

Low Voltage/Low Power CMOS 16-Bit Microcontroller

TMP93CS36UG

1. Outline and Device Characteristics

The TMP93CS36 is high-speed, advanced 16-bit microcontroller developed for controlling medium to large-scale equipment.

The TMP93CS36UG is housed in 44-pin flat package.

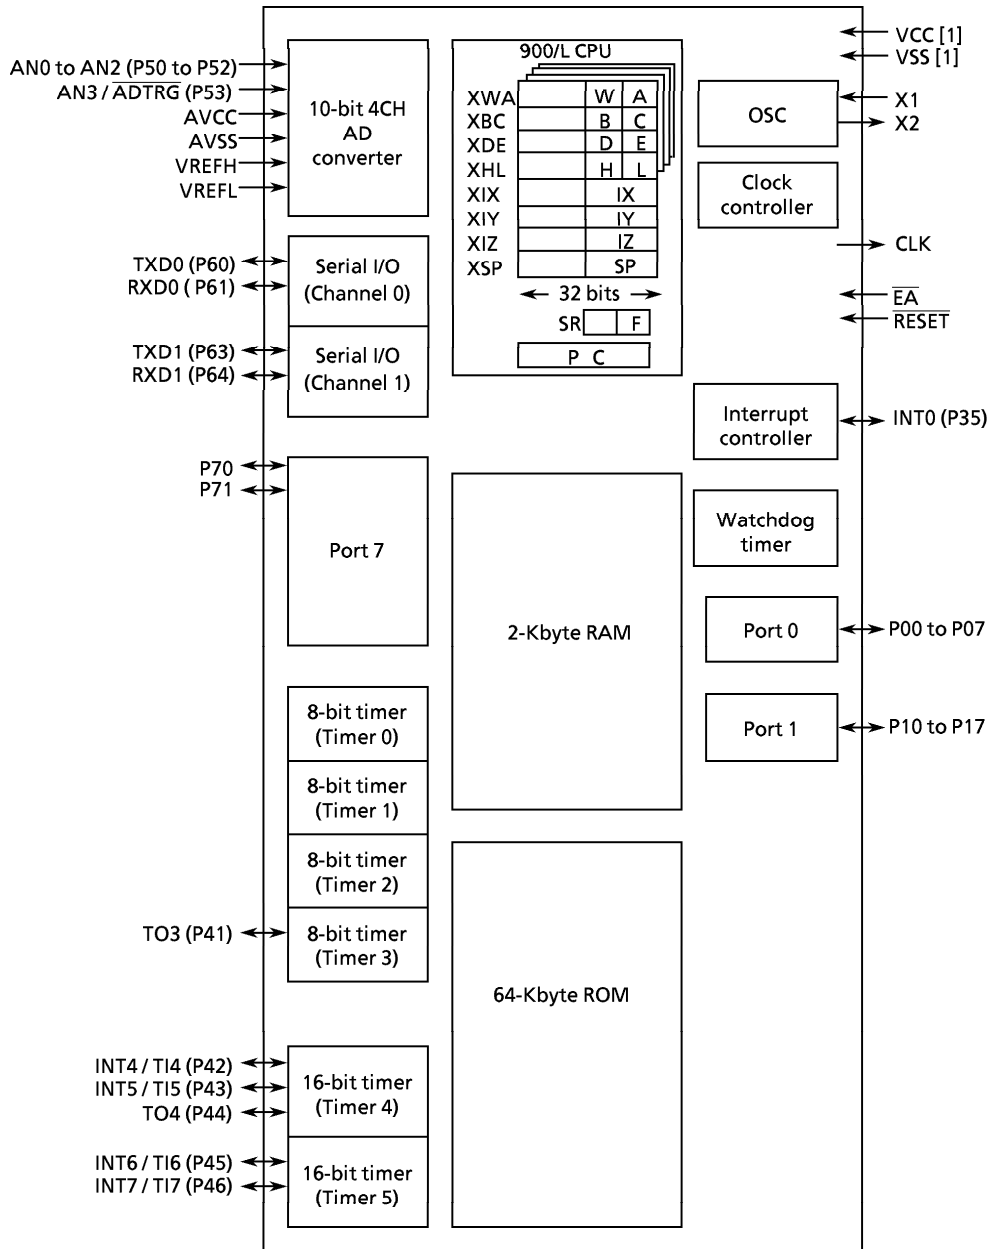

The device characteristics are as follows:

- (1) Original 16-bit CPU (900/L CPU)
 - TLCS-90 instruction mnemonic upward compatible
 - 16-Mbyte linear address space
 - General-purpose registers and register bank system
 - 16-bit multiplication/division and bit transfer/arithmetic instructions
 - Micro DMA: 4 channels (1.6 μ s per 2 bytes at 20 MHz)
- (2) Minimum instruction execution time: 200 ns at 20 MHz
- (3) Internal RAM: 2 Kbytes
Internal ROM: 64 Kbytes
- (4) 8-bit timer: 4 channels
- (5) 16-bit timer: 2 channels
- (6) Serial interface: 2 channels
- (7) 10-bit AD converter: 4 channels
- (8) High current output: 2 ports
- (9) Watchdog timer
- (10) Interrupt functions: 30
 - 9 CPU interrupts (SWI instruction, and illegal instruction)
 - 16 internal interrupts
 - 5 external interrupts
] 7-level priority can be set.
- (11) I/O ports
33 pins for TMP93CS36
- (12) Standby function: 4 HALT modes (RUN, IDLE2, IDLE1, STOP)

030619EBP1

- The information contained herein is subject to change without notice.
- The information contained herein is presented only as a guide for the applications of our products. No responsibility is assumed by TOSHIBA for any infringements of patents or other rights of the third parties which may result from its use. No license is granted by implication or otherwise under any patent or patent rights of TOSHIBA or others.
- TOSHIBA is continually working to improve the quality and reliability of its products. Nevertheless, semiconductor devices in general can malfunction or fail due to their inherent electrical sensitivity and vulnerability to physical stress. It is the responsibility of the buyer, when utilizing TOSHIBA products, to comply with the standards of safety in making a safe design for the entire system, and to avoid situations in which a malfunction or failure of such TOSHIBA products could cause loss of human life, bodily injury or damage to property.
In developing your designs, please ensure that TOSHIBA products are used within specified operating ranges as set forth in the most recent TOSHIBA products specifications. Also, please keep in mind the precautions and conditions set forth in the "Handling Guide for Semiconductor Devices," or "TOSHIBA Semiconductor Reliability Handbook" etc..
- The TOSHIBA products listed in this document are intended for usage in general electronics applications (computer, personal equipment, office equipment, measuring equipment, industrial robotics, domestic appliances, etc.). These TOSHIBA products are neither intended nor warranted for usage in equipment that requires extraordinarily high quality and/or reliability or a malfunction or failure of which may cause loss of human life or bodily injury ("Unintended Usage"). Unintended Usage include atomic energy control instruments, airplane or spaceship instruments, transportation instruments, traffic signal instruments, combustion control instruments, medical instruments, all types of safety devices, etc.. Unintended Usage of TOSHIBA products listed in this document shall be made at the customer's own risk.
- The products described in this document are subject to the foreign exchange and foreign trade laws.
- TOSHIBA products should not be embedded to the downstream products which are prohibited to be produced and sold, under any law and regulations.
- For a discussion of how the reliability of microcontrollers can be predicted, please refer to Section 1.3 of the chapter entitled Quality and Reliability Assurance/Handling Precautions.

- (13) Clock-gear function
 - Clock can be changed from f_c to $f_c/16$.
- (14) Wide range of operating voltage
 - $V_{cc} = 2.7$ to 5.5 V
- (15) Package
 - P-LQFP44-1010-0.80A

Note: The items in parentheses () are the initial setting after reset.

2. Pin Assignment and Functions

The assignment of input and output pins for the TMP93CS36, their names and functions are described below.

2.1 Pin Assignment

Figure 2.1.1 shows pin assignment of the TMP93CS36.

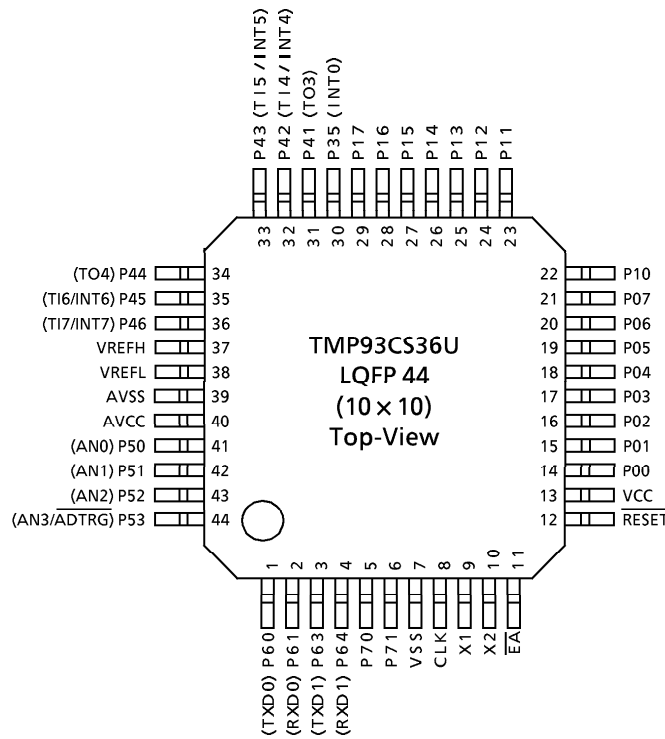

Figure 2.1.1 Pin Assignment (44-pin LQFP)

2.2 Pin Names and Functions

The names of input/output pins and their functions are described below.

Table 2.2.1 Pin Names and Functions (1/2)

Pin Name	Number of Pins	I/O	Functions
P00 to P07	8	I/O	Port 0: I/O port that allows selection of I/O on a bit basis
P10 to P17	8	I/O	Port 1: I/O port that allows selection of I/O on a bit basis
P35 INT0	1	I/O Input	Port 35: I/O port Interrupt request pin 0: Interrupt request pin with programmable level/rising edge 
P41 TO3	1	I/O Output	Port 41: I/O port PWM output 3: 8-bit PWM timer 3 output
P42 TI4 INT4	1	I/O Input Input	Port 42: I/O port Timer input 4: Timer 4 input Interrupt request pin 4: Interrupt request pin with programmable rising/falling edge 
P43 TI5 INT5	1	I/O Input Input	Port 43: I/O port Timer input 5: Timer 4 input Interrupt request pin 5: Interrupt request pin with rising edge 
P44 TO4	1	I/O Output	Port 44: I/O port Timer output 4: Timer 4 output pin
P45 TI6 INT6	1	I/O Input Input	Port 45: I/O port Timer input 6: Timer 5 input Interrupt request pin 6: Interrupt request pin with programmable rising/falling edge 
P46 TI7 INT7	1	I/O Input Input	Port 46: I/O port Timer input 7: Timer 5 input Interrupt request pin 7: Interrupt request pin with rising edge 
P50 to P52 AN0 to AN2	3	Input Input	Port 50 to Port 52: Input port Analog input: Analog signal input for AD converter
P53 AN3 ADTRG	1	Input Input Input	Port53: Input Port Analog input: Analog signal input for AD converter AD converter external start trigger input
P60 TXD0	1	I/O Output	Port 60: I/O port (with pull-up resistor) Serial send data 0
P61 RXD0	1	I/O Input	Port 61: I/O port (with pull-up resistor) Serial receive data 0
P63 TXD1	1	I/O Output	Port 63: I/O port (with pull-up resistor) Serial send data 1
P64 RXD1	1	I/O Input	Port 64: I/O port (with pull-up resistor) Serial receive data 1

Table 2.2.1 Pin Names and Functions (2/2)

Pin Name	Number of Pins	I/O	Functions
P70	1	I/O	Port 70: I/O port (High current output available)
P71	1	I/O	Port 71: I/O port (High current output available)
CLK	1	Output	Clock output: Outputs " $f_{SYS} \div 2$ " Clock. Pulled-up during reset. Can be disabled for reducing noise.
\overline{EA}	1	Input	"1" should be inputted with TMP93CS36.
\overline{RESET}	1	Input	Reset: Initializes TMP93CS36. (with pull-up resistor)
VREFH	1	Input	Pin for high level reference voltage input to AD converter
VREFL	1	Input	Pin for low level reference voltage input to AD converter
AVCC	1	Input	Power supply pin for AD converter
AVSS	1	Input	GND pin for AD converter (0 V)
X1	1	Input	Oscillator connecting pin
X2	1	Output	Oscillator connecting pin
VCC	1	Input	Power supply pin (All Vcc pins are connected to the power supply.)
VSS	1	Input	GND pin (All Vss pins are connected to the GND (0 V).)

Note: Built-in pull-up resistors can be released from the pins other than the \overline{RESET} pin by software.

3. Operation

This section describes the functions and basic operational blocks of TMP93CS36 devices. See the 7. “Points of Concern and Restriction” for the using notice and restrictions for each block.

3.1 CPU

The TMP93CS36 device has a built-in high-performance 16-bit CPU (900/L CPU). (For CPU operation, see TLCS-900/L CPU in the previous section.)

This section describes CPU functions unique to the TMP93CS36 that are not described in the previous section.

3.1.1 Reset

When resetting the TMP93CS36 microcontroller, ensure that the power supply voltage is within the operating voltage range, and that the internal high-frequency oscillator has stabilized. Then set the $\overline{\text{RESET}}$ input to Low level at least for 10 system clocks (16 μs at 20 MHz). Thus, when turn on the switch, be set to the power supply voltage is within the operating voltage range, and that the internal high-frequency oscillator has stabilized. Then hold the $\overline{\text{RESET}}$ input to Low level at least for 10 system clocks.

Clock gear is initialized 1/16 mode by reset operation. It means that the system clock mode f_{SYS} is set to $f_c/32 (= f_c/16 \times 1/2)$.

When the reset is accept, the CPU:

- Program counter (PC) according to reset vector that is stored FFFF00H to FFFF02H.
 - PC<7:0> ← Data in location FFFF00H
 - PC<15:8> ← Data in location FFFF01H
 - PC<23:16> ← Data in location FFFF02H
- Stack pointer (XSP) for system mode to 100H.
- IFF2 to IFF0 bits of status register to 111. (Sets mask register to interrupt level 7.)
- MAX bit of status register to 1. (Sets to maximum mode.)
- Bits RFP2 to 0 of status register to 000. (Sets register banks to 0.)

When reset is released, instruction execution starts from PC (Reset vector). CPU internal registers other than the above are not changed.

When reset is accepted, processing for built-in I/Os, ports, and other pins is as follows

- Initializes built-in I/O registers as per specifications.
- Sets port pins (including pins also used as built-in I/Os) to general-purpose input/output port mode.
- Pulls up the CLK pin to “H” level.

Note 1: By resetting, register in the CPU except program counter (PC), status register (SR) and stack pointer (XSP) and the data in internal RAM are not changed.

Note 2: The CLK pin is pulled up to “H” level during reset. When the voltage is put down externally, there is possible to cause malfunctions.

Figure 3.1.1 shows the reset timing chart of TMP93CS36.

Figure 3.1.1 TMP93CS36 Reset Timing Chart

3.2 Memory Map

Figure 3.2.1 is a memory map of the TMP93CS36.

Figure 3.2.1 Memory Map

3.3 Standby Function

Standby control circuits consist of (1) System clock controller, (2) Prescaler clock controller and (3) Standby controller.

Figure 3.3.1 shows a transition figure. Figure 3.3.2 shows the block diagram.

Figure 3.3.3 shows I/O registers. Table 3.3.1 shows the internal operation and system clock.

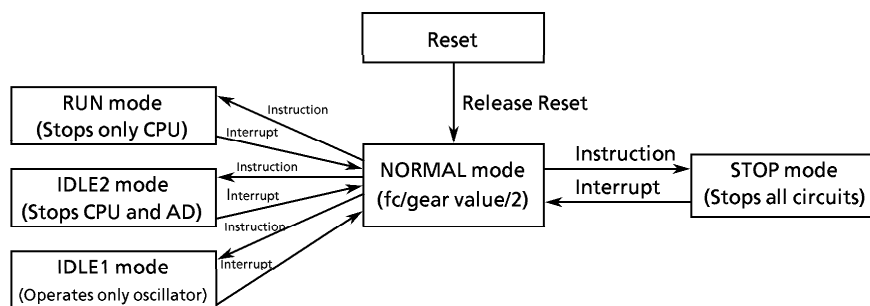

Figure 3.3.1 Operating Mode Transition Figure

The Clock Frequency input from X1, X2 pin is called f_c . The clock frequency selected by $SYSCR1<GEAR2;0>$ is called system clock f_{PPH} . The divided clock of f_{PPH} is called system clock f_{SYS} , and the 1 cycle of f_{SYS} is called 1 state.

Table 3.3.1 Internal Operation and System Clock

Operating Mode	Oscillator f_c	CPU	Internal I/O	System Clock f_{SYS}
RESET	Oscillation	Reset	Reset	$f_c/32$
NORMAL		Operate	Operate	Programmable ($f_c/2, f_c/4, f_c/8, f_c/16, f_c/32$)
RUN		Stop		
IDLE2			Stop	
IDLE1				
STOP	Stop		Stop	Stop

Note 1: SYSCR1<bit 7:4> are read as "1".

Note 2: Resetting sets <CLKEN> bit to "0". The CLK pin is internally pulled up during reset.

Figure 3.3.3 I/O Registers about Standby

3.3.1 System Clock Controller

The system clock controller generates system clock (f_{SYS}) for CPU core and internal I/O. It contains an oscillation circuit and clock gear circuit. The register SYSCR1<GEAR2:0> changes clock gear to either 1, 2, 4, 8 or 16 (f_c , $f_c/2$, $f_c/4$, $f_c/8$ or $f_c/16$), and these functions can reduce the power consumption of the equipment in which the device is installed.

The system clock (f_{SYS}) is set to $f_c/32$ ($f_c/16 \times 1/2$) because of <GEAR2:0> = "100" by resetting.

For example, f_{SYS} is set to 0.625 MHz by resetting the case of 20 MHz oscillator is connected to X1, X2 pins.

The f_c clock can be easily obtained by connecting a resonator to the X1/X2 pins, respectively. Clock input from an external oscillator is also possible.

Figure 3.3.4 Examples of Resonator Connection

Note: Accurate Adjustment of the Oscillation Frequency

The CLK pin outputs at 1/2 the system clock frequency ($f_{SYS}/2$) is used to monitor the oscillation clock. With a system requiring adjustment of the oscillation frequency, an adjusting program must be written.

(1) Clock gear controller

The clock gear select register SYSCR1<GEAR2:0> sets f_{PPH} to either f_c , $f_c/2$, $f_c/4$, $f_c/8$, $f_c/16$. Switching f_{PPH} with the clock gear reduces the power consumption.

Clock setting example:

Changing gear value of the high-frequency clock

```
SYSCR1 EQU 006FH
LD (SYSCR1), XXXX0000B ; Changes  $f_{SYS}$  to  $f_c/2$ 
LD (SYSCR1), XXXX0100B ; Changes  $f_{SYS}$  to  $f_c/32$ 
```

X: Don't care

(High-frequency clock gear changing)

To change the frequency of the clock gear, write the value to SYSCR1<GEAR2:0> register. It is necessary to continue the warm-up time until changing after writing the register value.

There is a possibility that the instruction next to the clock-gear-changing instruction is executed by the clock gear before changing. To execute the instruction next to the clock-gear-changing instruction by the clock gear after changing, input the dummy instruction (Instruction to execute the write cycle) as follows.

Example:

```
SYSCR1 EQU 006FH
LD (SYSCR1), XXXX0001B ; Changes  $f_{SYS}$  to  $f_c/4$ .
LD (DUMMY), 00H ; Dummy instruction
Instruction to be executed by the clock gear after changing
```

X: Don't care

3.3.2 Prescaler Clock Controller

The 9-bit prescaler provides a clock to 8-bit timer 0, 1, 2, 3, 16-bit timer 4, 5, and serial interface 0, 1. The clock input to the 9-bit prescaler is selected either f_{PPH} or $f_c/16$ by SYSCR0 < PRCK1:0 > register. < PRCK1:0 > register is initialized to “00” by resetting.

When the IDLE1 mode (Operates only oscillator) is used, set TRUN < PRRUN > to “0” to reduce the power consumption of 9-bit prescaler before “HALT” instruction is executed.

3.3.3 Internal Clock Pin Output Function

CLK pin outputs f_{SYS} divided by 2 internal clock.

Outputs are specified by the clock output control register CKOCR < CLKEN >. Writing “1” sets clock output, and writing “0” sets high impedance.

During reset, CLK pin is internally pulled up regardless of the value of < CLKEN > register. See “TMP93CS36 Reset Timing Chart” in Figure 3.1.1.

Note: To set < CLKEN > = “0” and set CLK pin to high impedance, pull up externally to prevent through current which follows to the input buffer of CLK pin.

3.3.4 Standby Controller

(1) HALT mode

When the HALT instruction is executed, the operating mode changes RUN, IDLE2, IDLE1 or STOP mode depending on the contents of the HALT mode setting register WDMOD<HALTM1:0>. Figure 3.3.5 shows the alternative states of the watchdog timer mode registers.

Figure 3.3.5 Watchdog Timer Mode Register

The futures of RUN, IDLE2, IDLE1 and STOP modes are as follows.

- ① RUN: Only the CPU halts ; power consumption remains unchanged.
- ② IDLE2: The built-in oscillator and the specified I/O operates.
The power consumption is redced to 1/2 than that during NORMAL operation.
- ③ IDLE1: Only the built-in oscillator operates, while all other built-in circuits stop. The power consumption is reduced to 1/5 or less than that during NORMAL operation.
- ④ STOP: All internal circuits including the built-in oscillator stop. This greatly reduces power consumption.

The operations in the halt state is described in Table 3.3.2.

Table 3.3.2 I/O Operation during HALT Mode

HALT Mode		RUN	IDLE2	IDLE1	STOP
WDMOD<HALTM1:0>		00	11	10	01
Block	CPU	Stop			
	I/O port	Keep the state when the "HALT" instruction was executed.			See Table 3.3.5
	8-bit timer				
	16-bit timer				
	Serial channel				
	AD converter				
	Watchdog timer				
	Interrupt controller				

(2) How to Release the HALT mode

These halt states can be released by resetting or requesting an interrupt. The halt release sources are determined by the combinations between the states of interrupt mask register <IFF2:0> and the HALT modes. The details for releasing the halt status are shown in Table 3.3.3.

- Released by requesting an interrupt

The operating released from the HALT mode depends on the interrupt enabled status. When the interrupt request level set before executing the HALT instruction exceeds the value of the interrupt mask register, the interrupt due to the source is processed after releasing the HALT mode, and CPU starts executing an instruction that follows the HALT instruction. When the interrupt request level set before executing the HALT instruction is less than the value of the interrupt mask register, releasing the HALT mode is not executed. (In non-maskable interrupts, interrupt processing is processed after releasing the HALT mode regardless of the value of the mask register.)

However only for INT0 interrupts, even if the interrupt request level set before executing the HALT instruction is less than the value of the interrupt mask register, releasing the HALT mode is executed. In this case, interrupt processing is not processed, and CPU starts executing the instruction next to the HALT instruction, but the interrupt request flag is held at "1".

Note: Usually, interrupts can release all halts status. However, the interrupts = (INT0) which can release the HALT mode may not be able to do so if they are input during the period CPU is shifting to the HALT mode (for about 3 clocks of f_{FPH}) with IDLE1 or STOP mode (RUN and IDLE2 are not applicable to this case). (In this case, an interrupt request is kept on hold internally.)

If another interrupt is generated after it has shifted to HALT mode completely, halt status can be released without difficulty. The priority of this interrupt is compare with that of the interrupt kept on hold internally, and the interrupt with higher priority is handled first followed by the other interrupt.

- Release by resetting

Releasing all halt status is executed by resetting.

When the STOP mode is released by RESET, it is necessary enough resetting time (3 ms or more) to set the operation of the oscillator to be stable.

When releasing the HALT mode by resetting, the internal RAM data keeps the state before the "HALT" instruction is executed. However the other setting contents are initialized. (Releasing due to interrupts keep the state before the "HALT" instruction is executed.)

Table 3.3.3 HALT Releasing Source and HALT Releasing Operation

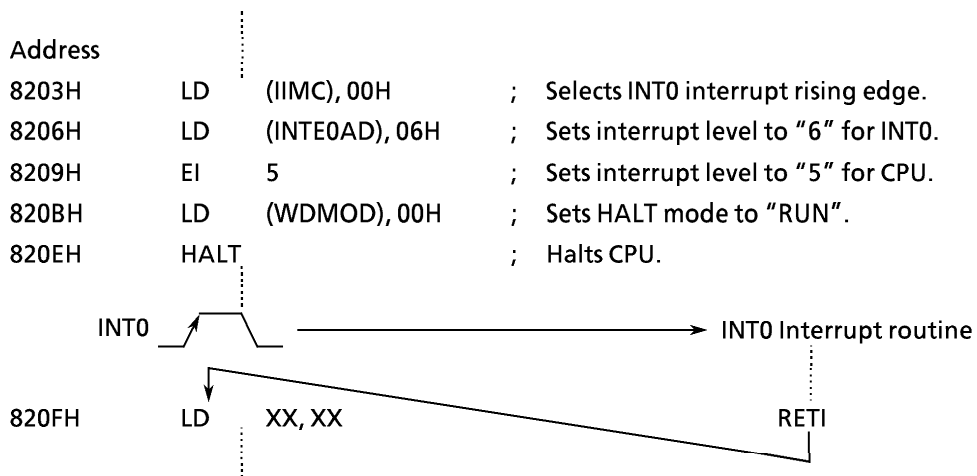

Interrupt Receiving Status		Interrupt Enable (Interrupt level) ≥ (Interrupt mask)				Interrupt Disable (Interrupt level) < (Interrupt mask)				
		RUN	IDLE2	IDLE1	STOP	RUN	IDLE2	IDLE1	STOP	
HALT releasing source	Interrupt	INTWDT	◆	×	×	×	–	–	–	–
		INT0	◆	◆	◆	◆*1	○	○	○	○*1
		INT4 to 7	◆	◆	×	×	×	×	×	×
		INTT0 to 3	◆	◆	×	×	×	×	×	×
		INTTR4 to 7	◆	◆	×	×	×	×	×	×
		INTO4, 5	◆	◆	×	×	×	×	×	×
		INTRX0, TX0	◆	◆	×	×	×	×	×	×
		INTRX1, TX1	◆	◆	×	×	×	×	×	×
		INTAD	◆	×	×	×	×	×	×	×
	RESET	◆	◆	◆	◆	◆	◆	◆	◆	

- ◆: After releasing the HALT mode, CPU starts interrupt processing. (RESET initializes LSI.)
- : After releasing the HALT mode, CPU starts executing an instruction that follows the HALT instruction.
- ×: It can not be used to release the HALT mode.
- : This combination type does not exist because the priority level(interrupt request level) of non-maskable interrupts is fixed to highest priority level "7".
- *1: Releasing the HALT mode is executed after passing the warm-up time.

Note: When releasing the HALT mode is executed by INT0 interrupt of the level mode in the interrupt enabled status, hold level "H" until starting interrupt processing. If level "L" is set, interrupt processing is correctly started.

(Example releasing "RUN" mode)

INT0 interrupt releases halt state when the RUN mode is on.

(3) Operation

① RUN mode

In the RUN mode, the system clock continues to operate even after a HALT instruction is executed. Only the CPU stops executing the instruction. In the halt state, an interrupt request is sampled with the falling edge of the “CLK” signal.

Releasing the RUN mode is executed by the external/internal interrupts. (See Table 3.3.3 “Halt Releasing Source and Halt Releasing Operation”.)

Figure 3.3.6 shows the interrupt timing for releasing the halt state by interrupts in the RUN/IDLE2 mode.

Figure 3.3.6 Timing Chart for Releasing the Halt State by Interrupt in RUN/IDLE2 Modes

② IDLE2 mode

In the IDLE2 mode, the system clock is supplied to only specific internal I/O devices, and the CPU stops executing the current instruction.

In the IDLE2 mode, the halt state is released by an interrupt with the same timing as in the RUN mode. The IDLE2 mode is released by external/internal interrupt, except INTWDT/INTAD interrupts. (See Table 3.3.3 “Halt Releasing Source and Halt Releasing Operation”.)

In the IDLE2 mode, the watchdog timer should be disabled before entering the halt status to prevent the watchdog timer interrupt occurring just after releasing the HALT mode.

③ IDLE1 mode

In the IDLE1 mode, only the internal oscillator operates. The system clock in the MCU stops, the CLK pin is fixed at the level “H” in the output enable ($CKOCR < CLKEN > = “1”$).

In the halt state, and interrupt request is sampled aynchronunsly with the system clock, however the halt release (restart of operation) is performed synchronously with it.

IDLE1 mode is released by external interrupts (INT0). (See Table 3.3.3 “Halt Releasing Source and Halt Releasing Operation”.)

When the IDLE1 mode is used, setting $TRUN < PRRUN >$ to “0” to stop 9, 5 bit prescaler before “HALT” instruction reduces the power consumption.

Figure 3.3.7 illustrates the timing for releasing the halt state by interrupts in the IDLE1 mode.

Figure 3.3.7 Timing Chart of Halt Released by Interrupts in IDLE1 Mode

④ STOP mode

The STOP mode is selected to stop all internal circuits including the internal oscillator. The pin status in the STOP mode depends on setting of a bit in the watchdog timer mode register WDMOD<DRVE>. (See Figure 3.3.5 for setting of WDMOD<DRVE>.) Table 3.3.5 summarizes the state of these pins in the STOP mode.

The STOP mode is released by external interrupts (INT0). When the STOP mode is released, the system clock output starts after the warm-up time required to attain stable oscillation. The warm-up time can be set using WDMOD<WARM>. See the example of warm-up time (Table 3.3.4).

In a system which supplies stable clock generated by an external oscillator, the warm-up time can be reduced by using the setting of T45CR<QCU>.

