

FEATURES

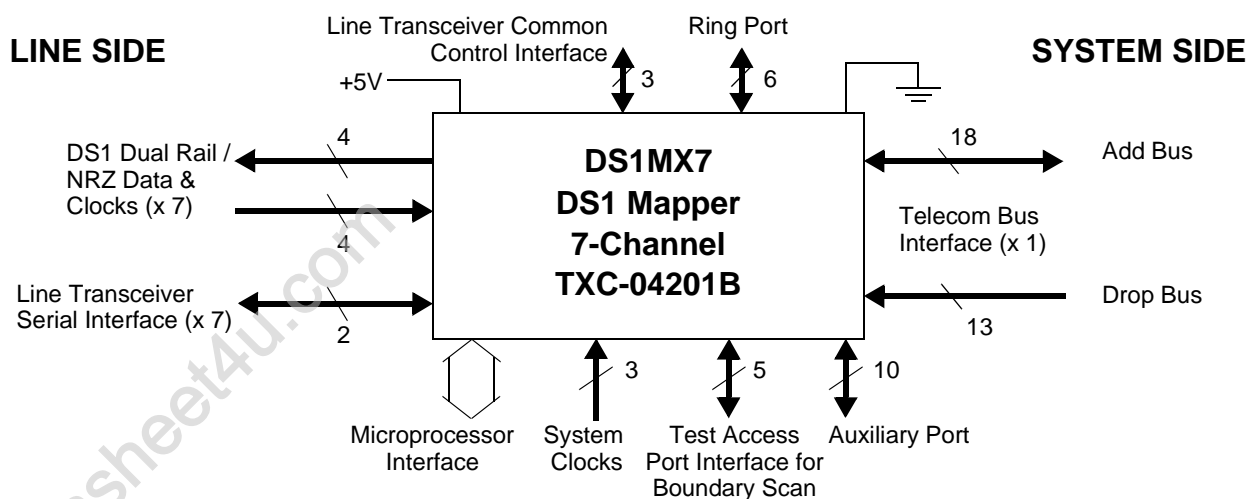

- Seven independent 1.544 Mbit/s DS1 mappers
- Single byte-parallel Telecom Bus @ 6.48 MHz (28 Slots) or 19.44 MHz (84 Slots)
- Floating VT1.5 byte-synchronous mapping with signaling only for use with or without a slip buffer
- Asynchronous mapping for DS1
- SONET mapping (VT1.5) or SDH mapping (TU-11 in AU-3 or TU-11 in TUG-3)
- AMI, B8ZS or NRZ codec for DS1s
- Serial I/O for control of DS1 line interface transceivers or framers
- Telecom Bus and DS1 loopbacks with integral PRBS generator and analyzer
- VT1.5/TU-11 pointer tracking and generation
- VT1.5/TU-11 overhead processing and insertion
- one-second latched performance registers and counters
- DS1 alarm detection and generation
- Auxiliary port for J2, V5, Z6/N2, Z7/K4 and O-bit access
- Ring port for USHR/P support
- Gapped clock option for Internet Applications without need for a framer
- Intel / Motorola-compatible microprocessor interface
- 3-bit RDI support
- Boundary Scan capability (IEEE 1149.1)
- Single +5 V, $\pm 5\%$ power supply
- 208-pin plastic quad flat package

DESCRIPTION

The DS1MX7 is a seven-channel byte-synchronous and asynchronous DS1 mapper. Both SONET and SDH mappings are provided per Bellcore GR-253-CORE (VT1.5) and ITU-T G.707 3-96 (TU-11). A single add/drop Telecom Bus is provided that can operate at either 6.48 or 19.44 MHz, which is compatible with other TranSwitch devices. VT1.5/TU-11 pointer tracking and overhead extraction/processing with full error and alarm control is provided. VT1.5/TU-11 pointer calculation and overhead assembly is also provided. Alarm and error mappings from drop to add and SONET/SDH to/from DS1 are provided. Jitter performance is achieved with a fully digital threshold modulator and DPLL that meets GR-253-CORE MTIE requirements without external de-jitter buffers. For the DS1 line, AMI, B8ZS and NRZ line codes are supported with full alarm detection and generation per ANSI T1.231-1997 draft. Each channel is independently programmable for mixed service applications. Access to status and control bits is provided via an Intel/Motorola-compatible microprocessor interface. Diagnostic, test, and maintenance functions are provided, including boundary scan, PRBS generator/analyzer and loopbacks.

APPLICATIONS

- SONET/SDH terminal or add/drop multiplexers supporting both asynchronous and byte-synchronous modes
- Unidirectional or bidirectional ring applications
- SONET Remote Digital Terminal Equipment
- SONET CPE Equipment requiring access to DS0s
- SONET/SDH Test Equipment
- Internet Access Equipment

FEATURE LIST

The DS1MX7 device is a highly-featured seven-channel DS1 (T1) mapper for use in a wide variety of interface, transmission and switching applications. Seven independent DS1 asynchronous / byte-synchronous mappers are provided in a single monolithic VLSI device using sub-micron CMOS technology. Powered from a single +5.0 volt supply, the device dissipates less than one watt typically. The DS1MX7 is provided in a 208-pin plastic quad flat package. Its ambient operating temperature range extends from -40 °C to 85 °C with 0 ft/min airflow.

The DS1MX7 device has been designed to meet the latest industry standards, namely:

- ANSI T1.102- 1993
- ANSI T1.105- 1991
- ANSI T1.107- 1995
- ANSI T1.231 (1993 and 1997 draft)
- ANSI T1.403-1995
- AT&T Pub. 62411 (December 1990)
- Bellcore GR-253-CORE (Issue 2)
- Bellcore TR-NWT-000496 (Issue 3)
- Bellcore GR-499-CORE (Issue 1)
- IEEE 1149.1- 1990, -1994
- ITU-T G.707 3-96
- ITU-T G.783

FEATURES THAT ARE INDEPENDENTLY SELECTABLE FOR EACH OF THE MAPPERS

Line Interface Options

- Meets ANSI and Bellcore input jitter requirements
- Rail (for asynchronous mapping only)
 - B8ZS or AMI
 - ANSI compliant LOS detector
 - ANSI compliant AIS detector
 - 12-Bit BPV counters with excessive zeros option
- NRZ option (for asynchronous and byte-synchronous mapping)
 - Clock polarity selection for clock in/out
 - NRZ data inversion and clock edge options (separate transmit and receive control)
 - For asynchronous use, negative rail can be used to count externally detected code violations
- Programmable clock edges for transmit and receive data
- External pin per channel for status (may be programmed to combine with internal AIS and LOS to support external LOC detector)
- Clock slave for asynchronous input; clock and multiframe synchronization (3 ms), master or slave, for byte-synchronous input
- Separate signaling highway for byte-synchronous, carries ABCD signaling bits and AIS / Yellow alarm information in and out of the DS1MX7
- External pin-controlled shut down of all DS1 line drive pins for card protection
- Gapped clock option in place of signaling for 1536 kHz datacom in byte-synchronous operation
- CRC-6 generation (DS1 input) and error counting (DS1 output) in byte-synchronous mapping

Mapping And Synchronizer Features

- Mapping to SONET or SDH columns according to GR-253-CORE or ITU G.709
- Per channel selectable asynchronous and byte-synchronous mapping to a floating VT1.5 or TU-11 for both mapping and demapping
- Overhead assembly with BIP-2 calculation, REI-FEBE (microprocessor or received BIP-2 error), signal label (microprocessor value), RDI (microprocessor value or via received signal label mismatch, VT AIS, VT LOP, or unequipped) and RFI (microprocessor value or DS1 Yellow from signaling highway)
- Pointer calculation (fixed at 78 for asynchronous, calculated for byte-synchronous mode) with generated pointer increment and decrement counters (4 bits each)
- In byte-synchronous mode, line clock may be an input ('modified byte-synchronous') or an output ('true byte-synchronous')
- Multiplexing of signaling bits from the signaling highway with P₀/P₁ bit generation
- Unequipped and Unassigned VT payload generation
- VT AIS generation (microprocessor value, AIS from signaling highway, loss of frame on byte-synchronous, or AIS / LOS / external pin from line decoder)
- Threshold modulator to reduce demapping jitter and wander
- Tracking of input multiframe pulses by pointer movements in byte-synchronous mode

Demapping And Desynchronizer Features

- Asynchronous or byte-synchronous per channel, programmable to match mapper mode
- Digital PLL with 2 Hz low pass filter to track up to ± 250 Hz nominal DS1 signal providing a smooth clock output with no need for an external de-jitter buffer
- Separate ± 5 byte pointer leak buffer with programmable dual slope leak rate (8 ms to 2048 ms per bit in 8 ms steps, automatically doubled to 16 ms to 4096 ms per bit in 16 ms steps within ± 12 bits of center of pointer leak buffer)
- Power down with all-zeros or all-ones sent to line interface
- Demapping of SONET or SDH columns according to GR-253-CORE or ITU G.709
- Asynchronous and byte-synchronous demapping of a floating VT1.5 / TU-11
- Pointer tracking and extraction of overhead (V5 and Z7/K4), LOP, AIS, SS and NDF with received pointer increment and decrement counters (4 bits each)
- Overhead processing with BIP-2 calculation and error counting (12-bit, with overflow), REI (FEBE) counting (12-bit, with overflow), RDI (1- and 3-bit)/ RFI / signal label de-bouncing and detection, signal label mismatch / unequipped detection
- De-multiplexing of signaling bits to the signaling highway with multiframe generation for byte-synchronous
- DS1 AIS from microprocessor value, VT AIS, VT LOP, signal label mismatch or unequipped
- DS1 Yellow to signaling highway from RFI

