Semiconductor Company

Preface

Thank you very much for making use of Toshiba microcomputer LSIs.
Before use this LSI, refer the section, "Points of Note and Restrictions".

CMOS 32-bit Micro-controller

TMP92CM27FG

1. Outline and Device Characteristics

TMP92CM27 is high-speed advanced 32-bit micro-controller developed for controlling equipment which processes mass data.

TMP92CM27 is a micro-controller which has a high-performance CPU (TLCS-900/H1 CPU) and various built-in I/Os.

TMP92CM27FG is housed in a 144-pin flat package.

Device characteristics are as follows:

(1) CPU : 32-bit CPU(TLCS-900/H1 CPU)

- Compatible with TLCS-900/L1 instruction code
- 16Mbytes of linear address space
- General-purpose register and register banks
- Micro DMA : 8channels (250ns/4bytes at $f_c = 40\text{MHz}$, best case)

(2) Minimum instruction execution time : 50ns(at $f_c=40\text{MHz}$)

(3) Internal memory

- Internal RAM : 32K-byte (32-bit 1 clock access and program execution are possible)
- Internal ROM : None

(4) External memory expansion

- Expandable up to 16M bytes (shared program/data area)
- Can simultaneously support 8/16-bit width external data bus
... Dynamic data bus sizing
- Separate bus system

(5) Memory controller

- Chip select output : 6 channels

030619EBP1

- The information contained herein is subject to change without notice.
- The information contained herein is presented only as a guide for the applications of our products. No responsibility is assumed by TOSHIBA for any infringements of patents or other rights of the third parties which may result from its use. No license is granted by implication or otherwise under any patent or patent rights of TOSHIBA or others.
- TOSHIBA is continually working to improve the quality and reliability of its products. Nevertheless, semiconductor devices in general can malfunction or fail due to their inherent electrical sensitivity and vulnerability to physical stress. It is the responsibility of the buyer, when utilizing TOSHIBA products, to comply with the standards of safety in making a safe design for the entire system, and to avoid situations in which a malfunction or failure of such TOSHIBA products could cause loss of human life, bodily injury or damage to property.
In developing your designs, please ensure that TOSHIBA products are used within specified operating ranges as set forth in the most recent TOSHIBA products specifications. Also, please keep in mind the precautions and conditions set forth in the "Handling Guide for Semiconductor Devices," or "TOSHIBA Semiconductor Reliability Handbook" etc.
- The TOSHIBA products listed in this document are intended for usage in general electronics applications (computer, personal equipment, office equipment, measuring equipment, industrial robotics, domestic appliances, etc.). These TOSHIBA products are neither intended nor warranted for usage in equipment that requires extraordinarily high quality and/or reliability or a malfunction or failure of which may cause loss of human life or bodily injury ("Unintended Usage"). Unintended Usage include atomic energy control instruments, airplane or spaceship instruments, transportation instruments, traffic signal instruments, combustion control instruments, medical instruments, all types of safety devices, etc.. Unintended Usage of TOSHIBA products listed in this document shall be made at the customer's own risk.
- The products described in this document are subject to the foreign exchange and foreign trade laws.
- TOSHIBA products should not be embedded to the downstream products which are prohibited to be produced and sold, under any law and regulations.
- For a discussion of how the reliability of microcontrollers can be predicted, please refer to Section 1.3 of the chapter entitled Quality and Reliability Assurance/Handling Precautions.

Purchase of TOSHIBA I²C components conveys a license under the Philips I²C Patent Rights to use these components in an I²C system, provided that the system conforms to the I²C Standard Specification as defined by Philips.

- (6) 8-bit timers : 8 channels
- (7) 16-bit timers : 6 channels
- (8) Pattern generator : 2 channels
- (9) General-purpose serial interface : 4 channels
 - UART/Synchronous mode : 4 channels (ch.0 to ch.3)
 - IrDA Ver.1.0(115kbps) mode selectable : 1 channels (ch.0)
- (10) Serial bus interface : 2 channels
 - I²C bus mode/clock synchronous mode selectable
- (11) High Speed serial interface : 2 channels
- (12) SDRAM controller : 1 channels
 - Supported 16M, 64M-bit SDR (Single Data Rate)-SDRAM
 - Supported not only operate as RAM and Data for LCD display but also programming directly from SDRAM
- (13) 10-bit AD converter : 12 channels
- (14) 8-bit DA converter : 2 channels
- (15) Watchdog timer
- (16) Key-on wake up (only for HALT release) : 8 channels
- (17) Interrupts : 71 interrupts
 - 9 CPU interrupts : Software interrupt instruction and illegal instruction
 - 49 internal interrupts : Seven selectable priority levels
 - 13 external interrupts(INT0 to INTB, $\overline{\text{NMI}}$) : Seven selectable priority levels (INT0 to INTB)
(INT0 to INTB are selectable edge or level interrupt)
- (18) External bus release function
- (19) Input/output ports : 83 pins
- (20) Stand-by function
 - Three Halt modes : Idle2 (programmable), Idle1, Stop
- (21) Clock controller
 - Clock doubler (PLL) : $f_c = f_{\text{OSCH}} \times 4$ ($f_c=40\text{MHz}$ @ $f_{\text{OSCH}}=10\text{MHz}$)
 - Clock gear function : Select a High-frequency clock f_c to $f_c/16$
- (22) Operating voltage
 - VCC = 3.0 V to 3.6 V (f_c max = 40MHz)
- (23) Package
 - 144 pin QFP : P-LQFP144-1616-0.40C

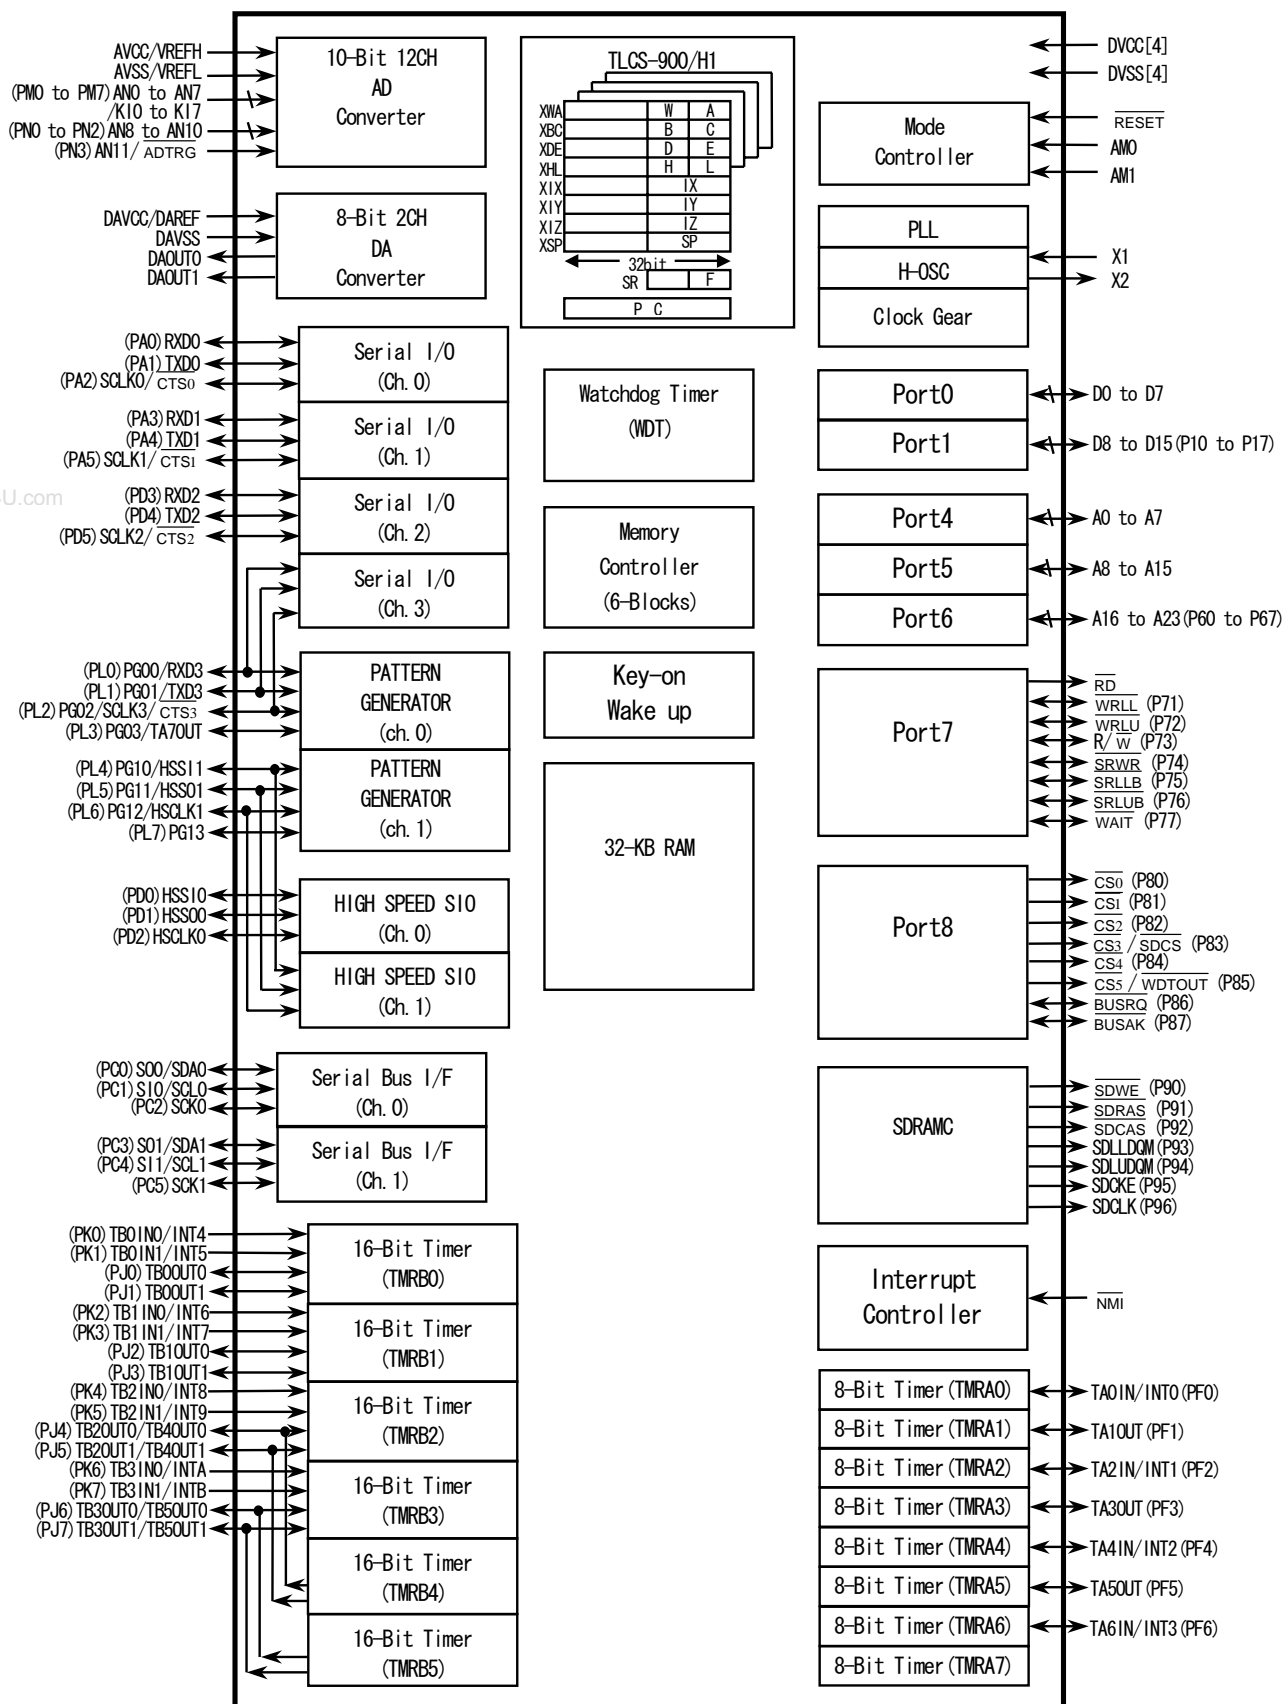

Figure 1.1 TMP92CM27 block diagram

2.2 Pin names and functions

The following table shows the names and functions of the input/output pins

Table 2.2.1 Pin names and functions (1/5)

Pin name	Number of Pin	I/O	Function
D0 to D7	8	I/O	Data: Data bus D0 to D7
P10 to P17	8	I/O	Port 1: I/O port Input or output specifiable in units of bits
D8 to D15		I/O	Data: Data bus D8 to D15
A0 to A7	8	Output	Address: Address bus A0 to A7
A8 to A15	8	Output	Address: Address bus A8 to A15
P60 to P67	8	I/O	Port 6: I/O port
A16 to A23		Output	Address: Address bus A16 to A23
\overline{RD}	1	Output	Read: Outputs strobe signal for read external memory (with pull-up register)
P71	1	I/O	Port 71: I/O port (Schmitt input, with pull-up register)
\overline{WRLL}		Output	Write: Output strobe signal for writing data on pins D0 to D7
P72	1	I/O	Port 72: I/O port (schmitt input, with pull-up register)
\overline{WRLU}		Output	Write: Output strobe signal for writing data on pins D8 to D15
P73	1	I/O	Port 73: I/O port (schmitt input)
R/\overline{W}		Output	Read/Write: 1 represents read or dummy cycle; 0 represents write cycle
P74	1	I/O	Port 74: I/O port (Schmitt input, with pull-up register)
\overline{SRWR}		Output	Write enable for SRAM: Strobe signal for writing data
P75	1	I/O	Port 75: I/O port (Schmitt input, with pull-up register)
\overline{SRLLB}		Output	Data enable for SRAM on pins D0 to D7
P76	1	I/O	Port 76: I/O port (Schmitt input, with pull-up register)
\overline{SRLUB}		Output	Data enable for SRAM on pins D8 to D15
P77	1	I/O	Port 77: I/O port (Schmitt input)
\overline{WAIT}		Input	Wait: Signal used to request CPU bus wait
P80	1	Output	Port 80: Output port
$\overline{CS0}$		Output	Chip select 0: Outputs "Low" when address is within specified address area
P81	1	Output	Port 81: Output port
$\overline{CS1}$		Output	Chip select 1: Outputs "Low" when address is within specified address area
P82	1	Output	Port 82: Output port
$\overline{CS2}$		Output	Chip select 2: Outputs "Low" when address is within specified address area
P83	1	Output	Port 83: Output port
$\overline{CS3}$		Output	Chip select 3: Outputs "Low" when address is within specified address area
\overline{SDCS}		Output	Chip select for SDRAM: Outputs "Low" when address is within SDRAM address area
P84	1	Output	Port 84: Output port
$\overline{CS4}$		Output	Chip select 4: Outputs "Low" when address is within specified address area
P85	1	Output	Port 85: Output port
$\overline{CS5}$		Output	Chip select 5: Outputs "Low" when address is within specified address area
\overline{WDTOUT}		Output	Watchdog timer output pin
P86	1	I/O	Port 86: I/O port (Schmitt input)
\overline{BUSRQ}		Input	Bus request: request pin that set external memory bus to high-impedance (for External DMAC)
P87	1	I/O	Port 87: I/O port (Schmitt input)
\overline{BUSAk}		Output	Bus acknowledge: this pin show that external memory bus pin is set to high-impedance by receiving \overline{BUSRQ} (for External DMAC)

Table 2.2.2 Pin names and functions (2/5)

Pin name	Number of Pin	I/O	Function
P90 SDWE	1	Output Output	Port 90: Output port Write enable for SDRAM
P91 SDRAS	1	Output Output	Port 91: Output port Row address strobe for SDRAM
P92 SDCAS	1	Output Output	Port 92: Output port Column address strobe for SDRAM
P93 SDLLDQM	1	Output Output	Port 93: Output port Data enable for SDRAM on pins D0 to D7
P94 SDLUDQM	1	Output Output	Port 94: Output port Data enable for SDRAM on pins D8 to D15
P95 SDCKE	1	Output Output	Port 95: Output port Clock enable for SDRAM
P96 SDCLK	1	Output Output	Port 96: Output port Clock for SDRAM
PA0 RXD0	1	I/O Input	Port A0: I/O port (Schmitt input) Serial 0 receive data
PA1 TXD0	1	I/O Output	Port A1: I/O port (Schmitt input) Serial 0 send data: Open-drain output programmable
PA2 SCLK0 CTS0	1	I/O I/O Input	Port A2: I/O port (Schmitt input) Serial 0 clock I/O Serial 0 data send enable (Clear To Send)
PA3 RXD1	1	I/O Input	Port A3: I/O port (Schmitt input) Serial 1 receive data
PA4 TXD1	1	I/O Output	Port A4: I/O port (Schmitt input) Serial 1 send data: Open-drain output programmable
PA5 SCLK1 CTS1	1	I/O I/O Input	Port A5: I/O port (Schmitt input) Serial 1 clock I/O Serial 1 data send enable (Clear To Send)
PC0 SO0 SDA0	1	I/O Output I/O	Port C0: I/O port (Schmitt input) Serial bus interface 0 send data at SIO mode Serial bus interface 0 send/receive data at I ² C mode Open-drain output programmable
PC1 SI0 SCL0	1	I/O Input I/O	Port C1: I/O port (Schmitt input) Serial bus interface 0 receive data at SIO mode Serial bus interface 0 clock I/O data at I ² C mode Open-drain output programmable
PC2 SCK0	1	I/O I/O	Port C2: I/O port (Schmitt input) Serial bus interface 0 clock I/O data at SIO mode
PC3 SO1 SDA1	1	I/O Output I/O	Port C3: I/O port (Schmitt input) Serial bus interface 1 send data at SIO mode Serial bus interface 1 send/receive data at I ² C mode Open-drain output programmable
PC4 SI1 SCL1	1	I/O Input I/O	Port C4: I/O port (Schmitt input) Serial bus interface 1 receive data at SIO mode Serial bus interface 1 clock I/O data at I ² C mode Open-drain output programmable
PC5 SCK1	1	I/O I/O	Port C5: I/O port (Schmitt input) Serial bus interface 1 clock I/O data at SIO mode

Table 2.2.3 Pin names and functions (3/5)

Pin name	Number of Pin	I/O	Function
PD0 HSSI0	1	I/O Input	Port D0: I/O port High speed Serial 0 receive data
PD1 HSSO0	1	I/O Output	Port D1: I/O port (Schmitt input) High speed Serial 0 send data
PD2 HSCLK0	1	I/O Output	Port D2: I/O port (Schmitt input) High speed Serial 0 clock I/O
PD3 RXD2	1	I/O Input	Port D3: I/O port (Schmitt input) Serial 2 receive data
PD4 TXD2	1	I/O Output	Port D4: I/O port (Schmitt input) Serial 2 send data: Open-drain output programmable
PD5 SCLK2 CTS2	1	I/O I/O Input	Port D5: I/O port (Schmitt input) Serial 2 clock I/O Serial 2 data send enable (Clear To Send)
PF0 TA0IN INT0	1	I/O Input Input	Port F0: I/O port (Schmitt input) 8-bit timer 0 input: Input pin of 8-bit timer TMRA0 Interrupt request pin 0: Interrupt request pin with programmable level/rising/falling edge
PF1 TA1OUT	1	I/O Output	Port F1: I/O port (Schmitt input) 8-bit timer 1 output: Output pin of 8-bit timer TMRA0 or TMRA1
PF2 TA2IN INT1	1	I/O Input Input	Port F2: I/O port (Schmitt input) 8-bit timer 2 input: Input pin of 8-bit timer TMRA2 Interrupt request pin 1: Interrupt request pin with programmable level/rising/falling edge
PF3 TA3OUT	1	I/O Output	Port F3: I/O port (Schmitt input) 8-bit timer 3 output: Output pin of 8-bit timer TMRA2 or TMRA3
PF4 TA4IN INT2	1	I/O Input Input	Port F4: I/O port (Schmitt input) 8-bit timer 4 input: Input pin of 8-bit timer TMRA4 Interrupt request pin 2: Interrupt request pin with programmable level/rising/falling edge
PF5 TA5OUT	1	I/O Output	Port F5: I/O port (Schmitt input) 8-bit timer 5 output: Output pin of 8-bit timer TMRA4 or TMRA5
PF6 TA6IN INT3	1	I/O Input Input	Port F6: I/O port (Schmitt input) 8-bit timer 6 input: Input pin of 8-bit timer TMRA6 Interrupt request pin 3: Interrupt request pin with programmable level/rising/falling edge
PJ0 TB0OUT0	1	I/O Output	Port J0: I/O port (Schmitt input) 16-bit timer 0 output 0: Output pin of 16-bit timer TMRB0
PJ1 TB0OUT1	1	I/O Output	Port J1: I/O port (Schmitt input) 16-bit timer 0 output 1: Output pin of 16-bit timer TMRB0
PJ2 TB1OUT0	1	I/O Output	Port J2: I/O port (Schmitt input) 16-bit timer 1 output 0: Output pin of 16-bit timer TMRB1
PJ3 TB1OUT1	1	I/O Output	Port J3: I/O port (Schmitt input) 16-bit timer 1 output 1: Output pin of 16-bit timer TMRB1
PJ4 TB2OUT0 TB4OUT0	1	I/O Output Output	Port J4: I/O port (Schmitt input) 16-bit timer 2 output 0: Output pin of 16-bit timer TMRB2 16-bit timer 4 output 0: Output pin of 16-bit timer TMRB4
PJ5 TB2OUT1 TB4OUT1	1	I/O Output Output	Port J5: I/O port (Schmitt input) 16-bit timer 2 output 1: Output pin of 16-bit timer TMRB2 16-bit timer 4 output 1: Output pin of 16-bit timer TMRB4
PJ6 TB3OUT0 TB5OUT0	1	I/O Output Output	Port J6: I/O port (Schmitt input) 16-bit timer 3 output 0: Output pin of 16-bit timer TMRB3 16-bit timer 5 output 0: Output pin of 16-bit timer TMRB5
PJ7 TB3OUT1 TB5OUT1	1	I/O Output Output	Port J7: I/O port (Schmitt input) 16-bit timer 3 output 1: Output pin of 16-bit timer TMRB3 16-bit timer 5 output 1: Output pin of 16-bit timer TMRB5

Table 2.2.4 Pin names and functions (4/5)

Pin name	Number of Pin	I/O	Function
PK0 TB0IN0 INT4	1	Input Input Input	Port K0: Input port (Schmitt input) 16-bit timer 0 input 0: Input of count/capture trigger in 16-bit TMRB0 Interrupt request pin 4 : Interrupt request pin with programmable level/rising/falling edge
PK1 TB0IN1 INT5	1	Input Input Input	Port K1: Input port (Schmitt input) 16-bit timer 0 input 1: Input of count/capture trigger in 16-bit TMRB0 Interrupt request pin 5 : Interrupt request pin with programmable level/rising/falling edge
PK2 TB1IN0 INT6	1	Input Input Input	Port K2: Input port (Schmitt input) 16-bit timer 1 input 0: Input of count/capture trigger in 16-bit TMRB1 Interrupt request pin 6 : Interrupt request pin with programmable level/rising/falling edge
PK3 TB1IN1 INT7	1	Input Input Input	Port K3: Input port (Schmitt input) 16-bit timer 1 input 1: Input of count/capture trigger in 16-bit TMRB1 Interrupt request pin 7 : Interrupt request pin with programmable level/rising/falling edge
PK4 TB2IN0 INT8	1	Input Input Input	Port K4: Input port (Schmitt input) 16-bit timer 2 input 0: Input of count/capture trigger in 16-bit TMRB2 Interrupt request pin 8 : Interrupt request pin with programmable level/rising/falling edge
PK5 TB2IN1 INT9	1	Input Input Input	Port K5: Input port (Schmitt input) 16-bit timer 2 input 1: Input of count/capture trigger in 16-bit TMRB2 Interrupt request pin 9 : Interrupt request pin with programmable level/rising/falling edge
PK6 TB3IN0 INTA	1	Input Input Input	Port K6: Input port (Schmitt input) 16-bit timer 3 input 0: Input of count/capture trigger in 16-bit TMRB3 Interrupt request pin A : Interrupt request pin with programmable level/rising/falling edge
PK7 TB3IN1 INTB	1	Input Input Input	Port K7: Input port (Schmitt input) 16-bit timer 3 input 1: Input of count/capture trigger in 16-bit TMRB3 Interrupt request pin B : Interrupt request pin with programmable level/rising/falling edge
PL0 PG00 RXD3	1	I/O Output Input	Port L0: I/O port (Schmitt input) Pattern generator output 00 Serial 3 receive data
PL1 PG01 TXD3	1	I/O Output Output	Port L1: I/O port (Schmitt input) Pattern generator output 01 Serial 3 send data: Open-drain output programmable
PL2 PG02 SCLK3 CTS3	1	I/O Output I/O Input	Port L2: I/O port (Schmitt input) Pattern generator output 02 Serial 3 clock I/O Serial 3 data send enable (Clear To Send)
PL3 PG03 TA7OUT	1	I/O Output Output	Port L3: I/O port (Schmitt input) Pattern generator output 03 8-bit timer 7 output: Output pin of 8-bit timer TMRA6 or TMRA7
PL4 PG10 HSS11	1	I/O Output Input	Port L4: I/O port Pattern generator output 10 High speed Serial 1 receive data
PL5 PG11 HSS01	1	I/O Output Output	Port L5: I/O port (Schmitt input) Pattern generator output 11 High speed Serial 1 send data
PL6 PG12 HCLK1	1	I/O Output Output	Port L6: I/O port (Schmitt input) Pattern generator output 12 High speed Serial 1 clock I/O
PL7 PG13	1	I/O Output	Port L7: I/O port (Schmitt input) Pattern generator output 13

Table 2.2.5 Pin names and functions (5/5)

Pin name	Number of Pin	I/O	Function
PM0 to PM7 AN0 to AN7 KI0 to KI7	8	Input	Port M: Input port (Schmitt input) Analog input 0 to 7: Pin used to input to AD converter Key input 0 to 7: Pin used of Key-on wakeup 0 to 7
PN0 to PN3 AN8 to AN11 ADTRG	4	Input	Port N: Input port (Schmitt input) Analog input 8 to 11: Pin used to input to AD converter AD trigger: Signal used for request AD start (Shared with PN3)
NMI	1	Input	Non-maskable interrupt request pin: Interrupt request pin with programmable falling edge level or with both edge levels programmable (Schmitt input)
DAOUT0	1	Output	Digital output 0: Pin used to output to DA converter 0
DAOUT1	1	Output	Digital output 1: Pin used to output to DA converter 1
AM0, AM1	2	Input	Operation mode: Fixed to AM1="0",AM0="1" External 16-bit bus start Fixed to AM1="1",AM0="0" External 8-bit bus start Fixed to AM1="1",AM0="1" Reserved Fixed to AM1="0",AM0="0" Reserved
X1 / X2	2	I/O	High-frequency oscillator connection I/O pins
RESET	1	Input	Reset: Initializes TMP92CM27 (Schmitt input, with pull-up register)
AVCC / VREFH	1	Input	Pin used to both power supply pin for AD converter and standard power supply for AD converter (H)
AVSS / VREFL	1	Input	Pin used to both GND pin for AD converter (0V) and standard power supply pin for AD converter (L)
DAVCC / DAREF	1	Input	Pin used to both power supply pin for DA converter and standard power supply for DA converter
DAVSS	1	Input	Pin used to both GND pin for DA converter (0V)
DVCC	4	-	Power supply pin (All DVCC pins should be connected with the power supply pin)
DVSS	4	-	GND pins (0V) (All DVSS pins should be connected with GND (0V))

3. Operation

This section describes the basic components, functions and operation of the TMP92CM27.

3.1 CPU

The TMP92CM27 contains an advanced high-speed 32-bit CPU (TLCS-900/H1 CPU)

3.1.1 CPU Outline

TLCS-900/H1 CPU is high-speed and high-performance CPU based on TLCS-900/L1 CPU. TLCS-900/H1 CPU has expanded 32-bit internal data bus to process instructions more quickly.

Outline is as follows:

Table 3.1.1 TMP92CM27 Outline

Parameter	TMP92CM27	
Width of CPU address bus	24 bits	
Width of CPU data bus	32 bits	
Internal operating frequency	Max 20MHz	
Minimum bus cycle	1-clock access (50ns at $f_{SYS} = 20\text{MHz}$)	
Internal RAM	32-bit 1-clock access	
Internal I/O	8-bit, 2-clock access	CGEAR, INTC, PORT, MEMC, TMRA, TMRB, PG, SIO, SBI, SDRAMC, ADC, DAC, WDT
	16-bit, 2-clock access	HSIO
External memory (SRAM etc)	8 to 16-bit 2-clock access (can insert some waits)	
External memory (SDRAM)	16-bit 1-clock access	
Minimum instruction Execution cycle	1-clock(50ns at $f_{SYS} = 20\text{MHz}$)	
Conditional jump	2-clock(100ns at $f_{SYS} = 20\text{MHz}$)	
Instruction queue buffer	12 bytes	
Instruction set	Compatible with TLCS-900/L1 (LDX instruction is deleted)	
CPU mode	Only maximum mode	
Micro DMA	8 channel	

3.1.2 Reset Operation

When resetting the TMP92CM27, ensure that the power supply voltage is within the operating voltage range, and that the internal high-frequency oscillator has stabilized. Then hold the $\overline{\text{RESET}}$ input low for at least 20 system clocks (16 μs at $f_c = 40 \text{ MHz}$).

At reset, since the clock doubler (PLL) is bypassed and clock-gear is set to 1/16, system clock operates at 1.25 MHz ($f_c = 40 \text{ MHz}$).

When the reset has been accepted, the CPU performs the following:

- Sets the program counter (PC) as follows in accordance with the reset vector stored at address FFFF00H to FFFF02H:
 $\text{PC}\langle 7:0 \rangle \leftarrow \text{data in location FFFF00H}$
 $\text{PC}\langle 15:8 \rangle \leftarrow \text{data in location FFFF01H}$
 $\text{PC}\langle 23:16 \rangle \leftarrow \text{data in location FFFF02H}$
- Sets the stack pointer (XSP) to 00000000H.
- Sets bits $\langle \text{IFF2}:0 \rangle$ of the status register (SR) to "111"
 (thereby setting the interrupt level mask register to level 7).
- Clears bits $\langle \text{RFP1}:0 \rangle$ of the status register to "00"
 (there by selecting register bank 0).

When the reset is released, the CPU starts executing instructions according to the program counter settings. CPU internal registers not mentioned above do not change when the reset is released.

When the reset is accepted, the CPU sets internal I/O, ports and other pins as follows.

- Initializes the internal I/O registers as table of "special function register" in section 5.
- Sets the port pins, including the pins that also act as internal I/O, to general-purpose input or output port mode.

Internal reset is released as soon as external reset is released.

The operation of memory controller cannot be insured until power supply becomes stable after power-on reset. The external RAM data provided before turning on the TMP92CM27 may be spoiled because the control signals are unstable until power supply becomes stable after power-on reset.

Figure 3.1.1 Power on Reset Timing Example

3.1.3 Setting of AM0 and AM1

Set AM1 and AM0 pins like Table 3.1.2 according to system usage.

Table 3.1.2 Operation Mode Setup Table

Operation mode	Mode Setup Input Pin		
	RESET	AM1	AM0
16-bit external bus start (Multi 16 Mode)		0	1
8-bit external bus start (Multi 8 Mode)		1	0
Reserved		1	1
Reserved		0	0

3.2 Memory Map

Figure 3.2.1 is a memory map of the TMPP92CM27.

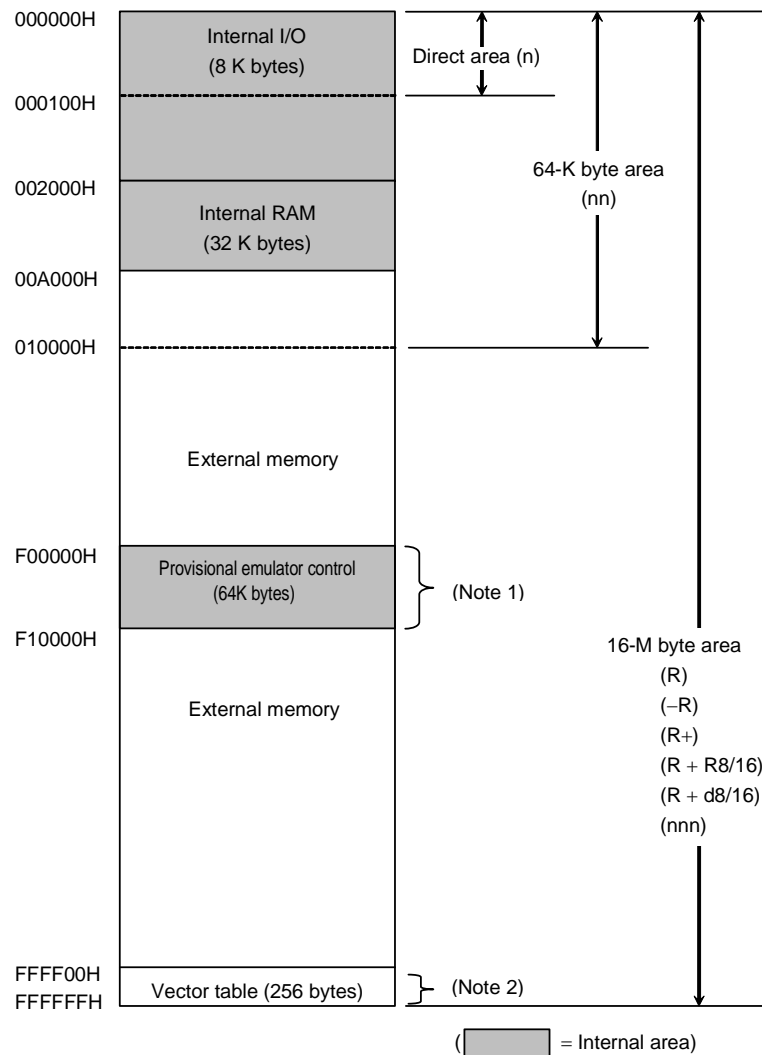

Figure 3.2.1 Memory Map

Note 1: Provisional emulator control area is for an emulator, it is mapped F00000H to F0FFFFH after reset. On emulator \overline{WR} signal and \overline{RD} signal are asserted, when this area is accessed. Be carefull to use external memory.

Note 2: Don't use the last 16-bytes area (FFFFFF0H to FFFFFFFH). This area is reserved for an emulator.

3.3 Clock Function and Stand-by Function

TMP92CM27 contains (1) clock gear, (2) clock doubler (PLL), (3) stand-by controller and (4) noise reducing circuit. They are used for low power, low noise systems.

This chapter is organized as follows:

- 3.3.1 Block diagram of system clock
- 3.3.2 SFR
- 3.3.3 System clock controller
- 3.3.4 Clock doubler (PLL)
- 3.3.5 Noise reducing circuits
- 3.3.6 Stand-by controller

The clock operating modes are as follows: (a) single clock mode (X1, X2 pins only), (b) dual clock mode (X1, X2 pins and PLL).

Figure 3.3.1 shows a transition figure.

Note 1: If you shift from NORMAL mode with use of PLL to NORMAL mode, execute following setting in the same order.

- 1) Change CPU clock (PLLCR0 <FCSEL> ← "0")
- 2) Stop PLL circuit (PLLCR1 <PLLON> ← "0")

Note 2: It's prohibited to shift from NORMAL mode with use of PLL to STOP mode directly.

You should set NORMAL mode once, and then shift to STOP mode. (You should stop high-frequency oscillator after you stop PLL.)

Figure 3.3.1 System Clock Block Diagram

The clock frequency input from the X1 and X2 pins is called f_{OSCH} and clock frequency selected by SYSCR1<SYSCK> is called the system clock f_{FPH} . The system clock f_{SYS} is defined as the divided clock of f_{FPH} , and one cycle of f_{SYS} is defined to as one state.

3.3.1 Block Diagram of System Clock

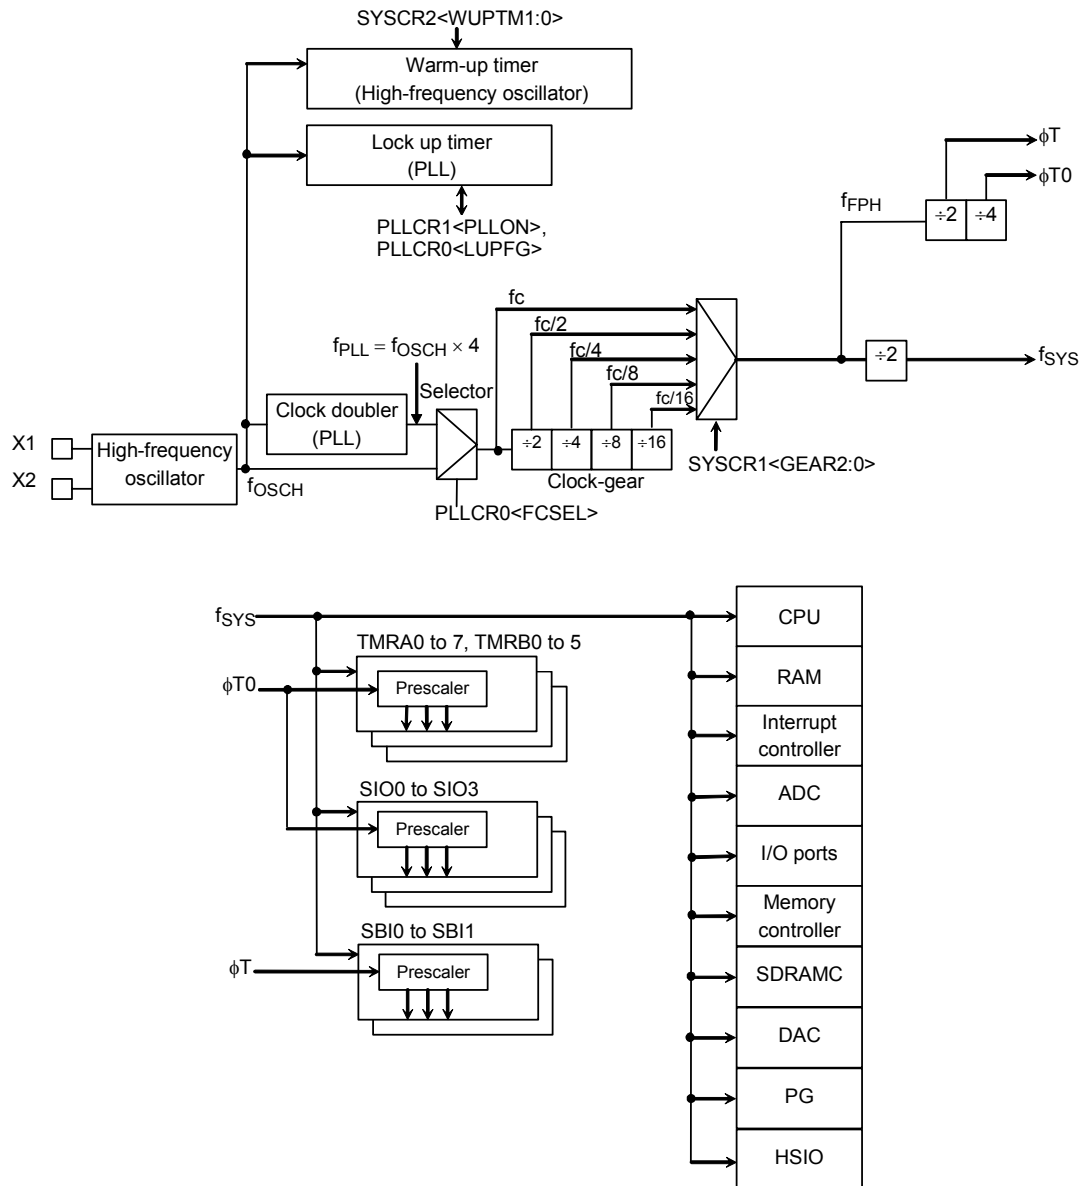

Figure 3.3.2 Block Diagram of System Clock

3.3.2 SFR

		7	6	5	4	3	2	1	0
SYSCR0 (10E0H)	Bit symbol						–		
	Read/Write						R/W		
	After reset						0		
	Function						Always write "0"		
		7	6	5	4	3	2	1	0

3.3.3 System Clock Controller

The system clock controller generates the system clock signal (f_{SYS}) for the CPU core and internal I/O. It contains a oscillation circuits, PLL and a clock gear circuit for high-frequency (f_c) operation. The register SYSCR1<GEAR2:0> sets the high-frequency clock gear to either 1, 2, 4, 8 or 16 (f_c , $f_c/2$, $f_c/4$, $f_c/8$ or $f_c/16$). These functions can reduce the power consumption of the equipment in which the device is installed.

The initialization <GEAR2:0> = "100" will cause the system clock (f_{SYS}) to be set to $f_c/32$ ($f_c/16 \times 1/2$) after reset.

For example, f_{SYS} is set to 1.25 MHz when the 40 MHz oscillator is connected to the X1 and X2 pins.

(1) Clock gear controller

The f_{PPH} is set according to the contents of the clock gear select register SYSCR1<GEAR2:0> to either f_c , $f_c/2$, $f_c/4$, $f_c/8$ or $f_c/16$. Using the clock gear to select a lower value of f_{PPH} reduces power consumption.

Example: Changing to a high-frequency gear

```
SYSCR1    EQU    10E1H

          LD      (SYSCR1), XXXXX001B    ; Changes fSYS to fc/2.
          LD      (DUMMY), 00H           ; Dummy instruction

          X: Don't care
```

(High-speed clock gear changing)

To change the clock gear, write the register value to the SYSCR1 <GEAR2:0> register. It is necessary the warm-up time until changing after writing the register value.

There is the possibility that the instruction next to the clock gear changing instruction is executed by the clock gear before changing. To execute the instruction next to the clock gear switching instruction by the clock gear after changing, input the dummy instruction as follows (instruction to execute the write cycle).

Example:

```
SYSCR1    EQU    10E1H

          LD      (SYSCR1), XXXXX010B    ; Changes fSYS to fc/4.
          LD      (DUMMY), 00H           ; Dummy instruction
          Instruction to be executed after clock gear has changed
```

3.3.4 Clock Doubler (PLL)

PLL outputs the f_{PLL} clock signal, which is four times as fast as f_{OSCH} . It can use the low-speed-frequency oscillator, even though the internal clock is high-frequency.

A reset initializes PLL to stop status, setting to PLLCR0, PLLCR1 register is needed before use.

Like an oscillator, this circuit requires time to stabilize. This is called the lock up time and it is measured by 16-stage binary counter. Lock up time is about 1.6 ms at $f_{OSCH} = 10$ MHz.

Note 1: Input frequency limitation for PLL

The limitation of input frequency (High-frequency oscillation) for PLL is following.

$f_{OSCH} = 6$ to 10 MHz ($V_{CC} = 3.0$ to 3.6 V)

Note 2: PLLCR0 <LUPFG>

The logic of PLLCR0 <LUPFG> is different from 900/L1's DFM.

Be careful to judge an end of lock up time

The following is an setting example for PLL starting and PLL stopping.

Example 1: PLL starting

```

PLLCR0    EQU    10E8H
PLLCR1    EQU    10E9H
LD        (PLLCR1), 1 X X X X X X B ; Enables PLL operation and starts lock up.
LUP:      BIT     5, (PLLCR0)          ; Detects end of lock up.
JR        Z, LUP
LD        (PLLCR0), X 1 X X X X X B ; Changes fc from 10 MHz to 40 MHz.
X: Don't care

```

Example 2: PLL stopping

PLLCR0	EQU	10E8H	
PLLCR1	EQU	10E9H	
	LD	(PLLCR0), 0XXXXXXXB	; Changes fc from 40 MHz to 10 MHz.
	LD	(PLLCR1), 0XXXXXXXB	; Stop PLL.

X: Don't care

<FCSEL>

<PLLON>

PLL output: f_{PLL} System clock f_{SYS} 

Limitation point on the use of PLL

1. If you stop PLL operation during using PLL, you should execute following setting in the same order.

```
LD      (PLLCR0), 00H      ; Change the clock  $f_{PLL}$  to  $f_{OSCH}$ 
LD      (PLLCR1), 00H      ; PLL stop
```

Examples of settings are below.

(2) Change/stop control

(OK) PLL use mode (f_{PLL}) → Set the STOP mode → High-frequency oscillator operation mode (f_{OSCH}) → PLL stop → Halt (High-frequency oscillator stop)

```
LD      (SYSCR2), 0 X - - 0 1 X - B ; Set the STOP mode
                                           (This command can execute before use of PLL)
LD      (PLLCR0), X 0 - X X X X X B ; Change the system clock  $f_{PLL}$  to  $f_{OSCH}$ 
LD      (PLLCR1), 0 X X X X X X X B ; PLL stop
HALT                                           ; Shift to STOP mode
```

(Error) PLL use mode (f_{PLL}) → Set the STOP mode → Halt (High-frequency oscillator stop)

```
LD      (SYSCR2), 0 X - - 0 1 X - B ; Set the STOP mode
                                           (This command can execute before use of PLL)
HALT                                           ; Shift to STOP mode
```

3.3.5 Noise Reduction Circuits

Noise reduction circuits are built-in, allowing implementation of the following features.

- (1) Reduced drivability for high-frequency oscillator
- (2) Single drive for high-frequency oscillator
- (3) SFR protection of register contents

These functions need a setup by EMCCR0, EMCCR1, and EMCCR2 register.
(1) to (3) is explained below.

(1) Reduced drivability for high-frequency oscillator

(Purpose)

Reduces noise and power for oscillator when a resonator is used.

(Block diagram)

(Setting method)

The drive ability of the oscillator is reduced by writing "0" to EMCCR0 <DRVOSCH> register. By reset, <DRVOSCH> is initialized to "1" and the oscillator starts oscillation by normal drivability when the power-supply is on.

Note: This function (EMCCR0 <DRVOSCH> = "0") is available to use in case of $f_{OSCH} = 6$ to 10 MHz condition.

(2) Single drive for high-frequency oscillator

(Purpose)

Not need twin drive and protect mistake operation by inputted noise to X2 pin when the external oscillator is used.

(Block diagram)

(Setting method)

The oscillator is disabled and starts operation as buffer by writing “1” to EMCCR0 <EXTIN> register. X2 pin is always outputted “1”.

By reset, <EXTIN> is initialized to “0”.

(3) Runaway provision with SFR protection register

(Purpose)

Provision in runaway of program by noise mixing.

Write operation to specified SFR is prohibited so that provision program in runaway prevents that it is in the state which is fetch impossibility by stopping of clock, memory control register (memory controller) is changed.

And error handling in runaway becomes easy by INTP0 interruption.

Specified SFR list

1. Memory controller

B0CSL/H, B1CSL/H, B2CSL/H, B3CSL/H, B4CSL/H, B5CSL/H, BEXCSL/H
MSAR0, MSAR1, MSAR2, MSAR3, MSAR4, MSAR5
MAMR0, MAMR1, MAMR2, MAMR3, MAMR4, MAMR5, PMEMCR

2. Clock gear

SYSCR0, SYSCR1, SYSCR2, EMCCR0

3. PLL

PLLCR0, PLLCR1

(Operation explanation)

Execute and release of protection (write operation to specified SFR) becomes possible by setting up a double key to EMCCR1 and EMCCR2 register.

(Double key)

1st KEY: Succession writes in 5AH at EMCCR1 and A5H at EMCCR2

2nd KEY: Succession writes in A5H at EMCCR1 and 5AH at EMCCR2

A state of protection can be confirmed by reading EMCCR0 <PROTECT>.

By reset, protection becomes OFF.

And INTP0 interruption occurs when write operation to specified SFR was executed with protection on state.

3.3.6 Stand-by Controller

(1) HALT modes and port drive register

When the HALT instruction is executed, the operating mode switches to IDLE2, IDLE1 or STOP mode, depending on the contents of the SYSCR2 <HALTM1:0> register.

The subsequent actions performed in each mode are as follows:

1. IDLE2: Only the CPU halts.

The internal I/O is available to select operation during IDLE2 mode by setting the following register.

Table 3.3.1 shows the registers of setting operation during IDLE2 mode.

Table 3.3.1 SFR Setting Operation during IDLE2 Mode

Internal I/O	SFR
TMRA01	TA01RUN<I2TA01>
TMRA23	TA23RUN<I2TA23>
TMRA45	TA45RUN<I2TA45>
TMRA67	TA67RUN<I2TA67>
TMRB0	TB0RUN<I2TB0>
TMRB1	TB1RUN<I2TB1>
TMRB2	TB2RUN<I2TB2>
TMRB3	TB3RUN<I2TB3>
TMRB4	TB4RUN<I2TB4>
TMRB5	TB5RUN<I2TB5>
SIO0	SC0MOD1<I2S0>
SIO1	SC1MOD1<I2S1>
SIO2	SC2MOD1<I2S2>
SIO3	SC3MOD1<I2S3>
SBI0	SBI0BR0<I2SBI0>
SBI1	SBI1BR0<I2SBI1>
AD Converter	ADMOD1<I2AD>
WDT	WDMOD<I2WDT>

2. IDLE1: Only the oscillator and the Special timer for clock operate.

3. STOP: All internal circuits stop operating.

The operation of each of the different HALT modes is described in Table 3.3.2

Table 3.3.2 I/O Operation during HALT Modes

HALT Mode		IDLE2	IDLE1	STOP
SYSCR2<HALTM1:0>		11	10	01
Block	CPU	Stop		
	I/O ports	The state at the time of "HALT" instruction execution is held.	Table 3.3.8 references	
	TMRA, TMRB	Available to select operation block	Stop	
	SIO, SBI			
	AD converter			
	WDT			
	SDRAMC, Interrupt controller, HSIO, PG (Note)	Operate		

Note 1: When operating PG in the IDLE2 mode, it is necessary to set operation at the time of the IDLE2 mode of the block (TMRA or TMRB) chosen as a trigger as permission.

Note 2: It is necessary to set up the state in each HALT mode of a D/A converter in DAC0CNT0/DAC1CNT0 register before HALT instruction execution.

(2) How to release the HALT mode

These halt states can be released by resetting or requesting an interrupt. The halt release sources are determined by the combination between the states of interrupt mask register <IFF2:0> and the HALT modes. The details for releasing the halt status are shown in Table 3.3.3.

- Released by requesting an interrupt

The operating released from the HALT mode depends on the interrupt enabled status. When the interrupt request level set before executing the “HALT” instruction exceeds the value of interrupt mask register, the interrupt due to the source is processed after releasing the HALT mode, and CPU status executing an instruction that follows the “HALT” instruction. When the interrupt request level set before executing the “HALT” instruction is less than the value of the interrupt mask register, releasing the HALT mode is not executed. (in non-maskable interrupts, interrupt processing is processed after releasing the HALT mode regardless of the value of the mask register.) However only for INT0 to INT7 interrupts, even if the interrupt request level set before executing the halt instruction is less than the value of the interrupt mask register, releasing the HALT mode is executed. In this case, interrupt processing is not performed, and CPU starts executing the instruction next to the halt instruction, but the interrupt request flag is held at “1”.

- Releasing by resetting

Releasing all halt status is executed by resetting.

When the STOP mode is released by RESET, it is necessary enough resetting time (see Table 3.3.4 Example of a setting of Warm-up time of oscillator) to set the operation of the oscillator to be stable.

When releasing the HALT mode by resetting, the internal RAM data keeps the state before the “HALT” instruction is executed. However the other settings contents are initialized. (Releasing due to interrupts keeps the state before the “HALT” instruction is executed.)

Table 3.3.3 Source of Halt State Clearance and Halt Clearance Operation

Status of Received Interrupt			Interrupt Enabled (Interrupt level) \geq (Interrupt mask)			Interrupt Disabled (Interrupt level) $<$ (Interrupt mask)		
HALT Mode			IDLE2	IDLE1	STOP	IDLE2	IDLE1	STOP
Source of Halt State Clearance	Interrupt	NMI	◆	◆	◆ ^{*1}	—	—	—
		INTWDT	◆	×	×	—	—	—
		INT0 to 3 (Note 1)	◆	◆	◆ ^{*1}	○	○	○ ^{*1}
		INT4 to 7 (PORT) (Note 1) (Note 3)	◆	◆	◆ ^{*1}	○	○	○ ^{*1}
		INT4 to 7 (TMRB0 to 1) (Note 3)	◆	×	×	×	×	×
		INT8 to B (PORT) (Note 1) (Note 3)	◆	×	×	×	×	×
		INT8 to B (TMRB2 to 3) (Note 3)	◆	×	×	×	×	×
		INTTA0 to 7	◆	×	×	×	×	×
		INTTB00 to 51, INTTBOX	◆	×	×	×	×	×
		INTRX0 to 3, INTTX0 to 3	◆	×	×	×	×	×
		INTAD	◆	×	×	×	×	×
		INTSBI0 to 1	◆	×	×	×	×	×
		INTHSC0 to 1	◆	×	×	×	×	×
		KI (Key On WakeUp) (Note 2)	○	○	○ ^{*1}	○	○	○ ^{*1}
	RESET		Initialize LSI					

◆: After clearing the HALT mode, CPU starts interrupt processing.

○: After clearing the HALT mode, CPU resumes executing starting from instruction following the Halt instruction.

×: It can not be used to release the HALT mode.

—: The priority level (interrupt request level) of non-maskable interrupts is fixed to “7”, the highest priority level. There is not this combination type.

*1: Releasing the HALT mode is executed after passing the warm-up time.

Note 1: When the HALT mode is cleared by an INT0 to B interrupt of the level mode in the interrupt enabled status, hold level “H” until starting interrupt processing. If level “L” is set before holding level “L”, interrupt processing is correctly started.

Note 2: Although a KI can cancel all HALT mode states, the function as interruption does not have it.

Note 3: The operation of the HALT release of INT4 to INTB becomes operation of (PORT) when setting it to the INTn input by the port setting. It becomes operation of (TMRB) when setting it to 16 bit timer input.

Note 4: Set the INTSEL register when you use interrupt to which the interrupt factor is used combinedly. Details wish the reference to "Interrupt control of 3.3.4 interrupt controllers (3)".

Example: Releasing IDLE1 mode

An INT0 interrupt clears the halt state when the device is in IDLE1 mode.

Address				
10003H	LD	(IIMC1), 00H	;	Selects INT0 interrupt rising edge.
10006H	LD	(IIMC2), 00H	;	Selects INT0 interrupt edge
10009H	LD	(INTE01), 06H		Sets INT0 interrupt level to 6.
1000CH	EI	5	;	Sets interrupt level to 5 for CPU.
1000EH	LD	(SYSCR2), 28H	;	Sets HALT mode to IDLE1 mode.
10011H	HALT		;	Halts CPU.

(3) Operation

1. IDLE2 mode

In IDLE2 mode only specific internal I/O operations, as designated by the IDLE2 setting register, can take place. Instruction execution by the CPU stops.

Figure 3.3.6 illustrates an example of the timing for clearance of the IDLE2 mode halt state by an interrupt.

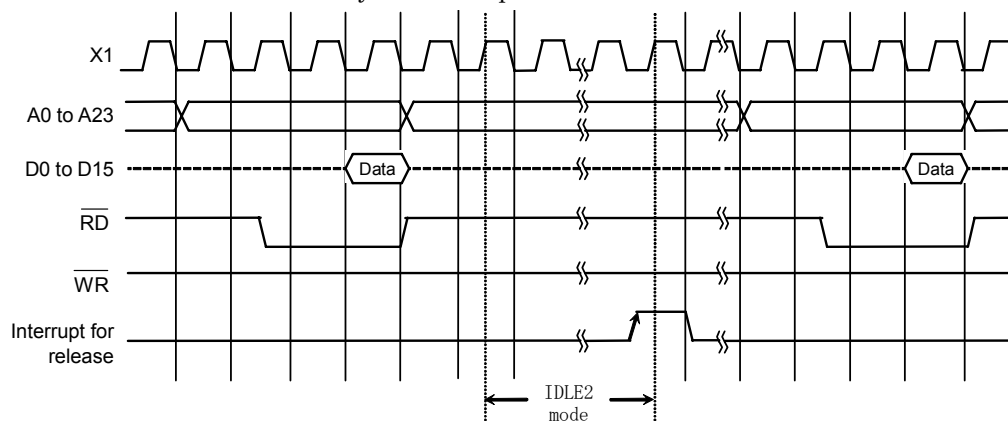

Figure 3.3.6 Timing Chart for IDLE2 Mode Halt State Cleared by Interrupt

2. IDLE1 mode

In IDLE1 mode, only the internal oscillator and Special timer for Clock continue to operate. The system clock stops.

In the halt state, the interrupt request is sampled asynchronously with the system clock; however, clearance of the halt state (e.g., restart of operation) is synchronous with it.

Figure 3.3.7 illustrates the timing for clearance of the IDLE1 mode halt state by an interrupt.

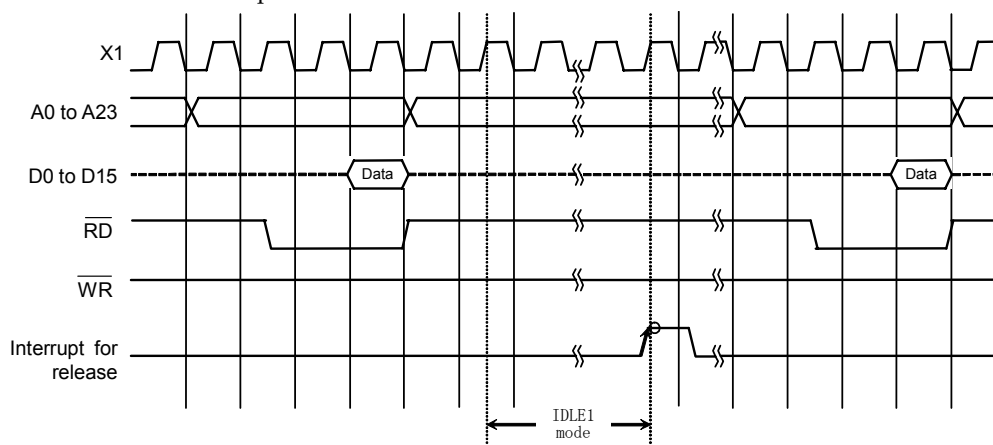

Figure 3.3.7 Timing Chart for IDLE1 Mode Halt State Cleared by Interrupt

3. STOP mode

When STOP mode is selected, all internal circuits stop, including the internal oscillator.

After STOP mode has been cleared system clock output starts when the warm-up time has elapsed, in order to allow oscillation to stabilize.

The example of a setting of the Warm-up time at the time of STOP mode release is shown in Table 3.3.4.

Figure 3.3.8 illustrates the timing for clearance of the STOP mode halt state by an interrupt.

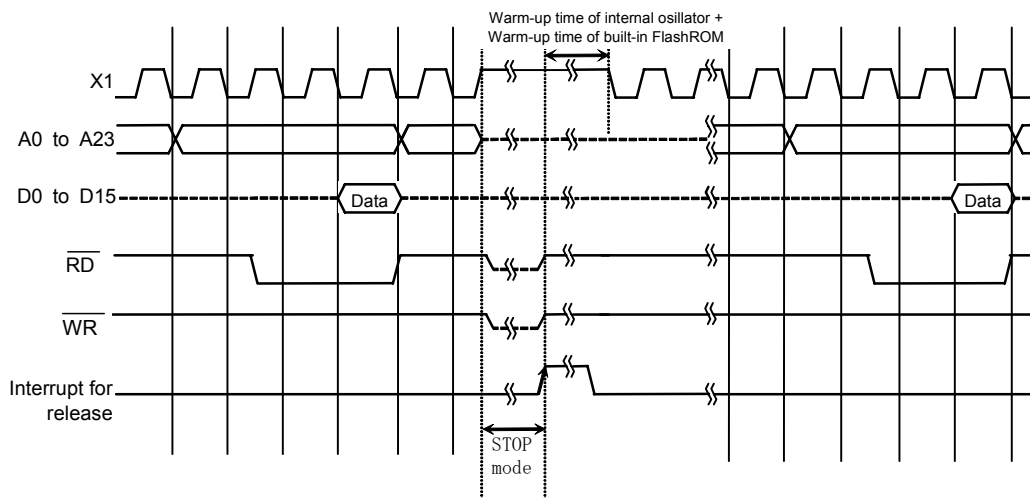

Figure 3.3.8 Timing Chart for STOP Mode Halt State Cleared by Interrupt

Table 3.3.4 Example of a setting of Warm-up time of oscillator (at the time of STOP mode release)

at $f_{OSCH} = 16 \text{ MHz}$

SYSCR2<WUPTM1:0>		
01 (2^8)	10 (2^{14})	11 (2^{16})
16 μs	1.024 ms	4.096 ms

3.3 Clock Function and Stand-by Function

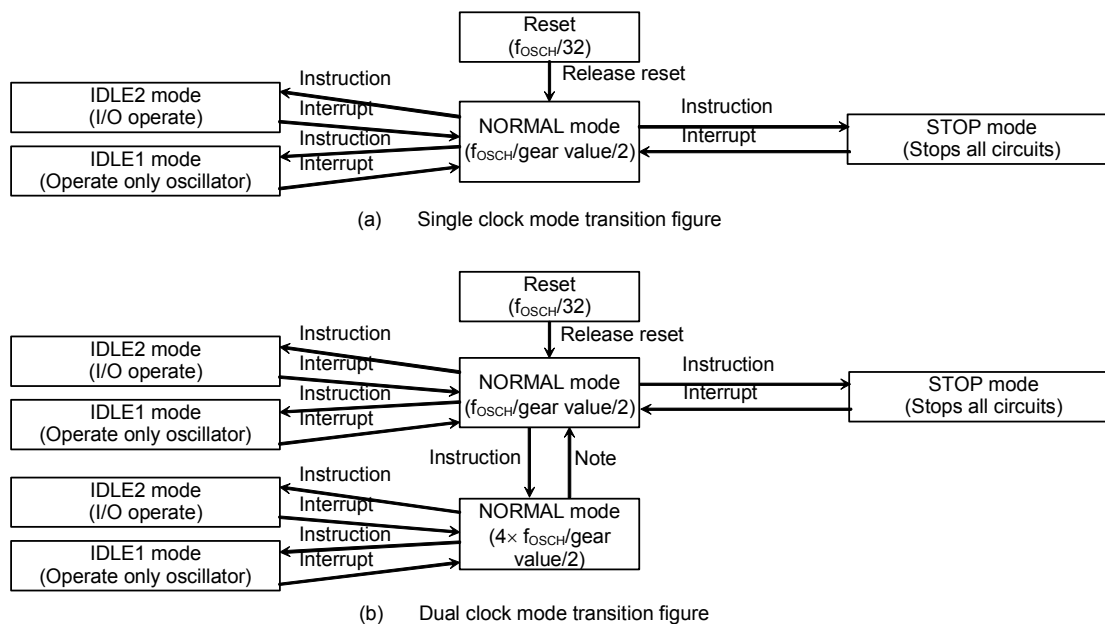

TMP92CM27 contains (1) clock gear, (2) clock doubler (PLL), (3) stand-by controller and (4) noise reducing circuit. They are used for low power, low noise systems.

This chapter is organized as follows:

- 3.3.1 Block diagram of system clock
- 3.3.2 SFR
- 3.3.3 System clock controller
- 3.3.4 Clock doubler (PLL)
- 3.3.5 Noise reducing circuits
- 3.3.6 Stand-by controller

The clock operating modes are as follows: (a) single clock mode (X1, X2 pins only), (b) dual clock mode (X1, X2 pins and PLL).

Figure 3.3.1 shows a transition figure.

Note 1: If you shift from NORMAL mode with use of PLL to NORMAL mode, execute following setting in the same order.

- 1) Change CPU clock (PLLCR0 <FCSEL> ← "0")
- 2) Stop PLL circuit (PLLCR1 <PLLON> ← "0")

Note 2: It's prohibited to shift from NORMAL mode with use of PLL to STOP mode directly.

You should set NORMAL mode once, and then shift to STOP mode. (You should stop high-frequency oscillator after you stop PLL.)

Figure 3.3.1 System Clock Block Diagram

The clock frequency input from the X1 and X2 pins is called f_{OSCH} and clock frequency selected by SYSCR1<SYSCK> is called the system clock f_{FPH} . The system clock f_{SYS} is defined as the divided clock of f_{FPH} , and one cycle of f_{SYS} is defined to as one state.

3.3.3 System Clock Controller

The system clock controller generates the system clock signal (f_{SYS}) for the CPU core and internal I/O. It contains a oscillation circuits, PLL and a clock gear circuit for high-frequency (f_c) operation. The register SYSCR1<GEAR2:0> sets the high-frequency clock gear to either 1, 2, 4, 8 or 16 (f_c , $f_c/2$, $f_c/4$, $f_c/8$ or $f_c/16$). These functions can reduce the power consumption of the equipment in which the device is installed.

The initialization <GEAR2:0> = "100" will cause the system clock (f_{SYS}) to be set to $f_c/32$ ($f_c/16 \times 1/2$) after reset.

For example, f_{SYS} is set to 1.25 MHz when the 40 MHz oscillator is connected to the X1 and X2 pins.

(1) Clock gear controller

The f_{PPH} is set according to the contents of the clock gear select register SYSCR1<GEAR2:0> to either f_c , $f_c/2$, $f_c/4$, $f_c/8$ or $f_c/16$. Using the clock gear to select a lower value of f_{PPH} reduces power consumption.

Example: Changing to a high-frequency gear

```
SYSCR1    EQU    10E1H

          LD      (SYSCR1), XXXXX001B    ; Changes fSYS to fc/2.
          LD      (DUMMY), 00H           ; Dummy instruction

          X: Don't care
```

(High-speed clock gear changing)

To change the clock gear, write the register value to the SYSCR1 <GEAR2:0> register. It is necessary the warm-up time until changing after writing the register value.

There is the possibility that the instruction next to the clock gear changing instruction is executed by the clock gear before changing. To execute the instruction next to the clock gear switching instruction by the clock gear after changing, input the dummy instruction as follows (instruction to execute the write cycle).

Example:

```
SYSCR1    EQU    10E1H

          LD      (SYSCR1), XXXXX010B    ; Changes fSYS to fc/4.
          LD      (DUMMY), 00H           ; Dummy instruction
          Instruction to be executed after clock gear has changed
```

3.3.4 Clock Doubler (PLL)

PLL outputs the f_{PLL} clock signal, which is four times as fast as f_{OSCH} . It can use the low-speed-frequency oscillator, even though the internal clock is high-frequency.

A reset initializes PLL to stop status, setting to PLLCR0, PLLCR1 register is needed before use.

Like an oscillator, this circuit requires time to stabilize. This is called the lock up time and it is measured by 16-stage binary counter. Lock up time is about 1.6 ms at $f_{OSCH} = 10$ MHz.

Note 1: Input frequency limitation for PLL

The limitation of input frequency (High-frequency oscillation) for PLL is following.