Figure 3.3.8 illustrates the timing for releasing the halt state by interrupts during the STOP mode.

Figure 3.3.8 Timing Chart of Halt State Release by Interrupts in STOP Mode

Table 3.3.4 The Example of Warm-up Time after Releasing the Stop Mode

Clock Operation Frequency after the Stop Mode	Warm-up Time [ms]		Remark
	WDMOD<WARM> = 0	WDMOD<WARM> = 1	
fc	0.8192	3.2768	fc = 20 MHz
fc/2	1.6384	6.5536	
fc/4	3.2768	13.1072	
fc/8	6.5536	26.2144	
fc/16	13.1072	52.4288	

How to calculate the warm-up time

WDMOD<WARM> = “0”: $2^{14}/(\text{Clock operation frequency after releasing the halt in STOP mode})$

WDMOD<WARM> = “1”: $2^{16}/(\text{Clock operation frequency after releasing the halt in STOP mode})$

Table 3.3.5 Pin States in STOP Mode

Pin Name	I/O	<DRVE> = 0	<DRVE> = 1
P00 to P07	Input mode Output mode	▲ High-Z	▲ Output
P10 to P17	Input mode Output mode/A8 to A15	▲ High-Z	▲ Output
P35	Input mode Output mode	Invalid High-Z	Invalid Output
P41 to P46	Input mode Output mode	Invalid High-Z	Invalid Output
P50 to P53	Input	▲	▲
P60, P61, P63, P64	Input mode Output mode	PU* PU*	PU Output
P70, P71	Input mode Output mode	Invalid High-Z	Invalid Output
CLK	Output (<CLKEN> = 1)	High-Z	"H" level output
RESET	Input	Input	Input
EA	Input	"H" level fix	"H" level fix
X1	Input	Invalid	Invalid
X2	Output	"H" level output	"H" level output

Input: Input gate in operation. Fix input voltage to 0 or 1 so that the input pin stays constant.

Output: Output state.

Invalid: Input is not accepted.

High-Z: Output is at high impedance.

PU: Programmable pull-up pin in input gate in operation. Fix the pin to avoid through current since the input gate operates when a pull-up pin resistance is not set.

PU*: Programmable pull-up pin in input gate disable state. No through current even if the pin is set to high impedance.

▲: When a HALT instruction is executed and the CPU stops at the address of the port register, an input gate operates. Fix the pin to avoid through current, and change the program. In all other cases, input is not accepted.

Note: Port registers are used for controlling programmable pull-up. If a pin is also used for an output function (e.g., TO3) and the output function is specified, whether pull up is selected depends on the output function data. If a pin is also used for an input function, whether pull up is selected depends on the port register setting value only.

3.4 Interrupts

TLCS-900 interrupts are controlled by the CPU interrupt mask flip-flop (IFF2 to IFF0) and the built-in interrupt controller.

Altogether the TMP93CS36 has the following 30 interrupt sources:

- | |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <ul style="list-style-type: none">● Internal interrupts 9
SWI instruction, illegal instruction execution● Interrupts from external pins (INT0, INT4 to INT7) 5● Interrupts from built-in I/Os16 |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

A fixed individual interrupt vector number is assigned to each interrupt source; six levels of priority can also be assigned to each maskable interrupt. Non-maskable interrupts have a fixed priority of 7.

When an interrupt is generated, the interrupt controller sends the value of the priority of the interrupt source to the CPU. When more than one interrupt is generated simultaneously, the interrupt controller sends the value of the highest priority (7 for non-maskable interrupts is the highest) to the CPU.

The CPU compares the value of the priority sent with the value in the CPU interrupt mask register <IFF2:0>. If the value is greater than that the CPU interrupt mask register, the interrupt is accepted. The value in the CPU interrupt mask register <IFF2:0> can be changed using the EI instruction (Executing EI n changes the contents of <IFF2:0> to n). For example, programming EI 3 enables acceptance of maskable interrupts with a priority of 3 or greater, and non-maskable interrupts which are set in the interrupt controller. The DI instruction (<IFF2:0> = 7) operates in the same way as the EI 7 instruction. Since the priority values for maskable interrupts are 0 to 6, the DI instruction is used to disable acceptance of maskable interrupts. The EI instruction becomes effective immediately after execution (with the TLCS-90, the EI instruction becomes effective after execution of the subsequent instruction).

In addition to the general-purpose interrupt processing mode described above, there is also a micro DMA processing mode. Micro DMA is a mode used by the CPU to automatically transfer byte or word data. It enables the CPU to process interrupts such as data saves to built-in I/Os at high speed.

Figure 3.4.1 is a flowchart showing overall interrupt processing.

Figure 3.4.1 Interrupt Processing Flowchart

3.4.1 General-purpose Interrupt Processing

When accepting an interrupt, the CPU operates as follows. In the cases of software interrupts or interrupts generated by the CPU because of attempts to execute illegal instructions, the following steps (1) and (3) are not executed.

- (1) The CPU reads the interrupt vector from the interrupt controller. When more than one interrupt with the same level is generated simultaneously, the interrupt controller generates interrupt vectors in accordance with the default priority (which is fixed as follows: the smaller the vector value, the higher the priority), then clears the interrupt request.
- (2) The CPU pushes the program counter and the status register to the system stack area. (Area indicated by the system mode stack pointer (XSP).)
- (3) The CPU sets a value in the CPU interrupt mask register <IFF2:0> that is higher by 1 than the value of the accepted interrupt level. However, if the value is 7, 7 is set without an increment.
- (4) The CPU increments the INTNEST (Interrupt nesting counter).
- (5) The CPU jumps to address stored at FFFF00H + interrupt vector, then starts the interrupt processing routine.

The following diagram shows all the above processing state number.

Bus Width of Stack Area	Bus Width of Interrupt Vector Area	Interrupt Processing State Number
8 bits	8 bits	35
	16 bits	31
16 bits	8 bits	29
	16 bits	25

To return to the main routine after completion of the interrupt processing, the RETI instruction is usually used. Executing this instruction restores the contents of the program counter and the status registers and decrements INTNEST (Interrupt nesting counter).

Though acceptance of non-maskable interrupts cannot be disabled by program, acceptance of maskable interrupts can. A priority can be set for each source of maskable interrupts. The CPU accepts an interrupt request with a priority higher than the value in the CPU mask register <IFF2:0>. The CPU mask register <IFF2:0> is set to a value higher by 1 than the priority of the accepted interrupt. Thus, if an interrupt with a level higher than the interrupt being processed is generated, the CPU accepts the interrupt with the higher level, causing interrupt processing to nest.

The interrupt request with a priority higher than the accepted now interrupt during the CPU is processing above (1) to (5) is accepted before the 1'st instruction in the interrupt processing routine, causing interrupt processing to nest. (This is the same case of over lapped each non-maskable interrupt (level "7").) (Non-maskable interrupts (Level "7") can be accepted, causing interrupt processing to rest.)

The CPU does not accept an interrupt request of the same level as that of the interrupt being processed.

Resetting initializes the CPU mask registers <IFF2:0> to 7; therefore, maskable interrupts are disabled.

The following ① to ⑤ show a flowchart of interrupt processing.

(1) Maskable interrupt

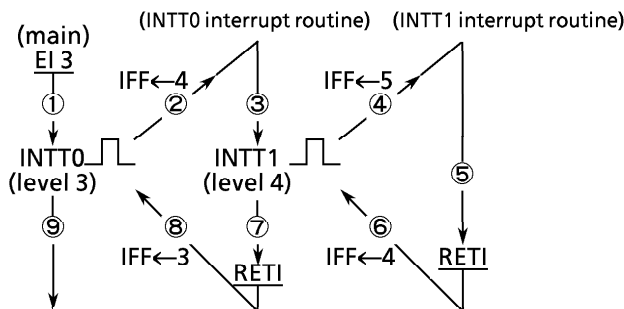

During execution of the main program, the CPU accepts an interrupt request. The CPU increments the IFF so that the interrupts of level 1 are not accepted during processing the interrupt routine.

(2) Non-maskable interrupt

DI instruction is executed in the main program, so that the interrupts of only level 7 are accepted. The CPU does not increment the IFF even if the CPU accepts an interrupt request of level 7.

(3) Interrupt nesting

During processing the interrupts of level 3, the IFF is set to 4. When an interrupt with a level higher than level 4 is generated, the CPU accepts the interrupt with the higher level, causing interrupt processing to nest.

(4) Software interrupt

The CPU accepts the software interrupt request during DI status (IFF = 7) because of the level 7. The IFF is not changed by the software interrupts.

(5) Interrupt sampling timing

If an interrupt with a level higher than the interrupt being processed is generated, the CPU accepts the interrupt with the higher level. The program counter which returns at ⑤ is the start address of INTT0 interrupt routine.

Example: (underline): Instruction
 ①, ②, ...: Execution flow

The addresses FFFF00H to FFFFFFFH (256 bytes) of the TMP93CS36 are assigned for interrupt vector area.

Table 3.4.1 TMP93CS36 Interrupt Table

Default Priority	Type	Interrupt Source	Vector Value "v"	Address Refer to Vector	Micro DMA Start Vector
1	Non-maskable	Reset or SWI0 instruction	0 0 0 0 H	FFFF00H	–

Setting to reset/interrupt vector

① Reset vector

FFFF00H	PC (7:0)
FFFF01H	PC (15:8)
FFFF02H	PC (23:16)
FFFF03H	XX

② Interrupt vector (Except reset vector)

Address refer to vector	+ 0	PC (7:0)
	+ 1	PC (15:8)
	+ 2	PC (23:16)
	+ 3	XX

XX: Don't care

(Setting example)

Sets the reset vector: FF0000H, INTAD vector : 123456H.

```
ORG    FFFF00H
DL     FF0000H    ; Reset = FF0000H
```

```
ORG    FFFF78H
DL     123456H    ; INTAD = 123456H
```

```
ORG    FF0000H
LD     A, B
```

Note:

ORG, DL are assembler directives.

```
ORG    FF9ABCH
LD     B, C
```

ORG: Control location counter

DL: Defines long word (32-bit) data

```
ORG    123456H
LD     C, A
```

3.4.2 Micro DMA

In addition to the conventional interrupt processing, the TLCS-900 also has a micro DMA function. When an interrupt is accepted, in addition to an interrupt vector, the CPU receives data indicating whether processing is micro DMA mode or general-purpose interrupt. If micro DMA mode is requested, the CPU performs micro DMA processing.

The TLCS-900 can process at very high speed because it has transfer parameters in dedicated registers in the CPU. Since those dedicated registers are assigned as CPU control registers, they can only be accessed by the LDC instruction.

(1) Micro DMA operation

Micro DMA operation starts when the accepted interrupt vector value matches the micro DMA start vector value. The micro DMA has four channels so that it can be set for up to four types of interrupt source.

When a micro DMA interrupt is accepted, data is automatically transferred from the transfer source address to the transfer destination address set in the control register, and the transfer counter is decremented. If the value in the counter after decrementing is other than 0, micro DMA processing is completed; if the value in the counter after decrementing is 0, general-purpose interrupt processing is performed.

32-bit control registers are used for setting transfer source/destination addresses. However, the TLCS-900 has only 24 address pins for output. A 16-Mbyte space is available for the micro DMA.

There are two data transfer modes: One-byte mode and one-word mode. Incrementing, decrementing, and fixing the transfer source/destination address after transfer can be done in both modes. Therefore data can easily be transferred between I/O and memory and between I/Os. For details of transfer modes, see the description of transfer mode registers.

The transfer counter has 16 bits, so up to 65536 transfers (The maximum when the initial value of the transfer counter is 0000H) can be performed for one interrupt source by micro DMA processing.

When the transfer counter is decremented to "0" after data is transferred with micro DMA, general-purpose interrupt processing is performed. After processing the general-purpose interrupt, starting the interrupts of the same channel restarts the transfer counter from 65536. If necessary, reset the transfer counter.

Interrupt sources processed by micro DMA processing are those with the micro DMA start vectors listed in Table 3.4.1.

The following timing chart is a micro DMA cycle of the transfer address increment mode (Condition: MAX mode, 16-bit bus width for 16 Mbytes, 0 waits).

(2) Register configuration (CPU control register)

These control register can not be set only "LDC cr, r" instruction.

Example:

```
LD    XWA, 100H
LDC   DMAS0, XWA
LD    XWA, 50H
LDC   DMAD0, XWA
LD    WA, 40H
LDC   DMAC0, WA
LD    A, 05H
LDC   DMAM0, A
```

(3) Transfer mode register details

Note: When setting values for this register, set the upper 4 bits to 0.

Z: 0 = Byte transfer, 1 = Word transfer

Execution time (Min) at 20 MHz

0	0	0	Z	Transfer destination address INC mode for I/O to memory (DMADn +) ← (DMASn) DMACn ← DMACn - 1 if DMACn = 0 then INT.	16 states (1.6 μs)
0	0	1	Z	Transfer destination address DEC mode for I/O to memory (DMADn -) ← (DMASn) DMACn ← DMACn - 1 if DMACn = 0 then INT.	16 states (1.6 μs)
0	1	0	Z	Transfer source address INC mode for memory to I/O (DMADn) ← (DMASn +) DMACn ← DMACn - 1 if DMACn = 0 then INT.	16 states (1.6 μs)
0	1	1	Z	Transfer source address DEC mode for memory to I/O (DMADn) ← (DMASn -) DMACn ← DMACn - 1 if DMACn = 0 then INT.	16 states (1.6 μs)
1	0	0	Z	Fixed address mode for I/O to I/O (DMADn) ← (DMASn) DMACn ← DMACn - 1 if DMACn = 0 then INT.	16 states (1.6 μs)
1	0	1	1	Counter mode for interrupt counter DMASn ← DMASn + 1 DMACn ← DMACn - 1 if DMACn = 0 then INT.	11 states (1.1 μs)

(1 state = 100 ns at 20 MHz, High-frequency mode)

Note 1: n: corresponds to micro DMA channels 0 to 3.

DMADn + / DMASn +: Post-increment (Increments register value after transfer.)

DMADn - / DMASn -: Post-decrement (Decrement register value after transfer.)

Note 2: Execution time: When setting source address/destination address area to 16-bit bus, 0 waits.

Clock condition: fc = 20 MHz, Clock gear: 1 (fc)

Note 3: Do not use the codes other than the above mentioned codes for transfer mode register.

3.4.3 Interrupt Controller

Figure 3.4.2 is a block diagram of the interrupt circuits. The left half of the diagram shows the interrupt controller; the right half includes the CPU interrupt request signal circuit and the halt release signal circuit.

Each interrupt channel (Total of 22 channels) in the interrupt controller has an interrupt request flip-flop, interrupt priority setting register, and a register for storing the micro DMA start vector. The interrupt request flip-flop is used to latch interrupt requests from peripheral devices. The flip-flop is cleared to 0 at reset, when the CPU reads the interrupt channel vector after the acceptance of interrupt, or when the CPU executes an instruction that clears the interrupt of that channel. (Writes 0 in the clear bit of the interrupt priority setting register).

For example, to clear the INT0 interrupt request, set the register **after the DI instruction** as follows.

For example, to clear the INT0 interrupt request, set the register after the DI instruction as follows.

```
INTE0AD ← ---- 0 --- B
```

The status of the interrupt request flip-flop is detected by reading the clear bit. Detects whether there is an interrupt request for an interrupt channel.

The interrupt priority can be set by writing the priority in the interrupt priority setting register (e.g., INTE0AD, INTE45, etc.) provided for each interrupt source. Interrupt levels to be set are from 1 to 6. Writing 0 or 7 as the interrupt priority disables the corresponding interrupt request. The priority of the non-maskable interrupt (Watchdog timer) is fixed to 7. If interrupt requests with the same interrupt level are generated simultaneously, interrupts are accepted in accordance with the default priority. (The smaller the vector value, the higher the priority.)

The interrupt controller sends the interrupt request with the highest priority among the simultaneous interrupts and its vector address to the CPU. The CPU compares the priority value <IFF2:0> set in the Status Register by the interrupt request signal with the priority value sent; if the latter is higher, the interrupt is accepted. Then the CPU sets a value higher than the priority value by 1 in the CPU SR<IFF2:0>. Interrupt requests where the priority value equals or is higher than the set value are accepted simultaneously during the previous interrupt routine. When interrupt processing is completed (after execution of the RETI instruction), the CPU restores the priority value saved in the stack before the interrupt was generated to the CPU SR<IFF2:0>.

The interrupt controller also has four registers used to store the micro DMA start vector. These are I/O registers; unlike other micro DMA registers (DMAS, DMAD, DMAM, and DMAC). Writing the start vector of the interrupt source for the micro DMA processing (See Table 3.4.1), enables the corresponding interrupt to be processed by micro DMA processing. The values must be set in the micro DMA parameter registers (e.g., DMAS and DMAD) prior to the micro DMA processing.

←Interrupt source
←Bit symbol
←Read/Write
←After reset

IxxM2	IxxM1	IxxM0	Function (Write)
0	0	0	Prohibits interrupt request.
0	0	1	Sets interrupt request level to "1".
0	1	0	Sets interrupt request level to "2".
0	1	1	Sets interrupt request level to "3".
1	0	0	Sets interrupt request level to "4".
1	0	1	Sets interrupt request level to "5".
1	1	0	Sets interrupt request level to "6".
1	1	1	Prohibits interrupt request.

IxxC	Function (Read)	Function (Write)
0	Indicates no interrupt request.	Clears interrupt request flag.
1	Indicates interrupt request.	----- Don't care -----

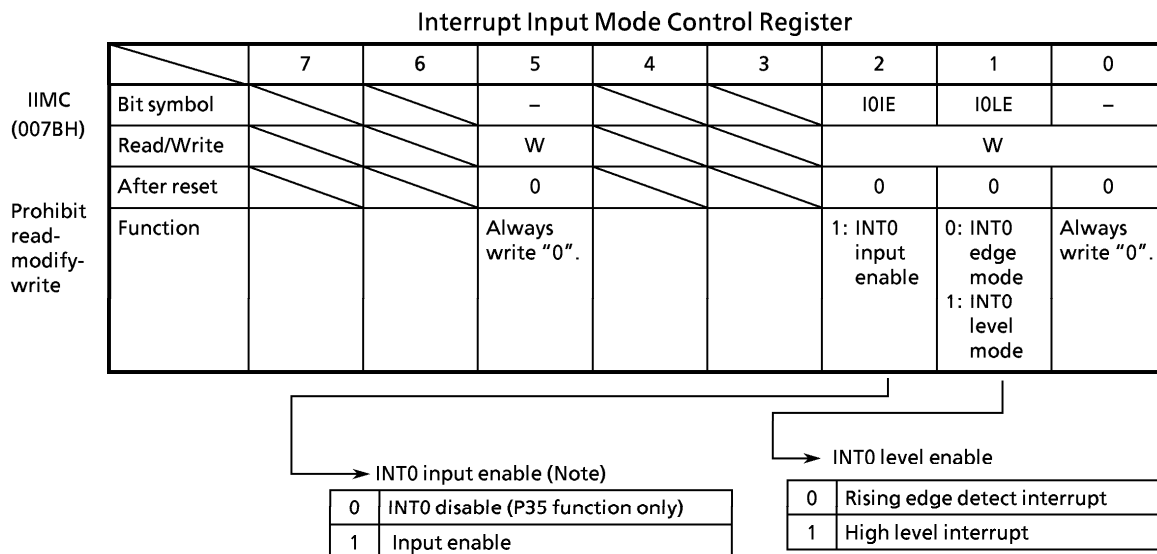

Note 1: Read-modify-write is prohibited.

Note 2: Note about clearing interrupt request flag

The interrupt request flag of INTRX0, INTRX1 are not cleared by writing "00" to IXXC because of they are level interrupts. They can be cleared only by resetting or reading SCBUF_n.

Figure 3.4.3 Interrupt Priority Setting Register

(2) External interrupt control

Note 1: The INTO pin can also be used for standby release as described later. Even if the pin is not used for standby release, setting this register to "0" maintains the port function during standby mode.

Note 2: Case of changing from level to edge for INTO pin mode (<IOLE> "1" → "0")
 Execution example:

```
LD (INTE0AD) , xxx0000B ; INTO disable, clean the request flag
LD (IIMC) , xxx010xB ; Change from level to edge
LD (INTE0AD) , xxx0nnnB ; Set interrupt level "n" for INTO, clear the request flag
```

Note 3: IIMC<bit 7:3> is always read as "1".

Note 4: See Electrical characteristics in section 4 for external 4 for external interrupt input pulse.

Figure 3.4.4 Interrupt Input Mode Control Register

Table 3.4.2 Setting of External Interrupt Pin Functions

Interrupt	Shared Pin	Mode	Setting Method
INT0	P35	Rising edge	IIMC<IOLE> = 0, <IOIE> = 1
		Level	IIMC<IOLE> = 1, <IOIE> = 1

INT6	P45	Rising edge	T5MOD<CAP34M1,0> = 0, 0 or 0, 1 or 1, 1
		Falling edge	T5MOD<CAP34M1, 0> = 1, 0
INT7	P46	Rising edge	—

(3) Micro DMA start vector

When the CPU reads the interrupt vector after accepting an interrupt, it simultaneously compares the interrupt vector (Bits 2 to 6 of the interrupt vector) with each channel's micro DMA start vector. When the two match, the interrupt from the channel whose value matched is processed in micro DMA mode. If the interrupt vector matches more than one channel, the channel with the lower channel number has a higher priority.

Figure 3.4.5 Micro DMA Start Vector Register

(4) Notes

The instruction execution unit and the bus interface unit of this CPU operate independently of each other. Therefore, if the instruction used to clear an interrupt request flag of an interrupt is fetched before the interrupt is generated, it is possible that the CPU might execute the fetched instruction to clear the interrupt request flag while reading the interrupt vector after accepting the interrupt.

To avoid the above occurring, clear the interrupt request flag by entering the instruction to clear the flag after the DI instruction. In the case of setting an interrupt enable again by EI instruction after the execution of clearing instruction, execute EI instruction after clearing instruction and following more than one instruction are executed. When EI instruction is placed immediately after clearing instruction, an interrupt becomes enable before interrupt request flags are cleared.

In the case of changing the value of the interrupt mask register <IFF2:0> by execution of POP SR instruction, disable an interrupt by DI instruction before execution of POP SR instruction.

3.5 Functions of Ports

The TMP93CS36 has 33 bits for I/O ports.

These port pins have I/O functions for the built-in CPU and internal I/Os as well as general-purpose I/O port functions. Table 3.5.1 lists the function of each port pin. Table 3.5.2 lists I/O registers and specification.

Resetting makes the port pins listed below function as general-purpose I/O ports.

I/O pins programmable for input or output are set to input ports.

To set port pins for built-in functions, a program is required.

Table 3.5.1 Functions of Ports

(PU = with programmable
pull-up resistor)

Port Name	Pin Name	Pin No.	Direction	R	Direction Setting Unit	Pin Name for Built-in Function
Port0	P00 to P07	8	I/O	–	Bit	AD0 to AD7
Port1	P10 to P17	8	I/O	–	Bit	AD8 to AD15/A8 to A15
Port3	P35	1	I/O	–	Bit	INT0
Port4	P41	1	I/O	–	Bit	TO3
	P42	1	I/O	–	Bit	T14/INT4
	P43	1	I/O	–	Bit	T15/INT5
	P44	1	I/O	–	Bit	TO4
	P45	1	I/O	–	Bit	T16/INT6
	P46	1	I/O	–	Bit	T17/INT7
Port5	P50 to P52	3	Input	–	(Fixed)	AN0 to AN2, AN3/ $\overline{\text{ADTRG}}$
	P53	1	Input	–	(Fixed)

Note 1: Using P35 pin as INT0, IIMC register hs to be set enable interrupt.

Note 2: Using P50 to P53 pins as input channels for the AD converter, the channels are selected by ADMOD1 <ADCH2:0>.

3.5.1 Port 0 (P00 to P07)

Port 0 is an 8-bit general-purpose I/O port. I/O can be set on a bit basis using the control register P0CR. Resetting sets all bits of P0CR to 0 and sets port 0 to input mode. Figure 3.5.3 shows the registers for Port 0. To access external memory area, port 0 functions as an address data bus (AD0 to AD7), and all bits of the control register P0CR are cleared to 0 automatically. Therefore please don't access external memory area.

Figure 3.5.1 Port 0

3.5.2 Port 1 (P10 to P17)

Port 1 is an 8-bit general-purpose I/O port. I/O can be set on a bit basis using control register P1CR and function register P1FC. Resetting sets all bits of output latch P1, control register P1CR, and function register P1FC to 0 and sets port 1 to input mode.

Figure 3.5.3 shows the registers for port 1.

Figure 3.5.2 Port 1

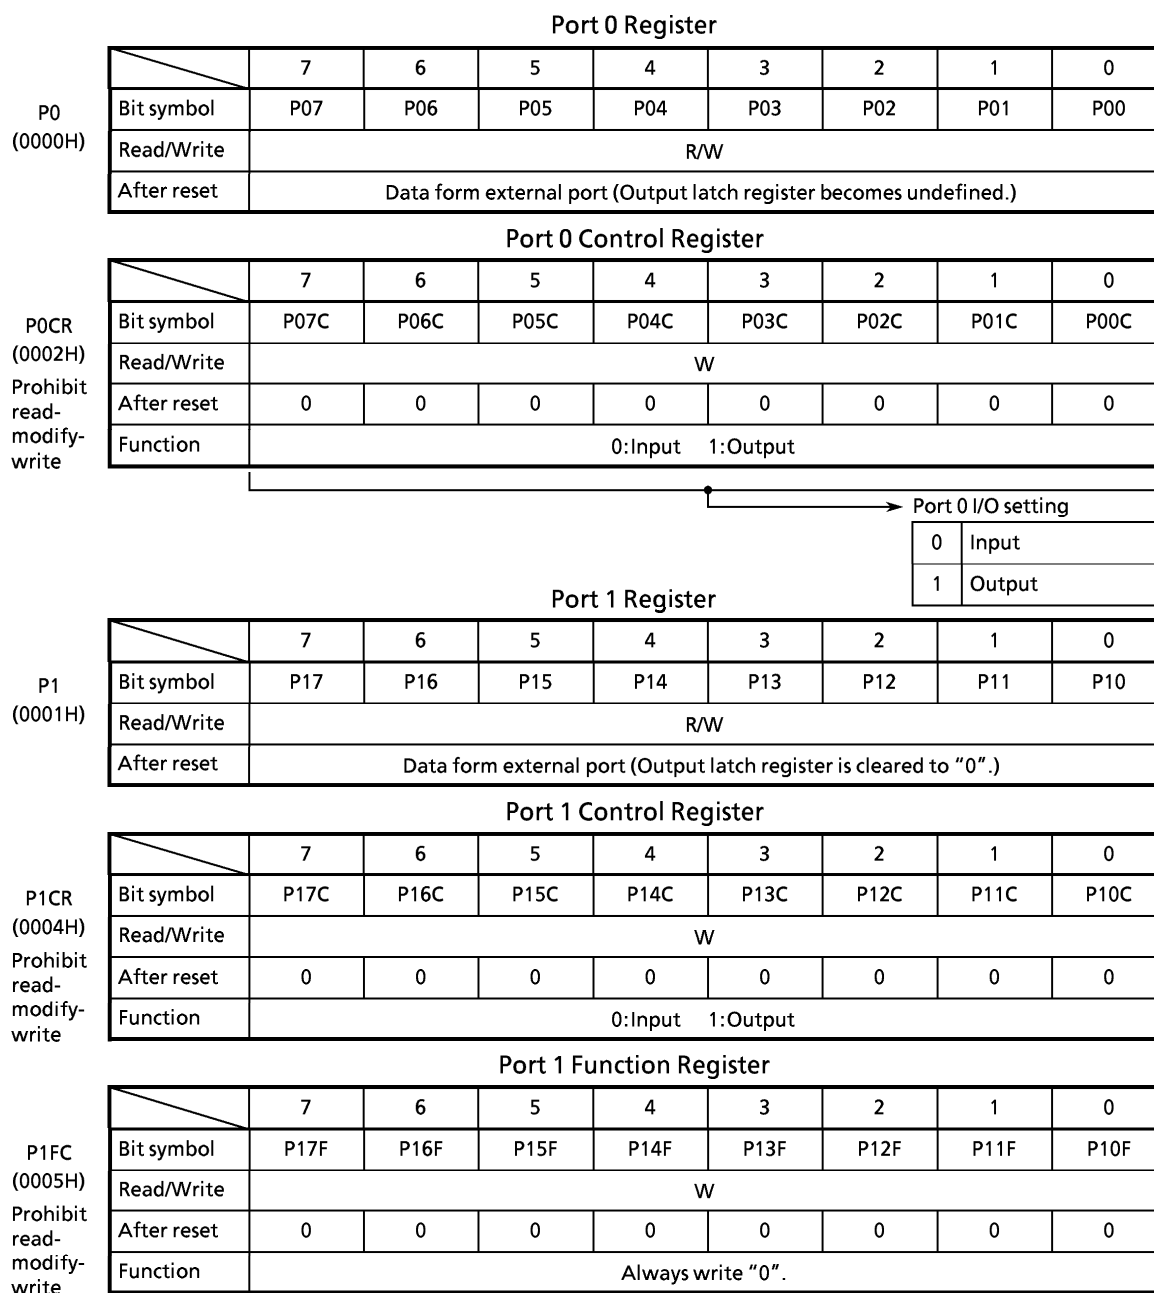

Figure 3.5.3 Registers for Ports 0 and 1

3.5.3 Port 3 (P35)

Port 3 is an 1-bit general-purpose I/O port.

I/O can be set on a bit basis. I/O is set using control register P3CR and function register P3FC. Resetting resets all bits of output latch P3, control register P3CR (Bits 0 and 1 are unused), and function register P3FC to 0.

P35 (INT0)

Port 35 is a general-purpose I/O port, and also used as an INT0 pin for external interrupt request input.