Fractional T1 For Frame Relay, ATM AAL1 Access

- Framer not required for many applications
- Receive and transmit gapped clock (1536 kbit/s) per mapper in byte-synchronous mode
- CRC-6 generation and checking
- Direct connection to multichannel HDLC or ATM devices for N x 56 or N x 64 kbit/s service
- Internal DPLL to minimize received jitter

Signaling Support For Byte-synchronous Mapping

- Receive and transmit temporary buffers to align VT1.5/TU-11 payloads to signaling highway
- Signaling bits mapped to and demapped from specific locations per GR-253-CORE and G.709
- A, AB, ABCD signaling bit support
- Byte synchronous operation with TranSwitch QT1F-Plus VLSI device:
 Signaling bit positions in received DS0s optionally replaced with ones by QT1F-Plus
 VT AIS and VT RFI to DS1 AIS and DS1 RAI (Yellow) respectively
 DS1 AIS and DS1 RAI (Yellow) to VT AIS and VT RFI respectively
- Unicode support (DS0 alarms) for byte-synchronous operation planned in future framers

Alarms And Errors

- Detection of VT AIS, VT RFI, unequipped, signal label mismatch, VT loss of pointer, single-bit RDI, 3-bit RDI, and demap error in the demap direction
- Detection of DS1 AIS, loss of signal, map error, and external pin alarm, in the mapping direction
- Counting of code violations (with or without excessive zeros) or CRC-6 errors, BIP-2, REI (FEBE), pointer generation and receive pointers with presets and overflow indications
- Microprocessor enable and insert of all alarms detected from line, calculated, or in overhead

Maintenance

- Loopbacks - DS1 line remote (toward DS1 line), DS1 line local (toward Telecom Bus), and Telecom Bus (toward DS1 line for all seven channels at once)
- PBRS generator in transmit framer and analyzer in receive path per T1 channel
 $2^{15}-1$ pattern.
 Separate control bits with software indication
- Power-down modes force transmit leads to low, high or tristate

Microprocessor Interface

- Nineteen-bit status register for VT AIS, VT RFI, unequipped, signal label mismatch, VT loss of pointer, single-bit RDI, 3-bit RDI, DS1 AIS, loss of signal, map error, demap error, external pin alarm, and counter overflow bits for code violation/CRC-6, BIP-2, REI (FEBE), pointer generation and receive pointers
- Latched event registers and interrupt mask registers to individually control each condition
- Twelve-bit CRC-6 (byte-synchronous)/ code violation (asynchronous), BIP-2, and REI (FEBE) error counters
- Four-bit increment and decrement pointer generation and receive pointer counters
- Shadow registers for all counters
- Full control of alarm mapping through enable bits
- Microprocessor forcing of alarm conditions
- Per channel reset and resynchronization
- Register access to J2, V5, Z6/N2, Z7/K4 bytes and O-bits for read and write

Performance and Fault Monitoring

- One second basis, via backplane one second clock
- Shadow registers for all 19 alarms and 7 counters
- Separate registers to indicate alarm changes (performance) and hard conditions (faults) are updated every second to simplify performance report generation

FEATURES THAT ARE ONLY SELECTABLE FOR THE SEVEN MAPPERS AS A GROUP

Telecom Bus Interface

- Single add bus and drop bus with individual timing
- Operation at 6.48 Mbyte/s or 19.44 Mbyte/s
- Compatible with TranSwitch SOT-1E and SOT-3 functional "B" version devices
- Parity generation and detection with device alarm (odd or even) on data and SPE / C1J1V1
- SONET mapping via VT1.5 at 6.48 and 19.44 Mbyte/s
- SDH mappings via TU-11 to AU-3 or to TUG-3 at 19.44 Mbyte/s
- Uses SPE and C1J1V1 to locate individual VTs
- Separate STS-1 phases permitted in an STS-3 for asynchronous and modified byte-synchronous operation
- Each transmit and receive time slot is programmable to one of 28 or 84 including internal and external add bus contention monitors with global alarm
- Add bus timing programmable to zero or one clock delay
- Drop or add bus clock edges programmable
- Add bus enable pin plus control pins for optional POH and/or TOH drive
- Per VT/ TU signal failure input via common pin
- Clock and SPE / C1J1V1 presence detectors on system in and system out buses, which generate device alarms on failure

External Line Interface Transceiver Support

- Three-wire serial port to read/write control up to seven line interface transceivers ('host mode')
- Designed to support integrated microprocessor control of loopbacks, alarms and line build out
- Per channel or broadcast for data out
- Internal registers to drive and read external devices

Common Microprocessor Support

- Microprocessor global reset, masks, polling registers, interrupt polarity and latch edge control
- Motorola split address/data or Intel split address/data
- Global alarm Indications ('or' of per channel alarms of the same type) with a channel pointer register indicating channels with any active alarms
- Global interrupt mask bits, one per alarm type
- Interrupt on alarm changes: on positive edge, negative edge or both edges
- Device level alarms for Telecom Bus signals and reference clocks using status and latched event registers with interrupt mask registers
- Device level alarms can be enabled to appear on separate interrupt line for card protection via hardware or software mechanisms
- Error insertion via the microprocessor for parity testing on the Telecom Bus
- Timed error insertion for REI (FEBE) and BIP-2 global value
- Hardware interrupt polarity selection
- Common hardware reset pin and global software reset register

Auxiliary Port Common

- Access to or from optional overhead bytes for special purposes with microprocessor enables
- Access to J2, V5, Z6/N2, Z7/K4 bytes and O-bits received via a shared serial port
- Insertion of J2, Z6/N2, Z7/K4 bytes and O-bits to mapping direction via a shared serial port

Ring Port Common

- Permits REI (FEBE) and single/three-bit RDI values to be sent from one DS1MX7 to another
- USHR/P support
- Shared serial port with clock and frame for transmit and receive
- Pair of DS1MX7s provides for dual Telecom Bus applications

Protection, Test and Maintenance Support

- IEEE 1149.1 boundary scan
- Ability to tristate all outputs for in-circuit testing with a single control pin
- Loss of clock detectors and parity generator/error detector for add and drop Telecom Buses
- Internal alarm output programmable to a variety of bus fault and clock fault conditions and a card switch-off feature to assist in implementing protection switching
- External shadow register clock input (1Hz \pm 32 ppm)
- PRBS generator and analyzer switchable to any of the seven mapper channels

BLOCK DIAGRAM

Note: n=1-7
(Channel blocks)

Figure 1. DS1MX7 TXC-04201B Block Diagram

BLOCK DIAGRAM DESCRIPTION

A simplified block diagram of the DS1MX7 device is shown in Figure 1. The major blocks are the seven Channel blocks, the Microprocessor Interface, the Serial Port Control Interface, the Ring port, the Auxiliary port, the PRBS (Pseudo-Random Binary Sequence) Generator and Analyzer, the Test Access Port Interface, the Mapper Timing block and the Telecom Bus Interface.

Each of the seven Channel blocks consists of the following component blocks: Decoder/Coder and Input/Output Timing (for Receive and Transmit Line Interfaces), Receive and Transmit Alarm Control, Receive and Transmit Signaling Store, Synchronizer/ Mapper and Desynchronizer/ Demapper, VT Termination, and Telecom Bus Input and Output Control blocks.

The Receive and Transmit Line Interface blocks connect each of the seven mapper channels to an external line interface transceiver, which performs the LIU and clock recovery functions for the asynchronous mode of operation. The interface to the transceiver can be configured for two interface modes: a dual unipolar (rail) interface or a NRZ interface. When the byte-synchronous mode of operation is used, the clock and synchronization signals to and from an external DS1 framer are handled by these blocks; data is always in the NRZ mode. These blocks also provide a tributary (transmit to receive) loopback and a facility or remote (receive line to transmit line) loopback.

When the dual unipolar interface mode is selected, input data from the external line interface transceiver is clocked into the DS1MX7 on pins RPOS_n and RNEG_n using the recovered receive clock present on the LRCLK_n input pins, where $n=1-7$ identifies one of the seven mappers (note: RNEG_n is one of several pins that has multiple functions, with a signal symbol for each). In the transmit direction, unipolar data is clocked out of the DS1MX7 on pins TPOS_n and TNEG_n by the transmit line clock present on the LTCLK_n output pins. Global control bits are provided in the memory map which enable the unipolar data to be clocked in and out of the DS1MX7 on either edge of the clocks. For the dual unipolar interface mode, the DS1MX7 provides either a Bipolar with Eight Zero Substitution (B8ZS), or an Alternate Mark Inversion (AMI), coder and decoder function, and Loss Of Signal detection. The Loss Of Signal detector meets the requirements specified in the ANSI T1.231 document listed above in the DS1MX7 Features section. An unframed AIS detector is also provided to assist in network fault isolation. A 12-bit performance counter is provided for each mapper, for counting B8ZS coding violation errors. An option is provided to also include excessive zeros in the coding violations counter.