$f_{OSCH} = 6$ to 10 MHz ($V_{CC} = 3.0$ to 3.6 V)

Note 2: PLLCR0 <LUPFG>

The logic of PLLCR0 <LUPFG> is different from 900/L1's DFM.

Be careful to judge an end of lock up time

The following is an setting example for PLL starting and PLL stopping.

Example 1: PLL starting

PLLCR0	EQU	10E8H	
PLLCR1	EQU	10E9H	
	LD	(PLLCR1), 1 X X X X X X B ;	Enables PLL operation and starts lock up.
LUP:	BIT	5, (PLLCR0)	} Detects end of lock up.
	JR	Z, LUP	
	LD	(PLLCR0), X 1 X X X X X B ;	Changes f_c from 10 MHz to 40 MHz.

X: Don't care

Example 2: PLL stopping

PLLCR0	EQU	10E8H	
PLLCR1	EQU	10E9H	
	LD	(PLLCR0), 0XXXXXXXB	; Changes fc from 40 MHz to 10 MHz.
	LD	(PLLCR1), 0XXXXXXXB	; Stop PLL.

X: Don't care

<FCSEL>

<PLLON>

PLL output: f_{PLL} System clock f_{SYS} 

Limitation point on the use of PLL

1. If you stop PLL operation during using PLL, you should execute following setting in the same order.

```
LD      (PLLCR0), 00H      ; Change the clock  $f_{PLL}$  to  $f_{OSCH}$ 
LD      (PLLCR1), 00H      ; PLL stop
```

Examples of settings are below.

(2) Change/stop control

(OK) PLL use mode (f_{PLL}) → Set the STOP mode → High-frequency oscillator operation mode (f_{OSCH}) → PLL stop → Halt (High-frequency oscillator stop)

```
LD      (SYSCR2), 0 X - - 0 1 X - B ; Set the STOP mode
                                         (This command can execute before use of PLL)
LD      (PLLCR0), X 0 - X X X X X B ; Change the system clock  $f_{PLL}$  to  $f_{OSCH}$ 
LD      (PLLCR1), 0 X X X X X X X B ; PLL stop
HALT                                         ; Shift to STOP mode
```

(Error) PLL use mode (f_{PLL}) → Set the STOP mode → Halt (High-frequency oscillator stop)

```
LD      (SYSCR2), 0 X - - 0 1 X - B ; Set the STOP mode
                                         (This command can execute before use of PLL)
HALT                                         ; Shift to STOP mode
```

3.3.5 Noise Reduction Circuits

Noise reduction circuits are built-in, allowing implementation of the following features.

- (1) Reduced drivability for high-frequency oscillator
- (2) Single drive for high-frequency oscillator
- (3) SFR protection of register contents

These functions need a setup by EMCCR0, EMCCR1, and EMCCR2 register.
(1) to (3) is explained below.

(1) Reduced drivability for high-frequency oscillator

(Purpose)

Reduces noise and power for oscillator when a resonator is used.

(Block diagram)

(Setting method)

The drive ability of the oscillator is reduced by writing "0" to EMCCR0 <DRVOSCH> register. By reset, <DRVOSCH> is initialized to "1" and the oscillator starts oscillation by normal drivability when the power-supply is on.

Note: This function (EMCCR0 <DRVOSCH> = "0") is available to use in case of $f_{OSCH} = 6$ to 10 MHz condition.

(2) Single drive for high-frequency oscillator

(Purpose)

Not need twin drive and protect mistake operation by inputted noise to X2 pin when the external oscillator is used.

(Block diagram)

(Setting method)

The oscillator is disabled and starts operation as buffer by writing “1” to EMCCR0 <EXTIN> register. X2 pin is always outputted “1”.

By reset, <EXTIN> is initialized to “0”.

(3) Runaway provision with SFR protection register

(Purpose)

Provision in runaway of program by noise mixing.

Write operation to specified SFR is prohibited so that provision program in runaway prevents that it is in the state which is fetch impossibility by stopping of clock, memory control register (memory controller) is changed.

And error handling in runaway becomes easy by INTP0 interruption.

Specified SFR list

1. Memory controller

B0CSL/H, B1CSL/H, B2CSL/H, B3CSL/H, B4CSL/H, B5CSL/H, BEXCSL/H
MSAR0, MSAR1, MSAR2, MSAR3, MSAR4, MSAR5
MAMR0, MAMR1, MAMR2, MAMR3, MAMR4, MAMR5, PMEMCR

2. Clock gear

SYSCR0, SYSCR1, SYSCR2, EMCCR0

3. PLL

PLLCR0, PLLCR1

(Operation explanation)

Execute and release of protection (write operation to specified SFR) becomes possible by setting up a double key to EMCCR1 and EMCCR2 register.

(Double key)

1st KEY: Succession writes in 5AH at EMCCR1 and A5H at EMCCR2

2nd KEY: Succession writes in A5H at EMCCR1 and 5AH at EMCCR2

A state of protection can be confirmed by reading EMCCR0 <PROTECT>.

By reset, protection becomes OFF.

And INTP0 interruption occurs when write operation to specified SFR was executed with protection on state.

3.3.6 Stand-by Controller

(1) HALT modes and port drive register

When the HALT instruction is executed, the operating mode switches to IDLE2, IDLE1 or STOP mode, depending on the contents of the SYSCR2 <HALTM1:0> register.

The subsequent actions performed in each mode are as follows:

1. IDLE2: Only the CPU halts.

The internal I/O is available to select operation during IDLE2 mode by setting the following register.

Table 3.3.1 shows the registers of setting operation during IDLE2 mode.

Table 3.3.1 SFR Setting Operation during IDLE2 Mode

Internal I/O	SFR
TMRA01	TA01RUN<I2TA01>
TMRA23	TA23RUN<I2TA23>
TMRA45	TA45RUN<I2TA45>
TMRA67	TA67RUN<I2TA67>
TMRB0	TB0RUN<I2TB0>
TMRB1	TB1RUN<I2TB1>
TMRB2	TB2RUN<I2TB2>
TMRB3	TB3RUN<I2TB3>
TMRB4	TB4RUN<I2TB4>
TMRB5	TB5RUN<I2TB5>
SIO0	SC0MOD1<I2S0>
SIO1	SC1MOD1<I2S1>
SIO2	SC2MOD1<I2S2>
SIO3	SC3MOD1<I2S3>
SBI0	SBI0BR0<I2SBI0>
SBI1	SBI1BR0<I2SBI1>
AD Converter	ADMOD1<I2AD>
WDT	WDMOD<I2WDT>

2. IDLE1: Only the oscillator and the Special timer for clock operate.

3. STOP: All internal circuits stop operating.

The operation of each of the different HALT modes is described in Table 3.3.2

Table 3.3.2 I/O Operation during HALT Modes

HALT Mode		IDLE2	IDLE1	STOP
SYSCR2<HALTM1:0>		11	10	01
Block	CPU	Stop		
	I/O ports	The state at the time of "HALT" instruction execution is held.	Table 3.3.8 references	
	TMRA, TMRB	Available to select operation block	Stop	
	SIO, SBI			
	AD converter			
	WDT			
	SDRAMC, Interrupt controller, HSIO, PG (Note)	Operate		

Note 1: When operating PG in the IDLE2 mode, it is necessary to set operation at the time of the IDLE2 mode of the block (TMRA or TMRB) chosen as a trigger as permission.

Note 2: It is necessary to set up the state in each HALT mode of a D/A converter in DAC0CNT0/DAC1CNT0 register before HALT instruction execution.

(2) How to release the HALT mode

These halt states can be released by resetting or requesting an interrupt. The halt release sources are determined by the combination between the states of interrupt mask register <IFF2:0> and the HALT modes. The details for releasing the halt status are shown in Table 3.3.3.

- Released by requesting an interrupt

The operating released from the HALT mode depends on the interrupt enabled status. When the interrupt request level set before executing the “HALT” instruction exceeds the value of interrupt mask register, the interrupt due to the source is processed after releasing the HALT mode, and CPU status executing an instruction that follows the “HALT” instruction. When the interrupt request level set before executing the “HALT” instruction is less than the value of the interrupt mask register, releasing the HALT mode is not executed. (in non-maskable interrupts, interrupt processing is processed after releasing the HALT mode regardless of the value of the mask register.) However only for INT0 to INT7 interrupts, even if the interrupt request level set before executing the halt instruction is less than the value of the interrupt mask register, releasing the HALT mode is executed. In this case, interrupt processing is not performed, and CPU starts executing the instruction next to the halt instruction, but the interrupt request flag is held at “1”.

- Releasing by resetting

Releasing all halt status is executed by resetting.

When the STOP mode is released by RESET, it is necessary enough resetting time (see Table 3.3.4 Example of a setting of Warm-up time of oscillator) to set the operation of the oscillator to be stable.

When releasing the HALT mode by resetting, the internal RAM data keeps the state before the “HALT” instruction is executed. However the other settings contents are initialized. (Releasing due to interrupts keeps the state before the “HALT” instruction is executed.)

Table 3.3.3 Source of Halt State Clearance and Halt Clearance Operation

Status of Received Interrupt			Interrupt Enabled (Interrupt level) \geq (Interrupt mask)			Interrupt Disabled (Interrupt level) $<$ (Interrupt mask)		
HALT Mode			IDLE2	IDLE1	STOP	IDLE2	IDLE1	STOP
Source of Halt State Clearance	Interrupt	NMI	◆	◆	◆ ^{*1}	—	—	—
		INTWDT	◆	×	×	—	—	—
		INT0 to 3 (Note 1)	◆	◆	◆ ^{*1}	○	○	○ ^{*1}
		INT4 to 7 (PORT) (Note 1) (Note 3)	◆	◆	◆ ^{*1}	○	○	○ ^{*1}
		INT4 to 7 (TMRB0 to 1) (Note 3)	◆	×	×	×	×	×
		INT8 to B (PORT) (Note 1) (Note 3)	◆	×	×	×	×	×
		INT8 to B (TMRB2 to 3) (Note 3)	◆	×	×	×	×	×
		INTTA0 to 7	◆	×	×	×	×	×

		KI (Key On WakeUp) (Note 2)	○	○	○ ^{*1}	○	○	○ ^{*1}
		RESET	Initialize LSI					

◆: After clearing the HALT mode, CPU starts interrupt processing.

○: After clearing the HALT mode, CPU resumes executing starting from instruction following the Halt instruction.

×: It can not be used to release the HALT mode.

—: The priority level (interrupt request level) of non-maskable interrupts is fixed to “7”, the highest priority level. There is not this combination type.

*1: Releasing the HALT mode is executed after passing the warm-up time.

Note 1: When the HALT mode is cleared by an INT0 to B interrupt of the level mode in the interrupt enabled status, hold level “H” until starting interrupt processing. If level “L” is set before holding level “L”, interrupt processing is correctly started.

Note 2: Although a KI can cancel all HALT mode states, the function as interruption does not have it.

Note 3: The operation of the HALT release of INT4 to INTB becomes operation of (PORT) when setting it to the INTn input by the port setting. It becomes operation of (TMRB) when setting it to 16 bit timer input.

Note 4: Set the INTSEL register when you use interrupt to which the interrupt factor is used combinedly. Details wish the reference to "Interrupt control of 3.3.4 interrupt controllers (3)".

Example: Releasing IDLE1 mode

An INT0 interrupt clears the halt state when the device is in IDLE1 mode.

Address				
10003H	LD	(IIMC1), 00H	;	Selects INT0 interrupt rising edge.
10006H	LD	(IIMC2), 00H	;	Selects INT0 interrupt edge
10009H	LD	(INTE01), 06H		Sets INT0 interrupt level to 6.
1000CH	EI	5	;	Sets interrupt level to 5 for CPU.
1000EH	LD	(SYSCR2), 28H	;	Sets HALT mode to IDLE1 mode.
10011H	HALT		;	Halts CPU.

(3) Operation

1. IDLE2 mode

In IDLE2 mode only specific internal I/O operations, as designated by the IDLE2 setting register, can take place. Instruction execution by the CPU stops.

Figure 3.3.6 illustrates an example of the timing for clearance of the IDLE2 mode halt state by an interrupt.

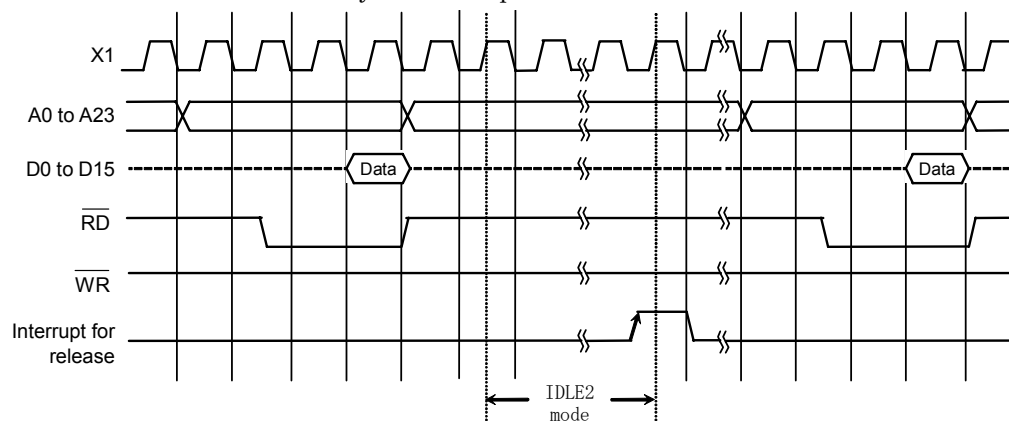

Figure 3.3.6 Timing Chart for IDLE2 Mode Halt State Cleared by Interrupt

2. IDLE1 mode

In IDLE1 mode, only the internal oscillator and Special timer for Clock continue to operate. The system clock stops.

In the halt state, the interrupt request is sampled asynchronously with the system clock; however, clearance of the halt state (e.g., restart of operation) is synchronous with it.

Figure 3.3.7 illustrates the timing for clearance of the IDLE1 mode halt state by an interrupt.

Figure 3.3.7 Timing Chart for IDLE1 Mode Halt State Cleared by Interrupt

3. STOP mode

When STOP mode is selected, all internal circuits stop, including the internal oscillator.

After STOP mode has been cleared system clock output starts when the warm-up time has elapsed, in order to allow oscillation to stabilize.

The example of a setting of the Warm-up time at the time of STOP mode release is shown in Table 3.3.4.

Figure 3.3.8 illustrates the timing for clearance of the STOP mode halt state by an interrupt.

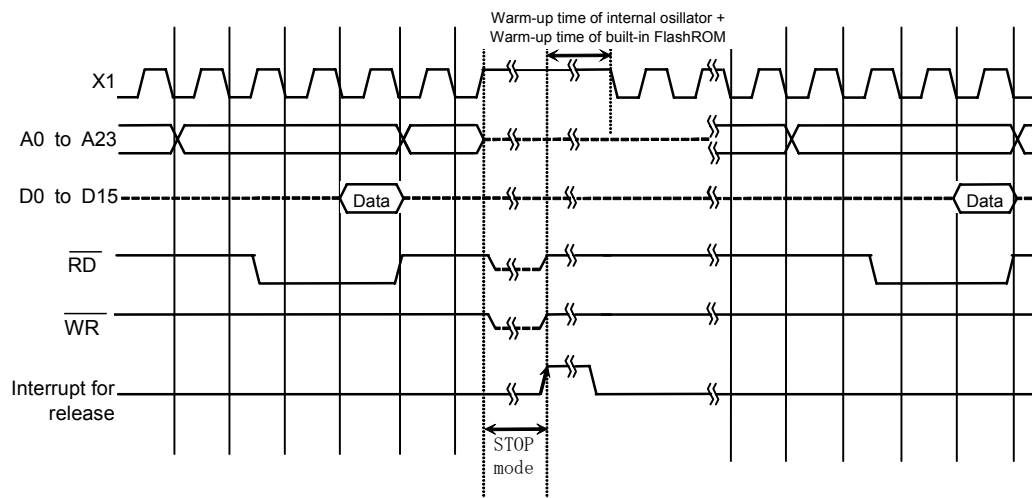

Figure 3.3.8 Timing Chart for STOP Mode Halt State Cleared by Interrupt

Table 3.3.4 Example of a setting of Warm-up time of oscillator (at the time of STOP mode release)

at $f_{OSCH} = 16 \text{ MHz}$

SYSCR2<WUPTM1:0>		
01 (2^8)	10 (2^{14})	11 (2^{16})
16 μs	1.024 ms	4.096 ms

3.4 Interrupt

Interrupts of TLCS-900/H1 are controlled by the CPU interrupt mask flip-flop (IFF2:0) and by the built-in interrupt controller.

The TMP92CM27 has a total of 71 interrupts divided into the following types:

- Interrupts generated by CPU: 9 sources
(Software interrupts: 8 sources, illegal instruction interrupt: 1 source)
- External interrupts ($\overline{\text{NMI}}$ and INT0 to INTB): 13 sources
- Internal I/O interrupts: 41 sources
- Micro DMA transfer end interrupts: 8 sources

A individual interrupt vector number (Fixed) is assigned to each interrupt.

One of six priority level (Variable) can be assigned to each maskable interrupt.

The priority level of non-maskable interrupts are fixed at “7” as the highest level.

When an interrupt is generated, the interrupt controller sends the priority of that interrupt to the CPU. If multiple interrupts are generated simultaneously, the interrupt controller sends the interrupt with the highest priority to the CPU. (The highest priority is level 7 using for non-maskable interrupts.)

The CPU compares the priority level of the interrupt with the value of the CPU interrupts mask register <IFF2:0>. If the priority level of the interrupt is higher than the value of the interrupt mask register, the CPU accepts the interrupt.

The interrupt mask register <IFF2:0> value can be updated using the value of the EI instruction (EI num sets <IFF2:0> data to num).

For example, specifying “EI3” enables the maskable interrupts which priority level set in the interrupt controller is 3 or higher, and also non-maskable interrupts.

Operationally, the DI instruction (<IFF2:0> = 7) is identical to the EI7 instruction. DI instruction is used to disable maskable interrupts because of the priority level of maskable interrupts is 0 to 6. The EI instruction is valid immediately after execution.

In addition to the above general-purpose interrupt processing mode, TLCS-900/H1 has a micro DMA interrupt processing mode as well. The CPU can transfer the data (1/2/4 bytes) automatically in micro DMA mode, therefore this mode is used for speed-up interrupt processing, such as transferring data to the internal or external peripheral I/O. Moreover, TMP92CM27 has software start function for micro DMA processing request by the software not by the hardware interrupt.

Figure 3.4.1 shows the overall interrupt processing flow.

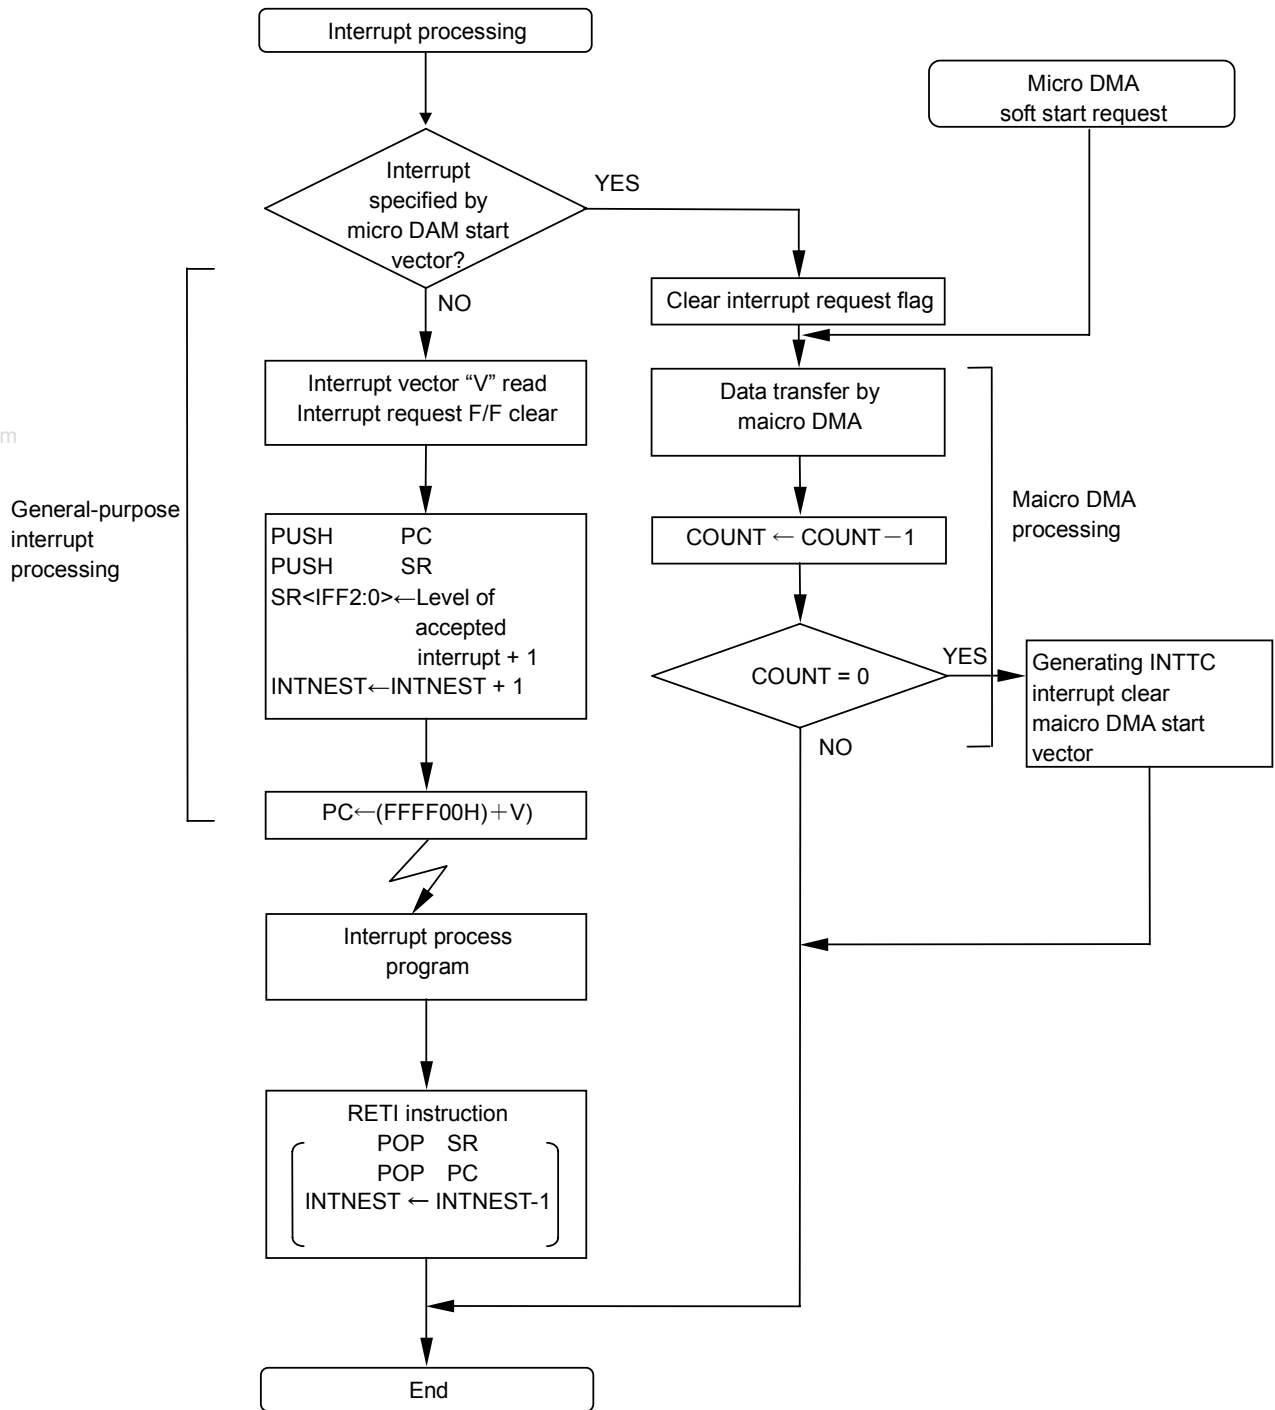

Figure 3.4.1 Interrupt and Micro DMA Processing Sequence

3.4.1 General-purpose Interrupt Processing

When the CPU accepts an interrupt, it usually performs the following sequence of operations. However, when a software interrupt and illegal instruction interrupt are generated by CPU, CPU flies (1) and (3) and performs only the process of (2), (4), and (5).

- (1) The CPU reads the interrupt vector from the interrupt controller.
If the same level interrupts occur simultaneously, the interrupt controller generates an interrupt vector in accordance with the default priority and clears the interrupt request.
(The default priority is already fixed for each interrupt: The smaller vector value has the higher priority level.)
- (2) The CPU pushes the value of program counter (PC) and status register (SR) onto the stack area (indicated by XSP).
- (3) The CPU sets the value which is the priority level of the accepted interrupt plus 1 (+1) to the interrupt mask register <IFF2:0>. However, if the priority level of the accepted interrupt is "7", the register's value is set to "7".
- (4) The CPU increases the interrupt nesting counter INTNEST by 1 (+1).
- (5) The CPU jumps to the address indicated by the data at address "FFFF00H + Interrupt vector" and starts the interrupt processing routine.

When the CPU completed the interrupt processing, use the "RETI" instruction to return to the main routine. "RETI" restores the contents of program counter (PC) and status register (SR) from the stack and decreases the interrupt nesting counter INTNEST by 1(-1).

Non-maskable interrupts cannot be disabled by a user program. However maskable interrupts can be enabled or disabled by a user program. A program can set the priority level for each interrupt source. (A priority level setting of 0 or 7 will disable an interrupt request.)

If an interrupt request which has a priority level equal to or greater than the value of the CPU interrupt mask register <IFF2:0> comes out, the CPU accepts its interrupt. Then, the CPU interrupt mask register <IFF2:0> is set to the value of the priority level for the accepted interrupt plus 1(+1). Therefore, if an interrupt is generated with a higher level than the current interrupt during its processing, the CPU accepts the later interrupt and goes to the nesting status of interrupt processing.

Moreover, if the CPU receives another interrupt request while performing the said (1) to (5) processing steps of the current interrupt, the latest interrupt request is sampled immediately after execution of the first instruction of the current interrupt processing routine. Specifying "DI" as the start instruction disables maskable interrupt nesting.

A reset initializes the interrupt mask register <IFF2:0> to "7", disabling all maskable interrupts.

Table 3.4.1 shows the TMP92CM27 interrupt vectors and micro DMA start vectors. The address FFFF00H to FFFFFFFH (256 bytes) is assigned for the interrupt vector area.

Table 3.4.1 TMP92CM27 Interrupt Vectors and Micro DMA Start Vectors

Default Priority	Type	Interrupt Source	Vector Value	Address Refer to Vector	Micro DMA Start Vector
1	Non-maskable	Reset or "SWI0" instruction	0000H	FFFF00H	
2		"SWI1" instruction	0004H	FFFF04H	
3		"Illegal instruction" or "SWI2" instruction	0008H	FFFF08H

60		INTTC7: Micro DMA end (Channel 7)	00ECH	FFFFECH	3BH
- to -		(Reserved)	00F0H : 00FCH	FFFFF0H : FFFFFCH	- to -

Note 1: When standing-up micro DMA, set at edge detect mode.

Note 2: The default priorities 24, 26, 47 to 49 are making the interruption factor serve a double purpose. It is necessary to choose the interruption factor used in an interruption factor selection register. Therefore, interruption cannot be used simultaneously.

Note 3: The default priority 50 is making the interruption factor serve a double purpose. The interruption factor assigned to this default priority 50 can be used simultaneously. Of which interruption factor interruption occurred should interrupt, and please check it in a generating flag register.

Note 4: Micro DMA stands up prior to other maskable interrupt.

3.4.2 Micro DMA

In addition to general purpose interrupt processing, the TMP92CM27 also includes a micro DMA function. Micro DMA processing for interrupt requests set by micro DMA is performed at the highest priority level for maskable interrupts (level 6), regardless of the priority level of the interrupt source.

Because the micro DMA function has been implemented with the cooperative operation of CPU, when CPU is a stand-by state by HALT instruction, the requirement of micro DMA will be ignored (pending).

Micro DMA is supported 8 channels and can be transferred continuously by specifying the micro DMA burst function in the following.

(1) Micro DMA operation

When an interrupt request specified by the micro DMA start vector register is generated, the micro DMA triggers a micro DMA request to the CPU at interrupt priority highest level and starts processing the request in spite of any interrupt source's level. The micro DMA is ignored on $\langle \text{IFF2:0} \rangle = "7"$. The 8 micro DMA channels allow micro DMA processing to be set for up to 8 types of interrupts at any one time.

When micro DMA is accepted, the interrupt request flip-flop assigned to that channel is cleared. The data are automatically transferred once (1/2/4 bytes) from the transfer source address to the transfer destination address set in the control register, and the transfer counter is decreased by 1 (-1).

If the decreased result is "0",

- CPU send micro DMA transfer end interrupt (INTTCn) to interrupt controller
- Interrupt controller is generated micro DMA transfer end interrupt
- Micro DMA start vector register is cleared to "0", the next micro DMA operation is disabled
- Micro DMA processing terminates

If the decreased result is not "0", the micro DMA processing completes if it isn't specified the say later burst mode. In this case, the micro DMA transfer end interrupt (INTTCn) aren't generated.

If an interrupt request is triggered for the interrupt source in use during the interval between the time at which the micro DMA start vector is cleared and the next setting, general-purpose interrupt processing is performed at the interrupt level set. Therefore, if the interrupt is only being used to initiate micro DMA (and not as a general-purpose interrupt), the interrupt level should first be set to "0" (e.g., interrupt requests should be disabled).

The priority of the micro DMA transfer end interrupt is defined by the interrupt level and the default priority as the same as the other maskable interrupt. If a micro DMA request is set for more than one channel at the same time, the priority is not based on the interrupt priority level but on the channel number. The smaller channel number has the higher priority (Channel 0 (High) > Channel 7 (Low)).

While the register for setting the transfer source/transfer destination addresses is a 32-bit control register, this register can only effectively output 24-bit addresses. Accordingly, micro DMA can access 16 Mbytes.

Three micro DMA transfer modes are supported: one-byte transfers, 2-byte transfer and 4-byte transfer. After a transfer in any mode, the transfer source and transfer destination

addresses will either be incremented or decremented, or will remain unchanged. This simplifies the transfer of data from memory to memory, from I/O to memory, from memory to I/O, and from I/O to I/O. For details of the various transfer modes, refer Section 3.4.2 (4) “Detailed description of the transfer mode register”.

Since a transfer counter is a 16-bit counter, up to 65536 micro DMA processing operations can be performed per interrupt source (Provided that the transfer counter for the source is initially set to 0000H).

Micro DMA processing can be initiated by any one of 51 different interrupts – the 50 interrupts shown in the micro DMA start vectors in Table 3.4.1 and a micro DMA soft start.

Figure 3.4.2 shows micro DMA cycle in transfer destination address INC mode (Micro DMA transfers are the same in every mode except counter mode). (The conditions for this cycle are as follows: Both source and destination memory are internal RAM and multiples by 4 numbered source and destination addresses.)

(Note) Actually, src and dst address are not output to A23 to A0 pins because they are address of internal RAM.

Figure 3.4.2 Timing for Micro DMA Cycle

- State (1),(2): Instruction fetch cycle (Prefetches the next instruction code)
- State (3) : Micro DMA read cycle
- State (4) : Micro DMA write cycle
- State (5) : (The same as in state (1), (2))

(2) Soft start function

In addition to starting the micro DMA function by interrupts, TMP92CM27 includes a micro DMA software start function that starts micro DMA on the generation of the write cycle to the DMAR register.

Writing “1” to each bit of DMAR register causes micro DMA once. At the end of transfer, the corresponding bit of the DMAR register is automatically cleared to “0”.

Only one channel can be set once for micro DMA.

When programming again “1” to the DMAR register, check whether the bit is “0” before programming “1”.

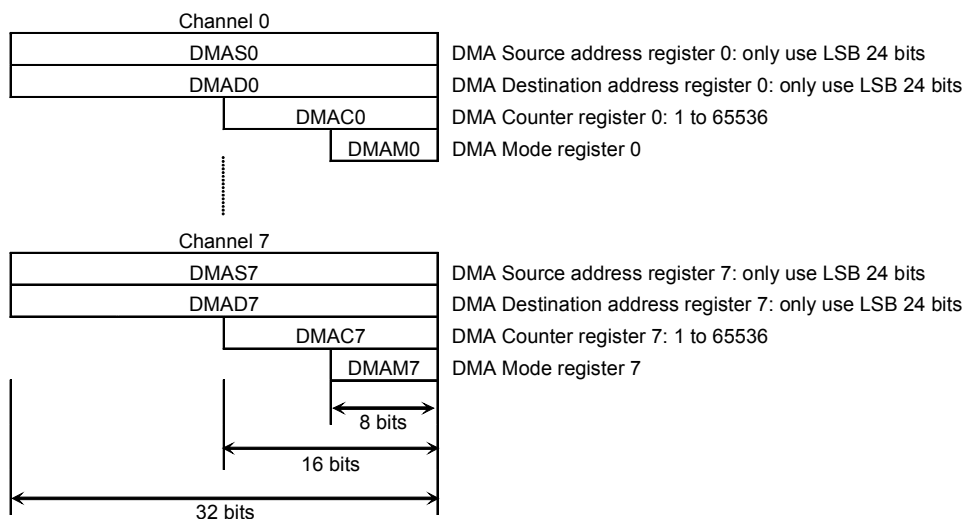

When a burst is specified by DMAB register, data is continuously transferred until the value in the micro DMA transfer counter is “0” after start up of the micro DMA.

			R/W							
			0	0	0	0	0	0	0	0

(3) Transfer control registers

The transfer source address and the transfer destination address are set in the following registers. Data setting for these registers is done by an “LDC cr, r” instruction.

(4) Detailed description of the transfer mode register

DMAMn[4:0]	Operation	Execution Time
0 0 0 z z	Destination address INC mode (DMADn +) \leftarrow (DMASn) DMACn \leftarrow DMACn - 1 If DMACn = 0 then INTTCn	5 states
0 0 1 z z	Destination address DEC mode (DMADn -) \leftarrow (DMASn) DMACn \leftarrow DMACn - 1 If DMACn = 0 then INTTCn	5 states
0 1 0 z z	Source address INC mode (DMADn) \leftarrow (DMASn +) DMACn \leftarrow DMACn - 1 If DMACn = 0 then INTTCn	5 states
0 1 1 z z	Source address DEC mode (DMADn) \leftarrow (DMASn -) DMACn \leftarrow DMACn - 1 If DMACn = 0 then INTTCn	5 states
1 0 0 z z	Source address and Destination address INC mode (DMADn +) \leftarrow (DMASn +) DMACn \leftarrow DMACn - 1 If DMACn = 0 then INTTCn	6 states
1 0 1 z z	Source address and Destination address DEC mode (DMADn -) \leftarrow (DMASn -) DMACn \leftarrow DMACn - 1 If DMACn = 0 then INTTCn	6 states
1 1 0 z z	Source address and Destination address Fixed mode (DMADn) \leftarrow (DMASn) DMACn \leftarrow DMACn - 1 If DMACn = 0 then INTTCn	5 states
1 1 1 0 0	Counter mode DMASn \leftarrow DMASn + 1 DMACn \leftarrow DMACn - 1 If DMACn = 0 then INTTCn	5 states

ZZ:

- 00 = 1-byte transfer
- 01 = 2-byte transfer
- 10 = 4-byte transfer
- 11 = (Reserved)

Note1: N stands for the micro DMA channel number (0 to 7)

DMADn+/DMASn+: Post-increment (register value is incremented after transfer)

DMADn-/DMASn-: Post-decrement (register value is decremented after transfer)

"I/O" signifies fixed memory addresses; "memory" signifies incremented or decremented memory addresses.

Note2: The transfer mode register should not be set to any value other than those listed above.

Note3: The execution state number shows number of best case (1-state memory access).

3.4.3 Interrupt Controller Operation

The block diagram in Figure 3.4.3 shows the interrupt circuits. The left-hand side of the diagram shows the interrupt controller circuit. The right-hand side shows the CPU interrupt request signal circuit and the halt release circuit.

For each of the 62 interrupts channels there is an interrupt request flag (Consisting of a flip-flop), an interrupt priority setting register and a micro DMA start vector register. The interrupt request flag latches interrupt requests from the peripherals.

The flag is cleared to zero in the following cases:

- When reset occurs
- When the CPU reads the channel vector after accepted its interrupt
- When executing an instruction that clears the interrupt (Write DMA start vector to INTCLR register)
- When the CPU receives a micro DMA request
- When the micro DMA burst transfer is terminated

An interrupt priority can be set independently for each interrupt source by writing the priority to the interrupt priority setting register (e.g., INTEPAD or INTB01). 6 interrupt priorities levels (1 to 6) are provided. Setting an interrupt source's priority level to 0 (or 7) disables interrupt requests from that source. If interrupt request with the same level are generated at the same time, the default priority (The interrupt with the lowest priority or, in other words, the interrupt with the lowest vector value) is used to determine which interrupt request is accepted first.

The 3rd and 7th bits of the interrupt priority setting register indicate the state of the interrupt request flag and thus whether an interrupt request for a given channel has occurred.

The interrupt controller sends the interrupt request with the highest priority among the simultaneous interrupts and its vector address to the CPU. The CPU compares the priority value <IFF2:0> in the status register by the interrupt request signal with the priority value set; if the latter is higher, the interrupt is accepted. Then the CPU sets a value higher than the priority value by 1 (+1) in the CPU SR<IFF2:0>. Interrupt request where the priority value equals or is higher than the set value are accepted simultaneously during the previous interrupt routine.

When interrupt processing is completed (after execution of the RETI instruction), the CPU restores the priority value saved in the stack before the interrupt was generated to the CPU SR<IFF2:0>.

The interrupt controller also has registers (8 channels) used to store the micro DMA start vector. Writing the start vector of the interrupt source for the micro DMA processing (See Table 3.4.1), enables the corresponding interrupt to be processed by micro DMA processing. The values must be set in the micro DMA parameter register (e.g., DMAS and DMAD) prior to the micro DMA processing.

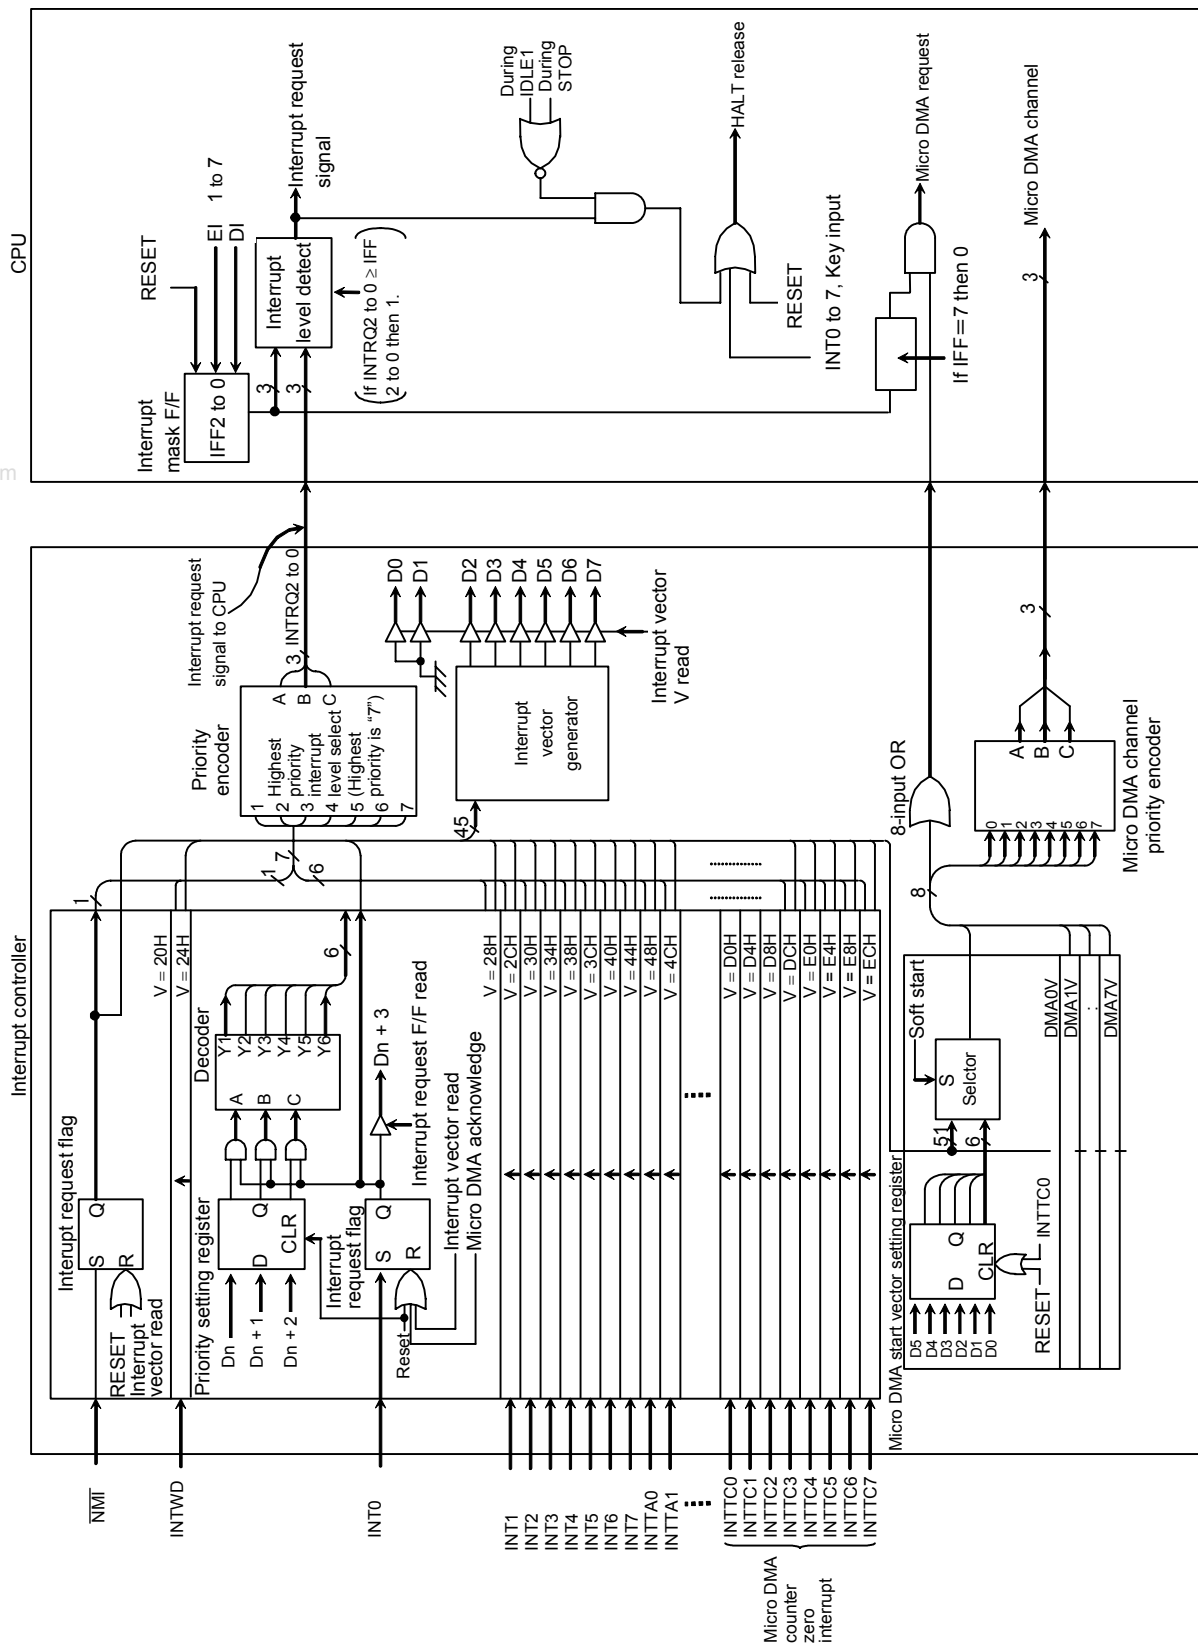

Figure 3.4.3 Block Diagram of Interrupt Controller

Note 1: The default priorities 24, 26, 47 to 49 are making the interruption factor serve a double purpose. It is necessary to choose the interruption factor used in an interruption factor selection register. Therefore, interruption cannot be used simultaneously.

Note 2: The default priority 50 is making the interruption factor serve a double purpose. The interruption factor assigned to this default priority 50 can be used simultaneously. Of which interruption factor interruption occurred should interrupt, and please check it in a generating flag register.

Note 3: The interruption level setting register of combination interruption should clear an interruption demand flag in an INTCLR register, before changing an INTSEL register.
Moreover, re-set an interrupt level as a desired level.

(4) Interrupt request flag clear register

The interrupt request flag is cleared by writing the appropriate micro DMA start vector.

For example, to clear the interrupt flag INT0, perform the following register operation **after execution of the DI instruction**.

INTCLR ← 0AH Clears interrupt request flag INT0

Symbol	NAME	address	7	6	5	4	3	2	1	0
INTCLR	Interrupt clear control	F8H (Prohibit RMW)	-	-	-	-	-	-	-	-
			W							
			0	0	0	0	0	0	0	0
			Interrupt vector							

www.DataSheet4U.com

(5) Micro DMA start vector registers

This register assigns micro DMA processing to which interrupt source. The interrupt source with a micro DMA start vector that matches the vector set in this register is assigned as the micro DMA start source.

When the micro DMA transfer counter value reaches “0”, the micro DMA transfer end interrupt corresponding to the channel is sent to the interrupt controller, the micro DMA start vector register is cleared, and the micro DMA start source for the channel is cleared. Therefore, to continue micro DMA processing, set the micro DMA start vector register again during the processing of the micro DMA transfer end interrupt.

If the same vector is set in the micro DMA start vector registers of more than one channel, the channel with the lowest number has a higher priority. Accordingly, if the same vector is set in the micro DMA start vector registers of two channels, the interrupt generated in the channel with the lower number is executed until micro DMA transfer is completed. If the micro DMA start vector for this channel is not set again, the next micro DMA is started for the channel with the higher number (Micro DMA chaining).

Symbol	NAME	address	7	6	5	4	3	2	1	0

					DMA7V5	DMA7V4	DMA7V3	DMA7V2	DMA7V1	DMA7V0
					R/W					
					0	0	0	0	0	0

(6) Specification of a micro DMA burst

Specifying the micro DMA burst function causes micro DMA transfer, once started, to continue until the value in the transfer counter register reaches 0. Setting any of the bits in the register DMAB which correspond to a micro DMA channel (as shown below) to 1 specifies that any micro DMA transfer on that channel will be a burst transfer.

Symbol	NAME	address	7	6	5	4	3	2	1	0
DMAB	DMA burst	108H	DBST7	DBST6	DBST5	DBST4	DBST3	DBST2	DBST1	DBST0
			R/W							
			0	0	0	0	0	0	0	0

(7) Notes

The instruction execution unit and the bus interface unit in this CPU operate independently. Therefore if, immediately before an interrupt is generated, the CPU fetches an instruction which clears the corresponding interrupt request flag (Note), the CPU may execute this instruction in between accepting the interrupt and reading the interrupt vector. In this case, the CPU will read the default vector 0004H and jump to interrupt vector address FFFF04H.

To avoid this, an instruction which clears an interrupt request flag should always be placed after a "DI" instruction. And in the case of setting an interrupt enable again by "EI" instruction after the execution of clearing instruction, execute "EI" instruction after clearing and more than 3-instructions (e.g., "NOP"× 1 times).

If placed "EI" instruction without waiting "NOP" instruction after execution of clearing instruction, interrupt will be enable before request flag is cleared. Thus, when be changed interrupt request level to "0", change it after cleared corresponding interrupt request by INTCLR instruction.

In the case of changing the value of the interrupt mask register <IFF2:0> by execution, disable an interrupt by "DI" instruction before execution of POP SR instruction.

In addition, please note that the following two circuits are exceptional and demand special attention.

INT0 to INTB level mode	<p>In level mode INT0 to INTB are not an edge-triggered interrupt. Hence, in level mode the interrupt request flip-flop for INT0 to INTB does not function. The peripheral interrupt request passes through the S input of the flip-flop and becomes the Q output. If the interrupt input mode is changed from edge mode to level mode, the interrupt request flag is cleared automatically.</p> <p>If the CPU enters the interrupt response sequence as a result of INT x (x = 0 to 7) going from "0" to "1", INTx must then be held at "1" until the interrupt response sequence has been completed. If INTx is set to Level mode so as to release a Halt state, INTx must be held at "1" from the time INTx changes from "0" to "1" until the Halt state is released. (Hence, it is necessary to ensure that input noise is not interpreted as a "0", causing INTx to revert to "0" before the Halt state has been released.)</p> <p>When the mode changes from level mode to edge mode, interrupt request flags which were set in level mode will not be cleared. Interrupt request flags must be cleared using the following sequence.</p> <pre> DI LD (IIMC2),00H ; Changes from level to edge. LD (INTCLR),0AH ; Clears interrupt request flag. NOP ; Wait EI execution. NOP NOP EI </pre>
INTRX0 to INTRX3	The interrupt request flip-flop can only be cleared by a reset or by reading the serial channel receive buffer. It cannot be cleared by an instruction.

Note: The following instructions or pin input state changes are equivalent to instructions that clear the interrupt request flag.

INT0 to INT 7: Instructions which switch to level mode after an interrupt request has been generated in edge mode.

The pin input change from high to low after interrupt request has been generated in level mode. ("H" → "L", "L" → "H")

INTRX0 to INTRX2: Instruction which read the receive buffer.

(8) About combination of an interruption factor

About the following interruption factor, interruption is made to serve a double purpose. Cautions are needed when using it.

1)INT8/INTTA5

The interruption table / interruption level setting register is made to serve a double purpose. Therefore, it cannot be used simultaneously. Micro DMA starting is also that only which or one of the two can be used. In order to change the interruption factor to be used, it is necessary to set up INTSEL<DP24SEL>. It disappears, even if interruption of INTTA5(8-bit timer 5) will occur, if INTSEL<DP24SEL> is set as "1." It disappears, even if interruption of INT8(INT8 terminal input) will occur, if INTSEL<DP24SEL> is set as "0."

www.DataSheet4U.com

2)INT9/INTTA7

The interruption table / interruption level setting register is made to serve a double purpose. Therefore, it cannot be used simultaneously. Micro DMA starting is also that only which or one of the two can be used. In order to change the interruption factor to be used, it is necessary to set up INTSEL<DP26SEL>. It disappears, even if interruption of INTTA7(8-bit timer 7) will occur, if INTSEL<DP26SEL> is set as "1." It disappears, even if interruption of INT9(INT9 terminal input) will occur, if INTSEL<DP26SEL> is set as "0."

3)INTTB31/INTTB30

The interruption table / interruption level setting register is made to serve a double purpose. Therefore, it cannot be used simultaneously. Micro DMA starting is also that only which or one of the two can be used. In order to change the interruption factor to be used, it is necessary to set up INTSEL<DP47SEL>. It disappears, even if interruption of INTTB30(16-bit timer 3) will occur, if INTSEL<DP47SEL> is set as "1." It disappears, even if interruption of INTTB31(16-bit timer 3) will occur, if INTSEL<DP47SEL> is set as "0."

4)INTTB41/INTTB40

The interruption table / interruption level setting register is made to serve a double purpose. Therefore, it cannot be used simultaneously. Micro DMA starting is also that only which or one of the two can be used. In order to change the interruption factor to be used, it is necessary to set up INTSEL<DP48SEL>. It disappears, even if interruption of INTTB40(16-bit timer 4) will occur, if INTSEL<DP48SEL> is set as "1." It disappears, even if interruption of INTTB41(16-bit timer 4) will occur, if INTSEL<DP48SEL> is set as "0."

5)INTTB51/INTTB50

The interruption table / interruption level setting register is made to serve a double purpose. Therefore, it cannot be used simultaneously. Micro DMA starting is also that only which or one of the two can be used. In order to change the interruption factor to be used, it is necessary to set up INTSEL<DP49SEL>. It disappears, even if interruption of INTTB50(16-bit timer 5) will occur, if INTSEL<DP49SEL> is set as "1." It disappears, even if interruption of INTTB51(16-bit timer 5) will occur, if INTSEL<DP49SEL> is set as "0."

When you change an interruption factor, please change in the following procedures.

It interrupts, an interruption level setting register is set as the ban on a demand, and an interruption demand flag is cleared. It is set as the interruption factor which uses an interruption combination selection register. An interrupt level is set as an interrupt level setting register.

3.5 Function Ports

TMP92CM27 has I/O port pins that are shown in Table 3.5.1 in addition to functioning as general-purpose I/O ports, these pins are also used by internal CPU and I/O functions. list I/O registers and their specifications.

Table 3.5.1 Port Function(R: PD = with programmable pull-down register, U = with pull-up register) (1/2)

ON : The buffer is always turned on. A current flows the input buffer if the input pin is not driven.

OFF : The buffer is always turned off.

- : No applicable

*1 : Port having a pull-up/pull-down resistor.

*2 : AIN input does not cause a current to flow through the buffer.

*3 : It becomes an input port after reset and an input buffer turns on during reset at AM 0= 0 and AM1= 1.

ON : The buffer is always turned on.

However, the output buffer of a specific terminal turns OFF at the time of bus release.

OFF : The buffer is always turned off.

- : No applicable

*1 : Port having a pull-up/pull-down resistor.

3.5.1 Port 1 (P10 to P17)

Port1 is 8-bit general-purpose I/O port. Bits can be individually set as either inputs or outputs by control register P1CR and function register P1FC. In addition to functioning as a general-purpose I/O port, port1 can also function as a data bus (D8 to D15). Moreover, with the combination of AM1 and AM0 shown below, Port1 is set as the following function after reset release.

AM1	AM0	Function Setting after Reset is Released
0	0	Don't use this setting
0	1	Data bus (D8 to D15)
1	0	Input port (P10 to P17)
1	1	Don't use this setting

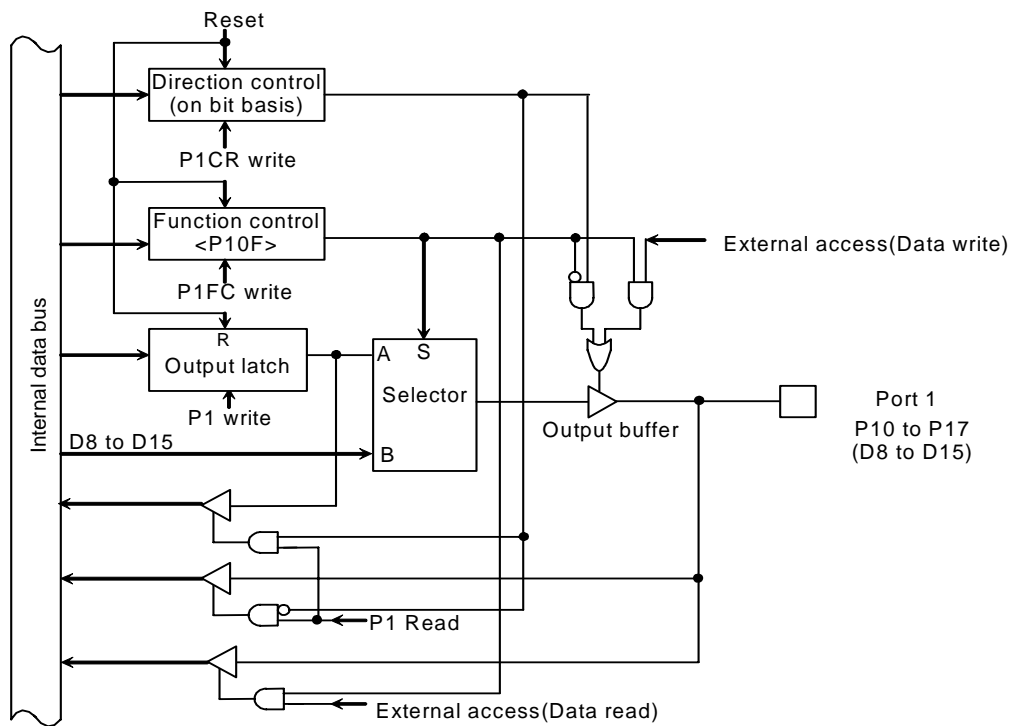

Figure 3.5.1 Port 1

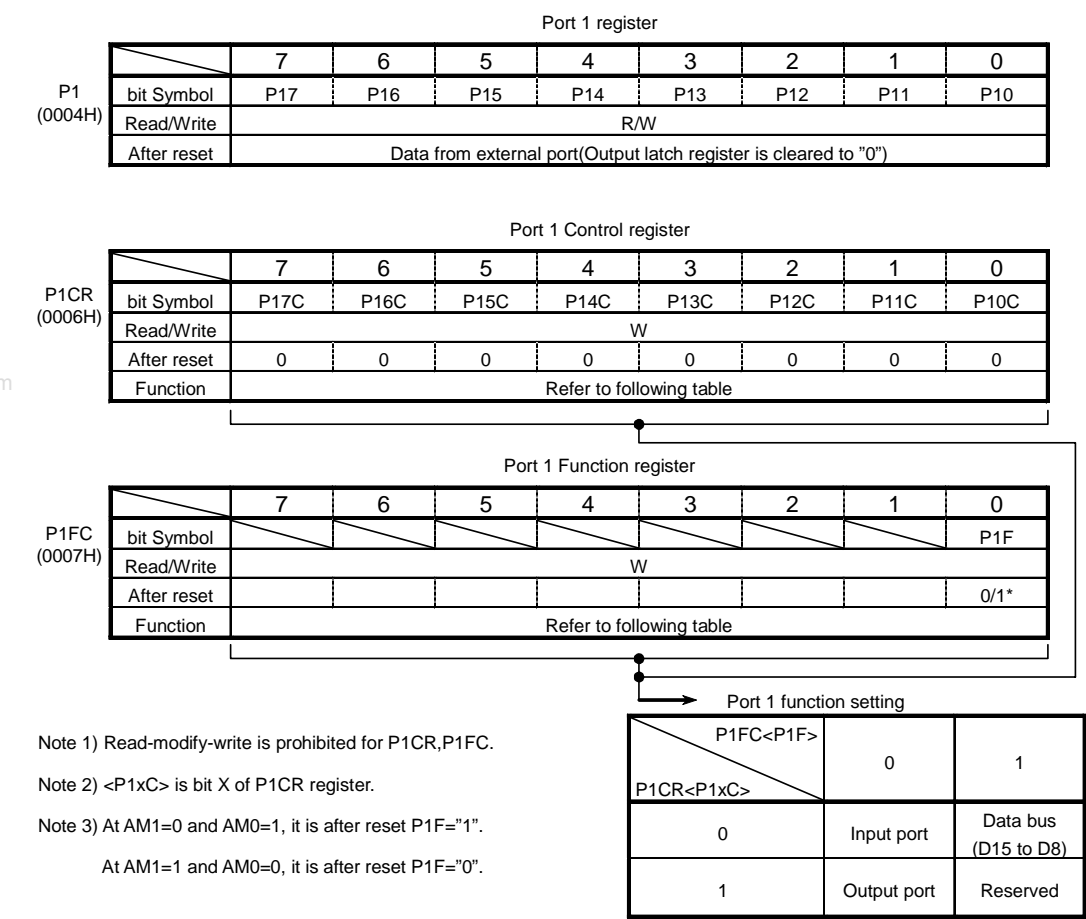

Figure 3.5.2 Port 1 register

3.5.2 Port 6 (P60 to P67)

Port6 is 8-bit general-purpose I/O port. Bits can be individually set as either inputs or outputs by control register P6CR and function register P6FC. In addition to functioning as a general-purpose I/O port, port6 can also function as an address bus (A16 to A23). Moreover, with the combination of AM1 and AM0 shown below, Port6 is set as the following function after reset release.

AM1	AM0	Function Setting after Reset is Released
0	0	Don't use this setting
0	1	Address bus(A16 to A23)
1	0	Address bus(A16 to A23)
1	1	Don't use this setting

Figure 3.5.4 Port 6 register

Note) Read-modify-write is prohibited for P6CR,P6FC.

3.5.3 Port 7 (P71 to P77)

Port 71 to P77 is a 7-bit general-purpose I/O port. Bits can be individually set as either inputs or outputs by control register P7CR and function register P7FC. Moreover, P71, P72 and P74 to P76 are ports with pull-up resistance. There is an external memory interface function in addition to a general-purpose I/O port function. P71 to P77 become input mode after reset.

(1)P71,P72,P74,P75,P76

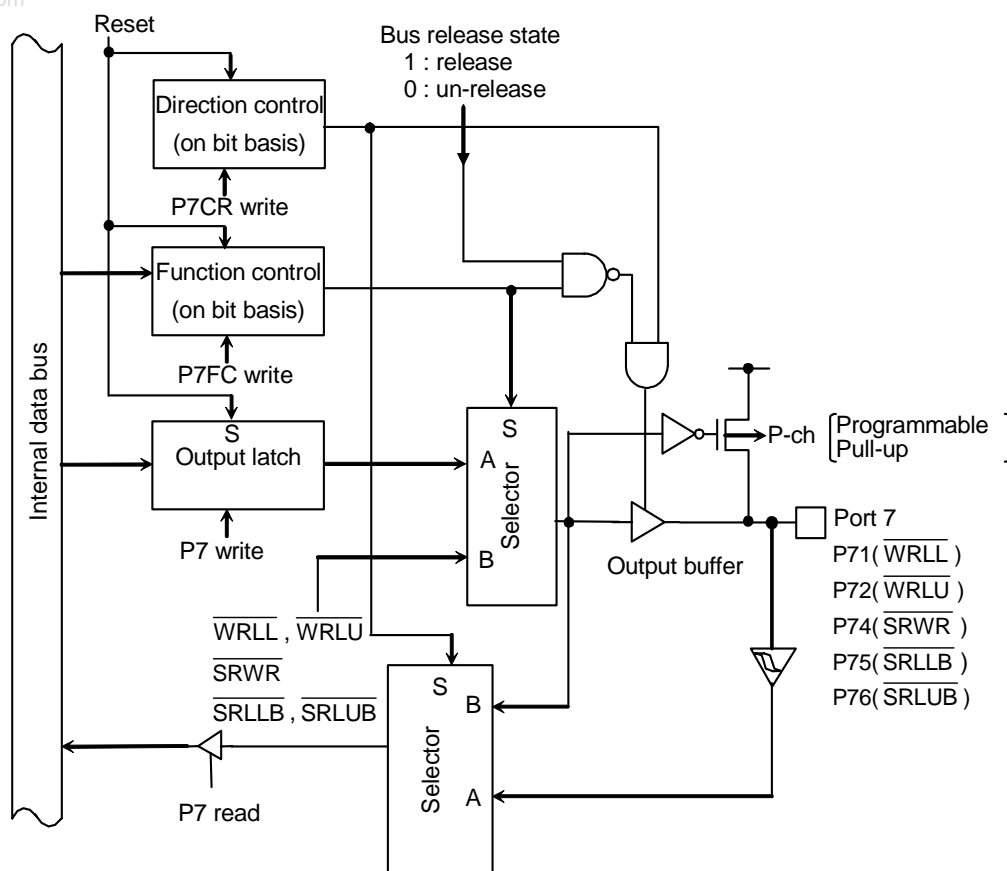

Figure 3.5.5 Port 7(P71,P72,P74,P75,P76)

Note) When a terminal is set as $\overline{\text{WRLL}}$, $\overline{\text{WRLU}}$, $\overline{\text{SRWR}}$, $\overline{\text{SRLB}}$, $\overline{\text{SRLUB}}$ and $\overline{\text{WAIT}}$, at the time of bus release, an output buffer is not concerned with an output setup of control register P7CR, but is turned OFF.

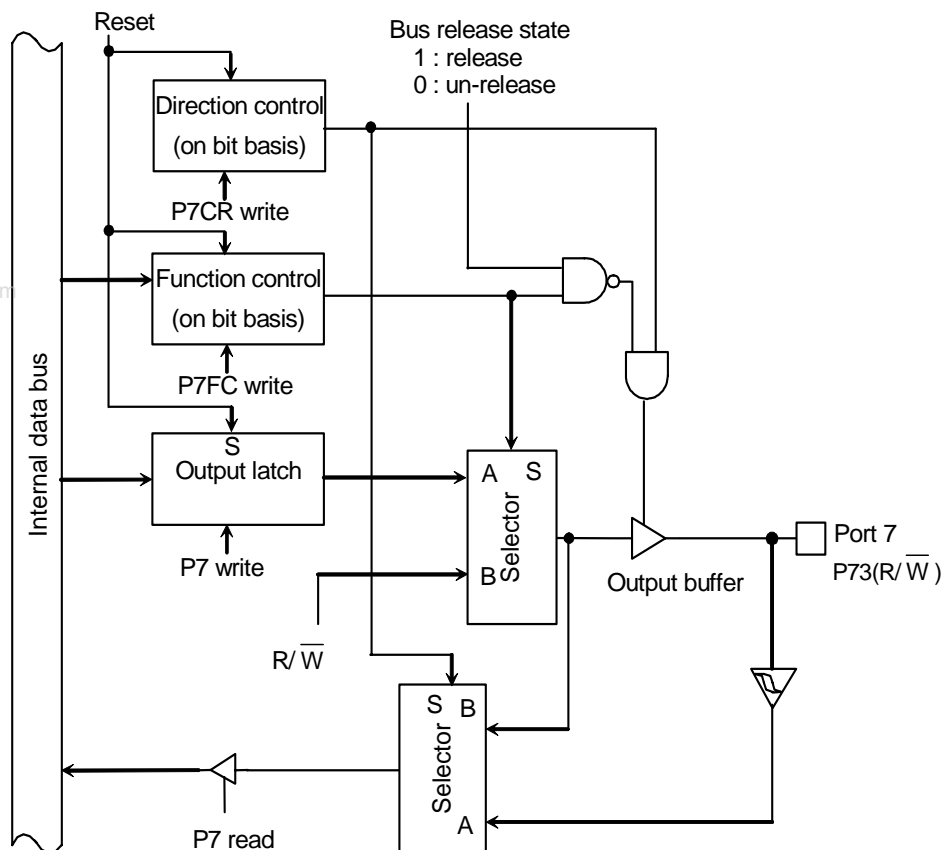

(2) P73 (R/\overline{W})

Figure 3.5.6 Port 7(P73)

Note) When a terminal is set as R/\overline{W} , at the time of bus release, an output buffer is not concerned with an output setup of control register P7CR, but is turned OFF.