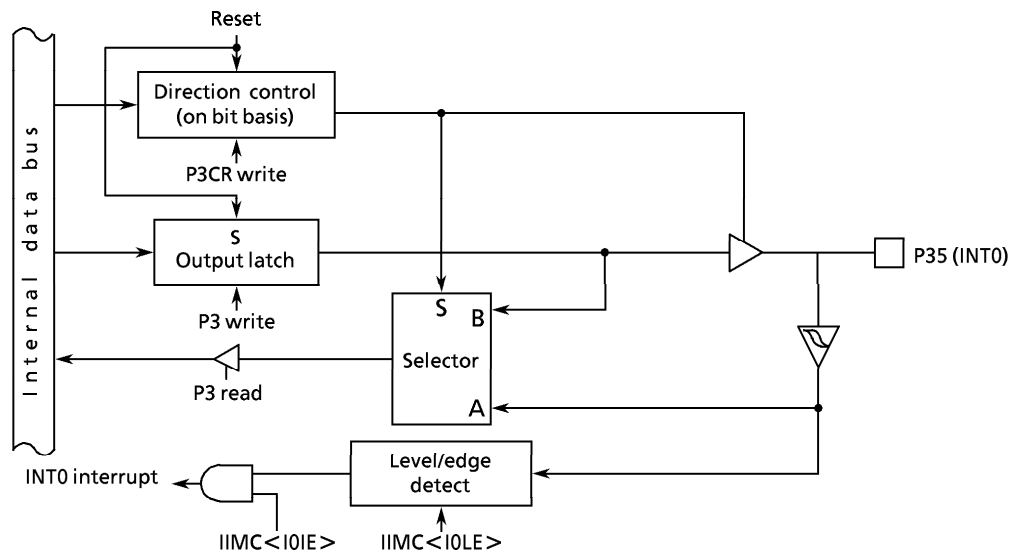

Figure 3.5.4 Port 35

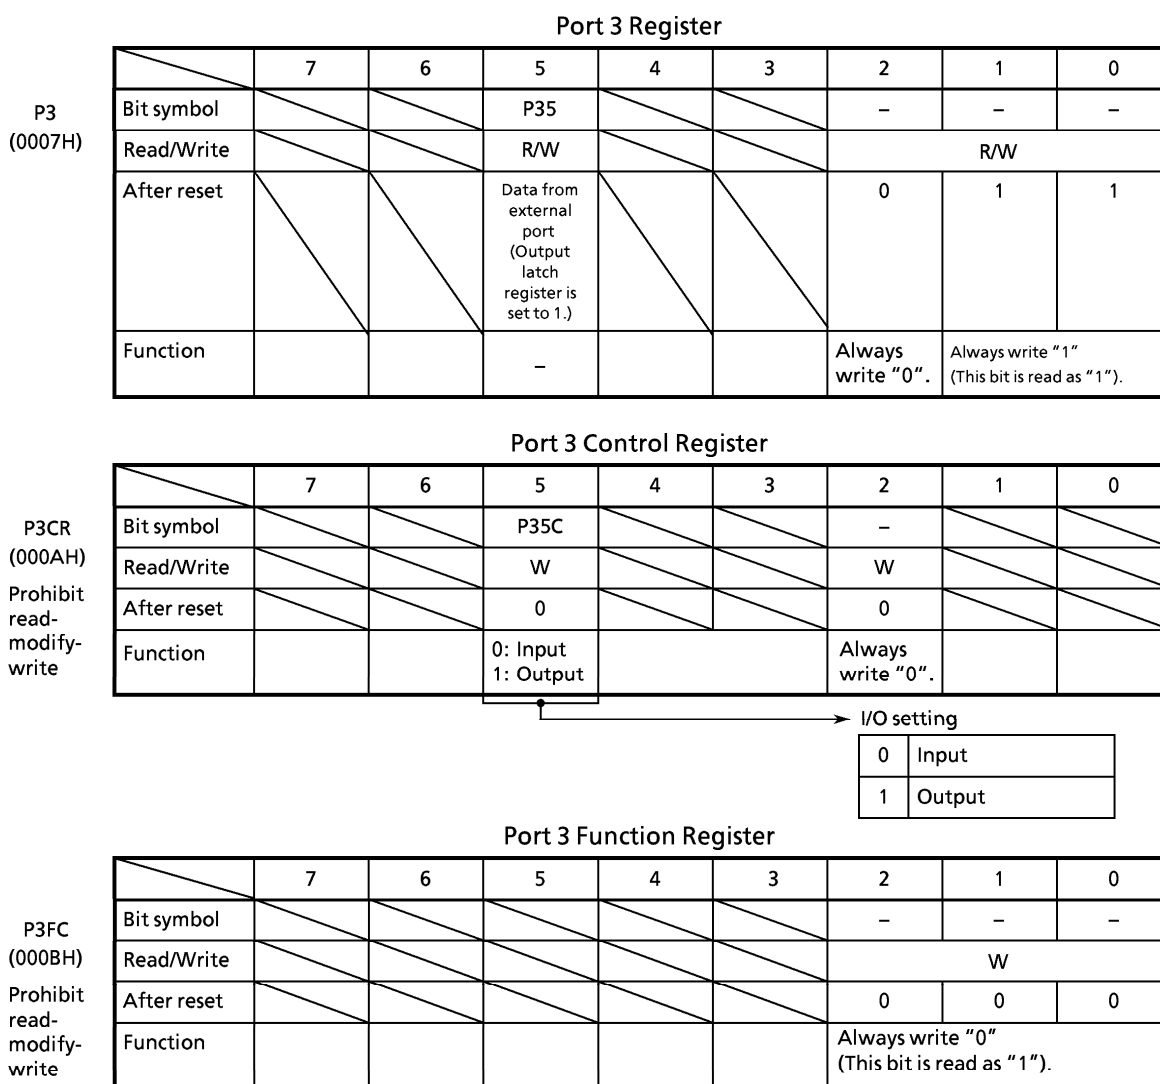

Figure 3.5.5 Registers for Port 3

3.5.4 Port 4 (P41 to P46)

Port 4 is a 6-bit general-purpose I/O port. I/O can be set on bit basis. Resetting sets Port 4 to the input port. In addition to functioning as a general-purpose I/O port, Port 4 also shares functions as 16-bit timer 4 and 5 clocks, an output for 8-bit timer F/F 3, 16-bit timer F/F4. Writing 1 in the corresponding bit of the Port 4 function register (P4FC) enables output of the timer.

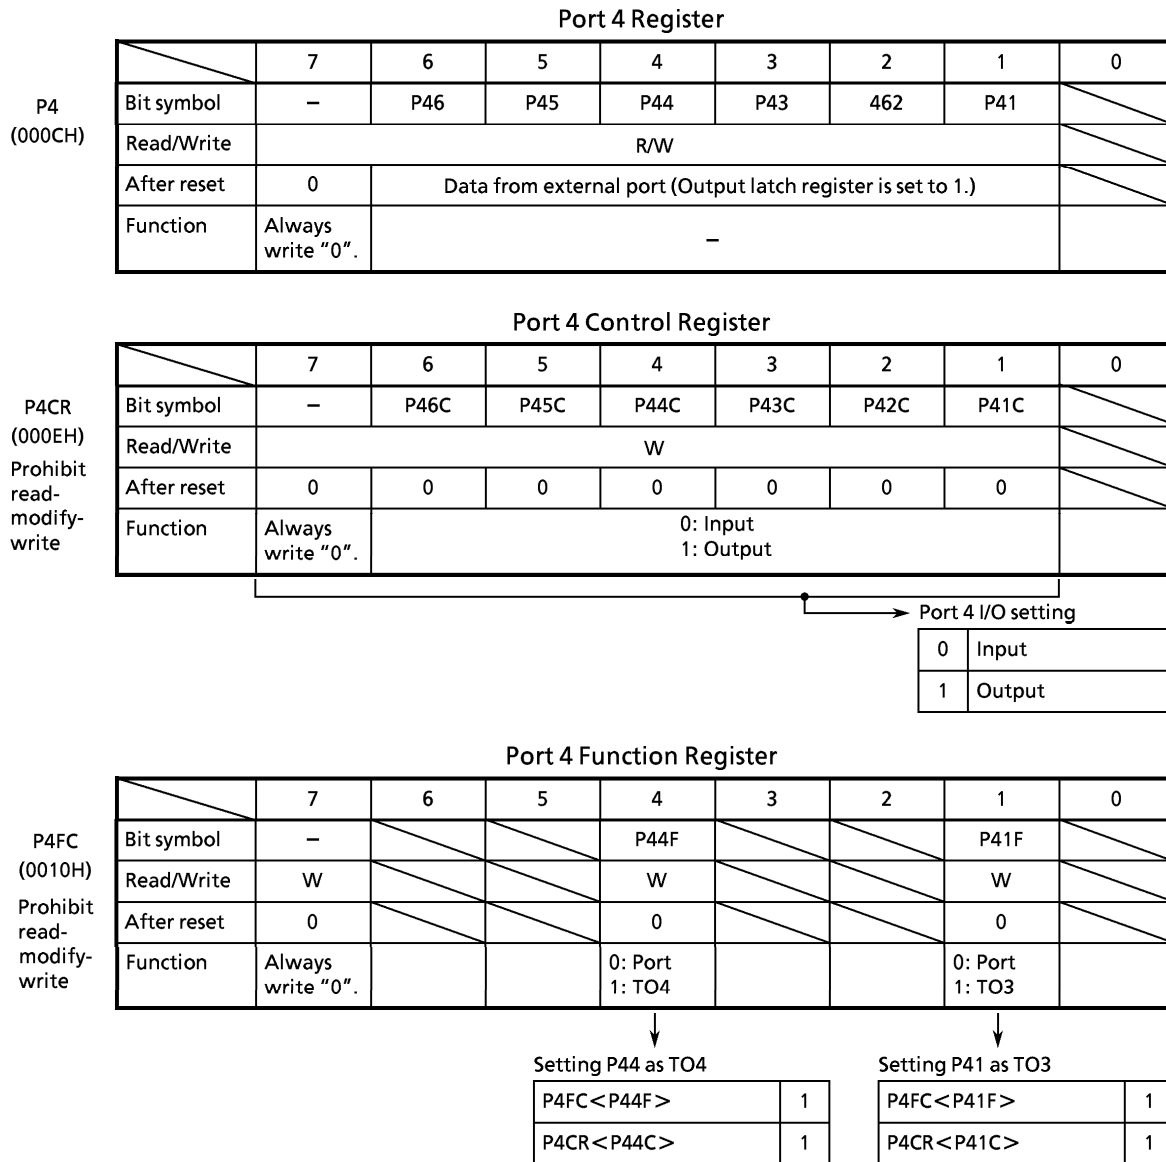

Figure 3.5.6 Port 4 (P41 to P46)

Note: P42/TI4, P43/TI5, P45/TI6, P46/TI7 pin does not have a register changing PORT/FUNCTION. For example, when it is used as an input port, the input signal for port is inputted to 8-/16-bit timer as a timer input.

Figure 3.5.7 Register for Port 4

3.5.5 Port 5 (P50 to P53)

Port 5 is an 4-bit input port, also used as an analog input pin for the internal AD converter. Additionally, P53 is also used as an analog conversion external trigger input pin ($\overline{\text{ADTRG}}$).

Figure 3.5.8 Port 5

	7	6	5	4	3	2	1	0

Bit symbol					R			
Read/Write					R			
After reset					Data from external port			

Note: The input channel selection of AD converter is set by AD converter mode register ADMOD1.

Figure 3.5.9 Registers for Port 5

3.5.6 Port 6 (P60, P61, P63, P64)

Port 60, 61, 63, 64 is a 4-bit general-purpose I/O port. I/Os can be set on a bit basis.

Resetting sets P60, P61, P63, P64 to an input port and connects a pull-up resistor.

It also sets all bits of the output latch register to 1.

In addition to functioning as a general-purpose I/O port, P60, P61, P63, P64 can also share function as an I/O for serial channels 0 and 1. Writing "1" in the corresponding bit of the port 6 function register (P6FC) enables this function.

Resetting sets the function register value to "0" and sets all bits to input ports.

(1) Port 60 (TXD0), 63 (TXD1)

Ports 60 and 63 also function as serial channel TXD output pins in addition to I/O ports.

They have a programmable open-drain function.

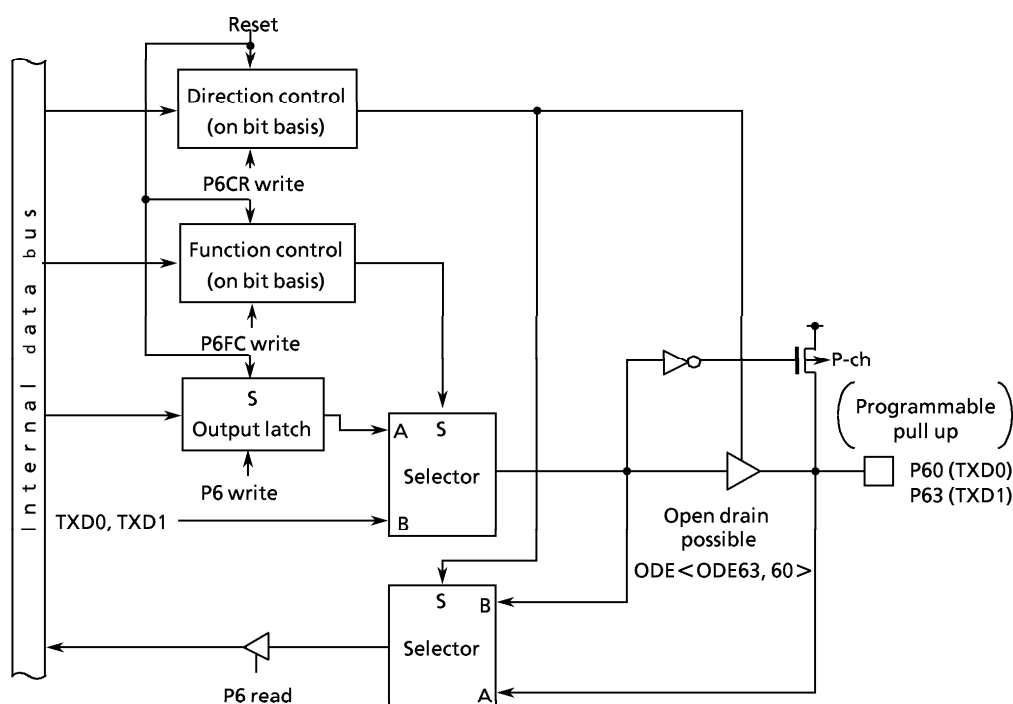

Figure 3.5.10 Ports 60 and 63

(2) Port 61 (RXD0), 64 (RXD1)

Port 61 and 64 are I/O ports, and also used as RXD input pins for serial channels.

Figure 3.5.11 Ports 61 and 64

Note 2: To set the TXD pin to open drain, write "1" in bit0 (for TXD0 pin) or bit1 (for TXD1 pin) of the ODE register.
P61/RXD0, P64/RXD1 pins do not have a register changing PORT/FUNCTION.
When using as input ports, the serial receive data is input to SIO.

Figure 3.5.12 Register for Port 6

3.5.7 Port 7 (P70, P71)

Port 7 is an 2-bit general-purpose I/O port. I/O can be set on a bit basis. Port 7 can output large current and drive LED directly. Resetting sets the function register P7CR to 0, and all bits to input ports.

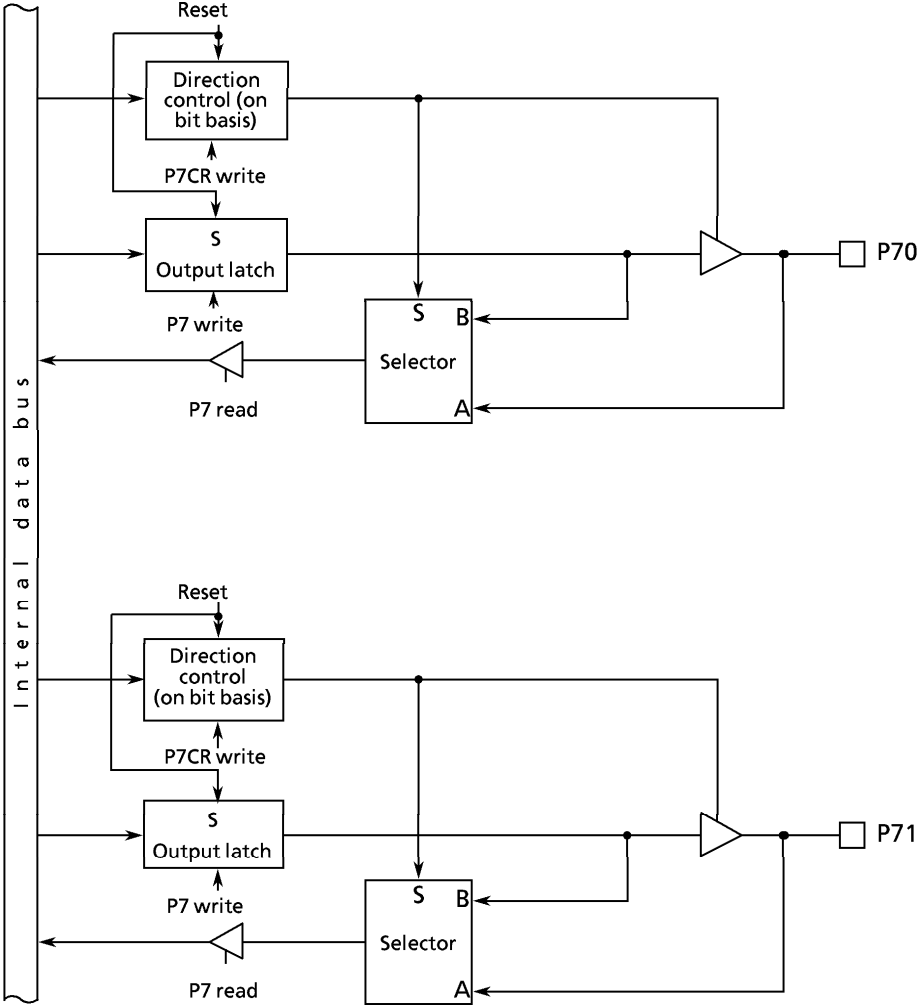

Figure 3.5.13 Port 70 to 71

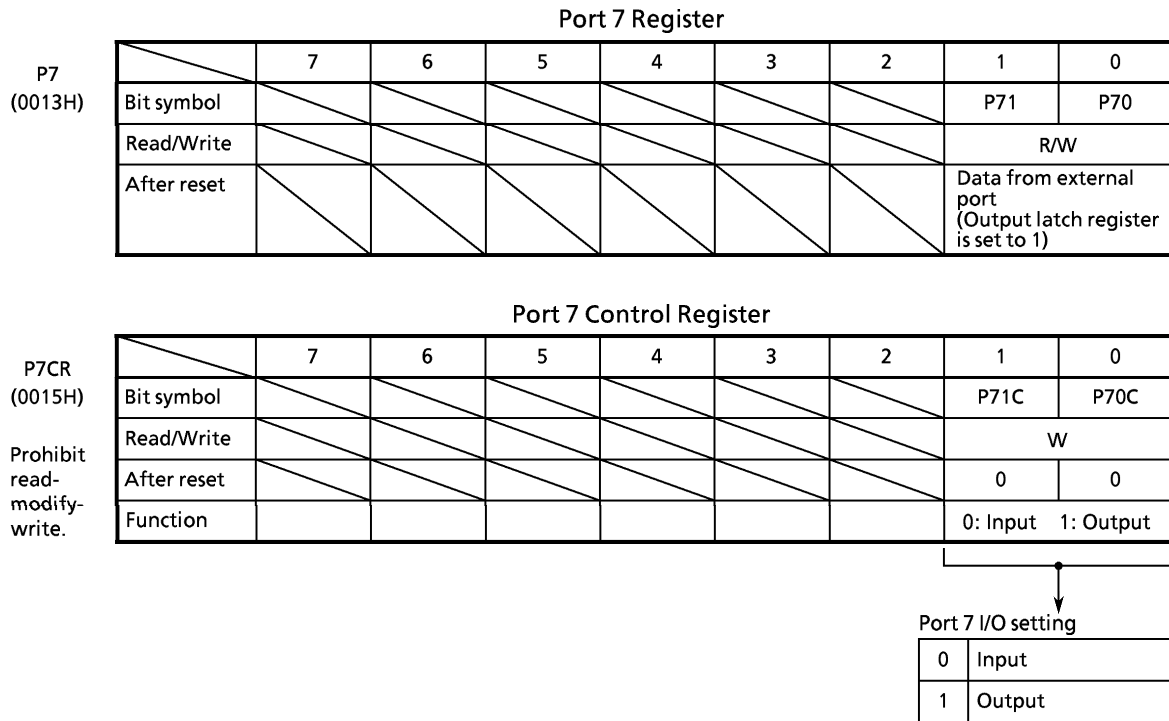

Figure 3.5.14 Registers for Port 7

3.6 8-Bit Timers

The TMP93CS36 contains four 8-bit timers (Timers 0, 1, 2, 3), each of which can be operated independently. The cascade connection allows these timers to be used as 16-bit timer. The following four operating modes are provided for the 8-bit timers.

- 8-bit interval timer mode (4 timers)
 - 16-bit interval timer mode (2 timers)
 - 8-bit programmable square wave pulse generation (PPG: Variable duty with variable cycle) output mode (1 timer)
 - 8-bit pulse width modulation (PWM: Variable duty with constant cycle) output mode (1 timer)
- } Variable combination
(8 bits×2, 16 bits×1, etc.)

Figure 3.6.1 shows the block diagram of 8-bit timer (Timer 0, 1), and Figure 3.6.2 shows the block diagram of 8-bit timer (Timer 2, 3).

Each interval timer consists of an 8-bit up counter, 8-bit comparator, and 8-bit timer register. Besides, timer flip-flops (TFF1, TFF3), are provided for pair of timer 0/1 and 2/3.

Among the input clock sources for the interval timers, the internal clocks of ϕ T1, ϕ T4, ϕ T16, and ϕ T256 are obtained from the 9-bit prescaler shown in Figure 3.6.3.

The operation modes and timer flip-flops of the 8-bit timer are controlled by five control registers T10MOD, T32MOD, TFFCR, TRUN and TRDC.

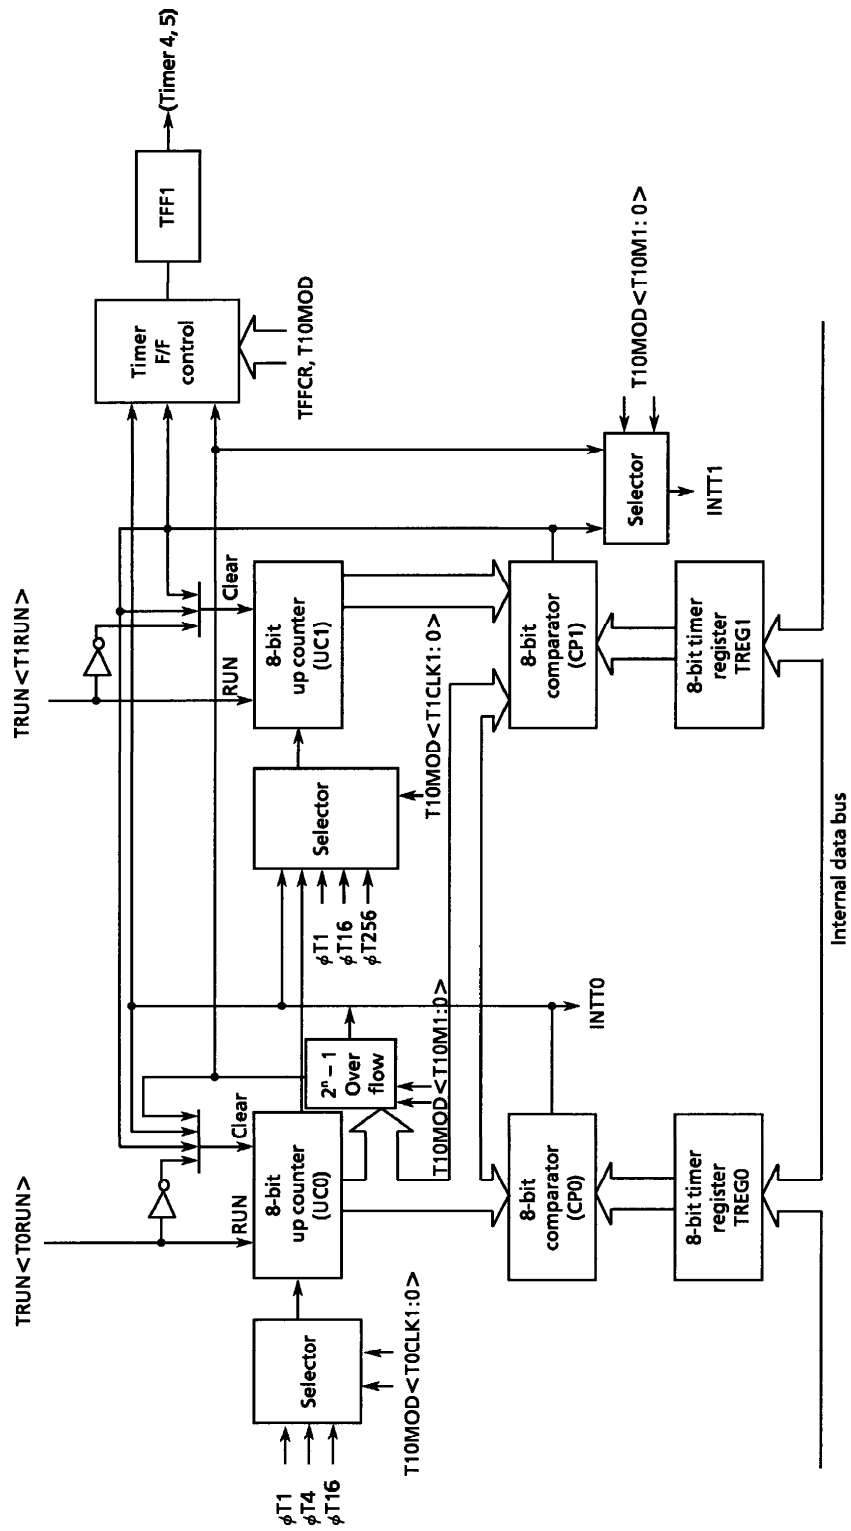

Figure 3.6.1 Block Diagram of 8-Bit Timers (Timers 0 and 1)

Figure 3.6.2 Block Diagram of 8-Bit Timers (Timers 2 and 3)

① Prescaler

There are 9-bit prescaler and prescaler clock selection registers to generate input clock for 8-bit timer 0, 1, 2, 3, 16-bit timer 4, 5 and serial interface 0, 1.

Figure 3.6.3 shows the block diagram. Table 3.6.1 shows prescaler clock resolution into 8-, 16-bit timer.

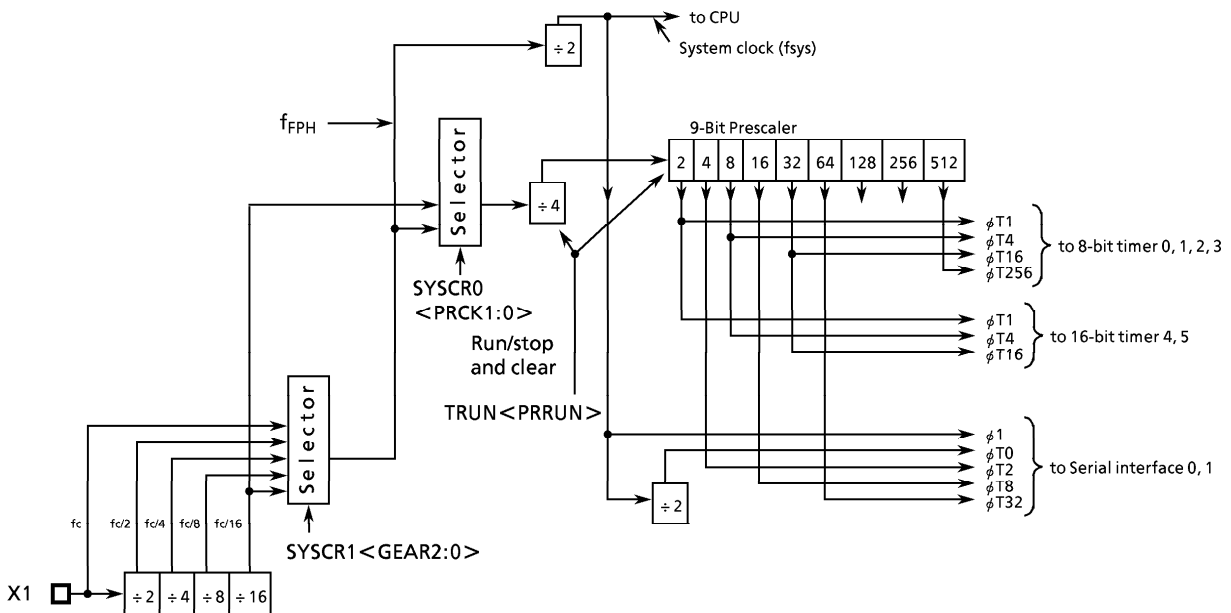

Figure 3.6.3 The Block Diagram of Prescaler

Table 3.6.1 Prescaler Clock Resolution to 8-, 16-Bit Timer

at $f_c = 20 \text{ MHz}$

Select Prescaler Clock <PRCK1:0>	Gear Value <GEAR2:0>	Prescaler Clock Resolution			
		$\phi T1$	$\phi T4$	$\phi T16$	$\phi T256$

	001 ($f_c/2$)	$f_c/2^4$ (0.8 μs)	$f_c/2^6$ (3.2 μs)	$f_c/2^8$ (12.8 μs)	$f_c/2^{12}$ (204.8 μs)
	010 ($f_c/4$)	$f_c/2^5$ (1.6 μs)	$f_c/2^7$ (6.4 μs)	$f_c/2^9$ (25.6 μs)	$f_c/2^{13}$ (409.6 μs)
	011 ($f_c/8$)	$f_c/2^6$ (3.2 μs)	$f_c/2^8$ (12.8 μs)	$f_c/2^{10}$ (51.2 μs)	$f_c/2^{14}$ (819.2 μs)
	100 ($f_c/16$)	$f_c/2^7$ (6.4 μs)	$f_c/2^9$ (25.6 μs)	$f_c/2^{11}$ (102.4 μs)	$f_c/2^{15}$ (1.6384 ms)
10 ($f_c/16$ clock)	XXX	$f_c/2^7$ (6.4 μs)	$f_c/2^9$ (25.6 μs)	$f_c/2^{11}$ (102.4 μs)	$f_c/2^{15}$ (1.6384 ms)
XXX: Don't care		<div style="display: flex; justify-content: space-between; align-items: center;"> <div style="width: 40%;"></div> <div style="width: 30%; text-align: center;">16-bit timer</div> <div style="width: 30%;"></div> </div> <div style="display: flex; justify-content: space-between; align-items: center; margin-top: 5px;"> <div style="width: 40%;"></div> <div style="width: 60%; text-align: center;">8-bit timer</div> </div>			

The clock selected among f_{PPH} clock and $f_c/16$ clock is divided by 4 and input to this prescaler. This is selected by prescaler clock selection register SYSCR0<PRCK1:0>.