When the NRZ interface mode is selected and the mapper channel is programmed for asynchronous mapping, NRZ data is clocked in at the RPOS_n pin by the recovered received clock input on the LRCLK_n pin. The NRZ data is clocked out of the DS1MX7 on the TPOS_n pins by the transmit system clock present on the LTCLK_n pins. Global control bits are provided in the memory map which enable the NRZ data to be inverted or clocked in and out of the DS1MX7 on either edge of the clocks. Bipolar violations which are detected in the external line interface transceiver may be clocked into the DS1MX7 on the RNEG_n/RCV_n pins and counted in the associated 12-bit coding violation performance counter. The TNEG_n output may be used in NRZ mode as a spare drive bit. The Remote Line Loopback function for each framer is also implemented in the Line Interface blocks.

When the NRZ interface mode is selected and the mapper channel is programmed for byte-synchronous mapping, NRZ data is clocked in at the RPOS_n pins by the clock present on pins LRCLK_n. The DS1MX7 can generate a clock on LRCLK_n and a 3.0 ms multiframe synchronization signal on pins RSYNC_n if an external slip buffer is provided in the framer or if the source of the signal is a clock slaved to the DS1MX7. If LRCLK_n and RSYNC_n are inputs, the DS1MX7 translates any clock phase movements with respect to the SONET/SDH clock via VT/TU pointer movements. For applications that do not require a framer but where the DS1 ESF CRC-6 performance monitoring function is desired (true byte-synchronous mode only), the DS1MX7 calculates and inserts CRC-6 into the defined frame bit positions in the VT1.5/ TU-11 structure in the mapping direction. After demapping, the CRC-6 is checked and any errors found are counted in the 12-bit counter shared for code violation counting.

Byte-synchronous mapping supports the independent transmission of signaling through defined nibbles in the VT1.5/ TU-11 structure, as shown in Figure 2. The DS1MX7 provides Receive and Transmit Signaling Stores to synchronize signaling and framing bits to and from a DS1 Framer or switching stage with the Mapper and

Demapper blocks. Signaling is received through the RNEGn/RSIGLn pins in byte-synchronous mode, being clocked in with LRCLKn. Signaling is sent out on the TNEGn/TSIGLn pins in byte-synchronous mode, using LTCLKn. TranSwitch framers like the QT1F-Plus (TXC-03103) can utilize the signaling bits on the signaling highways for automatic signaling propagation between SONET/SDH byte-synchronous mapping and DS1 lines. For applications using the full DS1 payload in byte-synchronous mode, the RNEGn/RSIGLn pins can be programmed to supply gapped clock (RGCO_n), as can the TNEGn/TSIGLn pins (TGCO_n).

The Receive and Transmit Alarm Control blocks work in conjunction with the Receive and Transmit Line Interface blocks as well as the Receive and Transmit Signaling Store blocks to move DS1 alarm signals in and out of the DS1MX7. The Receive Alarm Control block detects specific bits from the receive signaling highway, such as AIS or RAI (Yellow), for forwarding to the Mapper block as AIS and RFI. It also gathers LOS and AIS from the Receive Line Interface. The LAIS_n input pin may be used for forwarding an externally detected Loss of Signal or Loss of Clock, or as a general interrupt input. The Transmit Alarm Control block translates RFI and AIS from the Demapper block along with microprocessor controls to set specific bits on the transmit signaling highway. TranSwitch framers like the QT1F-Plus (TXC-03103) can utilize the control bits on the signaling highways for automatic alarm propagation between SONET/SDH and DS1 lines. For card protection schemes, control input pin CS₀, when driven low, causes all of the output pins for the seven Line Interfaces to go low.

The Synchronizer/ Mapper block takes the clock and data from the Receive Line Interface in asynchronous mode, threshold modulates it with SRCLK, buffers it in a FIFO and inserts the data bits in the information bit positions of the asynchronous VT1.5/ TU-11, and stuffs it using the two stuff opportunity bits with indication in the C1 and C2 bits, as shown in Figure 2. The stuffing matches the received DS1 clock to the bit positions available based on the SONET/SDH network clock supplied to the DS1MX7 in the Add Telecom Bus Clock, ACLK and the AC1J1V1 signal. Optional overhead bytes J2, Z6/N2, O and part of Z7 are taken from microprocessor-written values or the Auxiliary Port.

The Synchronizer/ Mapper block takes the clock, frame and data from the Receive Line Interface in byte-synchronous mode, buffers it in a FIFO and writes it to defined byte positions in the byte-synchronous VT1.5/ TU-11 along with the optional overhead bytes J2, Z6/N2 and part of Z7 which are taken from microprocessor-written values or the Auxiliary Port. For byte-synchronous mode the signaling bits are taken from the Receive Signaling Store and mapped to the correct positions in the VT1.5/ TU-11. The 500-microsecond long VT superframe shown in Figure 2 is repeated six times, being synchronized to the RSYNC_n 3.0 millisecond input. The P₁P₀ bits are generated to indicate which signaling bits are being carried in a specific VT superframe and are related to RSYNC_n. FIFO conditions are monitored and can lead to increment or decrement requests of the VT Termination block. Synchronization changes in RSYNC_n are monitored for possible NDF requests.

The VT Termination block takes the mapped data and optional overhead together with any frame, increment or decrement indications associated with byte-synchronous mode from the Synchronizer/ Mapper block. The V5 and Z7 bytes are built from one of several received DS1 alarm sources (the receive alarms, Ring Port error conditions, or microprocessor-written values). Parity is then calculated over the payload. V1 and V2 are set to 78, positioning V5 just after V1 for asynchronous mode only. For byte-synchronous mode (true byte-synchronous or modified byte-synchronous), the V1 and V2 bytes are generated to track the phase of the incoming DS1 signal relative to ACLK; two four-bit counters are provided to keep track of pointer increments and pointer decrements generated. If a new position for the RSYNC_n pulse is generated, this block will generate an NDF along with the new pointer. If the DS1MX7 acts as a clock source, the LO pin will be used to provide this clock and it must be frequency locked to the STS-1 or STM-1 clock, or pointer justifications and/or mapping errors will result. If AIS is to be generated the entire payload is ones. If unassigned (Idle) is to be generated, an all-zeros payload with a valid V5 is generated. If an unequipped is to be generated, an all-zeros payload including V5 is generated.

The VT termination block also provides the pointer tracking, V5 and Z7 overhead location and VT1.5/ TU-11 alarm detection and de-bouncing functions. The alarms (RDI in four flavors, RFI, Unequipped, Signal Label Mismatch, LOP, AIS, REI, BIP-2 errors, etc.) are made available to the common microprocessor block for latching, shadowing, counting and interrupting purposes. Alarms are provided on the Ring Port for RDI and REI to support ring applications. It also identifies the payload for the Desynchronizer/ Demapper block as well as any pointer movements.

Z ₇	Z ₆ = Reserved Byte	Z ₇
P ₁ P ₀ S ₁ S ₂ S ₃ S ₄ F R	Z ₇ = Reserved and 3-bit RDI Byte	C ₁ C ₂ R R R St ₁ St ₂ R
DS0 Channels 1 - 24		24 Information Bytes

V1 Byte						V2 Byte							
New Data Flag				Size		I	D	I	D	I	D	I	D
0	1	1	0	S1	S2	Pointer Range = 0 - 103 decimal							

A normal NDF is shown (new data flag = 1001); S1S2 = 11; Positive Justification = Invert the 5 I-bits; Negative Justification = Invert the 5 D-bits; shown MSB (bit 1) first.

1	V5 Byte				8
BIP-2	REI-V	RFI-V	Signal Label		RDI-V

Shown MSB (bit 1) first. REI-V is also known as FEBE. RDI-V set to a 1 for Unequipped, AIS-V and LOP-V.

1	Z7 Byte				8
R	R	R	R	3-bit RDI-V	R

3-bit RDI-V Codes: 001 = no defects; 010 = Signal label mismatch; 101 = AIS-V or LOP-V; 110 = Unequipped.

Figure 2. VT1.5/ TU-11 Asynchronous and Byte-synchronous Mappings

The Desynchronizer/ Demapper block takes the data and alarm information, along with pointer information, and extracts the DS1 signal. This block extracts the optional overhead bytes and sends V5, Z6/N2, O and Z7/ K4 to the Auxiliary Port for asynchronous mode. For byte-synchronous mode, the O bytes are omitted and the signaling bits are sent to the Transmit Signaling Store instead. In both modes the data is sent to a pointer leak buffer which is programmable for leak out rate. This is used to minimize jitter and wander on asynchronously mapped signals as well as to smooth out byte-synchronously mapped signals that utilize pointer movements for frequency adjustment. The pointer leak rate may be adjusted to meet MTIE requirements with a simple software algorithm which uses the one second latched pointer increment and decrement counters. The Desynchronizer uses a DPLL operated from the signal on SRCLK (48.636 MHz) that smooths out the stuffing jitter and compensates for the demapping gapped positions used for all orders of overhead. The Desynchronizer outputs a DS1 clock along with the DS1 data to the Transmit Line Interface block ready for transmission or framing without additional de-jittering. In byte-synchronous mode the Frame pulse (3.0 ms) is decoded from the P₁P₀ bits and is used to align the signaling highway to the Transmit Signaling Store, and it becomes the signal on TSYNCn. A correct P₁P₀ pattern must be supplied for proper operation even if signaling is not used. Alarm information (RFI and AIS) is sent to the Transmit Alarm block for forwarding on the signaling highway. AIS is used to cause the DPLL to output an in-frequency-range all-ones signal.