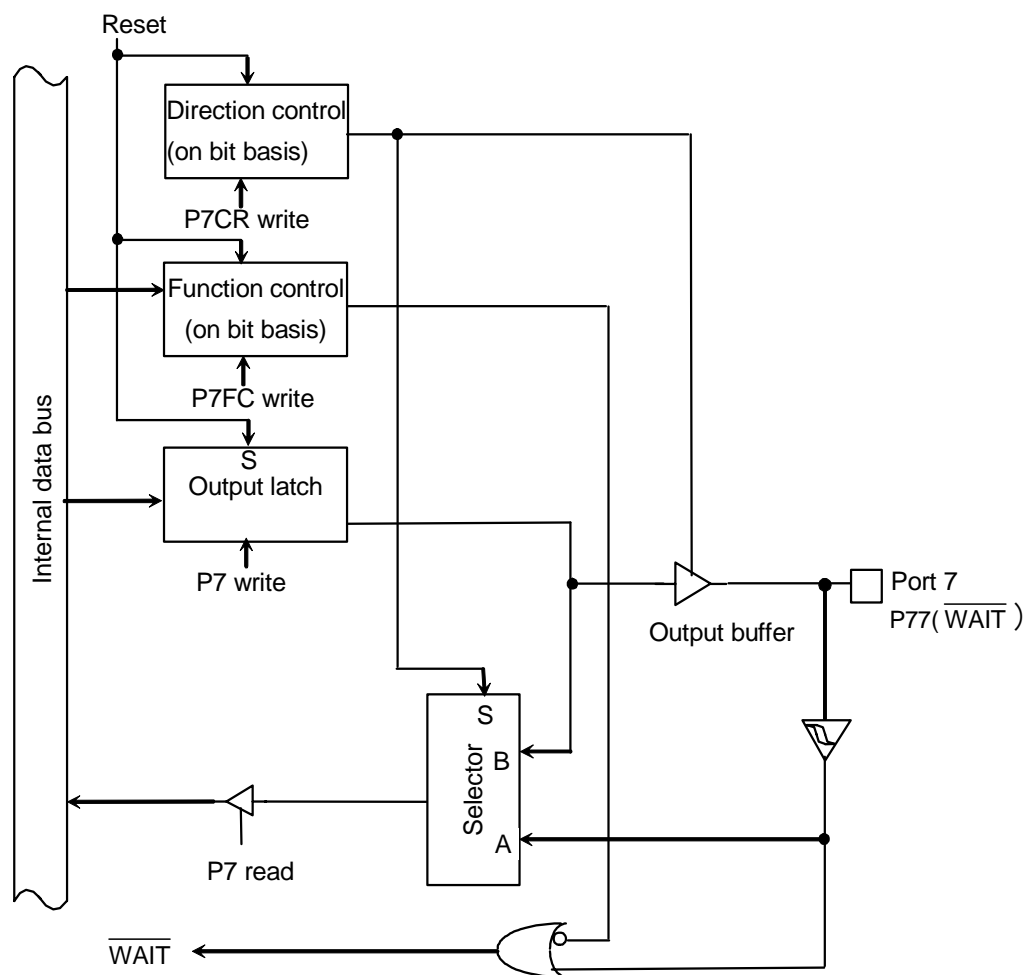

(3) P77($\overline{\text{WAIT}}$)

Note 1) When using P71, P72 and P74 to P76 in input mode, built-in pull-up resistance is controlled by port7 register. When using it, making input mode or I/O mode intermingled, a Read-modify-write is forbidden (When at least 1 bit of input terminals exists). A setup of built-in pull-up resistance may change according to the state of an input terminal.

Note 2) Read-modify-write is prohibited for P7CR and P7FC.

Note 3) In the case of a port function, about pull-up ON/OFF, it controls by the value of P7. When using it as a function, it controls by the value of a function.

Figure 3.5.8 Port 7 register

3.5.4 Port 8 (P80 to P87)

P80 to P85 are a port only for outputs. P86 and P87 are general-purpose I/O ports.

There are the following functions in addition to an output and a general-purpose I/O port.

- The output function of a standard chip select signal($\overline{CS0}$, $\overline{CS1}$, $\overline{CS2}$, $\overline{CS3}$, $\overline{CS4}$, $\overline{CS5}$).
- The output function of the chip select signal for SDRAM(\overline{SDCS}).
- The I/O function of a bus release function(\overline{BUSRQ} , \overline{BUSAK}).
- The output function of a watchdog timer(\overline{WDTOUT}).

These functions operate by setting the bit concerned of P8CR, P8FC and P8FC2 register. The value of each register of P8CR, P8FC, and P8FC2 is reset in "0" by the reset operation, P80 to P84 becomes an output port, P85 becomes \overline{WDTOUT} output, and P86 and P87 become the input ports. Moreover, P82 is reset in "0" as for the output latch, and P80, P81, and P83 to P87 are set in "1".

(1) P80($\overline{CS0}$), P81($\overline{CS1}$), P84($\overline{CS4}$)

P80, P81, and P84 function as standard chip select signal output ($\overline{CS0}$, $\overline{CS1}$, $\overline{CS4}$) besides the output port function.

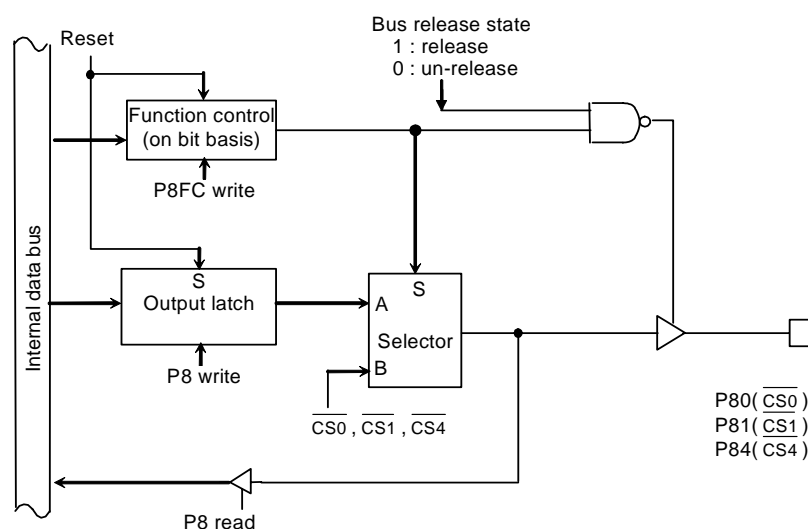

Figure 3.5.9 Port 8(P80,P81,P84)

(2) P82($\overline{\text{CS2}}$)

P82 functions as standard chip select signal output ($\overline{\text{CS2}}$) besides the output port function.

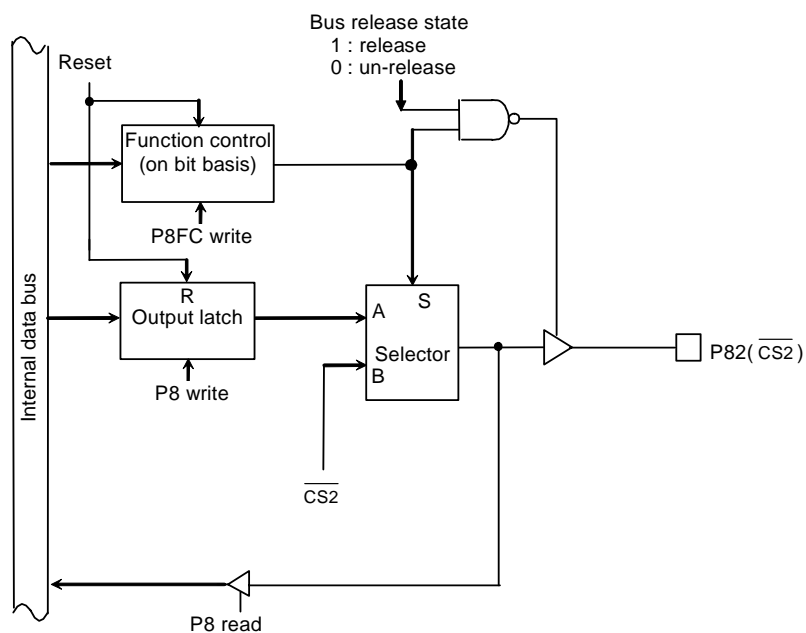

Figure 3.5.10 Port 8(P82)

(3) P83($\overline{CS3}$, \overline{SDCS})

P83 functions as standard chip selection signal output ($\overline{CS3}$) and chip select signal output (\overline{SDCS}) for SDRAM besides the output port function.

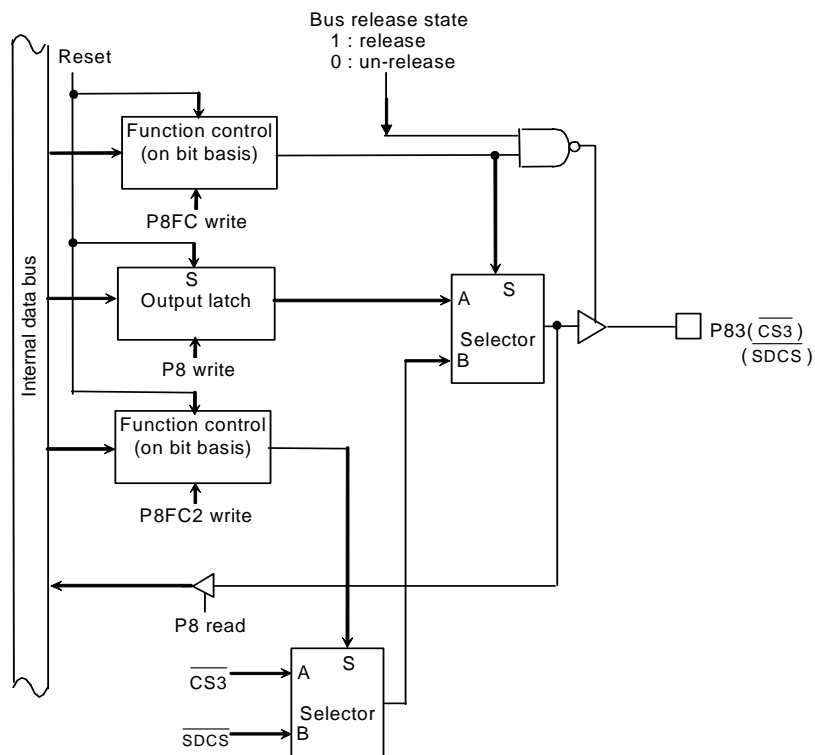

Figure 3.5.11 Port 8(P83)

(4) P85($\overline{CS5}$)

P85 functions as standard chip select signal output ($\overline{CS5}$) and watchdog timer signal output (\overline{WDTOUT}) besides the output port function.

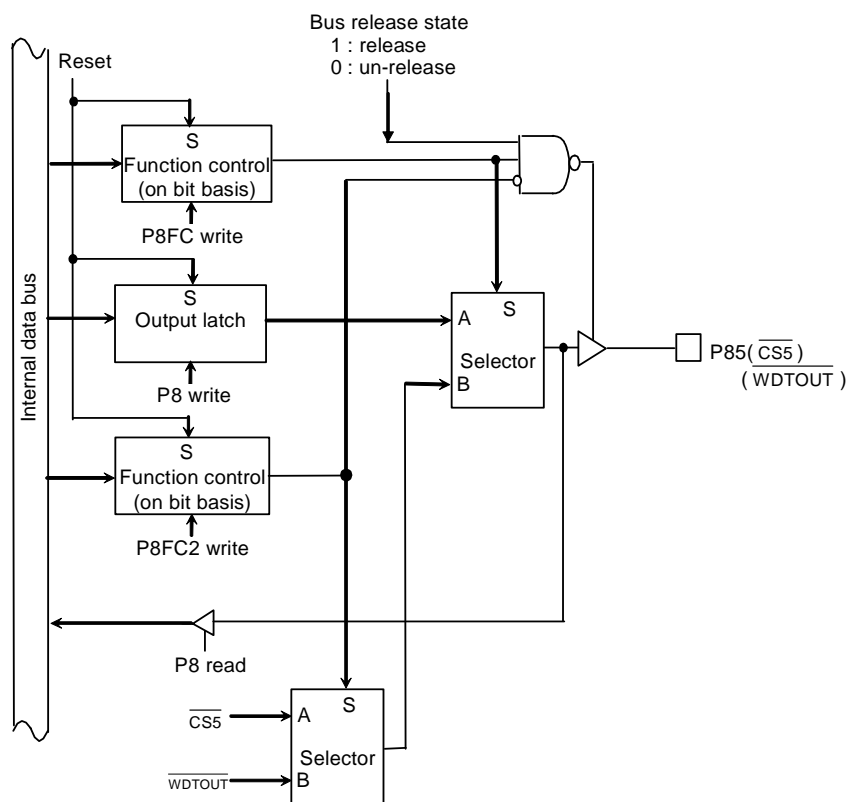

Figure 3.5.12 Port 8(P85)

(5) P86($\overline{\text{BUSRQ}}$)

P86 functions as input ($\overline{\text{BUSRQ}}$) of the function of bus open besides the I/O port function.

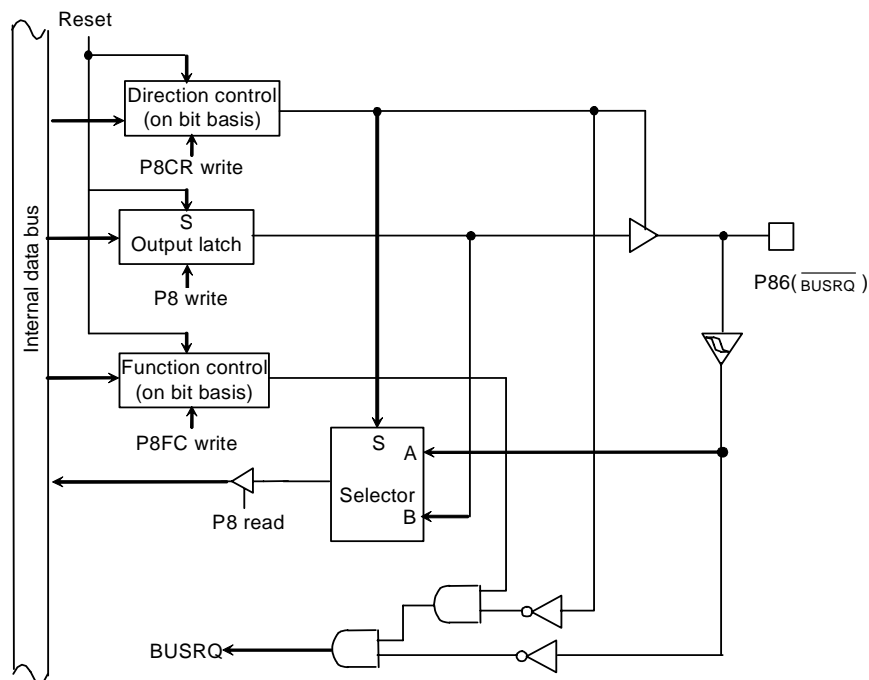

Figure 3.5.13 Port 8(P86)

(6)P87($\overline{\text{BUSAK}}$)

P87 functions as output ($\overline{\text{BUSAK}}$) of the function of bus open besides the I/O port function.

0		Port	$\overline{CS3}$
1		Reserved	SDCS

Note 1) Read-modify-write is prohibited for P8CR, P8FC and P8FC2.

Note 2) Don't do "1" to P8<P82> register in the write before setting P82 to $\overline{CS2}$ after releasing reset.

The period when (P8FC<P82F>=1) that sets the function register after the value of the output latch of P82 is made "1" (P8<P82>=1) and the output are not normally output exists and it is likely not to operate correctly.

Note 3) Use and set word instruction (LDW (P8FC),xxxxH) when you set P82 as $\overline{CS2}$.

Figure 3.5.15 Port 8 register

3.5.5 Port 9 (P90 to P96)

P90 to P96 are a port only for outputs.

There are the following functions in addition to an output port.

- The output function of a SDRAM controller

($\overline{\text{SDWE}}$, $\overline{\text{SDRAS}}$, $\overline{\text{SDCAS}}$, $\overline{\text{SDLLDQM}}$, $\overline{\text{SDLUDQM}}$, $\overline{\text{SDCKE}}$, $\overline{\text{SDCLK}}$).

These functions operate by setting the bit concerned of P9FC register. The value of P9FC<P95:P90> is reset in "0" by the reset operation, and P95 to P90 becomes an output port. The value of P9FC<P96F> is set in "1", and P96 becomes SDCLK function output. Moreover, all bits of the output latch are set in "1". Port 9 can bitting set the output in HALT. It sets it by the P9DR register.

Function			0: The inside of HALT is high impedance, 1: The inside of HALT is also driven						

(The purpose of use and the usage)

- This register sets up the state of each pin at the time of standby mode.
- Set the state of the pin expected before the "HALT" command as a register. CPU serves as enable, after executing a "HALT" command.
- It becomes effective in all the standby modes that have three kinds.(IDLE2,IDLE1, or STOP mode)
- The state of I/O is shown in the following tables.

OE	P9nD	Output buffer	Input buffer
1	0	OFF	OFF
1	1	ON	OFF

Note 1) OE means the output enable signal before the mode of the standby.

Note 2) "n" of P9nD means the bit number of PORT9.

Note) Read-modify-write is prohibited for P9FC.

Figure 3.5.18 Port 9 register

3.5.6 Port A (PA0 to PA5)

Port A is an 6-bit general-purpose I/O port.

PA1 and PA4 can be set as an open drain output.

There are the following functions in addition to an I/O port.

- The I/O function of the serial channel 0(RXD0, TXD0, SCLK0/ $\overline{\text{CTS0}}$).
- The I/O function of the serial channel 1(RXD1, TXD1, SCLK1/ $\overline{\text{CTS1}}$).

These functions operate by setting the bit concerned of PACR, PAFC and PAFC2 register. All the bits of PACR, PAFC and PAFC2 are cleared to "0" by the reset action, and all bits serve as an input port. Moreover, the output latch of all bit is set to "1".

www.DataSheet4U.com

(1) PA0(RXD0), PA3 (RXD1)

PA0 and PA3 have a function as a RXD input of the serial channel 0 and 1 in addition to an I/O port.

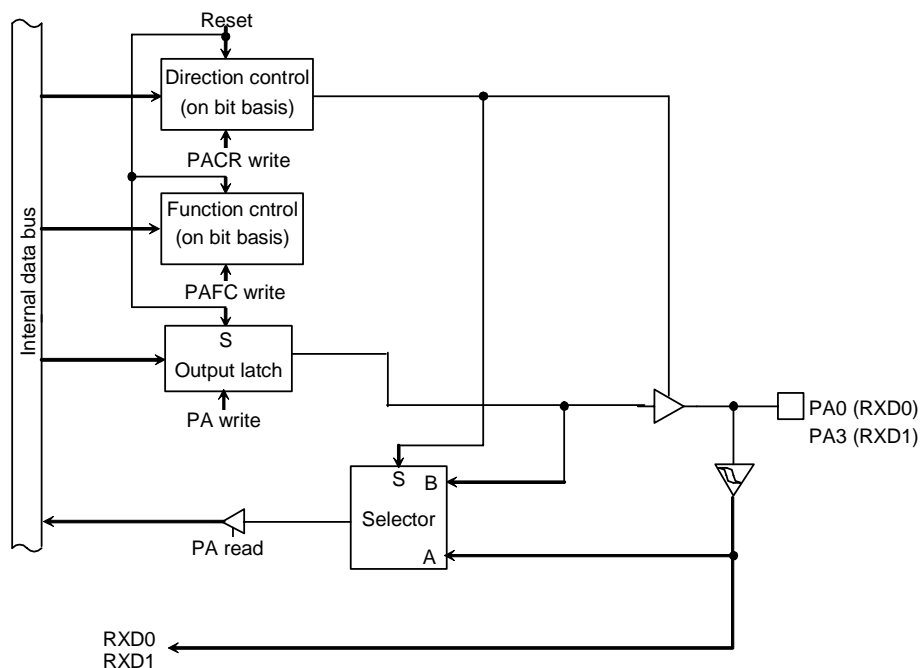

Figure 3.5.19 Port A(PA0,PA3)

(2) PA1(TXD0), PA4 (TXD1)

PA1 and PA4 have a function as a TXD output of the serial channel 0 and 1 in addition to an I/O port.

Moreover, when using it as an TXD output of the serial bus interfaces 0 and 1, the output buffer has the open drain function in which a program is possible. An open drain function can be set up by the PAFC<PA1F,PA4F> and PACR<PA1C,PA4C> register.

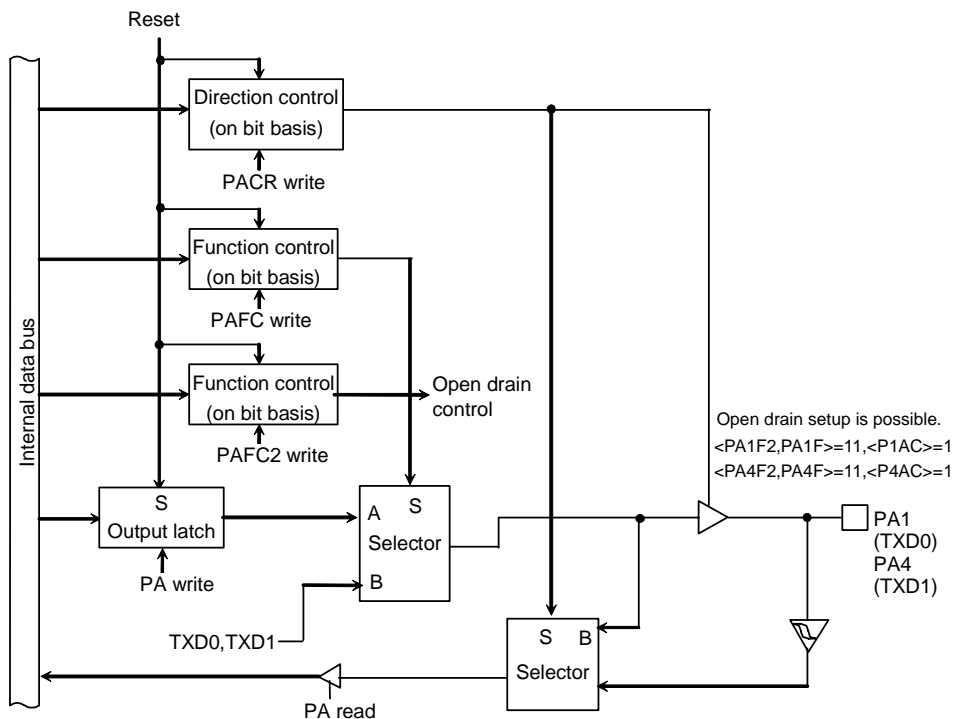

Figure 3.5.20 Port A(PA1,PA4)

(3)PA2($\overline{\text{CTS0}}$,SCLK0),PA5($\overline{\text{CTS1}}$,SCLK1)

PA2 and PA5 have a function as an $\overline{\text{CTS}}$ input or SCLK I/O in addition to the I/O port.

Note 2) RXD0/1, SCLK0/1, CTS0 and CTS1 input are inputted into the serial bus interface 0 and 1 irrespective of a functional setup of a port.

Note 3) PA1 and PA4 do not have a register for 3-state/open drain setup.

Moreover, there is no open drain function at the time of an output port.

Figure 3.5.22 Port A register

3.5.7 Port C(PC0 to PC5)

Port C is an 6-bit general-purpose I/O port.

PC0, PC1, PC3 and PC4 can be set as an open drain output.

There are the following functions in addition to an I/O port.

- The I/O function of the serial bus interface 0(SO0/SDA0, SI0/SCL0, SCK0).
- The I/O function of the serial bus interface 1(SO1/SDA1, SI1/SCL1, SCK1).

These functions operate by setting the bit concerned of PCCR, PCFC and PCFC2 register. All the bits of PCCR, PCFC and PCFC2 are cleared to "0" by the reset action, and all bits serve as an input port. Moreover, the output latch of all bit is set to "1".

(1)PC0(SO0/SDA0),PC3 (SO1/SDA1)

PC0 and PC3 have a function as I/O of the serial bus interface 0 and 1 in addition to an I/O port.

Moreover, when using it as an output of the serial bus interfaces 0 and 1, the output buffer has the open drain function in which a program is possible. An open drain function can be set up by the PCFC<PC0F,PC3F> and PCCR<PC0C,PC3C> register.

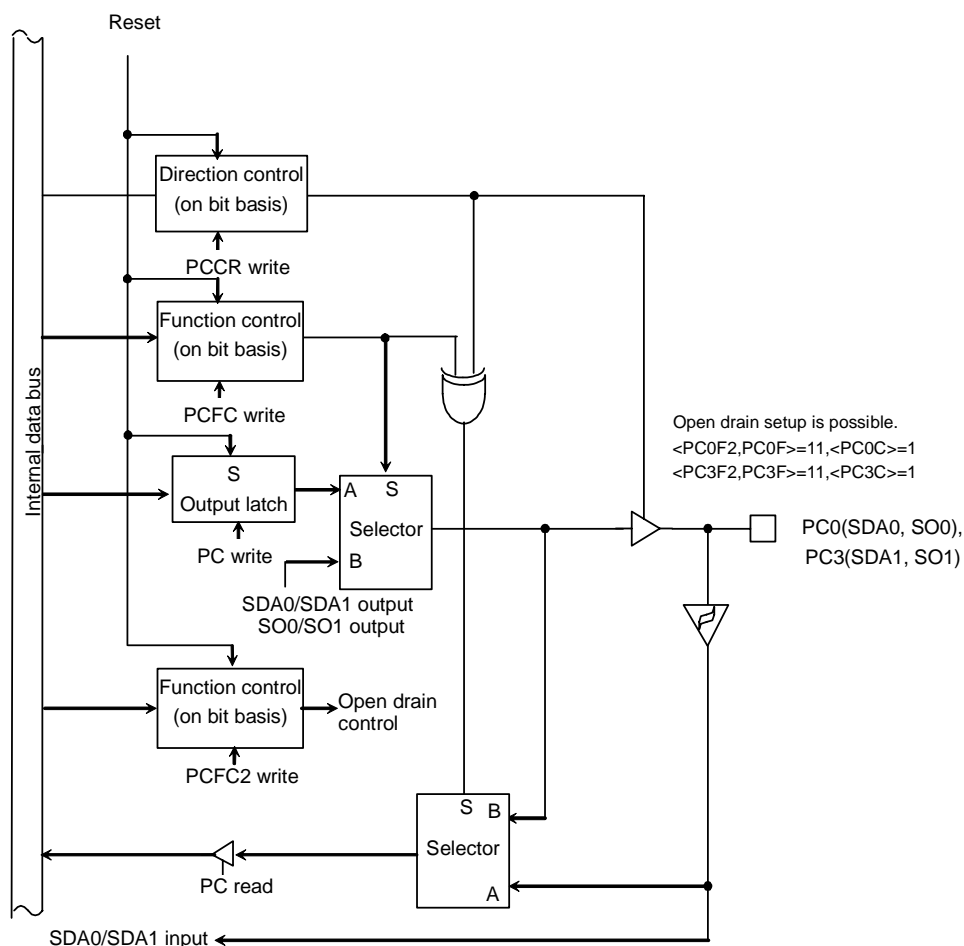

Figure 3.5.23 Port C(PC0,PC3)

(2) PC1(SI0/SCL0), PC4 (SI1/SCL1)

PC1 and PC4 have a function as I/O of the serial bus interface 0 and 1 in addition to an I/O port.

Moreover, when using it as an output of the serial bus interfaces 0 and 1, the output buffer has the open drain function in which a program is possible. An open drain function can be set up by the PCFC<PC1F,PC4F> and PCCR<PC1C,PC4C> register.

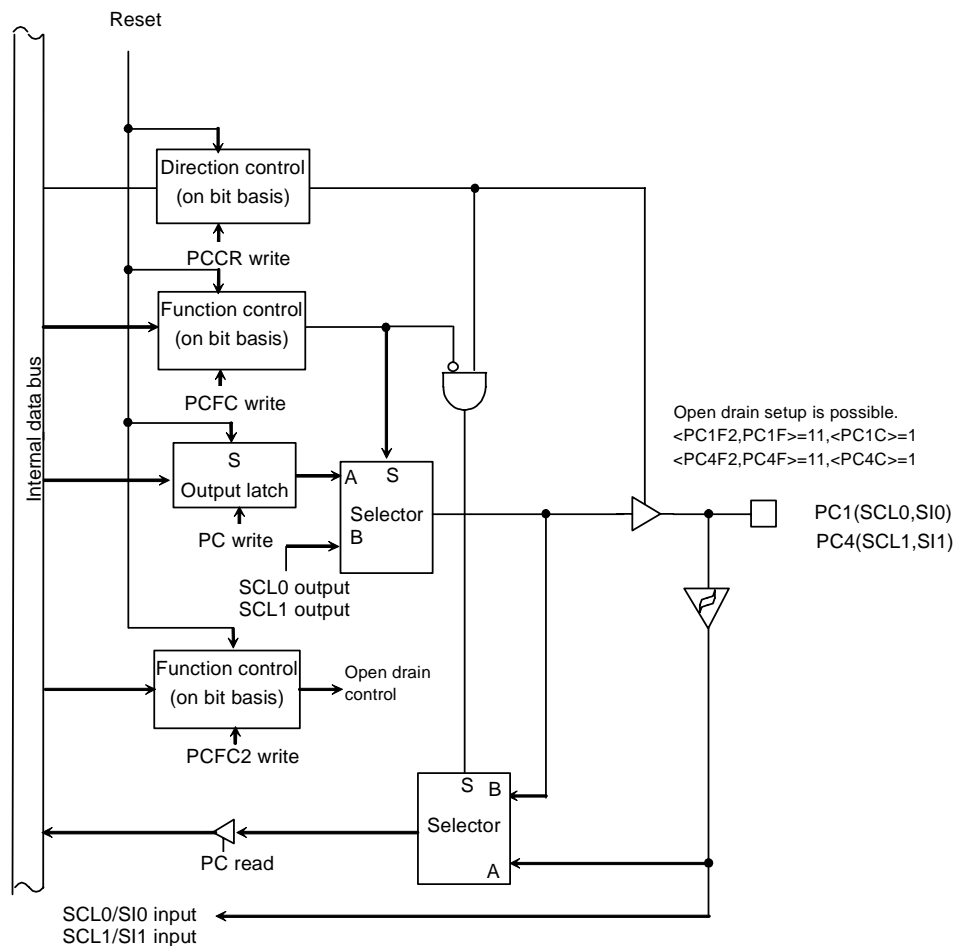

Figure 3.5.24 Port C(PC1,PC4)

(3)PC2(SCK0),PC5 (SCK1)

PC2 and PC5 have a function as I/O of the serial bus interface 0 and 1 in addition to an I/O port.

Note 3) PC0, PC1, PC3 and PC4 do not have a register for 3-state/open drain setup.

Moreover, there is no open drain function at the time of an output port.

Figure 3.5.26 Port C register

3.5.8 Port D(PD0 to PD5)

Port D is an 6-bit general-purpose I/O port.

PD4 can be set as an open drain output.

There are the following functions in addition to an I/O port.

- The I/O function of the serial channel 2(RXD2, TXD2, SCLK2/ $\overline{\text{CTS2}}$)
- The I/O function of the high speed channel 0(HSSI0, HSSO0, HSCLK0)

These functions operate by setting the bit concerned of PDCR, PDFC and PDFC2 register. All the bits of PDCR, PDFC and PDFC2 are cleared to "0" by the reset action, and all bits serve as an input port. Moreover, the output latch of all bit is set to "1".

Note 3) HSSI0 input are inputted into the high speed serial channel 0 irrespective of a functional setup of a port.

Note 4) PD4 do not have a register for 3-state/open drain setup.

Moreover, there is no open drain function at the time of an output port.

Figure 3.5.31 Port D register

3.5.9 Port F (PF0 to PF6)

Port F is an 7-bit general-purpose I/O port.

There are the following functions in addition to an I/O port.

- The input function of 8-bit timer 0(TA0IN)
- The output function of 8-bit timer 1(TA1OUT)
- The input function of 8-bit timer 2(TA2IN)
- The output function of 8-bit timer 3(TA3OUT)
- The input function of 8-bit timer 4(TA4IN)
- The output function of 8-bit timer 5(TA5OUT)
- The input function of 8-bit timer 6(TA6IN)
- The input function of external interrupt(INT0 to INT3)

These functions operate by setting the bit concerned of PFCR, PFFC and PFFC2 register. All the bits of PFCR, PFFC and PFFC2 are cleared to "0" by the reset action, and all bits serve as an input port. Moreover, the output latch of all bit is set to "1".

3.5.11 Port K (PK0 to PK7)

Port K are a port only for inputs.

There are the following functions in addition to an input port.

- The input function of 16-bit timer 0(TB0IN0, TB0IN1)
- The input function of 16-bit timer 1(TB1IN0, TB1IN1)
- The input function of 16-bit timer 2(TB2IN0, TB2IN1)
- The input function of 16-bit timer 3(TB3IN0, TB3IN1)
- The input function of external interrupt(INT4 to INTB)

These functions operate by setting the bit concerned of PKFC and PKFC2 register. All the bits of PKFC and PKFC2 are cleared to "0" by the reset action, and all bits serve as an input port.

1	0	Reserved	Reserved	Reserved	Reserved	Reserved	Reserved	Reserved	Reserved
1	1	INTB	INTA	INT9	INT8	INT7	INT6	INT5	INT4

Note 1) Read-modify-write is prohibited for PKFC and PKFC2.

Note 2) TB0IN0/1, TB1IN0/1, TB2IN0/1 and TB3IN0/1 input is inputted into the 8-bit timer TMRB0 to TMRB3 irrespective of a functional setup of a port.

Note 3) In setting (TB0IN0 to TB3IN1) of setting (INT4 to INTB) of <PKx2>=1 and <PKxF>=1 and <PKx2>=0 and <PKxF>=1, the operation of the HALT release is different.

Refer to Table 3.3.6 HALT release source of 3.3.6 standby control part and the operation of the HALT release for details.

Figure 3.5.39 Port K register

3.5.12 Port L (PL0 to PL7)

Port L is an 8-bit general-purpose I/O port.

PL1 can be set as an open drain output.

There are the following functions in addition to an I/O port.

- The output function of pattern generator 0(PG00 to PG03)
- The output function of pattern generator 1(PG10 to PG13)
- The I/O function of the serial channel 3(RXD3, TXD3, SCLK3/ $\overline{\text{CTS3}}$)
- The output function of 8-bit timer 7(TA7OUT)
- The I/O function of the high speed channel 1(HSSI1, HSSO1, HSCLK1)

These functions operate by setting the bit concerned of PLCR, PLFC and PLFC2 register. All the bits of PLCR, PLFC and PLFC2 are cleared to "0" by the reset action, and all bits serve as an input port. Moreover, the output latch of all bit is set to "1".

Note 1) Read-modify-write is prohibited for PLCR, PLFC and PLFC2.

Note 2) RXD3, SCLK3 and CTS3 input are inputted into the serial bus interface 3 irrespective of a functional setup of a port.

Note 3) HSS1 input are inputted into the high speed serial channel 0 irrespective of a functional setup of a port.

Note 4) PL1 does not have a register for 3-state/open drain setup.

Moreover, there is no open drain function at the time of an output port.

Figure 3.5.46 Port L register

3.5.8 Port D(PD0 to PD5)

Port D is an 6-bit general-purpose I/O port.

PD4 can be set as an open drain output.

There are the following functions in addition to an I/O port.

- The I/O function of the serial channel 2(RXD2, TXD2, SCLK2/ $\overline{\text{CTS2}}$)
- The I/O function of the high speed channel 0(HSSI0, HSSO0, HSCLK0)

These functions operate by setting the bit concerned of PDCR, PDFC and PDFC2 register. All the bits of PDCR, PDFC and PDFC2 are cleared to "0" by the reset action, and all bits serve as an input port. Moreover, the output latch of all bit is set to "1".

1	0	1		Reserved				
1	1	0		Reserved				
1	1	1		TXD2(O.D Ena)				

Note 1) Read-modify-write is prohibited for PDCR, PDFC and PDFC2.

Note 2) RXD2, SCLK2 and CTS2 input are inputted into the serial bus interface 0 irrespective of a functional setup of a port.

Note 3) HSSI0 input are inputted into the high speed serial channel 0 irrespective of a functional setup of a port.

Note 4) PD4 do not have a register for 3-state/open drain setup.

Moreover, there is no open drain function at the time of an output port.

Figure 3.5.31 Port D register

3.5.9 Port F (PF0 to PF6)

Port F is an 7-bit general-purpose I/O port.

There are the following functions in addition to an I/O port.

- The input function of 8-bit timer 0(TA0IN)
- The output function of 8-bit timer 1(TA1OUT)
- The input function of 8-bit timer 2(TA2IN)
- The output function of 8-bit timer 3(TA3OUT)
- The input function of 8-bit timer 4(TA4IN)
- The output function of 8-bit timer 5(TA5OUT)
- The input function of 8-bit timer 6(TA6IN)
- The input function of external interrupt(INT0 to INT3)

These functions operate by setting the bit concerned of PFCR, PFFC and PFFC2 register. All the bits of PFCR, PFFC and PFFC2 are cleared to "0" by the reset action, and all bits serve as an input port. Moreover, the output latch of all bit is set to "1".

Note 1) Read-modify-write is prohibited for PLCR, PLFC and PLFC2.

Note 2) RXD3, SCLK3 and CTS3 input are inputted into the serial bus interface 3 irrespective of a functional setup of a port.

Note 3) HSS1 input are inputted into the high speed serial channel 0 irrespective of a functional setup of a port.

Note 4) PL1 does not have a register for 3-state/open drain setup.

Moreover, there is no open drain function at the time of an output port.

Figure 3.5.46 Port L register

3.5.8 Port D(PD0 to PD5)

Port D is an 6-bit general-purpose I/O port.

PD4 can be set as an open drain output.

There are the following functions in addition to an I/O port.

- The I/O function of the serial channel 2(RXD2, TXD2, SCLK2/ $\overline{\text{CTS2}}$)
- The I/O function of the high speed channel 0(HSSI0, HSSO0, HSCLK0)

These functions operate by setting the bit concerned of PDCR, PDFC and PDFC2 register. All the bits of PDCR, PDFC and PDFC2 are cleared to "0" by the reset action, and all bits serve as an input port. Moreover, the output latch of all bit is set to "1".

Note 4) PD4 do not have a register for 3-state/open drain setup.

Moreover, there is no open drain function at the time of an output port.

Figure 3.5.31 Port D register

3.5.9 Port F (PF0 to PF6)

Port F is an 7-bit general-purpose I/O port.

There are the following functions in addition to an I/O port.

- The input function of 8-bit timer 0(TA0IN)
- The output function of 8-bit timer 1(TA1OUT)
- The input function of 8-bit timer 2(TA2IN)
- The output function of 8-bit timer 3(TA3OUT)
- The input function of 8-bit timer 4(TA4IN)
- The output function of 8-bit timer 5(TA5OUT)
- The input function of 8-bit timer 6(TA6IN)
- The input function of external interrupt(INT0 to INT3)

These functions operate by setting the bit concerned of PFCR, PFFC and PFFC2 register. All the bits of PFCR, PFFC and PFFC2 are cleared to "0" by the reset action, and all bits serve as an input port. Moreover, the output latch of all bit is set to "1".

Figure 3.5.34 Port F register

3.5.10 Port J (PJ0 to PJ7)

Port J is an 8-bit general-purpose I/O port.

There are the following functions in addition to an I/O port.

- The output function of 16-bit timer 0(TB0OUT0, TB0OUT1)
- The output function of 16-bit timer 1(TB1OUT0, TB1OUT1)
- The output function of 16-bit timer 2(TB2OUT0, TB2OUT1)
- The output function of 16-bit timer 3(TB3OUT0, TB3OUT1)
- The output function of 16-bit timer 4(TB4OUT0, TB4OUT1)
- The output function of 16-bit timer 5(TB5OUT0, TB5OUT1)

These functions operate by setting the bit concerned of PJCR, PJFC and PJFC2 register. All the bits of PJCR, PJFC and PJFC2 are cleared to "0" by the reset action, and all bits serve as an input port. Moreover, the output latch of all bit is set to "1".

Figure 3.5.37 Port J register

3.5.11 Port K (PK0 to PK7)

Port K are a port only for inputs.

There are the following functions in addition to an input port.

- The input function of 16-bit timer 0(TB0IN0, TB0IN1)
- The input function of 16-bit timer 1(TB1IN0, TB1IN1)
- The input function of 16-bit timer 2(TB2IN0, TB2IN1)
- The input function of 16-bit timer 3(TB3IN0, TB3IN1)
- The input function of external interrupt(INT4 to INTB)

These functions operate by setting the bit concerned of PKFC and PKFC2 register. All the bits of PKFC and PKFC2 are cleared to "0" by the reset action, and all bits serve as an input port.

Note 1) Read-modify-write is prohibited for PKFC and PKFC2.

Note 2) TB0IN0/1, TB1IN0/1, TB2IN0/1 and TB3IN0/1 input is inputted into the 8-bit timer TMRB0 to TMRB3 irrespective of a functional setup of a port.

Note 3) In setting (TB0IN0 to TB3IN1) of setting (INT4 to INTB) of <PKx2>=1 and <PKxF>=1 and <PKx2>=0 and <PKxF>=1, the operation of the HALT release is different.

Refer to Table 3.3.6 HALT release source of 3.3.6 standby control part and the operation of the HALT release for details.

Figure 3.5.39 Port K register

3.5.12 Port L (PL0 to PL7)

Port L is an 8-bit general-purpose I/O port.

PL1 can be set as an open drain output.

There are the following functions in addition to an I/O port.

- The output function of pattern generator 0(PG00 to PG03)
- The output function of pattern generator 1(PG10 to PG13)
- The I/O function of the serial channel 3(RXD3, TXD3, SCLK3/ $\overline{\text{CTS3}}$)
- The output function of 8-bit timer 7(TA7OUT)
- The I/O function of the high speed channel 1(HSSI1, HSSO1, HSCLK1)

These functions operate by setting the bit concerned of PLCR, PLFC and PLFC2 register. All the bits of PLCR, PLFC and PLFC2 are cleared to "0" by the reset action, and all bits serve as an input port. Moreover, the output latch of all bit is set to "1".

Note) Read-modify-write is prohibited for PNFC.

Figure 3.5.50 Port N register

3.6 Memory Controller

3.6.1 Functions

TMP92CM27 has a memory controller with a variable 6-block address area that controls as follows.

(1) 6-block address area support

Specifies a start address and a block size for 6-block address area (block 0 to 5).

- SRAM or ROM : All CS blocks (CS0 to CS5) are supported.
- SDRAM : Only CS3 blocks are supported.
- Page ROM : Only CS2 blocks are supported.

(2) Connecting memory specifications

Specifies SRAM, ROM and SDRAM as memories that connect with the selected address areas.

(3) Data bus width selection

Whether 8 bits, 16 bits is selected as the data bus width of the respective block address areas.

(4) Wait control

Wait specification bit in the control register and $\overline{\text{WAIT}}$ input pin control the number of waits in the external bus cycle. Read cycle and write cycle can specify the number of waits individually.

The number of waits is controlled in 6 mode mentioned below.

0 waits, 1 wait,

2 waits, 3 waits, 4 waits

N waits (controls with $\overline{\text{WAIT}}$ pin)

3.6.2 Control Register and Operation after Reset Release

This section describes the registers that control the memory controller, the after reset release state and necessary settings.

(1) Control register

The control registers of the memory controller are follows and Table 3.6.1 and Table 3.6.2.

- Control register: BnCSH/BnCSL (n = 0 to 5, EX)
Sets the basic functions of the memory controller; the memory type that is connected, the number of waits which is read and written.
- Memory start address register: MSARn (n = 0 to 5)
Sets a start address in the selected address areas.
- Memory address mask register: MAMR (n = 0 to 5)
Sets a block size in the selected address areas.
- Page ROM control register: PMEMCR
Sets method of accessing page ROM.

Note 2: Read modify write is prohibited for BnCSL, BnCSH(n = 4 to 5), BEXCSH and BEXCSL registers.

(2) Operation after reset release

The start data bus width is determined depending on state of AM1/AM0 pins just after reset release. Then, the external memory is accessed as follows

AM1	AM0	Start Mode
0	0	Don't use this setting
0	1	Start with 16-bit data bus (Note)
1	0	Start with 8-bit data bus (Note)
1	1	Don't use this setting

Note: A memory to be used as starting after reset is either NOR flash, masked ROM.

SDRAM can't be used.

AM1/AM0 pins are valid only just after release reset. In the other cases, the data bus width is the value which is set to the control register <BnBUS1:0>.

By reset, only control register (B2CSH/B2CSL) of the block address area 2 becomes effective automatically (B2CSH<B2E> is set to "1" by reset).

The data bus width which is specified by AM1/AM0 pins are loaded to the bit for specification the bus width of the control register in the block address area 2.

The block address area 2 is set to 000000H to FFFFFFFH address by reset (B2CSH<B2M> is reset to "0").

After release reset, the block address areas are specified by the memory start address register (MSARn) and the memory address mask register (MAMRn). Then the control register (BnCSH/L) is set.

Set the enable bit (BnCSH<BnE>) of the control register to "1" for enable the setting.

3.6.3 Basic Functions and Register Setting

In this section, setting of the block address area, the connecting memory and the number of waits out of the memory controller's functions are described.

(1) Block address area specification

The block address area is specified by two registers.

The memory start address register (MSARn) sets the start address of the block address areas. The memory controller compares between the register value and the address every bus cycles. The address bit which is masked by the memory address mask register (MAMRn) is not compared by the memory controller. The block address area size is determined by setting the memory address mask register. The value that is set to the register is compared with the block address area on the bus. If the compared result is a match, the memory controller sets the chip select signal (CSn) to "low".

(i) Memory start address register setting

The MS23 to 16 bits of the memory start address register correspond with addresses A23 to A16 respectively. The lower start addresses A15 to A0 are always set to address 0000H.

Therefore the start addresses of the block address area are set to addresses 000000H to FF0000H every 64 Kbytes.

(ii) Memory address mask registers setting

The memory address mask register sets whether an address bit is compared or not. In register setting, "0" is "compare", or "1" is "not compare".

The address bits that can set depend on the block address area.

Block address area 0: A20 to A8

Block address area 1: A21 to A8

Block address area 2 to 5: A22 to A15

The upper bits are always compared. The block address area size is determined by the compared result.

The size to be set depending on the block address area is as follows.

Size (bytes) CS area	256	512	32 K	64 K	128 K	256 K	512 K	1 M	2 M	4 M	8 M
CS0	○	○	○	○	○	○	○	○	○		
CS1	○	○		○	○	○	○	○	○	○	
CS2 to CS5			○	○	○	○	○	○	○	○	○

Note: After release reset, only the control register of the block address area 2 is valid. The control register of the block address area 2 has <B2M> bit. If <B2M> bit set to "0", the block address area 2 is set to addresses 000000H to FFFFFFFH. (After release reset state is this state). If <B2M> bit set to "1", the start address and the address area size is set, as in the other block address area.

(iii) Example of register setting

To set the block address area 512bytes from address 110000H, set the register as follows.

MSAR1 Register

Bit	7	6	5	4	3	2	1	0
Bit symbol	M1S23	M1S22	M1S21	M1S20	M1S19	M1S18	M1S17	M1S16
Specified value	0	0	0	1	0	0	0	1

M1S23 to M1S16 bits of the memory start address register MSAR1 correspond with address A23 to A16.

A15 to A0 are set to “0”. Therefore if MSAR1 is set to above values, the start address of the block address area is set to address 110000H.

MAMR1 Register

Bit	7	6	5	4	3	2	1	0
Bit symbol	M1V21	M1V20	M1V19	M1V18	M1V17	M1V16	M1V15 to M1V9	M1V8
Specified value	0	0	0	0	0	0	0	1

M1V21 to M1V16 and M1V8 bits of the memory address mask register MAMR1 set whether address A21 to A16 and A8 are compared or not. In register setting, “0” is “compare”, or “1” is “not compare”. M1V15 to M1V9 bits set whether address A15 to A9 are compared or not with 1 bit. A23 and A22 are always compared.

If it set to like an above setting, A23 to A9 is compared with the value that is set as the start addresses. Therefore 512 bytes (addresses 110000H to 1101FFH) are set as the block address area 1, and if it is compared with the addresses on the bus, the chip select signal CS1 is set to “low”.

The other block address area sizes are specified like this.

A23 and A22 are always compared in the block address area 0. Whether A20 to A8 are compared or not is set to register.

Similarly, A23 is always compared in block address areas 2 to 5. Whether A22 to A15 are compared or not is set to register.

Note 1: When the set block address area overlaps with the built-in memory area, or both two address areas overlap, the block address area is processed according to priority as follows.

Built-in I/O > Built-in memory > Block address area 0 > 1 > 2 > 3 > 4 > 5

Note 2: If address area that is set in $\overline{CS0}$ to $\overline{CS5}$ was accessed, area is regarded as \overline{CSEX} area. Therefore, wait number and data bus width controls becomes setting of \overline{CSEX} (BEXCSH, BEXCSL register).

(2) Connection memory specification

Setting the <BnOM1:0> bit of the control register (BnCSH) specifies the memory type that is connected with the block address areas. The interface signal is outputted according to the set memory as follows.

<BnOM1:0> Bit (BnCSH Register)

<BnOM1>	<BnOM0>	Function
0	0	SRAM/ROM (Default)
0	1	(Reserved)
1	0	(Reserved)
1	1	SDRAM

Note 1: SDRAM should be set to block either 3.

(3) Data bus width specification

The data bus width is set for every block address area. The bus size is set by setting the control register (BnCSH)<BnBUS1:0> as follows.

<BnBUS1:0> bit (BnCSH Register)

BnBUS 1	BnBUS 0	Function
0	0	8-bit bus mode (Default)
0	1	16-bit bus mode
1	0	Don't use this setting
1	1	Don't use this setting

Note: SDRAM should be set to either "01" (16-bit bus).

This method of changing the data bus width depending on the accessing address is called "dynamic bus sizing". Part which data is outputted is changed by changing data size, bus width and start address.

Note: Since there is a possibility of abnormal writing/reading of the data if two memories with different bus width are put in consecutive address, do not execute a access to both memories with one command.

Operand Data Size (bit)	Operand Start Address	Memory Data Size (bit)	CPU Address	CPU Data	
				D15 to D8	D7 to D0
8	4n + 0	8/16	4n + 0	xxxxx	b7 to b0
		8	4n + 1	xxxxx	b7 to b0
	4n + 2	8/16	4n + 2	xxxxx	b7 to b0
		8	4n + 3	xxxxx	b7 to b0
		16	4n + 3	b7 to b0	xxxxx

			(2) 4n + 2	b31 to b24	b23 to b16
	4n + 1	8	(1) 4n + 0	xxxxx	b7 to b0
			(2) 4n + 1	xxxxx	b15 to b8
			(3) 4n + 2	xxxxx	b23 to b16
			(4) 4n + 3	xxxxx	b31 to b24
		16	(1) 4n + 1	b7 to b0	xxxxx
			(2) 4n + 2	b23 to b16	b15 to b8
			(3) 4n + 4	xxxxx	b31 to b24
	4n + 2	8	(1) 4n + 2	xxxxx	b7 to b0
			(2) 4n + 3	xxxxx	b15 to b8
			(3) 4n + 4	xxxxx	b23 to b16
			(4) 4n + 5	xxxxx	b31 to b24
		16	(1) 4n + 2	b15 to b8	b7 to b0
			(2) 4n + 4	b31 to b24	b23 to b16
	4n + 3	8	(1) 4n + 3	xxxxx	b7 to b0
			(2) 4n + 4	xxxxx	b15 to b8
			(3) 4n + 5	xxxxx	b23 to b16
			(4) 4n + 6	xxxxx	b31 to b24
		16	(1) 4n + 3	b7 to b0	xxxxx
			(2) 4n + 4	b23 to b16	b15 to b8
			(3) 4n + 6	xxxxx	b31 to b24

xxxxx: During a read, data input to the bus ignored. At write, the bus is at high impedance and the write strobe signal remains non to active.

(4) Wait control

The external bus cycle completes a wait of two states at least (100 ns at $f_{SYS} = 20$ MHz).

Setting the <BnWW2:0> and <BnWR2:0> of BnCSL specifies the number of waits in the read cycle and the write cycle. <BnWW2:0> is set with the same method as <BnWR2:0>.

<BnWW>/<BnWR> (BnCSL Register)

<BnWW2> <BnWR2>	<BnWW1> <BnWR1>	<BnWW0> <BnWR0>	Function
0	0	1	2 states (0 waits) access fixed mode
0	1	0	3 states (1 wait) access fixed mode (Default)
1	0	1	4 states (2 waits) access fixed mode
1	1	0	5 states (3 waits) access fixed mode
1	1	1	6 states (4 waits) access fixed mode
0	1	1	\overline{WAIT} pin input mode
Others			(Reserved)

Note 1: For SDRAM, above setting is invalid. So, refer 3.13 SDRAM controller.

(i) Waits number fixed mode

The bus cycle is completed with the states which is set. The number of states is selected from 2 states (0 waits) to 6 states (4 waits).

(ii) \overline{WAIT} pin input mode

This mode samples the \overline{WAIT} input pins. And this mode inserts wait continuously in during signal is activated. The bus cycle is minimum 2 states. The bus cycle is completed if the wait signal is non active ("High" level) at 2 states. The bus cycle continue with that is extended if the wait signal is active at 2 states and more.

(5) Recovery (Data hold) cycle control

Some memory is defined an AC specification about data hold time by \overline{CE} or \overline{OE} for read cycle. Therefore, a data confliction problem may occur. To avoid this problem, 1-dummy cycle can be inserted after CSm-block access cycle by setting "1" to BmCSH<BmREC>.

This 1-dummy cycle is inserted when the next cycle is for another CS-block.

<BmREC> (BmCSH register)

0	No dummy cycle is inserted (Default).
1	Dummy cycle is inserted.

- When no inserting a dummy cycle (0 waits)

- When inserting a dummy cycle (0 waits)

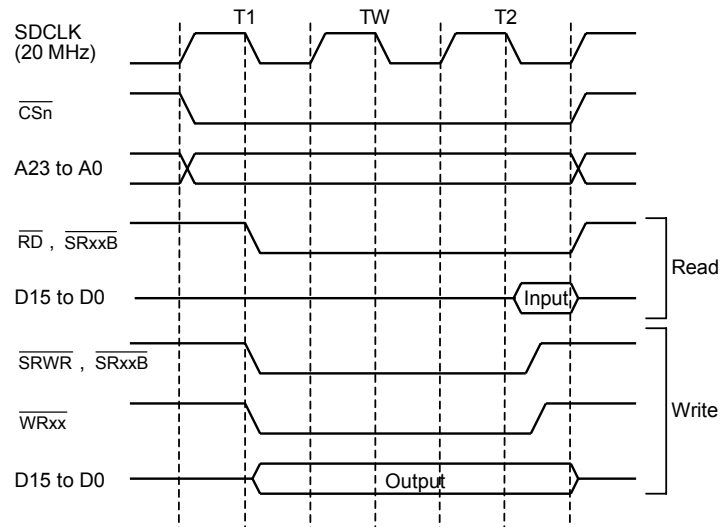

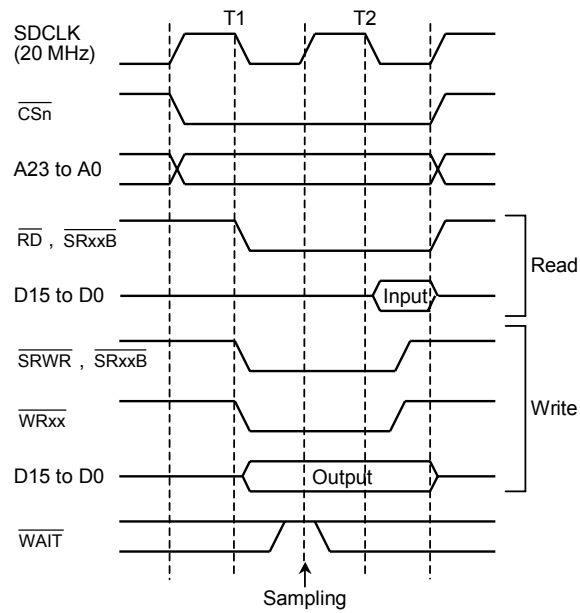

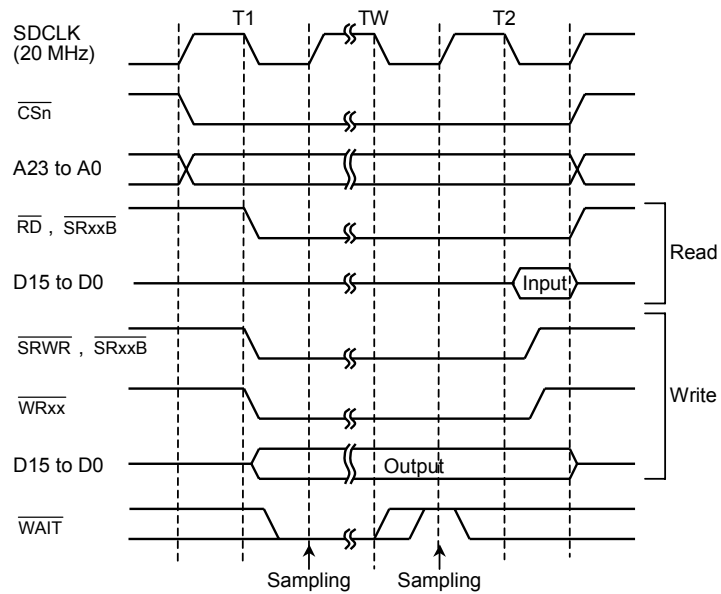

(6) Basic bus timing

(a) External read/write cycle (0 waits)

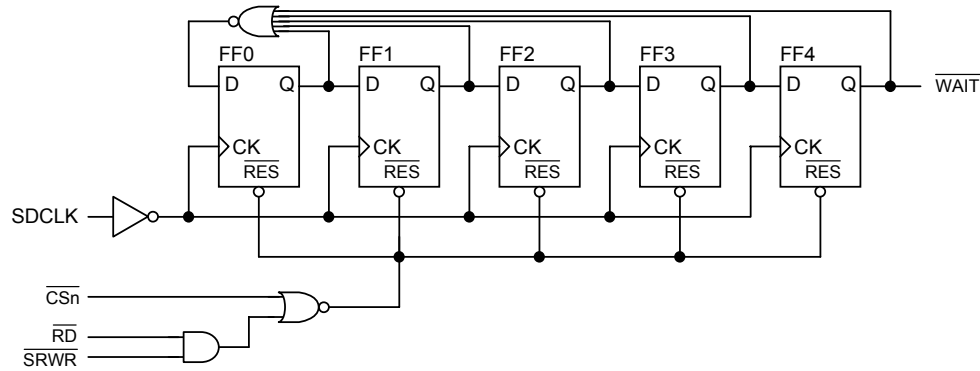

(b) External read/write cycle (1 wait)

(c) External read/write cycle (0 waits at $\overline{\text{WAIT}}$ pin input mode)(d) External read/write cycle (n waits at $\overline{\text{WAIT}}$ pin input mode)

Example of wait input cycle (5 waits)

www.DataSheet4U.com

(7) Connecting external memory

Figure 3.6.1 shows an example of method of connecting external 16-bit SRAM and 16-bit NOR flash to the TMP92CM27.

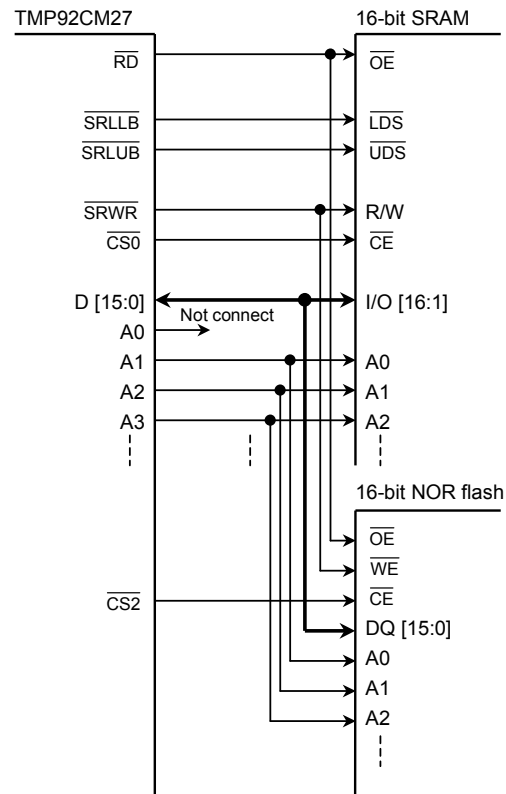

Figure 3.6.1 Example of External 16-Bit SRAM and NOR Flash Connection

3.6.4 ROM Control (Page mode)

This section describes ROM page mode accessing and how to set registers. ROM page mode is set by the page ROM control register.

(1) Operation and how to set the registers

TMP92CM27 supports ROM access of the page mode. The ROM access of the page mode is specified only in the block address area 2.

ROM page mode is set by the page ROM control register (PMEMCR). Setting <OPGE> of the PMEMCR register to "1" sets the memory access of the block address area to ROM page mode access.

The number of read cycles is set by the <OPWR1:0> of the PMEMCR register.

<OPWR1:0> (PMEMCR register)

<OPWR1>	<OPWR0>	Number of Cycle in a Page
0	0	1 state (n-1-1-1 mode) ($n \geq 2$)
0	1	2 state (n-2-2-2 mode) ($n \geq 3$)
1	0	3 state (n-3-3-3 mode) ($n \geq 4$)
1	1	(Reserved)

Note: Set the number of waits "n" to the control register (BnCSL) in each block address area.

The page size (the number of bytes) of ROM in the CPU size is set to the <PR1:0> of the PMEMCR register. When data is read out until a border of the set page, the controller completes the page reading operation. The start data of the next page is read in the normal cycle. The following data is set to page read again.

<PR1:0> Bit (PMEMCR register)

<PR1>	<PR0>	ROM Page Size
0	0	64 bytes
0	1	32 bytes
1	0	16 bytes (Default)
1	1	8 bytes

For the signal timing pulse, see ROM read cycle in section 4.3.2.

3.6.5 Cautions

- (1) Note the timing between \overline{CS} and \overline{RD}

If the parasitic capacitance of the \overline{RD} (Read signal) is greater than that of the \overline{CS} (Chip select signal), it is possible that an unintended read cycle occurs due to a delay in the read signal. Such an unintended read cycle may cause a trouble as in the case of (a) in Figure 3.6.2.

Figure 3.6.2 Read Signal Delay Read Cycle

Example: When using an externally connected NOR flash which users JEDEC standard commands, note that the toggle bit may not be read out correctly. If the read signal in the cycle immediately preceding the access to the NOR flash does not go high in time, as shown in Figure 3.6.3, an unintended read cycle like the one shown in (b) may occur.

Figure 3.6.3 NOR Flash Toggle Bit Read Cycle

When the toggle bit reverse with this unexpected read cycle, CPU always reads same value of the toggle bit, and cannot read the toggle bit correctly. To avoid this phenomenon, the data polling function control is recommended.

(2) The cautions at the time of the functional change of a \overline{CSn} .

A chip select signal output has the case of a combination terminal with a general-purpose port function. In this case, an output latch register and a function control register are initialized by the reset action, and an object terminal is initialized by the port output ("1" or "0") by it.

Functional change

Although an object terminal is changed from a port to a chip select signal output by setting up a function control register (PnFC register), the short pulse for several ns may be outputted to the changing timing. Although it does not become especially a problem when using the usual memory, it may become a problem when using a special memory.

※ XX is a function register address. (When an output port is initialized by "0")

The measure by software

The countermeasures in S/W for avoiding this phenomenon are explained.

Since CS signal decodes the address of the access area and is generated, an unnecessary pulse is outputted by access to the object CS area immediately after setting it as a \overline{CSn} function. Then, if internal area is accessed also immediately after setting a port as CS function, an unnecessary pulse will not output.

1. Prohibition of use of an NMI function
2. The ban on interruption under functional change (DI command)
3. A dummy command is added in order to carry out continuous internal access.

(Access to a functional change register is corresponded by 16-bit command.
(LDW command))

3.7 8-Bit Timers (TMRA)

The TMP92CM27 features 8 built-in 8-bit timers.

These timers are paired into four modules: TMRA01, TMRA23, TMRA45 and TMRA67. Each module consists of two channels and can operate in any of the following four operating modes.

- 8-bit interval timer mode
- 16-bit interval timer mode
- 8-bit programmable square wave pulse generation output mode (PPG: Variable duty cycle with variable period)
- 8-bit pulse width modulation output mode (PWM: Variable duty cycle with constant period)

www.DataSheet4U.com

Figure 3.7.1 to Figure 3.7.4 show block diagrams for TMRA01, TMRA23, TMRA45 and TMRA67.

Each channel consists of an 8-bit up counter, an 8-bit comparator and an 8-bit timer register. In addition, a timer flip-flop and a prescaler are provided for each pair of channels.

The operation mode and timer flip-flops are controlled by five-byte controls SFR (Special-function registers).

Each of the four modules (TMRA01, TMRA23, TMRA45 and TMRA67) can be operated independently. All modules operate in the same manner; hence only the operation of TMRA01 is explained here.

The contents of this chapter are as follows.

3.7.1 Block diagrams

3.7.2 Operation of Each Circuit

3.7.3 SFRs

3.7.4 Operation in Each Mode

- (1) 8-bit timer mode
- (2) 16-bit timer mode
- (3) 8-bit PPG (Programmable pulse generation) output mode
- (4) 8-bit PWM (Pulse width modulation) output mode
- (5) Mode settings

Table 3.7.1 Registers and Pins for Each Module

Module		TMRA01	TMRA23	TMRA45	TMRA67
Specification					
External pin	Input pin for external clock	TA0IN (Shared with PF0)	TA2IN (Shared with PF2)	TA4IN (Shared with PF4)	TA6IN (Shared with PF6)
	Output pin for timer flip-flop	TA1OUT (Shared with PF1)	TA3OUT (Shared with PF3)	TA5OUT (Shared with PF5)	TA7OUT (Shared with PL3)
SFR (Address)	Timer RUN register	TA01RUN (1100H)	TA23RUN (1108H)	TA45RUN (1110H)	TA67RUN (1118H)
	Timer register	TA0REG (1102H) TA1REG (1103H)	TA2REG (110AH) TA3REG (110BH)	TA4REG (1112H) TA5REG (1113H)	TA6REG (111AH) TA7REG (111BH)
	Timer mode register	TA01MOD(1104H)	TA23MOD(110CH)	TA45MOD(1114H)	TA67MOD(111CH)
	Timer flip-flop control register	TA1FFCR(1105H)	TA3FFCR(110DH)	TA5FFCR(1115H)	TA7FFCR(111DH)

3.7.2 Operation of Each Circuit

(1) Prescaler

A 9-bit prescaler generates the input clock to TMRA01.

The prescaler's operation can be controlled using TA01RUN <TA0PRUN> in the timer control register. Setting <TA0PRUN> to "1" starts the count; setting <TA0PRUN> to "0" clears the prescaler to zero and stops operation. Table 3.7.2 shows the various prescaler output clock resolutions.