Resetting sets <PRCK1:0> to "00", therefore $f_{PPH}/4$ clock is input.

The 8-bit timer selects between 4 clock inputs: $\phi T1$, $\phi T4$, $\phi T16$, and $\phi T256$ among the prescaler output. This prescaler can be run or stopped by the timer control register TRUN<PRRUN>. Counting starts when <PRRUN> is set to "1", while the prescaler is cleared to zero and stops operation when <PRRUN> is set to "0".

When the IDLE1 mode (Operates only oscillator) is used, set TRUN<PRRUN> to "0" to stop this prescaler before "HALT" instruction is executed.

② Up counter

This is an 8-bit binary counter which counts up by the input clock pulse specified by T10MOD and T32MOD.

The input clock of timer 0, 2 is selected from the three internal clocks $\phi T1$, $\phi T4$, and $\phi T16$, according to the set value of T10MOD/T32MOD registers.

The input clock of timer 1 and 3 differs depending on the operation mode. When set to 16-bit timer mode, the overflow outputs of timer 0 and 2 are used as the input clock. When set to any other mode than 16-bit timer mode, the input clock is selected from the internal clocks $\phi T1$, $\phi T16$, and $\phi T256$ as well as the comparator output (Match detection signal) of timer 0, 2 according to the set value of T10MOD and T32MOD registers.

Example: When T10MOD<T10M1:0> = 01, the overflow output of timer 0 becomes the input clock of timer 1 (16-bit timer mode).

When T10MOD<T10M1:0> = 00 and T10MOD<T1CLK1:0> = 01, $\phi T1$ becomes the input of timer 1 (8-bit timer mode).

Operation mode is also set by T10MOD and T32MOD registers. When reset, it is initialized to T10MOD<T10M1:0> = 00 and T32MOD<T32M1:0> = 00 whereby the up counter is placed in the 8-bit timer mode.

The counting and stop and clear of up counter can be controlled for each interval timer by the timer operation control register TRUN. When reset, all up counters will be cleared to stop the timers.

③ Timer register

This is an 8-bit register for setting an interval time. When the set value of timer registers TREG0, TREG1, TREG2, TREG3, matches the value of up counter, the comparator match detect signal becomes active. If the set value is 00H, this signal becomes active when the up counter overflows.

Timer registers TREG2 are double buffer structure, each of which makes a pair with register buffer.

The timer flip-flop control register TRDC <TR2DE> bits control whether the double buffer structure in the TREG2 should be enabled or disabled. They are disabled when <TR2DE> = 0 and enabled when they are set to 1.

In the condition of double buffer enable state, the data is transferred from the register buffer to the timer register when the $2^n - 1$ overflow occurs in PWM mode, or at the PPG cycle in PPG mode. Therefore, during timer mode, the double buffer can not be used.

When reset, it will be initialized to <TR2DE> = 0 to disable the double buffer. To use the double buffer, write data in the timer register, set <TR2DE> to 1, and write the following data in the register buffer.

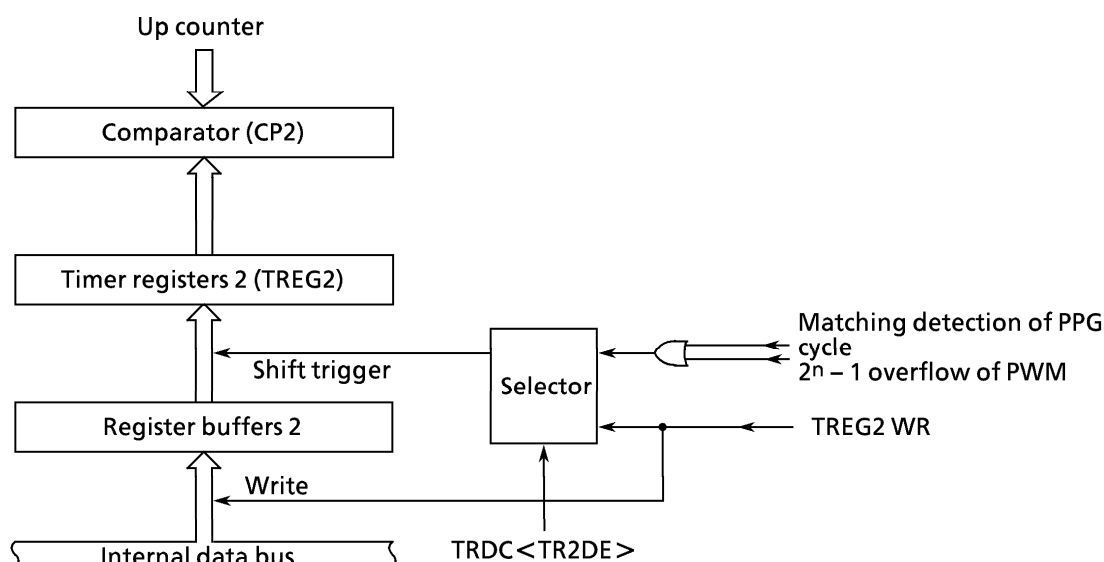

Figure 3.6.4 Configuration of Timer Register 2

Note: Timer register and the register buffer are allocated to the same memory address. When <TR2DE> = 0, the same value is written in the register buffer as well as the timer register, while when <TR2DE> = 1 only the register buffer is written.

The memory address of each timer register is as follows.

TREG0: 000022H TREG2: 000026H

TREG1: 000023H TREG3: 000027H

All the registers are write-only and cannot be read.

④ Comparator

A comparator compares the value in the up counter with the values to which the timer register is set. When they match, the up counter is cleared to zero and an interrupt signal (INTT0, INTT1, INTT2, INTT3) is generated. If the timer flip-flop inversion is enabled, the timer flip-flop is inverted at the same time.

⑤ Timer flip-flop (Timer F/F: TFF1, TFF3)

The timer flip-flop (TFF1, TFF3) is a flip-flop inverted by the match detect signal (8-bit comparator output) of each interval timer.

Inverting is disabled or enabled by the timer flip-flop control register TFFCR<TFF3IE, TFF1IE>.

After reset operation, the value of TFF1, TFF3 is undefined. Writing “01” or “10” to TFFCR<TFF3C1:0, TFF1C1:0>sets “0” or “1” to TFF1, TFF3. Additionally, writing “00” to this bit inverts the value of TFF1, TFF3 (Software inversion).

The signal of TFF3 is output through the TO3 pin (also used as P41). When using as the timer output, the timer flip-flop should be set by port 4 function register P4FC beforehand. The output pin of TFF1 does not exist.

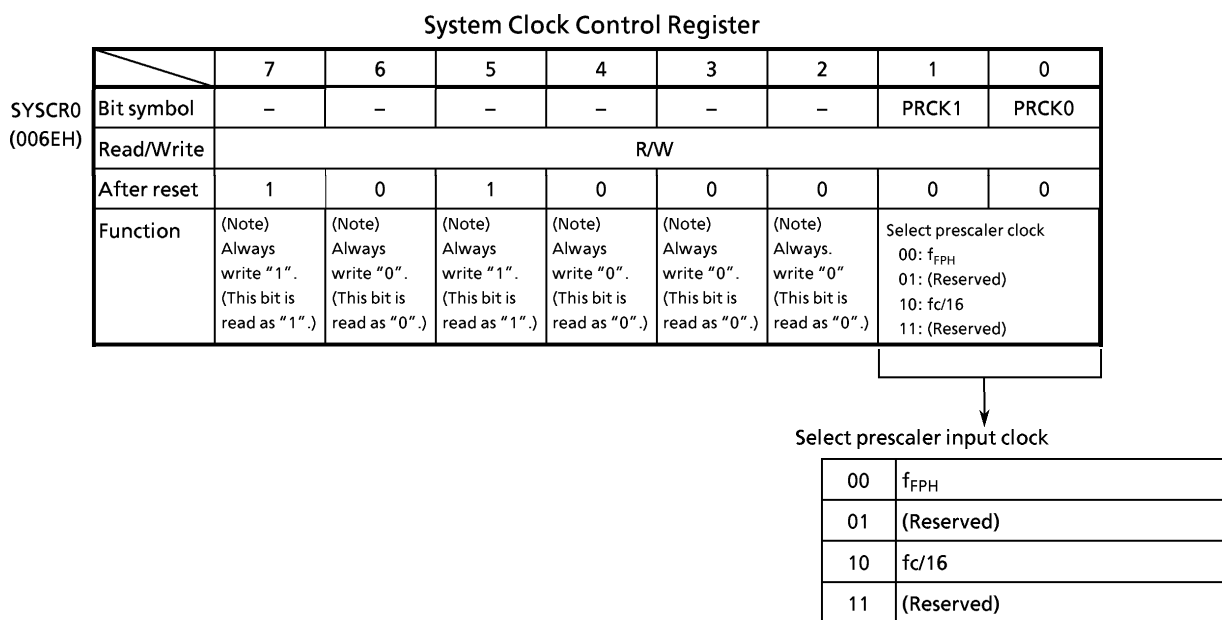

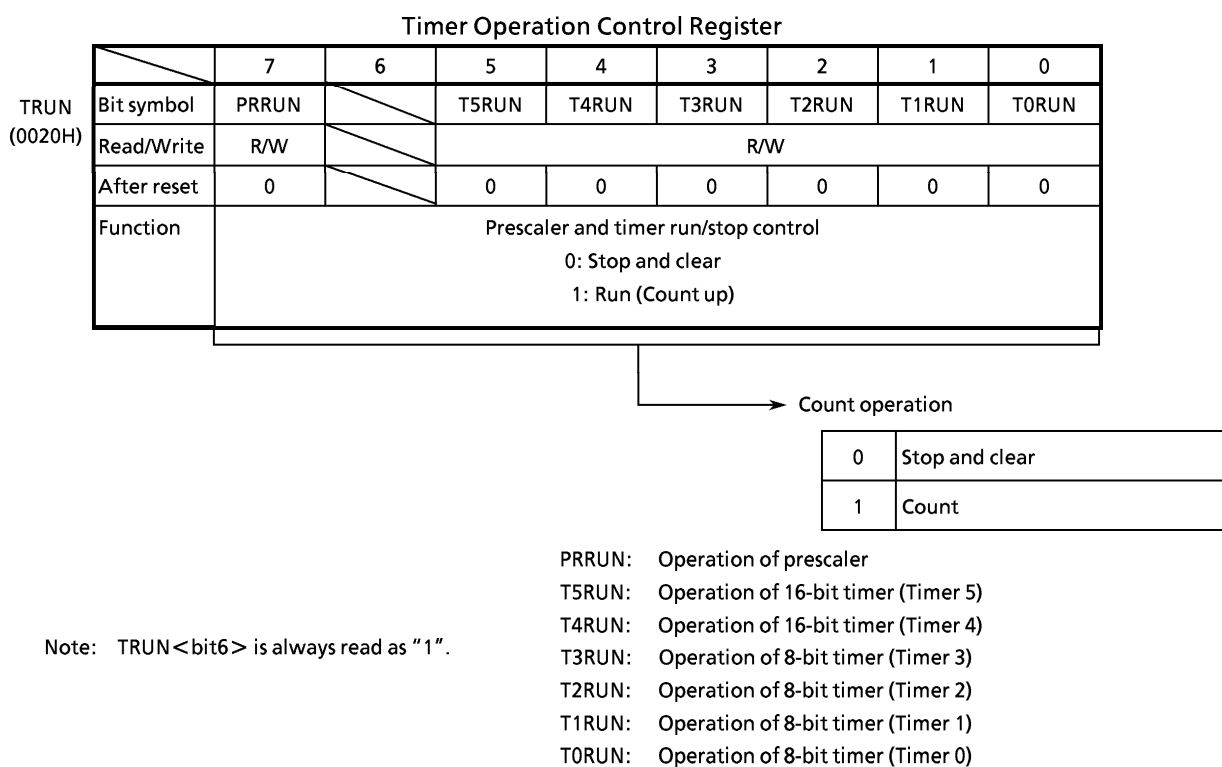

Figure 3.6.5 8-Bit Timer Related Registers (1/5)

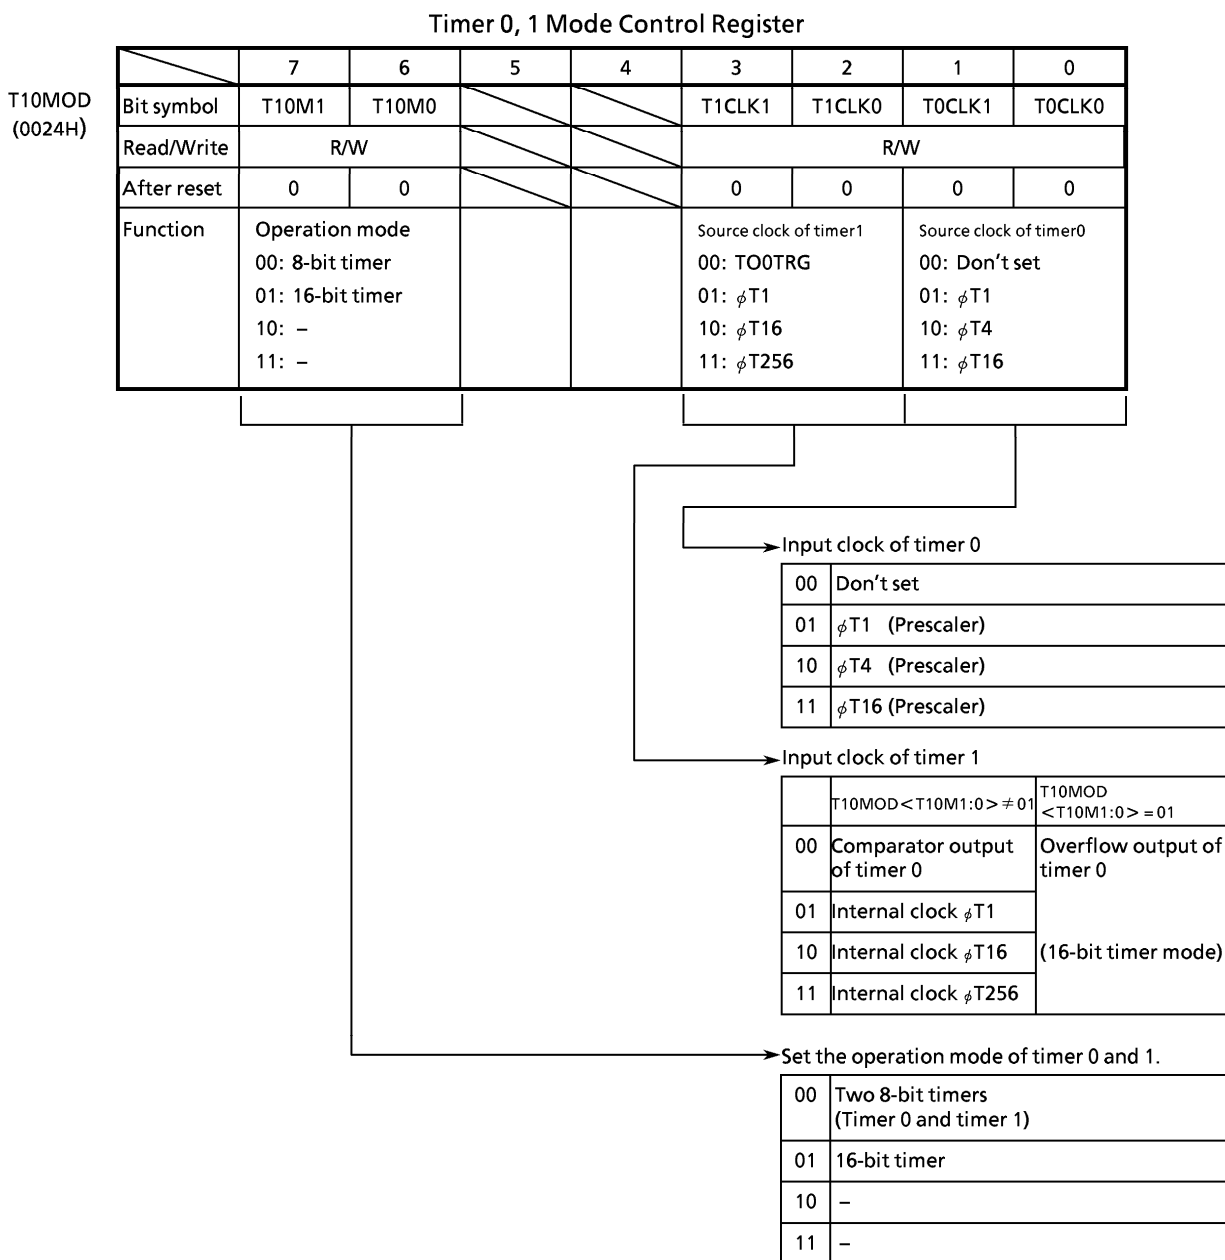

Figure 3.6.6 8-Bit Timer Related Register (2/5)

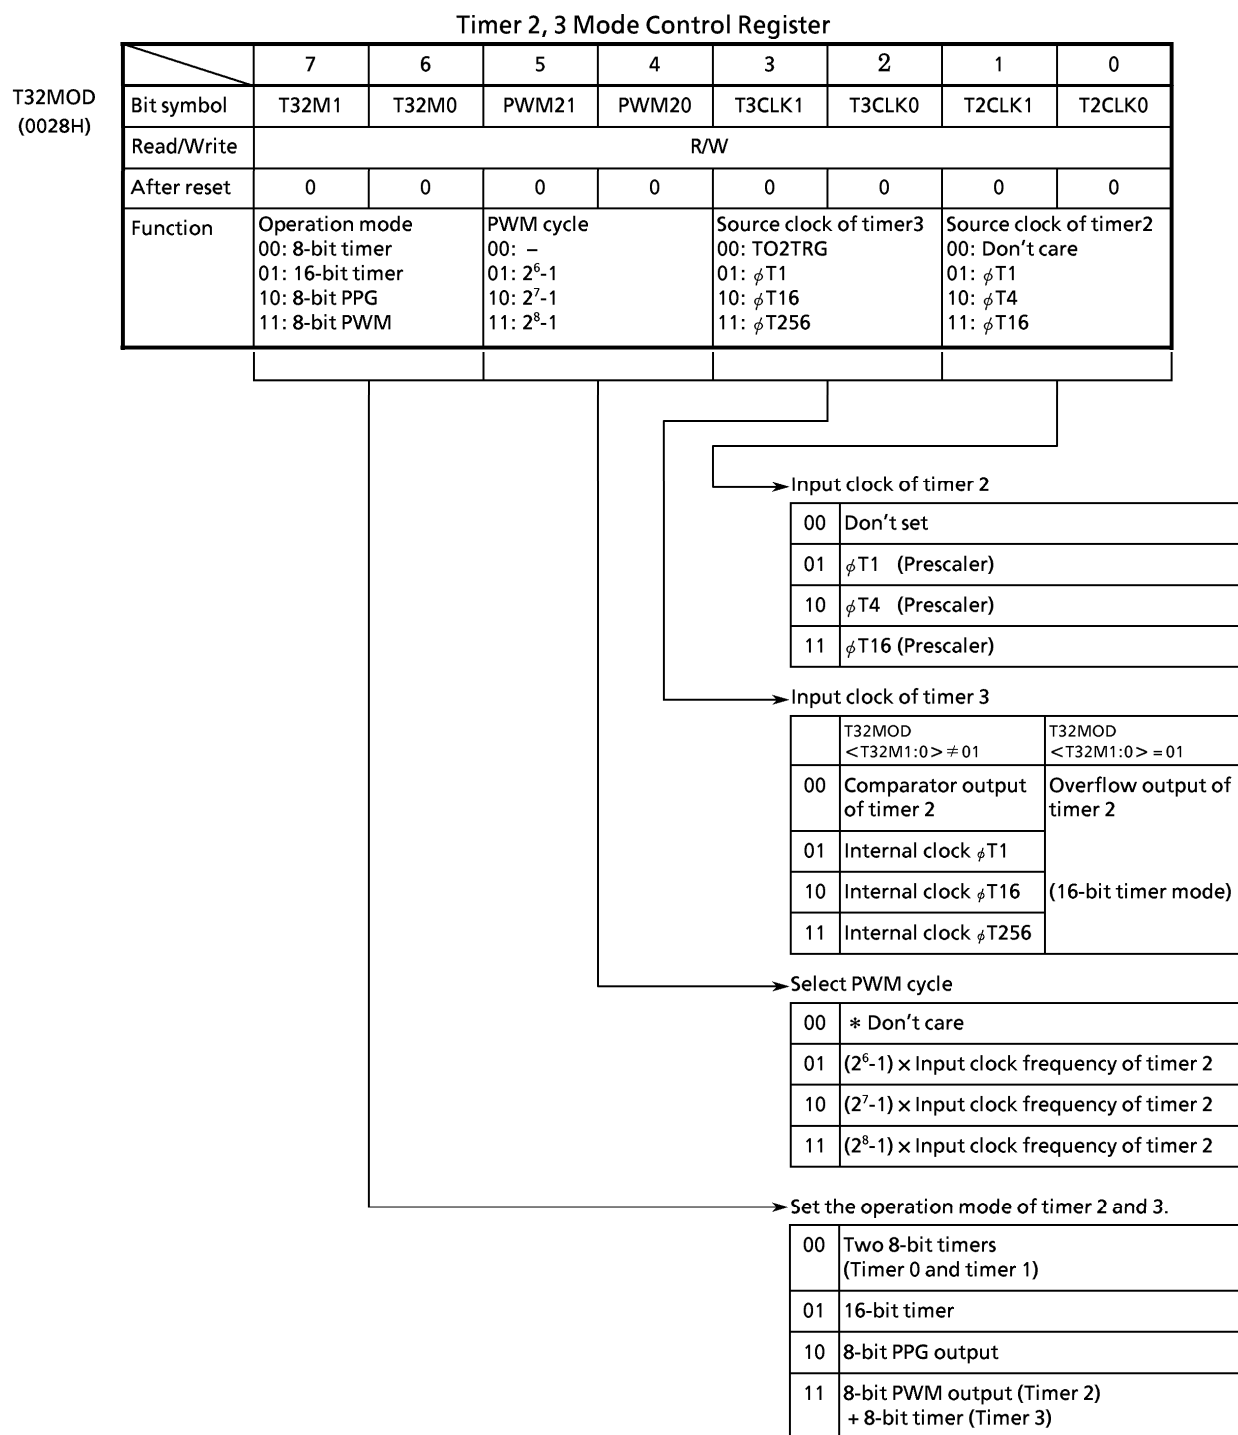

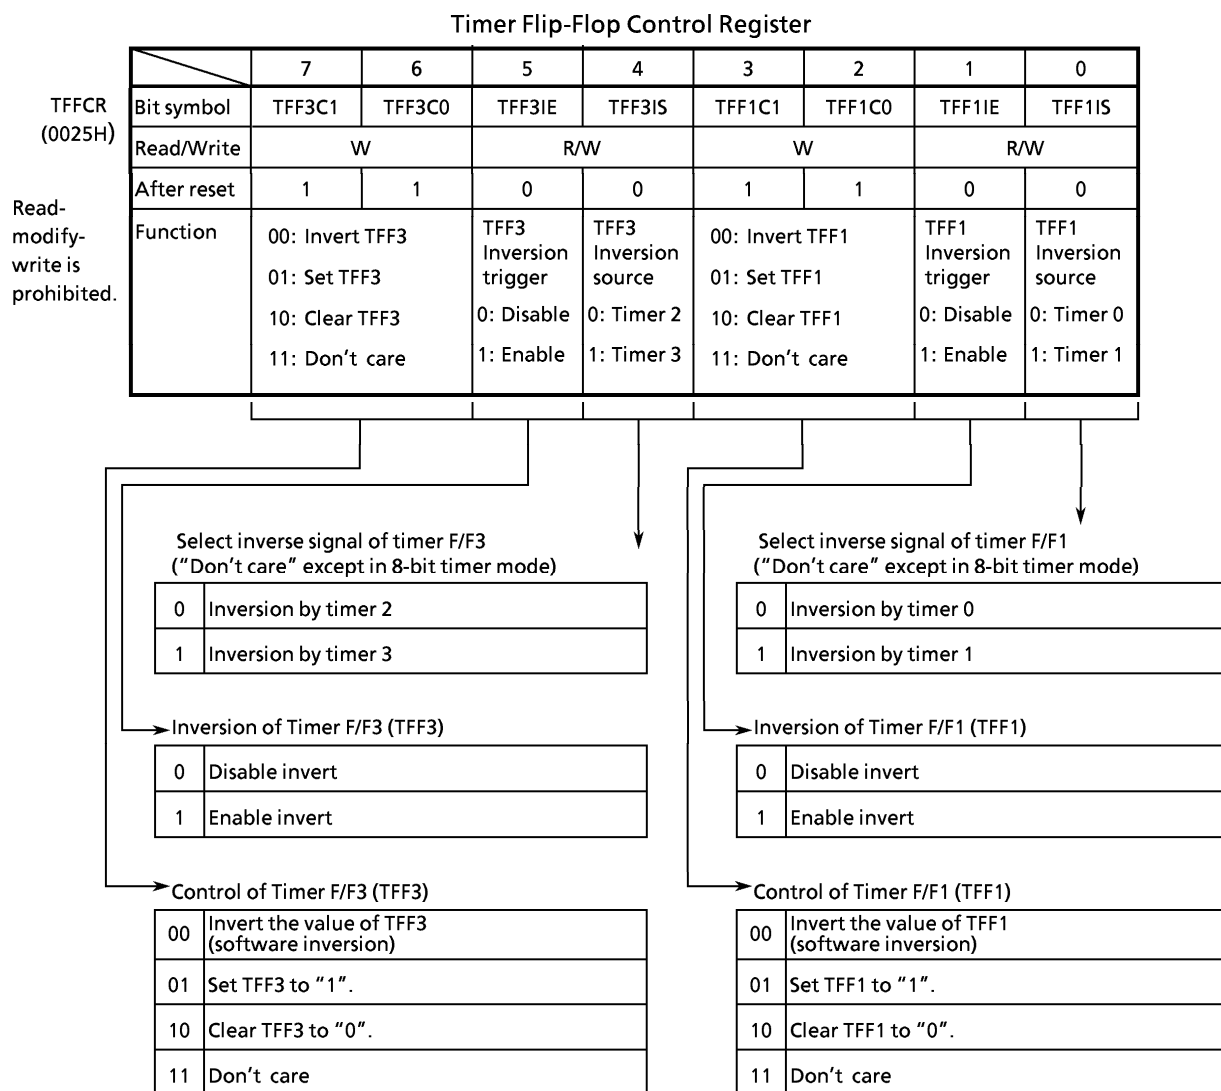

Figure 3.6.7 8-Bit Timer Related Register (3/5)

Note: TFFCR<TFF3C1:0, TFF1C1:0> is always read as "1".

Figure 3.6.8 8-Bit Timer Related Register (4/5)

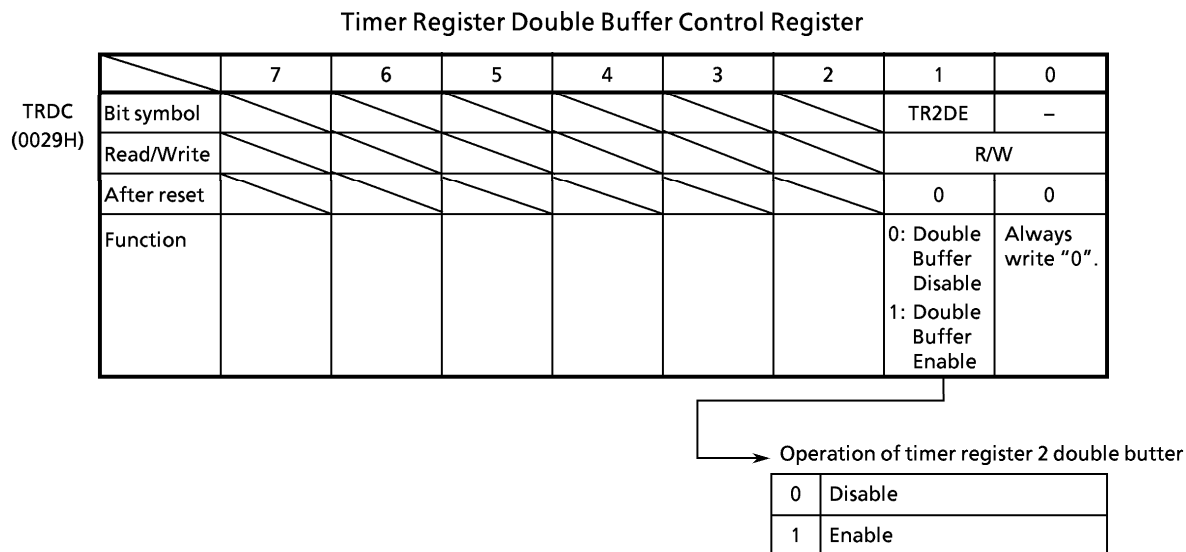

Figure 3.6.9 8-Bit Timer Related Register (5/5)

(1) 8-bit timer mode

Four interval timers 0, 1, 2, 3, can be used independently as 8-bit interval timer.