The Telecom Bus Input and Output Control blocks buffer the assembled VT1.5/ TU-11 bytes for insertion to or extraction from the Telecom Bus Interface. Each of the seven mapper channels can independently be placed on or independently taken from any one of three STS-1s or TUG-3s (19.44 MHz Telecom bus only), any one of seven VT groups or TUG-2s, and any one of four VT1.5 or TU-11s. Enable control bits allow a channel to be disconnected in transmit and/or receive from the Telecom Bus.

The Telecom Bus Interface block combines the signals from the seven mapper channels and synchronizes them to the Add Bus half of the Telecom Bus based on the ACLK, AC1J1V1 and ASPE signals. It can be configured as a single STS-1 (6.48 MHz), an STS-3 (19.44 MHz) or an STM-1 (19.44 MHz). Contention checks are made for the seven mapper channels; this feature is extended using the BUSCHK pins to up to 3 additional DS1MX7 devices sharing an Add Bus. Parity (pin APAR) and an add indication (pin AADD) are included with the byte-wide data (pins AD(0-7)). The DATEN and MASTER pins allow optional drive of overhead and stuff columns, when the data delay option is not used. The Drop Bus part of the Telecom Bus provides DCLK, DC1J1V1 and DSPE signals along with a failure indication (pin DFAIL) to indicate to the seven mapper channels that the received data is errored due to higher order path, section or line failures. Parity (pin DPAR) is included with the data (pins DD(0-7)). Parity covers add and drop data and optionally SPE and C1J1V1 signals. All signals are monitored for failure and maskable interrupts may be generated both to the microprocessor interrupt pin and to a separate failure pin (IAO).

The DS1MX7 has a PRBS Generator and Analyzer block. The Generator and Analyzer supports the 2¹⁵-1 pattern. The Generator output may be substituted in place of the NRZ data stream output from each Receive Line Interface Decoder. The Analyzer monitors one of the NRZ data stream outputs from the seven Receive Line Interface Decoders. By setting the Telecom Bus Loopback (a function of the Telecom Bus Interface block) and a Tributary Loopback for one of the seven channels, the entire channel's transmit and receive path can be verified (Synchronizer/ Mapper, VT Termination, Telecom Bus Interface, Desynchronizer/ Demapper, Transmit Line Interface and Receive Line Interface). By moving the loopbacks to Framers, LIUs, VT Switches or remote end Mappers an entire path can be verified.

The Line Interface Control block is a common block to all seven mapper channels that provides a serial port for communicating with an external line interface transceiver that supports 'Host Mode' operation. This allows the system microprocessor to control the transceiver through the DS1MX7. The interface consists of a data output pin (LSDO), clock output pin (LSCLK), and a data input pin (LSDI). These signals are shared between all of the transceivers. Each transceiver is selected by the DS1MX7, using chip select output signals (LCSn). In addition, a general purpose input pin (LAISn) can be used in NRZ mode to generate a maskable interrupt.

The Test Access Port block is common to all seven mapper channels and includes a five-pin Test Access Port (TAP) that conforms to the IEEE 1149.1 standard. This block provides external boundary scan to read and write the DS1MX7 input and output pins from the TAP for board and component testing. In addition, a four-byte read only memory location is provided for reading the JEDEC manufacturer ID, DS1MX7 part number, and version number of the part. For non-boundary scan testing a HIGHZ pin is provided to tristate all output pins.

The DS1MX7 provides a common six-wire Ring Port block. A pair of DS1MX7 devices can operate on a dual bus-based Add Drop Multiplexer. Since each DS1MX7 is configured to operate in a single one direction of the ring, RDI and REI (FEBE) values need to be sent to the mate DS1MX7 so that they are returned in the opposite direction. The Ring Port is shared among the seven mapper channels to facilitate the function of sending, receiving and buffering REI (FEBE) and RDI values from and for each of the seven mapper channels. The REI (FEBE) and RDI information used by the Mapper may either come from the demap direction within the DS1MX7 (non-ring mode), from a microprocessor-forced value, or from the Ring Port. The Ring Port outputs clock, data and frame (pins ORPCKO, ORPDTO and ORPFMO), and it expects clock, data and frame as inputs (pins IRPCKI, IRPDTI and IRPFMI).

A common Auxiliary Port block is provided that makes the optional and reserved overhead bytes to and from each of the seven mapper channels available on multiplexed DS1MX7 device pins. The Auxiliary Port outputs the V5, J2, Z6/N2, Z7/K4 and O bytes as they arrive, if enabled. When mapping opportunities for J2, Z6/N2, Z7/K4 and O bytes come up the Auxiliary Port requests and inputs these bytes, if enabled. Microprocessor read and write access of these bytes is also provided.

The DS1MX7 can be configured to operate with either Intel or Motorola-compatible microprocessors via the Microprocessor Input/Output Interface block. Separate address, data and control pins are provided. Interrupt capability is provided with global and individual framer mask bits as well as activity registers to guide software to the exact cause of an interrupt in the most expeditious manner. A wide variety of alarms is provided on a global level as well as on a per mapper channel level. Each alarm or error is reflected in a current status register or counter as well as a latched value register that may be set on the rising, falling or both edges of an alarm. Shadow registers for alarms and counters are provided, with the alarm shadow registers doubled to indicate either a change (performance item) or a persistent condition (fault). Any latched value may trigger an interrupt, unless it is masked to prevent it causing an interrupt. An option is provided in software which permits the interrupt polarity to be inverted. An external system clock provided at pin PCKI is used to run the internal state machines.

TRANSWITCH**PIN DESCRIPTIONS****Power Supply and Ground**

Symbol	Pin No.	I/O/P*	Type	Name/Function
VDD	11, 23, 35, 47, 63, 75, 87, 99, 115, 127, 139, 151, 167, 179, 191, 203	P		VDD: +5 volt supply, $\pm 5\%$
GND	5, 17, 29, 41, 57, 69, 81, 93, 109, 121, 133, 145, 161, 173, 185, 197	P		GND: Ground
NC	13, 25, 27, 33, 37, 65, 73, 77, 101, 117, 129, 141, 153, 169, 181, 198, 205			NC: Not Connected. Leave floating. Do not make any external connections to these pins or connect them to one another. Connection may impair performance or cause damage to the device.

*Note: I = Input; O = Output; P = Power; T = Tristate

Per Channel Tributary I/O (n = 1 to 7)

Symbol	Pin No.	I/O/P	Type *	Name/Function
LRCLKn	104, 116, 130, 143, 156, 168, 182	I/O	CMOS	Line Receive Clock Input: 1.544 MHz \pm 200 Hz clock from DSX-1 receiver for asynchronous mapping mode; (tolerance is ± 50 Hz per ANSI and Bellcore for byte-synchronous operation). Global control bit RCAE (bit 6) in register 007H determines the active edge of this clock. Input jitter tolerance is 5 UI peak to peak from 10 Hz to 500 Hz and 0.1 UI peak to peak from 8 kHz to 40 kHz. See Bellcore TR-TSY-000499. For byte-synchronous operation with an external slip buffer for which control bits MODE1,0 (bits 1 and 0) in register X+00H are set to 10, LRCLKn is an output derived from pin LO.
RSYNCn	105, 118, 131, 144, 157, 170, 183	I/O	CMOS	Receive Frame Sync.: 3.0 millisecond multi-frame sync from framer, or to framer for byte-synchronous mode. Sampled on LRCLKn falling edge if global control bit RCAE (bit 6) in register 007H is set to a 0. For byte-synchronous operation with an external slip buffer for which control bits MODE1,0 (bits 1 and 0) in register X+00H are set to 10, RSYNCn is an output derived from pin LO.
RPOSn	102, 113, 126, 140, 154, 165, 178	I	CMOS	Tributary Receive Data (Positive): NRZ/Positive rail. DS1 data from framer or DSX-1 Receiver. RPOSn is sampled on LRCLKn falling edge if global control bit RCAE (bit 6) in register 007H is set to a 0. In NRZ mode, global control bit RXNRZP (bit 4) in register 007 selects the polarity (a 1 selects a low as a logical one).

*Note: See Input, Output and Input/Output Parameters section below for Type definitions.