Table 3.7.2 Prescaler Output Clock Resolution

at $f_c = 40$ MHz

System clock selection <SYSCK>	Gear Value <GEAR2:0>	Cycle			
		$\phi T1$	$\phi T4$	$\phi T16$	$\phi T256$
0(f_c)	000 (f_c)	$2^3/f_c$ (0.2 μs)	$2^5/f_c$ (0.8 μs)	$2^7/f_c$ (3.2 μs)	$2^{11}/f_c$ (51.2 μs)
	001 ($f_c/2$)	$2^4/f_c$ (0.4 μs)	$2^6/f_c$ (1.6 μs)	$2^8/f_c$ (6.4 μs)	$2^{12}/f_c$ (102.4 μs)
	010 ($f_c/4$)	$2^5/f_c$ (0.8 μs)	$2^7/f_c$ (3.2 μs)	$2^9/f_c$ (12.8 μs)	$2^{13}/f_c$ (204.8 μs)
	011 ($f_c/8$)	$2^6/f_c$ (1.6 μs)	$2^8/f_c$ (6.4 μs)	$2^{10}/f_c$ (25.6 μs)	$2^{14}/f_c$ (409.6 μs)
	100 ($f_c/16$)	$2^7/f_c$ (3.2 μs)	$2^9/f_c$ (12.8 μs)	$2^{11}/f_c$ (51.2 μs)	$2^{15}/f_c$ (819.2 μs)

xxx: Don't care

(2) Up counters (UC0 and UC1)

These are 8-bit binary counters which count up the input clock pulses for the clock specified by TA01MOD.

The input clock for UC0 is selectable and can be either the external clock input via the TA0IN pin or one of the three internal clocks $\phi T1$, $\phi T4$, or $\phi T16$. The clock setting is specified by the value set in TA01MOD <TA0CLK1:0>.

The input clock for UC1 depends on the operation mode. In 16-bit timer mode, the overflow output from UC0 is used as the input clock. In any mode other than 16-bit timer mode, the input clock is selectable and can be either one of the internal clocks $\phi T1$, $\phi T16$, or $\phi T256$, or the comparator output (The match detection signal) from TMRA0.

For each interval timer the timer operation control register bits TA01RUN<TA0RUN> and TA01RUN<TA1RUN> can be used to stop and clear the up counters and to control their count. A reset releases both up counters, stopping the timers.

(3) Timer registers (TA0REG and TA1REG)

These are 8-bit registers, which can be used to set a time interval. When the value set in the timer register TA0REG or TA1REG matches the value in the corresponding up counter, the comparator match detect signal goes Active. If the value set in the timer register is 00H, the signal goes active when the up counter overflows.

The TA0REG are double buffer structure, each of which makes a pair with register buffer0.

The setting of the bit TA01RUN <TA0RDE> determines whether TA0REG's double buffer structure is enabled or disabled. It is disabled if <TA0RDE> = "0" and enabled if <TA0RDE> = "1".

When the double buffer is enabled, data is transferred from the register buffer0 to the timer register0 when a 2ⁿ overflow occurs in PWM mode, or at the start of the PPG cycle in PPG mode. Hence the double buffer cannot be used in timer mode.

A reset initializes <TA0RDE> to "0", disabling the double buffer. To use the double buffer, write data to the timer register0, set <TA0RDE> to "1", and write the following data to the register buffer0 3.7.5 show the configuration of TA0REG.

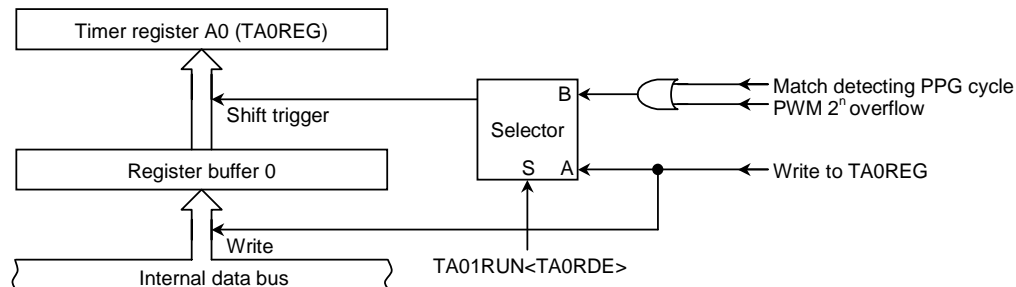

Figure 3.7.5 Timer Register A0 (TA0REG)

Note: The same memory address is allocated to TA0REG and the register buffer0. When <TA0RDE> = "0", the same value is written to the register buffer0 and TA0REG, when <TA0RDE> = 1, only the register buffer0 is written to.

The address of each timer register is as follows.

TA0REG: 001102H	TA1REG: 001103H
TA2REG: 00110AH	TA3REG: 00110BH
TA4REG: 001112H	TA5REG: 001113H
TA6REG: 00111AH	TA7REG: 00111BH

All these registers are write-only and cannot be read.

(4) Comparator (CP0, CP1)

The comparator compares the value in an up counter with the value set in a timer register. If they match, the up counter is cleared to 0 and an interrupt signal (INTTA0 or INTTA1) is generated. If timer flip-flop inversion is enabled, the timer flip-flop is inverted at the same time.

Note) The timer causes the overflow when the value below the improvement counter value is written in the timer register while the timer is working, and the generation of interrupt by the expected value is not obtained.

(It is possible to operate normally if the changed set value is more than the improvement counter value.)

Moreover, the Compare circuit doesn't operate in writing only 8-bit subordinate position bits when operating in 16-bit mode.

Therefore, please write it in 16-bit in order in 8-bit subordinate position bits and 8-bit high rank bits.

(5) Timer flip-flop (TA1FF)

The timer flip-flop (TA1FF) is a flip-flop inverted by the match detects signal (8-bit comparator output) of each interval timer.

Whether inversion is enabled or disabled is determined by the setting of the bit TA1FFCR <TA1FFIE> in the timer flip-flops control register. A reset clears the value of TA1FF to "0". Programming "01" or "10" to TA1FFCR <TA1FFC1:0> sets TA1FF to 0 or 1. Programming "00" to these bits inverts the value of TA1FF. (This is known as software inversion.)

The TA1FF signal is output via the TA1OUT pin (which can also be used as PF1). When this pin is used as the timer output, the timer flip-flop should be set beforehand using the port F function register PFCR and PFFC.

Inversion of TA1FF by each mode

8-bit timer mode : Agreement of UC0 and TA0REG or agreements of UC1 and TA1REG.

16-bit timer mode : Agreement of UC0 and TA0REG and agreements of UC1 and TA1REG.

8-bit PWM mode : Agreement of overflow or UC0 and TA0REG.

8-bit PPG mode : Agreement of UC0 and TA0REG or agreements of UC0 and TA1REG.

Note) When the change request by inversion and the register setting with the timer is done at the same time, it is necessary to note it because it becomes the following operation by the state at that time.

- When inversion by the timer and inversion by register setup occur simultaneously.
→ Only once inversion.
- When inversion by the timer and "1" set by register setup occur simultaneously.
→ Set to "1".
- When inversion by the timer and "0" clear by register setup occur simultaneously.
→ Clear to "0".

Figure 3.7.10 8-bit timer register(TA0REG to TA7REG)

3.7.4 Operation in Each Mode

(1) 8-bit timer mode

Both TMRA0 and TMRA1 can be used independently as 8-bit interval timers.

When set function and count data, TMRA0 and TMRA1 should be stopped.

1. Generating interrupts at a fixed interval (using TMRA1)

To generate interrupts at constant intervals using TMRA1 (INTTA1), first stop TMRA1 then set the operation mode, input clock and a cycle to TA01MOD and TA1REG register, respectively. Then, enable the interrupt INTTA1 and start TMRA1 counting.

Example: To generate an INTTA1 interrupt every 40 μ s at $f_c = 40$ MHz, set each register as follows:

	MSB				LSB					
	7	6	5	4	3	2	1	0		
TA01RUN	←	–	X	X	X	–	–	0	–	Stop TMRA1 and clear it to 0.
TA01MOD	←	0	0	X	X	0	1	–	–	Select 8-bit timer mode and select $\phi T1$ (0.2 μs at $f_c = 40$ MHz) as the input clock.
TA1REG	←	1	1	0	0	1	0	0	0	Set $40 \mu s \div \phi T1 = 200 = C8H$ to TAREG.
INTETA01	←	X	1	0	1	–	–	–	–	Enable INTTA1 and set it to Level 5.
TA01RUN	←	–	X	X	X	–	1	1	–	Start TMRA1 counting.

X : Don't care, – : No change

X : Don't care, – : No change

Note: The input clocks for TMRA0 and TMRA1 differ as follows:

TMRA0: Uses TMRA0 input (TA0IN) and can be selected from $\phi T1$, $\phi T4$, or $\phi T16$.

TMRA1: Match output of TMRA0 (TA0TRG) and can be selected from $\phi T1$, $\phi T16$, $\phi T256$.

2. Generating a 50% duty ratio square wave pulse

The state of the timer flip-flop (TA1FF) is inverted at constant intervals and its status output via the timer output pin (TA1OUT).

Example: To output a $1.2\ \mu\text{s}$ square wave pulse from the TA1OUT pin at $f_{\text{SYS}} = 20\ \text{MHz}$, use the following procedure to make the appropriate register settings. This example uses TMRA1; however, either TMRA0 or TMRA1 may be used.

	MSB				LSB					
	7	6	5	4	3	2	1	0		
TA01RUN	←	–	X	X	X	–	–	0	–	Stop TMRA1 and clear it to 0.
TA01MOD	←	0	0	X	X	0	1	–	–	Select 8-bit timer mode and select ϕT1 ($0.2\ \mu\text{s}$ at $f_c = 40\ \text{MHz}$) as the input clock.
TA1REG	←	0	0	0	0	0	0	1	1	Set the timer register to $1.2\ \mu\text{s} \div \phi\text{T1} \div 2 = 3$.
TA1FFCR	←	X	X	X	X	1	0	1	1	Clear TA1FF to 0 and set it to invert on the match detect signal from TMRA1.
PFCR	←	X	–	–	–	–	–	1	–	Set PF1 to function as the TA1OUT pin
PFFC	←	X	–	–	–	–	–	1	–	
TA01RUN	←	–	X	X	X	–	1	1	–	Start TMRA1 counting.

X : Don't care, – : No change

X : Don't care, – : No change

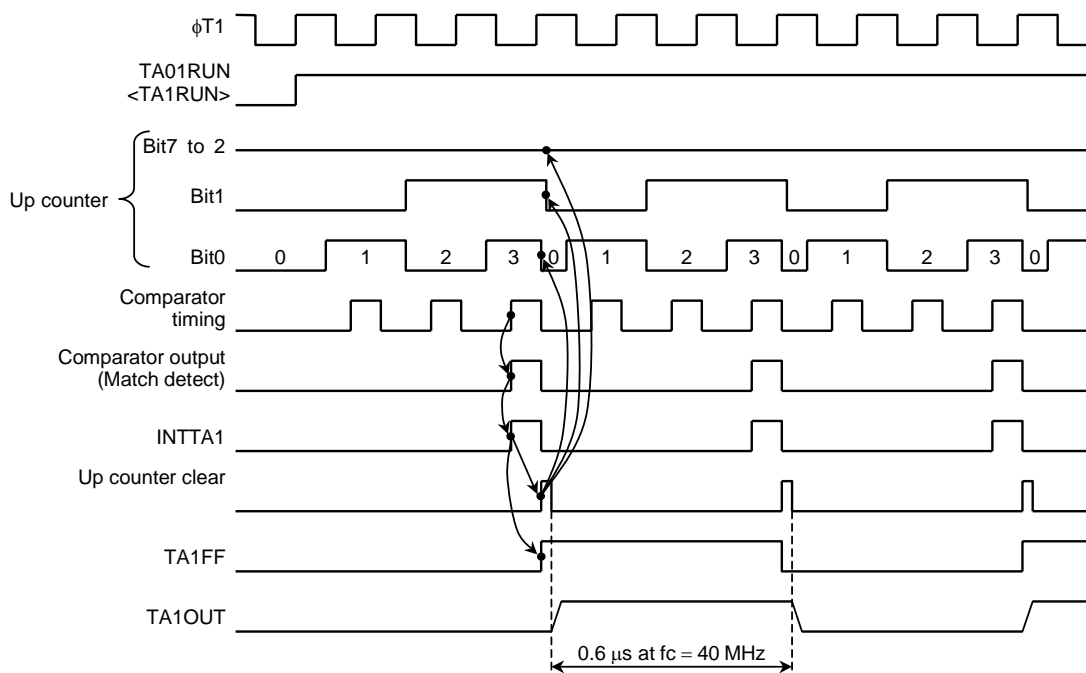

Figure 3.7.11 Square Wave Output Timing Chart (50% duty)

3. Making TMRA1 count up on the match signal from the TMRA0 comparator

Select 8-bit timer mode and set the comparator output from TMRA0 to be the input clock to TMRA1.

Figure 3.7.12 TMRA1 Count up on Signal from TMRA0

(2) 16-bit timer mode

A 16-bit interval timer is configured by pairing the two 8-bit timers TMRA0 and TMRA1.

To make a 16-bit interval timer, in which TMRA0 and TMRA1 are cascaded together, set TA01MOD <TA01M1:0> to "01".

In 16-bit timer mode, the overflow output from TMRA0 is used as the input clock for TMRA1, regardless of the value set in TA01MOD<TA1CLK1:0> Table 3.7.2 shows the relationship between the timer (Interrupt) cycle and the input clock selection.

To set the timer interrupt interval, set the lower eight bits in timer register TA0REG and the upper eight bits in TA1REG. Be sure to set TA0REG first (As entering data in TA0REG temporarily disables the compare, while entering data in TA1REG starts the compare).

Example: To generate an INTTA1 interrupt every 0.2 s at $f_c = 40$ MHz, set the timer registers TA0REG and TA1REG as follows:

If ϕT_{16} (3.2 μ s at 40 MHz) is used as the input clock for counting, set the following value in the registers:

$$0.2 \text{ s} \div 3.2 \mu\text{s} = 62500 = \text{F424H};$$

e.g., set TA1REG to F4H and TA0REG to 24H.

The comparator match signal is output from TMRA0 each time the up-counter UC0 matches TA0REG, though the up-counter UC0 is not be cleared.

In the case of the TMRA1 comparator, the match detect signal is output on each comparator pulse on which the values in the up-counter UC1 and TA1REG match. When the match detect signal is output simultaneously from both the comparator TMRA0 and TMRA1, the up-counters UC0 and UC1 are cleared to "0" and the interrupt INTTA1 is generated. Also, if inversion is enabled, the value of the timer flip-flop TA1FF is inverted.

Example: When TA1REG = 04H and TA0REG = 80H

Figure 3.7.14 Timer Output by 16-Bit Timer Mode

(3) 8-bit PPG (Programmable pulse generation) output mode

Square wave pulses can be generated at any frequency and duty ratio by TMRA0. The output pulses may be active-low or active-high. In this mode TMRA1 cannot be used.

TMRA0 outputs pulses on the TA1OUT pin (Shared with PF1).

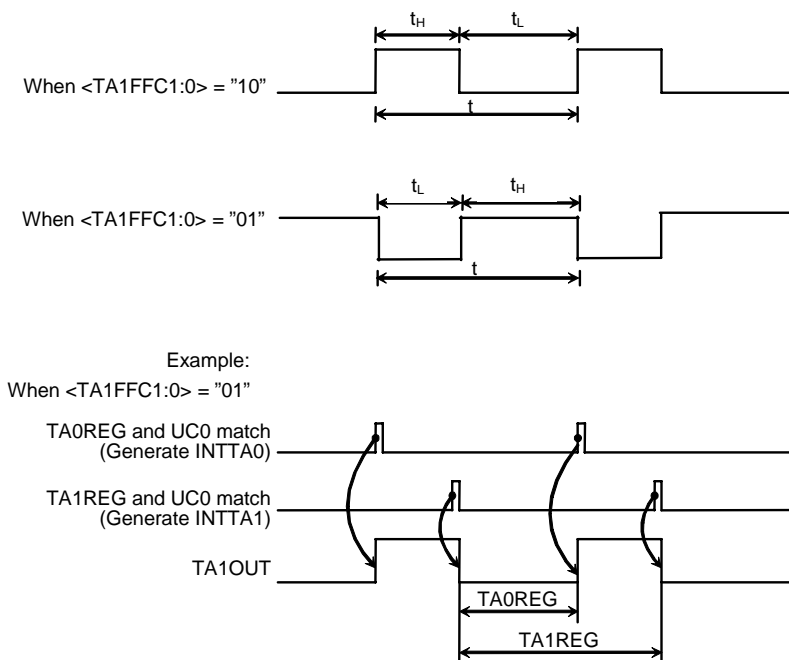

Figure 3.7.15 8-Bit PPG Output Waveforms

In this mode, a programmable square wave is generated by inverting the timer output each time the 8-bit up-counter (UC0) matches the value in one of the timer registers TA0REG or TA1REG.

The value set in TA0REG must be smaller than the value set in TA1REG.

Although the up-counter for TMRA1 (UC1) is not used in this mode, TA01RUN<TA1RUN> should be set to "1", so that UC1 is set for counting.

Figure 3.7.16 shows a block diagram representing this mode.

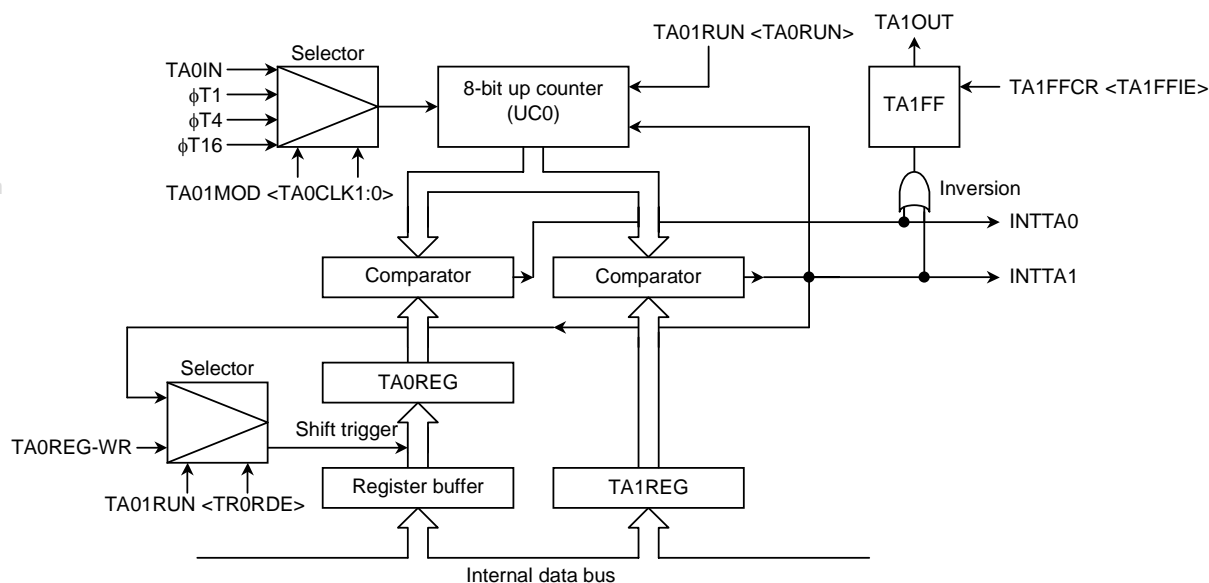

Figure 3.7.16 Block Diagram of 8-Bit PPG Output Mode

If the TA0REG double buffer is enabled in this mode, the value of the register buffer will be shifted into TA0REG each time TA1REG matches UC0.

Use of the double buffer facilitates the handling of low-duty waves (when duty is varied).

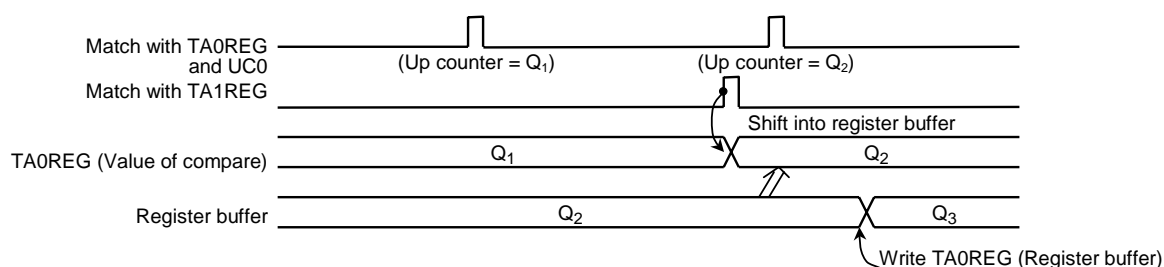

Figure 3.7.17 Operation of Register Buffer0

Example: To generate 1/4 duty 62.5 kHz pulses (at $f_c = 40$ MHz):

Calculate the value that should be set in the timer register.

To obtain a frequency of 62.5 kHz, the pulse cycle t should be: $t = 1/62.5 \text{ kHz} = 16 \mu\text{s}$

$\phi T1 = 0.2 \mu\text{s}$ (at $f_c = 40$ MHz);

$$16 \mu\text{s} / 0.2 \mu\text{s} = 80$$

Therefore set $TA1REG = 80 = 50H$

The duty is to be set to 1/4: $t \times 1/4 = 16 \mu\text{s} \times 1/4 = 4 \mu\text{s}$

$$4 \mu\text{s} / 0.2 \mu\text{s} = 20$$

Therefore, set $TA0REG = 20 = 14H$

www.DataSheet4U.com

X : Don't care, — : No change

(4) 8-bit PWM (Pulse width modulation) output mode

This mode is only valid for TMRA0. In this mode, a PWM pulse with the maximum resolution of 8 bits can be output.

When TMRA0 is used the PWM pulse is output on the TA1OUT pin (which is also used as PF1). TMRA1 can also be used as an 8-bit timer.

The timer output is inverted when the up-counter (UC0) matches the value set in the timer register TA0REG or when 2^n counter overflow occurs ($n = 6, 7$, or 8 as specified by TA01MOD <PWM01:00>). The up-counter UC0 is cleared when 2^n counter overflow occurs.

The following conditions must be satisfied before this PWM mode can be used.

Value set in TA0REG < Value of set for 2^n counter overflow

Value set in TA0REG $\neq 0$

Figure 3.7.18 8-Bit Output Wave Form

Figure 3.7.19 shows a block diagram representing this mode.

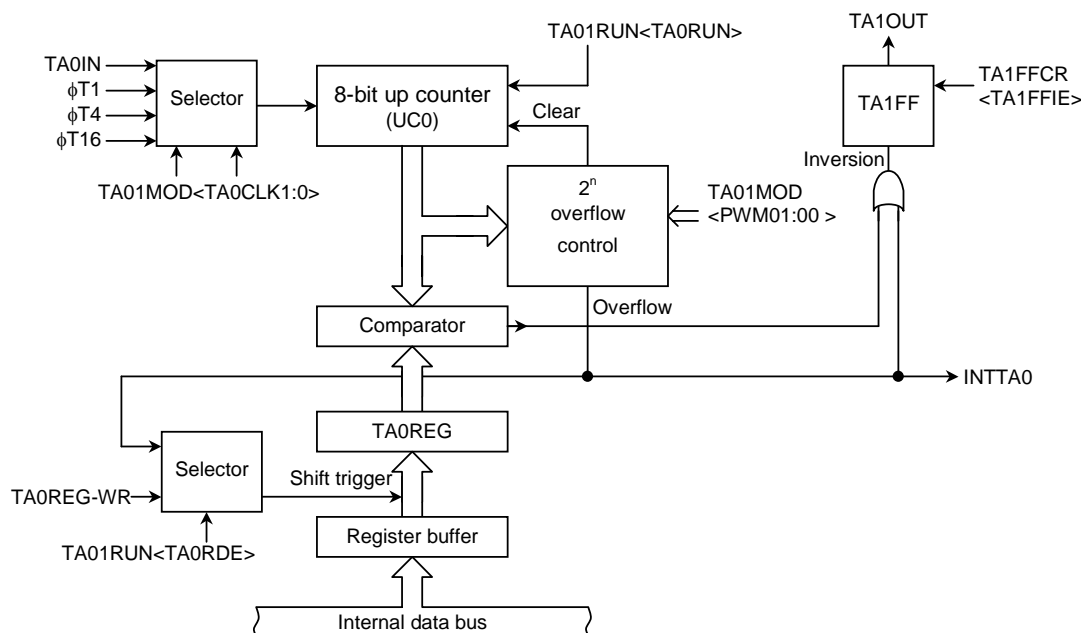

Figure 3.7.19 Block Diagram of 8-Bit PWM Output Mode

In this mode, the value of the register buffer will be shifted into TA0REG if 2^n overflow is detected when the TA0REG double buffer is enabled.

Use of the double buffer facilitates the handling of low duty ratio waves.

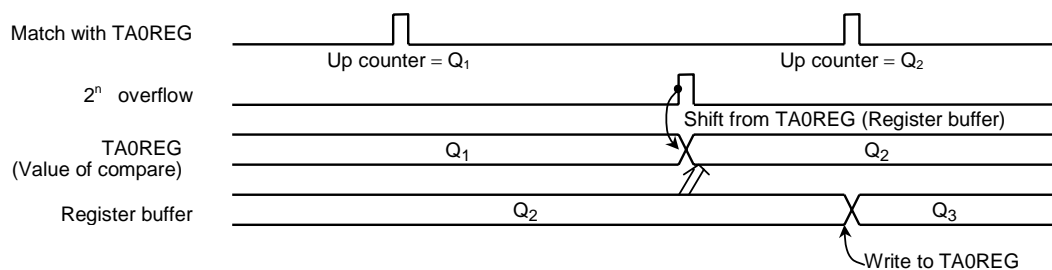

Figure 3.7.20 Operation of Register Buffer

Example: To output the following PWM waves on the TA1OUT pin at $f_c = 40$ MHz:

To achieve a $25.6 \mu s$ PWM cycle by setting $\phi T1$ to $0.2 \mu s$ (at $f_c = 40$ MHz):

$$25.6 \mu s / 0.2 \mu s = 128 = 2^n$$

Therefore n should be set to 7.

Since the low-level period is $18.0 \mu s$ when $\phi T1 = 0.2 \mu s$,
set the following value for TA0REG:

$$18.0 \mu s / 0.2 \mu s = 90 = 5AH$$

	MSB				LSB					
	7	6	5	4	3	2	1	0

3.8 16-Bit Timer/Event Counters (TMRB)

The TMP92CM27 contains 6 channels 16-bit timer/event counter (TMRB0 to TMRB5) which have the following operation modes:

- 16-bit interval timer mode
- 16-bit event counter mode
- 16-bit programmable square wave pulse generation output mode (PPG: Variable duty cycle with variable period)

Can be used following operation modes by capture function:

- Frequency measurement mode
- Pulse width measurement mode
- Time differential measurement mode

Figure 3.8.1 to Figure 3.8.2 show block diagram of TMRB0 to TMRB5. Each timer/event counter consists of a 16-bit up counter, two 16-bit timer registers (One of them with a double-buffer structure), two 16-bit capture registers, two comparators, a capture input controller, a timer flip-flop and a control circuit.

Each timer/event counter is controlled by 11-byte control register (SFR).

Each of the six modules (TMRB0 to TMRB5) can be operated independently. All modules operate in the same manner; hence only the operation of TMRA01 is explained here.

Table 3.8.1 Pins and SFR of TMRB

Note 1) Since TB2OUT0/TB4OUT0, TB2OUT1/TB4OUT1, TB3OUT0/TB5OUT0, and TB3OUT1/TB5OUT1 are making the output terminal serve a double purpose, they cannot be used simultaneously.

Note 2) Since INTTB30/INTTB31, INTTB40/INTTB41 and INTTB50/INTTB51 are making the interruption factor serve a double purpose, they cannot be used simultaneously.

Note 3) Although INTTBOF0/INTTBOF1/INTTBOF2/INTTBOF3/INTTBOF4/INTTBOF5 is making the interruption factor serve a double purpose, it can be used simultaneously. Which interruption occurred should lead an INTST register.

This chapter consists of the following items:

- 3.8.1 Block diagram
- 3.8.2 Operation
- 3.8.3 SFRs
- 3.8.4 Operation in Each Mode

3.8.2 Operation

(1) Prescaler

The 5-bit prescaler generates the source clock for TMRB1. Input clock $\phi T0$ to Priscara is a clock that was four dividing fFPH.

This prescaler can be started or stopped using TB0RUN<TB0PRUN>. Counting starts when <TB0PRUN> is set to 1; the prescaler is cleared to zero and stops operation when <TB0PRUN> is cleared to 0.

Table 3.8.2 show prescaler output clock resolution.

Table 3.8.2 Prescaler Output Clock Resolution

at $f_c = 40 \text{ MHz}$

Gear Value SYSCR1 <GEAR2:0>	Cycle		
	$\phi T1$	$\phi T4$	$\phi T16$
000 (f_c)	$2^3/f_c$ (0.2 μs)	$2^5/f_c$ (0.8 μs)	$2^7/f_c$ (3.2 μs)
001 ($f_c/2$)	$2^4/f_c$ (0.4 μs)	$2^6/f_c$ (1.6 μs)	$2^8/f_c$ (6.4 μs)
010 ($f_c/4$)	$2^5/f_c$ (0.8 μs)	$2^7/f_c$ (3.2 μs)	$2^9/f_c$ (12.8 μs)
011 ($f_c/8$)	$2^6/f_c$ (1.6 μs)	$2^8/f_c$ (6.4 μs)	$2^{10}/f_c$ (25.6 μs)
100 ($f_c/16$)	$2^7/f_c$ (3.2 μs)	$2^9/f_c$ (12.8 μs)	$2^{11}/f_c$ (51.2 μs)

xxx: Don't care

(2) Up counter (UC0)

UC0 is a 16-bit binary counter that counts up according to input from the clock specified by TB0MOD<TB0CLK1:0> register.

As the input clock, one of the prescaler internal clocks $\phi T1$, $\phi T4$, and $\phi T16$ can be selected. Counting or stopping and clearing of the counter is controlled by timer operation control register TB0RUN<TB0RUN>. And an external clock from TB0IN0 pin can be selected in TB0MOD.

When clearing is enabled, the up counter UC0 will be cleared to zero each time its value matches the value in the timer register TB0RG1H/L. Clearing can be enabled or disabled using TB0MOD<TB0CLE>.

If clearing is disabled, the counter operates as a free-running counter.

A timer overflow interrupt (INTTBO0) is generated when UC0 overflow occurs.

(3) Timer registers (TB0RG0H/L and TB0RG1H/L)

These two 16-bit registers are used to set the interval time. When the value in the up counter UC0 matches the value set in this timer register, the comparator match detect signal will go active.

Setting data for both upper and lower timer registers TB0RG0H/L and TB0RG1H/L is always needed. For example, either using 2-byte data transfer instruction or using 1-byte data transfer instruction twice for lower 8 bits and upper 8 bits in order.

The TB0RG0H/L timer register has a double-buffer structure, which is paired with register buffer 0. The value set in TB0RUN<TB0RDE> determines whether the double-buffer structure is enabled or disabled: It is disabled when <TB0RDE> = 0, and enabled when <TB0RDE> = 1.

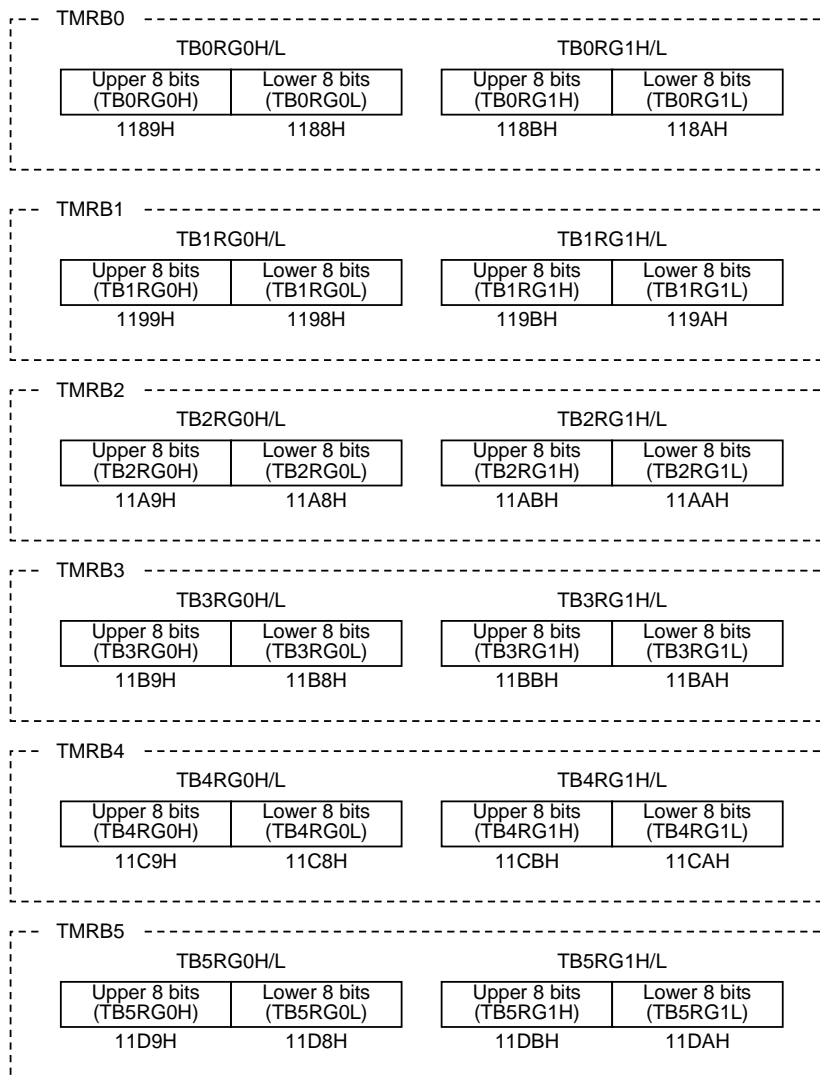

When the double buffer is enabled, data is transferred from the register buffer to the timer register when the values in the up counter (UC0) and the timer register TB0RG1 match.

After a reset, TB0RG0H/L and TB0RG1H/L are undefined. If the 16-bit timer is to be used after a reset, data should be written to it beforehand.

On a reset <TB0RDE> is initialized to 0, disabling the double buffer. To use the double buffer, write data to the timer register, set <TB0RDE> to 1, then write data to the register buffer as shown below.

TB0RG0H/L and the register buffer both have the same memory addresses (001189H and 001188H) allocated to them. If <TB0RDE> = 0, the value is written to both the timer register and the register buffer. If <TB0RDE> = 1, the value is written to the register buffer only.

The addresses of the timer registers are as follows:

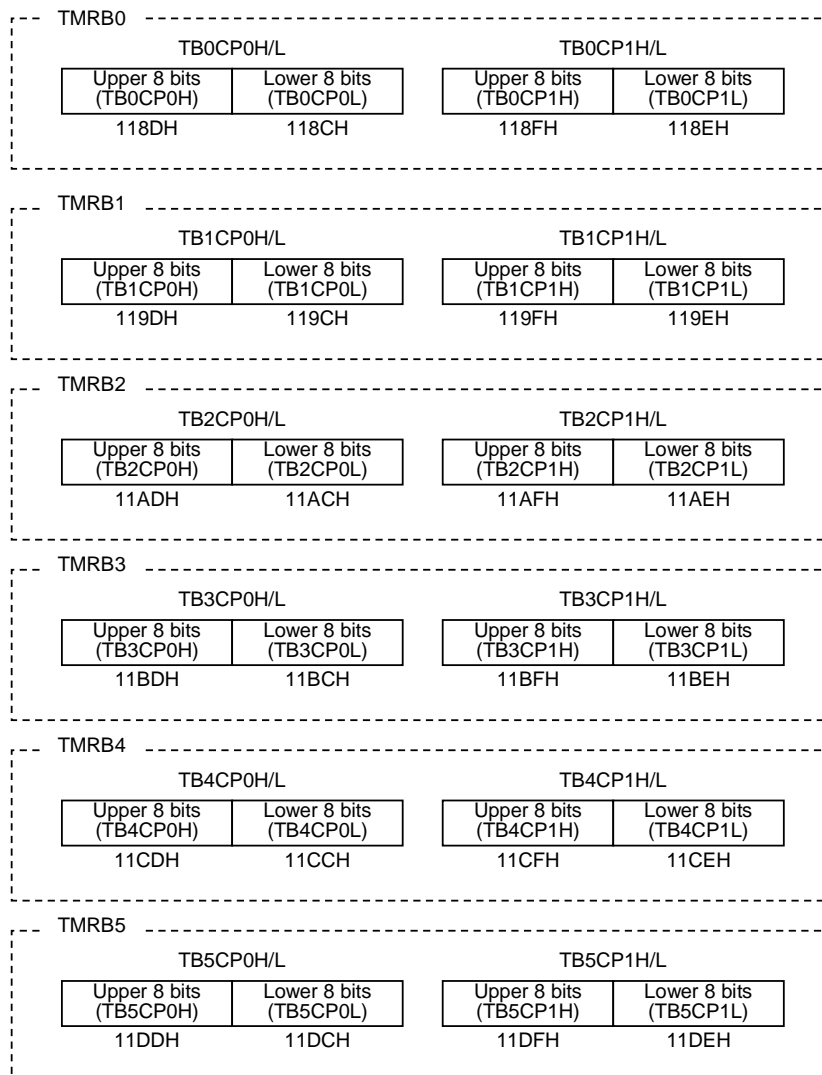

The timer registers are write-only registers and thus cannot be read.

(4) Capture registers

These 16-bit registers are used to latch the values in the up counters UC0.

Data in the capture registers should be read both upper and lower all 16 bits. For example, using 2-byte data transfer instruction or using 1-byte data transfer instruction twice for lower 8 bits and upper 8 bits in order.

The addresses of the capture registers are as follows:

The capture registers are read-only registers and thus cannot be written.

(5) Capture and external interrupt control

This circuit controls the timing to latch the value of up counter UC0 into TB0CP0H/L, TB0CP1H/L and generating for external interrupt.

Interrupt timing of capture register and selection edge of external interrupt are set by TB0MOD<TB0CPM1:0>. (TMRB4 and TMRB5 does not include the selection edge of external interrupt.)

External interrupt INT5 is fixed to the rising edge.

The value in the up counter (UC0) can be loaded into a capture register by software. Whenever 0 is programmed to TB0MOD<TB0CP0I>, the current value in the up counter is loaded into capture register TB0CP0H/L. It is necessary to keep the prescaler in Run mode (e.g., TB0RUN<TB0PRUN> must be held at a value of 1).

Note) External interrupt can be controlled with this control circuit by seeing when the port setting is set to input function (TB0IN0) of TMRB0. When the port setting is set to INT4, it controls by interrupt input mode control 1 and 2(IIMC1,IIMC2).

(6) Comparators (CP0 and CP1)

CP0 and CP1 are 16-bit comparators which compare the value in the up counter UC0 with the value set in TB0RG0H/L or TB0RG1H/L respectively, in order to detect a match. If a match is detected, the comparator generates an interrupt (INTTB00 or INTTB01 respectively).

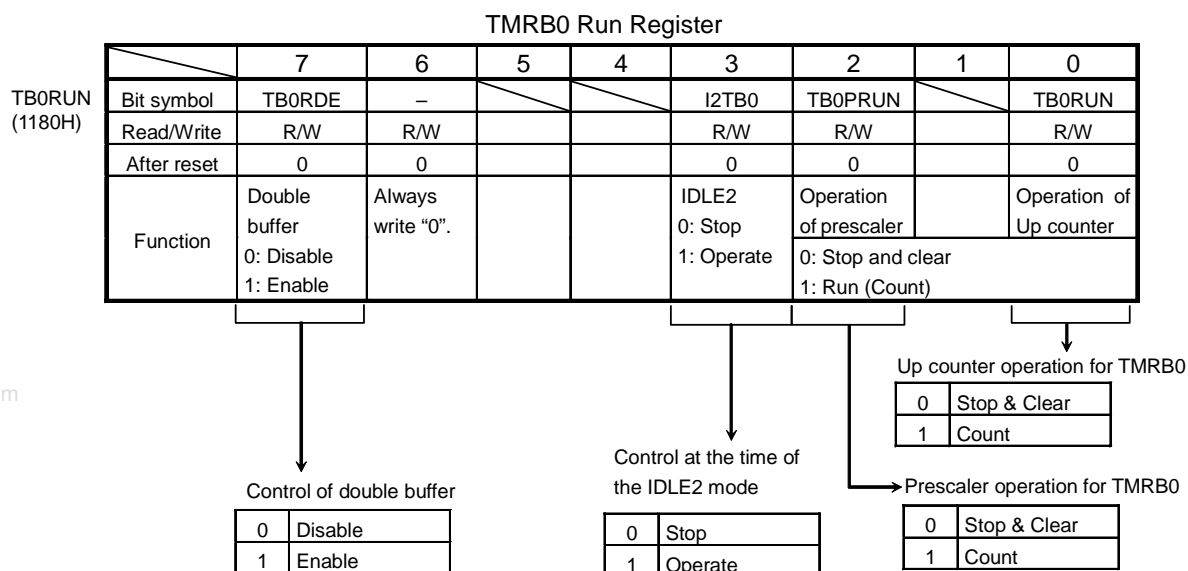

(7) Timer flip-flop (TB0FF0 and TB0FF1)

These flip-flops (TB0FF0 and TB0FF1) are inverted by the match detect signals from the comparators and the latch signals to the capture registers. Inversion can be enabled and disabled for each element using TB0FFCR<TB0C1T1, TB0C0T1, TB0E1T1, TB0E0T1>. Moreover, control of TB0FF0 and TB0FF1 is controllable by TB0MOD<TB0CT1, TB0ET1>.

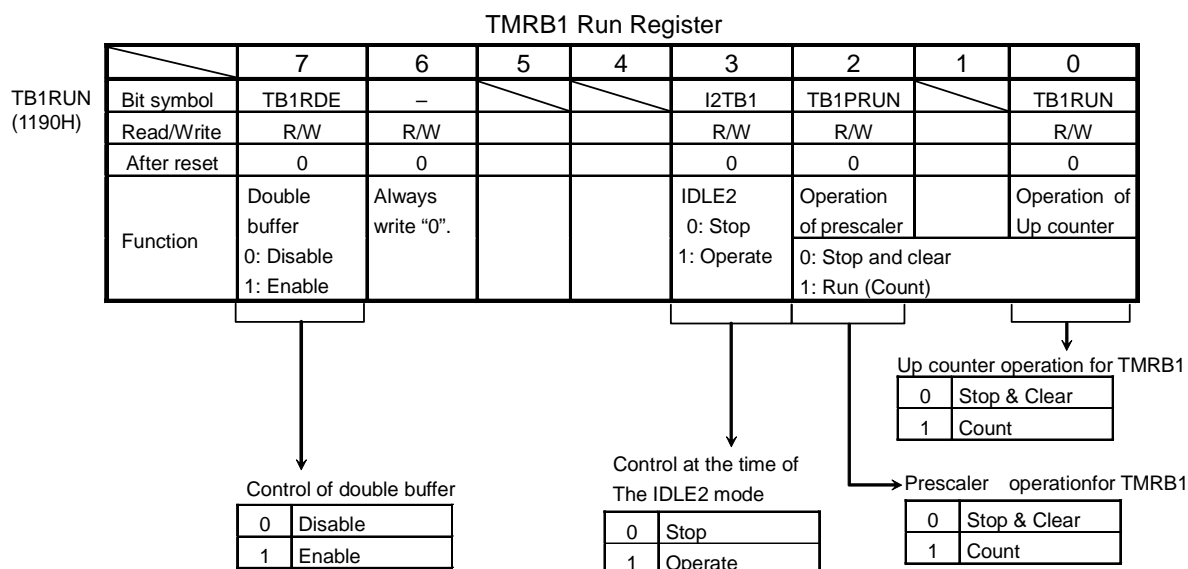

After a reset the values of TB0FF0 and TB0FF1 are undefined. If "00" is programmed to TB0FFCR<TB0FF0C1:0> or <TB0FF1C1:0>, TB0FF0 will be inverted. If "01" is programmed to the capture registers, the value of TB0FF0 will be set to "1". If "10" is programmed to the capture registers, the value of TB0FF0 will be cleared to "0".

The values of TB0FF0 and TB0FF1 can be output via the timer output pins TB0OUT0 (which is shared with PJ0), TB0OUT1 (which is shared with PJ1). Because the timer output terminal of TMRB2/TMRB3 and TMRB4/TMRB5 uses the terminal combinedly, it is not possible to use it at the same time. Timer output should be specified using the port function register.

3.8.4 Operation in Each Mode

(1) 16-bit interval timer mode

Generating interrupts at fixed intervals in this example, the interval time is set the timer register TB0RG1H/L to generate the interrupt INTTB01.

	7	6	5	4	3	2	1	0		
TB0RUN	←	0	0	X	X	–	0	X	0	Stop TMRB0.
INTETB0	←	X	1	0	0	X	0	0	0	Enable INTTB01 and set interrupt level 4. Disable INTTB00.
TB0FFCR	←	1	1	0	0	0	0	1	1	Disable the trigger.
TB0MOD	←	0	0	1	0	0	1	*	*	Set input clock to prescaler clock, and set capture function to disable.
									(** = 01, 10, 11)	
TB0RG1H/ L	←	*	*	*	*	*	*	*	*	Set the interval time (16 bits).
			*	*	*	*	*	*	*	
TB0RUN	←	0	0	X	X	–	1	X	1	Start TMRB0.

X : Don't care, – : No change

(2) 16-bit event counter mode

In 16-bit timer mode as described in above, the timer can be used as an event counter by selecting the external clock (TB0IN0 pin input) as the input clock.

Up counter counting up by rising edge of TB0IN0 pin input. And execution software capture and reading capture value enable reading count value.

	7	6	5	4	3	2	1	0		
TB0RUN	←	0	0	X	X	–	0	X	0	Stop TMRB0.
PKFC	←	–	–	–	–	–	–	–	1	Set PK0 to TB0IN0 input mode.
PKFC2	←	–	–	–	–	–	–	–	0	
INTETB0	←	X	1	0	0	X	0	0	0	Set INTTB01 to enable (Interrupt level4).
										Set INTTB00 to disable.
TB0FFCR	←	1	1	0	0	0	0	1	1	Set trigger to disable.
TB0MOD	←	0	0	1	0	0	1	0	0	Set input clock to TB0IN0 pin input.
TB0RG1H/L	←	*	*	*	*	*	*	*	*	Set number of count. (16 bits)
TB0RUN	←	0	0	X	X	–	1	X	1	Start TMRB0.

X: Don't care, –: No change

Note: When used as an event counter, set the prescaler to "RUN" (TB0RUN<TB0PRUN> = "1").

(3) 16-bit programmable pulse generation (PPG) output mode

Square wave pulses can be generated at any frequency and duty ratio. The output pulse may be either low active or high active.

The PPG mode is obtained by inversion of the timer flip-flop TB0FF0 that is to be enabled by the match of the up counter UC0 with timer register TB0RG0H/L or TB0RG1H/L and to be output to TB0OUT0. In this mode, the following conditions must be satisfied.

$$(\text{Set value of TB0RG0H/L}) < (\text{Set value of TB0RG1H/L})$$

Figure 3.8.28 Programmable Pulse Generation (PPG) Output Waveform

When the TB0RG0H/L double buffer is enabled in this mode, the value of register buffer 0 will be shifted into TB0RG0H/L at match with TB0RG1H/L. This feature makes easy the handling of low-duty waves.

Figure 3.8.29 Operation of Register Buffer

The following block diagram illustrates this mode.

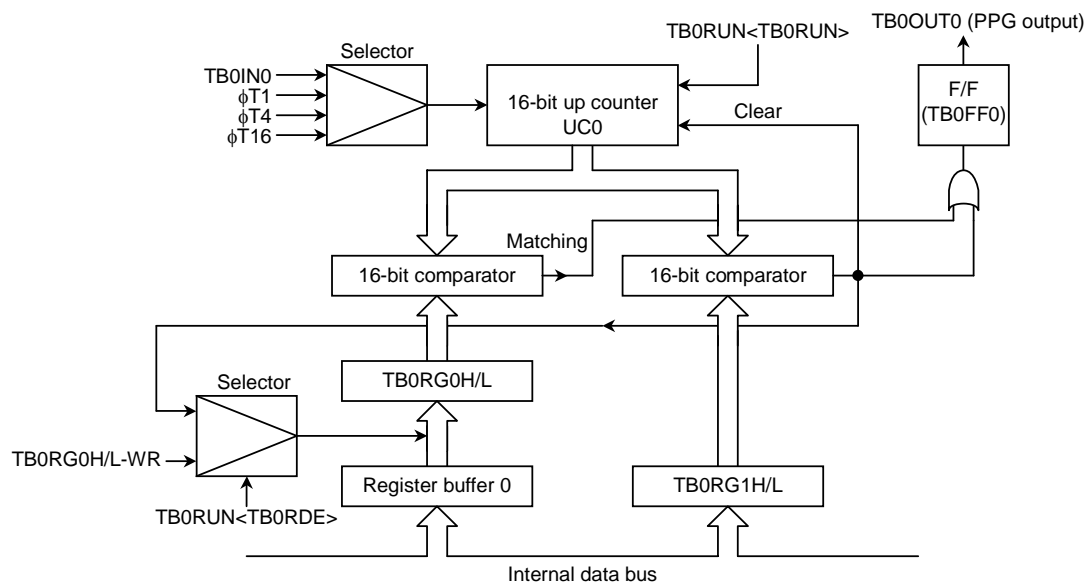

Figure 3.8.30 Block Diagram of 16-Bit PPG Mode

The following example shows how to set 16-bit PPG output mode:

		7	6	5	4	3	2	1	0	
TB0RUN	←	0	0	X	X	—	0	X	0	Disable the TB0RG0H/L double buffer and stop TMRB0. Set the duty ratio (16 bits).
	TB0RG0H/L	←	*	*	*	*	*	*	*	
			*	*	*	*	*	*	*	
	TB0RG1H/L	←	*	*	*	*	*	*	*	Set the frequency (16 bits).
		*	*	*	*	*	*	*	*	
TB0RUN	←	1	0	X	X	—	0	X	0	Enable the TB0RG0H/L double buffer. (The duty and frequency are changed on an INTTB01 interrupt.)
TB0FFCR	←	X	X	0	0	1	1	1	0	Set the mode to invert TB0FF0 at the match with TB0RG0H/L, TB0RG1H/L. Clear TB0FF0 to 0.

X : Don't care, — : No change

X : Don't care, — : No change

(4) Capture function examples

Used capture function, they can be applicable in many ways, for example:

1. One-shot pulse output from external trigger pulse
2. Frequency measurement
3. Pulse width measurement
4. Measurement of difference time

1. One-shot pulse output from external trigger pulse

Set the up counter UC0 in free-running mode with the internal input clock, input the external trigger pulse from TB0IN0 pin, and load the value of up counter into capture register TB0CP0H/L at the rise edge of external trigger pulse.

When the interrupt INT4 is generated at the rise edge of external trigger pulse, set the TB0CP0H/L value (c) plus a delay time (d) to TB0RG0H/L ($= c + d$), and set the above set value ($c + d$) plus a one-shot width (p) to TB0RG1H/L ($= c + d + p$). And, set "11" to timer flip-flop control register TB0FFCR<TB0E1T1, TB0E0T1>. Set to trigger enable for be inverted timer flip-flop TB0FF0 by UC0 matching with TB0RG0H/L and with TB0RG1H/L. When interrupt INTTB01 occurs, this inversion will be disabled after one-shot pulse is output.

The (c), (d), and (p) correspond to c, d, and p in Figure 3.8.31.

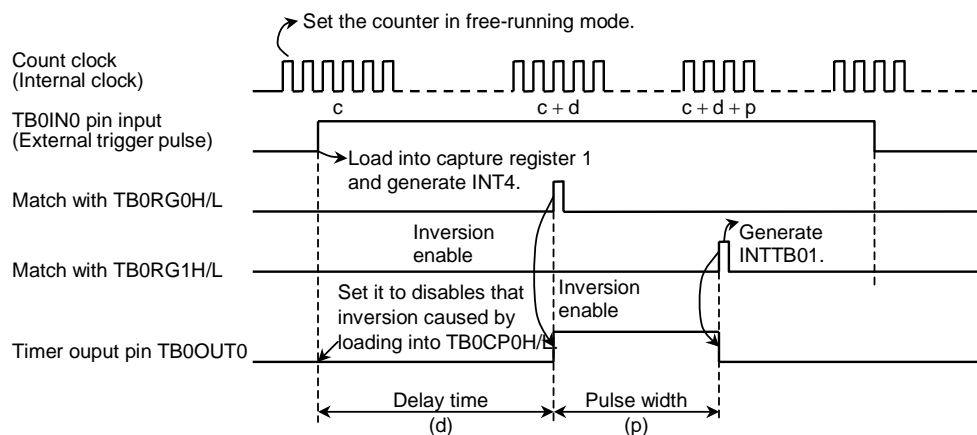

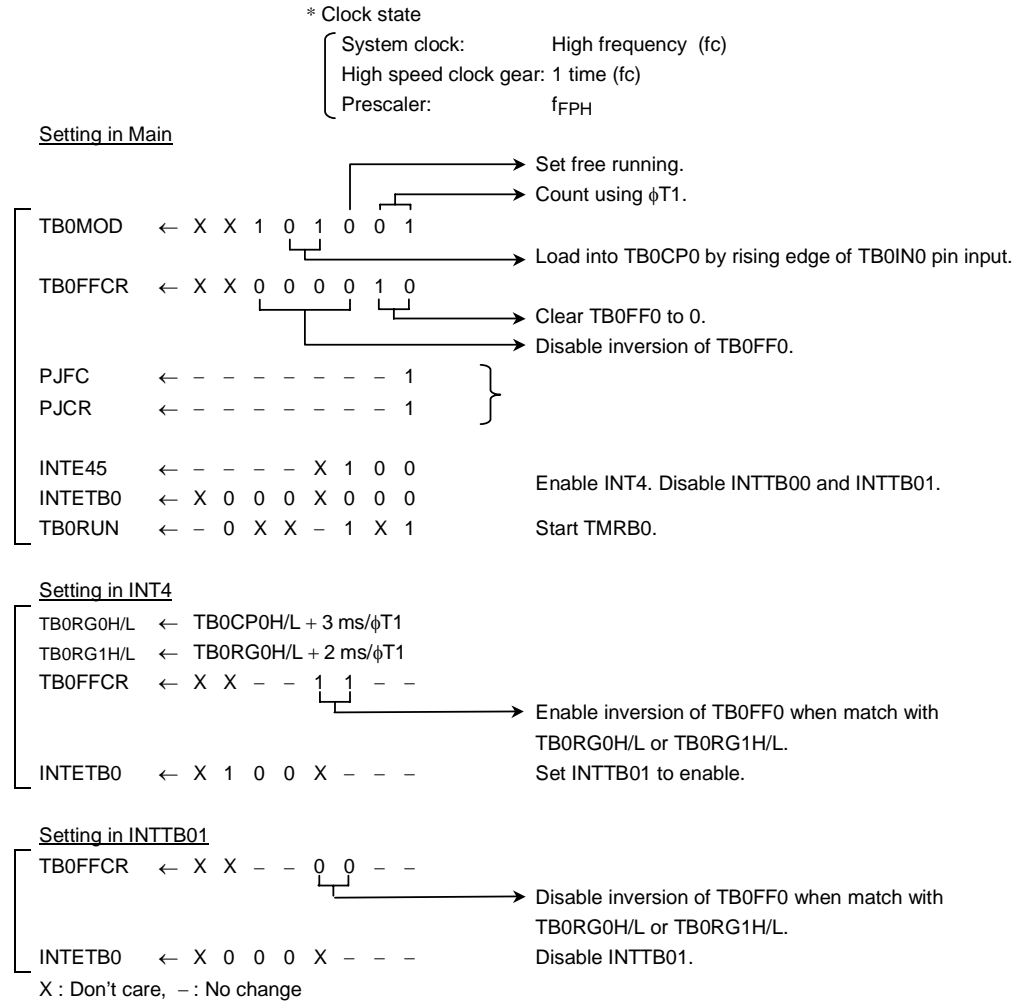

Figure 3.8.31 One-shot Pulse Output (with delay)

Example: To output a 2 [ms] one-shot pulse with a 3 [ms] delay to the external trigger pulse via the TB0IN0 pin.

When delay time is unnecessary, invert timer flip-flop TB0FF0 when up counter value is loaded into capture register (TB0CP0H/L), and set the TB0CP0H/L value (c) plus the one-shot pulse width (p) to TB0RG1H/L when the interrupt INT4 occurs. The TB0FF0 inversion should be enable when the up counter (UC0) value matches TB0RG1H/L, and disabled when generating the interrupt INTTB01.

Figure 3.8.32 One-shot Pulse Output of External Trigger Pulse (without delay)

2. Frequency measurement

The frequency of the external clock can be measured in this mode. Frequency is measured by the 8-bit timers TMRA01 and the 16-bit timer/event counter.

TMRA01 is used to setting of measurement time by inversion TA1FF.

Counter clock in TMRB0 select TB0IN0 pin input, and count by external clock input. Set to $TB0MOD<TB0CPM1:0> = "11"$. The value of the up counter (UC0) is loaded into the capture register TB0CP0H/L at the rise edge of the timer flip-flop TA1FF of 8-bit timers (TMRA01), and into TB0CP1H/L at its fall edge.

The frequency is calculated by difference between the loaded values in TB0CP0H/L and TB0CP1H/L when the interrupt (INTTA0 or INTTA1) is generates by either 8-bit timer.

Figure 3.8.33 Frequency Measurement

For example, if the value for the level 1 width of TA1FF of the 8-bit timer is set to 0.5 s and the difference between the values in TB0CP0H/L and TB0CP1H/L is 100, the frequency is $100 \div 0.5 \text{ s} = 200 \text{ Hz}$.

3. Pulse width measurement

This mode allows measuring the high level width of an external pulse. While keeping the 16-bit timer/event counter counting (Free running) with the prescaler output clock input, external pulse is input through the TB0IN0 pin. Then the capture function is used to load the UC0 values into TB0CP0H/L and TB0CP1H/L at the rising edge and falling edge of the external trigger pulse respectively. The interrupt INT4 occurs at the falling edge of TB0IN0.

The pulse width is obtained from the difference between the values of TB0CP0H/L and TB0CP1H/L and the internal clock cycle.

For example, if the prescaler output clock is $0.8\ \mu\text{s}$ and the difference between TB0CP0H/L and TB0CP1H/L is 100, the pulse width will be $100 \times 0.8\ \mu\text{s} = 80\ \mu\text{s}$.

Additionally, the pulse width that is over the UC0 maximum count time specified by the clock source can be measured by changing software.

Figure 3.8.34 Pulse Width Measurement

Note: Pulse Width measure by setting "10" to TB0MOD<TB0CPM1:0>. The external interrupt INT4 is generated in timing of falling edge of TB0IN0 input. In other modes, it is generated in timing of rising edge of TB0IN0 input.

The width of low level can be measured from the difference between the first C2 and the second C1 at the second INT4 interrupt.

4. Measurement of difference time

This mode is used to measure the difference in time between the rising edges of external pulses input through TB0IN0 and TB0IN1.

Keep the 16-bit timer/event counter (TMRB0) counting (Free running) with the prescaler output clock, and load the UC0 value into TB0CP0H/L at the rising edge of the input pulse to TB0IN0. Then the interrupt INT4 is generated.

Similarly, the UC0 value is loaded into TB0CP1H/L at the rising edge of the input pulse to TB0IN1, generating the interrupt INT5.

The time difference between these pulses can be obtained by multiplying the value subtracted TB0CP0H/L from TB0CP1H/L and the internal clock cycle together at which loading the UC0 value into TB0CP0H/L and TB0CP1H/L has been done.

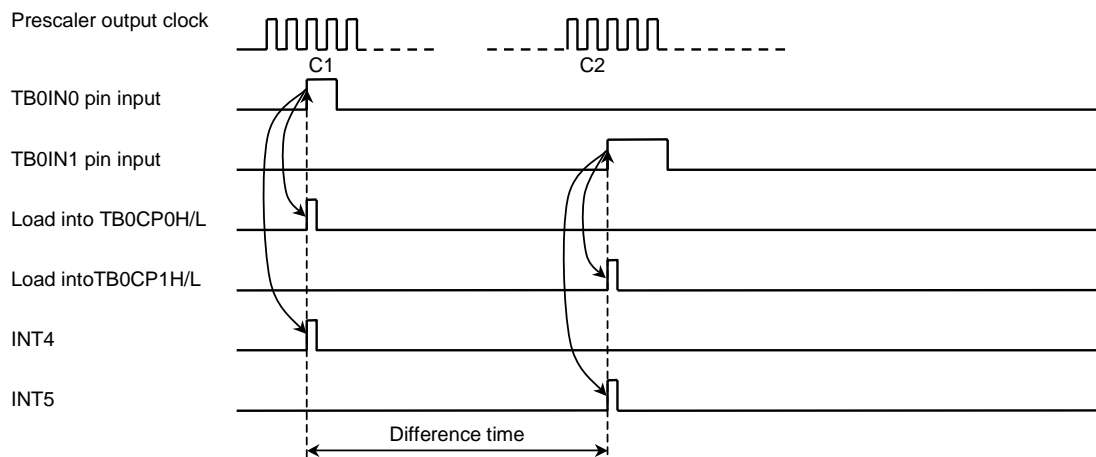

Figure 3.8.35 Measurement of Difference Time

3.9 Pattern Generator/Stepping Motor Control(PG)

The TMP92CM27 contains two 4-bit hardware pattern generator/stepping motor control channels, PG0 and PG1, (hereinafter called PG) which actuate in synchronization with the (8-bit/16-bit) timers. PG (PG0 and PG1) shares the 8-bit input/output port with PL.

The output on channel 0 (PG0) is updated in synchronization with the 8-bit timer 0, 1 (TMRA01) or 16-bit timer 0 (TMRB0). The output on channel 1 (PG1) is updated in synchronization with the 8-bit timer 2, 3 (TMRA23) or 16-bit timer 1 (TMRB1). Figure 3.9.1 show block diagram.

The PG ports are controlled by the control register (PG01CR) and can select either stepping motor control mode or pattern generation mode. Each bit of PL can be used for a PG port.

PG0 and PG1 can be used independently.

Since the two PG channels operate in the same manner, except for the following points, only the operation of PG0 will be explained below.

Differences between PG0 and PG1

	PG0	PG1
Trigger signal	8-bit timer 0,1 (TMRA01) or 16-bit timer 0 (TMRB0)	8-bit timer 2,3 (TMRA23) or 16-bit timer 1 (TMRB1)

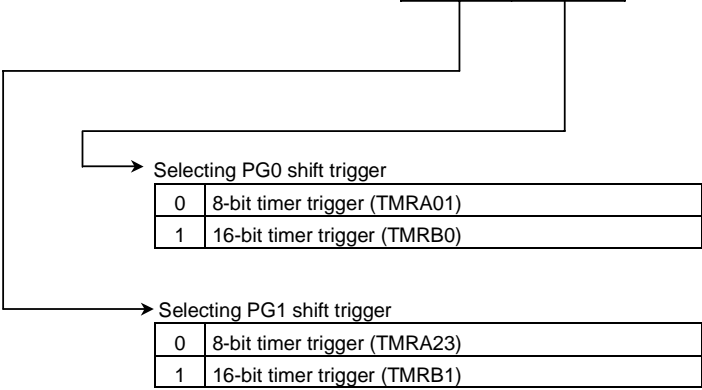

Figure 3.9.6 Pattern Generation Control Register 2 (PG01CR2)

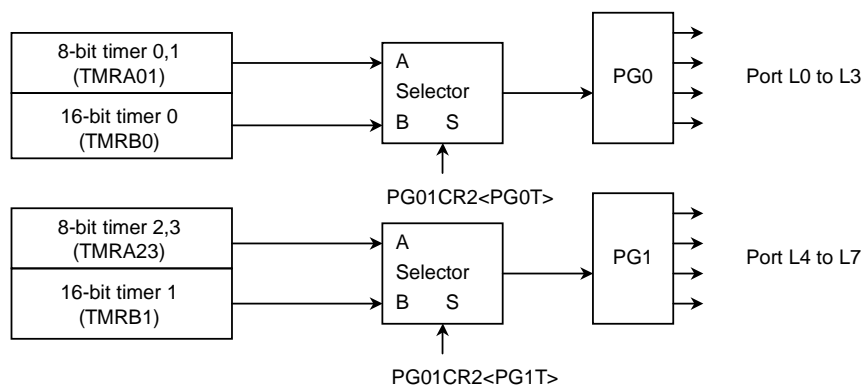

Figure 3.9.7 Connection between Timer and Pattern Generator

(1) Pattern generation mode

When PG01CR<PAT0> = “1”, PG functions as a pattern generator. In this mode data is written from the CPU to the shift alternate register only. The pattern data is then written from the shift alternate register to the pattern generator register synchronized to the shift trigger interrupt from the timer.

In this mode, PG01CR<PG0M> should be set to “1”, PG01CR<CCW0> to “0”, and PG01CR<PG0TE> to “1”.

The output from the pattern generator goes to port L; since port or functions can be switched by the bit settings in the port function control register (PLFC) and port function control register 2 (PLFC2), any port pin can be assigned to pattern generator output.

Figure 3.3.9 shows the block diagram for this mode.

