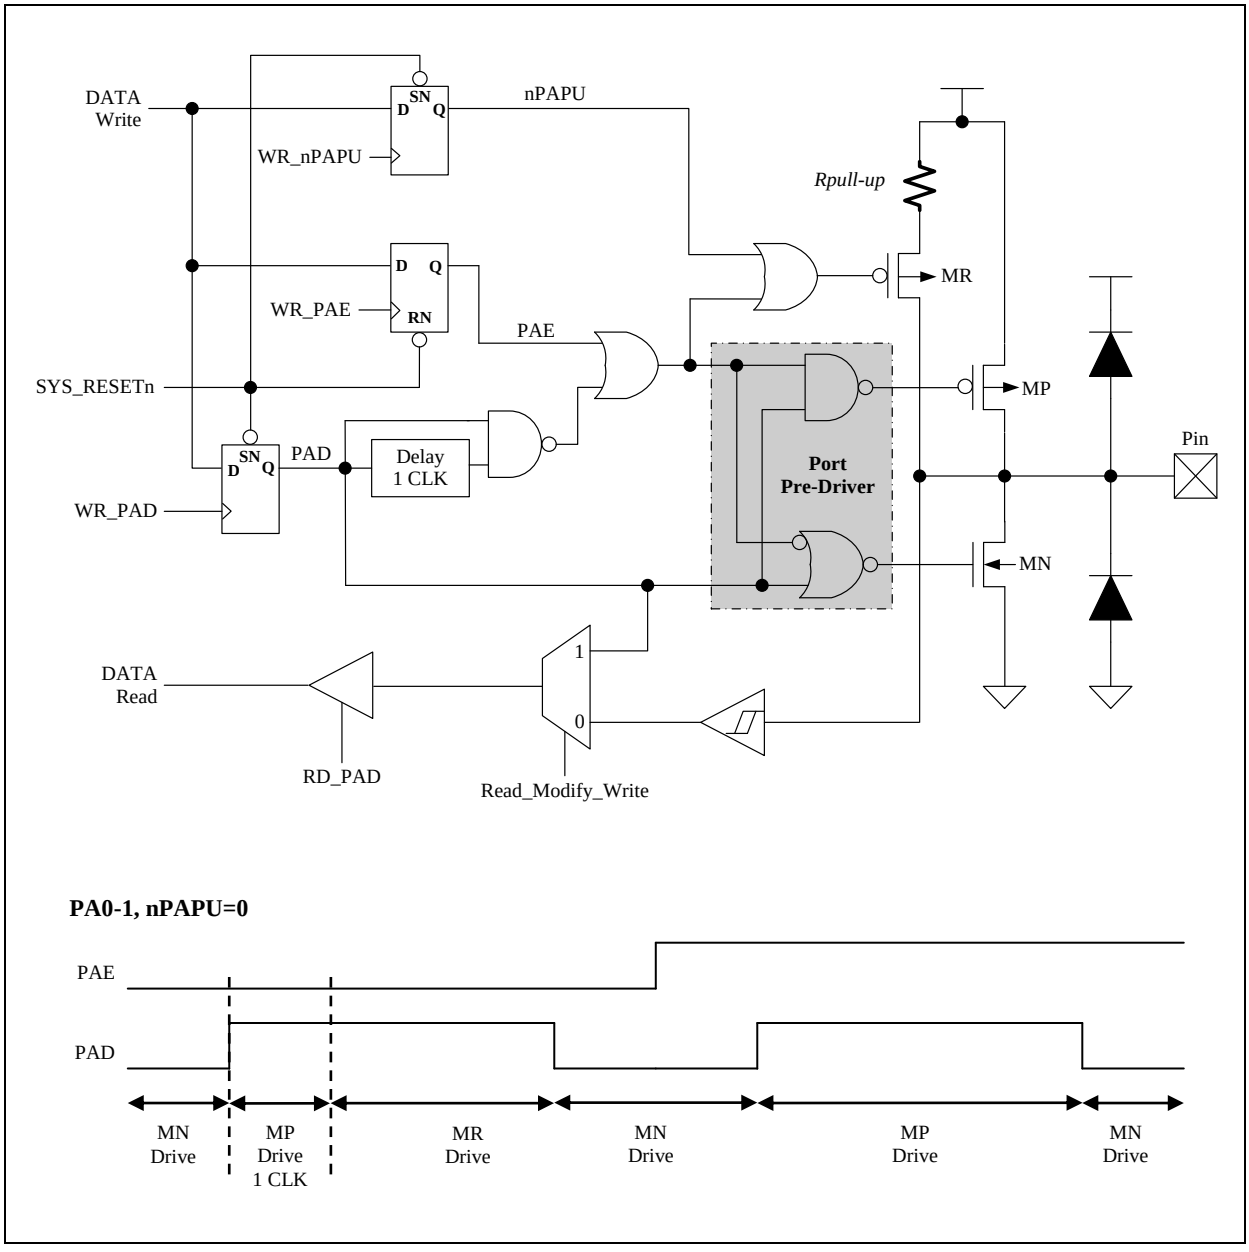
4. I/O Port

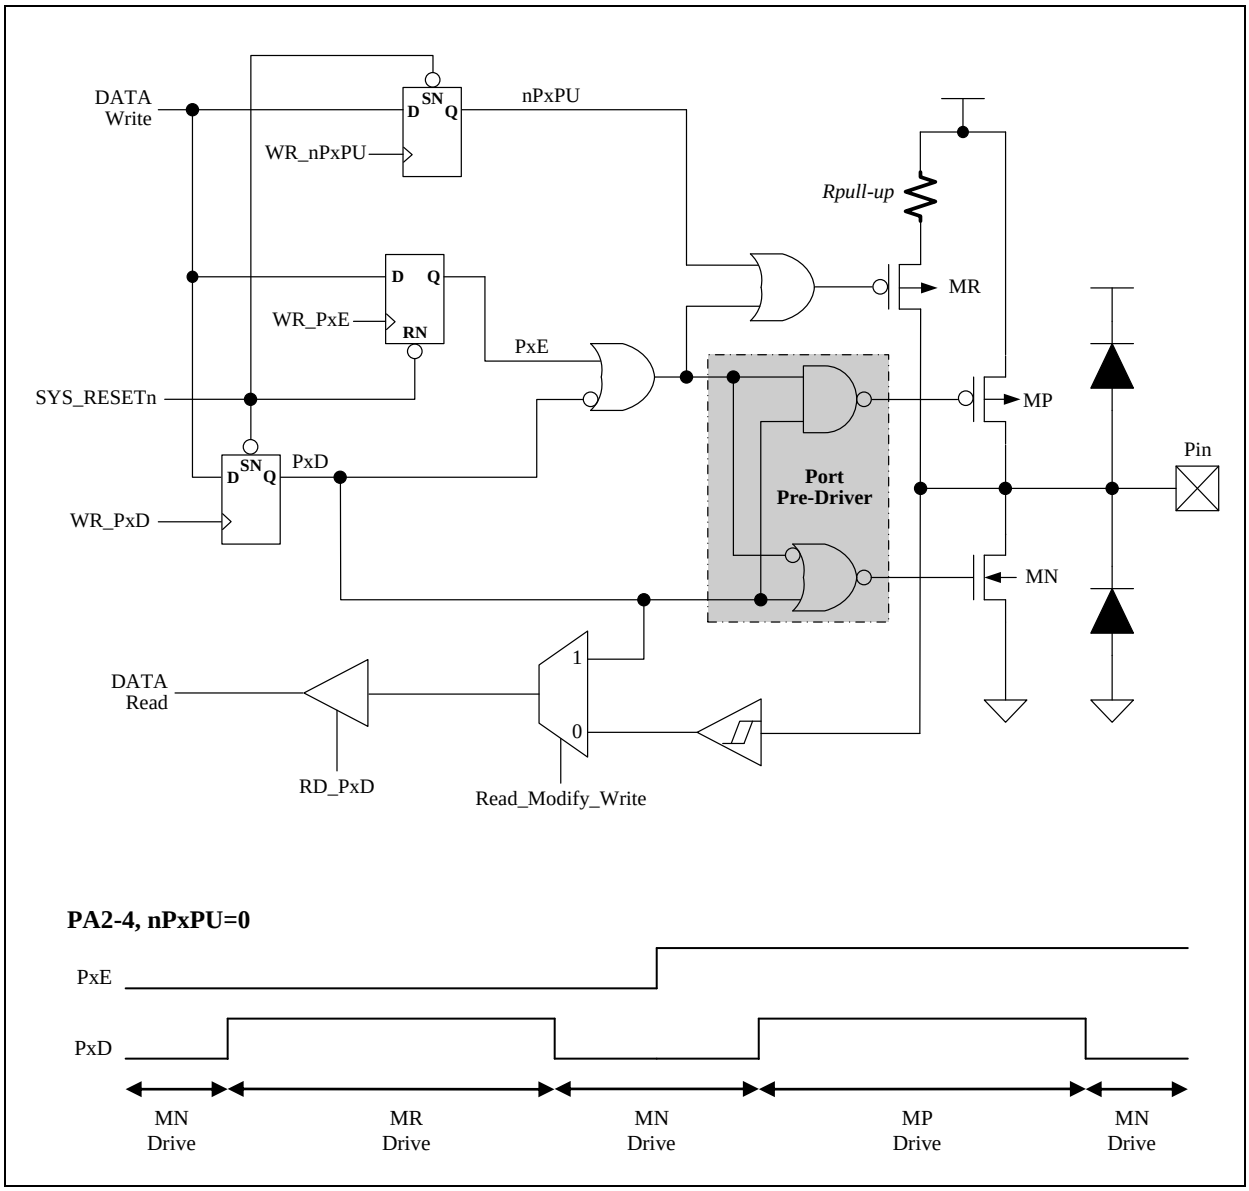
4.1 PA0-1

These pins can be used as Schmitt-trigger input, CMOS push-pull output or "pseudo-open-drain" output. The pull-up resistor is assignable to each pin by S/W setting. To use the pin in Schmitt-trigger input mode, S/W needs to set the PAE=0 and PAD=1. To use the pin in pseudo-open-drain mode, S/W sets the PAE=0.The benefit of pseudo-open-drain structure is that the output rise time can be much faster than pure open-drain structure. S/W sets PAE=1 to use the pin in CMOS push-pull output mode. Reading the pin data (PAD) has different meaning. In "Read-Modify-Write" instruction, CPU actually reads the output data register. In the others instructions, CPU reads the pin state. The so-called "Read-Modify-Write" instruction includes BSF, BCF and all instructions using F-Plane as destination.



4.2 PA2-4

These pins are almost the same as PA0-1, except they do not support pseudo-open-drain mode. They can be used in pure open-drain mode, instead.



4.3 PA7

PA7 can be only used in Schmitt-trigger input mode. The pull-up resistor is always connected to this pin.

INSTRUCTION SET

Each instruction is a 14-bit word divided into an Op Code, which specifies the instruction type, and one or more operands, which further specify the operation of the instruction. The instructions can be categorized as byte-oriented, bit-oriented and literal operations list in the following table.

For byte-oriented instructions, “f” or “r” represents the address designator and “d” represents the destination designator. The address designator is used to specify which address in Program memory is used by the instruction. The destination designator specifies where the result of the operation is placed. If “d” is “0”, the result is placed in the W register. If “d” is “1”, the result is placed in the address specified in the instruction.

For bit-oriented instructions, “b” represents a bit field designator, which selects the number of the bit affected by the operation, while “f” represents the address designator. For literal operations, “k” represents the literal or constant value.