TXC-04201B

Symbol	Pin No.	I/O/P	Type	Name/Function
RNEGn/ RSIGLn/ RCVn RGCON	103, 114, 128, 142, 155, 166, 180	I/O	CMOS	<p>Tributary Receive Data (Negative): Negative rail DS1 data from DSX-1 receiver. This pin is sampled on LRCLKn falling edge if global control bit RCAE (bit 6) in register 007H is set to a 0.</p> <p>Receive Signaling Highway Input: Signaling Highway from framer. Sampled on LRCLKn falling edge if global control bit RCAE (bit 6) in register 007H is set to a 0.</p> <p>Tributary Receive Code Violations: Code violation counter input. Sampled on LRCLKn falling edge if global control bit RCAE (bit 6) in register 007H is set to a 0.</p> <p>Receive Gapped Clock Output: When the datacom mode is selected (only available for byte-synchronous operation) via control bit DATACOM (bit 5) in per channel register X+00H being set to a 1, this pin provides a gapped clock output in which the gap appears at the Frame bit times on RPOSn.</p>
LAI Sn	100, 112, 125, 138, 152, 164, 177	I	CMOS	<p>Line Alarm Input: Line transceiver interrupt, AIS or Loss of Signal / Clock from DSX-1 receiver. The active level is determined by global control bit RXNRZP (bit 4) in register 007, which selects the polarity (a 1 selects a low as a logical one). A per channel control bit EXPLOS (bit 6) in register X+00H enables this pin to act as LOS if set to a 1. Control bit LOS2AIS (bit 6) in register X+01H, when set to a 1, causes this signal to propagate VT AIS upstream. When EXPLOS is set to a 0, status bit XPS (bit 7) in register X+10H becomes a separate status indication with latched, mask, performance and fault registers plus global mask and status capability.</p>
LTCLKn	108, 122, 135, 148, 160, 174, 187	O	CMOS	<p>Line Transmit Clock Output: 1.544 MHz \pm 200 Hz clock to DSX-1 line driver or framer. Global control bit TCAE (bit 7) in register 007H determines the active edge of this clock. See $\overline{\text{CSO}}$ below. The output frequency tracks the input frequency as defined by the synchronized payload. Output jitter caused by de-synchronization and single pointer movements is 0.4 UI or less peak to peak at 10 Hz and above (0.075 UI peak to peak or less from 8 kHz to 40 kHz).</p>
TPOSn	106, 119, 132, 146, 158, 171, 184	O	CMOS	<p>Tributary Transmit Data (Positive): NRZ/Positive DS1 data to DSX-1 line driver or framer. Output on LTCLKn rising edge if global control bit TCAE (bit 7) in register 007H is set to a 1. In NRZ mode, global control bit TXNRZP (bit 0) in register 007H selects the polarity (a 1 selects a low as a logical one). Also see $\overline{\text{CSO}}$ below.</p>

TRANSWITCH

Symbol	Pin No.	I/O/P	Type	Name/Function
TNEG _n /	107, 120, 134, 147, 159, 172, 186	O	CMOS	Tributary Transmit Data (Negative): Negative rail DS1 data to DSX-1 line driver output on LTCLK _n rising edge if global control bit TCAE (bit 7) in register 007H is set to a 1. When NRZ mode is used in asynchronous mode this pin can be used as a spare output (e.g., select B8ZS/AMI in line I/F transceiver). Also see CSO below.
TSIGL _n				Transmit Signaling Highway Output: Signaling highway to framer. Output on LTCLK _n rising edge if global control bit TCAE (bit 7) in register 007H is set to a 1. Also see CSO below.
TGCO _n				Transmit Gapped Clock Output: When the Datacom mode is selected (only available for byte-synchronous operation) via control bit DATACOM (bit 5) in per channel register X+00H being set to a 1, this pin provides a gapped clock output in which the gap appears at the frame bit times on TPOS _n .
TSYNC _n	110, 123, 136, 149, 162, 175, 188	O	CMOS	Transmit Frame Sync: 3.0 millisecond multi-frame sync to framer. Output on LTCLK _n rising edge if global control bit TCAE (bit 7) in register 007H is set to a 1. Also see CSO below.
$\overline{\text{LCS}}_n$	111, 124, 137, 150, 163, 176, 189	O	CMOS	Line Interface Transceiver Chip Select: An active low signal that enables communications in both directions between the external line interface transceiver for channel n and the DS1MX7. This pin is under control of global register 01AH where ENSRP (bit 4) enables transmission to channel n, which is selected by BDCST (bit 7) to select all channels or the channel selection controls (bits 2-0) which select one of the 7 channels.

Tributary Common Control

Symbol	Pin No.	I/O/P	Type	Name/Function
LO	98	I	CMOS	Local Oscillator: 1.544 MHz \pm 32 ppm system clock input used for byte-synchronous mode. 1.544 MHz synchronized to system (ASPE, ACLK and a specific J1 of AC1J1V1) for byte-synchronous operation where LRCLK _n and RSYNC _n are outputs. This signal is also used to generate the serial port clock output LSCLK.
SRCLK	206	I	CMOS	System Reference Clock: 48.636 MHz \pm 32 ppm (31.5 times 1.544 MHz) system clock input used to operate the synchronizer, desynchronizer, PRBS generator/ analyzer, and to generate DS1 AIS.

DATA SHEET

DS1MX7
TXC-04201B

Symbol	Pin No.	I/O/P	Type	Name/Function
LSDO	91	O	CMOS	Line Interface Transceiver Data Output Signal: Common serial control data bus output shared by the seven channels. A command byte followed by a data byte, as stored in control registers 017H and 018H respectively, is transmitted to the line interface transceiver selected by LCSn.
LSDI	92	I	CMOS	Line Interface Transceiver Data Input Signal: Common serial control data bus input. A data byte coincident with the data byte on LSDO is clocked into the DS1MX7 and stored in register 019H from the line interface transceiver selected by LCSn.
LSCLK	94	O	CMOS	Line Interface Transceiver Clock Signal: Common serial control bus clock output. A 1.544 MHz clock derived from LO. LSDO is clocked out of the DS1MX7 on the falling edge of LSCLK and LSDI is clocked into the DS1MX7 on the rising edge of LSCLK.
T1SI	207	I	TTL	One Second Performance Clock Input: Shadow register latch. This input operates the latched counters and PM/FM registers. The following parameter value limits are suggested to prevent counters from overflowing when operating in noisy environments or other unfavorable conditions: min. high time 0.50 ms; min. low time 3.0 ms; max. low time 1.5 s. Operation at 1.0 Hz \pm 32 ppm, 1.0 ms high time, is recommended. This clock is used in conjunction with global control bit ENPMFM (bit 3) in register 006H to clear per channel event registers (not device event registers) after the PM and FM registers have been updated.
$\overline{\text{IAO}}$	208	O	CMOS open drain (4 mA)	Internal Alarm Output: Internal Alarm detected, active low output. Control bits in registers 01BH and 01CH, if set to a 1, enable Telecom Bus clock, payload and synch. failures, as well as parity errors and PRBS out of lock, to generate an alarm or interrupt on this pin.
$\overline{\text{CSO}}$	6	I	TTL	Card Switch Off: When driven low, LTCLKn, TPOSn, TNEGn/TSIGLn and TSYNCn are driven to a logic low level.

DS1MX7
TXC-04201B

DATA SHEET

System Interface

Symbol	Pin No.	I/O/P	Type	Name/Function
DCLK	64	I	TTL	Drop Bus Clock: Telecom Bus clock for data from system; 6.48 MHz for pin CONFIGI tied high or 19.44 MHz for pin CONFIGI tied low. Control bit TBRCI (bit 4) in register 01EH set to a 0 selects the rising edge of DCLK as the active edge.
DC1J1V1	66	I	TTL	Drop Bus C1J1V1 Indicator: Telecom Bus C1#1, J1#1, or V1#1 valid from system. Valid on the rising edge of DCLK when control bit TBRCI (bit 4) in register 01EH is set to a 0. Used with DSPE to identify the start of the payload.
DSPE	67	I	TTL	Drop Bus SPE Indicator: Telecom Bus SPE valid from system. Valid on rising edge of DCLK when control bit TBRCI (bit 4) in register 01EH is set to a 0. This signal is high during all VT1.5 or TU-11 bytes from the system.
DD(0-7)	61, 60, 59, 58, 56, 55, 54, 53	I	TTL	Drop Bus Data: Telecom Bus data from system; DD0 is LSB. Valid on rising edge of DCLK when control bit TBRCI (bit 4) in register 01EH is set to a 0.
DPAR	62	I	TTL	Drop Bus Parity Bit: Telecom Bus parity received over DD(0-7), DSPE and DC1J1V1. Valid on rising edge of DCLK when control bit TBRCI (bit 4) in register 01EH is set to a 0; odd/even selectable by control bit TBPE (bit 2) in register 007H; when set to a 1, even parity is selected. When control bit TBPIS (bit 3) in register 007H is set to a 0 only DD(0-7) is checked for parity.
DFAIL	68	I	TTL	Drop Bus Signal Fail: Signal fail indication valid on the rising edge of DCLK when control bit TBRCI (bit 4) in register 01EH is set to a 0. If DFAIL is high the specific VT slot contains invalid data (DD(0-7)); the per VT alarms are invalid and are masked; DS1 AIS is generated.
ACLK	76	I	TTL	Add Bus Clock: Telecom Bus clock for data to system; 19.44 MHz for pin CONFIGI tied high or 6.48 MHz for pin CONFIGI tied low. When control bit TBTCI (register 01EH, bit 5) is set to a 0, the ASPE and AC1J1V1 signals are clocked in on the rising edge of ACLK. The falling edge of ACLK is used to clock the AD(0-7), APAR and AADD signals out to the Add Bus so that these signals can be sampled on the next rising edge. When TBTCI = 1 the opposite clock edges are used.
AC1J1V1	72	I	TTL	Add Bus C1J1V1 Indicator: Telecom Bus C1#1, J1#1, V1#1 valid for data to system. This signal is sampled on the rising edge of ACLK when control bit TBTCI (register 01EH, bit 5) is set to a 0. Used with ASPE to indicate the start of the payload to the system.