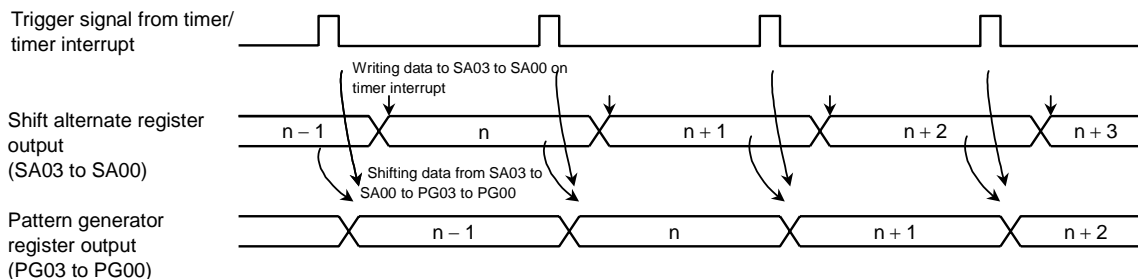

Figure 3.9.8 Example of Pattern Generation Mode

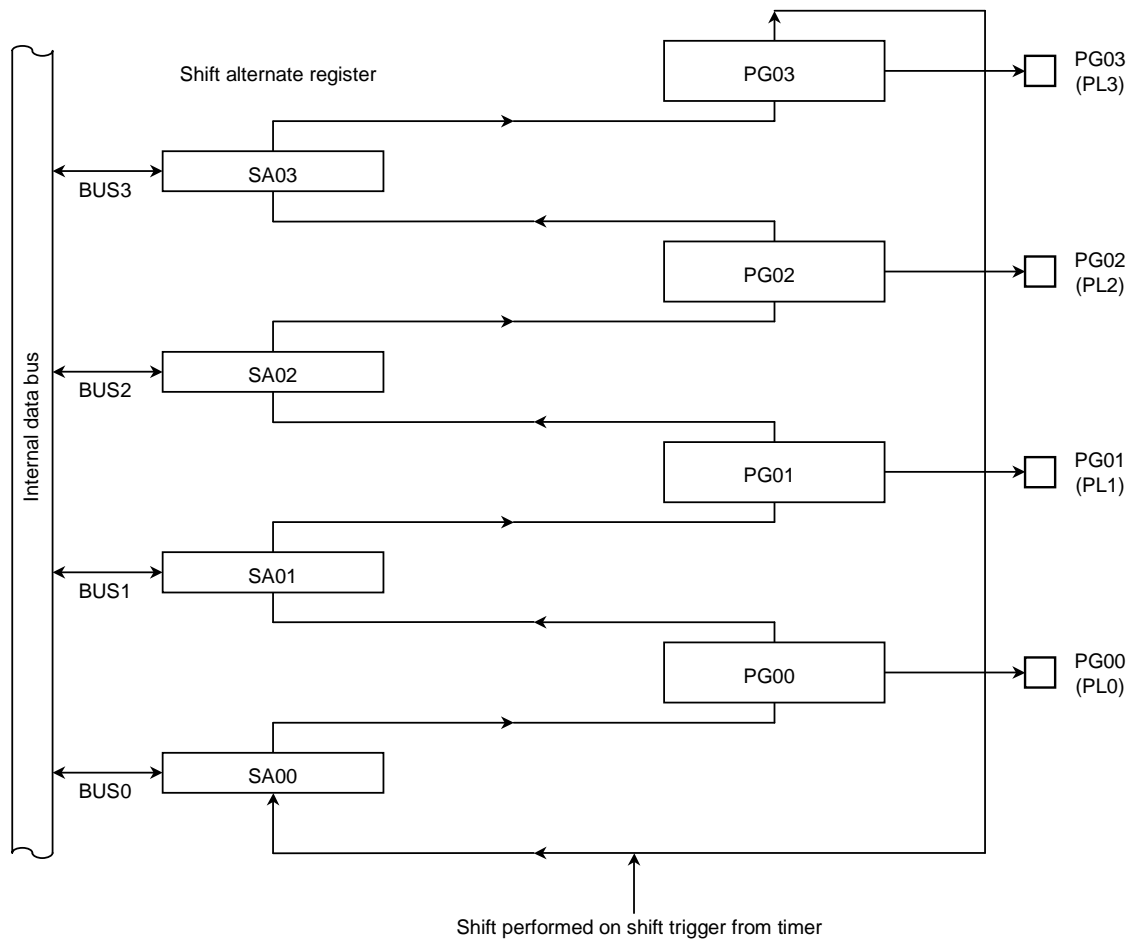

Figure 3.9.9 Pattern Generation Mode Block Diagram (PG0)

In pattern generation mode, only writing to the output latch can be disabled by hardware. All other functions behave in the same way as 1 to 2 step excitation in stepping motor control port mode. Hence, data shifted on the trigger signal from a timer must be written before the next trigger signal is output.

(2) Stepping motor control mode

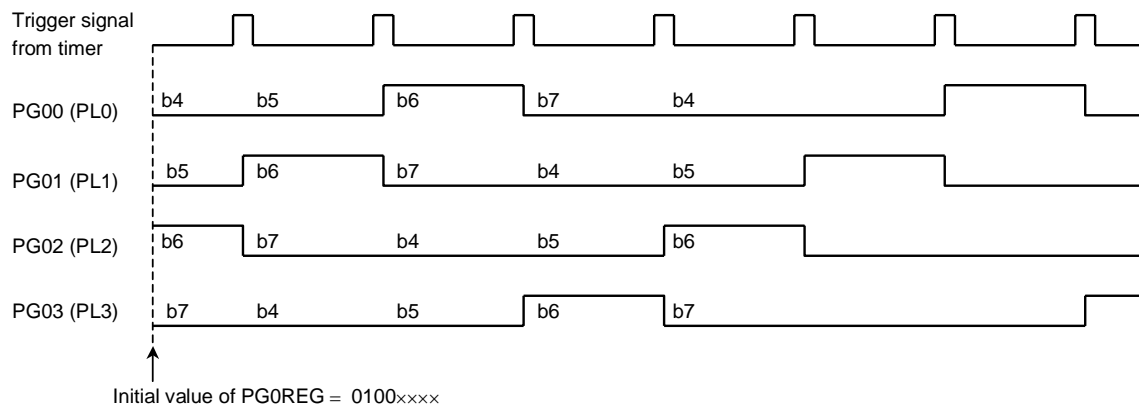

a. 4-phase 1-step/2-step excitation

Figure 3.9.10 and Figure 3.9.11 show the output waveforms for 4-phase 1 excitation and 4-phase 2 excitation respectively when channel 0 (PG0) is selected.

Note: bn indicates the initial value of PG0REG ← b7 b6 b5 b4 × × × ×

(1) Normal rotation

(2) Reverse rotation

Figure 3.9.10 Output Waveforms for 4-Phase 1-Step Excitation
(Normal rotation and Reverse rotation)

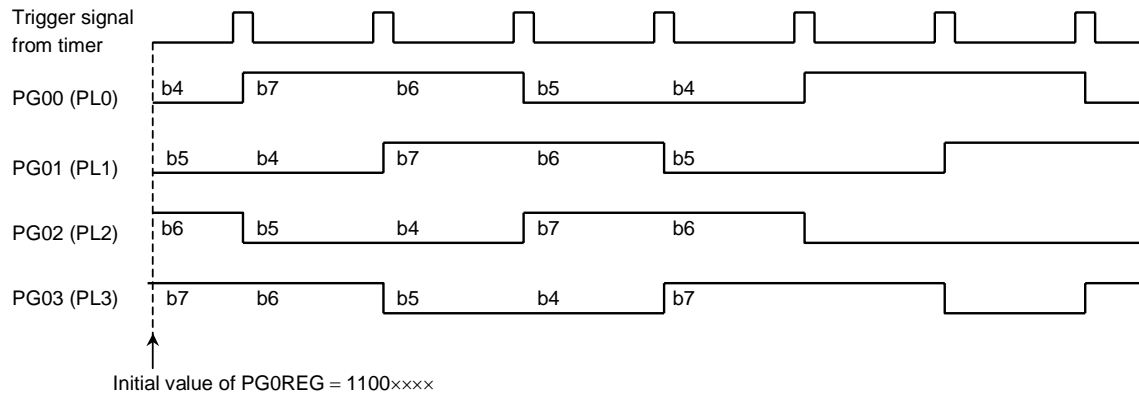

Figure 3.9.11 Output Waveforms for 4-Phase 2-Step Excitation (Normal rotation)

The output from PG0 (PL) is latched on the rising edge of the trigger signal from the timer.

The direction of shift is specified by the setting of PG01CR<CCW0>: Normal rotation (PG00→PG01→PG02→PG03) is selected when <CCW0> is set to “0”; reverse rotation (PG00←PG01←PG02←PG03) is selected when <CCW0> is set to “1”. 4-phase 1-step excitation will be selected when only one bit is set to “1” during the initialization of PG, while 4-phase 2-step excitation will be selected when two consecutive bits are set to “1”.

The value in the shift alternate registers are ignored when 4-phase 1-step/2-step excitation mode is selected.

Figure 3.9.12 shows the block diagram.

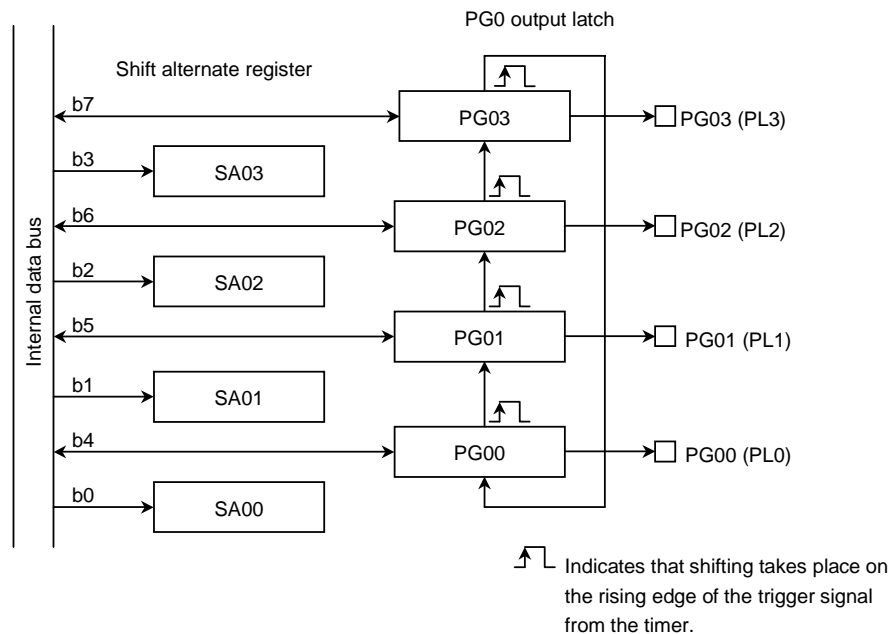

Figure 3.9.12 Block Diagram 4-Phase 1-step Excitation/2-step Excitation (Normal rotation)

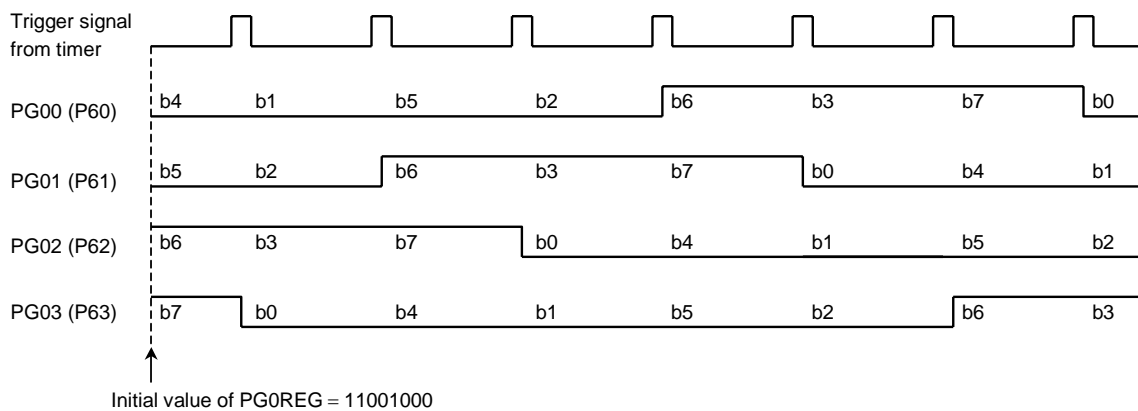

b. 4-phase 1 to 2 step excitation

Figure 3.9.12 shows the output waveforms for 4-phase 1 to 2 step excitation.

Note: b_n denotes the initial value PG0REG \leftarrow b7 b6 b5 b4 b3 b2 b1 b0

(1) Normal rotation

(2) Reverse rotation

Figure 3.9.12 Output Waveforms for 4-phase 1 to 2 step Excitation

(Normal rotation and reverse rotation)

The initialization sequence for 4-phase 1-2 step excitation is as follows.

By rearranging the initial value b7 b6 b5 b4 b3 b2 b1 b0 to b7 b3 b6 b2 b5 b1 b4 b0, three consecutive bits are set to 1 and the other bits are set to 0 (Positive logic).

For example, if b7, b3, and b6 are set to 1, the initial value becomes 11001000, producing the output waveforms shown in Figure 3.9.12.

To generate a negative logic output waveform, the 1's and 0's in the initial value must be inverted. For example, to change the output waveform shown in Figure 3.9.12 negative logic, change the initial value to 00110111.

The operation will be explained below for channel 0.

The output from PG0 (PL) and from the shift alternate register (SA0) for pattern generation is latched on the rising edge of the trigger signal from the timer. The shift direction is set by PG01CR<CCW0>.

Figure 3.9.13 shows the block diagram.

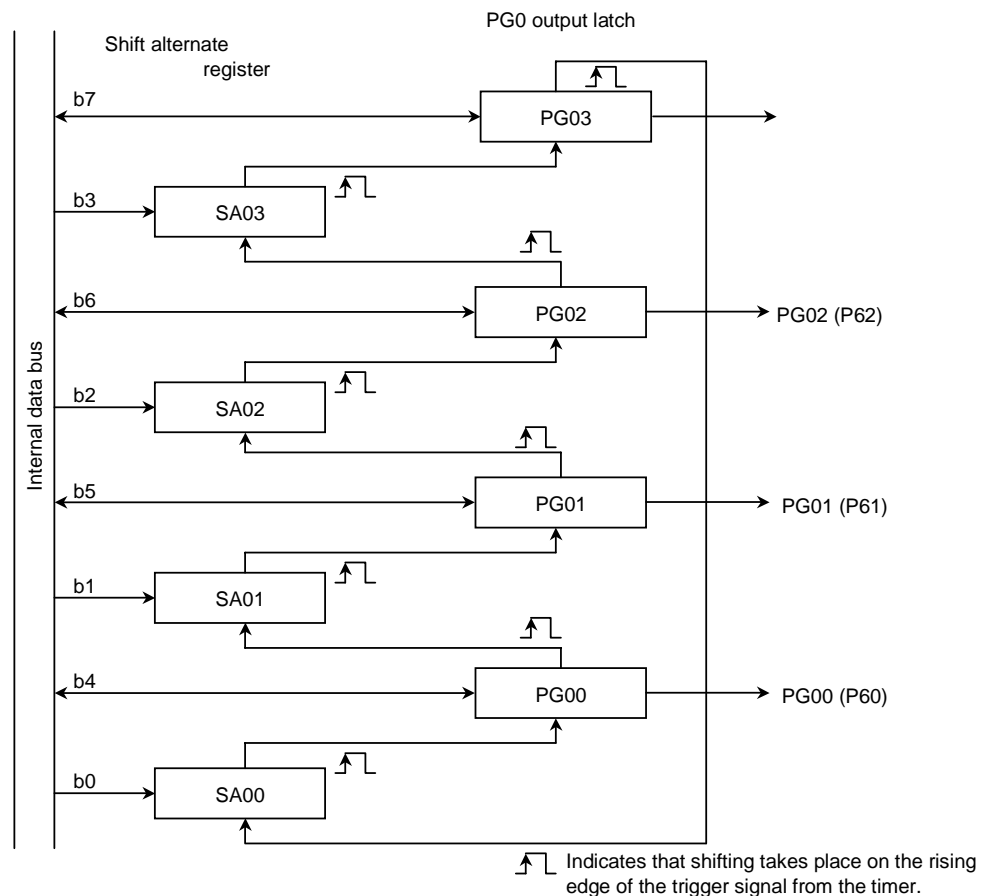

Figure 3.9.13 Block Diagram for 4-phase 1 to 2-step Excitation (Normal rotation)

Setting example: To drive channel 0 (PG0) using 4-phase 1 to 2-step excitation (Normal rotation) when timer 0 is selected, set each register as follows.

	7	6	5	4	3	2	1	0	
TA01RUN	←	0	X	X	X	—	0	0	0
TA01MOD	←	0	0	0	0	—	—	0	1
TA1FFCR	←	X	X	X	X	1	0	1	0
TA0REG	←	*	*	*	*	*	*	*	*
PLCR	←	—	—	—	—	1	1	1	1
PLFC	←	—	—	—	—	1	1	1	1
PLFC2	←	—	—	—	—	0	0	0	0
PG01CR	←	—	—	—	—	0	0	1	1
PG0REG	←	1	1	0	0	1	0	0	0
TA01RUN	←	0	X	X	X	—	1	—	1

Stop timer 0, and clear it to zero.

Set 8-bit timer mode and select $\phi T1$ as the input clock.

Clear TA1FF to zero and enable the inversion trigger using timer 0.

Set the cycle in the timer register.

Set bits PL0 to PL3 to PG0 output.

Select PG0 4-phase 1 to 2-step excitation mode and normal rotation.

Set an initial value.

Start timer 0.

X: Don't care, —: No change

(3) Trigger signal from timer

The trigger signal from the timer used by PG is not the same as the trigger signal for the timer flip-flop (TA1FF, TA3FF, TB0FF0, TB0FF1, TB1FF0 and TB1FF1); they differ as shown in Table 3.9.1 depending on the operation mode of the timer.

Table 3.9.1 Trigger Signal Selection

	TA1FF Inversion	PG Shift
8-bit timer mode	Selected by TA1FFCR<TA1FFIS> when the up counter value matches TA0REG or TA1REG value.	Selected by TA1FFCR<TA1FFIS> when the up counter value matches TA0REG or TA1REG value.
16-bit timer mode	When the up counter value matches both TA0REG and TA1REG values (the value of up counter = $TA1REG \times 2^8 + TA0REG$).	When the up counter value matches both TA0REG and TA1REG values (the value of up counter = $TA1REG \times 2^8 + TA0REG$).
PPG output mode	When the up counter value matches both TA0REG and TA1REG.	When the up counter value matches TA1REG value (PPG cycle).
PWM output mode	When the up counter value matches TA0REG value and PWM cycle.	Trigger signal for PG is not generated.

Note: To shift PG, TA1FFCR<TA1FFIE> must be set to 1 to enable TA1FF inversion.

PG can be synchronized with the 16-bit timer timer 0/16-bit timer 1. In this case, the PG shift trigger signal from the 16-bit timer is output only when the up counter UC0/UC1 value matches TB0RG1H/L/TB1RG1H/L.

(4) Application of PG and timer output

As explained in the previous section trigger signal from timer, the timings for shifting PG and inverting TFF differ depending on the timer mode. An application which operates PG while operating an 8-bit timer in PPG mode is explained below.

To drive a stepping motor, a synchronizing signal is required for the excitation timing, in addition to the value of each phase (PG output). In this application, port L is used as a stepping motor control port to output a synchronizing signal to the TA1OUT pin (shared with PF1).

Figure 3.9.14 Output Waveforms for 4-phase 1-step Excitation

Setting example:

	7	6	5	4	3	2	1	0	
TA01RUN	← 0	X	X	X	—	0	0	0	Stop timer 0, 1 and clear it to zero.
TA01MOD	← 1	0	X	X	X	X	0	1	Set timer 0, 1 to PPG output mode and select $\phi T1$ as the input clock.
TA1FFCR	← X	X	X	X	0	1	1	X	Enable TA1FF inversion and set TA1FF to "1".
TA0REG	← *	*	*	*	*	*	*	*	Set the duty of TA1OUT to TA0REG.
TA1REG	← *	*	*	*	*	*	*	*	Set the cycle of TA1OUT to TA1REG.
PFCR	← X	—	—	—	—	—	1	—	} Assign PF1 as TA1OUT.
PFFC	← X	—	—	—	—	—	1	—	
PLCR	← —	—	—	—	1	1	1	1	
PLFC	← —	—	—	—	1	1	1	1	
PLFC2	← —	—	—	—	0	0	0	0	} Assign PL0 to PL3 as PG0.
PG01CR	← —	—	—	—	0	0	0	1	
PG0REG	← *	*	*	*	*	*	*	*	Set PG0 to 4-phase 1-step excitation mode.
TA01RUN	← 0	X	X	X	—	1	1	1	Set an initial value.
									Start timer 0, 1.

X: Don't care, —: No change

3.10 Serial Channels (SIO)

TMP92CM27 includes 4 serial I/O channels. Each channel is called SIO0, SIO1, SIO2 and SIO3. For all both channels either UART Mode (Asynchronous transmission) or I/O interface mode (Synchronous transmission) can be selected.

- I/O interface mode — Mode 0: For transmitting and receiving I/O data using the synchronizing signal SCLK for extending I/O.
- UART mode
 - Mode 1: 7-bit data
 - Mode 2: 8-bit data
 - Mode 3: 9-bit data

In mode 1 and mode 2 a parity bit can be added. Mode 3 has a wakeup function for making the master controller start slave controllers via a serial link (Multi-controller system).

Figure 3.10.2 and Figure 3.10.3 are block diagrams for each channel. Each channel is structured in prescaler, serial clock generation circuit, receiving buffer and control circuit, and transfer buffer and control circuit.

Serial channels 0 to 3 can be used independently.

All channels operate in the same function except for the following points; hence only the operation of channel 0 is explained below.

Table 3.10.1 Differences between each Channels

	Channel 0	Channel 1	Channel 2	Channel 3
Pin name	TXD0 (PA1) RXD0 (PA0) $\overline{\text{CTS0}}$ /SCLK0 (PA2)	TXD1 (PA4) RXD1 (PA3) $\overline{\text{CTS1}}$ /SCLK1 (PA5)	TXD2 (PD4) RXD2 (PD3) $\overline{\text{CTS2}}$ /SCLK2 (PD5)	TXD3 (PL1) RXD3 (PL0) $\overline{\text{CTS3}}$ /SCLK3 (PL2)
IrDA mode	Yes	Non	Non	Non

This chapter contains the following sections:

3.10.2 Operation of Each Circuit

(1) Prescaler

There is a 6-bit prescaler for generating a clock to SIO0. The prescaler can be run only case of selecting the baud rate generator as the serial transfer clock.

Table 3.10.2 shows prescaler clock resolution into the baud rate generator.

Table 3.10.2 Prescaler Clock Resolution to Baud Rate Generator

System Clock <SYSCK>	Clock Gear <GEAR2:0>	Clock Resolution			
		$\phi T0$	$\phi T2$	$\phi T8$	$\phi T32$
0 (fc)	000 (fc)	$2^2 / fc$	$2^4 / fc$	$2^6 / fc$	$2^8 / fc$
	001 ($^{fc}/2$)	$2^3 / fc$	$2^5 / fc$	$2^7 / fc$	$2^9 / fc$
	010 ($^{fc}/4$)	$2^4 / fc$	$2^6 / fc$	$2^8 / fc$	$2^{10} / fc$
	011 ($^{fc}/8$)	$2^5 / fc$	$2^7 / fc$	$2^9 / fc$	$2^{11} / fc$
	100 ($^{fc}/16$)	$2^6 / fc$	$2^8 / fc$	$2^{10} / fc$	$2^{12} / fc$

XXX:Don't care

The serial interface baud rate generator selects between 4 clock inputs: $\phi T0$, $\phi T2$, $\phi T8$, and $\phi T32$ among the prescaler outputs.

(2) Baud rate generator

The baud rate generator is a circuit that generates transmission and receiving clocks that determine the transfer rate of the serial channels.

The input clock to the baud rate generator, $\phi T0$, $\phi T2$, $\phi T8$, or $\phi T32$, is generated by the 6-bit prescaler which is shared by the timers. One of these input clocks is selected using the $BR0CR<BR0CK1:0>$ field in the baud rate generator control register.

The baud rate generator includes a frequency divider, which divides the frequency by 1 or $N + (16 - K)/16$ to 16 values, determining the transfer rate.

The transfer rate is determined by the settings of $BR0CR<BR0ADDE>$, $BR0S3:0>$ and $BR0ADD<BR0K3:0>$.

- In UART mode

- (1) When $BR0CR<BR0ADDE> = 0$

The settings $BR0ADD<BR0K3:0>$ are ignored. The baud rate generator divides the selected prescaler clock by N ($N = 1, 2, 3 \dots 16$), which is set in $BR0CR<BR0S3:0>$.

- (2) When $BR0CR<BR0ADDE> = 1$

The $N + (16 - K)/16$ division function is enabled. The baud rate generator divides the selected prescaler clock by $N + (16 - K)/16$ using the value of N ($N = 2, 3 \dots 15$) set in $BR0CR<BR0S3:0>$ and the value of K ($K = 1, 2, 3 \dots 15$) set in $BR0ADD<BR0K3:0>$.

Note: If $N = 1$ and $N = 16$, the $N + (16 - K)/16$ division function is disabled.

Clear $BR0CR<BR0ADDE>$ register to "0".

- In I/O interface mode

The $N + (16 - K)/16$ division function is not available in I/O interface mode. Clear $BR0CR<BR0ADDE>$ to 0 before dividing by N .

The method for calculating the transfer rate when the baud rate generator is used is explained below.

- UART mode

$$\text{Baud rate} = \frac{\text{Input clock of baud rate generator}}{\text{Frequency divider for baud rate generator}} \div 16$$

- I/O interface mode

$$\text{Baud rate} = \frac{\text{Input clock of baud rate generator}}{\text{Frequency divider for baud rate generator}} \div 2$$

- Integer divider (N divider)

For example, when the $f_c = 12.288$ MHz, the input clock frequency = $\phi T2$, the frequency divider N (BR0CR<BR0S3:0>) = 5, and BR0CR<BR0ADDE> = 0, the baud rate in UART mode is as follows:

* Clock state

System clock: High speed (f_c)
High speed gear: 1 time (f_c)

$$\begin{aligned}\text{Baud rate} &= \frac{f_c/16}{5} \div 16 \\ &= 12.288 \times 10^6 \div 16 \div 5 \div 16 = 9600 \text{ (bps)}\end{aligned}$$

Note: The $N + (16 - K)/16$ division function is disabled and setting BR0ADD<BR0K3:0> is invalid.

- $N + (16 - K)/16$ divider (UART mode only)

Accordingly, when $f_c = 4.8$ MHz, the input clock frequency = $\phi T0$, the frequency divider N (BR0CR<BR0S3:0>) = 7, K (BR0ADD<BR0K3:0>) = 3, and BR0CR<BR0ADDE> = 1, the baud rate is as follows:

* Clock state

System clock: High speed (f_c)
High speed gear: 1 time (f_c)

$$\begin{aligned}\text{Baud rate} &= \frac{f_c/4}{7 + \frac{(16-3)}{16}} \div 16 \\ &= 4.8 \times 10^6 \div 16 \div \left(7 + \frac{13}{16}\right) \div 16 = 9600 \text{ (bps)}\end{aligned}$$

Table 3.10.3 and Table 3.10.4 show examples of UART mode transfer rates.

Additionally, the external clock input is available in the serial clock (Serial channels 0 and 1). The method for calculating the baud rate is explained below:

- In UART mode

Baud rate = External clock input frequency $\div 16$

It is necessary to satisfy (External clock input cycle) $\geq 4/f_c$

- In I/O interface mode

Baud rate = External clock input frequency

It is necessary to satisfy (External clock input cycle) $\geq 16/f_c$

Table 3.10.3 UART Baud Rate Selection
(when using baud rate generator and BR0CR<BR0ADDE> = 0) Unit (kbps)

fc [MHz]	Input Clock Divider N (Set to BR0CR<BR0S3:0>)	φT0	φT2	φT8	φT32
9.830400	2	76.800	19.200	4.800	1.200
↑	4	38.400	9.600	2.400	0.600
↑	8	19.200	4.800	1.200	0.300
↑	0	9.600	2.400	0.600	0.150
12.288000	5	38.400	9.600	2.400	0.600
↑	A	19.200	4.800	1.200	0.300
14.745600	2	115.200			
↑	3	76.800	19.200	4.800	1.200
↑	6	38.400	9.600	2.400	0.600
↑	C	19.200	4.800	1.200	0.300

Note 1: Transfer rates in I/O interface mode are eight times faster than the values given above.

Note 2: The values in this table are calculated for when f_{SYS} is selected as the system clock, f_{SYS}/1 is selected as the clock gear.

Table 3.10.4 UART Baud Rate Selection
(when using trigger output of TMRA0 and input clock of TMRA0 is φT1.) Unit (kbps)

fc TA0REG0	12.288 MHz	12 MHz	9.8304 MHz	8 MHz	6.144 MHz
1H	96		76.8	62.5	48
2H	48		38.4	31.25	24
3H	32	31.25			16
4H	24		19.2		12
5H	19.2				9.6
8H	12		9.6		6
AH	9.6				4.8
10H	6		4.8		3
14H	4.8				2.4

Method for calculating the transfer rate (when TMRA0 is used):

$$\text{Transfer rate} = \frac{f_{\text{FPH}}}{\text{TA0REG} \times 2^3 \times 16}$$

↑
(When input clock of TMRA0 is φT1)

Note 1: The TMRA0 match detect signal cannot be used as the transfer clock in I/O interface mode.

Note 2: The values in this table are calculated for when f_c is selected as the system clock, f_c is selected as the clock gear.

(3) Serial clock generation circuit

This circuit generates the basic clock for transmitting and receiving data.

- In I/O interface mode

In SCLK output mode with the setting SC0CR<IOC> = 0, the basic clock is generated by dividing the output of the baud rate generator by 2, as described previously.

In SCLK input mode with the setting SC0CR<IOC> = 1, the rising edge or falling edge will be detected according to the setting of the SC0CR<SCLKS> register to generate the basic clock.

- In UART mode

The SC0MOD0<SC1:0> setting determines whether the baud rate generator clocks, the internal system clock f_{sys}, the trigger output signal from TMRA0 or the external clock (SCLK0 pin) is used to generate the basic clock SIOCLK.

(4) Receiving counter

The receiving counter is a 4-bit binary counter used in UART mode that counts up the pulses of the SIOCLK clock. It takes 16 SIOCLK pulses to receive 1 bit of data; each data bit is sampled three times – on the 7th, 8th, and 9th clock cycles.

The value of the data bit is determined from these three samples using the majority rule.

For example, if the data bit is sampled respectively as 1, 0, and 1 on 7th, 8th, and 9th clock cycles, the received data bit is taken to be 1. A data bit sampled as 0, 0, and 1 are taken to be 0.

(5) Receiving control

- In I/O interface mode

In SCLK output mode with the setting SC0CR<IOC> = 0, the RXD0 pin is sampled on the rising or falling edge of the shift clock which is output on the SCLK0 pin according to the SC0CR<SCLKS> setting.

In SCLK input mode with the setting SC0CR<IOC> = 1, the RXD0 pin is sampled on the rising or falling edge of the SCLK input, according to the SC0CR<SCLKS> setting.

- In UART mode

The receiving control block has a circuit that detects a start bit using the majority rule. Received bits are sampled three times; when two or more out of three samples are 0, the bit is recognized as the start bit and the receiving operation commences.

The values of the data bits that are received are also determined using the majority rule.

(6) The receiving buffers

To prevent overrun errors, the receiving buffers are arranged in a double-buffer structure.

Received data is stored one bit at a time in receiving buffer 1 (which is a shift register). When 7 or 8 bits of data have been stored in receiving buffer 1, the stored data is transferred to receiving buffer 2 (SC0BUF); this causes an INTRX0 interrupt to be generated.

The CPU only reads receiving buffer 2 (SC0BUF). Even before the CPU reads receiving buffer 2 (SC0BUF), the received data can be stored in receiving buffer 1.

However, unless receiving buffer 2 (SC0BUF) is read before all bits of the next data are received by receiving buffer 1, an overrun error occurs. If an overrun error occurs, the contents of receiving buffer 1 will be lost, although the contents of receiving buffer 2 and SC0CR<RB8> will be preserved.

SC0CR<RB8> is used to store either the parity bit – added in 8-bit UART mode – or the most significant bit (MSB) – in 9-bit UART mode.

In 9-bit UART mode the wake-up function for the slave controller is enabled by setting SC0MOD0<WU> to 1; in this mode INTRX0 interrupts occur only when the value of SC0CR<RB8> is 1.

SIO interruption mode can be set up by the SIMC register.

(7) Transmission counter

The transmission counter is a 4-bit binary counter that is used in UART mode and which, like the receiving counter, counts the SIOCLK clock pulses; a TXDCLK pulse is generated every 16 SIOCLK clock pulses.

Figure 3.10.6 Generation of Transmission Clock

(8) Transmission controller

- In I/O interface mode

In SCLK output mode with the setting SC0CR<IOC> = 0, the data in the transmission buffer is output one bit at a time to the TXD0 pin on the rising or falling edge of the shift clock which is output on the SCLK0 pin, according to the SC0CR<SCLKS> setting.

In SCLK input mode with the setting SC0CR<IOC> = 1, the data in the transmission buffer is output one bit at a time on the TXD0 pin on the rising or falling edge of the SCLK0 input, according to the SC0CR<SCLKS> setting.

- In UART mode

When transmission data sent from the CPU is written to the transmission buffer, transmission starts on the rising edge of the next TXDCLK, generating a transmission shift clock TXDSFT.

Handshake function

Serial channels 0 and 1 each has a $\overline{\text{CTS}}$ pin. Use of this pin allows data can be sent in units of one data format; thus, overrun errors can be avoided. The handshake functions is enabled or disabled by the SC0MOD0<CTSE> setting.

When the $\overline{\text{CTS0}}$ pin condition is high level, after completed the current data transmission, data transmission is halted until the $\overline{\text{CTS0}}$ pin state is low again. However, the INTTX0 interrupt is generated, it requests the next send data to the CPU. The next data is written in the transmission buffer and data transmission is halted.

Though there is no $\overline{\text{RTS}}$ pin, a handshake function can be easily configured by setting any port assigned to be the $\overline{\text{RTS}}$ function. The $\overline{\text{RTS}}$ should be output "High" to request send data halt after data receive is completed by software in the receive interrupt routine.

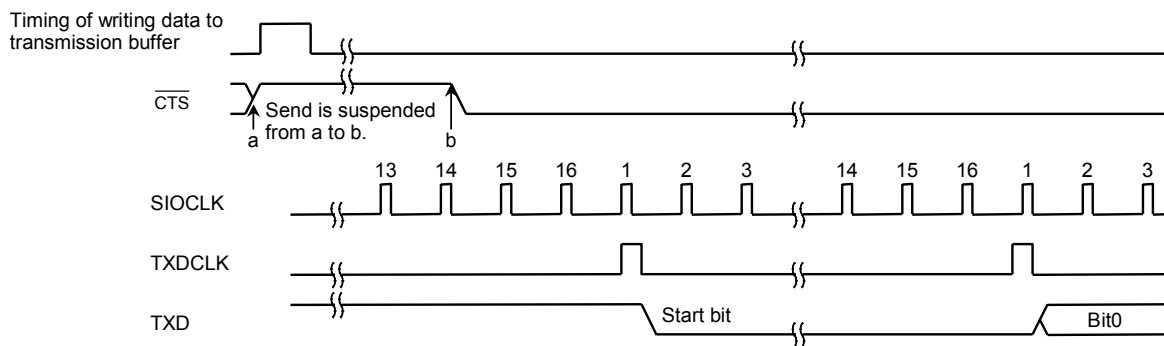

Figure 3.10.7 Handshake Function

Note 1: If the $\overline{\text{CTS}}$ signal goes high during transmission, will be stop next transmission data after completion of the current transmission.

Note 2: Transmission starts on the first falling edge of the TXDCLK clock after the $\overline{\text{CTS}}$ signal has fallen.

Figure 3.10.8 $\overline{\text{CTS}}$ (Clear to send) Signal Timing

(9) Transmission buffer

The transmission buffer (SC0BUF) shifts out and sends the transmission data written from the CPU from the least significant bit in order. When all the bits are shifted out, the transmission buffer becomes empty and generates an INTRX0 interrupt.

(10) Parity control circuit

When SC0CR<PE> in the serial channel control register is set to 1, it is possible to transmit and receive data with parity. However, parity can be added only in 7-bit UART mode or 8-bit UART mode. The SC0CR<EVEN> field in the serial channel control register allows either even or odd parity to be selected.

In the case of transmission, parity is automatically generated when data is written to the transmission buffer SC0BUF. The data is transmitted after the parity bit has been stored in SC0BUF<TB7> in 7-bit UART mode or in SC0MOD0<TB8> in 8-bit UART mode. SC0CR<PE> and SC0CR<EVEN> must be set before the transmission data is written to the transmission buffer.

In the case of receiving, data is shifted into receiving buffer 1, and the parity is added after the data has been transferred to receiving buffer 2 (SC0BUF), and then compared with SC0BUF<RB7> in 7-bit UART mode or with SC0CR<RB8> in 8-bit UART mode. If they are not equal, a parity error is generated and the SC0CR<PERR> flag is set.

(11) Error flags

Three error flags are provided to increase the reliability of data reception.

1. Overrun error <OERR>

If all the bits of the next data item have been received in receiving buffer 1 while valid data still remains stored in receiving buffer 2 (SC0BUF), an overrun error is generated.

The below is a recommended flow when the overrun error is generated.

(INTRX interrupt routine)

- 1) Read receiving buffer
- 2) Read error flag
- 3) if <OERR> = "1"
then
 - a) Set to disable receiving (Program "0" to SC0MOD0<RXE>)
 - b) Wait to terminate current frame
 - c) Read receiving buffer
 - d) Read error flag
 - e) Set to enable receiving (Program "1" to SC0MOD0<RXE>)
 - f) Request to transmit again
- 4) Other

2. Parity error <PERR>

The parity generated for the data shifted into receiving buffer 2 (SC0BUF) is compared with the parity bit received via the RXD pin. If they are not equal, a parity error is generated.

3. Framing error <FERR>

The stop bit for the received data is sampled three times around the center. If the majority of the samples are 0, a framing error is generated.

(12) Timing generation

1. In UART mode

Receiving

Mode	9 Bits	8 Bits + Parity	8 Bits, 7 Bits + Parity, 7 Bits
Interrupt generation timing	Center of last bit (Bit8)	Center of last bit (Parity bit)	Center of stop bit
Framing error generation timing	Center of stop bit	Center of stop bit	Center of stop bit
Parity error generation timing	—	Center of last bit (Parity bit)	Center of stop bit
Overrun error generation timing	Center of last bit (Bit8)	Center of last bit (Parity bit)	Center of stop bit

Note: In 9 Bits mode and 8 Bits + Parity mode, interrupts coincide with the ninth bit pulse. Thus, when servicing the interrupt, it is necessary to wait for a 1-bit period (to allow the stop bit to be transferred) to allow checking for a framing error.

Transmission

Mode	9 Bits	8 Bits + Parity	8 Bits, 7 Bits + Parity, 7 Bits
Interrupt generation timing	Just before stop bit is transmitted	Just before stop bit is transmitted	Just before stop bit is transmitted

2. In I/O interface mode

Transmission interrupt timing	SCLK output mode	Immediately after last bit data. (See Figure 3.10.31)
	SCLK input mode	Immediately after rise of last SCLK signal rising mode, or immediately after fall in falling mode. (See Figure 3.10.32)
Receiving interrupt timing	SCLK output mode	Timing used to transfer received to data receive buffer 2 (SC0BUF) (e.g., immediately after last SCLK). (See Figure 3.10.33)
	SCLK input mode	Timing used to transfer received data to receive buffer 2 (SC0BUF) (e.g., immediately after last SCLK). (See Figure 3.10.34)

3.10.4 Operation in Each Mode

(1) Mode 0 (I/O interface mode)

This mode allows an increase in the number of I/O pins available for transmitting data to or receiving data from an external shift register.

This mode includes the SCLK output mode to output synchronous clock SCLK and SCLK input mode to input external synchronous clock SCLK.

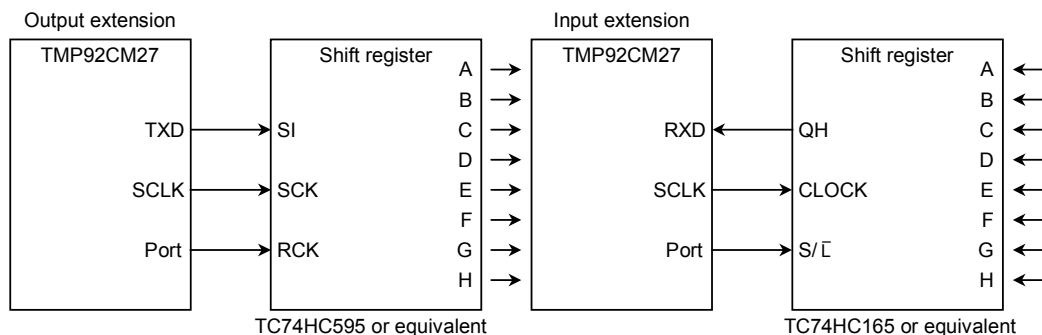

Figure 3.10.29 Example of SCLK Output Mode Connection

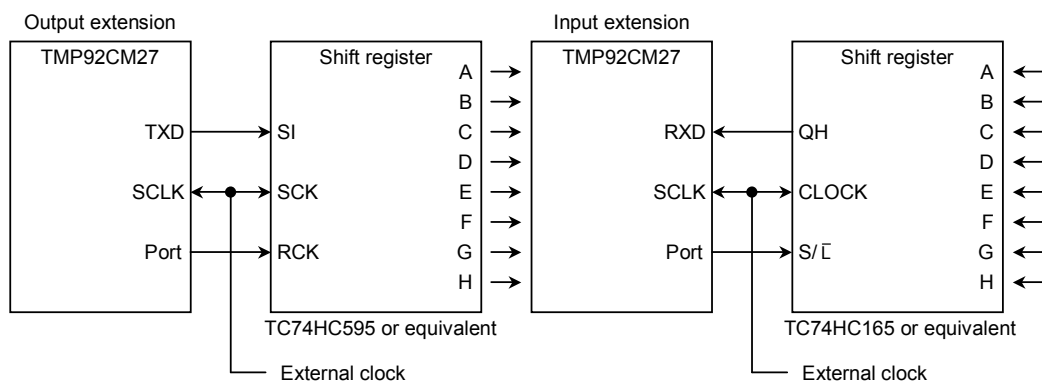

Figure 3.10.30 Example of SCLK Output Mode Connection

1. Transmission

In SCLK output mode 8-bit data and a synchronous clock are output on the TXD0 and SCLK0 pins respectively each time the CPU writes the data to the transmission buffer. When all data is outputted, INTES0<ITX0C> will be set to generate the INTTX0 interrupt.

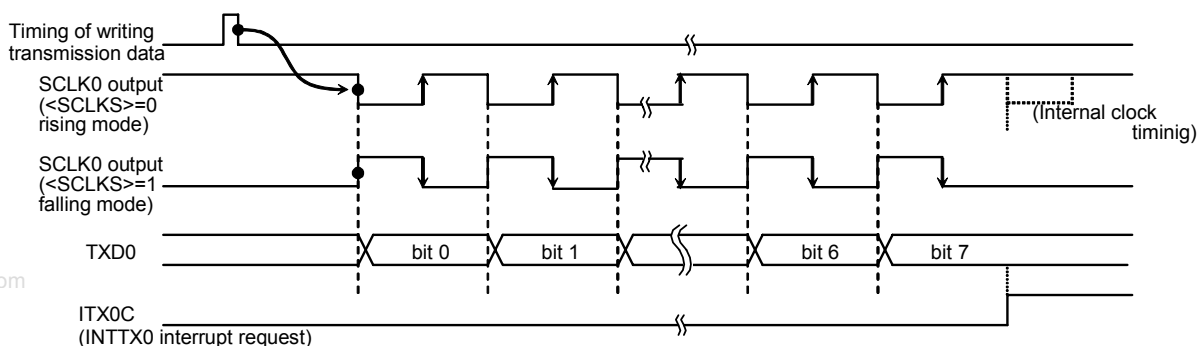

Figure 3.10.31 Transmission Operation in I/O Interface Mode (SCLK0 output mode)

In SCLK input mode, 8-bit data is output from the TXD0 pin when the SCLK0 input becomes active after the data has been written to the transmission buffer by the CPU.

When all data is outputted, INTES0<ITX0C> will be set to generate INTTX0 interrupt.

Figure 3.10.32 Transmission Operation in I/O Interface Mode (SCLK0 input mode)

2. Receiving

In SCLK output mode, the synchronous clock is outputted from SCLK0 pin and the data is shifted to receiving buffer 1. This starts when the receive interrupt flag INTES0<IRX0C> is cleared by reading the received data. When 8-bit data are received, the data will be transferred to receiving buffer 2 (SC0BUF according to the timing shown below) and INTES0<IRX0C> will be set to generate INTRX0 interrupt.

The outputting for the first SCLK0 starts by setting SC0MOD0<RXE> to 1.

Figure 3.10.33 Receiving Operation in I/O Interface Mode (SCLK0 output mode)

In SCLK input mode, the data is shifted to receiving buffer 1 when the SCLK input becomes active after the receive interrupt flag INTES0<IRX0C> is cleared by reading the received data. When 8-bit data is received, the data will be shifted to receiving buffer 2 (SC0BUF according to the timing shown below) and INTES0<IRX0C> will be set again to generate INTRX0 interrupt.

Figure 3.10.34 Receiving Operation in I/O Interface Mode (SCLK0 input mode)

Note: If receiving, set to the receive enable state (SC0MOD0<RXE> = 1) in both SCLK input mode and output mode.

3. Transmission and receiving (Full duplex mode)

When the full duplex mode is used, set the level of receive interrupt to "0" and set enable the interrupt level (1 to 6) to the transfer interrupts. In the transfer interrupt program, the receiving operation should be done like the below example before setting the next transfer data.

Example: Channel 0, SCLK output

Baud rate = 9600 bps

$f_c = 19.6608$ MHz

Main routine

	7	6	5	4	3	2	1	0
INTES0	x	0	0	1	x	0	0	0
PACR	-	-	-	-	-	1	1	0
PAFC	-	-	-	-	-	1	1	1
PAFC2	x	x	-	-	-	0	-	-
SC0MOD0	0	0	0	0	0	0	0	0
SC0MOD1	1	1	0	0	0	0	0	0
SC0CR	0	0	0	0	0	0	0	0
BR0CR	0	0	1	1	0	1	0	0
SC0MOD0	0	0	1	0	0	0	0	0
SC0BUF	*	*	*	*	*	*	*	*

Set transmission interrupt level, and disable receiving interrupt.

Set to PA0 (RXD0), PA1 (TXD0), and PA2 (SCLK0).

Set to I/O interface mode.

Set to full duplex mode.

Output SCLK, select rising edge.

Set to 9600 bps.

Set receive to enable.

Set transmission data.

Transmission interrupt routine

Acc SC0BUF

SC0BUF	*	*	*	*	*	*	*	*

Read receiving data.

Set transmission data.

X: Don't care, -: No change

(2) Mode 1 (7-bit UART mode)

7-bit UART mode is selected by setting serial channel mode register SC0MOD0<SM1:0> to 01.

In this mode, a parity bit can be added. Use of a parity bit is enabled or disabled by the setting of the serial channel control register SC0CR<PE> bit; whether even parity or odd parity will be used is determined by the SC0CR<EVEN> setting when SC0CR<PE> is set to 1 (Enabled).

Example: When transmitting data of the following format, the control registers should be set as described below. This explanation applies to channel 0.

	7	6	5	4	3	2	1	0		
PACR	←	—	—	—	—	—	—	1	} Set PA1 to as TXD0 pin.	
PAFC	←	—	—	—	—	—	—	1		
PAFC2	←	X	X	X	—	X	X	0		
SC0MOD	←	X	0	—	X	0	1	0	1	Set to 7-bit UART mode.
SC0CR	←	X	1	1	X	X	X	0	0	Add even parity.
BR0CR	←	0	0	1	0	1	0	0	0	Set to 2400 bps.
INTES0	←	X	1	0	0	—	—	—	—	Set INTTX0 interrupt to enable, set to level 4.
SC0BUF	←	*	*	*	*	*	*	*	*	Set transmission data.

X : Don't care, — : No change

(3) Mode 2 (8-bit UART mode)

8-bit UART mode is selected by setting SC0MOD0<SM1:0> to 10. In this mode, a parity bit can be added (Use of a parity bit is enabled or disabled by the setting of SC0CR<PE>); whether even parity or odd parity will be used is determined by the SC0CR<EVEN> setting when SC0CR<PE> is set to 1 (Enabled).

Example: When receiving data of the following format, the control registers should be set as described below.

Main routine

	7	6	5	4	3	2	1	0
PACR	←	-	-	-	-	-	-	0
PAFC	←	-	-	-	-	-	-	1
SC0MOD	←	-	0	1	X	1	0	0
SC0CR	←	X	0	1	X	X	X	0
BR0CR	←	0	0	0	1	1	0	0
INTES0	←	X	-	-	-	X	1	0

Set PA0 (RXD0) to input pin.

Set to 8-bit UART mode, set receives to enable.

Add odd parity.

Set to 9600 bps.

Set INTTX0 interrupt to enable, set to level 4.

Interrupt routine processing

Acc ← SC0CR AND 00011100

if Acc ≠ 0 then ERROR

Acc ← SC0BUF

X : Don't care, - : No change

} Check for error.

Read receiving data.

www.DataSheet4U.com

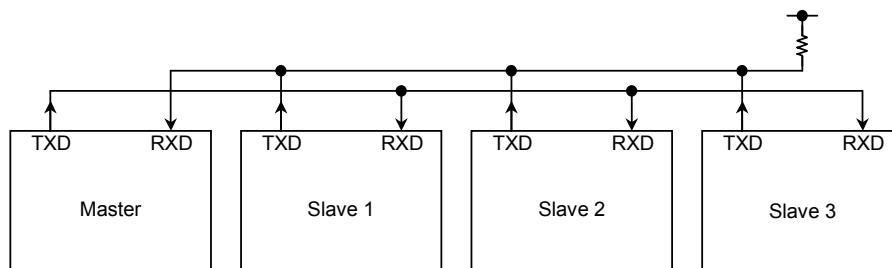

(4) Mode 3 (9-bit UART mode)

9-bit UART mode is selected by setting SC0MOD0<SM1:0> to 11. In this mode parity bit cannot be added.

In the case of transmission the MSB (9th bit) is programmed to SC0MOD0<TB8>. In the case of receiving it is stored in SC0CR<RB8>. When the buffer is written and read, the MSB is read or written first, before the rest of the SC0BUF data.

Wakeup function

In 9-bit UART mode, the wakeup function for slave controllers is enabled by setting SC0MOD0<WU> to 1. The interrupt INTRX0 occurs only when <RB8> = 1.

Note: The TXD pin of each slave controller must be in open-drain output mode.

Figure 3.10.35 Serial Link Using Wakeup Function

Protocol

1. Select 9-bit UART mode on the master and slave controllers.
2. Set the SC0MOD0<WU> bit on each slave controller to 1 to enable data receiving.
3. The master controller transmits one-frame data including the 8-bit select code for the slave controllers. The MSB (Bit8) <TB8> is set to "1".

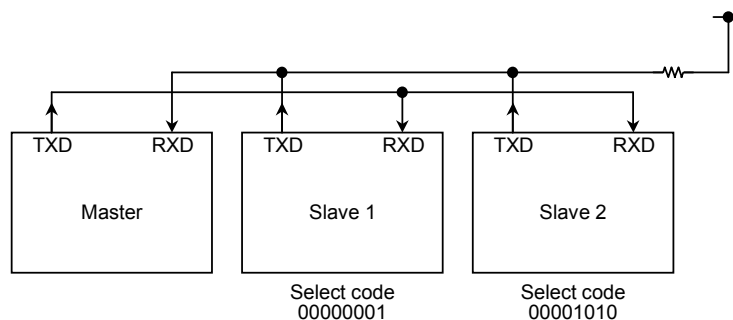

4. Each slave controller receives the above frame. If it matches with own select code, clears <WU> bit to "0".
5. The master controller transmits data to the specified slave controller whose SC0MOD0<WU> bit is cleared to "0". The MSB (Bit8) <TB8> is cleared to "0".

6. The other slave controllers (whose <WU> bits remain at 1) ignore the received data because their MSB (Bit8 or <RB8>) are set to "0", disabling INTRX0 interrupts. The slave controller (<WU> bit = "0") can transmit data to the master controller, and it is possible to indicate the end of data receiving to the master controller by this transmission.

Example: To link two slave controllers serially with the master controller using the system clock f_{SYS} as the transfer clock.

• Master controller setting

Main routine

	7	6	5	4	3	2	1	0
PACR	←	-	-	-	-	-	1	0

Clear to <WU> = "0".

3.10.5 Support for IrDA Mode

SIO0 includes support for the IrDA 1.0 infrared data communication specification. Figure 3.10.36 shows the block diagram.

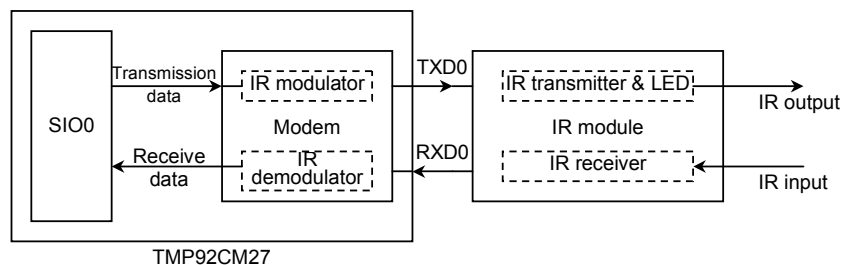

Figure 3.10.36 Block Diagram of IrDA (SIO0)

(1) Modulation of transmission data

When the transmission data is 0, output “H” level with either 3/16 or 1/16 times for width of baud-rate (Selectable in software). Moreover, pulse width is chosen in SIR0CR<PLSEL>. When data is “1”, modem output “L” level.

Figure 3.10.37 Example of Modulation of Transmission Data (SIO0)

(2) Modulation of receiving data

When the receive data has the effective high level pulse width (Software selectable), the modem outputs “0” to SIO0. Otherwise modem outputs “1” to SIO0. Effective pulse width is chosen in SIR0CR<SIR0WD3:0>.

Figure 3.10.38 Example of Modulation of Receiving Data (SIO0)

(3) Data format

Format of transmission/receiving must set to data length 8-bit, without parity bit, 1 bit of stop bit.

Any other settings don't guarantee the normal operation.

(4) SFR

Figure 3.10.39 shows the control register SIR0CR. If change setting this register, must set it after set operation of transmission/receiving to disable (Both <TXEN> and <RXEN> of this register should be clear to 0).

Any changing for this register during transmission or receiving operation doesn't guarantee the normal operation.

The following example describes how to set this register:

- 1) SIO setting ; Set SIO side.
↓
- 2) LD (SIR0CR), 07H ; Set receiving effect pulse width to 16X+100ns.
- 3) LD (SIR0CR), 37H ; TXEN, RXEN enable the transmission and receiving.
↓
- 4) Transmission/receiving ; The modem operates as follows:
 - SIO0 starts transmitting.
 - IR receiver starts receiving.

(5) Notes

1. Making baud rate when using IrDA

In baud rate during using IrDA, must set "01" to SC0MOD0<SC1:0> in SIO by using baud rate generator.

TA0TRG, fSYS, SCLK0 input of except for it can not using.

2. Output pulse width and baud rate generator during transmission IrDA

As the IrDA 1.0 physical layer specification, the data transfer speed and infra-red pulse width is specified.

Table 3.10.5 Specification of Transfer Rate and Pulse Width

Transfer Rate	Modulation	Transfer Rate Tolerance (% of Rate)	Minimum of Pulse Width	Typical of Pulse Width 3/16	Maximum of Pulse Width
2.4 kbps	RZI	± 0.87	1.41 μs	78.13 μs	88.55 μs
9.6 kbps	RZI	± 0.87	1.41 μs	19.53 μs	22.13 μs
19.2 kbps	RZI	± 0.87	1.41 μs	9.77 μs	11.07 μs
38.4 kbps	RZI	± 0.87	1.41 μs	4.88 μs	5.96 μs
57.6 kbps	RZI	± 0.87	1.41 μs	3.26 μs	4.34 μs
115.2 kbps	RZI	± 0.87	1.41 μs	1.63 μs	2.23 μs

The infra-red pulse width is specified either baud rate $T \times 3/16$ or 1.6 μs (1.6 μs is equal to $T \times 3/16$ pulse width when baud rate is 115.2 kbps).

The TMP92CM27 has function which is selectable the transmission pulse width either 3/16 or 1/16. But $T \times 1/16$ pulse width can be selected when the baud rate is equal or less than 38.4 kbps only. When 57.6 kbps and 115.2 kbps, the output pulse width should not be set to $T \times 1/16$.

As the same reason, + (16 – K)/16 division function in the baud rate generator of SIO0 cannot be used to generate 115.2 kbps baud rate.

Also when the 38.4 kbps and 1/16 pulse width, + (16 – K)/16 division function cannot be used.

Table 3.10.6 shows baud rate and pulse width for (16 – K)/16 division function.

Table 3.10.6 Baud Rate and Pulse Width for (16 – K)/16 Division Function

Output Pulse Width	Baud Rate 115.2 kbps	57.6 kbps	38.4 kbps	19.2 kbps	9.6 kbps	2.4 kbps
$T \times 3/16$	×	○	○	○	○	○
$T \times 1/16$	–	–	×	○	○	○

○: Can be used (16 – K)/16 division function.

×: Cannot be used (16 – K)/16 division function.

–: Cannot be set to $T \times 1/16$ pulse width.

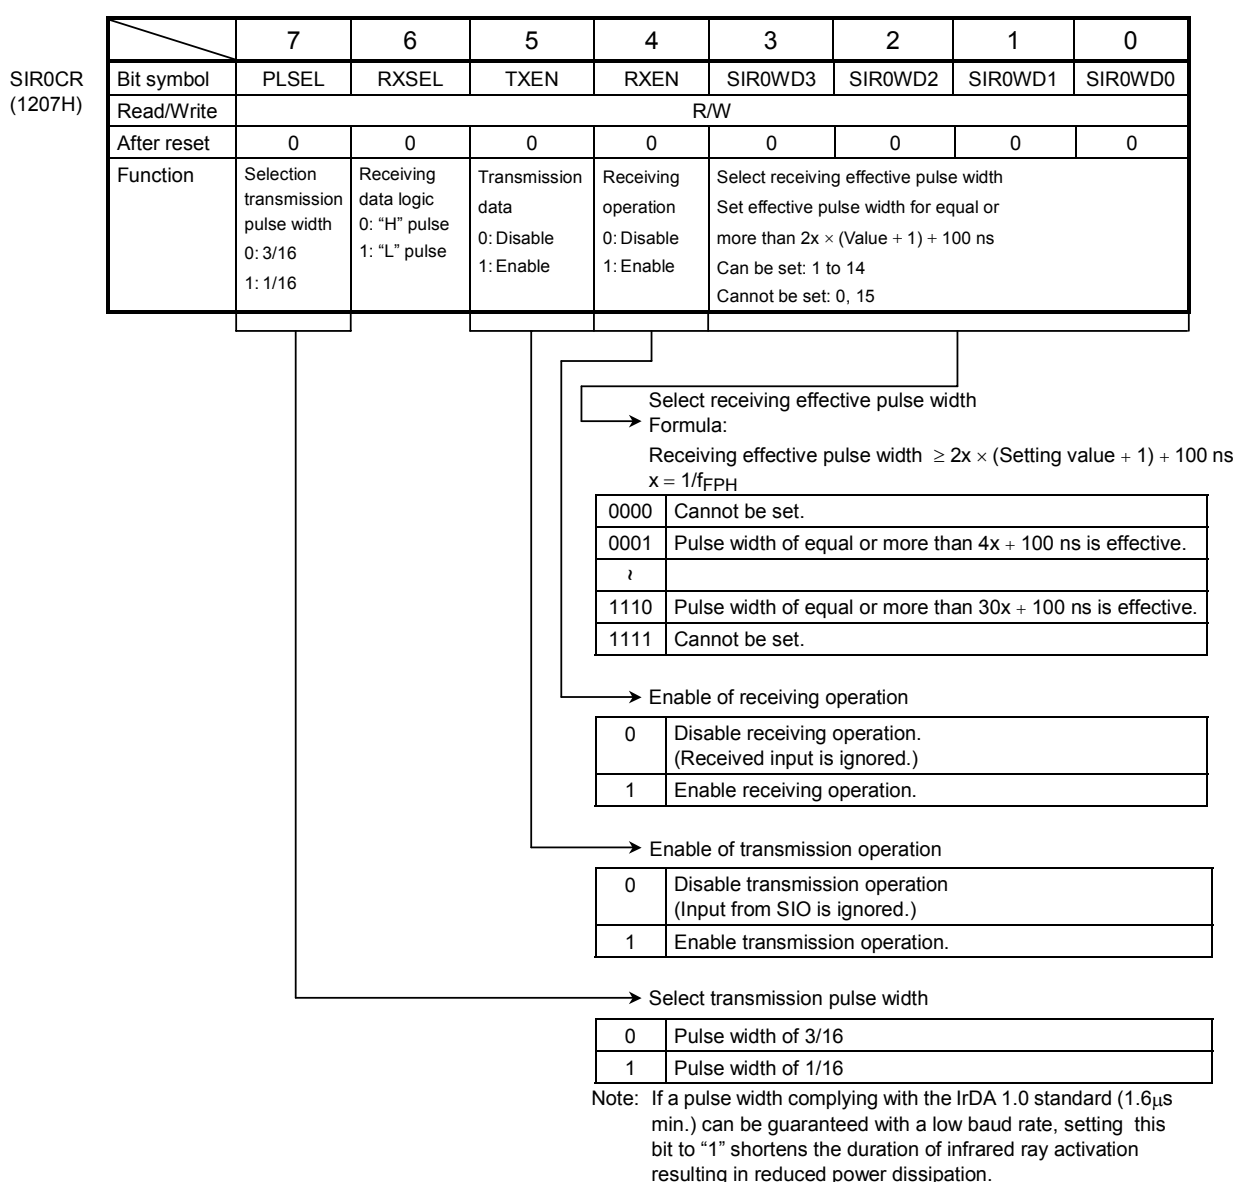

Figure 3.10.39 IrDA Control Register0 (for SIO0)

3.11 Serial Bus Interface (SBI)

The TMP92CM27 has 2-channel serial bus interface. Serial bus interface (SBI0, SBI1) include following 2 operation modes.

I²C bus mode (Multi master)

Clocked-synchronous 8-bit SIO mode

The serial bus interface is connected to an external device through PC0(SDA0), PC1(SCL0), PC3(SDA1) and PC4(SCL1) in the I²C bus mode; and through PC0(SO0), PC1(SI0), PC2(SCK0), PC3(SO1), PC4(SI1) and PC5(SCK1) in the clocked-synchronous 8-bit SIO mode.

Each of the channels can be operated independently. Since both SBI0 and SBI1 channels operate in the same manner, a channel explains only the case of SBI0.

Each pin is specified as follows: (SBI0)

	PCCR<PC2C, PC1C, PC0C>	PCFC<PC2F, PC1F, PC0F>	PCFC2<PC1F2, PC0F2>
I ² C bus mode	X11	X11	11
Clocked-synchronous 8-bit SIO mode	000(SCK input) 100(SCK output)	111	On(Note)

X: Don't care

Note) Set PCFC2<PC0F2 > in the clocked-synchronous 8-bit SIO mode to "1" when the oped drain output is necessary.

Each pin is specified as follows: (SBI1)

	PCCR<PC5C, PC4C, PC3C>	PCFC<PC5F, PC4F, PC3F>	PCFC2<PC4F2, PC3F2>
I ² C bus mode	X11	X11	11
Clocked-synchronous 8-bit SIO mode	000(SCK input) 100(SCK output)	111	On(Note)

X: Don't care

Note) Set PCFC2<PC3F2 > in the clocked-synchronous 8-bit SIO mode to "1" when the oped drain output is necessary.

3.11.1 Configuration

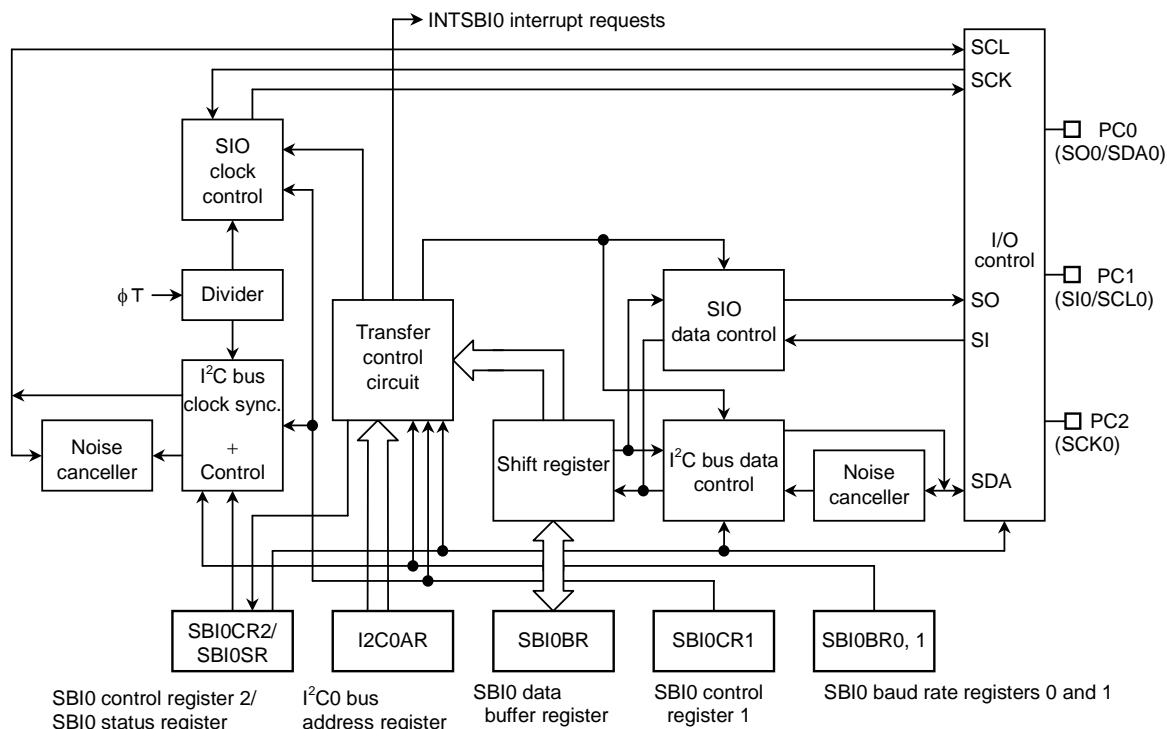

Figure 3.11.1 Serial Bus Interface (SBI0)

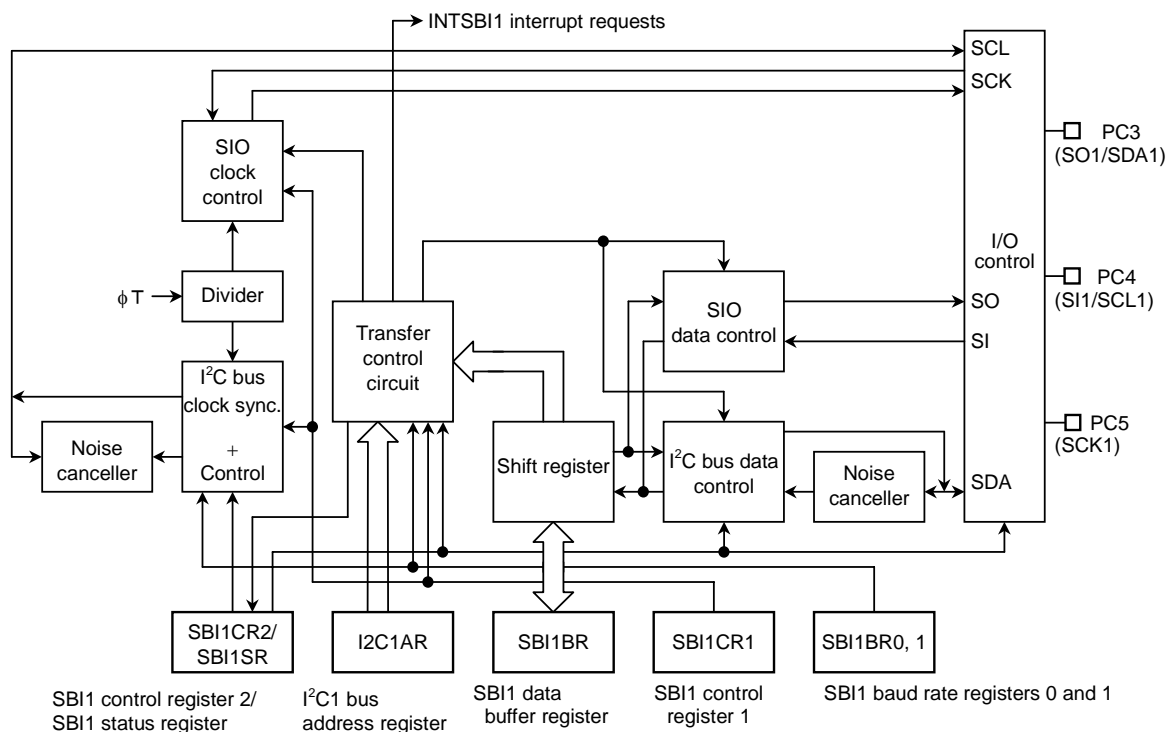

Figure 3.11.2 Serial Bus Interface (SBI1)

3.11.2 Control

The following registers are used to control the serial bus interface and monitor the operation status.