① Generating interrupts in a fixed cycle (in case of timer 3)

To generate timer 3 interrupt at constant intervals using timer 3 (INTT3), first stop timer 3, then set the operation mode, input clock, and a cycle to T32MOD and TREG3 register, respectively. Then, enable interrupt INTT3 and start the counting of timer 3.

Example: To generate timer 3 interrupt every 10 μ s at $f_c = 20$ MHz, set each register in the following manner.

* Clock condition

Clock gear:	1 (f_c)
Prescaler clock:	f_{PPH}

	MSB		LSB			
	7	6	5	4	3 2 1 0	
TRUN	← -	X -	- -	0 -	- -	Stop timer 3, and clear it to "0".
T32MOD	← 0	0	X X	0 1	- -	Set the 8-bit timer mode, and select $\phi T1$ (0.4 μ s at $f_c = 20$ MHz) as the input clock.
TREG3	← 0	0	0 1	1 0	0 1	Set the timer register $10 \mu s \div \phi T1 = 25 = 19H$
INTET32	← 1	1	0 1	- -	- -	Enable INTT3, and set it to "Level 5".
TRUN	← 1	X	- -	1 -	- -	Start timer 3 counting.

X: Don't care, -: No change

Use the Table 3.6.1 for selecting the input clock.

Note: The input clock of timer 2 and timer 3 are different from as follows.

Timer 2: $\phi T1, \phi T4, \phi T16$

Timer 3: Match output of timer 2, $\phi T1, \phi T16, \phi T256$

② Generating a 50% duty square wave pulse

The timer flip-flop is included in timer 1 and 3.

The timer flip-flop (TFF3) is inverted at constant intervals, and its status is output to timer output pin (TO3). The output pin of TFF1 does not exist.

Example: To output a 2.4 μ s square wave pulse from TO3 pin at $f_c = 20$ MHz, set each register in the following procedures. Either timer 2 or timer 3 may be used, but this example uses timer 3.

* Clock condition

<table border="0"> <tr> <td> <table border="0"> <tr> <td>Clock gear:</td> <td>1 (f_c)</td> </tr> <tr> <td>Prescaler clock:</td> <td>f_{PPH}</td> </tr> </table> </td> </tr> </table>	<table border="0"> <tr> <td>Clock gear:</td> <td>1 (f_c)</td> </tr> <tr> <td>Prescaler clock:</td> <td>f_{PPH}</td> </tr> </table>	Clock gear:	1 (f_c)	Prescaler clock:	f_{PPH}
<table border="0"> <tr> <td>Clock gear:</td> <td>1 (f_c)</td> </tr> <tr> <td>Prescaler clock:</td> <td>f_{PPH}</td> </tr> </table>	Clock gear:	1 (f_c)	Prescaler clock:	f_{PPH}	
Clock gear:	1 (f_c)				
Prescaler clock:	f_{PPH}				

	7	6	5	4	3	2	1	0	
TRUN	←	X	-	-	0	-	-	-	
T32MOD	←	0	0	X	X	0	1	-	
TREG3	←	0	0	0	0	0	0	1	1
TFFCR	←	1	0	1	1	-	-	-	
P4CR	←	X	X	X	X	-	-	1	-
P4FC	←	X	X	X	X	-	-	1	X
TRUN	←	1	X	-	-	1	-	-	

Stop timer 3, and clear it to "0".

Set the 8-bit timer mode, and select $\phi T1$ (0.4μ s at $f_c = 20$ MHz) as the input clock.

Set the timer register at 2.4μ s $\div \phi T1 \div 2 = 3$.

Set TFF3 to "0", and set to invert by the match detect signal from timer 3.

Select P41 as TO3 pin.

Start timer 3 counting.

X: Don't care, -: No change

Figure 3.6.10 Square Wave (50% duty) Output Timing Chart

- ③ Making timer 1 count up by match signal from timer 0 comparator
(Same function is achieved by using timer 3 and timer 2)

Set the 8-bit timer mode, and set the comparator output of timer 0 as the input clock to timer 1.

Figure 3.6.11 Timer 1 Count Up by Timer 0

(2) 16-bit timer mode

A 16-bit interval timer is configured by using the pair of timer 0 and timer 1 or timer 2 and timer 3.

To make a 16-bit interval timer by cascade connecting timer 0 and timer 1, set timer 1/0 mode register T10MOD<T10M1:0> to "01".

When set in 16-bit timer mode, the overflow output of timer 0 and 2 will become the input clock of timer 1 and 3, regardless of the set value of T10MOD<T1CLK1:0> and T32MOD<T3CLK1:0>. Table 3.7.1 shows the relation between the cycle of timer (Interrupt) and the selection of input clock.

The lower 8 bits of the timer (Interrupt) cycle are set by the timer register TREG0 or TREG2, and the upper 8 bits are set by TREG1 or TREG3. Note that TREG0 and TREG2 always must be set first. (Writing data into TREG0 and TREG2 disables the comparator temporarily, and the comparator is restarted by writing data into TREG1 and TREG3.)

Setting example: To generate an interrupt INTT3 every 0.4 seconds at $f_c = 20$ MHz, set the following values for timer registers TREG2 and TREG3.

* Clock condition

Clock gear:	1 (f_c)
Prescaler clock:	f_{PH}

When counting with input clock of ϕ T16 ($6.4 \mu s$ at 20 MHz)

$$0.4 \text{ s} \div 6.4 \mu s = 62500 = F424H$$

Therefore, set TREG3 = F4H and TREG2 = 24H, respectively.

The comparator match signal is output from timer 2 each time the up counter UC2 matches TREG2, where the up counter UC2 is not be cleared, and the interrupt INTT2 is not generated.

With the timer 3 comparator, the match detect signal is output at each comparator timing when up counter UC3 and TREG3 values match. When the match detect signal is output simultaneously from both comparators of timer 2 and timer 3, the up counters UC2 and UC3 are cleared to "0", and the interrupt INTT3 is generated. If inversion is enabled, the value of the timer flip-flop TFF3 is inverted.

Example: When TREG3 = 04H and TREG2 = 80H

Figure 3.6.12 Timer Output by 16-bit Timer Mode

(3) 8-bit PPG (Programmable pulse generation) output mode

Square wave pulse can be generated at any frequency and duty by timer 2. The output pulse may be either low-active or high-active. In this mode, timer 3 cannot be used.

Timer 2 outputs pulse to TO3 pin (also used as P41).

In this mode, a programmable square wave is generated by inverting timer output each time the 8-bit up counter (UC2) matches the timer registers TREG2 and TREG3.

However, it is required that the set value of TREG2 is smaller than that of TREG3.

Though the up counter (UC3) of timer 3 is not used in this mode, UC3 should be set for counting by setting TRUN < T3RUN > to 1.

Figure 3.6.14 shows the block diagram for this mode.

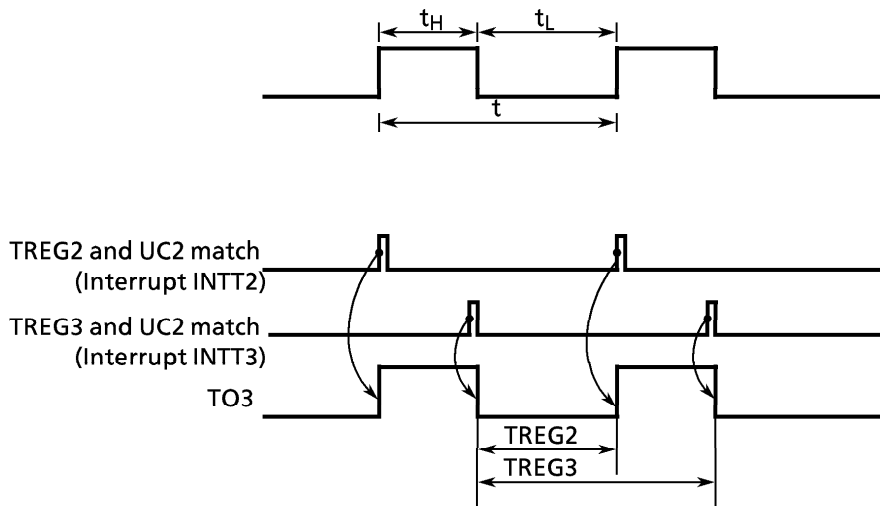

Figure 3.6.13 8-Bit PPG output waveforms

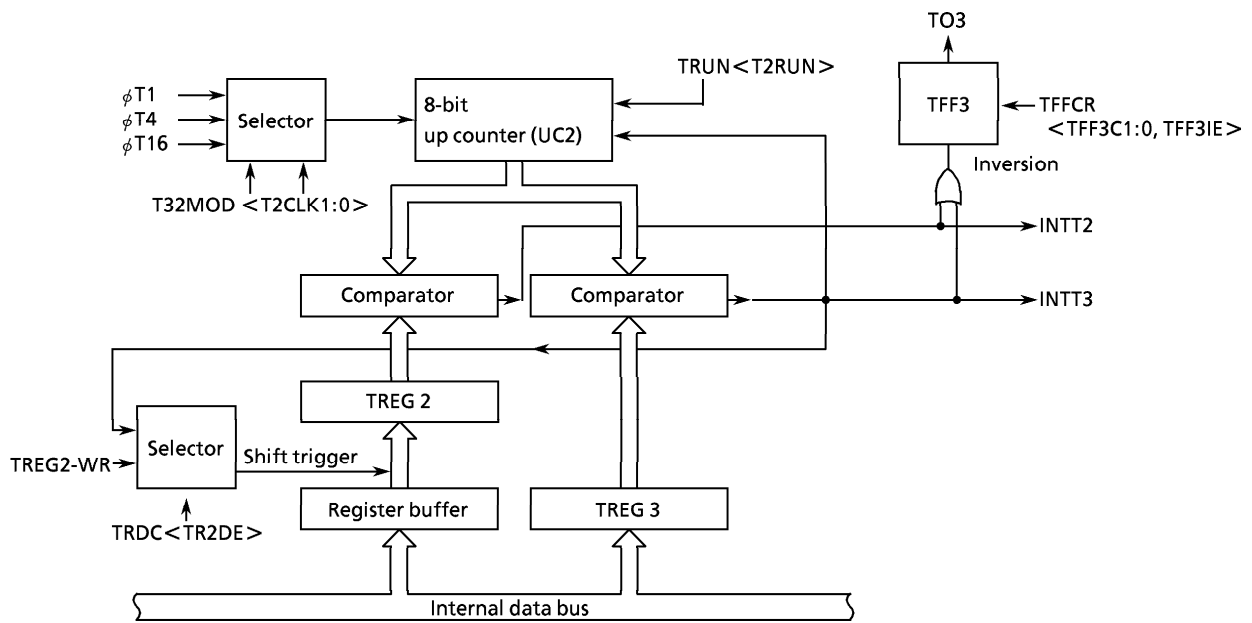

Figure 3.6.14 Block Diagram of 8-Bit PPG Output Mode

When the double buffer of TREG2 is enabled in this mode, the value of register buffer will be shifted in TREG2 each time TREG3 matches UC2.

Use of the double buffer makes easy the handling of low duty waves (when duty is varied).

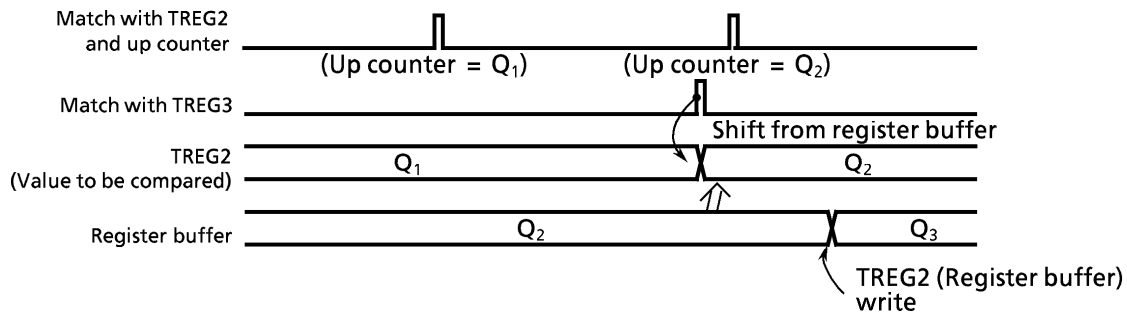

Figure 3.6.15 Operation of Register Buffer

Example: Generating 1/4 duty 62.5 kHz pulse (at $f_c = 20$ MHz)

* Clock condition
 { Clock gear: 1 (f_c)
 Prescaler clock: f_{PPH}

- Calculate the value to be set for timer register.
 To obtain the frequency 62.5 kHz, the pulse cycle t should be: $t = 1/62.5 \text{ kHz} = 16 \mu\text{s}$.
 Given $\phi T1 = 0.4 \mu\text{s}$ (at 20 MHz),
 $16 \mu\text{s} \div 0.4 \mu\text{s} = 40$
 Consequently, to set the timer register 3 (TREG3) to $TREG3 = 40 = 28\text{H}$
 and then duty to 1/4, $t \times 1/4 = 16 \mu\text{s} \times 1/4 = 4 \mu\text{s}$
 $4 \mu\text{s} \div 0.4 \mu\text{s} = 10$
 Therefore, set timer register 2 (TREG2) to $TREG2 = 10 = 0\text{AH}$.

7 6 5 4 3 2 1 0	
TRUN ← - X - - 0 0 - -	Stop timer 2, 3 and clear it to "0".
T32MOD ← 1 0 X X X X 0 1	Set the 8-bit PPG mode, and select $\phi T1$ as input clock.
TREG2 ← 0 0 0 0 1 0 1 0	Write "0AH".
TREG3 ← 0 0 1 0 1 0 0 0	Write "28H".
TFFCR ← 0 1 1 X - - - -	Sets TFF3 and enable the inversion and double buffer enable.
	Writing "10" provides negative logic pulse.
P4CR ← X X X X - - 1 -	} Set P41 as the TO3 pin.
P4FC ← X X X X - - 1 X	
TRUN ← 1 X - - 1 1 - -	Start timer 2 and timer 3 counting.

X: Don't care, -: No change

(4) 8-bit PWM output mode

This mode is valid only for timer 2. In this mode, maximum 8-bit resolution of PWM pulse can be output.

PWM pulse is output to TO3 pin (also used as P41) when using timer 2. Timer 3 can also be used as 8-bit timer.

Timer output is inverted when up counter (UC2) matches the set value of timer register TREG2 or when $2^n - 1$ ($n = 6, 7, \text{ or } 8$; specified by $T32MOD \langle PWM21:20 \rangle$) counter overflow occurs. Up counter UC2 is cleared when $2^n - 1$ counter overflow occurs.

To use this PWM mode, the following conditions must be satisfied.

$$\begin{aligned} &(\text{Set value of timer register}) < (\text{Set value of } 2^n - 1 \text{ counter overflow}) \\ &(\text{Set value of timer register}) \neq 0 \end{aligned}$$

Figure 3.6.16 8-Bit PWM Waveforms

Figure 3.6.17 shows the block diagram of this mode.

Figure 3.6.17 Block Diagram of 8-Bit PWM Mode

In this mode, the value of register buffer will be shifted in TREG2 if $2^n - 1$ overflow is detected when the double buffer of TREG2 is enabled.

Use of the double buffer makes easy the handling of small duty waves.

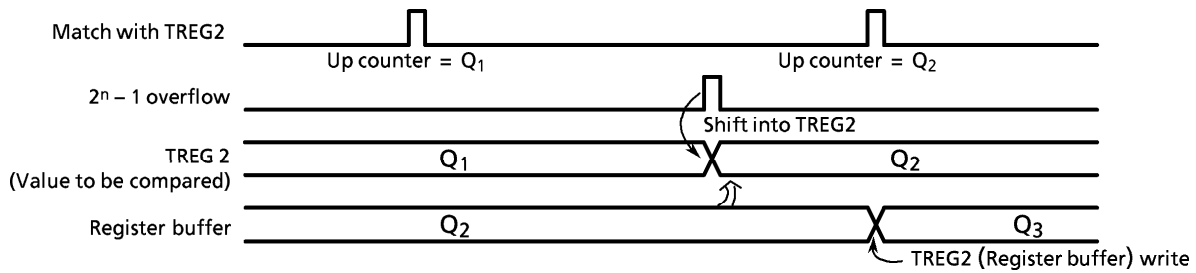

Figure 3.6.18 Operation of Register Buffer

Example: To output the following PWM waves to TO3 pin at $f_c = 20$ MHz.

* Clock condition
 { Clock gear: 1 (f_c)
 Prescaler clock: f_{FPH}

To realize $50.8 \mu s$ of PWM cycle by $\phi T1 = 0.4 \mu s$ (at $f_c = 20$ MHz),

$$50.8 \mu s \div 0.4 \mu s = 127 = 2^n - 1$$

Consequently, n should be set to 7.

As the period of low level is $28.8 \mu s$, for $\phi T1 = 0.4 \mu s$, set the following value for TREG2.

$$28.8 \mu s \div 0.4 \mu s = 72 = 48H$$

	MSB		LSB							
	7	6	5	4	3	2	1	0		
TRUN	←	-	X	-	-	-	0	-	Stop timer 2, and clear it to "0".	
T32MOD	←	1	1	1	0	-	-	0	1	Set 8-bit PWM mode (cycle: $2^7 - 1$) and select $\phi T1$ as the input clock.

3.7 16-Bit Timers/Event Counters

The TMP93CS36 contains two (Timer 4 and timer 5) multifunctional 16-bit timer/event counter with the following operation modes.

- 16-bit interval timer mode
- 16-bit event counter mode
- 16-bit programmable pulse generation (PPG) mode

Can be used following operation modes by capture function.

- Frequency measurement mode
- Pulse width measurement mode
- Time differential measurement mode

Timer/event counter consists of 16-bit up counter, two 16-bit timer registers, two 16-bit capture registers (One of them applies double-buffer), two comparators, capture input controller, and timer flip-flop and the control circuit.

Timer/event counter is controlled by 4 control registers: T4MOD/T5MOD, T4FFCR/T5FFCR, TRUN and T45CR.

Figure 3.7.1, 3.7.2 shows the block diagram of 16-bit timer/event counter (Timer 4 and timer 5) .

Timer 4 and 5 can be used independently.

All timer operate in the same manner, and thus only the operation of timer 4 will be explained below.

XXX: Don't care

← 16-bit timer →

← 8-bit timer →

The clock selected among f_{FPH} clock and $f_{\text{c}/16}$ clock is divided by 4 and input to this prescaler. This is selected by prescaler clock selection register SYSCR0<PRCK1:0>.

Resetting sets <PRCK1:0> to “00”, therefore $f_{\text{FPH}}/4$ clock is input.

The 16 bit timer 4, 5 selects between 3 clock inputs: ϕT1 , ϕT4 , and ϕT16 among the prescaler outputs.

This prescaler can be run or stopped by the timer operation control register TRUN<PRRUN>. Counting starts when <PRRUN> is set to “1”, while the prescaler is cleared to zero and stops operation when <PRRUN> is set to “0”.

When the IDLE1 mode (Operates only oscillator) is used, set TRUN<PRRUN> to “0” to stop this prescaler before “HALT” instruction is executed.

② Up counter

UC4 is a 16-bit binary counter which counts up according to the input clock specified by T4MOD<T4CLK1:0> register.

As the input clock, one of the internal clocks ϕT1 , ϕT4 , and ϕT16 from 9-bit prescaler (also used for 8-bit timer), and external clock from TI4 pin (also used as P42/INT4 pin) can be selected. When reset, it will be initialized to <T4CLK1:0> = 00 to select TI4 input mode. Counting or stop and clear of the counter is controlled by timer operation control register TRUN<T4RUN>.

When clearing is enabled, up counter UC4 will be cleared to zero each time it coincides matches the timer register TREG5. The “Clear enable/disable” is set by T4MOD<CLE>.

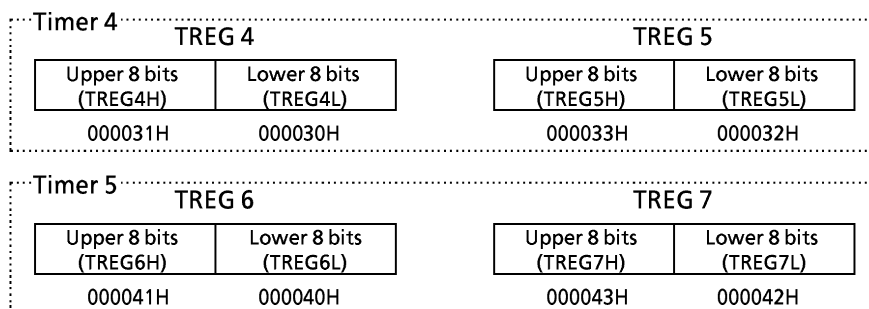

If clearing is disabled, the counter operates as a free-running counter.

A timer overflow interrupt (INTT04) is generated when UC4 overflow occurs.

③ Timer registers

These two 16-bit registers are used to set the interval time. When the value of up counter UC4 matches the set value of this timer register, the comparator match detect signal will be active.

Setting data for lower and upper registers (TREG4 and TREG5) is always needed. For example, either using 2 byte data transfer instruction or using 1 byte data transfer instruction twice for lower 8 bits and upper 8 bits in order.

TREG4 to 7 are write-only registers, so these registers can not be read by software.

TREG4 timer register is of double buffer structure, which is paired with register buffer. The timer control register T45CR<DB4EN> controls whether the double buffer structure should be enabled or disabled. Disabled when <DB4EN> = 0, while enabled when <DB4EN> = 1.

When the double buffer is enabled, the timing to transfer data from the register buffer to the timer register is at the match between the up counter (UC4) and timer register TREG5.

After reset, TREG4 and TREG5 are undefined. To use the 16-bit timer after reset, data should be written beforehand.

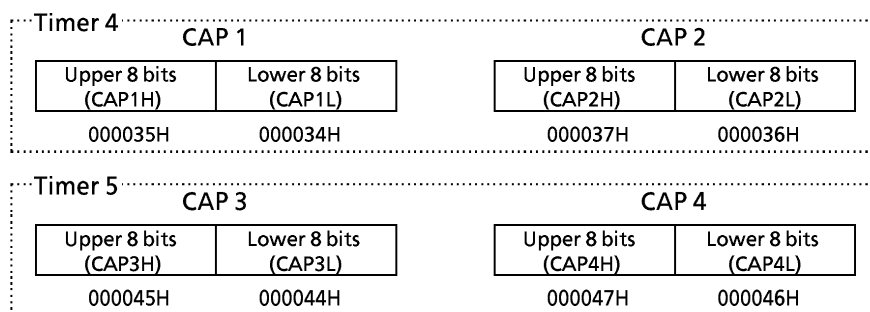

When reset, it will be initialized to <DB4EN> = 0, whereby the double buffer is disabled. To use the double buffer, write data in the timer register, set <DB4EN> = 1, and then write the following data in the register buffer.

TREG4 and register buffer are allocated to the same memory addresses 000030H/000031H. When <DB4EN> = 0, same value will be written in both the timer register and register buffer. When <DB4EN> = 1, the value is written into only the register buffer. To write the initial-value to the timer register, the register buffer should be disabled.

④ Capture register

These 16-bit registers are used to latch the values of the up counter.

Data in the capture registers should be read all 16 bits. For example, using a 2-byte data load instruction or two 1-byte data load instruction, from the lower 8 bits followed by the upper 8 bits.

CAP 1 to 4 are read-only registers, so these registers cannot be written by software.

⑤ Capture input control

This circuit controls the timing to latch the value of up counter UC4 into (CAP1, CAP2). The latch timing of capture register is controlled by register T4MOD <CAP12M 1:0>.

- When T4MOD <CAP12M 1:0> = 00

Capture function is disabled. Disable is the default on reset.

- When T4MOD <CAP12M1:0> = 01

Data is loaded to CAP1 at the rise edge of TI4 pin (also used as P42/INT4) input, while data is loaded to CAP2 at the rise edge of TI5 pin (also used as P43/INT5) input.

- When T4MOD <CAP12M1:0> = 10

Data is loaded to CAP1 at the rise edge of TI4 pin input, while to CAP2 at the fall edge. Only in this setting, interrupt INT4 occurs at fall edge.

- When T4MOD <CAP12M1:0> = 11

Data is loaded to CAP1 at the rise edge of timer flip-flop TFF1, while to CAP2 at the fall edge.

Besides, the value of up counter can be loaded to capture registers by software. Whenever “0” is written in T4MOD <CAP1IN> the current value of up counter will be loaded to capture register CAP1. It is necessary to keep the prescaler in RUN mode (TRUN <PRRUN> to be “1”).

⑥ Comparator

These are 16-bit comparators which compare the up counter UC4 value with the set value of (TREG4, TREG5) to detect the match. When a match is detected, the comparators generate an interrupt (INTTR4, INTTR5) respectively. The up counter UC4 is cleared only when UC4 matches TREG5 (The clearing of up counter UC4 can be disabled by setting T4MOD <CLE> = 0).

⑦ Timer flip-flop (TFF4)

This flip-flop is inverted by the match detect signal from the comparators and the latch signals to the capture registers. Disable/enable of inversion can be set for each element by T4FFCR <CAP2T4, CAP1T4, EQ5T4, EQ4T4>. After reset, the value of TFF4 is undefined. TFF4 will be inverted when “00” is written in T4FFCR <TFF4C1,0>. Also it is set to “1” when “01” is written, and set to “0” when “10” is written. The value of TFF4 can be output to the timer output pin TO4 (also used as P44). Timer output should be specified by the function register of port 4. (See Register for port 4 in figure 3.5.6.)

(1) 16-bit timer mode

Generating interrupts at fixed intervals

In this example, the interval time is set in the timer register TREG5 to generate the interrupt INTTR5.

	7	6	5	4	3	2	1	0	
TRUN	←	-	X	-	0	-	-	-	Stop timer 4.
INTET54	←	1	1	0	0	1	0	0	Enable INTTR5 and sets interrupt level 4. Disable INTTR4.
T4FFCR	←	X	X	0	0	0	0	1	Disable trigger.
T4MOD	←	0	0	1	0	0	1	**	Select internal clock for input and disable the capture function.
									(** = 01, 10, 11)
TREG5	←	*	*	*	*	*	*	*	Set the interval time (16 bits).
TRUN	←	1	X	-	1	-	-	-	Start timer 4.

X: Don't care, -: No change

(2) 16-bit event counter mode

In 16-bit timer mode as described in above, the timer can be used as an event counter by selecting the external clock (TI4 pin input) as the input clock. To read the value of the counter, first perform "software capture" once and read the captured value.

The counter counts at the rise edge of TI4 pin input.

TI4 pin can also be used as P42/INT4.

Since both timers operate in exactly the same way, timer 4 is used for the purposes of explanation.

	7	6	5	4	3	2	1	0	
TRUN	←	-	X	-	0	-	-	-	Stop timer 4.
P4CR	←	-	-	-	-	0	-	-	Set P42 to input mode
INTET54	←	1	1	0	0	1	0	0	Enable INTTR5 and sets interrupt level 4, while disables INTTR4.
T4FFCR	←	X	X	0	0	0	0	1	Disable trigger.
T4MOD	←	0	0	1	0	0	1	0	Select TI4 as the input clock.
TREG5	←	*	*	*	*	*	*	*	Set the number of counts (16 bits).
TRUN	←	1	X	-	1	-	-	-	Start timer 4.

X: Don't care, -: No change

Note: When used as an event counter, set the prescaler in RUN mode.
(TRUN<PRRUN> = "1")

(3) 16-bit programmable pulse generation (PPG) output mode

Square wave pulse can be generated at any frequency and duty by timer 4. The output pulse may be either low-active or high-active.

The PPG mode is obtained by inversion of the timer flip-flop TFF4 that is to be enabled by the match of the up counter UC4 with the timer register TREG4 or 5 and to be output to TO4 (also used as P44). In this mode, the following conditions must be satisfied.

$$(\text{Set value of TREG4}) < (\text{Set value of TREG5})$$

Figure 3.7.10 Programmable Pulse Generation (PPG) Output Waveforms

When the double buffer of TREG4 is enabled in this mode, the value of register buffer 4 will be shifted in TREG4 at match with TREG5. This feature makes easy the handling of low duty waves.

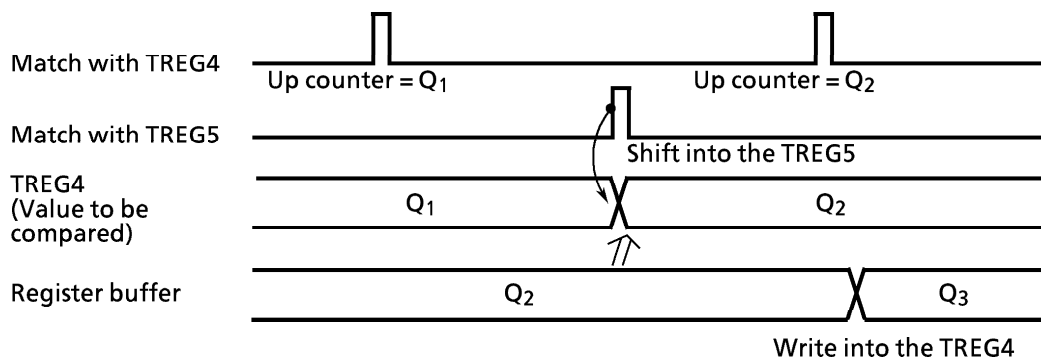

Figure 3.7.11 Operation of Register Buffer

Shows the block diagram of this mode.

							(** = 01, 10, 11)		
P4CR	← -	-	-	1	-	-	-	1	Assign P44 as TO4.
P4FC	← -	X	X	1	X	X	-	X	
TRUN	← 1	X	-	1	-	-	-	-	Start timer 4.