DATA SHEET

DS1MX7
TXC-04201B

Symbol	Pin No.	I/O/P	Type	Name/Function
ASPE	71	I	TTL	Add Bus SPE Indicator: Telecom Bus SPE valid for data to system. This signal is sampled on the rising edge of ACLK when control bit TBTCI (register 01EH, bit 5) is set to a 0. This signal is high during all VT1.5 or TU-11 bytes to the system.
AD(0-7)	86, 85, 84, 83, 82, 80, 79, 78	O(T)	TTL 4mA	Add Bus Data: Telecom Bus data to system; AD0 is LSB. The DS1MX7 will output the data on the falling edge of ACLK when control bit TBTCI (register 01EH, bit 5) is set to a 0. Control bit TBDD (bit 3) in register 01EH selects zero ACLK clock period delay if set to a 0 and a single ACLK clock period delay if set to a 1. These signals are in the tristate condition when the DS1MX7 is not driving the Add Bus.
APAR	70	O(T)	TTL 4mA	Add Bus Parity Bit: Telecom Bus parity generated for any AD(0-7), ASPE and AC1J1V1 placed on the Telecom Bus. The DS1MX7 will output parity on the falling edge of ACLK when control bit TBTCI (register 01EH, bit 5) is set to a 0. Control bit TBPE (register 007H, bit 2) selects odd/even parity. When TBPE is set to a 0, odd parity is selected. When control bit TBPIS (bit 3) in register 007H is set to a 0 only AD(0-7) is included in the parity calculation. Control bit TBDD (bit 3) in register 01EH selects zero ACLK clock period delay if set to a 0 and a single ACLK clock period delay if set to a 1. This signal is in the tristate condition when the DS1MX7 is not driving the Add Bus.
$\overline{\text{AADD}}$	74	O	TTL 4mA	Add Bus Add Data Present Indicator: Telecom Bus device outputs valid. This signal goes low on the falling edge of ACLK when control bit TBTCI (register 01EH, bit 5) is set to a 0. This signal is active when the DS1MX7 writes to the Telecom Bus, allowing for external drivers to be used. Control bit TBDD (bit 3) in register 01EH selects zero ACLK clock period delay if set to a 0 and a single ACLK clock period delay if set to a 1. This signal is high when the DS1MX7 is not driving the Add Bus.
$\overline{\text{BUSCHK}}(0-2)$	88, 89, 90	I	TTL	Add Bus Check: Used to determine if another DS1MX7 on the same Telecom Bus is driving in the same slot. Each BUSCHK input is connected to the AADD of another DS1MX7. If a collision is detected, status bit TBXES (bit 0) in register 00BH is set to a 1. Latched value, mask PM, and FM register bits are also supplied.
$\overline{\text{MASTER}}$	97	I	TTLp	Add Bus Master: When tied to ground, POH and stuff columns are driven to zero on AD(0-7) with correct parity. See the Telecom Bus Operations subsection.
DATEN	96	I	TTL	Add Bus Data Enable: When high, AD(0-7), APAR and AADD are enabled. It is normally tied to ASPE to float the Telecom Bus during TOH.

ORPCKO	190	O	CMOS	Output Ring Port Clock: Burst of 56 clock pulses at 1.944 Mbit/s.
ORPFMO	192	O	CMOS	Output Ring Port Frame: Active High signal during Bit 0 of Channel 1. ORPFMO is clocked out on the falling edge of ORPCKO.
ORPDTO	193	O	CMOS	Output Ring Port Data: REI-V (FEBE), RDI-VPD, RDI-VSD, and RDI-VCD data from all seven channels for use in PPS Ring applications. Information is clocked out on the falling edge of ORPCKO.
IRPCKI	194	I	TTL	Input Ring Port Clock: Burst of 56 clock pulses at 1.944 Mbit/s.
IRPFMI	195	I	TTL	Input Ring Port Frame: Active High signal during Bit 0 of Channel 1. IRPFMI is clocked on the rising edge of IRPCKI.
IRPDTI	196	I	TTL	Input Ring Port Data: REI-V (FEBE), RDI-VPD, RDI-VSD, and RDI-VCD data for all seven channels for use in PPS Ring applications. Information is clocked in on the rising edge of IRPCKI.

Microprocessor Interface

Symbol	Pin No.	I/O/P	Type	Name/Function
$\overline{\text{RSTI}}$	4	I	TTLp	Hardware Reset: Device reset. This active low signal will reset all seven DS1 mappers. It should be held low for a minimum of 4 clock periods of PCKI.
MOTOI	38	I	TTL	Motorola Mode: Motorola - Intel microprocessor mode select. High selects Motorola. Low selects Intel.
DTB(0-7)	19, 20, 21, 22, 24, 26, 28, 30	I/O	TTL 8mA	Data: Microprocessor bidirectional, tristate data bus; DTB0 is LSB.
ADDR(0-8)	7, 8, 9, 10, 12, 14, 15, 16, 18	I	TTL	Address Bus: Microprocessor address bus; ADDR0 is LSB.
$\overline{\text{SELI}}$	36	I	TTLp	Select: Microprocessor Interface select. A low selects the interface and allows the transfer of information between the DS1MX7 and the microprocessor.
$\overline{\text{READI}}$ / $\overline{\text{READI/WRI}}$	34	I	TTL	Read: Read or Read/Write. Intel: low to read DS1MX7. Motorola: high to read/low to write.
$\overline{\text{WRI}}$	39	I	TTL	Write: Intel mode only; low to write to DS1MX7.

DS1MX7
TXC-04201B

DATA SHEET

TRANSWITCH
X

Symbol	Pin No.	I/O/P	Type	Name/Function
RDYO/ $\overline{\text{DTACKO}}$	31	O(T)	TTL 8mA	Ready: Intel mode: A high acknowledges that data transfer can take place this cycle. A low indicates wait states. Data Transfer Acknowledge: Motorola mode: A low during read indicates data bus is valid. A low during write indicates data is accepted.
INTO/ $\overline{\text{IRQO}}$	32	O	TTL 4mA	Interrupt: Intel mode: If control bit IPOL (bit 4) in register 006H is set to a 0, a high indicates an interrupt request to the microprocessor. Interrupt Request: Motorola mode: If control bit IPOL (bit 4) in register 006H is set to a 0, a low indicates an interrupt request to the microprocessor.
PCKI	40	I	TTL	Processor Clock: Processor Clock Input. Required for device operation; 8 to 20 MHz. DS1MX7 will continue to pass data on loss of PCKI, but microprocessor access will be blocked.

Boundary Scan and Test Port

Symbol	Pin No.	I/O/P	Type	Name/Function
TCK	204	I	TTL	Test Clock: IEEE 1149.1 Boundary Scan Clock input. This clock is used to shift data into TDI on the rising edge and out of TDO on the falling edge.
TDI	201	I	TTLp	Test Data Input: Boundary Scan Data input. Serial test instructions and data are clocked into this pin on the rising edge of TCK.
TDO	202	O(T)	TTL 4mA	Test Data Output: Boundary Scan Data output. Serial data and test instructions are clocked out of this pin on the falling edge of TCK.
TMS	199	I	TTLp	Test Mode Select: Boundary Scan Test Mode Select input; sampled by TCK rising edge to put DS1MX7 into test mode.
$\overline{\text{TRS}}$	200	I	TTLp	Test Reset: Boundary Scan Reset input. This pin will asynchronously reset the Test Access Port (TAP) controller if held low for a minimum duration of 300 ns. This pin is to be held low, asserted low or pulsed low to reset the TAP controller on DS1MX7 power-up.
$\overline{\text{HIGHZ}}$	3	I	CMOS	High Impedance Select: Grounding this pin causes all outputs except TDO to go high impedance but alters no internal registers.
TSTA	1	I	CMOS	Test A: Device test pin. Must be connected to ground.
TSTB	2	I	CMOS	Test B: Device test pin. Must be connected to ground.

X**INPUT, OUTPUT AND INPUT/OUTPUT PARAMETERS****Input Parameters for CMOS**

Parameter	Min	Typ	Max	Unit	Test Conditions
V_{IH}	$0.7 \times V_{DD}$			V	$4.75 \leq V_{DD} \leq 5.25$
V_{IL}			$0.3 \times V_{DD}$	V	$4.75 \leq V_{DD} \leq 5.25$
Input leakage current			10	μA	$V_{DD} = 5.25$
Input capacitance		2.5		pF	

Input Parameters for TTL

Parameter	Min	Typ	Max	Unit	Test Conditions
V_{IH}	2.0			V	$4.75 \leq V_{DD} \leq 5.25$
V_{IL}			0.8	V	$4.75 \leq V_{DD} \leq 5.25$
Input leakage current			10	μA	
Input capacitance		2.5		pF	

Input Parameters for TTLp

Parameter	Min	Typ	Max	Unit	Test Conditions
V_{IH}	2.0			V	$4.75 \leq V_{DD} \leq 5.25$
V_{IL}			0.8	V	$4.75 \leq V_{DD} \leq 5.25$
Input leakage current		0.5	1.4	mA	$V_{DD} = 5.25$; Input = 0 volts
Input capacitance		2.5		pF	

Note: Input has a 9K (nominal) internal pull-up resistor.