- Serial bus interface control register 1 (SBI0CR1), (SBI1CR1)
- Serial bus interface control register 2 (SBI0CR2), (SBI1CR2)
- Serial bus interface data buffer register (SBI0DBR), (SBI1DBR)
- I²C bus address register (I2C0AR), (I2C1AR)
- Serial bus interface status register (SBI0SR), (SBI1SR)
- Serial bus interface baud rate register 0 (SBI0BR0), (SBI1BR0)
- Serial bus interface baud rate register 1 (SBI0BR1), (SBI1BR1)

The above registers differ depending on a mode to be used.

Refer to Section 3.11.4 “I²C Bus Mode Control Register” and 3.11.7 “Clocked-synchronous 8-Bit SIO Mode Control”.

3.11.3 Data Format in I²C Bus Mode

Data format in I²C bus mode is shown Figure 3.11.3

(a) Addressing format

(b) Addressing format (with restart)

(c) Free data format (transfer format transfer from master device to slave device)

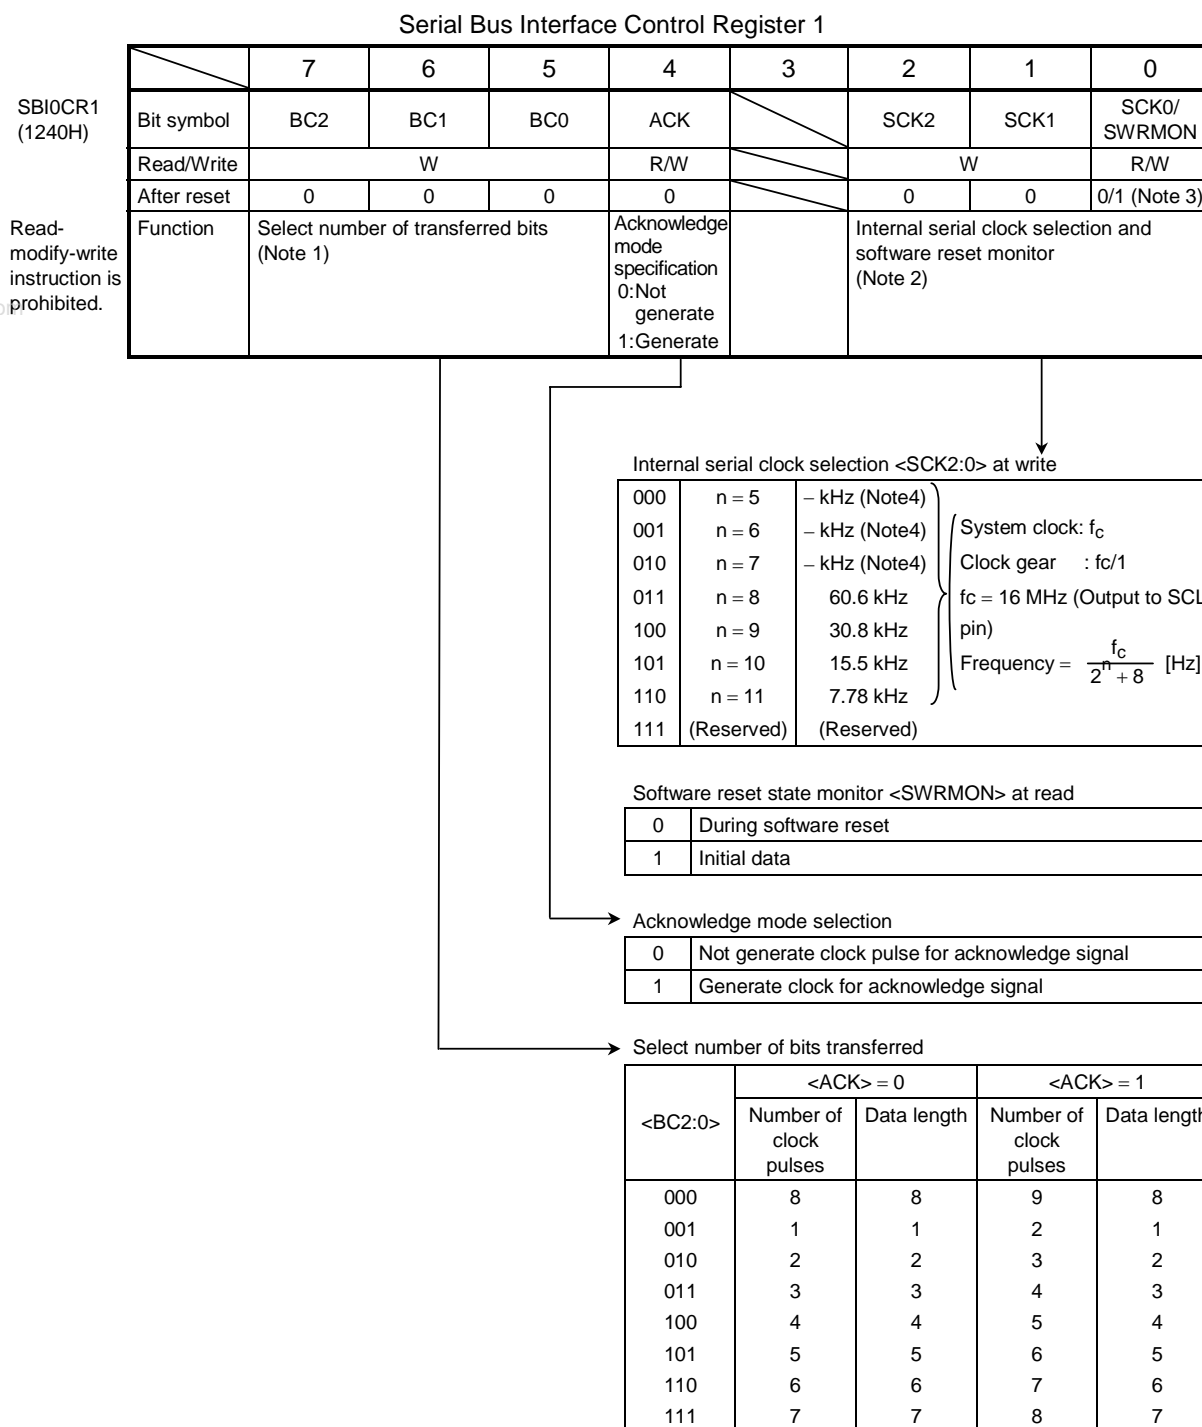

S: Start condition
 R/W: Direction bit
 ACK: Acknowledge bit
 P: Stop condition

Figure 3.11.3 Data Format in I²C Bus Mode

3.11.4 I²C Bus Mode Control Register

The following registers are used to control and monitor the operation status when using the serial bus interface (SBI0, SBI1) in the I²C bus mode.

Note 1: Set the <BC2:0> to "000" before switching to a clocked-synchronous 8-bit SIO mode.

Note 2: For the frequency of the SCL line clock, see section 3.11.5 (3) "Serial clock".

Note 3: Initial data of SCK0 is "0", SWRMON is "1".

Note 4: This I²C bus circuit does not support fast mode, it supports standard mode only. The f_{scl} speed can be selected over 100kbps by f_c and <SCK2:0>, however it's irregular operation.

Figure 3.11.11 Register for I²C Bus Mode (SBI1, SBI1BR0, SBI1BR1, SBI1DBR, I2C1AR)

3.11.5 Control in I²C Bus Mode

(1) Acknowledge mode specification

Set the SBI0CR1<ACK> to 1 for operation in the acknowledge mode. The TMP92CM27 generates an additional clock pulse for an acknowledge signal when operating in master mode. In the transmitter mode during the clock pulse cycle, the SDA0 pin is released in order to receive the acknowledge signal from the receiver. In the receiver mode during the clock pulse cycle, the SDA0 pin is set to the low in order to generate the acknowledge signal.

Clear the <ACK> to 0 for operation in the non-acknowledge mode, the TMP92CM27 does not generate a clock pulse for the acknowledge signal when operating in the master mode.

(2) Select number of transfer bits

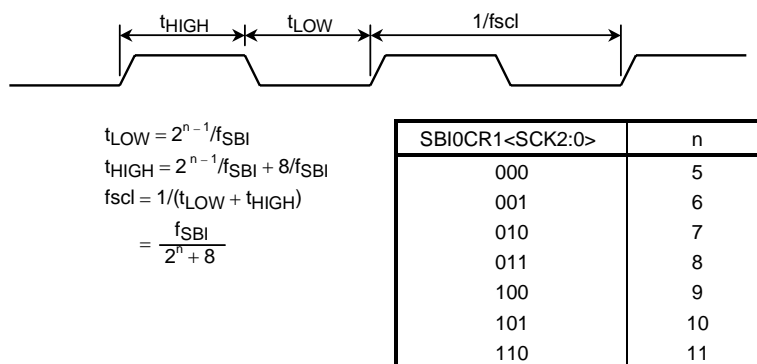

The SBI0CR1<BC2:0> is used to select a number of bits for next transmission/receiving data.

Since the <BC2:0> is cleared to 000 as a start condition, a slave address and direction bit are transferred in 8 bits. Other than these, the <BC2:0> retains a specified value.

(3) Serial clock

1. Clock source

The SBI0CR1<SCK2:0> is used to select a maximum transfer frequency outputted on the SCL pin in master mode. Set the baud rates, which have been calculated according to the formula below, to meet the specifications of the I²C bus, such as the smallest pulse width of t_{LOW}.

Note1: f_{SBI} shows f_{SY}.

Note2: In a setup of prescaler of SYSCR0, the fc/16 mode cannot be used at the time of SBI circuit use.

Figure 3.11.12 Clock Source

2. Clock synchronization

In the I²C bus mode, in order to wired-AND a bus, a master device which pulls down a clock line to low level, in the first place, invalidate a clock pulse of another master device which generates a high-level clock pulse. The master device with a high-level clock pulse needs to detect the situation and implement the following procedure.

The TMP92CM27 has a clock synchronization function for normal data transfer even when more than one master exists on the bus.

The example explains the clock synchronization procedures when two masters simultaneously exist on a bus.

Figure 3.11.13 Clock Synchronization

As master A pulls down the internal SCL output to the low level at point “a”, the SCL line of the bus becomes the low level. After detecting this situation, master B resets a counter of high-level width of an own clock pulse and sets the internal SCL output to the low level.

Master A finishes counting low-level width of an own clock pulse at point “b” and sets the internal SCL output to the high level. Since master B holds the SCL line of the bus at the low level, master A waits for counting high-level width of an own clock pulse. After master B finishes counting low-level width of an own clock pulse at point “c” and master A detects the SCL line of the bus at the high level, and starts counting high level of an own clock pulse. The clock pulse on the bus is determined by the master device with the shortest high-level width and the master device with the longest low-level width from among those master devices connected to the bus.

(4) Slave address and address recognition mode specification

When the TMP92CM27 is used as a slave device, set the slave address <SA6:0> and <ALS> to the I2C0AR. Clear the <ALS> to “0” for the address recognition mode.

(5) Master/slave selection

Set the SBI0CR2<MST> to “1” for operating the TMP92CM27 as a master device. Clear the SBI0CR2<MST> to “0” for operation as a slave device. The <MST> is cleared to “0” by the hardware after a stop condition on the bus is detected or arbitration is lost.

(6) Transmitter/receiver selection

Set the SBI0CR2<TRX> to "1" for operating the TMP92CM27 as a transmitter. Clear the <TRX> to "0" for operation as a receiver. In slave mode, when transfer data in addressing format, when received slave address is same value with setting value to I2C0AR, or GENERAL CALL is received (All 8-bit data are "0" after a start condition), the <TRX> is set to "1" by the hardware if the direction bit (R/\bar{W}) sent from the master device is "1", and <TRX> is cleared to "0" by the hardware if the bit is "0".

In the master mode, after an acknowledge signal is returned from the slave device, the <TRX> is cleared to "0" by the hardware if a transmitted direction bit is "1", and is set to "1" by the hardware if it is "0". When an acknowledge signal is not returned, the current condition is maintained.

The <TRX> is cleared to "0" by the hardware after a stop condition on the bus is detected or arbitration is lost.

(7) Start/stop condition generation

When programmed "1111" to SBI0CR2 <MST, TRX, BB, PIN> in during SBI0SR<BB> is "0", slave address and direction bit which are set to SBI0DBR and start condition are output on a bus. And it is necessary to set transmitted data to the data buffer register (SBI0DBR) and set "1" to <ACK> beforehand.

Figure 3.11.14 Generation of Start Condition and Slave Address

When programmed "0" to SBI0CR2<BB> and "111" to <MST, TRX, PIN> in during SBI0SR<BB> is "1", start a sequence of stop condition output. Do not modify the contents of <MST, TRX, BB, and PIN> until a stop condition is generated on a bus.

Figure 3.11.15 Generation of Stop Condition

The state of the bus can be ascertained by reading the contents of SBI0SR<BB>. SBI0SR<BB> will be set to 1 (Bus busy status) if a start condition has been detected on the bus, and will be cleared to 0 if a stop condition has been detected (Bus free status).

In addition, since there is a restrictions matter about stop condition generating in master mode, please refer to 3.11.6.(4) " Stop condition generation ".

(8) Interrupt service requests and interrupt cancellation

When a serial bus interface interrupt request 0 (INTSBI0) occurs, the SBI0SR2<PIN> is cleared to "0". During the time that the SBI0SR2<PIN> is "0", the SCL line is pulled down to the low level.

The <PIN> is cleared to "0" when end of transmission or receiving 1 word of data. And when writing data to SBI0DBR or reading data from SBI0DBR, <PIN> is set to "1".

The time from the <PIN> being set to "1" until the SCL line is released takes t_{LOW} .

In the address recognition mode (<ALS> = 0), <PIN> is cleared to "0" when the received slave address is the same as the value set at the I2C0AR or when a GENERAL CALL is received (All 8-bit data are "0" after a start condition). Although SBI0CR2<PIN> can be set to "1" by the program, the <PIN> is not clear it to "0" when it is programmed "0".

(9) Serial bus interface operation mode selection

SBI0CR2<SBIM1:0> is used to specify the serial bus interface operation mode. Set SBI0CR2<SBIM1:0> to "10" when the device is to be used in I²C bus mode after confirming pin condition of serial bus interface to "H".

Switch a mode to port after confirming a bus is free.

(10) Arbitration lost detection monitor

Since more than one master device can exist simultaneously on the bus in I²C bus mode, a bus arbitration procedure has been implemented in order to guarantee the integrity of transferred data.

Data on the SDA line is used for I²C bus arbitration.

The following shows an example of a bus arbitration procedure when two master devices exist simultaneously on the bus. Master A and master B output the same data until point "a". After master A outputs "L" and master B, "H", the SDA line of the bus is wire-AND and the SDA line is pulled down to the low level by master A. When the SCL line of the bus is pulled up at point b, the slave device reads the data on the SDA line, that is, data in master A. A data transmitted from master B becomes invalid. The state in master B is called "ARBITRATION LOST". Master B device that loses arbitration releases the internal SDA output in order not to affect data transmitted from other masters with arbitration. When more than one master sends the same data at the first word, arbitration occurs continuously after the second word.

Figure 3.11.16 Arbitration Lost

The TMP92CM27 compares the levels on the bus's SDA line with those of the internal SDA output on the rising edge of the SCL line. If the levels do not match, arbitration is lost and SBI0SR<AL> is set to "1".

When SBI0SR<AL> is set to "1", SBI0SR<MST, TRX> are cleared to "00" and the mode is switched to slave receiver mode. Thus, clock output is stopped in data transfer after setting <AL> = "1".

SBI0SR <AL> is cleared to "0" when data is written to or read from SBI0DBR or when data is written to SBI0CR2.

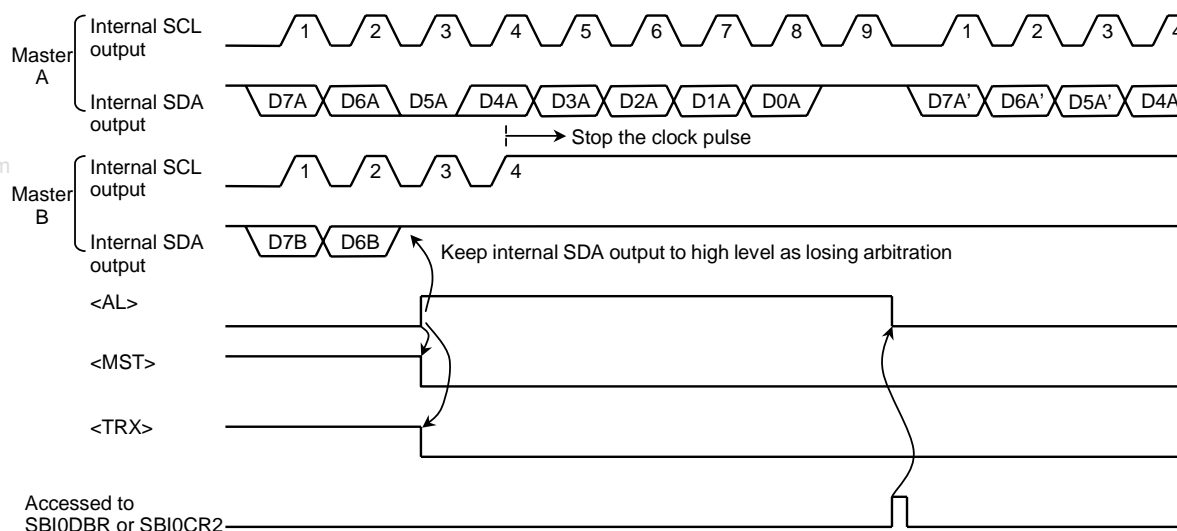

Figure 3.11.17 Example of when TMP92CM27 is a Master Device B (D7A = D7B, D6A = D6B)

(11) Slave address match detection monitor

SBI0SR<AAS> operates following in during slave mode; In address recognition mode (e.g., when I2C0AR<ALS> = "0"), when received GENERAL CALL or same slave address with value set to I2C0AR, SBI0SR<AAS> is set to "1". When <ALS> = "1", SBI0SR<AAS> is set to "1" after the first word of data has been received. SBI0SR<AAS> is cleared to "0" when data is written to SBI0DBR or read from SBI0DBR.

(12) GENERAL CALL detection monitor

SBI0SR<AD0> operates following in during slave mode; when received GENERAL CALL (all 8-bit data is "0", after a start condition), SBI0SR<AD0> is set to "1". And SBI0SR<AD0> is cleared to "0" when a start condition or stop condition on the bus is detected.

(13) Last received bit monitor

The value on the SDA line detected on the rising edge of the SCL line is stored in the SBI0SR<LRB>. In the acknowledge mode, immediately after an INTSBI0 interrupt request has been generated, an acknowledge signal is read by reading the contents of the SBI0SR<LRB>.

(14) Software reset function

The software reset function is used to initialize the SBI circuit, when SBI is rocked by external noises, etc.

When write first "10" next "01" to SBI0CR2<SWRST1:0>, reset signal is inputted to serial bus interface circuit, and circuit is initialized. All command registers except SBI0CR2<SBIM1:0> and status flag except SBI0CR2<SBIM1:0> are initialized to value of just after reset. SBI0CR1<SWRMON> is set to "1" automatically when completed initialization of serial bus interface.

(15) Serial bus interface data buffer register (SBI0DBR)

The received data can be read and transmission data can be written by reading or writing SBI0DBR.

In the master mode, after the slave address and the direction bit are set in this register, the start condition is generated.

(16) I²C bus address register (I2C0AR)

I2C0AR<SA6:0> is used to set the slave address when the TMP92CM27 functions as a slave device.

The slave address outputted from the master device is recognized by setting the I2C0AR<ALS> to "0". And, the data format becomes the addressing format. When set <ALS> to "1", the slave address is not recognized, the data format becomes the free data format.

(17) Baud rate register (SBI0BR1)

Write "1" to baud rate circuit control register SBI0BR1<P4EN> before using I²C bus.

(18) Setting register for IDLE2 mode operation (SBI0BR0)

SBI0BR0<I2SBI0> is the register setting operation/stop during IDLE2 mode. Therefore, setting <I2SBI0> is necessary before the HALT instruction is executed.

3.11.6 Data Transfer in I²C Bus Mode

(1) Device initialization

In first, set the SBI0BR1<P4EN>, SBI0CR1<ACK, SCK2:0>. Set SBI0BR1<P4EN> to "1" and clear bits 7 to 5 and 3 in the SBI0CR1 to "0".

Next, set a slave address <SA6:0> and the <ALS> (<ALS> = "0" when an addressing format) to the I2C0AR.

And, write "000" to SBI0CR2<MST, TRX, BB>, "1" to <PIN>, "10" to <SBIM1:0> and "00" to <SWRST1:0>. Set initialization status to slave receiver mode by this setting.

(2) Start condition and slave address generation

1. Master mode

In the master mode, the start condition and the slave address are generated as follows.

In first, check a bus free status (when SBI0SR<BB> = "0"). Set the SBI0CR1<ACK> to "1" (Acknowledge mode) and specify a slave address and a direction bit to be transmitted to the SBI0DBR.

When SBI0SR<BB> = "0", the start condition are generated by writing "1111" to SBI0CR2<MST, TRX, BB, PIN>. Subsequently to the start condition, nine clocks are output from the SCL pin. While eight clocks are output, the slave address and the direction bit which are set to the SBI0DBR. At the 9th clock, the SDA line is released and the acknowledge signal is received from the slave device.

An INTSBI interrupt request generate at the falling edge of the 9th clock. The <PIN> is cleared to "0". In the master mode, the SCL pin is pulled down to the low level while <PIN> is "0". When an interrupt request is generated, the <TRX> is changed according to the direction bit only when an acknowledge signal is returned from the slave device.

2. Slave mode

In the slave mode, the start condition and the slave address are received.

After the start condition is received from the master device, while eight clocks are output from the SCL pin, the slave address and the direction bit that are output from the master device are received.

When a GENERAL CALL or the same address as the slave address set in I2C0AR is received, the SDA line is pulled down to the low level at the 9th clock, and the acknowledge signal is output.

An INTSBI0 interrupt request is generated on the falling edge of the 9th clock. The <PIN> is cleared to "0". In slave mode the SCL line is pulled down to the low level while the <PIN> = "0".

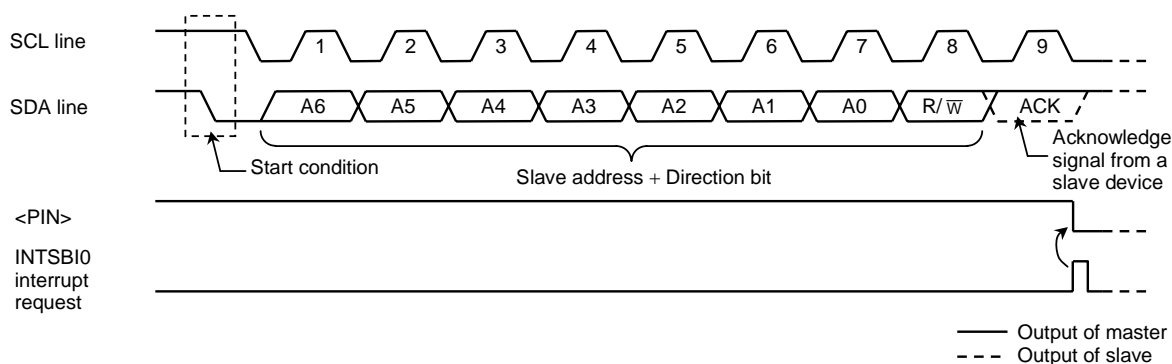

Figure 3.11.18 Start Condition and Slave Address Generation

(3) 1-word data transfer

Check the <MST> by the INTSBI0 interrupt process after the 1-word data transfer is completed, and determine whether the mode is a master or slave.

1. If <MST> = "1" (Master mode)

Check the <TRX> and determine whether the mode is a transmitter or receiver.

When the <TRX> = "1" (Transmitter mode)

Check the <LRB>. When <LRB> is "1", a receiver does not request data. Implement the process to generate a stop condition (Refer to 3.11.6 (4)) and terminate data transfer.

When the <LRB> is "0", the receiver requests new data. When the next transmitted data is 8 bits, write the transmitted data to SBI0DBR. When the next transmitted data is other than 8 bits, set the <BC2:0> <ACK> and write the transmitted data to SBI0DBR. After written the data, <PIN> becomes "1", a serial clock pulse is generated for transferring a new 1-word of data from the SCL0 pin, and then the 1-word data is transmitted. After the data is transmitted, an INTSBI0 interrupt request generates. The <PIN> becomes "0" and the SCL0 line is pulled down to the low level. If the data to be transferred is more than one word in length, repeat the procedure from the <LRB> checking above.

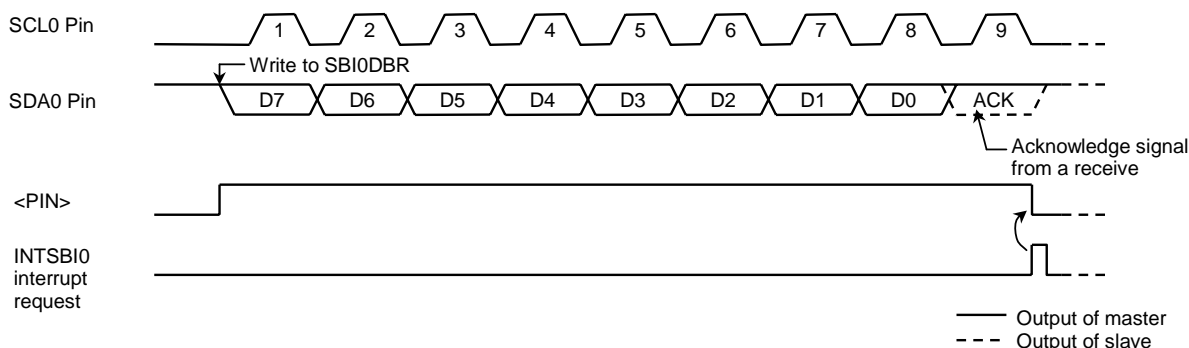

Figure 3.11.19 Example in which <BC2:0> = "000" and <ACK> = "1" (Transmitter mode)

When the <TRX> is "0" (Receiver mode)

When the next transmitted data is other than 8 bits, set <BC2:0> <ACK> and read the received data from SBI0DBR to release the SCL0 line (Data which is read immediately after a slave address is sent is undefined). After the data is read, <PIN> becomes "1". Serial clock pulse for transferring new 1 word of data is defined SCL and outputs "L" level from SDA0 pin with acknowledge timing.

An INTSBI0 interrupt request then generates and the <PIN> becomes "0". Then the TMP92CM27 pulls down the SCL pin to the low level. The TMP92CM27 outputs a clock pulse for 1 word of data transfer and the acknowledge signal each time that received data is read from the SBI0DBR.

Figure 3.11.20 Example of when <BC2:0> = "000", <ACK> = "1" (Receiver mode)

In order to terminate the transmission of data to a transmitter, clear <ACK> to "0" before reading data which is 1 word before the last data to be received. The last data word does not generate a clock pulse as the acknowledge signal. After the data has been transmitted and an interrupt request has been generated, set <BC2:0> to "001" and read the data. The TMP92CM27 generates a clock pulse for a 1-bit data transfer. Since the master device is a receiver, the SDA0 line on the bus remains high. The transmitter receives the high signal as an ACK signal. The receiver indicates to the transmitter that the data transfer is completed.

After the one data bit has been received and an interrupt request has been generated, the TMP92CM27 generates a stop condition (See section 3.11.6 (4)) and terminates data transfer.

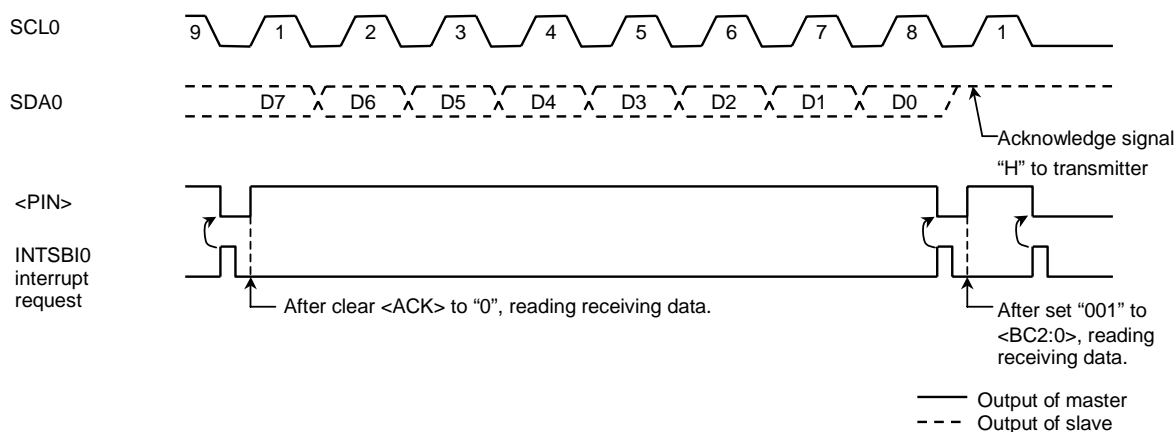

Figure 3.11.21 Termination of Data Transfer (Master receiver mode)

2. If <MST> = 0 (Slave mode)

In the slave mode the TMP92CM27 operates either in normal slave mode or in slave mode after losing arbitration.

In the slave mode, an INTSBI0 interrupt request generate when the TMP92CM27 receives a slave address or a GENERAL CALL from the master device, or when a GENERAL CALL is received and data transfer is completed, or after matching received address. In the master mode, the TMP92CM27 operates in a slave mode if it losing arbitration. An INTSBI0 interrupt request is generated when a word data transfer terminates after losing arbitration. When an INTSBI0 interrupt request is generated the <PIN> is cleared to "0" and the SCL pin is pulled down to the low level. Either reading/writing from/to the SBI0DBR or setting the <PIN> to "1" will release the SCL pin after taking tLOW time.

Check the SBI0SR<AL>, <TRX>, <AAS>, and <AD0> and implements processes according to conditions listed in the next table.

Table 3.11.1 Operation in the Slave Mode

<TRX>	<AL>	<AAS>	<AD0>	Conditions	Process
1	1	1	0	The TMP92CM27 detects arbitration lost when transmitting a slave address, and receives a slave address for which the value of the direction bit sent from another master is "1".	Set the number of bits of single word to <BC2:0>, and write the transmit data to SBI0DBR.
	0	1	0	In slave receiver mode, the TMP92CM27 receives a slave address for which the value of the direction bit sent from the master is "1".	
		0	0	In slave transmitter mode, transmission of data of single word is terminated.	Check the <LRB>, If <LRB> is set to "1", set <PIN> to "1", reset "0" to <TRX> and release the bus for the receiver no request next data. If <LRB> was cleared to "0", set bit number of single word to <BC2:0> and write the transmit data to SBI0DBR for the receiver requests next data.
0	1	1	1/0	The TMP92CM27 detects arbitration lost when transmitting a slave address, and receives a slave address or GENERAL CALL for which the value of the direction bit sent from another master is "0".	Read the SBI0DBR for setting the <PIN> to "1" (Reading dummy data) or set the <PIN> to "1".
		0	0	The TMP92CM27 detects arbitration lost when transmitting a slave address or data, and transfer of word terminates.	
	0	1	1/0	In slave receiver mode the TMP92CM27 receives a slave address or GENERAL CALL for which the value of the direction bit sent from the master is "0".	
		0	1/0	In slave receiver mode the TMP92CM27 terminates receiving word data.	Set bit number of single word to <BC2:0>, and read the receiving data from SBI0DBR.

(4) Stop condition generation

When $SBI0SR<BB> = 1$, the sequence for generating a stop condition is started by writing "111" to $SBI0CR2<MST, TRX, PIN>$ and "0" to $SBI0CR2<BB>$. Do not modify the contents of $SBI0CR2<MST, TRX, PIN, BB>$ until a stop condition has been generated on the bus. When the bus's SCL line has been pulled low by another device, the TMP92CM27 generates a stop condition when the other device has released the SCL line and SDA0 pin rising.

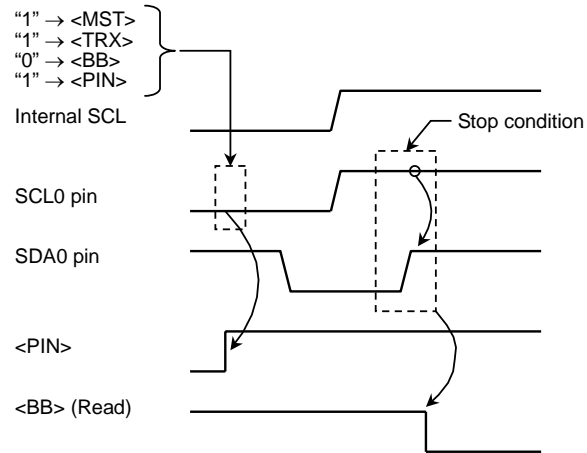

Figure 3.11.22 Stop Condition Generation (Single master)

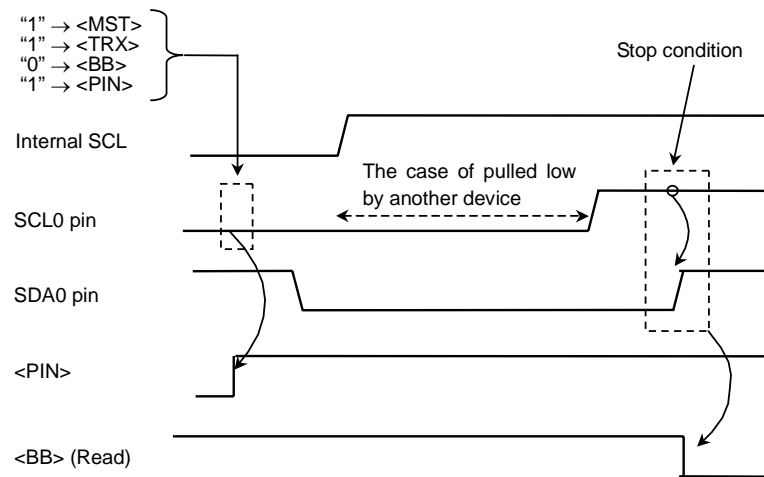

Figure 3.11.23 Stop Condition Generation (Multi master)

(5) Restart

Restart is used during data transfer between a master device and a slave device to change the data transfer direction. The following description explains how to restart when this device is in the master mode.

Clear the SBI0CR2<MST, TRX, BB> to "000" and set the SBI0CR2<PIN> to "1" to release the bus. The SDA0 line remains the high level and the SCL0 pin is released. Since a stop condition is not generated on the bus, other devices assume the bus to be in a busy state. Check the SBI0SR<BB> until it becomes "0" to check that the SCL0 pin of this device is released. Check the <LRB> until it becomes 1 to check that the SCL line on a bus is not pulled down to the low level by other devices. After confirming that the bus stays in a free state, generate a start condition with procedure described in 3.11.6 (2).

In order to meet setup time when restarting, take at least 4.7 μ s of waiting time by software from the time of restarting to confirm that the bus is free until the time to generate the start condition.

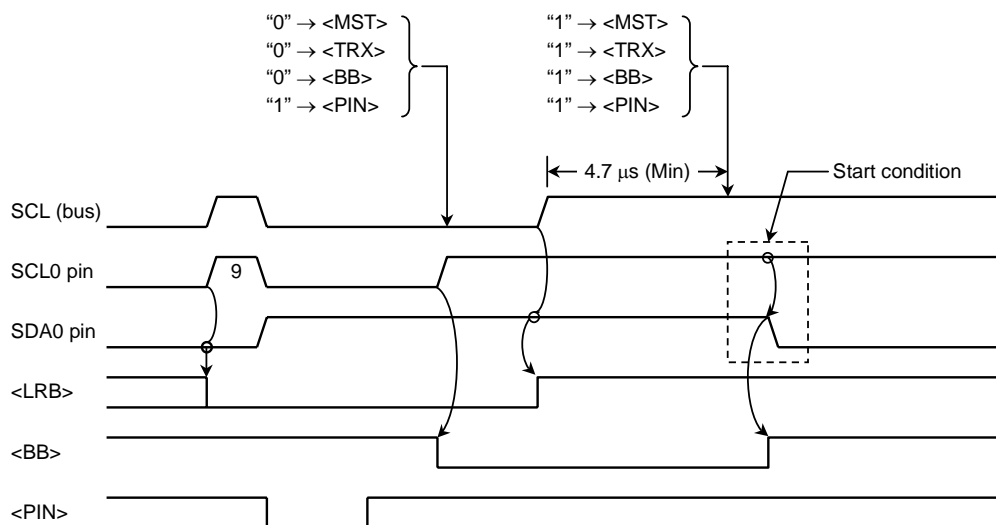

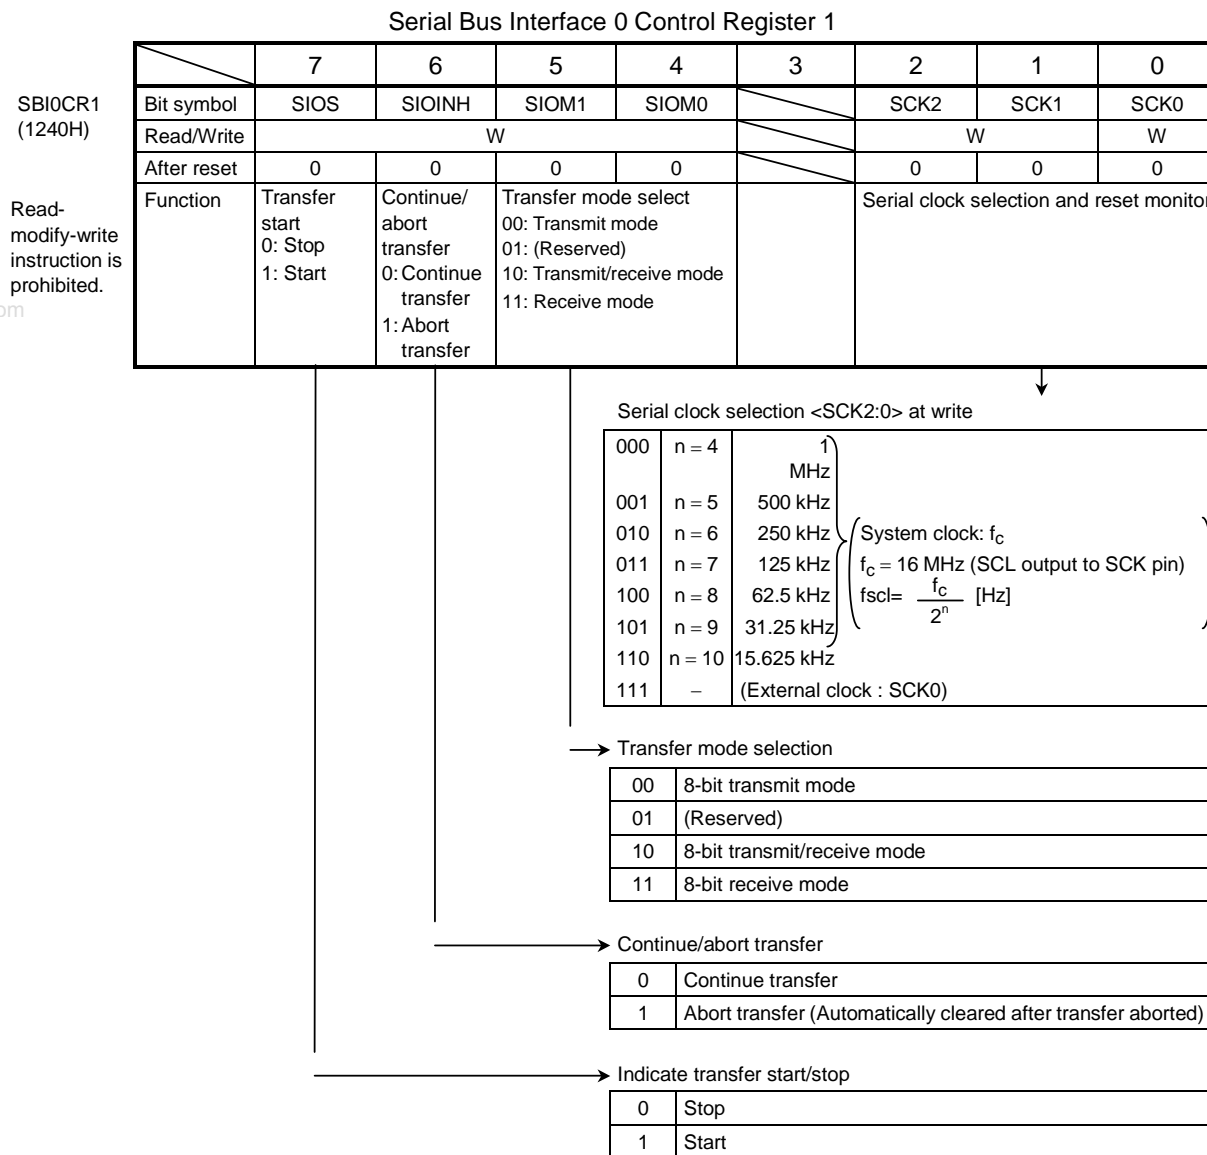

Figure 3.11.24 Timing Diagram when Restarting

3.11.7 Clocked-synchronous 8-bit SIO Mode Control

The following registers are used to control and monitor the operation status when the serial bus interface (SBI) is being operated in clocked synchronous 8-bit SIO mode.

Note: Set the transfer mode and the serial clock after setting <SIOS> to "0" and <SIOINH> to "1".

Serial Bus Interface 0 Data Buffer Register

(1) Serial Clock

1. Clock source

SBI0CR1<SCK2:0> is used to select the following functions:

Internal clock

In internal clock mode one of seven frequencies can be selected. The serial clock signal is output to the outside on the SCK0 pin. The SCK0 pin goes high when data transfer starts. When the device is writing (in transmit mode) or reading (in receive mode), data cannot follow the serial clock rate, so an automatic wait function is executed which automatically stops the serial clock and holds the next shift operation until reading or writing has been completed.

Figure 3.11.29 Automatic Wait Function

External clock (<SCK2:0> = "111")

An external clock input via the SCK0 pin is used as the serial clock. In order to ensure the integrity of shift operations, both the high and low-level serial clock pulse widths shown below must be maintained. The maximum data transfer frequency is 1MHz (when $f_C = 16 \text{ MHz}$).

Figure 3.11.30 Maximum Data Transfer Frequency when External Clock Input

2. Shift edge

Data is transmitted on the leading edge of the clock and received on the trailing edge.

Leading edge shift

Data is shifted on the leading edge of the serial clock (on the falling edge of the SCK0 pin input/output).

Trailing edge shift

Data is shifted on the trailing edge of the serial clock (on the rising edge of the SCK0 pin input/output).

(a) Leading shift

(b) Trailing shift

*: Don't care

Figure 3.11.31 Shift Edge

(2) Transfer modes

The SBI0CR1<SIOM1:0> is used to select a transmit, receive or transmit/receive mode.

1. 8-bit transmit mode

Set a control register to a transmit mode and write transmission data to the SBI0DBR.

After the transmit data has been written, set the SBI0CR1<SIOS> to “1” to start data transfer. The transmitted data is transferred from the SBI0DBR to the shift register and output, starting with the least significant bit (LSB), via the SO0 pin and synchronized with the serial clock. When the transmission data has been transferred to the shift register, the SBI0DBR becomes empty. The INTSBIO (Buffer empty) interrupt request is generated to request new data.

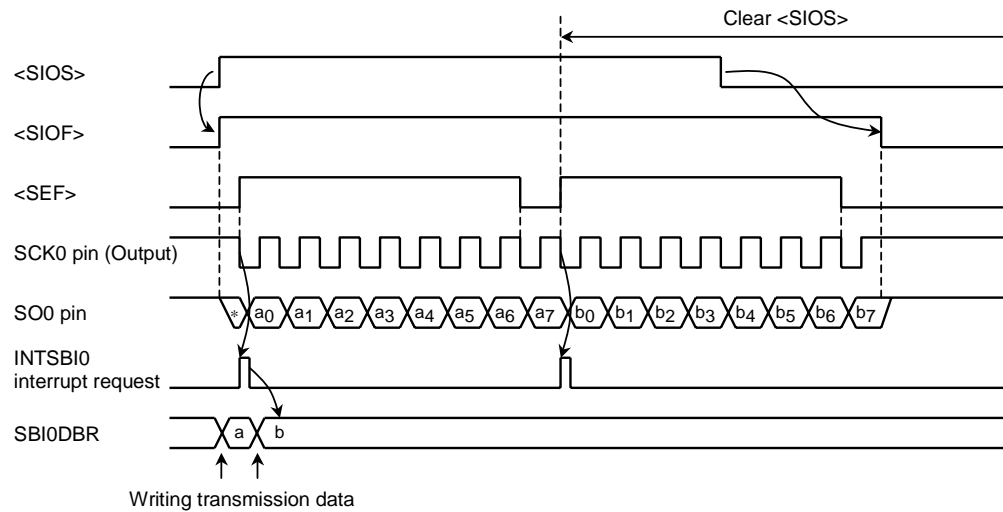

When the internal clock is used, the serial clock will stop and the automatic wait function will be initiated if new data is not loaded to the data buffer register after the specified 8-bit data is transmitted. When new transmission data is written, the automatic wait function is canceled.

When the external clock is used, data should be written to the SBI0DBR before new data is shifted. The transfer speed is determined by the maximum delay time between the time when an interrupt request is generated and the time when data is written to the SBI0DBR by the interrupt service program.

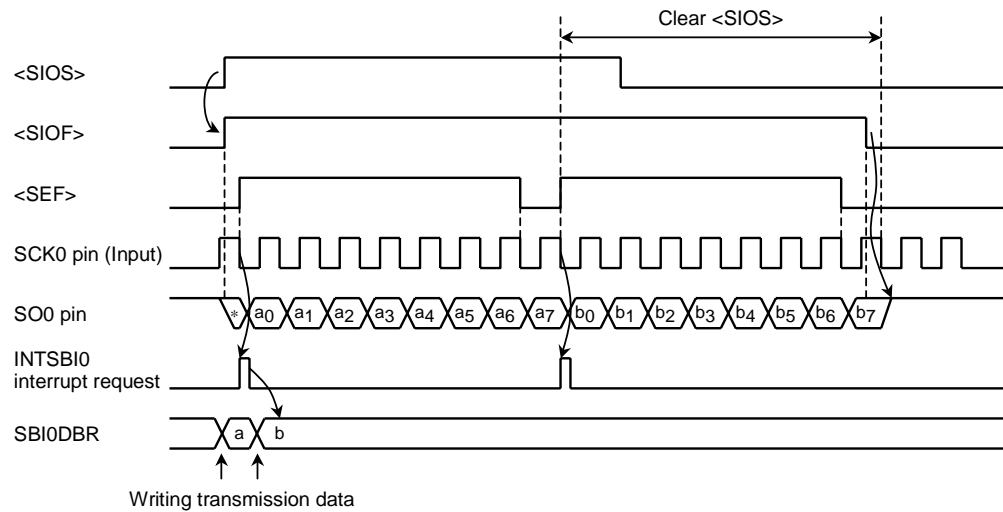

When the transmit is started, after the SBI0SR<SIOF> goes “1” output from the SO0 pin holds final bit of the last data until falling edge of the SCK.

For stopping data transmission, when the <SIOS> is cleared to “0” by the INTSBIO interrupt service program or when the <SIOINH> is set to “1”. When the <SIOS> is cleared to “0”, the transmitted mode ends when all data is output. In order to confirm whether data is being transmitted properly by the program, the <SIOF> to be sensed. The SBI0SR<SIOF> is cleared to “0” when transmission has been completed. When the <SIOINH> is set to “1”, transmitting data stops. The <SIOF> turns “0”.

When the external clock is used, it is also necessary to clear the <SIOS> to “0” before new data is shifted; otherwise, dummy data is transmitted and operation ends.

(a) Internal clock

(b) External clock

Figure 3.11.32 Transmission Mode

Example: Program to stop data transmission (when an external clock is used)

```

STEST1 :   BIT    SEF, (SBI0SR)           ; If <SEF> = 1 then loop.
           JR      NZ, STEST1
STEST2 :   BIT     0, (PN)                 ; If SCK = 0 then loop.
           JR      Z, STEST2
           LD      (SBI0CR1), 00000111B   ; <SIOF> ← 0

```

Figure 3.11.33 Transmission Data Hold Time at End Transmit

2. 8-bit receive mode

Set the control register to receive mode and set the SBI0CR1<SIOS> to “1” for switching to receive mode. Data is received into the shift register via the SIO pin and synchronized with the serial clock, starting from the least significant bit (LSB). When the 8-bit data is received, the data is transferred from the shift register to the SBI0DBR. The INTSBI0 (Buffer full) interrupt request is generated to request that the received data be read. The data is then read from the SBI0DBR by the interrupt service program.

When the internal clock is used, the serial clock will stop and the automatic wait function will be in effect until the received data is read from the SBI0DBR.

When the external clock is used, since shift operation is synchronized with an external clock pulse, the received data should be read from the SBI0DBR before the next serial clock pulse is input. If the received data is not read, further data to be received is canceled. The maximum transfer speed when an external clock is used is determined by the delay time between the time when an interrupt request is generated and the time when the received data is read.

Receiving of data ends when the <SIOS> is cleared to “0” by the INTSBI0 interrupt service program or when the <SIOINH> is set to “1”. If <SIOS> is cleared to “0”, received data is transferred to the SBI0DBR in complete blocks. The received mode ends when the transfer is completed. In order to confirm whether data is being received properly by the program, the SBI0SR<SIOF> to be sensed. The <SIOF> is cleared to “0” when receiving is completed. When it is confirmed that receiving has been completed, the last data is read. When the <SIOINH> is set to “1”, data receiving stops. The <SIOF> is cleared to “0” (The received data becomes invalid, therefore no need to read it).

Note: When the transfer mode is changed, the contents of the SBI0DBR will be lost. If the mode must be changed, conclude data receiving by clearing the <SIOS> to “0”, read the last data, then change the mode.

Figure 3.11.34 Receiver Mode (Example: Internal clock)

3. 8-bit transmit/receive mode

Set a control register to a transmit/receive mode and write data to the SBI0DBR. After the data is written, set the SBI0CR1<SIOS> to "1" to start transmitting/receiving. When data is transmitted, the data is output from the SO0 pin, starting from the least significant bit (LSB) and synchronized with the leading edge of the serial clock signal. When data is received, the data is input via the SI0 pin on the trailing edge of the serial clock signal. 8-bit data is transferred from the shift register to the SBI0DBR and the INTSBI0 interrupt request is generated. The interrupt service program reads the received data from the data buffer register and writes the data which is to be transmitted. The SBI0DBR is used for both transmitting and receiving. Transmitted data should always be written after received data is read.

When the internal clock is used, the automatic wait function will be in effect until the received data is read and the new data is written.

When the external clock is used, since the shift operation is synchronized with the external clock, the received data is read and transmitted data is written before a new shift operation is executed. The maximum transfer speed when the external clock is used is determined by the delay time between the time when an interrupt request is generated and the time at which received data is read and transmitted data is written.

When the transmit is started, after the SBI0SR<SIOF> goes "1" output from the SO0 pin holds final bit of the last data until falling edge of the SCK.

Transmitting/receiving data ends when the <SIOS> is cleared to "0" by the INTSBI0 interrupt service program or when the SBI0CR1<SIOINH> is set to "1". When the <SIOS> is cleared to "0", received data is transferred to the SBI0DBR in complete blocks. The transmit/receive mode ends when the transfer is completed. In order to confirm whether data is being transmitted/received properly by the program, set the SBI0SR to be sensed. The <SIOF> is cleared to "0" when transmitting/receiving is completed. When the <SIOINH> is set to "1", data transmitting/receiving stops. The <SIOF> is then cleared to "0".

Note: When the transfer mode is changed, the contents of the SBI0DBR will be lost. If the mode must be changed, conclude data transmitting/receiving by clearing the <SIOS> to "0", read the last data, and then change the transfer mode.

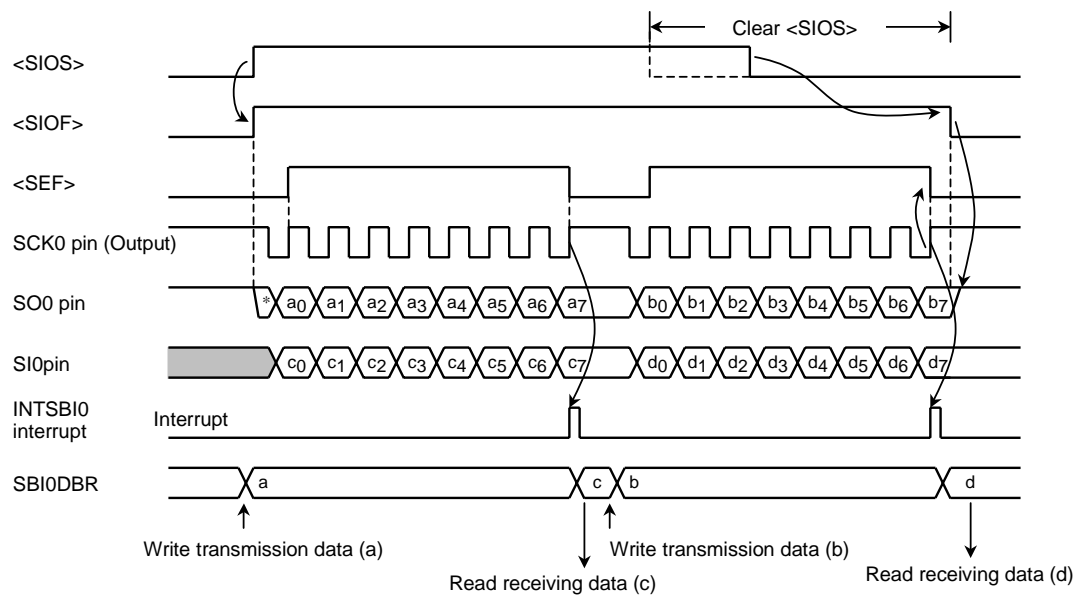

Figure 3.11.35 Transmission/Receiving Mode (when an external clock is used)

Figure 3.11.36 Transmission Data Hold Time at End of Transmission/Receiving
(Transmission/receiving mode)

3.12 High Speed SIO (HSC)

TMP92CM27 includes 2 High Speed SIO channels. Each channel is called HSC0 and HSC1. Each channel supports only the master mode in I/O interface mode (synchronous transmission). The features as follows.

- 1) Double buffer (Transmit/Receive)
- 2) Generate CRC7 and CRC16 of Transmit/Receive data
- 3) Baud Rate : 10Mbps max
- 4) MSB/LSB-first
- 5) 8/16bit data length
- 6) Clock Rising/Falling edge
- 7) The interruption function of each 1 channel : INTHSC0/INTHSC1

Read, Mask, Clear interrupt and Clear enable can control each 4 interrupts:

RFR0/1 (Receive buffer of HSC0RD/HSC1RD: Full),
 RFW0/1 (Transmission buffer of HSC0TD/HSC1TD: Empty),
 REND0/1 (Receive buffer of HSC0RS/HSC1RS: Full),
 TEND0/1 (Transmission buffer of HSC0TS/HSC1TS: Empty).
 RFR0/1, RFW0/1 can high-speed transaction by micro DMA.

High Speed SIO channels 0 to 1 can be used independently.

All channels operate in the same function except for the following points; hence only the operation of channel 0 is explained below.

Table 3.12.1 Differences between each Channels

	HSC0	HSC1
Pin name	HSSI0 (PD0) HSSO0 (PD1) HSSCLK0 (PD2)	HSSI1 (PL4) HSSO1 (PL5) HSCLK1 (PL6)
SFR (address)	HSC0MD (C00H/C01H) HSC0CT (C02H/C03H) HSC0ST (C04H/C05H) HSC0CR (C06H/C07H) HSC0IS (C08H/C09H) HSC0WE (C0AH/C0BH) HSC0IE (C0CH/C0DH) HSC0IR (C0EH/C0FH) HSC0TD (C10H/C11H) HSC0RD (C12H/C13H) HSC0TS (C14H/C15H) HSC0RS (C16H/C17H)	HSC1MD (C20H/C21H) HSC1CT (C22H/C23H) HSC1ST (C24H/C25H) HSC1CR (C26H/C27H) HSC1IS (C28H/C29H) HSC1WE (C2AH/C2BH) HSC1IE (C2CH/C2DH) HSC1IR (C2EH/C2FH) HSC1TD (C30H/C31H) HSC1RD (C32H/C33H) HSC1TS (C34H/C35H) HSC1RS (C36H/C37H)

3.12.1 Block diagram

The block diagram of each channel is shown in the figure 3.12.1 and figure 3.12.2.

Note) By Reset, HCLK0, HSSO0, HSSI0 pin are set to input port (PortD0, D1, D2) so that pull-up resister is needed.

Figure 3.12.1 HSC0 Block diagram

Note) By Reset, HCLK1, HSSO1, HSSI1 pin are set to input port (PortL4, L5, L6) so that pull-up resistor is needed.

Figure 3.12.2 HSC1 Block diagram

3.12.2 SFR

SFR is explained below. These are connected to CPU with 16bit data bus.

(1) Mode setting register

Register is for operation mode or clock etc.

HSC0MD Register

HSC0MD
(0C00H)

Figure 3.12.4 HSC1MD Register

(a) <LOOPBACK0>

Because Internal HSSO0 can be input to internal HSSI0, it can be used as test.
Please change the setting when transmitting/receiving is not in operation.

Figure 3.12.5 <LOOPBACK0> Register Function

(b) <MSB1ST0>

Select the start bit of transmit/receive data
Please change the setting when transmitting/receiving is not in operation.

(c) <DOSTAT0>

Set the status of HSSO0 pin during no transmitting (after transmitting or during receiving).
Please change the setting when transmitting/receiving is not in operation.

(d) <TCPOL0>

Select the edge of synchronous clock during transmitting.
Please change the setting during <XEN0> = "0". And set the same value of <RCPOL0>.

Figure 3.122.6 <TCPOL0> Register function

(e) <RCPOL0>

Select the edge of synchronous clock during receiving.
Please change the setting during <XEN0> = "0". And set the same value of <TCPOL0>.

Figure 3.12.7 <TCPOL0> Register function

(f) <TDINV0>

Select logical invert/no invert when output transmitted data from HSSO0 pin.

Please change the setting when transmitting/receiving is not in operation.

Data that input to CRC calculation circuit is transmission data that is written to HSC0TD.

This input data is not corresponded to <TDINV0>.

<TDINV0> is not corresponded to <DOSTAT0>: it set condition of HSSO0 pin when it is not transferred.

(g) <RDINV0>

Select logical invert/no invert for received data from HSSI0 pin.

Please change the setting when transmitting/receiving is not in operation.

Data that input to CRC calculation circuit is selected by <RDINV0>.

(h) <XEN0>

Select the operation for the internal clock.

(i) <CLKSEL02:00>

Select baud rate. Baud rate is created from f_{SYS} and settings are in under table.

Please change the setting when transmitting/receiving is not in operation.

Table 3.12.2 Example of baud rate

<CLKSEL02:00>	Baud rate [Mbps]		
	$f_{SYS}=12\text{MHz}$	$f_{SYS}=16\text{MHz}$	$f_{SYS}=20\text{MHz}$
$f_{SYS}/2$	6	8	10
$f_{SYS}/4$	3	4	5
$f_{SYS}/8$	1.5	2	2.5
$f_{SYS}/16$	0.75	1	1.25
$f_{SYS}/32$	0.375	0.5	0.625
$f_{SYS}/64$	0.1875	0.25	0.3125

(2) Control Register

Register is for data length or CRC etc.

HSC0CT Register

HSC0CT (0C02H)		7	6	5	4	3	2	1	0
	bit Symbol	–	–	UNIT160			ALGNEN0	RXWEN0	RXUEN0

Figure 3.12.9 HSC1CT Register

(a) <CRC16_7_B0>

Select CRC7 or CRC16 to calculate.

(b) <CRCRX_TX_B0>

Select input data to CRC calculation circuit.

(c) <CRCRESET_B0>

Initialize CRC calculate register.

The process that calculating CRC16 of transmits data and sending CRC next to transmit data is explained as follows.

1. Set HSC0CT<CRC16_7_B0> for select CRC7 or CRC16 and <CRCRX_TX_B0> for select calculating data.
2. For reset HSC0CR register, write "1" after set <CRCRESET_B0> to "0".
3. Write transmit data to HSC0TD register, and wait for finish transmission all data.
4. Read HSC0CR register, and obtain the result of CRC calculation.
5. Transmit CRC which is obtained in (4) by the same way as (3).

CRC calculation of receive data is the same process.

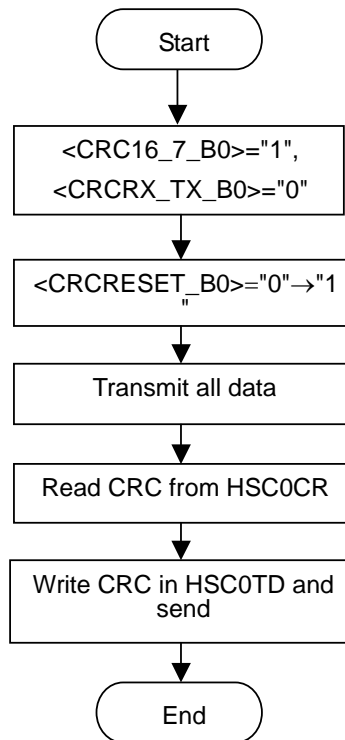

Figure 3.12.10 Flow chart of CRC calculation

(d) <DMAERFW0>

Set clearing interrupt in CPU to unnecessary because be supported RFW0 interrupt to Micro DMA. If write "1" to, it be set to one-shot interrupt, clearing interrupt by HSC0WE register become to unnecessary. HSC0ST<RFW0> flag generate 1-shot interrupt when change from "0" to "1"(Rising).

(e) <DMAERFR0>

Set clearing interrupt in CPU to unnecessary because be supported RFR0 interrupt to Micro DMA. If write "1" to, it be set to one-shot interrupt, clearing interrupt by HSC0WE register become to unnecessary. HSC0ST<RFR0> flag generate 1-shot interrupt when change from "0" to "1"(Rising).

www.DataSheet4U.com

(f) <UNIT160>

Select the length of transmit/receive data. Data length is described as UNIT downward. Please change the setting when transmitting/receiving is not in operation.

(g) <ALGNEN0>

Select whether using alignment function for transmit/receive per UNIT during full duplex.

Please change the setting when transmitting/receiving is not in operation.

(h) <RXWEN0>

Set enable/disable of sequential receiving.

(i) <RXUEN0>

Set enable/disable of receiving operation per UNIT. In case <RXWEN0> = "1", this bit is not valid.

Please change the setting when transmitting/receiving is not in operation.

[Transmit / receive operation mode]

It is supported 6 operation modes. They are selected in <ALGNEN0>, <RXWEN0> and <RXUEN0> registers.

Table 3.12.3 transmit/receive operation mode

Operation mode	Register setting			Note
	<ALGNEN0>	<RXWEN0>	<RXUEN0>	
(1) Transmit UNIT	0	0	0	Transmit written data per UNIT
(2) Sequential transmit	0	0	0	Transmit written data sequentially
(3) Receive UNIT	0	0	1	Receive data of only 1 UNIT
(4) Sequential receive	0	1	0	Receive automatically if buffer has space
(5) Transmit/Receive UNIT with alignment	1	0	1	Transmit/receive 1 UNIT with alignment per each UNIT
(6) Sequential Transmit/Receive UNIT with alignment	1	1	0	Transmit/receive sequentially with alignment per each UNIT

Difference between UNIT transmission and Sequential transmission

UNIT transmit mode is transmitted every 1 UNIT by writing data after confirmed $HSC0ST<TEND0>=1$. The written transmission data is shifted in turn. In hardware, transmission is kept executing as long as data exists. If it transmit data sequentially, write next data when HSC0TD is empty and $HSC0ST<RFD0>=1$.

UNIT transmission and sequential transmission depend on the way of using. Hardware doesn't depend on.

Figure 3.12.11 show Flow chart of UNIT transmission and Sequential transmission.

Figure 3.12.11 Flow chart of UNIT transmission and Sequential transmission

Difference between UNIT receive and Sequential receive

UNIT receive is the mode that receiving only 1 UNIT data.

By writing "1" to HSC0CT<RXUEN0>, receives 1UNIT data, and received data is loaded in receive data register (HSC0RD). When HSC0RD register is read, read it after wrote "0" to HSC0CT<RXUEN0>.

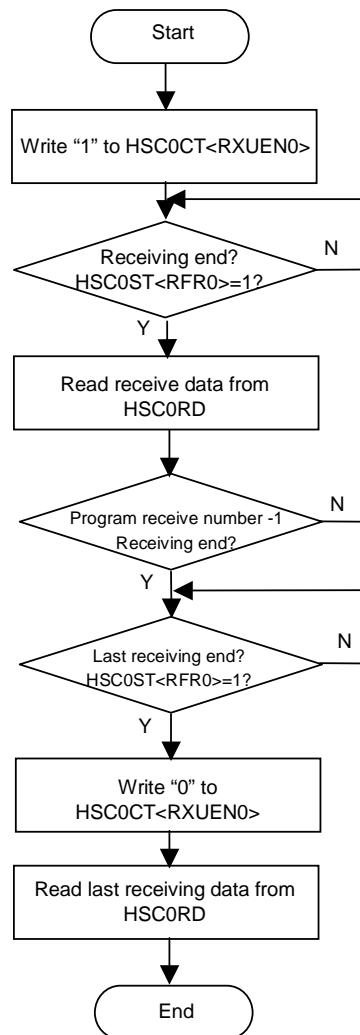

If data was read from HSC0RD with the condition HSC0CT<RXE0>= "1", 1 UNIT data is received again automatically. In hardware, this mode receives sequentially by Single buffer.