X: Don't care, -: No change

(4) Application examples of capture function

Used capture function, they can be applied in many ways, for example:

- ① One-shot pulse output from external trigger pulse
 - ② Frequency measurement
 - ③ Pulse width measurement
 - ④ Time difference measurement
- ① One-shot pulse output from external trigger pulse

Set to $T4MOD \langle CAP12M1:0 \rangle = 01$.

Set the up counter UC4 in free-running mode with the internal input clock, input the external trigger pulse from TI4 pin, and load the value of up counter into capture register CAP1 at the rise edge of the TI4 pin.

When the interrupt INT4 is generated at the rise edge of TI4 input, set the CAP1 value (c) plus a delay time (d) to TREG4 ($= c + d$), and set the above set value (c + d) plus a one-shot pulse width (p) to TREG5 ($= c + d + p$). When the interrupt INT4 occurs the $T4FFCR \langle EQ5T4, EQ4T4 \rangle$ register should be set "11" and that the TFF4 inversion is enabled only when the up counter value matches TREG4 or TREG5.

When interrupt INTTR5 occurs, this inversion will be disabled after one-shot pulse is output.

The (c), (d) and (p) correspond to c, d and p in Figure 3.7.13.

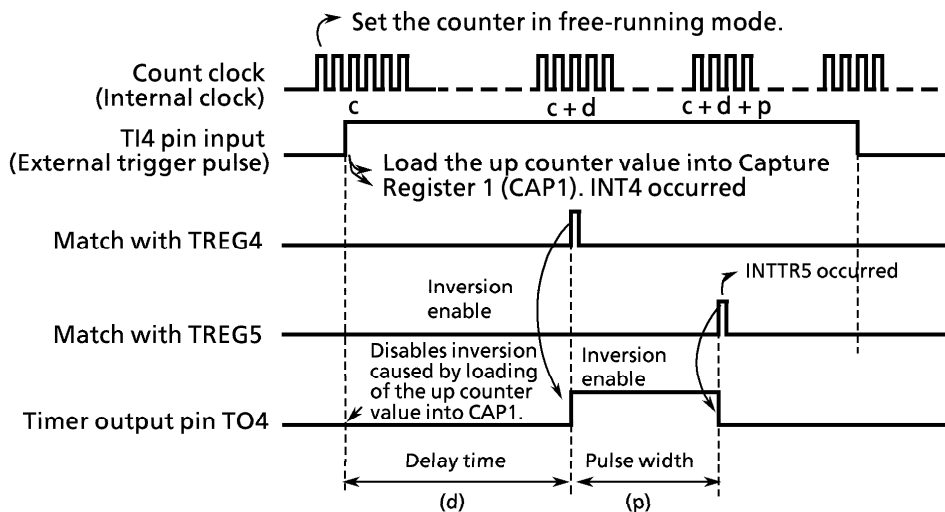

Figure 3.7.13 One-Shot Pulse Output (with delay)

Setting example: To output 2 ms one-shot pulse with 3 ms delay to the external trigger pulse to TI4 pin

* Clock condition

Clock gear: 1 (fc)
Prescaler clock: f_{FPH}

Main setting

T4MOD	←	- - 1 0 1 0 0 1	Keep counting (Free running) Count with $\phi T1$.
T4FFCR	←	X X 0 0 0 1 0	Load the up counter value into CAP1 at the rise edge of TI4 pin input. Clear TFF4 to zero. Disable TFF4 inversion.
P4CR	←	- - - 1 - - - 1	} Select P44 as the TO4 pin.
P4FC	←	- X X 1 X X - X	
INTE45	←	- - - - 1 1 0 0	Enable INT4, and disable INTTR4 and INTTR5.
INTET54	←	1 0 0 0 1 0 0 0	
TRUN	←	1 X - 1 - - - -	Start timer 4.

Setting of INT4

TREG4	←	CAP1+3ms/ $\phi T1$	
TREG5	←	TREG4+2ms/ $\phi T1$	
T4FFCR	←	X X - - 1 1 - -	Enable TFF4 inversion when the up counter value matches TREG4 or 5.
INTET54	←	1 1 0 0 - - - -	Enable INTTR5.

Setting of INTTR5

T4FFCR	←	X X - - 0 0 - -	Disable TFF4 inversion when the up counter value matches TREG4 or 5.
INTET54	←	1 0 0 0 - - - -	Disable INTTR5.

X: Don't care, -: No change

When delay time is unnecessary, invert timer flip-flop TFF4 when the up counter value is loaded into capture register 1 (CAP1), and set the CAP1 value (c) plus the one-shot pulse width (p) to TREG5 when the interrupt INT4 occurs. The TFF4 inversion should be enabled when the up counter (UC4) value matches TREG5, and disabled when generating the interrupt INTTR5.

Figure 3.7.14 One-Shot Pulse Output (without delay)

② Frequency measurement

The frequency of the external clock can be measured in this mode. The clock is input through the TI4 pin, and its frequency is measured by the 8-bit timers (Timer 0 and timer 1) and the 16-bit timer/event counter (Timer 4).

The TI4 pin input should be selected for the input clock of timer 4. The value of the up counter is loaded into the capture register CAP1 at the rise edge of the timer flip-flop TFF1 of 8-bit timers (Timer 0 and timer 1), and into CAP2 at its fall edge.

The frequency is calculated by the difference between the loaded values in CAP1 and CAP2 when the interrupt (INTT0 or INTT1) is generated by either 8-bit timer.

Figure 3.7.15 Frequency Measurement

For example, if the value for the level "1" width of TFF1 of the 8-bit timer is set to 0.5 s. and the difference between CAP1 and CAP2 is 100, the frequency will be $100 \div 0.5 [s] = 200[Hz]$.

③ Pulse width measurement

This mode allows to measure the “H” level width of an external pulse. While keeping the 16-bit timer/event counter counting (Free running) with the internal clock input, the external pulse is input through the TI4 pin. Then the capture function is used to load the UC4 values into CAP1 and CAP2 at the rising edge and falling edge of the external trigger pulse respectively. The interrupt INT4 occurs at the falling edge of TI4.

The pulse width is obtained from the difference between the values of CAP1 and CAP2 and the internal clock cycle.

For example, if the internal clock is 0.8 microseconds and the difference between CAP1 and CAP2 is 100, the pulse width will be $100 \times 0.8 \mu\text{s} = 80 \mu\text{s}$.

Additionally, the pulse width which is over the UC4 maximum count time specified by the clock source can be measured by changing software.

Figure 3.7.16 Pulse Width Measurement

Note: Only in this pulse width measuring mode ($T4MOD \langle CAP12M1:0 \rangle = 10$), external interrupt INT4 occurs at the falling edge of TI4 pin input. In other modes, it occurs at the rising edge.

The width of “L” level can be measured by multiplying the difference between the first C2 and the second C1 at the second INT4 interrupt and the internal clock cycle together. See Figure 3.7.17 “Time Difference Measurement”.

④ Time difference measurement

This mode is used to measure the difference in time between the rising edges of external pulses input through TI4 and TI5.

Keep the 16-bit timer/event counter (Timer 4) counting (Free running) with the internal clock, and load the UC4 value into CAP1 at the rising edge of the input pulse to TI4. Then the interrupt INT4 is generated.

Similarly, the UC4 value is loaded into CAP2 at the rising edge of the input pulse to TI5, generating the interrupt INT5.

The time difference between these pulses can be obtained from the difference between the time counts at which loading the up counter value into CAP1 and CAP2 was performed. ($\Delta = (CAP2 - CAP1) \times$ the internal clock cycle)

Figure 3.7.17 Time Difference Measurement

3.8 Serial Channel

TMP93CS36 contains 2 serial I/O channels for full duplex asynchronous transmission (UART). The serial channel has the following operation modes.

- UART mode (Channel 0 and 1)
 - Mode 1: 7-bit data
 - Mode 2: 8-bit data
 - Mode 3: 9-bit data

In mode 1 and mode 2, a parity bit can be added. Mode 3 has wake-up function for making the master controller start slave controllers in serial link.

Figure 3.8.1 shows the data format (for one frame) in each mode.

Serial Channel 0 and 1 can be used independently.

Figure 3.8.1 Data Formats

The serial channel has a buffer register for transmitting and receiving operations, in order to temporarily store transmitted or received data, so that transmitting and receiving operations can be done independently (full duplex).

The receiving data register is of a double buffer structure to prevent the occurrence of overrun error and provides one frame of margin before CPU reads the received data. The receiving data register stores the already received data while the buffer register receives the next frame data.

In the UART mode, a check function is added not to start the receiving operation by error start bits due to noise. The channel starts receiving data only when the start bit is detected to be normal at least twice in three samplings.

When the transmission buffer becomes empty and requests the CPU to send the next transmission data, or when data is stored in the receiving data register and the CPU is requested to read the data, INTTX or INTRX interrupt occurs. Besides, if an overrun error, parity error, or framing error occurs during receiving operation, flag SC0CR/SC1CR <OERR, PERR, FERR> will be set.

The serial channel 0/1 includes a special baud rate generator, which can set any baud rate by dividing the frequency of 4 clocks (ϕ T0, ϕ T2, ϕ T8, and ϕ T32) from the internal prescaler (shared by 8-bit/16-bit timer) by the value 1 to 16.

3.8.1 Control registers

The serial channel 0 is controlled by 3 control registers SC0CR, SC0MOD and BR0CR. Transmitted and received data are stored in register SC0BUF.

The serial channel 1 has same registers (SC1CR, SC1MOD, BR1CR and SC1BUF).

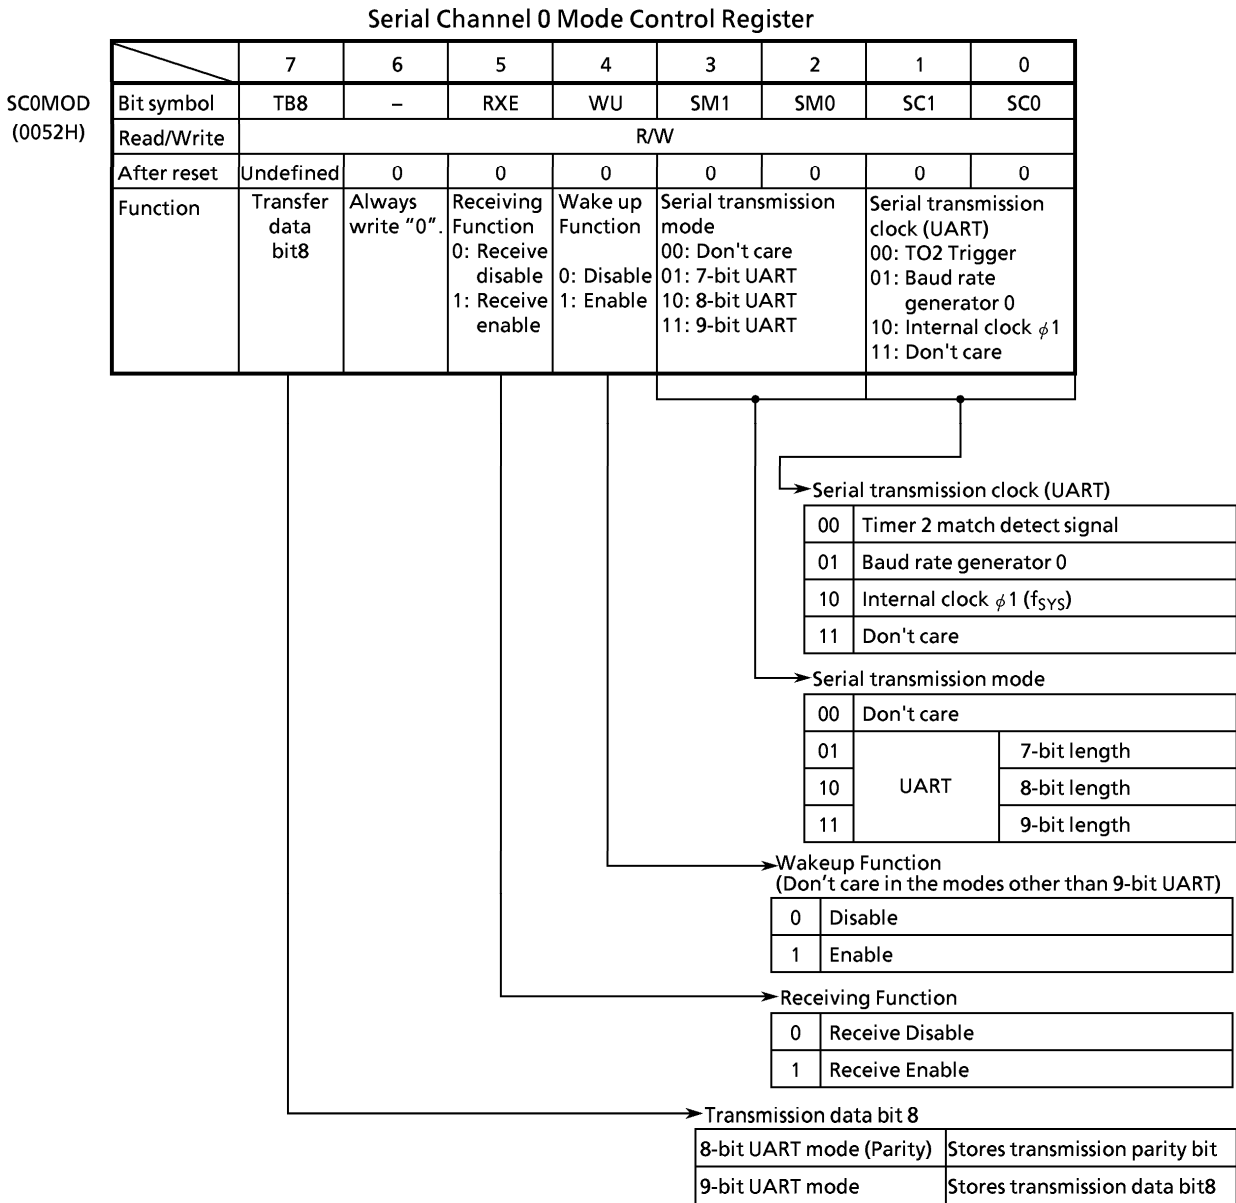

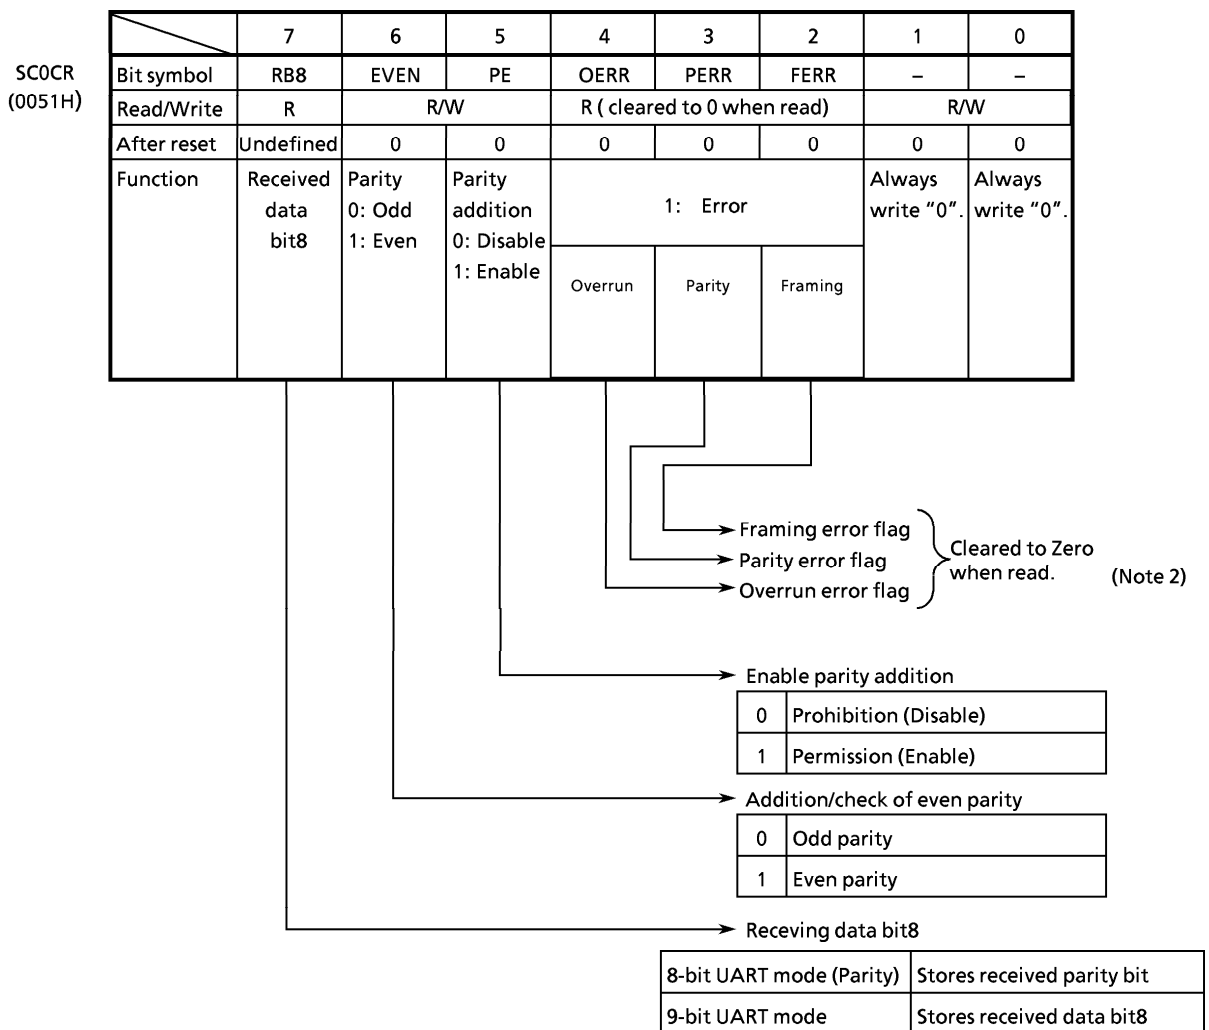

Figure 3.8.2 Serial Channel 0 Related Register (1/7)

Serial Channel 0 Control Register

Note 1: To use baud rate generator, set TRUN<PRRUN> to "1", putting the prescaler in RUN mode.

Note 2: As all error flags are cleared after reading, do not test only a single bit with a bit-testing instruction.

3.8.2 Configuration

Figure 3.8.9 shows the block diagram of the serial channel 0.

Figure 3.8.9 Block Diagram of the Serial Channel 0

Figure 3.8.10 shows the block diagram of the serial channel 1.

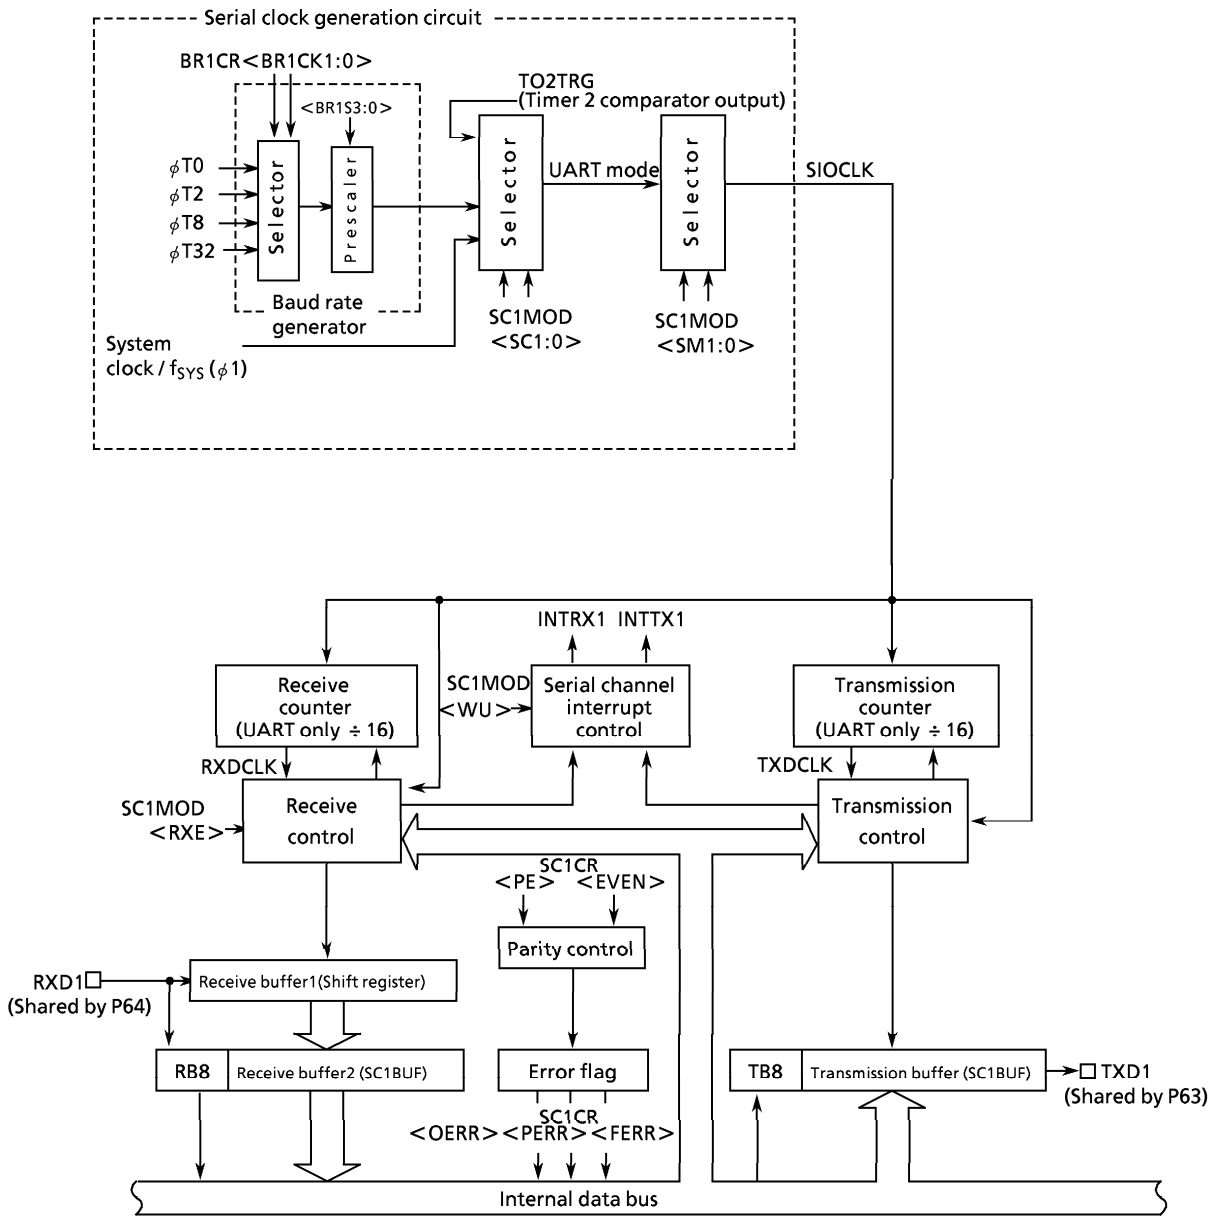

Figure 3.8.10 Block Diagram of the Serial Channel 1

Serial channel 0 and 1 can be used independently. All serial channels operate in the same manner, and thus only operation of serial channel 0 will be explained below.

① Prescaler

There are 9-bit prescaler and prescaler clock selection registers to generate input clock for 8-bit timer 0, 1, 2, 3, 16-bit timer 4, 5, and serial interface 0, 1.

Figure 3.8.5 shows the block diagram. Table 3.8.1 shows prescaler clock resolution into the baud rate generator.

Figure 3.8.11 The Block Diagram of Prescaler

Table 3.8.1 Prescaler Clock Resolution to Baud Rate Generator

at $f_c = 20$ MHz

XXX: Don't care, - : Can not use

The clock selected among f_{FPH} clock and $f_c/16$ clock is divided by 4 and input to this prescaler. This is selected by prescaler clock selection register SYSCR0<PRCK1:0>

Resetting sets <PRCK1:0> to "00" and selects the f_{FPH} clock input divided by 4.

The baud rate generator selects between 4 clock inputs ϕ T0, ϕ T2, ϕ T8, and ϕ T32 among the prescaler outputs.

The prescaler can be run or stopped by the timer operation control register TRUN<PRRUN>. Counting starts when <PRRUN> is set to "1", while the prescaler is cleared to zero and stops operation when <PRRUN> is set to "0".

When the IDLE1 mode (Operates only oscillator) is used, set TRUN<PRRUN> to "0" to reduce the power consumption of this prescaler before "HALT" instruction is executed.

② Baud rate generator

Baud rate generator comprises a circuit that generates transmission and receiving clocks to determine the transfer rate of the serial channel.

The input clock to the baud rate generator, $\phi T0$, $\phi T2$, $\phi T8$, or $\phi T32$ is generated by the 9-bit prescaler which is shared by the timers. One of these input clocks is selected by the baud rate generator control register $BR0CR<BR0CK1:0>$.

The baud rate generator includes a 4-bit frequency divider, which divides frequency by 1 to 16 values to determine the transfer rate.

How to calculate a transfer rate when the baud rate generator is used is explained below.

● UART mode

$$\text{Baud rate} = \frac{\text{Input clock of baud rate generator}}{\text{Frequency divisor of baud rate generator}} \div 16$$

Accordingly, when source clock f_c is 12.288 MHz, input clock is $\phi T2$ ($f_c/16$), and frequency divisor is 5, the transfer rate in UART mode becomes as follows:

$$\begin{array}{l} * \text{ Clock condition} \\ \left\{ \begin{array}{l} \text{Clock gear: } 1 (f_c) \\ \text{Prescaler clock: } f_{\text{PPH}} \end{array} \right. \end{array}$$

$$\begin{aligned} \text{Baud rate} &= \frac{f_c/16}{5} \div 16 \\ &= 12.288 \times 10^6 \div 16 \div 5 \div 16 = 9600 \text{ (bps)} \end{aligned}$$

The maximum baud rate of this baud rate generator is 307.2 kbps.

Table 3.8.2 shows an example of the transfer rate in UART mode.

Also with 8-bit timer 2, the serial channel can get a transfer rate. Table 3.8.3 shows an example of baud rate using timer 2.

Table 3.8.2 Selection of UART Transfer Rate (1) (When baud rate generator is used)
Unit (kbps)

fc [MHz]	Input Clock		ϕT0 (4/fc)	ϕT2 (16/fc)	ϕT8 (64/fc)	ϕT32 (256/fc)

19.6608	2		153.600	38.400	9.600	2.400
↑	4		76.800	19.200	4.800	1.200
↑	8		38.400	9.600	2.400	0.600
↑	16		19.200	4.800	1.200	0.300

Note: This table is calculated when fc/1 is selected as a clock gear, and the system clock as a prescaler clock.

Table 3.8.3 Selection of UART Transfer Rate (2)
(when timer 2 (Input clock ϕ T1) is used)
Unit (kbps)

TREG2 \ fc	19.6608 MHz	14.7456 MHz	12.288 MHz	12 MHz	9.8304 MHz	8 MHz	6.144 MHz
1H	153.6	115.2	96		76.8	62.5	48
2H	76.8	57.6	48		38.4	31.25	24
3H	51.2	38.4	32	31.25			16
4H	38.4	28.8	24		19.2		12
5H	30.72	23.04	19.2				9.6
8H	19.2	14.4	12		9.6		6
AH	15.36	11.52	9.6				4.8
10H	9.60	7.20	6		4.8		3
14H	7.68	5.76	4.8				2.4

How to calculate the transfer rate (when timer 2 is used):

$$\text{Transfer rate} = \frac{\text{The clock frequency selected by the register SYSCR0<PRCK1, 0>}}{\text{TREG2} \times 8 \times 16}$$

↑
(When Timer 2 (Input clock ϕ T1) is used)

Note: This table is calculated when fc/1 is selected as a clock gear, and f_{PPH} as a prescaler clock.

③ Serial clock generation circuit

This circuit generates the basic clock for transmitting and receiving data.

UART mode

According to the setting of SC0MOD<SC1:0>, the above baud rate generator clock, internal clock $\phi 1$ (Max 625 kbps at $f_c = 20$ MHz), the match detect signal from timer 2, or external clock SCLK0 will be selected to generate the basic clock SIOCLK.

④ Receiving counter

The receiving counter is a 4-bit binary counter used in UART mode and counts up by SIOCLK clock. 16 pulses of SIOCLK are used for receiving 1 bit of data, and the data bit is sampled three times at 7th, 8th and 9th clock.

With the three samples, the received data is evaluated by the rule of majority.

For example, if the sampled data bit is “1”, “0” and “1” at 7th, 8th and 9th clock respectively, the received data is evaluated as “1”. The sampled data “0”, “0” and “1” is evaluated that the received data is “0”.

⑤ Receiving control

UART mode

The receiving control has a circuit for detecting the start bit by the rule of majority. When two or more “0” are detected during 3 samples, it is recognized as start bit and the receiving operation is started.

Data being received are also evaluated by the rule of majority.

⑥ Receiving buffer

To prevent overrun error, the receiving buffer has a double buffer structure.

Received data are stored one bit by one bit in the receiving buffer 1 (Shift register type). When 7 bits or 8 bits of data is stored in the receiving buffer 1, the stored data are transferred to the receiving buffer 2 (SC0BUF), generating an interrupt INTRX0. The CPU reads only receiving buffer 2 (SC0BUF). Even before the CPU reads the receiving buffer 2 (SC0BUF), the received data can be stored in the receiving buffer 1. However, unless the receiving buffer 2 (SC0BUF) is read before all bits of the next data are received by the receiving buffer 1, an overrun error occurs. If an overrun error occurs, the contents of the receiving buffer 1 will be lost, although the contents of the receiving buffer 2 and SC0CR<RB8> is still preserved.