Output Parameters for CMOS or TTL 4 mA

Parameter	Min	Typ	Max	Unit	Test Conditions
V_{OH}	2.4			V	$V_{DD} = 4.75$; $I_{OH} = -4.0$
V_{OL}			0.4	V	$V_{DD} = 4.75$; $I_{OL} = 4.0$
I_{OL}			4.0	mA	
I_{OH}			-4.0	mA	
t_{RISE}			11	ns	$C_{LOAD} = 50$ pF
t_{FALL}			7.0	ns	$C_{LOAD} = 50$ pF
Leakage tristate			± 10	μA	0 to 5.25 V input

Output Parameters for CMOS Open Drain (4 mA)

Parameter	Min	Typ	Max	Unit	Test Conditions
V_{OL}			0.5	V	$V_{DD} = 4.75$; $I_{OL} = 4.0$
I_{OL}			4.0	mA	
t_{FALL}			7.0	ns	$C_{LOAD} = 50$ pF
High Z leakage current			10	μ A	$V_{DD} = 5.25$

Note: Open Drain requires use of 4.7k Ohm external pull-up resistor. If this resistor is not provided the output behaves as tristate.

Output Parameters for TTL 8 mA

Parameter	Min	Typ	Max	Unit	Test Conditions
V_{OH}	2.4			V	$V_{DD} = 4.75$; $I_{OH} = -8.0$
V_{OL}			0.4	V	$V_{DD} = 4.75$; $I_{OL} = 8.0$
I_{OL}			8.0	mA	
I_{OH}			-8.0	mA	
t_{RISE}			6.0	ns	$C_{LOAD} = 50$ pF
t_{FALL}			4.0	ns	$C_{LOAD} = 50$ pF

Input/output Parameters for CMOS

Parameter	Min	Typ	Max	Unit	Test Conditions

t_{FALL}			4.0	ns	$C_{LOAD} = 50$ pF

TIMING CHARACTERISTICS

Detailed timing diagrams for the DS1MX7 are illustrated in Figures 4 through 20, with values of the timing intervals tabulated below each diagram. All output times are measured with a maximum 25 pF load capacitance, unless otherwise indicated. Timing parameters are measured at voltage levels of $(V_{OH} + V_{OL})/2$ for output signals or $(V_{IH} + V_{IL})/2$ for input signals.

Figure 4. Tributary Input Timing

Parameter	Symbol	Min	Typ	Max	Unit
LRCLKn clock period	t_{CYC}	560	648		ns
LRCLKn high time	t_{PWH}	240			ns
LRCLKn low time	t_{PWL}	240			ns
RPOS/RNEG/RSIGL/RCV setup time to LRCLK↓	$t_{SU(1)}$	50			ns
RPOS/RNEG/RSIGL/RCV hold time after LRCLK↓	$t_{H(1)}$	50			ns
RSYNC pulse width as input	t_{PW}	500		750	ns
RSYNC pulse width as output	t_{PW}	560	648		ns
RSYNC setup as input before LRCLK↓	$t_{SU(2)}$	50			ns
RSYNC hold as an input after LRCLK↓	$t_{H(2)}$	50			ns
RSYNC delay as output after LRCLK↑	t_D			50	ns

Notes:

1. For true byte-synchronous mode (control bits MODE0 and MODE1 = 01) LRCLKn and RSYNCn are outputs. For the other modes LRCLKn and RSYNCn are inputs.
2. LRCLKn active edge may be inverted via control bit RCAE (bit 6) in register 007H; as shown RCAE = 0. RPOSn, RNEGn, RSIGLn, RSYNCn and RCVn are clocked in on the falling edge of LRCLKn. For true byte-synchronous mode of operation, LRCLKn and RSYNCn are outputs. RSYNCn is output delayed from the rising edge of LRCLKn when control bit RCAE = 0.

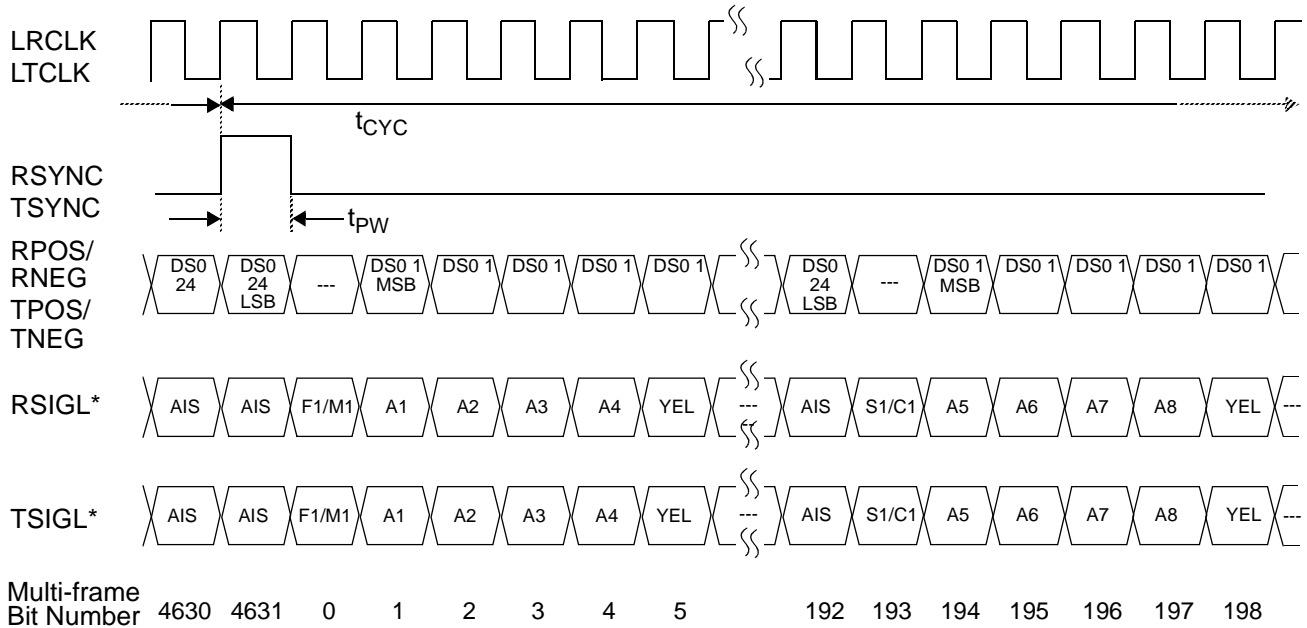

Figure 5. Tributary Output Timing

Parameter	Symbol	Min	Typ	Max	Unit
LTCLKn clock period	t_{CYC}	637	648	656	ns
LTCLKn duty cycle, t_{PWH}/t_{CYC}	--	45		55	%
TPOS/TNEG/TSIGL output delay after LTCLK \uparrow	t_{OD}	-5.0		50	ns
TSYNC delay after LTCLK \uparrow	t_D	-5.0		50	ns
TSYNC pulse width	t_{PW}	637	648	656	ns

* LTCLKn may be inverted via control bit TCAE (bit 7) in register 007H; as shown TCAE = 1.

Figure 6. Signaling Highway Structure

Note: n=1-7

Note 1: * shown for 16-state signaling. See Operation section.

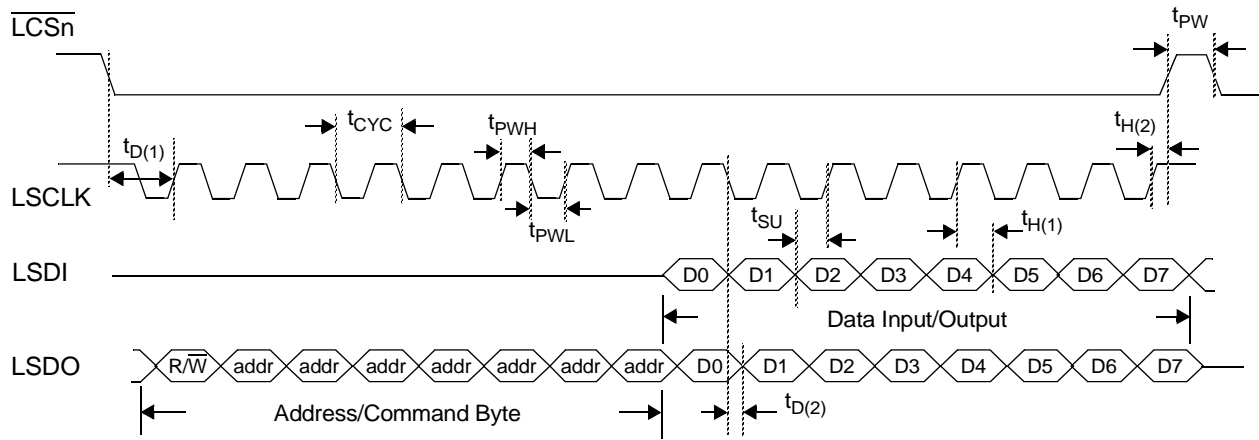

Note 2: "---" in TPOS, TNEG, RPOS, RNEG, RSIGL, and TSIGL are unused bits (see Operation section).