HSC0ST<REND0> is changed during UNIT receiving.

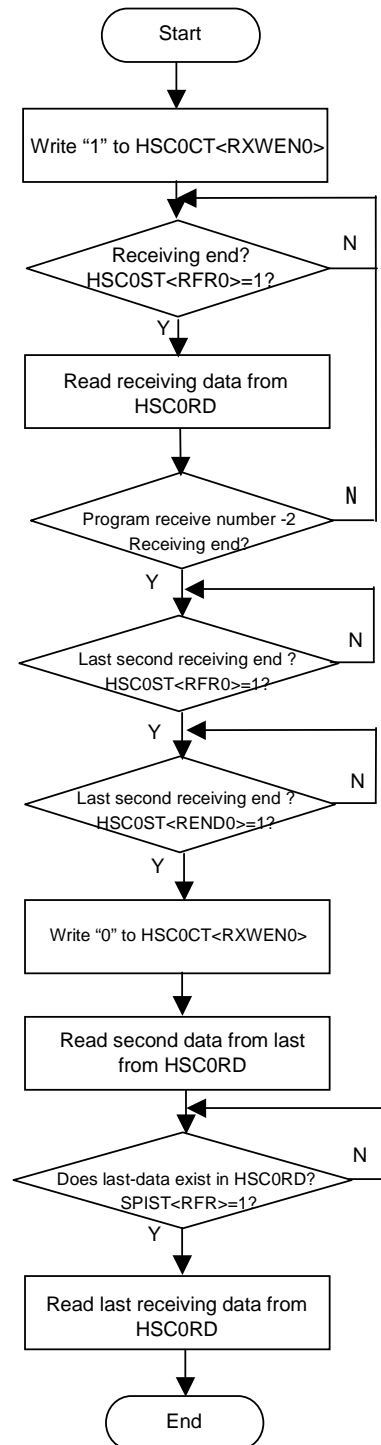

Sequential receive is the mode that receive data and automatically when receive FIFO has space.

Whenever buffer has space, next data is received automatically. Therefore, if data was read after data is loaded in HSC0RD, it is received sequentially every UNIT. In hardware, this mode receives sequentially by double buffer.

Figure 3.12.12 show Flow chart of UNIT receive and Sequential receive.

UNIT receive

Sequential receive

Figure 3.12.12 Flow chart of UNIT receive and Sequential receive

(3) Interrupt , Status register

Read of condition, Mask of condition, Clear interrupt and Clear enable can control each 4 interrupts; RFR0(HSC0RD receiving buffer is full), RFW0(HSC0TD transmission buffer is empty), REND0(HSC0RS receiving buffer is full), TEND0(HSC0TS transmission buffer is empty).

RFR0, RFW0 can high-speed transaction by micro DMA.

Following is description of Interrupt · status (example RFW0).

Status register HSC0ST<RFW0> show RFW0 (internal signal that show whether transmission data register exist or not). This register is “0” when transmission data exist. This register is “1” when transmission data doesn’t exist. It can read internal signal directly. Therefore, it can confirm transmission data at any time.

Interrupt status register HSC0IS<RFWIS0> is set by rising edge of RFW0. This register keeps that condition until write “1” to this register and reset when HSC0WE<RFWWE0> is “1”.

RFW0 interrupt generate when interrupt enable register HSC0IE<RFWIE0> is “1”. When it is “0”, interrupt is not generated.

Interrupt request register HSC0IR<RFWIR0> show whether interrupt is generating or not.

Interrupt status write enable register HSC0WE<RFWWE0> set that enables reset for reset interrupts status register by mistake.

Circuit config of transmission data shift register (HSC0TS), receiving register (HSC0RD), receiving data shift register (HSC0RS) are same with above register.

Control register HSC0CT<DMAERFW0>, HSC0CT<DMAERFR0> is register for using micro DMA. When micro DMA transfer is executed by using RFW0 interrupt, set “1” to <DMAERFW0>, and when it is executed by using RFR0 interrupt, set “1” to <DMAERFR0>, and prohibit other interrupt.

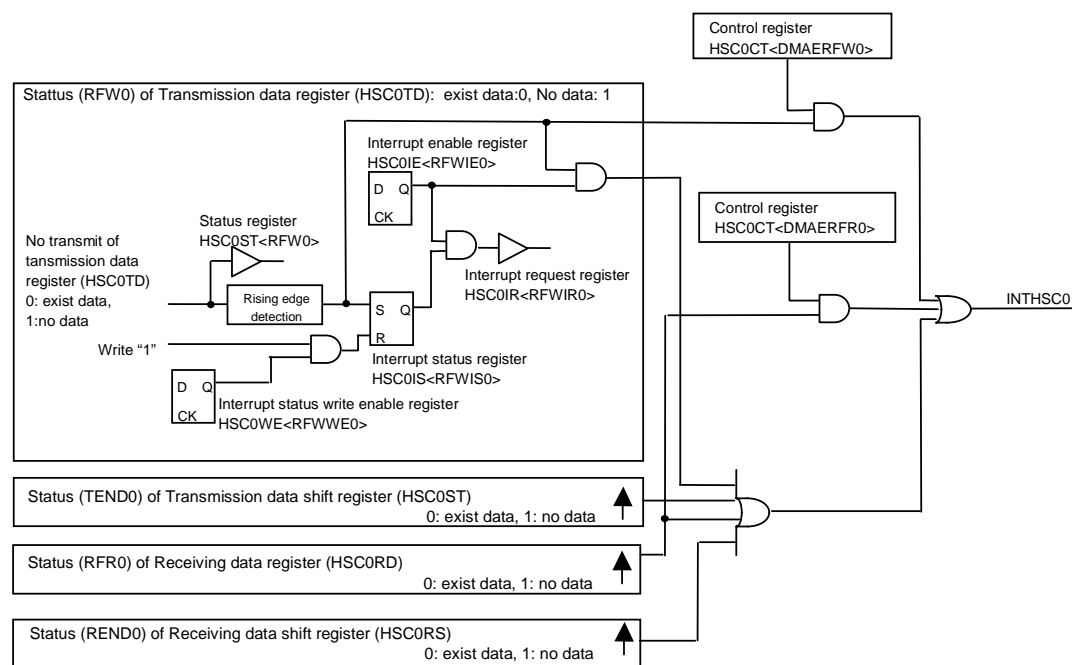

Figure 3.12.2 Figurer for interrupt, status

(3-1) Status register

Register shows 4 status.

HSC0ST Register								
	7	6	5	4	3	2	1	0
HSC0ST (0C04H)	bit Symbol				TEND0	REND0	RFW0	RFR0

	Function							

Figure 3.12.4 HSC1ST Register

(a) <TEND0>

This bit is set to “0” when valid data to transmit exists in the shift register for transmit. It is set to “1” when finish transmitting all the data.

(b) <REND0>

This bit is set to “0” when receiving is in operation or no valid data exist in receive shift register.

It is set to “1”, when valid data exist in receive read register and keep the data without shifting.

It is cleared to “0”, when CPU read the data and shift to receive read register.

(c) <RFW0>

After wrote the received data to receive data write register, shift the data to receive data shift register. It keeps “0” until all valid data has moved. And it is set to “1” when it can accept the next data with no valid data.

(d) <RFR0>

This bit is set to “1” when received data is shifted from received data shift register to received data read register and valid data exist. It is set to “0” when the data is read and no valid data.

(3-2) Interrupt status register

Register read 4 interrupt status and clear interrupt.

This register is cleared to “0” by writing “1” to applicable bit. Status of this register show interrupt source state. This register can confirm changing of interrupt condition, even if interrupt enable register is masked.

Figure 3.12.27 HSC1CR register

(a) <CRCD015:000>

The result that is calculated according to the setting: HSC0CT<CRC16_7_b0>, <CRCRX_TX_B0> and <CRCRESET_B0>, are loaded in this register.

In case CRC16, all bits are valid. In case CRC7, lower 7 bits are valid.

The flow will be showed to calculate CRC16 of received data for instance by flowchart.

Firstly, initialize CRC calculation register by writing <CRCRESET_B0> = "1" after set <CRC16_7_b0> = "1", <CRCRX_TX_B0> = "0", <CRCRESET_B0> = "0".

Next, finish transmitting all bits to calculate CRC by writing data in HSC0TD register.

Confirming whether receiving is finished or not use HSC0ST<TEND0>.

If HSC0CR register was read after finish, CRC16 of transmission data can read.

(5) Transmission data register

Register is register for write transmission data.

Figure 3.12.35 HSC1RS Register

(a) <RSD015:000>

This register is register for reading the status of receives data shift register.

In case HSC0CT<UNIT160>= "1", all bits are valid.

In case HSC0CT<UNIT160>="0", lower 7 bits are valid.

3.12.3 Operation timing

Following examples show operation timing.

- Setting condition 1:

Transmission in UNIT=8bit, LSB first

Figure 3.12.36 Transmission timing

In above condition, HSC0ST<RFW0> flag is set to “0” just after wrote transmission data. When data of HSC0TD register finish shifting to transmission register (HSC0TS), HSC0ST<RFW0> is set to “1”, it is informed that can write next transmission data, start transmission clock and data from HCLK0 pin and HSS00 pin at same time with inform.

In this case, HSC0IS, HSC0IR change and INTHSC0 interrupt generate by synchronization to rising of HSC0ST<RFW0> flag. When HSC0IR register is setting to “1”, interrupt is not generated even if HSC0ST<RFW0> was set to “1”.

When finish transmission and lose data that must to transmit to HSC0TD register and HSC0TS register, transmission data and clock are stopped by setting “1” to HSC0ST<TEND0>, and INTHSC0 interrupt is generated at same time. In this case, if HSC0ST<TEND0> is set to “1” at different interrupt source, INTHSC0 is not generated. Therefore must to clear HSC0IS<RFW0> to “0”.

- Setting condition 2:

UNIT transmission in UNIT=8bit, LSB first

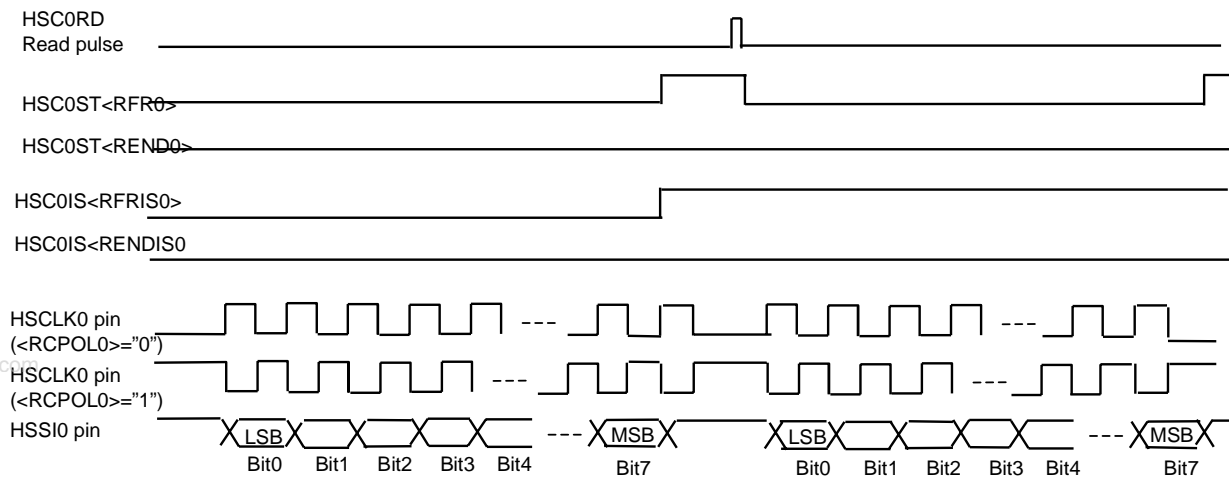

Figure 3.12.37 UNIT receiving (HSC0CT<RXUEN0>=1)

If set HSC0CT<RXUEN0> to “1” without valid receiving data to HSC0RD register (HSC0ST<RFR0>=0), UNIT receiving is started. When receiving is finished and stored receiving data to HSC0RD register, HSC0ST<RFR0> flag is set to “1”, and inform that can read receiving data. Just after read HSC0RD register, HSC0ST<RFR0> flag is cleared to “0” and it start receiving next data automatically.

If be finished UNIT receiving, set HSC0CT<RXUEN0> to “0” after confirmed that HSC0ST<RFR0> was set to “1”.

- Setting condition 3:
Sequential receiving in UNIT=8 bit, LSB first

Figure 3.12.38 continuous receiving (HSC0CT<RXWEN0>=1)

If set HSC0CT<RXWEN0> to “1” without valid receiving data in HSC0RD register (HSC0ST<RFR0>=0), sequential receiving is started. When first receiving is finished and stored receiving data to HSC0RD register, HSC0ST<RFR0> flag is set to “1”, and inform that can read receiving data. Sequential receiving is received until receiving data is stored to HSC0RD and HSC0RS registers. If finished sequential receiving, set HSC0CT<RXWEN0> to “0” after confirmed that HSC0ST<REND0> was set to “1”.

- Setting condition 4:

Transmission by using micro DMA in UNIT=8bit, LSB first

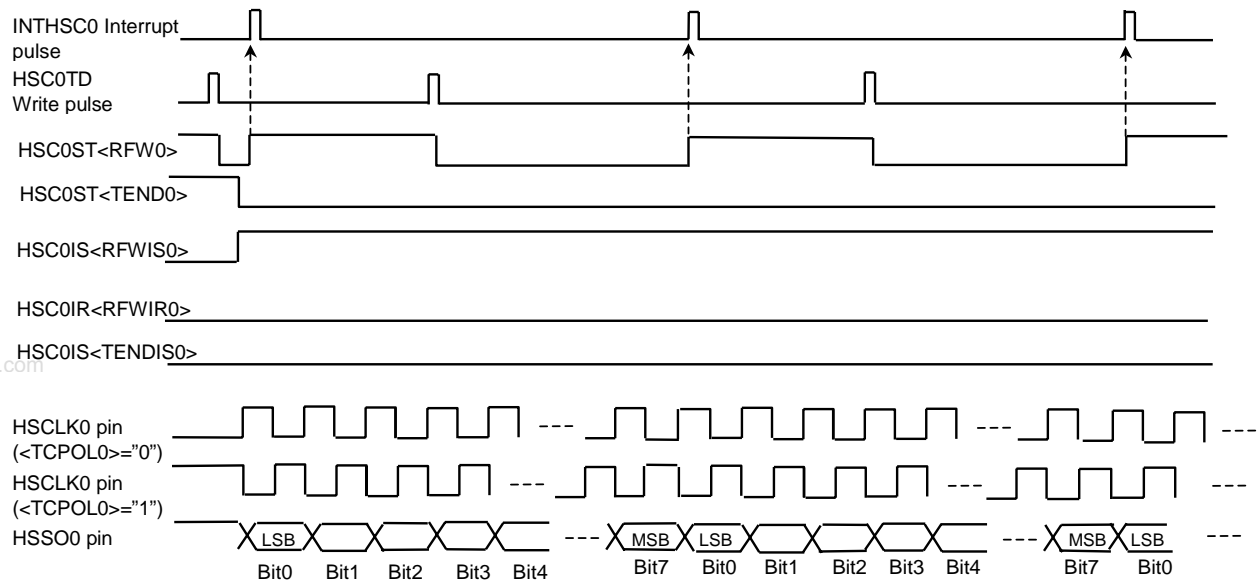

Figure 3.12.39 Micro DMA transmission (transmission)

If all bits of HSC0IE register are “0” and HSC0CT<DMAERFW0> is “1”, transmission is started by writing transmission data to HSC0TD register.

If data of HSC0TD register is shifted to HSC0TS register and HSC0ST<RFW0> is set to “1” and can write next transmission data, INTHSC0 interrupt (RFW0 interrupt) is generated. By starting Micro DMA at this interrupt, can transmit sequential data automatically.

However, If transmit it at Micro DMA, set Micro DMA beforehand.

- Setting condition 5:
Receiving by using micro DMA in UNIT=8bit, LSB first

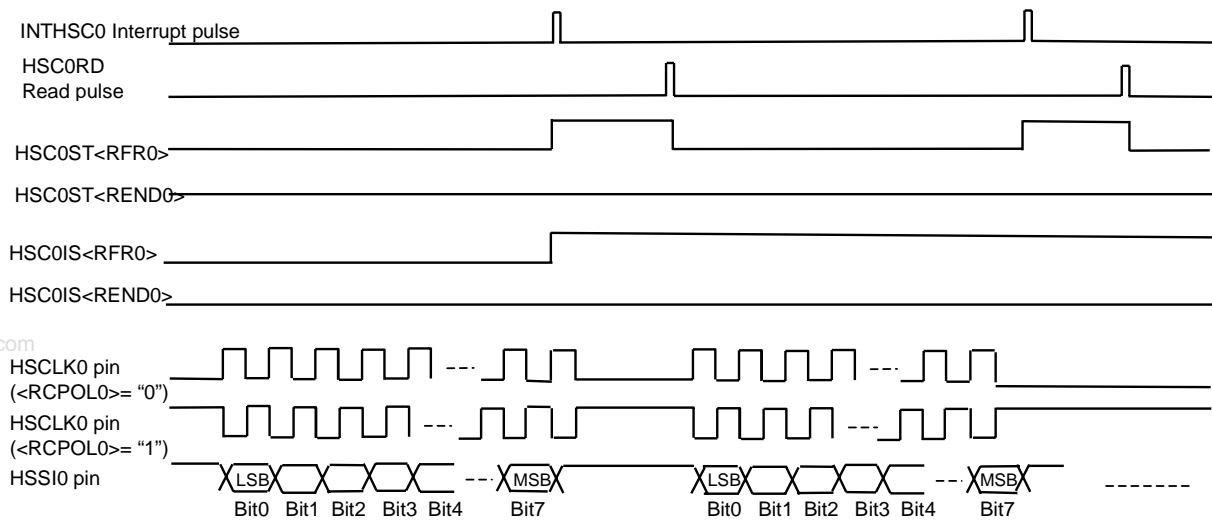

Figure 3.12.40 Micro DMA transmission (UNIT receiving (HSC0CT<RFUEN0>=1))

If all bits of HSC0IE register is "0" and HSC0CT<DMAERFR0> is "1", UNIT receiving is started by setting HSC0CT<RXUEN0> to "1". If receiving data is stored to HSC0RD register and can read receiving data, INTHSC0 interrupt (RFR0 interrupt) is generated. By starting Micro DMA at this interrupt, it can be received sequential data automatically.

However, If receive it at Micro DMA, set Micro DMA beforehand.

3.12.4 Example

Following is discription of HSC0 setting method.

(1) UNIT transmission

This example show case of transmission is executed by following setting, and it is generated INTTHSC0 interrupt by finish transmission.

UNIT: 8bit

LSB first

Baud rate : $f_{SYS}/8$

Synchronous clock edge: Rising

Setting expample

```
ld  (pdfc), 0x07      ; Port setting PD0: HSSI0, PD1: HSSO0, PK7: HSCLK0
ld  (pdcr), 0x06      ; port setting PD0: HSSI0, PD1: HSSO0, PK7: HSCLK0

ldw (hsc0ct), 0x0040   ; Set data length to 8bit
ldw (hsc0md), 0x2c43   ; System clock enable, baud rate selection:  $f_{SYS}/8$ 
                        ; LSB first, synchronous clock edge setting: set to Rising

ld  (hsc0ie), 0x08     ; Set to TEND0 interrupt enable
ld  (inteahsc0), 0x10  ; Set INTTHSC0 interrupt level to 1
ei                                     ; Interrupt enable (iff=0)

loop                                ; Confirm that transmission data register doesn't have no transmission data
bit  1, (hsc0st)        ; <RFW0>=1 ?
jr   z, loop

ld  (hsc0td), 0x3a     ; Write Transmission data and Start transmission
.
.
.
```

Figure 3.12.41 Example of UNIT transmission

(2) UNIT receiving

This example show case of receiving is executed by following setting, and it is generated INTHSC0 interrupt by finish receiving.

UNIT: 8bit

LSB first

Baud rate selection : $f_{SYS}/8$

Synchronous clock edge: Rising

Setting example

```
ld  (pdfc),0x07          ; Port setting PD0:HSSI0, PD1:HSSO0, PK7:HSCLK0
ld  (pdcr),0x06          ; Port setting PD0:HSSI0, PD1:HSSO0, PK7:HSCLK0

ldw (hsc0ct),0x0040      ; Set data length to 8bit
ldw (hsc0md),0x2c43      ; System clock enable, baud rate selection : fSYS/8
                          ; LSB first, synchronous clock edge setting: set to Rising

ld  (hsc0ie),0x01        ; Set to RFR0 interrupt enable
ld  (inteahsc0),0x10     ; Set INTHSC0 interrupt level to 1
ei                                ; Interrupt enable (iff=0)

set  0x0,(hsc0ct)        ; Start UNIT receiving
.
.
.
```

Figure 3.12.42 Example of UNIT receiving

(3) Sequential transmission

This example show case of transmission is executed by following setting, and it is executed 2byte sequential transmission.

UNIT: 8bit

LSB first

Baud rate selection: $f_{SYS}/8$

Synchronous clock edge: Rising

Setting example

```
ld  (pdfc),0x07          ; Port setting PD0:HSSI0, PD1:HSSO0, PK7:HSCLK0
```

```
ld  (pdcr),0x06          ; Port setting PD0:HSSI0, PD1:HSSO0, PK7:HSCLK0
```

```
ldw  (hsc0ct),0x0040      ; Set data length to 8bit
```

```
ldw  (hsc0md),0x2c43      ; System clock enable, baud rate selection:  $f_{SYS}/8$   
; LSB first, synchronous clock edge setting: set to Rising
```

```
loop1:                          ; Confirm that transmission data register doesn't have no transmission data
```

```
bit  1,(hsc0st)            ; <RFW0>=1 ?
```

```
jr   z,loop1
```

```
ld  (hsc0td),0x3a          ; Write transmission data of first byte and start transmission
```

```
loop2                          ; Confirm that transmission data register doesn't have no-transmission data
```

```
bit  1,(hsc0st)            ; <RFW0>=1 ?
```

```
jr   z,loop2
```

```
ld  (hsc0td),0x55          ; Write transmission data of second byte
```

```
loop3:                          ; Confirm that transmission data register doesn't have no-transmission data
```

```
bit  3,(hsc0st)            ; <TEND0>=1 ?
```

```
jr   z,loop3
```

```
.
```

```
; Finish transmission
```

```
.
```

HSC0TD
Write pulse

HSSO0 output

INTHSC0 (RFW0)
Interrupt signal

Note: Timing of this figure is an example. There is also that transmission interbal between first byte and sescond byte generate.
(High baud rate etc.)

Figure 3.12.43 Example of sequential transmission

(4) Sequential receiving

This example show case of receiving is executed by following setting, and it is executed 2byte sequential receiving.

UNIT: 8bit

LSB first

Baud rate selection: $f_{SYS}/8$

Synchronous clock edge: Rising

Setting example

```
ld  (pdfc),0x07          ; Port setting PD0:HSSI0, PD1:HSSO0, PD2:HSCLK0
```

```
ld  (pdcr),0x06          ; Port setting PD0:HSSI0, PD1:HSSO0, PD2:HSCLK0
```

```
ldw  (hsc0ct),0x0040      ; Set data length to 8bit
```

```
ldw  (hsc0md),0x2c43      ; System clock enable, baud rate selection:  $f_{SYS}/8$ 
```

```
                                ; LSB first, synchronous clock edge setting: set to Rising
```

```
set  0x01,(hsc0ct)        ; Start sequential receiving
```

```
loop1:                          ; Confirm that receiving data register has receiving data of first byte
```

```
    bit  0,(hsc0st)        ; <RFR0>=1 ?
```

```
    jr   z,loop1
```

```
loop2:                          ; Confirm that receiving data register has receiving data of second byte
```

```
    bit  2,(hsc0st)        ; <REND0>=1 ?
```

```
    jr   z,loop2
```

```
res  0x01,(hsc0ct)        ; Sequential receiving disable
```

```
ld  a,(hsc0rd)            ; Read receiving data of first byte
```

```
loop3:                          ; Confirm that receiving data of second byte is shifted from receiving data  
                                ; shift register to receiving data register
```

```
    bit  0,(hsc0st)        ; <RFR0>=1 ?
```

```
    jr   z,loop3
```

```
ld  w,(hsc0rd)            ; Read receiving data of second byte
```

Figure 3.12.44 Example of sequential receiving

(5) Sequential Transmission by using micro DMA

This example show case of sequential transmission of 4byte is executed at using micro DMA by following setting.

UNIT: 8bit

LSB first

Baud rate : $f_{SYS}/8$

Synchronous clock edge: Rising

Setting example

Main routine

-- micro DMA setting --

```
ld  (dma0v),0x25          ; Set micro DMA0 to INTHSC0
ld  wa,0x0003             ; Set number of micro DMA transmission to that number -1 (third time)

3.13 SDRAM Controller (SDRAMC)

TMP92CM27 includes SDRAM controller which supports SDRAM access by CPU.

The features are as follows.

(1) Support SDRAM

Data rate type:	Only SDR (Single data rate) type
Bulk of memory:	16/64 Mbits
Number of banks:	2/4 banks
Width of data bus:	16 bit
Read burst length:	1 word/full page
Write mode:	Single/burst

(2) Support Initialize sequence command

All banks precharge command
8 times auto refresh command
Mode Register setting command

(3) Access mode

	CPU Access
Read burst length	1 word/full page
Addressing mode	Sequential
CAS latency (clock)	2
Write mode	Single/burst

(4) Access cycle

CPU Access (Read/write)

Read cycle:	1 word – 4 states/full page – 1 state
Write cycle:	Single – 3 states/burst – 1 state
Data size:	8 bits/16 bits/32 bits

(5) Refresh cycle auto generate

- Auto refresh is generated during except SDRAM access.
- Refresh interval is programmable.
- Self refresh is supported

Note 1: Condition of SDRAM's area set by CS3 setting of memory controller.

3.13.1 Control Registers

Figure 3.13.1 shows the SDRAMC control registers. Setting these registers controls the operation of SDRAMC.

SDRAM Access Control Register 1

SDACR1 (0250H)		7	6	5	4	3	2	1	0
	Bit symbol	–	–	SMRD	SWRC	SBST	SBL1	SBL0	SMAC

Note 1: <SCMM2:0> is cleared to "000" after a command is executed. But <SCMM2:0> is not cleared by executing the self refresh Entry command. It is cleared by executing the self refresh Exit command.

Note 2: When command except the self refresh Exit command is executed, write command after checking that <SCMM2:0> are "000".

Figure 3.13.1 SDRAM Control Registers

3.13.2 Operation Description

(1) Memory access control

Access controller is enabled when $\overline{\text{SDACR1}}\langle\text{SMAC}\rangle = 1$. And then SDRAM control signals ($\overline{\text{SDCS}}$, $\overline{\text{SDRAS}}$, $\overline{\text{SDCAS}}$, $\overline{\text{SDWE}}$, $\overline{\text{SDLLDQM}}$, $\overline{\text{SDLUDQM}}$, $\overline{\text{SDCLK}}$ and $\overline{\text{SDCKE}}$) are operating during the time CPU accesses CS3 area.

In the access cycle, outputs row/column multiplex address through A0 to A15 pin. And multiplex width is decided by setting $\overline{\text{SDACR2}}\langle\text{SMUXW0:1}\rangle$. The relation between multiplex width and row/column address is shown in Table.

Table 3.13.1 Address Multiplex

TMP92CM27 Pin Name	Address of SDRAM Access Cycle				
	Row Address			Column Address	
	TypeA $\langle\text{SMUXW}\rangle = "00"$	TypeB $\langle\text{SMUXW}\rangle = "01"$	TypeC $\langle\text{SMUXW}\rangle = "10"$	16-Bit Data Bus Width $\text{B1CSH}\langle\text{BnBUS}\rangle = "01"$	32-Bit Data Bus Width $\text{B1CSH}\langle\text{BnBUS}\rangle = "10"$
A0	A9	A10	A11	A1	A2
A1	A10	A11	A12	A2	A3
A2	A11	A12	A13	A3	A4
A3	A12	A13	A14	A4	A5
A4	A13	A14	A15	A5	A6
A5	A14	A15	A16	A6	A7
A6	A15	A16	A17	A7	A8
A7	A16	A17	A18	A8	A9
A8	A17	A18	A19	A9	A10
A9	A18	A19	A20	A10	A11
A10	A19	A20	A21	AP	AP
A11	A20	A21	A22	Row address	
A12	A21	A22	A23		
A13	A22	A23	EA24		
A14	A23	EA24	EA25		
A15	EA24	EA25	EA26		

Burst length of SDRAM read/write by CPU can be select by setting $\overline{\text{SDACR1}}\langle\text{SBL1:0}\rangle$.

SDRAM access cycle is shown in Table 3.13.2 and Table 3.13.3.

SDRAM access cycle number is not depending on B3CSL registers setting.

In the full page burst read/write cycle, a mode register set cycle and a precharge cycle are inserted automatically to cycle front and back.

(2) Instruction executing on SDRAM

CPU can be executed instructions that are asserted to SDRAM. However, below function is not operated.

- Executing HALT instruction
- Executing instructions that write to SDCMM register

When the above mentioned is operated, it is necessary to execute it by another memory such as built-in RAM.

Figure 3.13.2 Timing of Burst Read Cycle

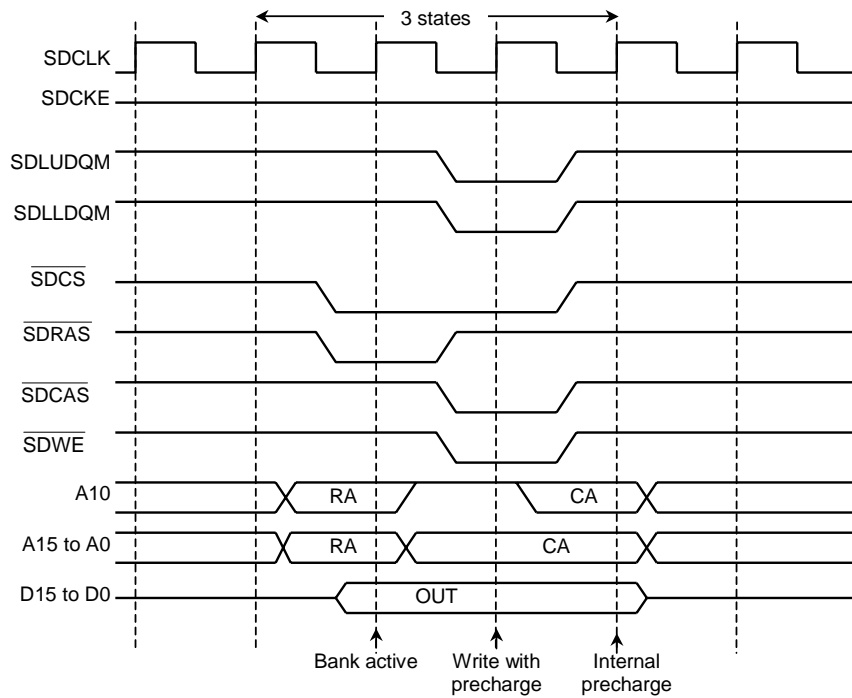

Figure 3.13.3 Timing of CPU Write Cycle

(Structure of Data Bus: 16 bits × 1, operand Size: 2 bytes, address: 2n + 0)

(3) Refresh control

This LSI supports two refresh commands of auto refresh and self refresh.

(a) Auto refresh

The auto refresh command is generated intervals that set to $\text{SDRCR}\langle\text{SRS2:0}\rangle$ automatically by setting $\text{SDRCR}\langle\text{SRC}\rangle$ to "1". The generation interval can be set between 47 to 312 states ($2.4\ \mu\text{s}$ to $15.6\ \mu\text{s}$ at $f_{\text{SYS}} = 20\ \text{MHz}$).

CPU operation (instruction fetch and execution) stops while performing the auto refresh command. The auto refresh cycle is shown in Figure 3.13.4 and the auto refresh generation interval is shown in Table 3.13.2. Auto self refresh doesn't operate at IDLE1 mode and STOP mode. It can be used only with CPU operation NORMAL mode or IDLE2 mode.

Figure 3.13.4 Timing of Auto Refresh Cycle

Table 3.13.2 Refresh Cycle Insertion Interval

(Unit: μs)

$\text{SDRCR}\langle\text{SRS2:0}\rangle$			Insertion Interval (State)	f_{SYS} Frequency (System clock)					
SRS2	SRS1	SRS0		6 MHz	10 MHz	12.5 MHz	15 MHz	17.5 MHz	20 MHz
0	0	0	47	7.8	4.7	3.8	3.1	2.7	2.4
0	0	1	78	13.0	7.8	6.2	5.2	4.5	3.9
0	1	0	97	16.2	9.7	7.8	6.5	5.5	4.9
0	1	1	124	20.7	12.4	9.9	8.3	7.1	6.2
1	0	0	156	26.0	15.6	12.5	10.4	8.9	7.8
1	0	1	195	32.5	19.5	15.6	13.0	11.1	9.8
1	1	0	249	41.5	24.9	19.9	16.6	14.2	12.4
1	1	1	312	52.0	31.2	25.0	20.8	17.8	15.6

(b) Self refresh

The self refresh command is generated by making it to SDCMM<SCMM2:0> to "101". The self refresh cycle is shown in Figure 3.13.5. During self refresh Entry, refresh is performed inside SDRAM (an auto refresh command is not needed).

Note 1: When stand-by mode is cancelled by a reset, the I/O registers are initialized, therefore, auto refresh is not performed.

Note 2: During self refresh Entry, it cannot be accessed to SDRAM.

Note 3: After the self refresh Entry command, shift CPU to IDLE1 or STOP mode. When during setting HALT instruction and SDCMM <SCMM2:0> to "101", execute NOP (more than 10 bytes) or another instructions.

www.DataSheet4U.com

Figure 3.13.5 Timing of Self Refresh Cycle

Self-Refresh condition is released by executing Self-Refresh command. Way to execute Self-Refresh EXIT command is 2 ways: write “110” to SDCMM<SCMM2:0>, or execute EXIT automatically by synchronizing to releasing HALT condition. Both ways, after it executes Auto-Refresh at once just after Self-Refresh EXIT, it executes Auto-Refresh at setting condition. When it became EXIT by writing “110” to <SCMM2:0>, <SCMM2:0> is cleared to “000”.

EXIT command that synchronize to release HALT condition can be prohibited by setting SDRCCR<SSAE> to “0”. If don't set to EXIT automatically, set to prohibit. If using condition of SDRAM is satisfied by operation clock frequency (clock gear down, SLOW mode condition and so on) is falling, set to prohibit. Figure 3.13.6 shows execution flow in this case.

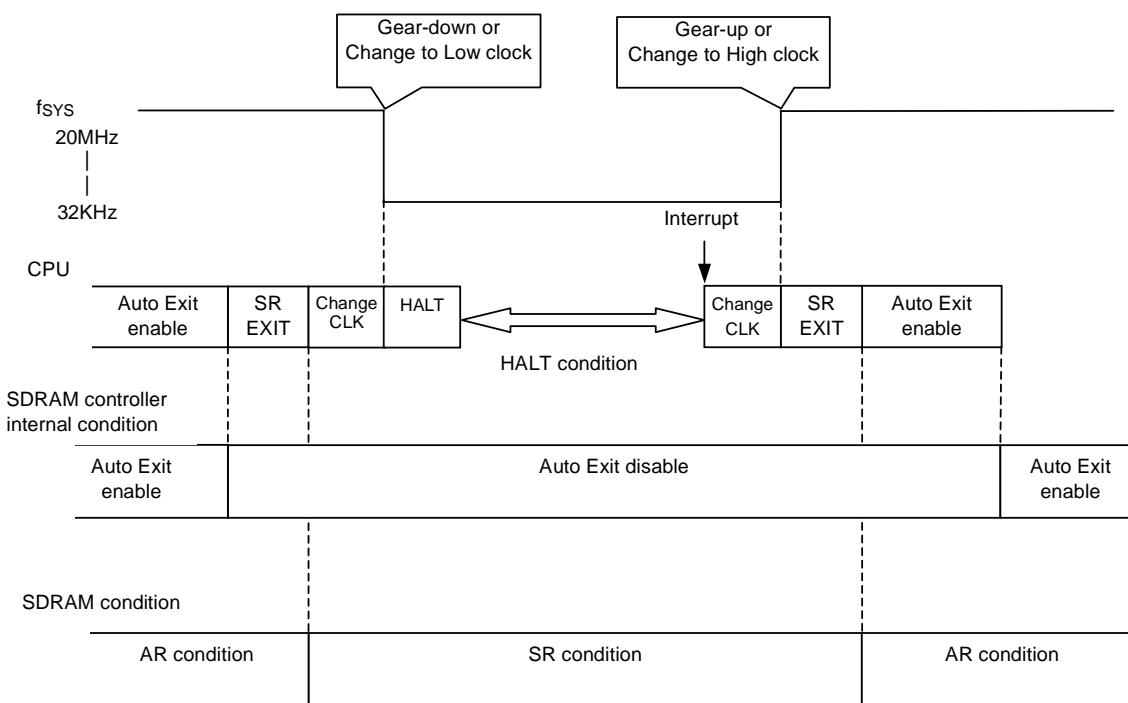

Figure 3.13.6 Execution flow example (Execute HALT instruction at low-speed clock).

; *****Sample program *****

LOOP1:

```
LDB      A, (SDCMM)                ; Check the command register clear
ANDB     A, 00000111B              ;
J        NZ, LOOP1                 ;

LDW      (SDRCR), 0000010100000011B ; Auto Exit disable→ Self refresh Entry

NOP×10                                ; Wait Self refresh Entry command executing
LD       (SYSCR1), XXXXX001B        ; fc/2
HALT
NOP                                ; Self refresh Exit (Internal signal only)