The parity bit added in 8-bit UART mode and the most significant bit (MSB) in 9-bit UART mode are stored in SC0CR<RB8>.

When in 9-bit UART mode, the wake-up function of the slave controllers is enabled by setting SC0MOD<WU> to “1”, and interrupt INTRX0 occurs only when SC0CR<RB8> is set to “1”.

⑦ Transmission counter

Transmission counter is a 4-bit binary counter which is used in UART mode and counts by SIOCLK clock, generating TXDCLK every 16 clock pulses.

Figure 3.8.12 Generation of Transmission Clock

⑧ Transmission controller

UART mode

When transmission data are written in the transmission buffer sent from the CPU, transmission starts at the rising edge of the next TXDCLK, generating a transmission shift clock TXDSFT.

⑨ Transmission buffer

Transmission buffer (SC0BUF) shifts out and sends the transmission data written from the CPU from the least significant bit (LSB) in order. When all bits are shifted out, the transmission buffer becomes empty and generates INTTX0 interrupt.

⑩ Parity control circuit

When serial channel control register SC0CR<PE> is set to “1”, it is possible to transmit and receive data with parity. However, parity can be added only in 7-bit UART or 8-bit UART mode. With SC0CR<EVEN> register, even (odd) parity can be selected.

For transmission, parity is automatically generated according to the data written in the transmission buffer SC0BUF, and data are transmitted after being stored in SC0BUF<TB7> when in 7-bit UART mode while in SC0MOD<TB8> when in 8-bit UART mode. <PE> and <EVEN> must be set before transmission data are written in the transmission buffer.

For receiving, data are shifted in the receiving buffer 1, and parity is added after the data are transferred in the receiving buffer 2 (SC0BUF), and then compared with SC0BUF<RB7> when in 7-bit UART mode and with SC0MOD<RB8> when in 8-bit UART mode. If they are not equal, a parity error occurs, and SC0CR<PERR> flag is set.

⑪ Error flag

Three error flags are provided to increase the reliability of receiving data.

1. Overrun error <OERR>

If all bits of the next data are received in receiving buffer 1 while valid data are stored in receiving buffer 2 (SC0BUF), an overrun error will occur.

2. Parity error <PERR>

The parity generated for the data shifted in receiving buffer 2 (SC0BUF) is compared with the parity bit received from RXD pin. If they are not equal, a parity error occurs.

3. Framing error <FERR>

The stop bit of received data is sampled three times around the center. If the majority is “0”, a framing error occurs.

⑫ Signal generation timing

In UART mode

Receive

Mode	9-Bit	8-Bit + Parity	8-Bit, 7-Bit + Parity, 7-Bit
Timing for interrupt generation	Center of last bit (Bit8)	Center of last bit (Parity bit)	Center of stop bit
Timing for framing error generation	Center of stop bit	Center of stop bit	Center of stop bit
Timing for parity error generation	—————	Center of last bit (Parity bit)	Center of stop bit
Timing for overrun error generation	Center of last bit (Bit8)	Center of last bit (Parity bit)	Center of stop bit

Note: In 9-Bit and 8-Bit + Parity mode, interrupts coincide with the ninth bit pulse. Thus, when servicing the interrupt, it is necessary to wait for a 1-bit period (to allow the stop bit to be transferred) to allow checking for a framing error.

Send

Mode	9-Bit	8-Bit + Parity	8-Bit, 7-Bit + Parity, 7-Bit
Timing for interrupt generation	Immediately before stop bit sent	←	←

3.8.3 Operational Description

(1) Mode 1 (7-bit UART mode)

7-bit mode can be set by setting serial channel mode register SC0MOD <SM1:0> to "01".

In this mode, a parity bit can be added, and the addition of a parity bit can be enabled or disabled by serial channel control register SC0CR <PE>, and even parity or odd parity is selected by SC0CR <EVEN> when <PE> is set to "1" (enable).

Setting example: When transmitting data with the following format, the control registers should be set as described below.

	7	6	5	4	3	2	1	0		
P6CR	←	X	X	-	-	-	-	1	} Select P60 as the TXD pin.	
P6FC	←	X	X	-	X	-	-	X		
SC0MOD	←	X	0	-	X	0	1	0	1	Set 7-bit UART mode.
SC0CR	←	X	1	1	X	X	X	0	0	Add an even parity.
BROCR	←	0	X	1	0	0	1	0	1	Set transfer rate at 2400 bps.
TRUN	←	1	X	-	-	-	-	-	-	Start the prescaler for the baud rate generator.
INTES0	←	1	1	0	0	-	-	-	-	Enable INTTX0 interrupt and set interrupt level 4.
SC0BUF	←	*	*	*	*	*	*	*	*	Set data for transmission.

X: Don't care, -: No change

(2) Mode 2 (8-bit UART mode)

8-bit UART mode can be specified by setting SC0MOD <SM1:0> to "10". In this mode, parity bit can be added, the addition of a parity bit is enabled or disabled by SC0CR <PE>, and even parity or odd parity is selected by SC0CR <EVEN> when <PE> is set to "1" (Enable).

Setting example: When receiving data with the following format, the control register should be set as described below.

Main setting

	7	6	5	4	3	2	1	0		
P6CR	←	X	X	-	-	-	0	-	Select P61 (RXD) as the input pin.	
SC0MOD	←	-	0	1	X	1	0	0	1	Enable receiving in 8-bit UART mode.
SC0CR	←	X	0	1	X	X	X	0	0	Add an odd parity.
BROCR	←	0	X	0	1	0	1	0	1	Set transfer rate at 9600 bps.
TRUN	←	1	X	-	-	-	-	-	-	Start the prescaler for the baud rate generator.
INTES0	←	-	-	-	-	1	1	0	0	Enable INTRX0 interrupt and set interrupt level 4.

Interrupt processing

Acc ← SC0CR AND 00011100	}	Check for error.
if Acc ≠ 0 then ERROR		
Acc ← SC0BUF		Read the received data.

X: Don't care, -: No change

(3) Mode 3 (9-bit UART mode)

9-bit UART mode can be specified by setting SC0MOD<SM1:0> to "11". In this mode, parity bit cannot be added.

For transmission, the MSB (9th bit) is written in SC0MOD<TB8>, while in receiving it is stored in SC0CR<RB8>. For writing and reading the buffer, the MSB is read or written first then SC0BUF.

Wake-up function

In 9-bit UART mode, the wake-up function of slave controllers is enabled by setting SC0MOD<WU> to "1". The interrupt INTRX0 occurs only when <RB8> = 1.

Note: TXD pin of the slave controllers must be in open drain output mode.

Figure 3.8.13 Serial Link Using Wakeup Function

Protocol

- ① Select the 9-bit UART mode for the master and slave controllers.
- ② Set SC0MOD<WU> bit of each slave controller to "1" to enable data receiving.
- ③ The master controller transmits one-frame data including the 8-bit select code for the slave controllers. The MSB (Bit8)<TB8> is set to "1".

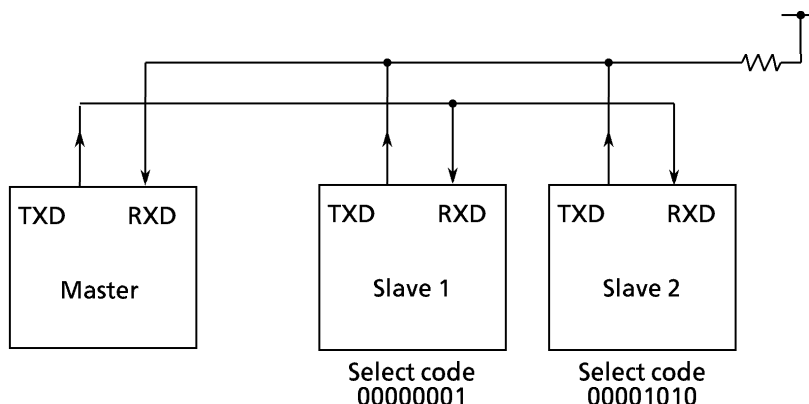

- ④ Each slave controller receives the above frame, and clears WU bit to "0" if the above select code matches its own select code.
- ⑤ The master controller transmits data to the specified slave controller whose SC0MOD<WU> bit is cleared to "0". The MSB (Bit8)<TB8> is cleared to "0".

- ⑥ The other slave controllers (with the <WU> bit remaining at "1") ignore the receiving data because their MSBs (Bit 8 or <RB8>) are set to "0" to disable the interrupt INTRX0. The slave controllers (<WU>=0) can transmit data to the master controller, and it is possible to indicate the end of data receiving to the master controller by this transmission.

Setting example: To link two slave controllers serially with the master controller, and use the internal clock $\phi 1$ as the transfer clock.

Since serial channels 0 and 1 operate in exactly the same way, channel 0 is used for the purposes of explanation.

● Setting the master controller

Main

P6CR	←	X X - - - 0 1	}	Select P60 as TXD0 pin and P61 as RXD0 pin.
P6FC	←	X X - X - 0 X 1		
INTES0	←	1 1 0 0 1 1 0 1		Enable INTTX0 and set the interrupt level 4.
				Enable INTRX0 and set the interrupt level 5.
SC0MOD	←	1 0 1 0 1 1 1 0		Set $\phi 1$ as the transmission clock in 9-bit UART mode.
SC0BUF	←	0 0 0 0 0 0 0 1		Set the select code for slave controller 1.

INTTX0 interrupt

SC0MOD	←	0 - - - - - - -	Sets TB8 to "0".

● Setting the slave controller 2

Main

P6CR	←	X X - - - 0 1	}	Select P61 as RXD0 pin and P60 as TXD0 pin (Open-drain output).
P6FC	←	X X - X - 0 X 1		
ODE	←	X X X X X X - 1		Enable INTRX0 and INTTX0.
INTES0	←	1 1 0 1 1 1 1 0		Set <WU> to "1" in the 9-bit UART transmission mode with transfer clock $\phi 1$.
SC0MOD	←	0 0 1 1 1 1 1 0		

INTRX0 interrupt

Acc	←	SC0BUF	
		if Acc = Select code	
		Then SC0MOD ← - - - 0 - - - -	Clear <WU> to "0".

3.9 Analog/Digital Converter

TMP93CS36 incorporate a high-speed, high-precision 10-bit analog/digital converter (AD converter) with 4-channel analog input.

Figure 3.9.1 is a block diagram of the AD converter. The 6-channel analog input pins (AN0 to AN3) are also used as input-only port P5 and can be also used as input ports.

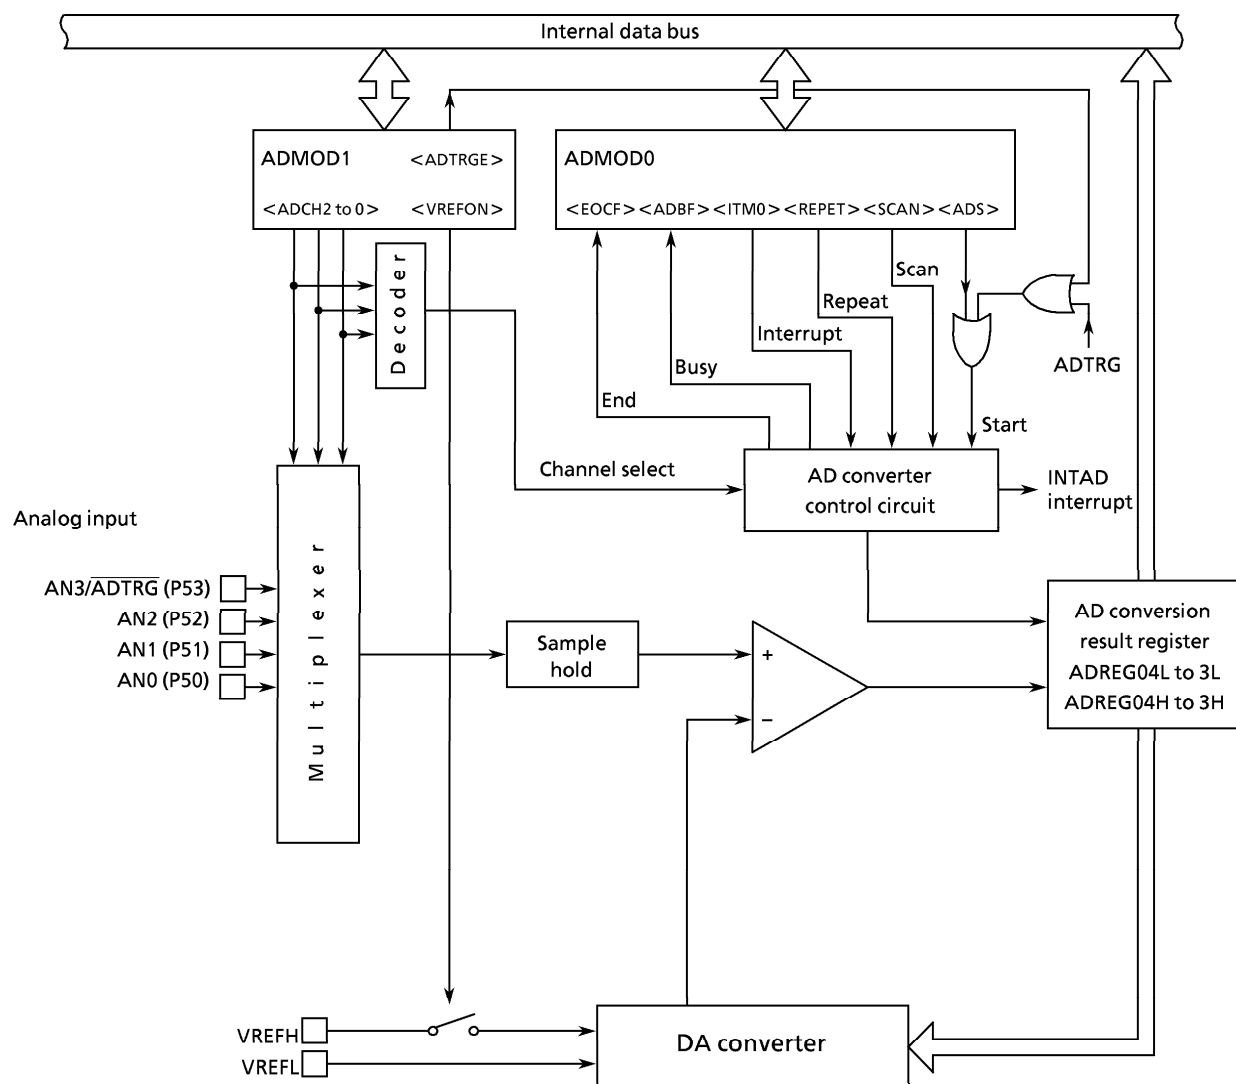

Figure 3.9.1 Block Diagram of AD Converter

Note 1: When the power supply current is reduced in IDLE2, IDLE1, STOP mode, there is possible to set a standby enabling the internal comparator due to a timing. Stop operation of AD converter before execution of "HALT" instruction.

Note 2: In regard to the lowest operation frequency.
The operation of AD converter is guaranteed with clock of $f_{FPH} \geq 4 \text{ MHz}$.

3.9.1 Analog/Digital Converter Registers

AD converter is controlled by two AD mode control registers (ADMOD0 and ADMOD1). AD conversion result is stored in eight AD conversion result registers (ADREG04H/L, ADREG15H/L, ADREG2H/L, ADREG3H/L).

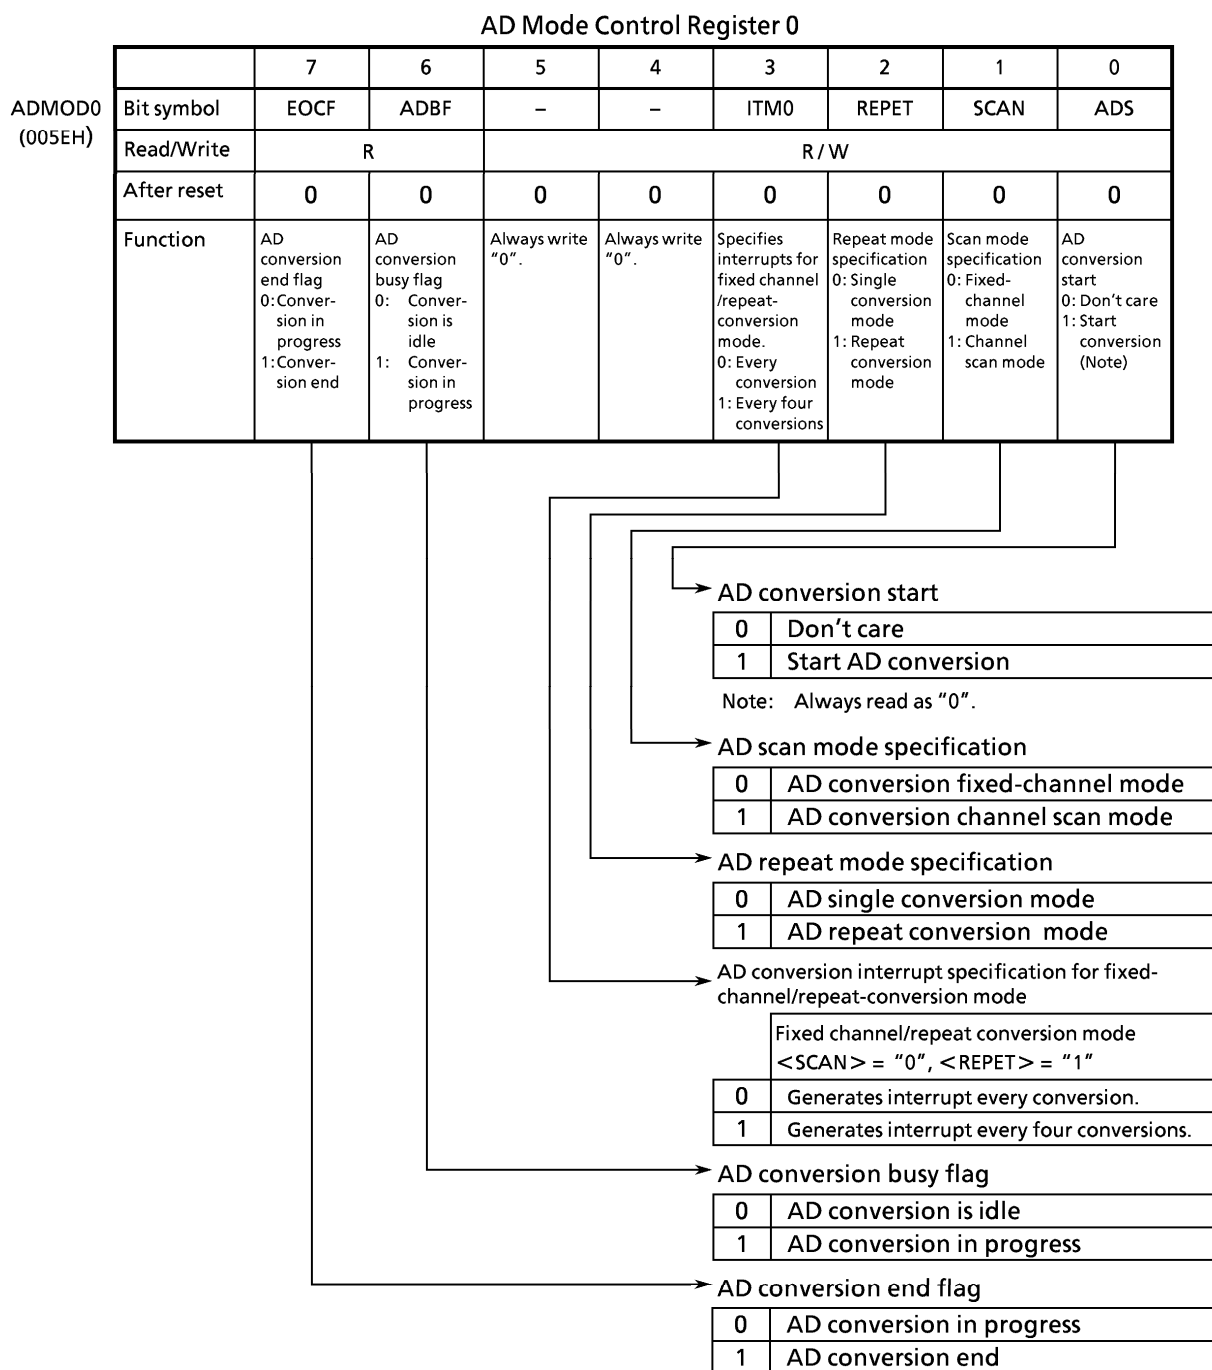

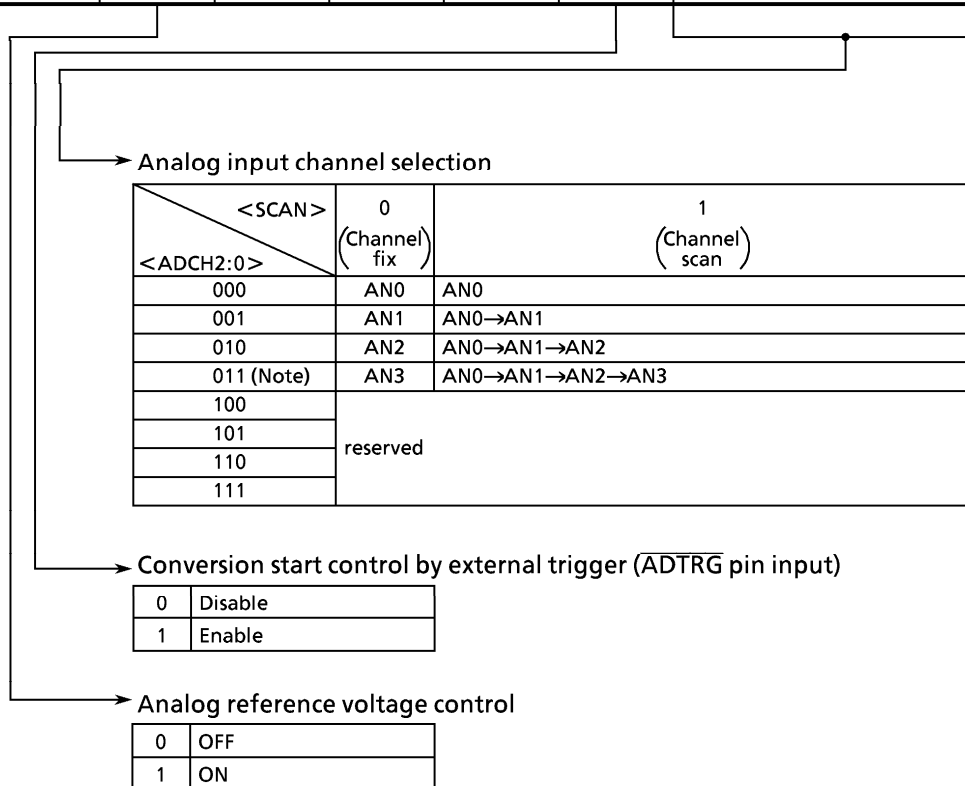

Figure 3.9.2 Register for AD Converter (1/4)

AD Mode Control Register 1

	7	6	5	4	3	2	1	0
Bit symbol	VREFON				ADTRGE	ADCH2	ADCH1	ADCH0
Read/Write	R / W				R / W			
After reset	1				0	0	0	0
Function	String resistance 0: OFF 1: ON				External trigger start control 0: Disable 1: Enable	Analog input channel selection		

Note: Set the <VREFON> bit to "1" before starting conversion (write "1" to ADMOD0<ADS>).

Note: As the AN3 and the $\overline{\text{ADTRG}}$ are the same pin, <ADCH2:0> = "011" can't be set when <ADTRGE> is set to 1 and $\overline{\text{ADTRG}}$ is used.

Figure 3.9.3 Register for AD Converter (2/4)

AD Conversion Result Register 0/4 Low

	Read/Write	R						R
	After reset	Undefined						0
	Function	Stores lower 2 bits of AD conversion result.						Conversion result stored flag 1: Exist result

AD Conversion Result Register 3 High

	7	6	5	4	3	2	1	0	
ADREG3H (0067H)	Bit symbol	ADR39	ADR38	ADR37	ADR36	ADR35	ADR34	ADR33	ADR32
	Read/Write	R							
	After reset	Undefined							
	Function	Stores upper 8 bits of AD conversion result.							

- Bits 5 to 1 are always read as “1”.
- Bit0 is conversion result stored flag bit <ADRxRF>. <ADRxRF> is set to “1” when the AD conversion result is stored. Reading either the ADREGxH or the ADREGxL registers clears <ADRxRF> to “0”.

Figure 3.9.5 Registers for AD Converter (4/4)

3.9.2 Operation

(1) Analog reference voltage

High analog reference voltage is applied to the VREFH pin, and low analog reference voltage is applied to the VREFL pin. The voltage between VREFH and VREFL is divided into 1024 increments using a string resistor. AD conversion is based on comparing the analog input voltage with these reference voltage increments.

To turn the switch between VREFH and VREFL off, write “0” to the ADMOD1<VREFON> bit.

To start AD conversion when the switch is off, first write “1” to <VREFON>. After that, wait at 3 μ s long enough to get the stabilized oscillation, write “1” to ADMOD0<ADS>.

(2) Selecting analog input channels

The procedure for selecting analog input channels depends on the operating mode of the AD converter.

- When analog input channel is used to fix (ADMOD0<SCAN> = “0”)
 - To set ADMOD1<ADCH2:0>, selecting one channel from analog input pins AN0 to AN3.
- When analog input channel is used to scan (ADMOD0<SCAN> = “1”)
 - To set ADMOD1<ADCH2:0>, selecting one channel from 4 scan mode.

Table 3.9.1 shows the analog input channel selection in each operating mode.

A reset initializes AD mode control register ADMOD1<ADCH2:0> to “000”, selecting pin AN0 for the AD converter input.

The pins not used as analog input channels can be used as general-purpose input ports (P5).

Table 3.9.1 Analog Input Channel Selection

<ADCH2 to 0>	Fixed Channel <SCAN> = 0	Channel Scan <SCAN> = 1
000	AN0	AN0
001	AN1	AN0→AN1
010	AN2	AN0→AN1→AN2
011	AN3	AN0→AN1→AN2→AN3
100	Reserved	
101		
110		
111		

(3) Starting AD conversion

AD conversion starts when $ADMOD0\langle ADS \rangle$ to "1", or $ADMOD1\langle ADTRGE \rangle$ is set to "1" and the falling edge is input through \overline{ADTRG} pin.

When AD conversion starts, AD conversion busy flag $ADMOD0\langle ADBF \rangle$ is set to "1", indicating AD conversion is in progress.

Writing "1" to $\langle ADS \rangle$ while conversion is in progress restarts the conversion. Check the conversion result stored flag $ADREGxL\langle ADRxRF \rangle$ to determine whether the AD conversion data are valid at this time.

Inputting the falling edge to the \overline{ADTRG} pin while conversion is in progress is invalid.

(4) AD conversion modes and completion interrupt

Follow the four AD conversion modes are supported.

- Fixed channel single conversion mode
- Channel scan single conversion mode
- Fixed channel repeat conversion mode
- Channel scan repeat conversion mode

AD conversion mode can be selected by setting AD mode control register $ADMOD0\langle REPET, SCAN \rangle$.

When AD conversion ends, AD conversion completion interrupt INTAD request occurs. And the $ADMOD0\langle EOCF \rangle$ flag is set to "1" to indicate that AD conversion has completed.

① Fixed channel single conversion mode

Fixed channel single conversion mode can be specified by setting $ADMOD0\langle REPET, SCAN \rangle$ to "00". In this mode, conversion of the specified single channel is executed once only. After conversion is completed, $ADMOD0\langle EOCF \rangle$ is set to "1", $ADMOD0\langle ADBF \rangle$ is cleared to "0" and occurs INTAD interrupt request.

② Channel scan single conversion mode

Channel scan single conversion mode can be specified by setting $ADMOD0\langle REPET, SCAN \rangle$ to "01". In this mode, conversion of the specified channel are executed once only. After conversion is completed, $ADMOD0\langle EOCF \rangle$ is set to "1", $ADMOD0\langle ADBF \rangle$ is cleared to "0" and occurs INTAD interrupt request.

③ Fixed channel repeat conversion mode

Fixed channel repeat conversion mode can be specified by setting $ADMOD0\langle REPET, SCAN \rangle$ to "10". In this mode, conversion of the specified single channel is executed repeatedly. After conversion is completed, $ADMOD0\langle EOCF \rangle$ is set to "1", $ADMOD0\langle ADBF \rangle$ remains "1", not changed to "0". The timing of INTAD interrupt request can be selected by setting of $ADMOD0\langle ITM0 \rangle$.

When $\langle ITM0 \rangle$ is set to "0", interrupt request occurs after every conversion.

When $\langle ITM0 \rangle$ is set to "1", interrupt request occurs after every fourth conversion.

④ Channel scan repeat conversion mode

Channel scan repeat conversion mode can be specified by setting ADMOD0<REPET, SCAN> to “11”. In this mode, specified channels are converted repeatedly. After every scan convert completion, ADMOD0<EOCF> is set to “1” and INTAD interrupt request occurs. ADMOD0<ADBF> remains “1”, not changed to “0”.

To stop the repeat conversion mode (③ and ④ modes), write “0” to ADMOD0<REPET>. After the current conversion is completed repeat conversion mode is terminated, and ADMOD0<ADBF> is cleared to “0”.

If the device enters the IDLE2, IDLE1 or STOP modes during AD conversion, the conversion halts immediately. After the HALT mode is released, AD conversion restarts from the beginning in repeat conversion mode (③ and ④), it does not restart in single conversion mode (① and ②).

Table 3.9.2 shows the relations between AD conversion modes and interrupt request.

Table 3.9.2 Relation between AD Conversion Modes and Interrupt Request

Mode	Interrupt Request Timing	ADMOD0		
		<ITM0>	<REPET>	<SCAN>
Fixed channel single conversion mode	After conversion	X	0	0
Channel scan single conversion mode	After conversion	X	0	1
Fixed channel repeat conversion mode (Every conversion)	After every conversion	0	1	0
Fixed channel repeat conversion mode (Every fourth conversion)	After every fourth conversion	1		
Channel scan repeat conversion mode	After every scan conversion	X	1	1

X: Don't Care

(5) AD conversion time

140 states ($14 \mu\text{s}$ at $f_c = 20 \text{ MHz}$) are required for AD conversion of one channel.

(6) Storing and reading the AD conversion result

AD conversion results are stored in AD conversion result registers high/low (ADREG04H/L to ADREG3H/L). These registers are read only.

In fixed channel repeat conversion mode, AD conversion results are stored in order from ADREG04H/L to ADREG3H/L. Except in this mode, AD conversion results for channel AN0, AN1, AN2, AN3 are stored severally ADREG04H/L, ADREG15H/L, ADREG2H/L, ADREG3H/L.

Table 3.9.3 shows correspondence between analog input channels and AD conversion result registers.

Table 3.9.3 Correspondence Between Analog Input Channels and AD Conversion Result Registers

Analog Input Channel (port 5)	AD Conversion Result Registers	
	Conversion Modes Except Right	Fixed Channel Repeat Conversion Mode (Every fourth conversion)
AN0	ADREG04H/L	ADREG04H/L
AN1	ADREG15H/L	↓ ADREG15H/L
AN2	ADREG2H/L	↓ ADREG2H/L
AN3	ADREG3H/L	↓ ADREG3H/L

AD conversion result registers bit “0” is AD conversion result stored flag <ADR_xRF>. The flag shows that whether those registers are read or not. When AD conversion results are stored in those registers (ADREG_xH or ADREG_xL), this flag is set to “1”. When each register is read, this flag is cleared to “0”, and AD conversion end flag ADMOD0 <EOCF> is also cleared to “0”.

Setting example :

- ① This example converts the analog input voltage at the AN3 pin. The INTAD interrupt routine writes the result to memory address 0800H.

Main routine setting:

7 6 5 4 3 2 1 0

INTE0AD	← 1 1 0 0 - - - -	Enables INTAD and sets level 4.
ADMOD1	← 1 X X X 0 0 1 1	Sets analog input channel to AN3.
ADMOD0	← X X 0 0 0 0 0 1	Starts AD conversion in fixed channel single conversion mode.

Example of interrupt routine processing:

WA	← ADREG3	Reads ADREG3L and ADREG3H values and writes them to WA (16 bits).
WA	>> 6	Shifts right WA six times and zero-fills the upper bits.
(0800H)	← WA	Writes contents of WA to memory address 0800H.

- ② This example repeatedly converts the analog input voltages at pins AN0 to AN2, using channel scan repeat conversion mode.

INTE0AD	← 1 0 0 0 - - - -	Disables INTAD.
ADMOD1	← 1 X X X 0 0 1 0	Sets AN0 to AN2 as analog input channels.
ADMOD0	← X X 0 0 0 1 1 1	Starts AD conversion in channel scan repeat conversion mode.

X: Don't care, -: No change

3.10 Watchdog Timer (Runaway detecting timer), Warm-up Timer

TMP93CS36 contains a watchdog timer of runaway detecting.

The watchdog timer (WDT) is used to return the CPU to the normal state when it detects that the CPU has started to malfunction (Runaway) due to causes such as noise. When the watchdog timer detects a malfunction, it generates a non-maskable interrupt INTWD to notify the CPU of the malfunction.

Connecting the watchdog timer output to the reset pin internally forces a reset.

This watchdog timer consists of 7-stage and 15-stage binary counters.

These binary counters are also used as a warm-up timer for the internal oscillator stabilization. This is used for releasing the STOP.

3.10.1 Configuration

Figure 3.10.1 shows the block diagram of the watchdog timer (WDT).

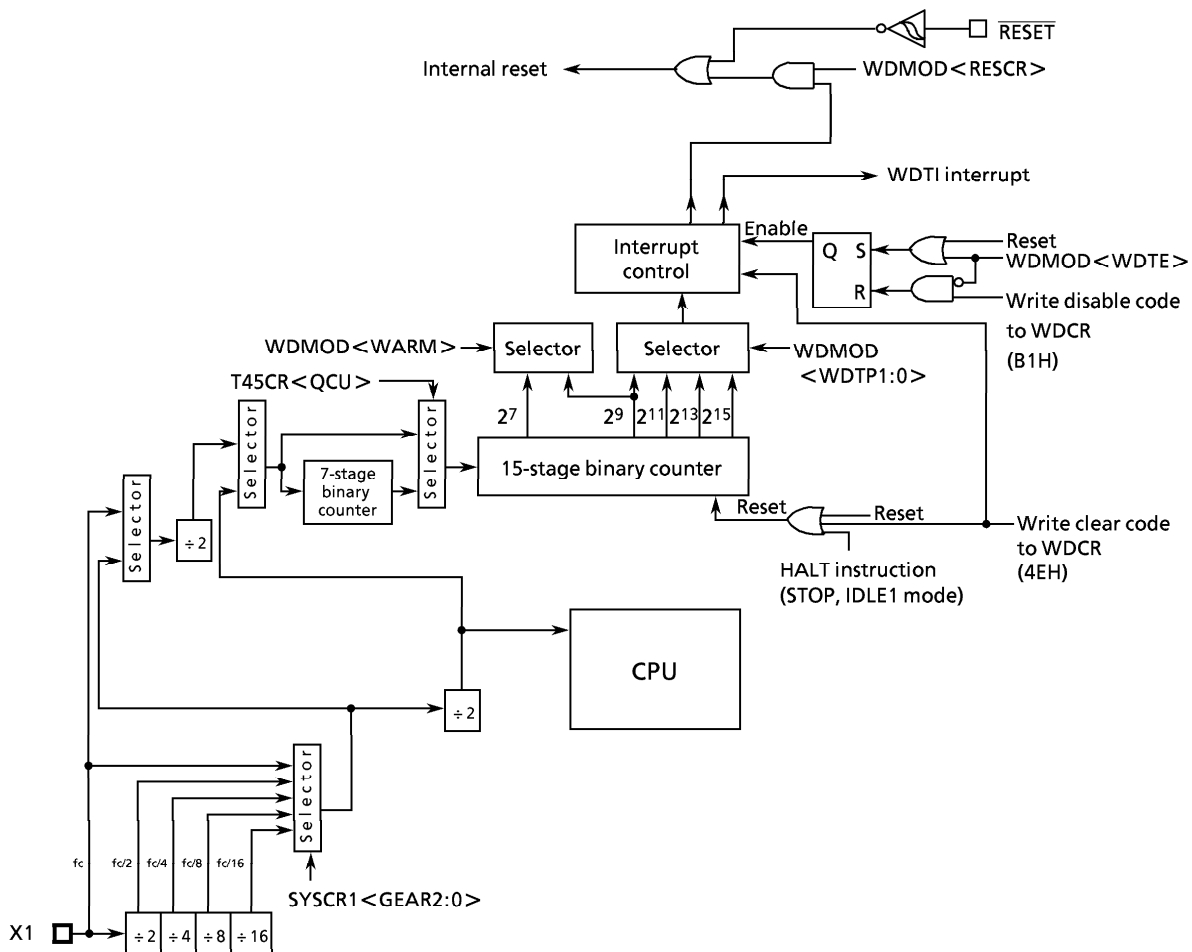

Figure 3.10.1 Block Diagram of Watchdog Timer/Warm-up Timer

The watchdog timer consists of 7-stage and 15-stage binary counters which use system clock (f_{SYS}) as the input clock. The 15-stage binary counter has $f_{SYS}/2^{15}$, $f_{SYS}/2^{17}$, $f_{SYS}/2^{19}$ and $f_{SYS}/2^{21}$ output. Selecting one of the outputs with the $WDMOD < WDTP1:0 >$ register generates a watchdog interrupt when an overflow occurs. The binary counter for the watchdog timer should be cleared to "0" with runaway detecting result software (instruction) before an interrupt occurs.

Example:

```
LDW    (WDMOD), B100H    ; Disable
LD     (WDCR), 4EH       ; Write clear code
SET    7, (WDMOD)        ; Enable again
```

The runaway detecting result can also be connected to the reset pin internally. In this case, the watchdog timer resets itself.

Figure 3.10.2 Normal Mode

Figure 3.10.3 Reset Mode

For warm-up counter, 2^7 and 2^9 output of 15-stage binary counter can be selected using $WDMOD < WARM >$ register. When a stable-external oscillator is used, shorter warm-up time is available using $T45CR < QCU >$ register. When $< QCU > = 1$, counting value 2^7 is selected.

When the watchdog timer is in operation, this shorter warm-up time function cannot be available. This function can be available by setting $< QCU > = 0$.

3.10.2 Control Registers

Watchdog timer WDT is controlled by two control registers WDMOD and WDCR.

(1) Watchdog timer mode register (WDMOD)

① Setting the detecting time of watchdog timer <WDTP>

This 2-bit register is used to set the watchdog timer interrupt time for detecting the runaway. This register is initialized to WDMOD<WDTP1:0>=00 when reset. The defecting time of WDT is shown Table 3.11.1.

② Watchdog timer enable/disable control register <WDTE>

When reset, WDMOD<WDTE> is initialized to “1” enable the watchdog timer. To disable, it is necessary to set this bit to “0” and write the disable code (B1H) in the watchdog timer control register WDCR. This makes it difficult for the watchdog timer to be disabled by runaway. However, it is possible to return from the disable state to enable state by merely setting <WDTE> to “1”.

③ Watchdog timer out reset connection <RESCR>

This register is used to connect the output of the watchdog timer with $\overline{\text{RESET}}$ terminal, internally. Since WDMOD<RESCR>is initialized to 0 at reset, a reset by the watchdog timer will not be performed.

(2) Watchdog timer control register (WDCR)

This register is used to disable and clear of binary counter the watchdog timer function.

● Disable control

By writing the disable code (B1H) in this WDCR register after clearing WDMOD<WDTE> to “0”, the watchdog timer can be disabled.

WDMOD	← 0 - - - - X X	Clear WDMOD<WDTE>to “0”.
WDCR	← 1 0 1 1 0 0 0 1	Write the disable code (B1H).

● Enable control

Set WDMOD<WDTE>to “1”.

● Watchdog timer clear control

The binary counter can be cleared and resume counting by writing clear code (4EH) into the WDCR register.

WDCR ← 0 1 0 0 1 1 1 0 Write the clear code (4EH).

X: Don't care, -: No change

Watchdog Timer Mode Control Register

Note: When the watchdog timer is in operation, T45CR<QCU> is set to "0".

Figure 3.10.4 Watchdog Timer Related Register (1/2)

Watchdog Timer Control Register

Note: When the watchdog timer is in operation, T45CR<QCU> is set to "0".

Figure 3.10.4 Watchdog Timer Related Register (2/2)

Table 3.10.1 Watchdog Timer Detecting Time

at $f_c = 20\text{ MHz}$

Gear Value <GEAR2:0>	Watchdog Timer Detecting Time			
	WDMOD<WDTP1:0>			
	00	01	10	11
000 (f_c)	3.277 ms	13.107 ms	52.429 ms	209.715 ms
001 ($f_c/2$)	6.554 ms	26.214 ms	104.858 ms	419.430 ms
010 ($f_c/4$)	13.107 ms	52.429 ms	209.715 ms	838.861 ms
011 ($f_c/8$)	26.214 ms	104.858 ms	419.430 ms	1.678 s
100 ($f_c/16$)	52.429 ms	209.715 ms	838.861 ms	3.355 s

3.10.3 Operation

The watchdog timer generates interrupt INTWD after the detecting time set in the WDMOD<WDTP1:0>. The watchdog timer must be zero-cleared by software before an INTWD interrupt is generated. If the CPU malfunctions (Runaway) due to causes such as noise, but does not execute the instruction used to clear the binary counter, the binary counter overflows and an INTWD interrupt is generated. The CPU detects malfunction (Runaway) due to the INTWD interrupt and it is possible to return to normal operation by an anti-mulfunction program. By connecting the watchdog timer out pin to peripheral devices' resets, a CPU malfunction can also be acknowledged to other devices.

The watchdog timer restarts operation immediately after resetting is released.

The watchdog timer stops its operation in the IDLE1 and STOP modes. In the RUN and IDLE2 modes, the watchdog timer is enabled.

However, the function can be disabled when entering the RUN, IDLE2 mode.

Example: ① Clear the binary counter

WDCR ← 0 1 0 0 1 1 1 0 Write clear code (4EH).

② Set the watchdog timer detecting time to $2^{17}/f_{SYS}$

WDMOD ← 1 0 1 - - - X X

③ Disable the watchdog timer.

WDMOD ← 0 - - - - X X Clear WDTE to "0".
WDCR ← 1 0 1 1 0 0 0 1 Write disable code (B1H).

④ Set IDLE1 mode.

WDMOD ← 0 - - - 1 0 X X Disables WDT and sets IDLE1 mode.
WDCR ← 1 0 1 1 0 0 0 1
Executes HALT command Set the HALT mode

⑤ Set the STOP mode (warming up time: $2^{16}/f_{SYS}$)

WDMOD ← - - - 1 0 1 X X Set the STOP mode.
Executes HALT command. Set the HALT mode.

X: Don't care, -: No change

4. Electrical Characteristics

4.1 Maximum Ratings

“X” used in an expression shows a cycle of clock f_{PPH} . If a clock gear or a low speed oscillator is selected, a value of “X” is different. The value as an example is gear = 1/fc (SYSCR1 < GEAR 2:0 > = “000”).

Parameter	Symbol	Rating	Unit
Power Supply Voltage	V _{CC}	- 0.5 to 6.5	V
Input Voltage	V _{IN}	- 0.5 to V _{CC} + 0.5	V
Output Current (Per 1 pin) P7	I _{OL1}	20	mA
Output Current (Per 1 pin) except P7	I _{OL2}	2	mA
Output Current (total)	Σ I _{OL}	120	mA
Output Current (total)	Σ I _{OH}	- 80	mA
Power Dissipation (Ta = 85°C)	P _D	350	mW
Soldering Temperature (10 s)	T _{SOLDER}	260	°C
Storage Temperature	T _{STG}	- 65 to 150	°C
Operating Temperature	T _{OPR}	- 40 to 85	°C

Note: The maximum ratings are rated values which must not be exceeded during operation, even for an instant. Any one of the ratings must not be exceeded. If any maximum rating is exceeded, a device may break down or its performance may be degraded, causing it to catch fire or explode resulting in injury to the user. Thus, when designing products which include this device, ensure that no maximum rating value will ever be exceeded.

Point of Note about Solderability of Lead Free Products (Attach “G” to package name)

Test Parameter	Test Condition	Note
Solderability	(1) Use of Sn-63Pb solder bath Solder bath temperature = 230°C, dipping time = 5 seconds The number of times = one, use of R-type flux	Pass: solderability rate until forming \geq 95%
	(2) Use of Sn-3.0Ag-0.5Cu solder bath Solder bath temperature = 245°C, dipping time = 5 seconds The number of times = one, use of R-type flux (use of lead free)	

4.2 DC Characteristics (1/2)

Ta = -40 to 85°C

RUN				5.0	9	
IDLE2				3.0	5	
IDLE1				0.8	1.5	
STOP	$T_a \leq 50^\circ\text{C}$	$V_{CC} = 2.7\text{ V}$ to 5.5 V		0.2	10	μA
	$T_a \leq 70^\circ\text{C}$				20	
	$T_a \leq 85^\circ\text{C}$				50	

Note 1: Typical values are for $T_a = 25^\circ\text{C}$ and $V_{CC} = 5\text{ V}$ unless otherwise noted.

Note 2: I_{DAR} is guaranteed for total of up to 8 ports.

Note 3: I_{CC} measurement conditions (NORMAL, SLOW):

Only CPU is operational; output pins are open and input pins are fixed.

(Reference) Definition of I_{DAR}

4.3 AD Conversion Characteristics

$$AV_{CC} = V_{CC}, AV_{SS} = V_{SS}$$

Parameter	Symbol	Power Supply	Min	Typ.	Max	Unit
Analog Reference Voltage (+)	V_{REFH}	$V_{CC} = 5V \pm 10\%$	$V_{CC} - 0.2$	V_{CC}	V_{CC}	V
		$V_{CC} = 3V \pm 10\%$	$V_{CC} - 0.2$	V_{CC}	V_{CC}	
Analog Reference Voltage (-)	V_{REFL}	$V_{CC} = 5V \pm 10\%$	V_{SS}	V_{SS}	$V_{SS} + 0.2$	
		$V_{CC} = 3V \pm 10\%$	V_{SS}	V_{SS}	$V_{SS} + 0.2$	
Analog Input Voltage Range	V_{AIN}		V_{REFL}		V_{REFH}	
Analog Current for Analog Reference Voltage <VREFON> = 1	I_{REF} ($V_{REFL} = 0V$)	$V_{CC} = 5V \pm 10\%$		0.5	1.5	mA
		$V_{CC} = 3V \pm 10\%$		0.3	0.9	
<VREFON> = 0		$V_{CC} = 2.7$ to $5.5V$		0.02	5.0	μA
Error (Except quantization errors)	-	$V_{CC} = 5V \pm 10\%$		± 1.0	± 3.0	LSB
		$V_{CC} = 3V \pm 10\%$		± 1.0	± 5.0	

Note 1: $1LSB = (V_{REFH} - V_{REFL})/2^{10}$ [V]

Note 2: The operation above is guaranteed for $f_{FPH} \geq 4$ MHz.

Note 3: The value I_{CC} includes the current which flows through the AVCC pin.

4.4 Event Counter Input Clock (External input clock: TI4, TI5, TI6, TI7)

Parameter	Symbol	Variable		12.5 MHz		20 MHz		Unit
		Min	Max	Min	Max	Min	Max	
Clock Cycle	t_{VCK}	$8X + 100$		740		500		ns
Low Level Clock Pulse Width	t_{VCKL}	$4X + 40$		360		240		ns
High Level Clock Pulse Width	t_{VCKH}	$4X + 40$		360		240		ns

4.5 Interrupt and Capture Operation

(1) INT0 Interrupts

Parameter	Symbol	Variable		12.5 MHz		20 MHz		Unit
		Min	Max	Min	Max	Min	Max	
INT0 Low Level Pulse Width	t_{INTAL}	$4X$		320		200		ns
INT0 High Level Pulse Width	t_{INTAH}	$4X$		320		200		ns

(2) INT4 to INT7 Interrupts and Capture

Parameter	Symbol	Variable		12.5 MHz		20 MHz		Unit
		Min	Max	Min	Max	Min	Max	
INT4 to INT7 Low Level Pulse Width	t_{INTBL}	$4X + 100$		420		300		ns
INT4 to INT7 High Level Pulse Width	t_{INTBH}	$4X + 100$		420		300		ns

5. Table of Special Function Registers

The special function registers (SFRs) include the I/O ports and peripheral control registers allocated to the 128-bytes addresses from 000000H to 00007FH.

- (1) I/O port
- (2) I/O port control
- (3) Clock control
- (4) Interrupt control
- (5) Timer control
- (6) Serial channel control
- (7) AD converter control
- (8) Watchdog timer control

Configuration of the table

Symbol	Name	Address	7	6			1	0	
									→ Bit symbol
									→ Read/Write
									→ Initial value after reset
									→ Remarks

Note: "Prohibit RMW" in the table means that you cannot use RMW instructions on these registers.

Example: When setting only bit0 of register P0CR, "SET 0, (0002H)" cannot be used. The LD (transfer) instruction must be used to write all eight bits.

Table 5 I/O Register Address Map

Address	Name	Address	Name	Address	Name	Address	Name

			R/W								
			Data from external port (Output latch register is cleared to 0)								
P3	Port 3	07H			P35			—	—	—	
					R/W			R/W			
					Data from external port (Output latch register is set to "1".)			0	1	1	
								Always write "0".	Always write "1". (This bit is read as 1)		
P4	Port 4	0CH	—	P46	P45	P44	P43	P42	P41		
			R/W	R/W							
			0	Data from external port (Output latch register is set to 1.)							
			Always write "0".								
P5	Port 5	0DH					P53	P52	P51	P50	
							R				
							Data from external port				
P6	Port 6	12H (Prohibit RMW*)			—	P64	P63	—	P61	P60	
					R/W	R/W		R/W	R/W		
					0	Data from external port (Output latch register is set to "1".)	0	Data from external port (Output latch register is set to "1".)			
P7	Port 7	13H							P71	P70	
								R/W			
							Data from external port (Output latch register is set to "1".)				

Read/Write

R/W: Either read or write is possible

R: Only read is possible

W: Only write is possible

Prohibit RMW: Prohibit read-modify-write. (Prohibit RES/SET/TSET/CHG/STCF/ANDCF/ORCF/XORCF instruction)

Prohibit RMW*: Read-modify-write is prohibited when controlling the PU resistor.

(2) I/O port control

Symbol	Name	Address	7	6	5	4	3	2	1	0

			R							R		
			Undefined		0		Conversion result stored flag					
			Stores lower two bits of AD conversion result									
AD REG3H	AD conversion result register 3 high	67H	ADR39	ADR38	ADR37	ADR36	ADR35	ADR34	ADR33	ADR32		
			R									
			Undefined									
			Stores upper eight bits of AD conversion result									

*1: Data to be stored in AD conversion result register low are the lower 2 bits of the conversion result. The contents of the 5 to 1 bits of this register are always read as "1".
 Bit 0 conversion result stored flag bit <ADR_xRF>
 <ADR_xRF> is set to "1" when the AD conversion result is stored.
 Reading either the ADREG_xH or the ADREG_xL registers clears <ADR_xRF> to "0".

(8) Watchdog timer control

6. Port Section Equivalent Circuit Diagram

- Reading the circuit diagram

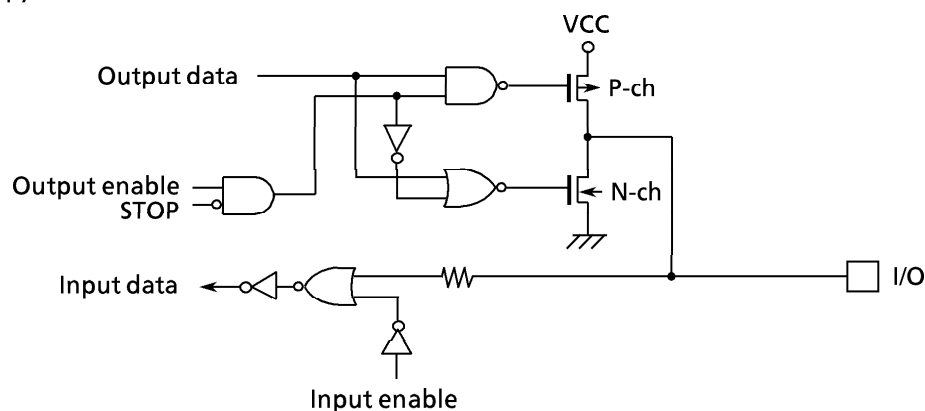

Basically, the gate symbols written are the same as those used for the standard CMOS logic IC [74HCXX] series.

The dedicated signal is described below.

STOP: This signal becomes active “1” when the HALT mode setting register is set to the STOP mode ($WDMOD \langle HALTM1:0 \rangle = 0, 1$) and the CPU executes the HALT instruction. When the drive enable bit $WDMOD \langle DRVE \rangle$ is set to “1”, however, STOP remains at “0”.

- The input protection resistance ranges from several tens of ohms to several hundreds of ohms.

■ P0, P1, P4, P7

■ P61, P64

■ P35 (INT0)

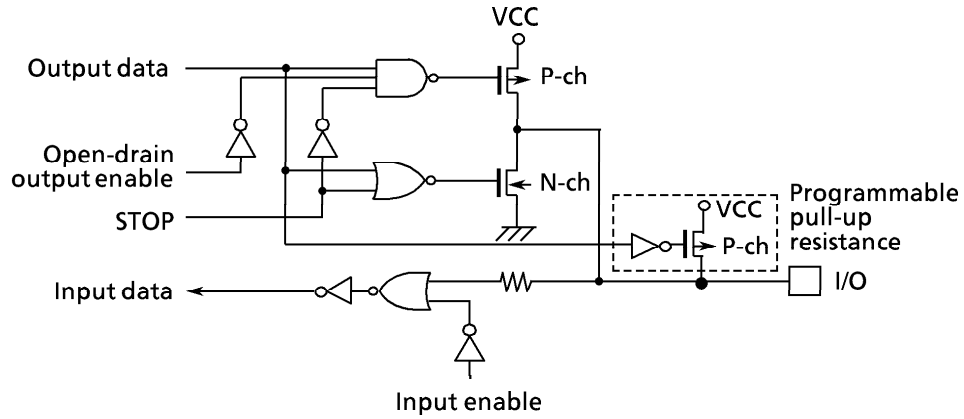

■ P50 to P52 (AN0 to AN2)

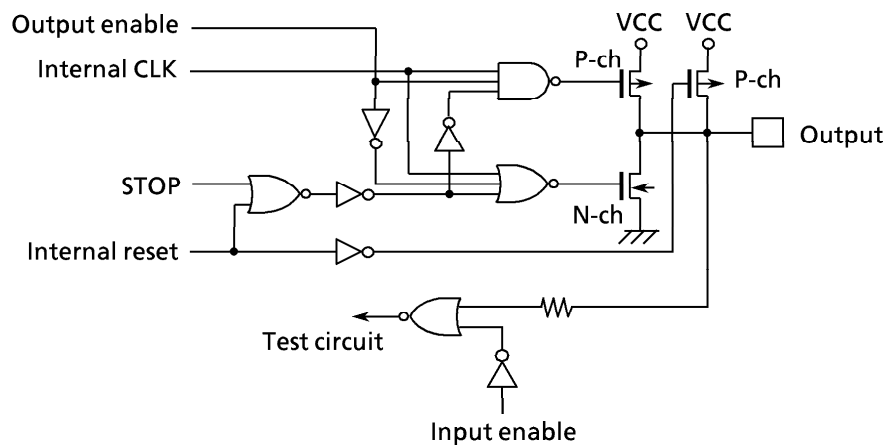

■ P53 (AN3/ADTRG)

■ P60 (TXD0), P63 (TXD1)

■ CLK

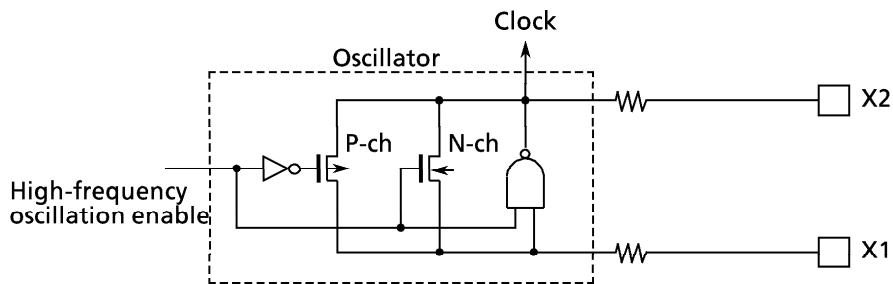

■ \overline{EA}

■ $\overline{\text{RESET}}$

■ X1, X2

■ VREFH, VREFL

7. Points of Concern and Restriction

(1) Notation

- ① Explanation of a built-in I/O register: Register Symbol <Bit symbol >
 e.g.) TRUN <TORUN > ... Bit TORUN of Register TRUN

② Read, modify and write instruction

An instruction in which the CPU executes following by one instruction.

1. CPU reads data of the memory.
2. CPU modifies the data.
3. CPU writes the data to the same memory.

ex1) SET 3, (TRUN) ... Set bit 3 of TRUN

ex2) INC 1, (100H) ... Increment the data of 100H

- A sample read-modify-write instructions using the TLCS-900

③ f_c , f_{FPH} , f_{SYS} , 1 state

The clock frequency input from pins X1 and X2 is called f_c . The clock frequency selected by SYSCR1 <GEAR2:0> is called system clock f_{FPH} , and the clock frequency given by f_{FPH} divided by 2 is called f_{SYS} . One cycle of f_{SYS} is called 1 state.

(2) Care points

① \overline{EA}

Fix these pins V_{CC} unless changing voltage.

② HALT mode (IDLE1)

When IDLE1 mode (Oscillator operation only) is used, set $TRUN < PRRUN >$ to "0" to stop prescaler before "HALT" instruction is executed.

③ Warm-up counter

The warm-up counter operates when STOP mode is released even if the system is using an external oscillator. As a result, it takes warm-up time from inputting the releasing request to outputting the system clock.

④ Programmable pull up resistance

The programmable pull up resistances can be turned ON/OFF by the program when the ports are used as input ports. When the ports are used as outputs, they can not be selected ON/OFF by the program. The data registers (e.g., P6 register ...) are used for the pull-up resistors ON/OFF. Consequently, read-modify-write instructions are prohibited.

⑤ Watchdog timer

The watchdog timer starts operation immediately after the reset is released. When the watchdog timer is not used, disable it.

⑥ AD converter

The string register between VREFH and VREFL pins can be cut by a program to reduce power consumption. When the standby mode is used, disable the resistor using the program before the "HALT" instruction is executed.

⑦ CPU (Micro DMA)

Only the "LDC r, r", "LDC r, cr" instructions can be used to access the control registers in the CPU like the transfer source address register (DMASn).

⑧ POP SR instruction

Please execute POP SR instruction during DI condition.

⑨ Releasing the HALT mode by requesting an interruption

Usually, interrupts can release all halts status. However, the interrupts = (INT0) which can release the HALT mode may not be able to do so if they are input during the period CPU is shifting to the HALT mode (for about 3 clocks of f_{FPH}) with IDLE1 or STOP mode (RUN and IDLE2 are not applicable to this case). (In this case, an interrupt request is kept on hold internally.)

If another interrupt is generated after it has shifted to HALT mode completely, halt status can be released without difficulty. The priority of this interrupt is compare with that of the interrupt kept on hold internally, and the interrupt with higher priority is handled first followed by the other interrupt.

8. Package Dimensions
P-LQFP44-1010-0.80A

Unit: mm

Note: palladium plating