LD       (SYSCR1), XXXXX000B        ; fc
LD       (SDCMM), 00000110B         ; Self refresh Exit (command)
LD       (SDRCR), 0001---1B         ; Auto Exit enable
```

(4) SDRAM initialize

After released reset, it can generate the following cycle that is needed to SDRAM. The cycle is shown in Figure 3.13.7.

1. Precharge all banks
2. The auto refresh cycle of 8 cycles
3. Set a Mode register

The above cycle is generated by setting SDCMM<SCMM2:0> to "001".

While performing this cycle, operation (an instruction fetch, command execution) of CPU is stopped.

In addition, before execute an initialization cycle, set port as SDRAM control signal and an address signal (A0 to A15).

After the initialization cycle was finished, SDCMM<SCMM2:0> is set to "000" automatically.

Figure 3.13.7 Timing of Initialization Cycle

(5) Connection example

The example of connection with SDRAM is shown in Table 3.13.3 and Figure 3.13.8.

Table 3.13.3 Connection with SDRAM

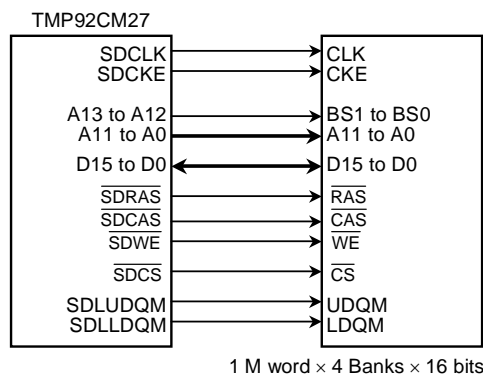

Figure 3.13.8 Connection with SDRAM (4 M word × 16 bits)

3.13.3 Limitation point to use SDRAM

There are some points to notice when using SDRAMC. Please refer to the section under below and please be careful.

1. WAIT access

When it uses SDRAM, some limitation is added if it access to memory except SDRAM. In N-WAIT setting of this LSI, if setting time is inserted as external WAIT, set time less than Auto Refresh cycle (Auto Refresh function that is controlled by SDRAM controller) \times 8190.

2. Execution of SDRAM command before HALT instruction (SR (Self refresh)-Entry, Initialize, Mode-set)

When command that SDRAM controller has (SR-Entry, Initialize and Mode-set) is executed, execution time is needed few states.

Therefore, when HALT instruction is executed after the SDRAM command, please insert NOP more than 10 bytes or other 10 instructions before executing HALT instruction.

3. AR (Auto Refresh) interval time

When using SDRAM, set CPU clock that satisfy minimum operation frequency for SDRAM and minimum refresh cycle.

When SLOW mode is used by using SDRAM or it use system that clock gear may become down, consider AR cycle for SDRAM.

When AR cycle is changed, set to disable by writing "0" to SDRCCR<SRC>.

4. Note of when changing access mode

If changing access mode from "full page read" to "1 word read", execute following program. This program must not execute on the SDRAM.

di		; Interrupt Disable (Added)
ld	a,(optional external memory address)	; Dummy read instruction (Added)
ld	(sdacr1),00001101b	; Change to "1-word read"
ld	(sdcmr),0x04	; Execute MRS (mode register setting)
ei		; Interrupt enable (Added)

3.14 Analog/Digital Converter

The TMP92CM27 incorporates a 10-bit successive approximation-type analog/digital converter (AD converter) with 12-channel analog input.

Figure 3.14.1 is a block diagram of the AD converter. The 12-channel analog input pins (AN0 to AN11) are shared with the input-only port M and port N so they can be used as an input port.

Note: When IDLE2, IDLE1, or STOP mode is selected, as to reduce the power, with some timings the system may enter a standby mode even though the internal comparator is still enabled. Therefore be sure to check that AD converter operations are halted before a HALT instruction is executed.

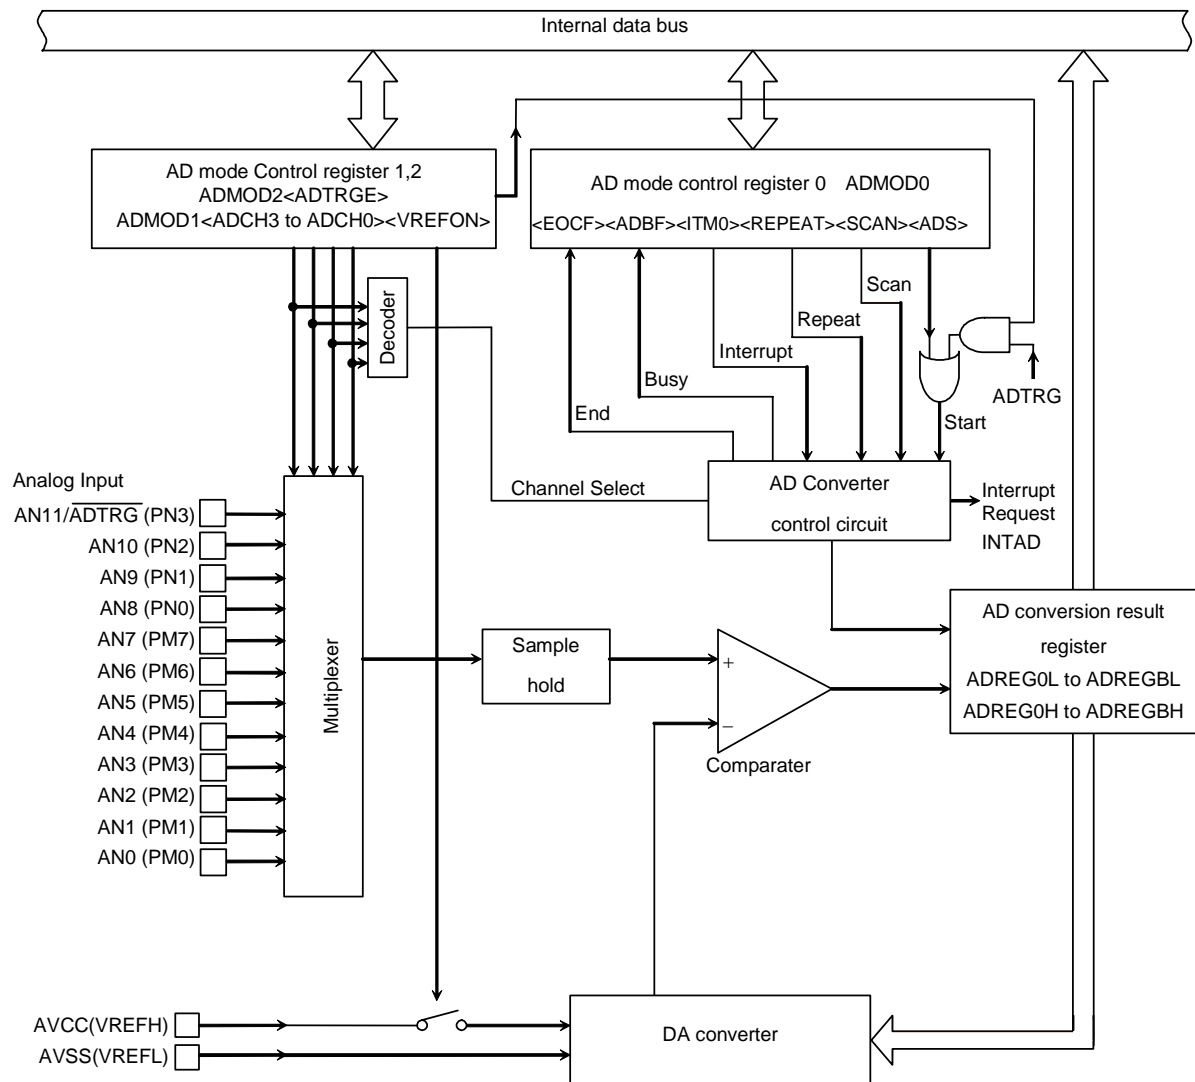

Figure 3.14.1 Block Diagram of AD Converter

3.14.1 Analog/Digital Converter Registers

The AD converter is controlled by the three AD mode control registers: ADMOD0, ADMOD1, and ADMOD2. The 24 AD conversion data result registers (ADREG0H/L to ADREGBH/L) store the results of AD conversion.

Figure 3.14.2 to Figure 3.14.6 shows the registers related to the AD converter.

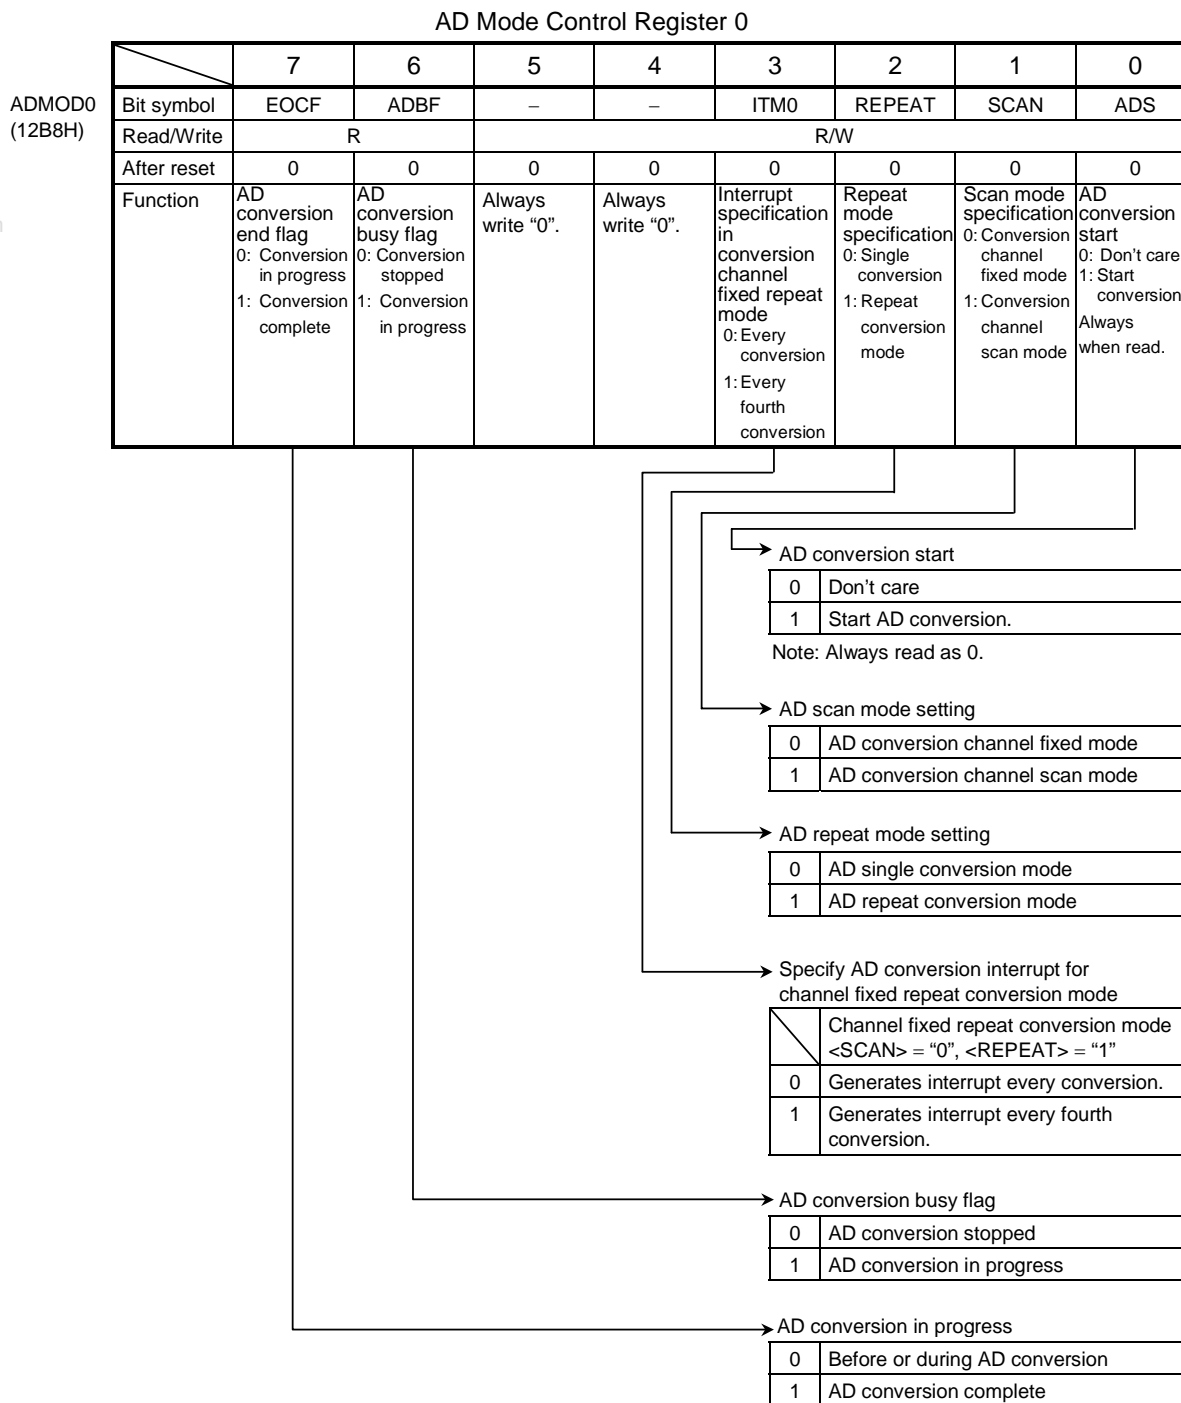

Figure 3.14.2 Register for AD Converter (1)

3.14.2 Description of Operation

(1) Analog reference voltage

A high-level analog reference voltage is applied to the AVCC pin; a low-level analog reference voltage is applied to the AVSS pin. To perform AD conversion, the reference voltage, the difference between AVCC and AVSS, is divided by 1024 using string resistance. The result of the division is then compared with the analog input voltage.

To turn off the switch between AVCC and AVSS, program a 0 to ADMOD1<VREFON> in AD mode control register 1. To start AD conversion in the OFF state, first write a 1 to ADMOD1<VREFON>, wait 3 μ s until the internal reference voltage stabilizes (This is not related to f_c), then set ADMOD0<ADS> to 1.

(2) Analog input channel selection

The analog input channel selection varies depends on the operation mode of the AD converter.

- In analog input channel fixed mode (ADMOD0<SCAN> = "0")
Setting ADMOD1<ADCH3:0> selects one of the input pins AN0 to AN11 as the input channel.
- In analog input channel scan mode (ADMOD0<SCAN> = 1)
Setting ADMOD1<ADCH3:0> selects one of the 12 scan modes.

Table 3.14.1 illustrates analog input channel selection in each operation mode.

On a reset, ADMOD0<SCAN> is cleared to "0" and ADMOD1<ADCH3:0> is initialized to "0000". Thus pin AN0 is selected as the fixed input channel. Pins not used as analog input channels can be used as standard input port pins.

Table 3.14.1 Analog Input Channel Selection

<ADCH3 to 0>	Channel fixed <SCAN> = "0"	Channel scan <SCAN> = "1"
0000	AN0	AN0
0001	AN1	AN0 → AN1
0010	AN2	AN0 → AN1 → AN2
0011	AN3	AN0 → AN1 → AN2 → AN3
0100	AN4	AN0 → AN1 → AN2 → AN3 → AN4
0101	AN5	AN0 → AN1 → AN2 → AN3 → AN4 → AN5
0110	AN6	AN0 → AN1 → AN2 → AN3 → AN4 → AN5 → AN6
0111	AN7	AN0 → AN1 → AN2 → AN3 → AN4 → AN5 → AN6 → AN7
1000	AN8	AN0 → AN1 → AN2 → AN3 → AN4 → AN5 → AN6 → AN7 → AN8
1001	AN9	AN0 → AN1 → AN2 → AN3 → AN4 → AN5 → AN6 → AN7 → AN8 → AN9
1010	AN10	AN0 → AN1 → AN2 → AN3 → AN4 → AN5 → AN6 → AN7 → AN8 → AN9 → AN10
1011	AN11	AN0 → AN1 → AN2 → AN3 → AN4 → AN5 → AN6 → AN7 → AN8 → AN9 → AN10 → AN11

(3) Starting AD conversion

To start AD conversion, program “1” to ADMOD0<ADS> in AD mode control register 0, or ADMOD2<ADTRGE> in AD mode control register 1 and input falling edge on $\overline{\text{ADTRG}}$ pin. When AD conversion starts, the AD conversion busy flag ADMOD0<ADBF> will be set to “1”, indicating that AD conversion is in progress.

(4) AD conversion modes and the AD conversion end interrupt

The four AD conversion modes are:

- Channel fixed single conversion mode
- Channel scan single conversion mode
- Channel fixed repeat conversion mode
- Channel scan repeat conversion mode

The ADMOD0<REPEAT> and ADMOD0<SCAN> settings in AD mode control register 0 determine the AD mode setting.

Completion of AD conversion triggers an INTAD conversion end interrupt request. Also, ADMOD0<EOCF> will be set to “1” to indicate that AD conversion has been completed.

a. Channel fixed single conversion mode

Setting ADMOD0<REPEAT> and ADMOD0<SCAN> to “00” selects conversion channel fixed single conversion mode.

In this mode data on one specified channel is converted once only. When the conversion has been completed, the ADMOD0<EOCF> flag is set to “1”, ADMOD0<ADBF> is cleared to “0”, and an INTAD interrupt request is generated.

b. Channel scan single conversion mode

Setting ADMOD0<REPEAT> and ADMOD0<SCAN> to “01” selects conversion channel scan single conversion mode.

In this mode data on the specified scan channels is converted once only. When scan conversion has been completed, ADMOD0<EOCF> is set to “1”, ADMOD0<ADBF> is cleared to “0”, and an INTAD interrupt request is generated.

c. Channel fixed repeat conversion mode

Setting ADMOD0<REPEAT> and ADMOD0<SCAN> to “10” selects conversion channel fixed repeat conversion mode.

In this mode data on one specified channel is converted repeatedly. When conversion has been completed, ADMOD0<EOCF> is set to “1” and ADMOD0<ADBF> is not cleared to “0” but held at “1”. INTAD interrupt request generation timing is determined by the setting of ADMOD0<ITM0>.

Clearing <ITM0> to “0” generates an interrupt request every time an AD conversion is completed.

Setting <ITM0> to “1” generates an interrupt request on completion of every fourth conversion.

d. Channel scan repeat conversion mode

Setting ADMOD0<REPEAT> and ADMOD0<SCAN> to “11” selects conversion channel scan repeat conversion mode.

In this mode data on the specified scan channels is converted repeatedly. When each scan conversion has been completed, ADMOD0<EOCF> is set to “1” and an INTAD interrupt request is generated. ADMOD0<ADBF> is not cleared to “0” but held at “1”.

To stop conversion in a repeat conversion mode (e.g., in cases c and d), program a “0” to ADMOD0<REPEAT>. After the current conversion has been completed, the repeat conversion mode terminates and ADMOD0<ADBF> is cleared to “0”.

Switching to a halt state (IDLE2 mode with ADMOD1<I2AD> cleared to “0”, IDLE1 mode or STOP mode) immediately stops operation of the AD converter even when AD conversion is still in progress. In repeat conversion modes (e.g., in cases c and d), when the halt is released, conversion restarts from the beginning. In single conversion modes (e.g., in cases a and b), conversion does not restart when the halt is released (The converter remains stopped).

Table 3.14.2 shows the relationship between the AD conversion modes and interrupt requests.

Table 3.14.2 Relationship between the AD Conversion Modes and Interrupt Requests AD

Mode	Interrupt Request Generation	ADMOD0		
		<ITM0>	<REPEAT>	<SCAN>
Channel fixed single conversion mode	After completion of conversion	X	0	0
Channel scan single conversion mode	After completion of scan conversion	X	0	1
Channel fixed repeat conversion mode	Every conversion	0	1	0
	Every forth conversion	1		
Channel scan repeat conversion mode	After completion of every scan conversion	X	1	1

X: Don't care

(5) AD conversion time

99 states ($4.95 \mu\text{s}$ at $f_{\text{sys}} = 20 \text{ MHz}$) are required for the AD conversion of one channel.

(6) Storing and reading the results of AD conversion

The AD conversion data upper and lower registers (ADREG0H/L to ADREGBH/L) store the results of AD conversion. (ADREG0H/L to ADREGBH/L are read-only registers.)

In channel fixed repeat conversion mode, the conversion results are stored successively in registers ADREG0H/L to ADREG3H/L. In other modes the AN0 to AN11 conversion results are stored in ADREG0H/L to ADREGBH/L respectively.

Table 3.14.3 shows the correspondence between the analog input channels and the registers which are used to hold the results of AD conversion.

www.DataSheet4U.com

Table 3.14.3 Correspondence between Analog Input Channel and AD Conversion Result Register

Analog Input Channel (Port G / Port L)	AD Conversion Result Register	
	Conversion Modes Other than at Right	Channel Fixed Repeat Conversion Mode (ADMOD0<ITM0>= "1")
AN0	ADREG0H/L	<pre> graph TD A[ADREG0H/L] --> B[ADREG1H/L] B --> C[ADREG2H/L] C --> D[ADREG3H/L] D --> A </pre>
AN1	ADREG1H/L	
AN2	ADREG2H/L	
AN3	ADREG3H/L	
AN4	ADREG4H/L	
AN5	ADREG5H/L	
AN6	ADREG6H/L	
AN7	ADREG7H/L	
AN8	ADREG8H/L	
AN9	ADREG9H/L	
AN10	ADREGAH/L	
AN11	ADREGBH/L	

<ADRxRF>, bit0 of the AD conversion data lower register, is used as the AD conversion data storage flag. The storage flag indicates whether the AD conversion result register has been read or not. When a conversion result is stored in the AD conversion result register, the flag is set to "1". When either of the AD conversion result registers (ADREGxH or ADREGxL) is read, the flag is cleared to "0".

Reading the AD conversion result also clears the AD conversion end flag ADMOD0<EOCF> to "0".

Example:

1. Convert the analog input voltage on the AN3 pin and write the result, to memory address 2800H using the AD interrupt (INTAD) processing routine.

Setting of main routine

		7	6	5	4	3	2	1	0		
┌	INTEPAD	←	X	—	—	—	X	1	0	0	Enable INTAD and set it to interrupt level 4.
	ADMOD1	←	1	1	0	0	0	0	1	1	Set pin AN3 to the analog input channel.
	ADMOD0	←	X	X	0	0	0	0	0	1	Start conversion in channel fixed single conversion mode.

Interrupt routine processing example

WA	←	ADREG3H/L	Read value of ADREG3L, ADREG3H to general purpose register WA (16 bits).
WA	>>	6	Shift contents read into WA six times to right and zero-fill upper bits.
(2800H)	←	WA	Write contents of WA to memory address 2800H.

2. Converts repeatedly the analog input voltages on the three pins AN0, AN1, and AN2, using channel scan repeat conversion mode.

INTEPAD	←	X	—	—	—	X	0	0	0	Disable INTAD.
ADMOD1	←	1	1	0	0	0	0	1	0	Set pins AN0 to AN2 to be the analog input channels.
ADMOD0	←	X	X	0	0	0	1	1	1	Start conversion in channel scan repeat conversion mode.

X : Don't care, — : No change

3.15 Digital/Analog Converter

8-bit resolution D/A converter of 2 channels is built into and it has the following features.

- 8-bit resolution D/A converter with two internal channels.
- A full range Buffer AMP is built in each channel.
- The standby can be set to each channel by the control register.

3.15.1 Operation

Control register 0 DACnCNT0<OPn><REFONn> is set to "11". Output CODE is set to output register DACnREG. And, the output voltage corresponding to CODE appears to output pin DAOUTn by doing "1" to Control register 1 DACnCNT1<VALIDn> in write. When <VALIDn> is not set, the value of the output register is not reflected in DAOUTn. Therefore, set DACnCNT1<VALIDn> after the data of eight bits is updated without fail in DACnREG when you renew CODE. When "1" is written to <VALIDn>, the data of DACnREG takes in to a DA converter as 8 bit data, and recognizes as CODE. Moreover, DACnCNT0<OPn> output DAOUTn becomes High-Z by setting it as "0". Iref is cut by setting DACnCNT0<REFONn> to "0", and current consumption can be reduced. The setting of DACnCNT0<OPn><REFONn> is needed before the HALT instruction is executed because the output voltage corresponding to CODE is output from output terminal DAOUTn after the HALT instruction is executed.

Figure 3.15.1 is block diagram of the D/A converter.

Note: From DAOUTn, "1" is outputted from immediately after setting DACnCNT0 <OPn> as "1."
Then, the value set up by DACnREG is outputted from DAOUTn.

3.16 Watchdog Timer (Runaway detection timer)

The TMP92CM27 contains a watchdog timer of runaway detecting.

The watchdog timer (WDT) is used to return the CPU to the normal state when it detects that the CPU has started to malfunction (Runaway) due to causes such as noise. When the watchdog timer detects a malfunction, it generates a non-maskable interrupt INTWD to notify the CPU of the malfunction, and outputs "0" from the watchdog timer out pin $\overline{\text{WDTOUT}}$ to notify peripheral devices of the malfunction.

Connecting the watchdog timer output to the reset pin internally forces a reset.

3.16.1 Configuration

Figure 3.16.1 is a block diagram of the watchdog timer (WDT).

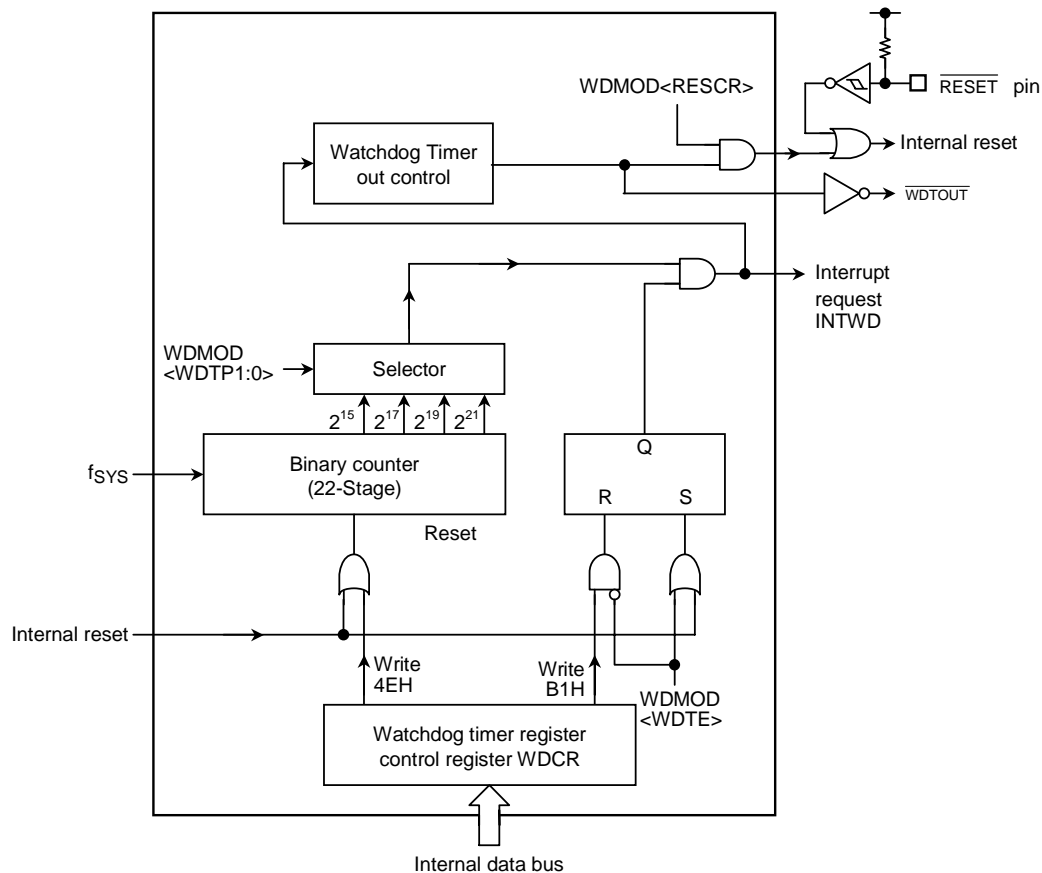

Figure 3.16.1 Block Diagram of Watchdog Timer

The watchdog timer consists of a 22-stage binary counter which uses the clock f_{SYS} as the input clock. The binary counter can output $2^{15}/f_{SYS}$, $2^{17}/f_{SYS}$, $2^{19}/f_{SYS}$, and $2^{21}/f_{SYS}$. Selecting one of the outputs using $WDMOD<WDTP1:0>$ generates a watchdog timer interrupt and output watchdog timer out when an overflow generate as shown in Figure 3.16.2.

Since the watchdog timer out pin (\overline{WDTOUT}) outputs “0” when there is a watchdog timer overflow, the peripheral devices can be reset. Clearing the watchdog timer (writing the clear code (4EH) to the WDCR register) sets the \overline{WDTOUT} pin to “1”. In normal mode, the \overline{WDTOUT} pin continually outputs “0” until the clear code is written to the WDCR register.

Figure 3.16.2 Normal Mode

The runaway detection result can also be connected to the reset pin internally. In this case, the reset time will be between 22 to 29 system clocks (2.2 to 2.9 μs at $f_{SYS} = 20$ MHz) as shown in Figure 3.16.3.

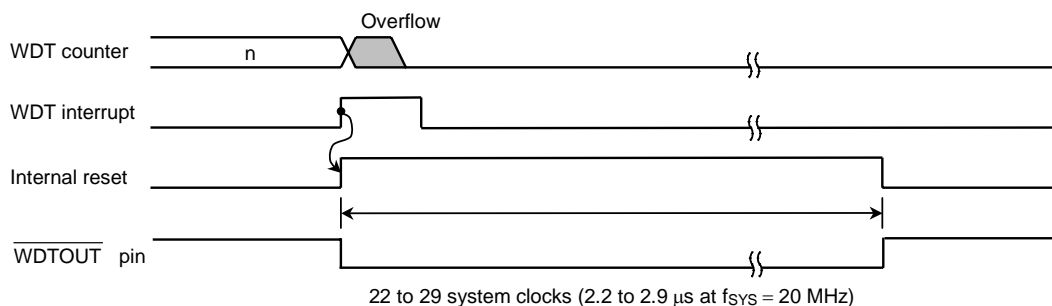

Figure 3.16.3 Reset Mode

3.16.2 Control Registers

The watchdog timer WDT is controlled by two control registers WDMOD and WDCR.

(1) Watchdog timer mode register (WDMOD)

1. Setting the detection time for the watchdog timer in <WDTP1:0>

This 2-bit register is used for setting the watchdog timer interrupt time used when detecting runaway. On a reset this register is initialized to WDMOD<WDTP1:0> = "00".

The detection time of the watch dog timer is shown in Figure 3.16.4.

2. Watchdog timer enable/disable control register <WDTE>

At reset, the WDMOD<WDTE> is initialized to 1, enabling the watchdog timer.

To disable the watchdog timer, it is necessary to clear this bit to 0 and to write the disable code (B1H) to the watchdog timer control register WDCR. This makes it difficult for the watchdog timer to be disabled by runaway.

However, it is possible to return the watchdog timer from the disabled state to the enabled state merely by setting <WDTE> to "1".

3. Watchdog timer out reset connection <RESCR>

This register is used to connect the output of the watchdog timer with the RESET terminal internally. Since WDMOD<RESCR> is initialized to "0" at reset, a reset by the watchdog timer will not be performed.

(2) Watchdog timer control register (WDCR)

This register is used to disable and clear the binary counter for the watchdog timer.

• Disable control

The watchdog timer can be disabled by clearing WDMOD<WDTE> to 0 and then writing the disable code (B1H) to the WDCR register.

WDMOD	← 0 - - - - - - -	Clear WDMOD<WDTE> to "0".
WDCR	← 1 0 1 1 0 0 0 1	Write the disable code (B1H).

• Enable control

Set WDMOD<WDTE> to "1".

• Watchdog timer clear control

To clear the binary counter and cause counting to resume, write the clear code (4EH) to the WDCR register.

WDCR	← 0 1 0 0 1 1 1 0	Write the clear code (4EH).
------	-------------------	-----------------------------

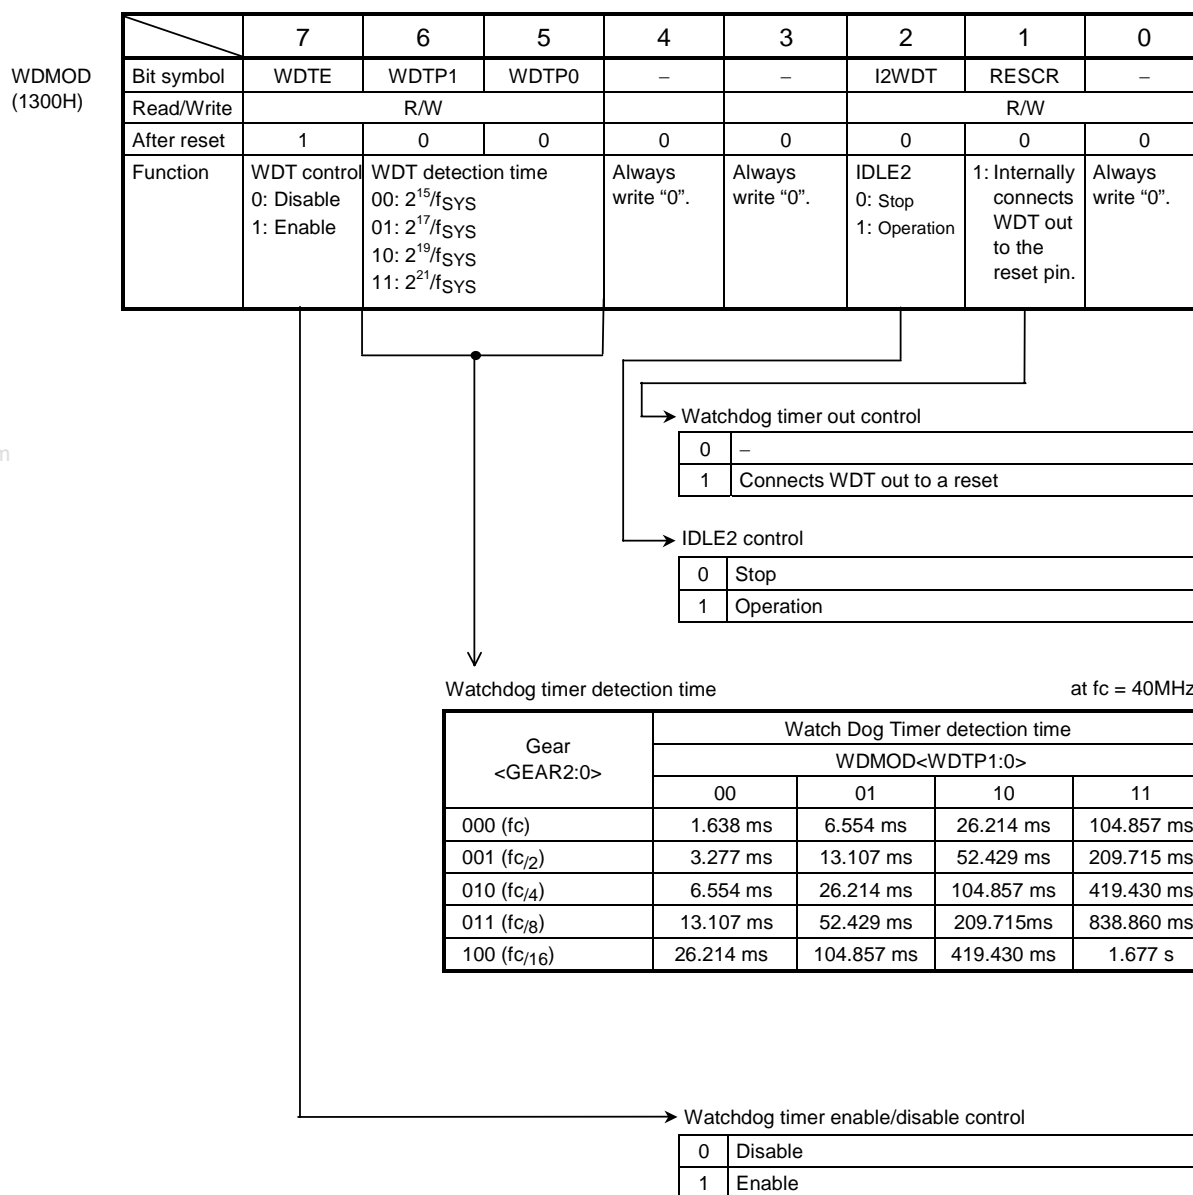

Figure 3.16.4 Watchdog Timer Mode Register

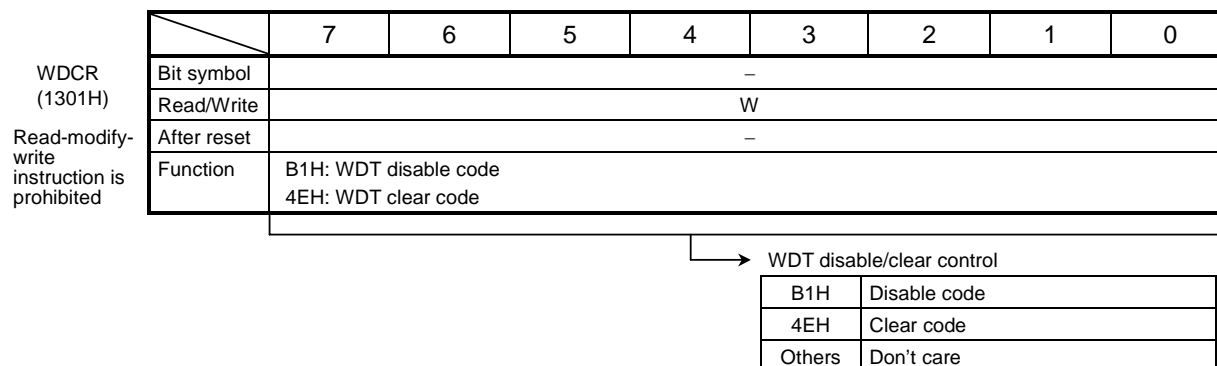

Figure 3.16.5 Watchdog Timer Control Register

3.16.3 Operation

After the detection time set by the WDMOD<WDTP1:0> register is reached, the watchdog timer generates interrupt INTWD and outputs a low signal to the watchdog timer out pin $\overline{\text{WDTOUT}}$. The binary counter for the watchdog timer must be cleared to 0 by software (Instruction) before INTWD is generated. If the CPU malfunctions (Runaway) due to causes such as noise and does not execute an instruction to clear the binary counter, the binary counter overflows and generates INTWD.

The CPU interprets INTWD as a malfunction detection signal, which can be used to start the malfunction recovery program to return the system to normal. A CPU malfunction can also be fixed by connecting the watchdog timer output to a reset pin for peripheral devices.

The watchdog timer begins operating immediately on release of the watchdog timer reset.

The watchdog timer is reset and halted in IDLE1 or STOP modes. The watchdog counter continues counting during bus release ($\overline{\text{BUSA}} = \text{Low}$).

When the device is in IDLE2 mode, the operation of WDT depends on the WDMOD<I2WDT> setting. Ensure that WDMOD<I2WDT> is set before the device enters IDLE2 mode.

Example: 1. Clear the binary counter.

WDCR \leftarrow 0 1 0 0 1 1 1 0 Write the clear code (4EH).

2. Set the watchdog timer detection time to $2^{17}/f_{\text{SYS}}$.

WDMOD \leftarrow 1 0 1 X 0 - - -

3. Disable the watchdog timer.

WDMOD \leftarrow 0 - - X 0 - - - Clear <WDTE> bit to 0.

WDCR \leftarrow 1 0 1 1 0 0 0 1 Write the disable code (B1H).

3.17 External bus release function

TMP92CM27 have external bus release function that can connect bus master to external. Bus release request ($\overline{\text{BUSRQ}}$), bus release answer ($\overline{\text{BUSAk}}$) pin is assigned to Port 86 and 87. And, it become effective by setting to P8CR and P8FC.

Figure 3.17.1 shows operation timing. Time that from $\overline{\text{BUSRQ}}$ pin inputted "0" until busis released ($\overline{\text{BUSAk}}$ is set to "0") depend on instruction that CPU execute at that time.

Figure 3.17.1 Bus release function operation timing

3.17.1 Non release pin

If it received bus release request, CPU release bus to external by setting $\overline{\text{BUSAk}}$ pin to "0" without start next bus. In this case, pin that is released have 4 types (A, B, C and D). Eve operation that set to high impedance (HZ) is different in 4 types.(Note) Table 3.17.1 shows support pin for 4 types. Any pin become non release pin only case of setting to that function by setting port. Therefore, if pin set to output port and so on, it is not set non relase pin, and it hold previous condition.

Table 3.17.1 Non release pin

Type	Eve operation that set to HZ	Support function (Pin name)
A	Drive "1"	A23 to A16(P67 to P60), A15 to A8, A7 to A0, $\overline{\text{CS0}}$ (P80), $\overline{\text{CS1}}$ (P81), $\overline{\text{CS2}}$ (P82), $\overline{\text{CS3}}$ (P83), $\overline{\text{SDCS}}$ (P83), $\overline{\text{CS4}}$ (P84), $\overline{\text{CS5}}$ (P85), $\overline{\text{SDWE}}$ (P90), $\overline{\text{SDRAS}}$ (P91), $\overline{\text{SDCAS}}$ (P92), $\overline{\text{SDLLDQM}}$ (P93), $\overline{\text{SDLUDQM}}$ (P94), $\overline{\text{SDCLK}}$ (P96)
B	Drive "1"	$\overline{\text{RD}}$, $\overline{\text{WRL}}$ (P71), $\overline{\text{WRLU}}$ (P72), $\overline{\text{R}/\overline{\text{W}}}$ (P73), $\overline{\text{SRWR}}$ (P74), $\overline{\text{SRLB}}$ (P75), $\overline{\text{SRLUB}}$ (P76)
C	Drive "0"	$\overline{\text{SDCKE}}$ (P95)
D	None operation	D15 to D8(P17 to P10), D7 to D0

Note) Although the output buffer of $\overline{\text{RD}}$, $\overline{\text{WRL}}$ (P71), $\overline{\text{WRLU}}$ (P72), $\overline{\text{R}/\overline{\text{W}}}$ (P73), $\overline{\text{SRWR}}$ (P74), $\overline{\text{SRLB}}$ (P75) and $\overline{\text{SRLUB}}$ (P76) is turned off at the time of bus release, a pull-up will be turned on and it will not become high impedance (HZ).

3.17.2 Connection example

Figure 3.17.2 show connection example.

Figure 3.17.2 Connection example

3.17.3 Note

If use bus release function, be careful following notes.

1) Prohibit using this function together SDRAM controller

Prohibit also SDRAMC basically, but if external bus master use SDRAM, set SDRAM to SR (self refresh) condition before bus release request. And, when finish bus release, release SR condition. In this case, confirm each condition by handshake of general purpose port.

2) Support standby mode

The condition that can receive this function is only CPU operating condition and during IDLE2 mode. During IDLE1 and STOP condition don't receive. (Bus release function is ignored).

3) Internal resource access disable

External bus master cannot access to internal memory and internal I/O of TMP92CM27. Internal I/O operation during bus releasing.

4) Internal I/O operation during bus releasing

Internal I/O continue operation during bus releasing, please be careful. And, if set the watchdog timer, set runaway time by consider bus release time.

4. Electrical Characteristics

4.1 Maximum Ratings

Parameter	Symbol	Rating	Unit
Power Supply Voltage	VCC	-0.5 to 4.0	V
Input Voltage	V _{IN}	-0.5 to VCC+0.5	V
Output Current (1 pin)	I _{OL}	2	mA
Output Current (1 pin)	I _{OH}	-2	mA
Output Current (total)	Σ I _{OL}	80	mA
Output Current (total)	Σ I _{OH}	-80	mA
Power Dissipation (Ta=85°C)	P _D	600	mW
Soldering Temperature (10 s)	T _{SOLDER}	260	°C
Storage Temperature	T _{STG}	-65 to 150	°C
Operation Temperature	T _{OPR}	-40 to 85	°C

Note: The maximum ratings are rated values that must not be exceeded during operation, even for an instant. Any one of the ratings must not be exceeded. If any maximum rating is exceeded, a device may break down or its performance may be degraded, causing it to catch fire or explode resulting in injury to the user. Thus, when designing products that include this device, ensure that no maximum rating value will ever be exceeded.

Point of note about solderability of lead free products (attach "G" to package name)

Test parameter	Test condition	Note
Solderability	Use of Sn-63Pb solder Bath Solder bath temperature = 230°C, Dipping time = 5 seconds The number of times = one, Use of R-type flux	Pass: solderability rate until forming ≥ 95%
	Use of Sn-3.0Ag-0.5Cu solder bath Solder bath temperature = 245°C, Dipping time = 5 seconds The number of times = one, Use of R-type flux (use of lead free)	

4.2 DC Electrical Characteristics

VCC = 3.3 ± 0.3V / X1 = 4 to 40MHz / Ta = -40 to 85°C

Symbol	Parameter	Min	Typ	Max	Unit	Condition
VCC	Power Supply Voltage (DVCC=AVCC=DAVCC) (DVSS=AVSS=DAVSS=0V)	3.0		3.6	V	X1 = 6 to 10MHz (Note 1) X1 = 4 to 40MHz (Note 2)
VIL0	Input Low Voltage for D0 to D7 P10 to P17(D8 to D15)	-0.3		0.6	V

VTH	Schmitt Width for P71 to P77, P86, P87, PA0 to PA5, PC2, PC5, PD1 to PD5, PF0 to PF7, PJ0 to PJ7, PK0 to PK7, PL0 to PL3, PL5 to PL7, PM0 to PM7, PN0 to PN3, <u>NMI</u> , <u>RESET</u>	0.4	1.0		V	
VTH2	Schmitt Width for PC0 to PC1, PC3 to PC4	0.2			V	
ICC	NORMAL (Note 2)		50.0	60.0	mA	VCC=3.6V, fc=40MHz(fsys=20MHz)
	IDLE2		25.0	31.5		
	IDLE1		7.5	11.5		
	STOP		0.2	50	μ A	VCC=3.6V

Note 1: Typical values are for when Ta = 25°C, Vcc = 3.3 V unless otherwise noted.

Note 2: ICC NORMAL measurement conditions:

All functions are operational; output pins except bus pin are open, and input pins are fixed. Bus pin CL=30pF.

4.3 AC Characteristics

4.3.1 Basic Bus Cycle

Read cycle

VCC = 3.3 ± 0.3V / fc = 4 to 40MHz / Ta = -40 to 85°C

No.	Parameter	Symbol	Variable		fc=40MHz fsys=20MHz	fc=27MHz fsys=13.5MHz	Unit
			Min	Max			
1	OSC period (X1/X2)	t _{OSC}	25	250	25	37.0	ns
2	System Clock period (=T)	t _{CYC}	50	500	50	74.0

28	Data Hold Time for SRAM	t _{SDH}	0.25T-5		7.5	13.5	

AC Measuring Condition

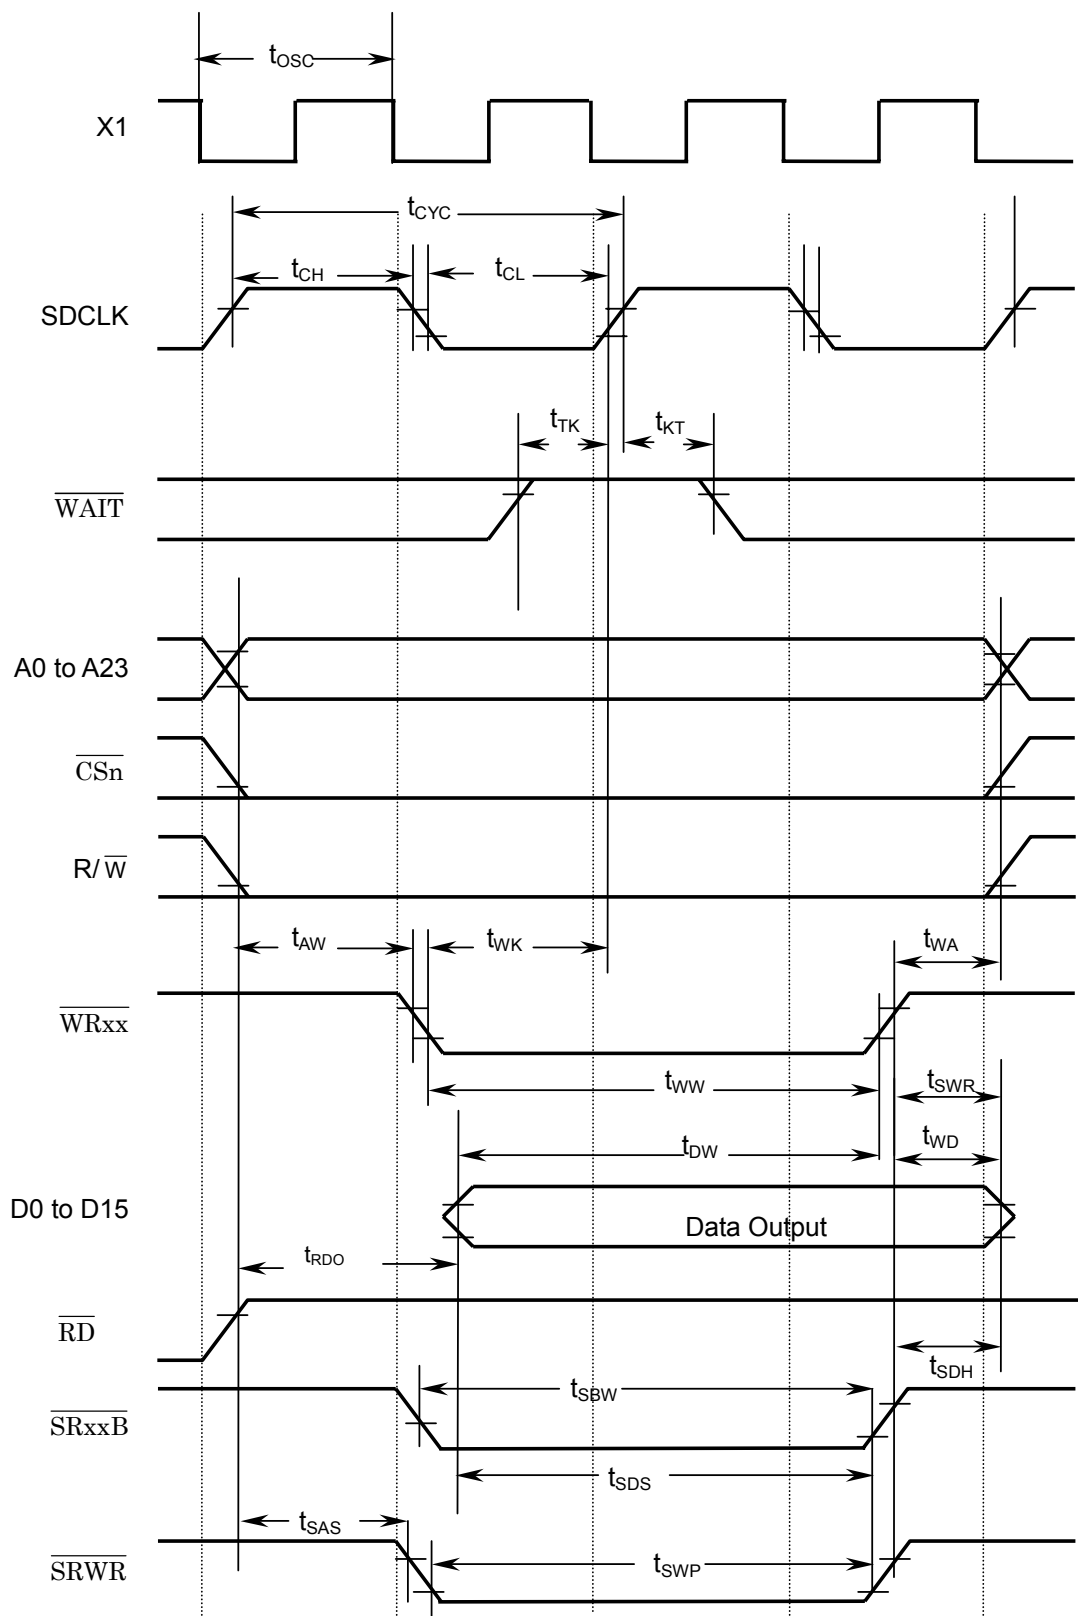

●Output level : High = 0.7Vcc, Low = 0.3Vcc, CL = 50pF ●Input level : High = 0.9Vcc, Low = 0.1Vcc

(1) Read cycle (0 wait, $f_c = f_{OSCH}$, $f_{FPH} = f_c/1$)

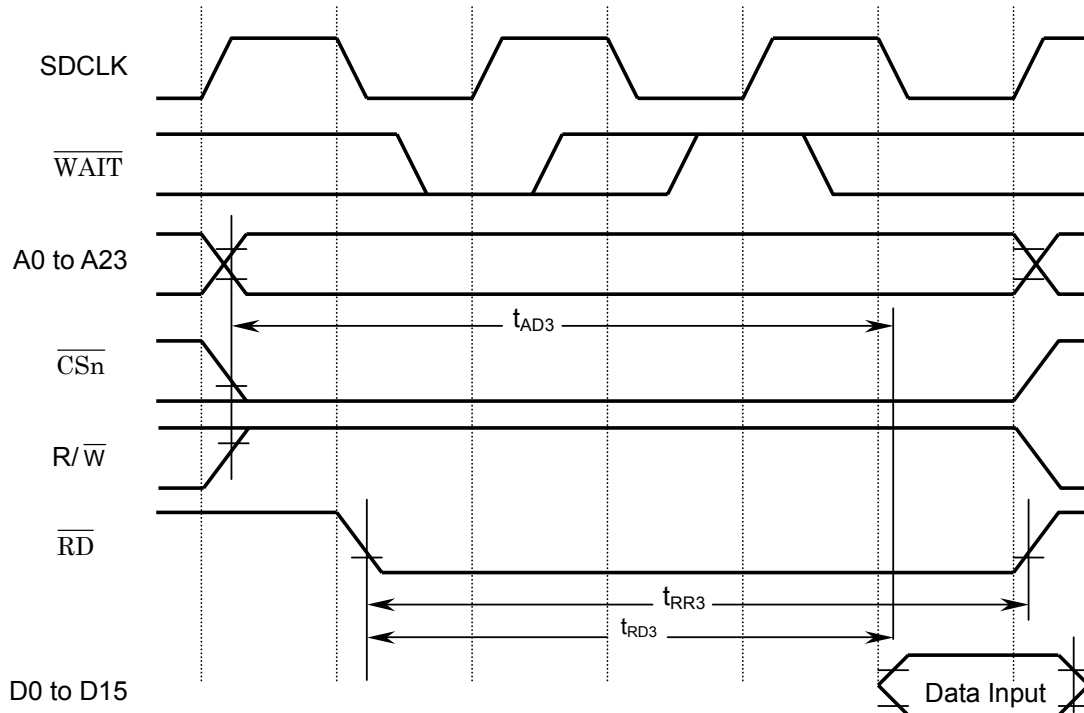

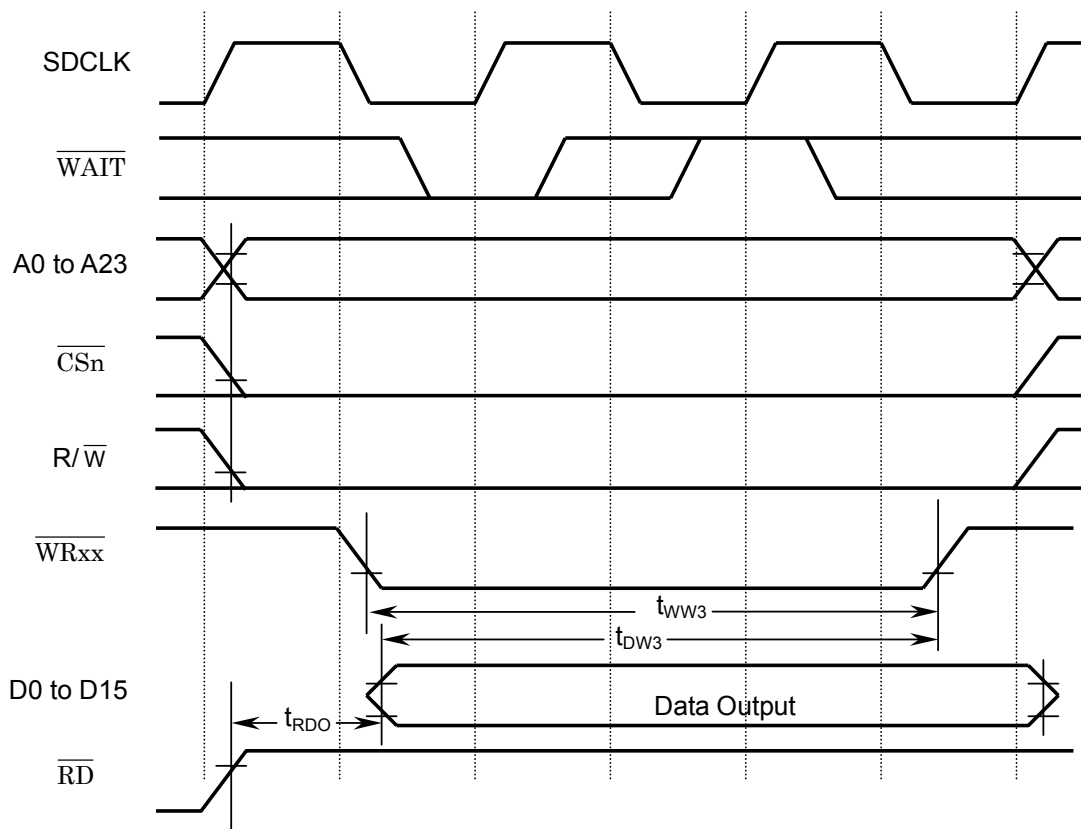

Note: The phase relation between X1 input signal and the other signals is undefined.
The above timing chart is an example.

(2) Write cycle (0 wait , $f_c = f_{\text{OSCH}}$, $f_{\text{FPH}} = f_c/1$)

Note: The phase relation between X1 input signal and the other signals is undefined.
The above timing chart is an example.

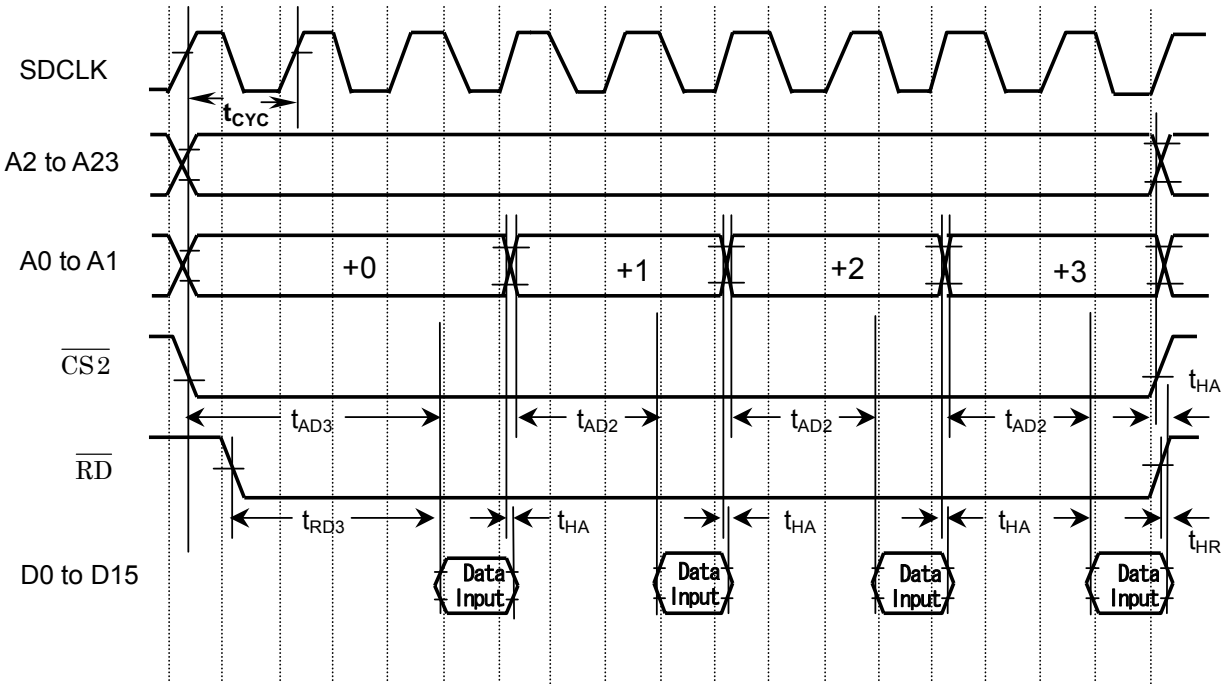

(3) Read cycle (1 wait, $f_c = f_{OSCH}$, $f_{FPH} = f_c/1$)(4) Write cycle (1 wait, $f_c = f_{OSCH}$, $f_{FPH} = f_c/1$)

4.3.2 Page ROM read cycle

(1) Page ROM Read Cycle (3-2-2-2 mode)

No	Symbol	Parameter	Variable		40MHz	27MHz	Unit
			Min	Max			
1	t_{CYC}	System Clock Period (=T)	50	166.7	50	74	ns
2	t_{AD2}	A0,A1 → D0 to D15 Input		2.0T-50	50	98	
3	t_{AD3}	A2 to A23 → D0 to D15 Input		3.0T-50	100	172	
4	t_{RD3}	\overline{RD} Fall → D0 to D15 Input		2.5T-45	80	140	
5	t_{HA}	A0 to A23 Invalid → D0 to D15 Hold	0		0	0	
6	t_{HR}	\overline{RD} Rise → D0 to D15 Hold	0		0	0	

AC Measuring Condition
●Output level: High = 0.7Vcc, Low = 0.3Vcc, CL = 50pF
●Input level: High = 0.9Vcc, Low = 0.1Vcc

4.3.3 SDRAM Controller AC Characteristics

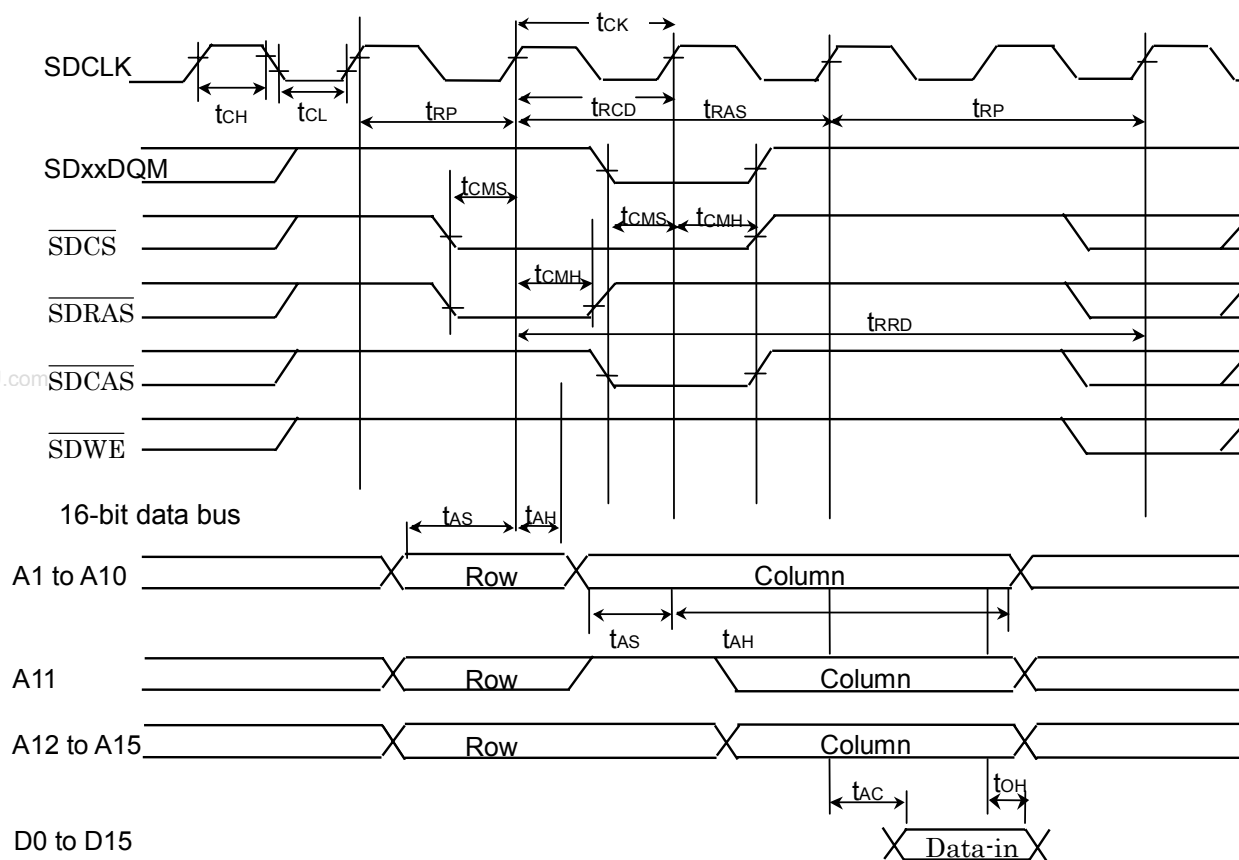

No	Symbol	Parameter	Variable		40MHz	27MHz	Unit
			Min	Max			
1	t_{RC}	Ref/Active to Ref/Active Command Period	2T		100	148	ns
2	t_{RAS}	Active to Precharge Command Period	2T	12210	100	148

18	t_{CMH}	Command Hold Time	0.5T-15		10	22	
19	t_{RSC}	Mode Register Set Cycle Time	T		50	74	

CL*: CAS latency.

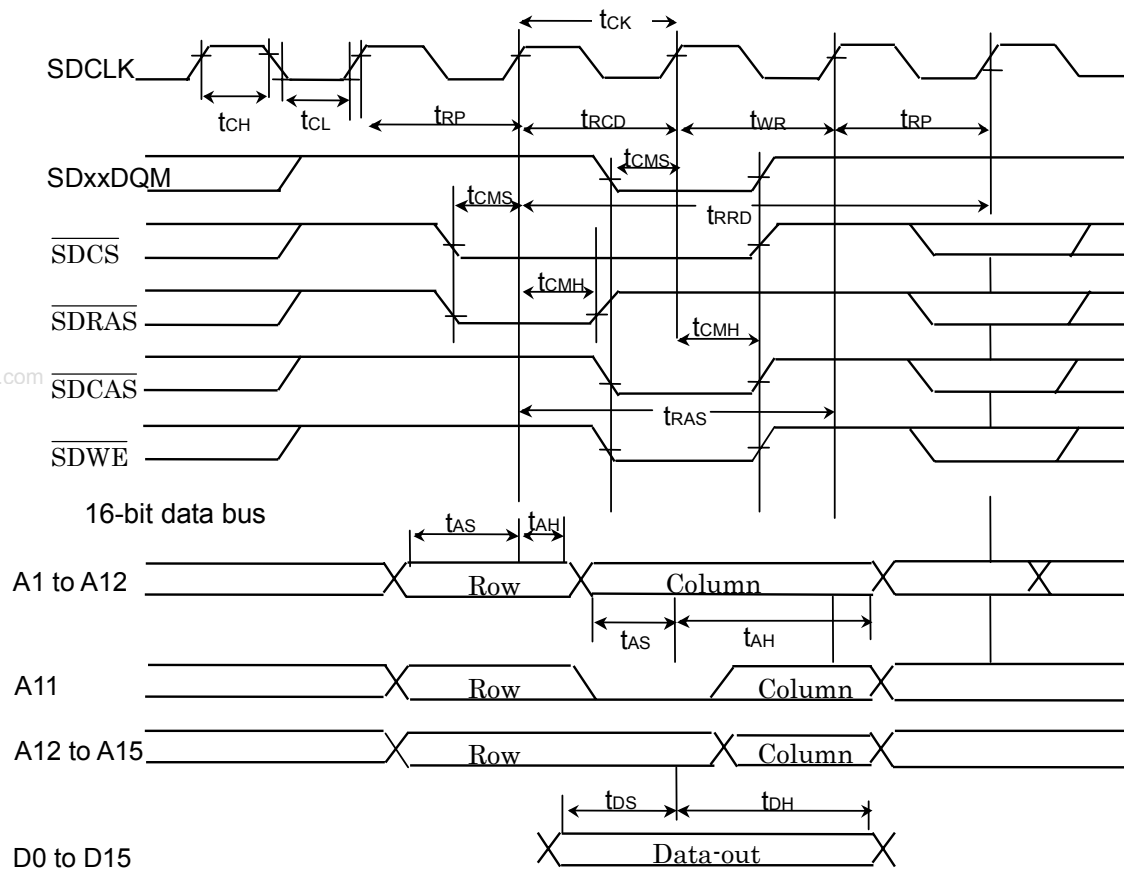

AC measuring conditions

- Output level: High = 0.7 Vcc, Low = 0.3 Vcc, CL = 50 pF
- Input level: High = 0.9 Vcc, Low = 0.1 Vcc.

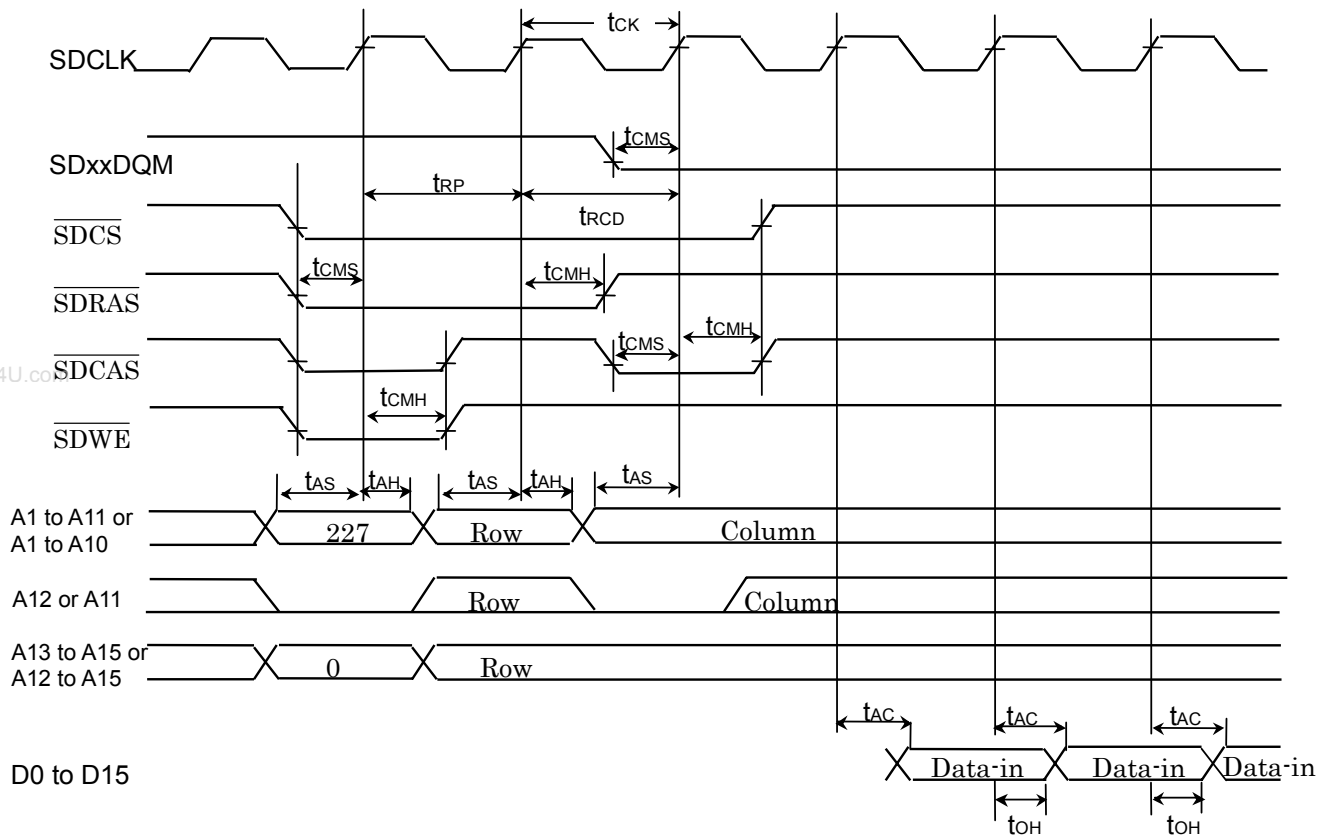

(1) SDRAM read timing (CPU access)

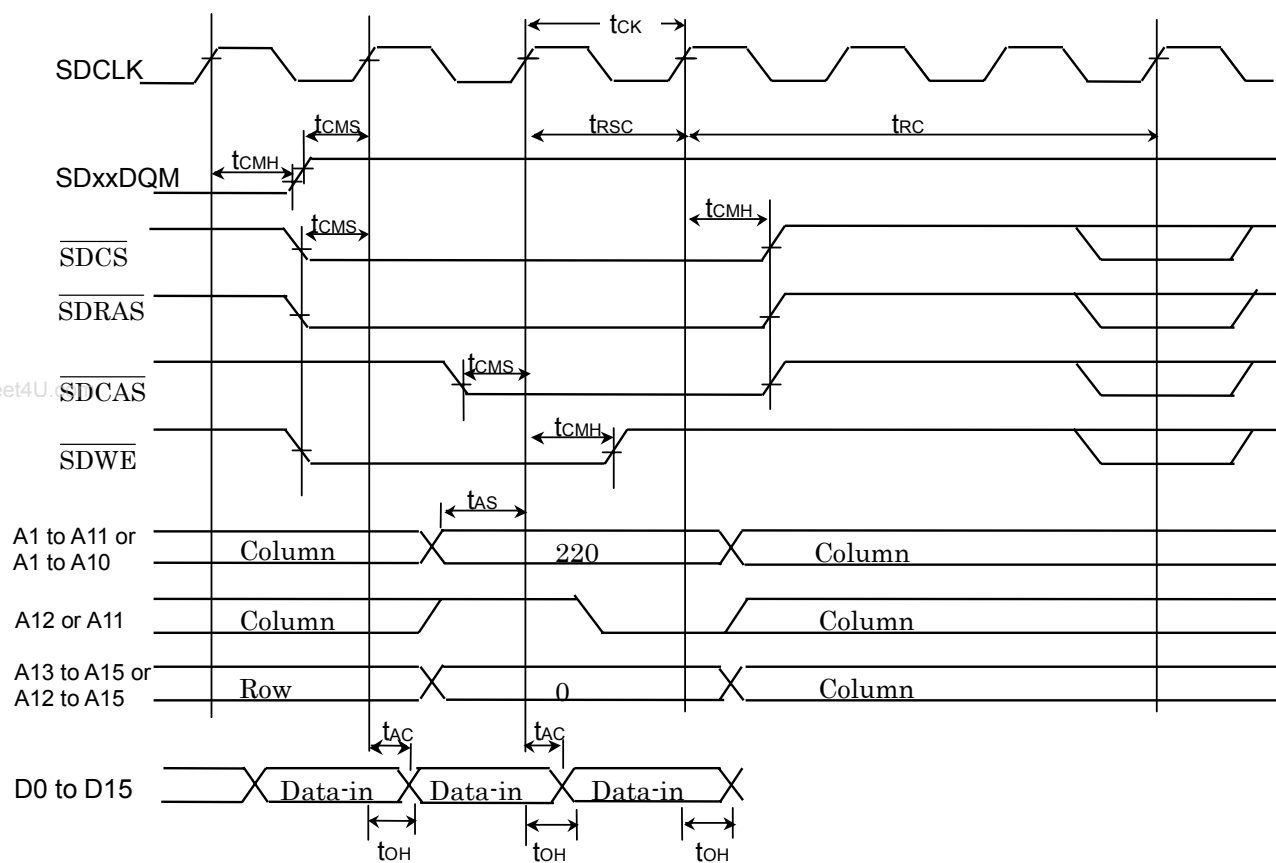

(2) SDRAM write timing (CPU access)

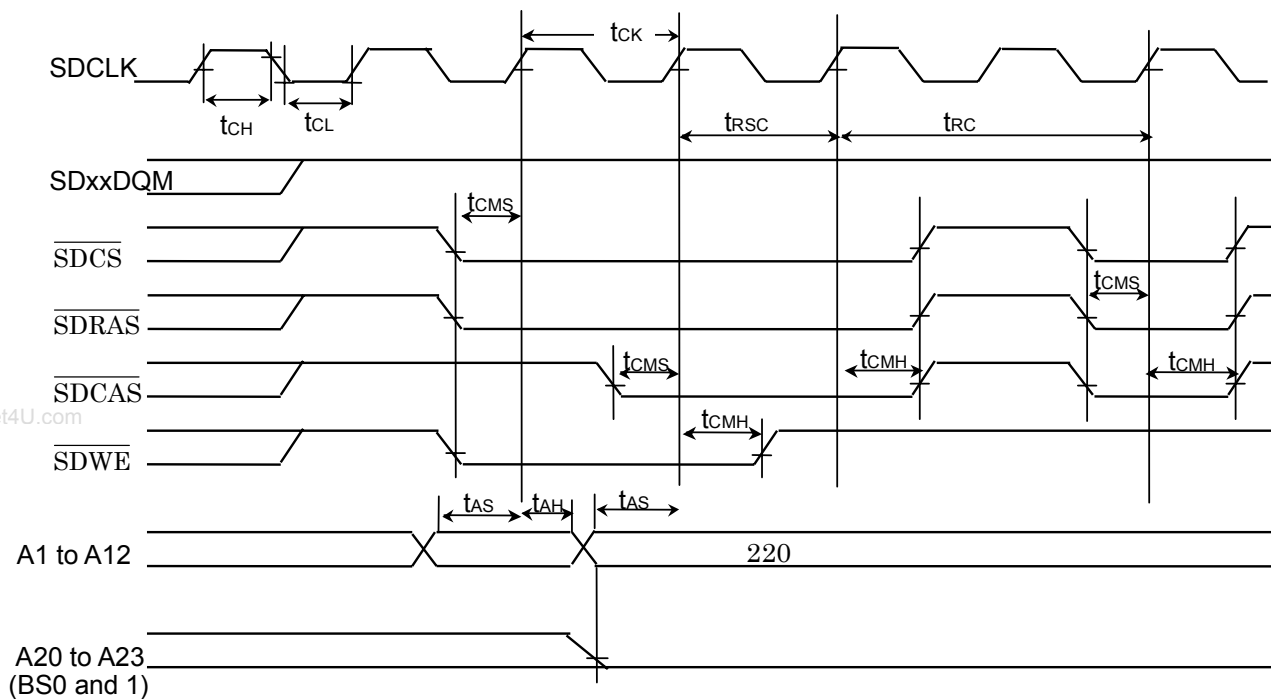

(3) SDRAM burst read timing (Start of burst cycle)

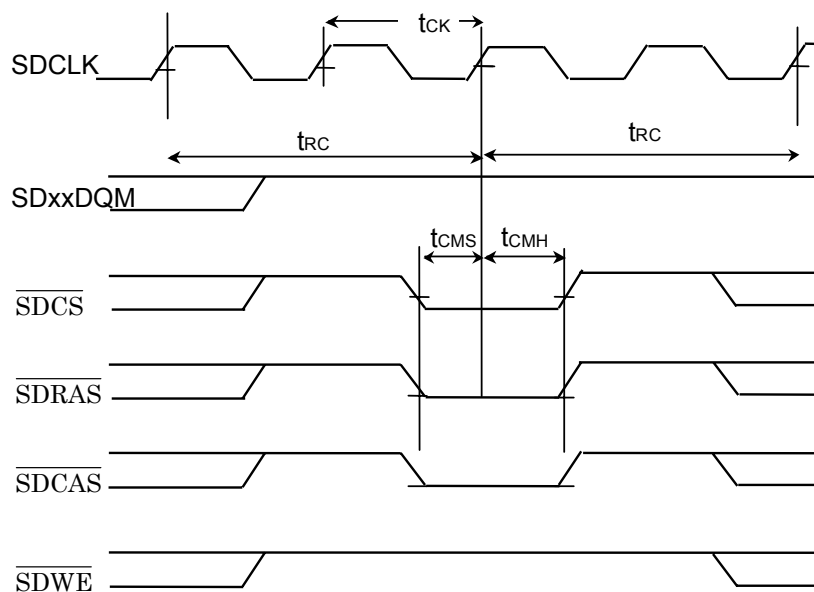

(4) SDRAM burst read timing (End of burst cycle)

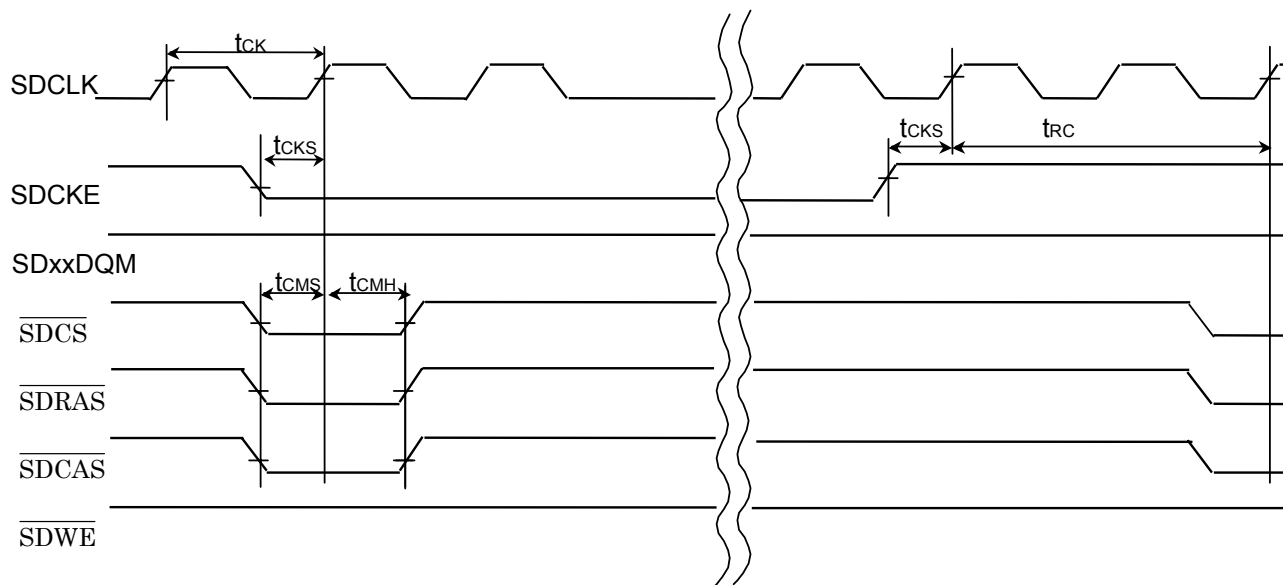

(5) SDRAM initialize timing

(6) SDRAM refresh timing

(7) SDRAM self refresh timing

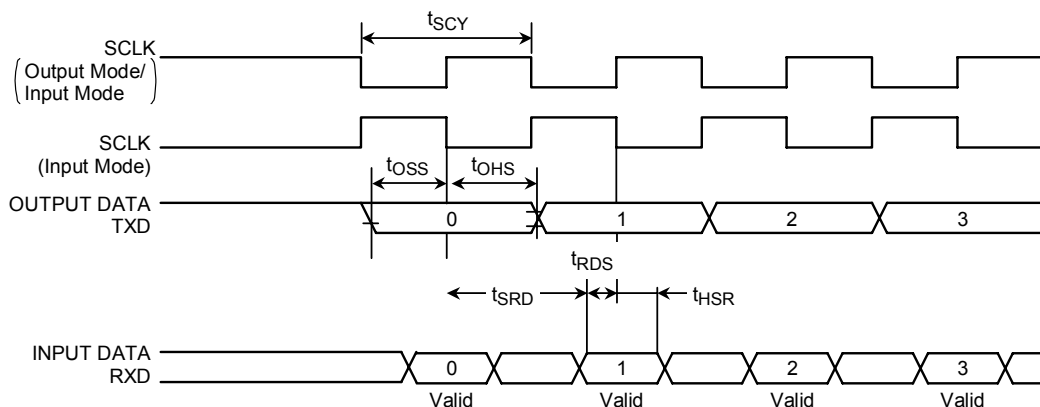

4.3.4 Serial Channel Timing

(1) SCLK input mode (I/O interface mode)

Parameter	Symbol	Variable		fc=40MHz fsys=20MHz		fc=27MHz fsys=13.5MHz		Unit
		Min	Max	Min	Max	Min	Max	
SCLK Cycle (Programmable)	t_{SCY}	16X		0.4		0.59		μs
Output Data → SCLK Rise/Fall	t_{OSS}	$t_{SCY}/2-4X-90$		10		58		ns
SCLK Rise/Fall → Output Data Hold	t_{OHS}	$t_{SCY}/2+2X+0$		250		370		
SCLK Rise/Fall → Input Data Hold	t_{HSR}	$3X+10$		85		121		
SCLK Rise/Fall → Input Data Hold	t_{SRD}		$t_{SCY}-0$		400		592	
Input Data Valid → SCLK Rise/Fall	t_{RDS}	0		0		0		

(2) SCLK output mode (I/O interface mode)

Parameter	Symbol	Variable		fc=40MHz fsys=20MHz		fc=27MHz fsys=13.5MHz		Unit
		Min	Max	Min	Max	Min	Max	
SCLK cycle (Programmable)	t_{SCY}	16X	8192X	0.4	204	0.59	303	μs
Output Data → SCLK Rise/Fall	t_{OSS}	$t_{SCY}/2-40$		160		256		ns
SCLK Rise/Fall → Output Data Hold	t_{OHS}	$t_{SCY}/2-40$		160		256		
SCLK Rise/Fall → Input Data Hold	t_{HSR}	0		0		0		
SCLK Rise/Fall → Input Data Valid	t_{SRD}		$t_{SCY}-1X-180$		195		375	
Input Data Valid → SCLK Rise/Fall	t_{RDS}	$1X+180$		205		217		

4.3.5 Interrupts

Parameter	Symbol	Variable		fc=40MHz fsys=20MHz		fc=27MHz fsys=13.5MHz		Unit
		Min	Max	Min	Max	Min	Max	
INT0 to INTB, $\overline{\text{NMI}}$ low level width	t_{INTAL}	4T+40		240		336		ns
INT0 to INTB, $\overline{\text{NMI}}$ high level width	t_{INTAH}	4T+40		240		336		

www.DataSheet4U.com

4.3.6 AD Conversion Characteristics

Symbol	Parameter	Min	Typ	Max	Unit
AVCC	AD Converter Power Supply Voltage	VCC	VCC	VCC	V
AVSS	AD Converter Ground	VSS	VSS	VSS	
AVIN	Analog Input Voltage	AVSS		AVCC	
E_T	Total error (Quantize error of $\pm 0.5\text{LSB}$ is included)		± 1.0	± 4.0	LSB

Note 1: $1\text{LSB} = (\text{AVCC} - \text{AVSS})/1024$ [V]

Note 2: Minimum frequency for operation

Clock frequency which is selected by clock is over than 4MHz, operation is guaranteed.

Note 3: The value for I_{CC} includes the current which flows through the AVCC pin.

4.3.7 DA Conversion Characteristics

Symbol	Parameter	Condition	Min	Typ	Max	Unit
DAOUT	Output voltage range	$R_L = 3.6\text{ K}\Omega$	$\text{DAVSS}+0.3$		$\text{DAVCC}-0.3$	V
E_T	Total error	$R_L = 3.6\text{ K}\Omega$		± 1.0	± 4.0	LSB
R_L	Resistive load	$\text{DAVSS}+0.3 \leq \text{DAOUT} \leq \text{DAVCC}-0.3$	3.6			$\text{K}\Omega$

Note 1: $1\text{LSB} = (\text{DAVCC} - \text{DAVSS})/256$ [V]Note 2: The value for I_{CC} includes the current which flows through the DVCC pin.

4.3.8 Event Counter (TA0IN, TA2IN, TA4IN, TA6IN, TB0IN0, TB0IN1, TB1IN0, TB1IN1, TB2IN0, TB2IN1, TB3IN0, TB3IN1)

Parameter	Symbol	Variable		fc = 40MHz fsys = 20MHz		fc = 27MHz fsys = 13.5MHz		Unit
		Min	Max	Min	Max	Min	Max	
Clock period	t_{VCK}	8X+100		300		396		ns
Clock low level width	t_{VCKL}	4X+40		140		188		ns
Clock high level width	t_{VCKH}	4X+40		140		188		ns

Note: Symbol x in the above table means the period of clock f_{FPH} , it's half period of the system clock f_{SYS} for CPU core. The period of f_{FPH} depends on the clock gear setting.

4.3.9 High Speed SIO Timing

Symbol	Parameter	Variable		40 MHz	36 MHz	27MHz	Unit
		Min	Max				
f_{PP}	HSCLK frequency (= 1/X)		10	10	9	6.75	MHz
t_r	HSCLK rising timing		8	8	8	8	ns
t_f	HSCLK falling time		8	8	8	8	
t_{WL}	HSCLK Low pulse width	0.5X-8		42	47	66	
t_{WH}	HSCLK High pulse width	0.5X-16		34	39	58	
t_{ODS1}	Output data valid → HSCLK rise	0.5X-18		32	37	56	
t_{ODS2}	Output data valid → HSCLK fall	0.5X-23		27	32	51	
t_{ODH}	HSCLK rise/fall → Output data hold	0.5X-10		40	45	64	
t_{IDS}	Input data valid → HSCLK rise/fall	0X+20		20	20	20	
t_{IDH}	HSCLK rise/fall → Input data hold	0X+5		5	5	5	

AC measuring conditions

Output level : High = 0.7 VCC, Low = 0.2 VCC, CL = 25 pF

Input level : High = 0.9 VCC, Low = 0.1 VCC

4.3.10 External bus release function

Parameter	Symbol	Variable		fc=40 MHz fsys=20MHz		Unit
		Min	Max	Min	Max	
Floating $\overline{\text{BUSAK}}$ falling	t_{ABA}	0	30	0	30	ns
Floating $\overline{\text{BUSAK}}$ rising	t_{BAA}	0	30	0	30	ns

Note 1: Even if the $\overline{\text{BUSRQ}}$ signal goes low, the bus will not be released while the $\overline{\text{WAIT}}$ signal is low. The bus will only be released when $\overline{\text{BUSRQ}}$ goes low while $\overline{\text{WAIT}}$ is high.

Note 2: This line shows only that the output buffer is in the off state. It does not indicate that the signal level is fixed. Just after the bus is released, the signal level set before the bus was released is maintained dynamically by the external capacitance. Therefore, to fix the signal level using an external resistor during bus release, careful design is necessary, as fixing of the level is delayed. The internal programmable pull-up/pull-down resistor is switched between the active and non-active states by the internal signal.

5 . Special Function Register

Special function register(SFR) is control of an input-and-output port and the control register of a circumference part, and it is assigned to 8 K bytes of address area of 000000H to 001FFFH.

- | | |
|---------------------------|--|
| (1) Input-and-Output port | (9) Pattern Generator |
| (2) Interrupt control | (10) High speed serial channels |
| (3) DMA controller | (11) UART mode / Serial channels |
| (4) Memory controller | (12) I ² C BUS mode / Serial channels |
| (5) Clock control / PLL | (13) AD converter |
| (6) SDRAM controller | (14) DA converter |
| (7) 8-bit timer | (15) Watch dog timer |
| (8) 16-bit timer | (16) Key-on wake up |

Composition of a table

Symbol	Name	Address	7	6			1	0	
									→ Symbol
									→ Read/Write
									→ The initial value at the time of reset
									→ Note

Note1 : "Prohibit RMW" of a table shows that it do not support read-modify-write operation for the register.

Example) When only bit 0 of a P1CR register is set to "1", usually "SET 0,(0006H)", but It is necessary to write in this register to a 8-bit register by the "LD" (transfer) command for "Prohibit RMW".

The meaning of a sign

R/W	:Read/Write enable
R	:Only Read enable
W	:Only Write enable
W*	:Read Write enable (However, always read as "1")
Prohibit	:Read-modify-write instruction is Prohibit ed
RMW	(EX, ADD, ADC, BUS, SBC, INC, DEC, AND, OR, XOR, STCF, RES, SET, CHG, TEST, RLC, RRC, RL, RR, SLA, SRA, SLL, SRL, RLD, RRD instruction is disable).
Prohibit RMW*	:Read-modify-write instruction is Prohibit ed in the case of pull-up control of the port.

Table 5. I/O Register Map

6. Points of Note and Restrictions

(1) Notation

- a. The notation for built-in/ I/O registers is as follows register symbol <Bit symbol> (e.g., TA01RUN <TA0RUN> denotes bit TA0RUN of register TA01RUN).

- b. Read-modify-write instructions

An instruction in which the CPU reads data from memory and writes the data to the same memory location in one instruction.

Example 1: SET 3, (TA01RUN) ... Set bit 3 of TA01RUN.

Example 2: INC 1, (100H) ... Increment the data at 100H.

- Examples of read-modify-write instructions on the TLCS-900

Exchange instruction

EX (mem), R

Arithmetic operations

ADD (mem), R/# ADC (mem), R/#

SUB (mem), R/# SBC (mem), R/#

INC #3, (mem) DEC #3, (mem)

Logic operations

AND (mem), R/# OR (mem), R/#

XOR (mem), R/#

Bit manipulation operations

STCF #3/A, (mem) RES #3, (mem)

SET #3, (mem) CHG #3, (mem)

TSET #3, (mem)

Rotate and shift operations

RLC (mem) RRC (mem)

RL (mem) RR (mem)

SLA (mem) SRA (mem)

SLL (mem) SRL (mem)

RLD (mem) RRD (mem)

- c. fc, fs, fFPH, fSYS and one state

The clock frequency input on X1 and 2 is called fSCH. The clock selected by PLLCR0<FCSEL> is called fc.

The clock selected by SYSCR1<SYSCK> is called fFPH. The clock frequency give by fFPH divided by 2 is called fSYS.

One cycle of fSYS is referred to as one state.

(2) Points of note

a. AM0 and AM1 pins

This pin is connected to the VCC or the VSS pin. Do not alter the level when the pin is active.

b. Reserved address areas

Since the 16 byte area of FFFFF0H ~ FFFFFFH is reserved as internal area, use of it is impossible. Moreover, when using an emulator, since it is used for control of an emulator, 64K bytes with arbitrary 16M byte area of use cannot be performed.

c. Warm-up counter

The warm-up counter operates when STOP mode is released, even if the system is using an external oscillator. As a result a time equivalent to the warm-up time elapses between input of the release request and output of the system clock.

d. Watchdog timer

The watchdog timer starts operation immediately after a reset is released. When the watchdog timer is not to be used, disable it.

e. AD converter

The string resistor between the VREFH and VREFL pins can be cut by a program so as to reduce power consumption. When STOP mode is used, disable the resistor using the program before the HALT instruction is executed.

f. CPU (Micro DMA)

Only the "LDC cr, r" and "LDC r, cr" instructions can be used to access the control registers in the CPU (e.g., the transfer source address register (DMASn)).

g. Undefined SFR

The value of an undefined bit in an SFR is undefined when read.

h. POP SR instruction

Please execute the POP SR instruction during DI condition.

i. Interrupt

When you use interruption, be sure to set "1" as the bit 7 of a SIMC register.

7. Package Dimensions

Package Name: P-LQFP144-1616-0.40C

Unit:mm