Note 3: AIS is present in DS0 bit positions 16 through 192 (DS0 3 - DS0 24); bits 6 through 15 are unused.

Parameter	Symbol	Min	Typ	Max	Unit
TSYNCn/RSYNCn clock period (n=1-7)	t_{CYC}		3.000		ms
TSYNCn/RSYNCn pulse width (n=1-7)	t_{PW}		One clock period of LTCLK or LRCLK*		ns

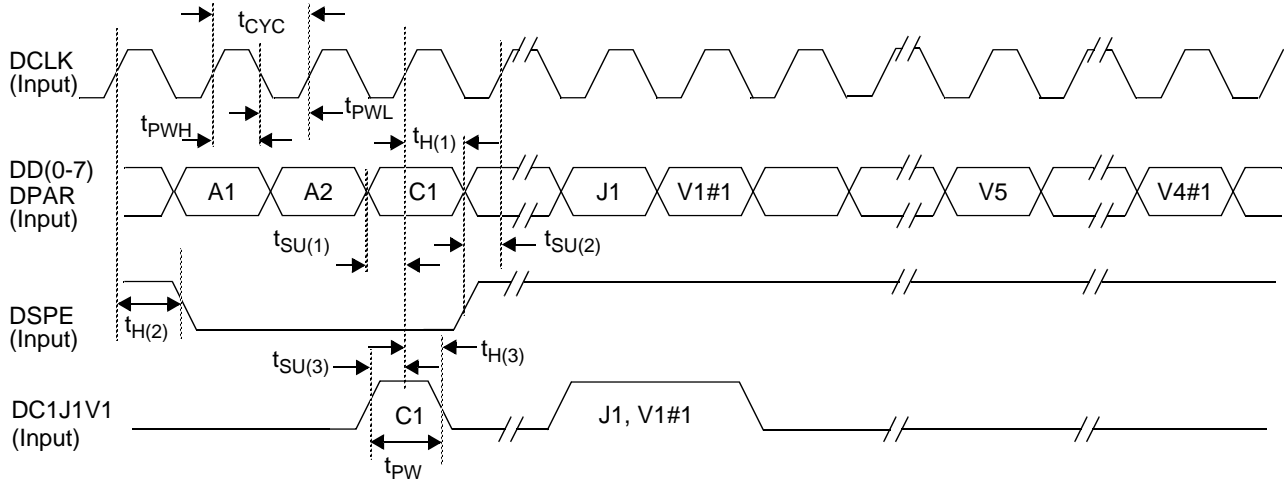

* TSYNC or RSYNC should be valid on the active edge of LTCLK or LRCLK, respectively.

Figure 7. Serial Control Port Structure and Timing

Parameter	Symbol	Min	Typ	Max	Unit
LSCLK clock period	t_{CYC}	560	648		ns
LSCLK high time	t_{PWH}	280			ns
LSCLK low time	t_{PWL}	280			ns
$\overline{\text{LCSn}}$ delay time to LSCLK \uparrow	$t_{\text{D}(1)}$	100	324	350	ns
$\overline{\text{LCSn}}$ inactive pulse width	t_{PW}	300			ns
LSDI setup time to LSCLK \uparrow	t_{SU}	100			ns
LSDI hold time after LSCLK \uparrow	$t_{\text{H}(1)}$	100			ns
LSCLK \uparrow to $\overline{\text{LCSn}}$ inactive	$t_{\text{H}(2)}$	100			ns
LSDO delay after LSCLK \downarrow	$t_{\text{D}(2)}$			100	ns
LSCLK rise and fall times (10% - 90%)	t_r, t_f			50	ns

Figure 8. Telecom Bus Input Timing - 6.48 MHz Operation

Parameter	Symbol	Min	Typ	Max	Unit
DCLK clock period	t_{CYC}	150	154.32		ns
DCLK high time	t_{PWH}	38		116	ns
DCLK low time	t_{PWL}	38		116*	ns
DD(0-7)/DPAR setup time to DCLK \uparrow	$t_{SU(1)}$	7.0			ns
DD(0-7)/DPAR hold time after DCLK \uparrow	$t_{H(1)}$	6.0			ns
DSPE setup time to DCLK \uparrow	$t_{SU(2)}$	7.0			ns
DSPE hold time after DCLK \uparrow	$t_{H(2)}$	6.0			ns
DC1J1V1 setup time to DCLK \uparrow	$t_{SU(3)}$	7.0			ns
DC1J1V1 hold time after DCLK \uparrow	$t_{H(3)}$	6.0			ns
DC1J1V1 pulse width for C1	t_{PW}	120			ns

* For gapped clock applications, skipping a rising (and next falling) edge of DCLK will extend the current low time to twice the listed value. All data is clocked in on the rising clock edge unless control bit TBRC1 (bit 4) in register 01EH is set to a 1, in which case all data is clocked in on the falling clock edge.

Figure 9. Telecom Bus Input Timing - 19.44 MHz Operation

Parameter	Symbol	Min	Typ	Max	Unit
DCLK clock period	t_{CYC}	50	51.44		ns
DCLK high time	t_{PWH}	23		29	ns
DCLK low time	t_{PWL}	23		29*	ns
DD(0-7)/DPAR setup time to DCLK \uparrow	$t_{SU(1)}$	7.0			ns
DD(0-7)/DPAR hold time after DCLK \uparrow	$t_{H(1)}$	6.0			ns
DSPE setup time to DCLK \uparrow	$t_{SU(2)}$	7.0			ns
DSPE hold time after DCLK \uparrow	$t_{H(2)}$	6.0			ns
DC1J1V1 setup time to DCLK \uparrow	$t_{SU(3)}$	7.0			ns
DC1J1V1 hold time after DCLK \uparrow	$t_{H(3)}$	6.0			ns
DC1J1V1 pulse width for an individual pulse (e.g., isolated J1)	t_{PW}	40			ns
DC1J1V1 J1#1 to V1#1 delay (STS-3 mode)	t_D		3 cycles of DCLK		ns
DC1J1V1 J1#1 to V1#1 delay (STM-1 mode)	t_D		6 cycles of DCLK		ns

* For gapped clock applications, skipping a rising (and next falling) edge of DCLK will extend the current low time to twice the listed value. All data is clocked in on the rising clock edge unless control bit TBRC1 (bit 4) in register 01EH is set to a 1, in which case all data is clocked in on the falling clock edge.

Figure 10. Telecom Bus Output Timing - 6.48 MHz Operation

Parameter	Symbol	Min	Typ	Max	Unit
ACLK clock period	t_{CYC}	150	154.32		ns
ACLK high time	t_{PWH}	38		116	ns
ACLK low time	t_{PWL}	38		116*	ns
AD(0-7)/APAR delay time after ACLK↓	$t_{D(1)}$	3.0		20	ns
AD(0-7)/APAR float time after ACLK↓	t_F	3.0		20	ns
ASPE setup time to ACLK↑	$t_{SU(1)}$	7.0			ns
ASPE hold time after ACLK↑	$t_{H(1)}$	3.0			ns
AC1J1V1 setup time to ACLK↑	$t_{SU(2)}$	7.0			ns
AC1J1V1 hold time after ACLK↑	$t_{H(2)}$	3.0			ns
AD(0-7)/APAR delay time after DATEN↑	$t_{D(2)}$			15.9	ns
AD(0-7)/APAR delay time after DATEN↓	$t_{D(3)}$			13.6	ns
AADD delay time after DATEN↑	$t_{D(4)}$			13.1	ns
AADD delay time after DATEN↓	$t_{D(5)}$			13.2	ns
AADD delay time after ACLK↓	$t_{D(6)}$	0.0		16.8	ns
AC1J1V1 pulse width for C1	t_{PW}	120			ns
AD(0-7)/APAR rise/fall times (10% - 90%)	t_r, t_f			10.9	ns

* For gapped clock applications, skipping a rising (and next falling) edge of ACLK will extend the current low time to twice the listed value. If control bit TBTCI (bit 5) in register 01EH is set to a 0, all data is clocked in on the rising ACLK clock edge and out on the falling ACLK clock edge, as is shown in the timing diagram. If control bit TBTCI = 1, all data is clocked in on the falling clock edge and out on the rising clock edge of ACLK. If control bit TBDD = 1, AD(0-7), APAR and AADD are delayed one clock period from what is shown in the timing diagram with reference to ASPE and AC1J1V1; Input to DATEN must also be delayed one clock period of ACLK.

Figure 11. Telecom Bus Output Timing - 19.44 MHz Operation

Parameter	Symbol	Min	Typ	Max	Unit
ACLK clock period	t_{CYC}	50	51.44		ns
ACLK high time	t_{PWH}	23		29	ns
ACLK low time	t_{PWL}	23		29*	ns

LTCLKn or TGCO n Low time	t_{PWL}	40%	50%	55%	t_{CYC}
Rise Time (10% - 90%) ³ - LTCLKn, TGCO n, TPOS n or TSYNC n	t_R			6.0	ns

Notes:

1. LTCLKn can be inverted with the control bit TCAE (bit 7) in register 007H.
2. LTCLKn shown with TCAE set to a 0.
3. 25 pF load

Figure 15. Datacom Mode Input Timing

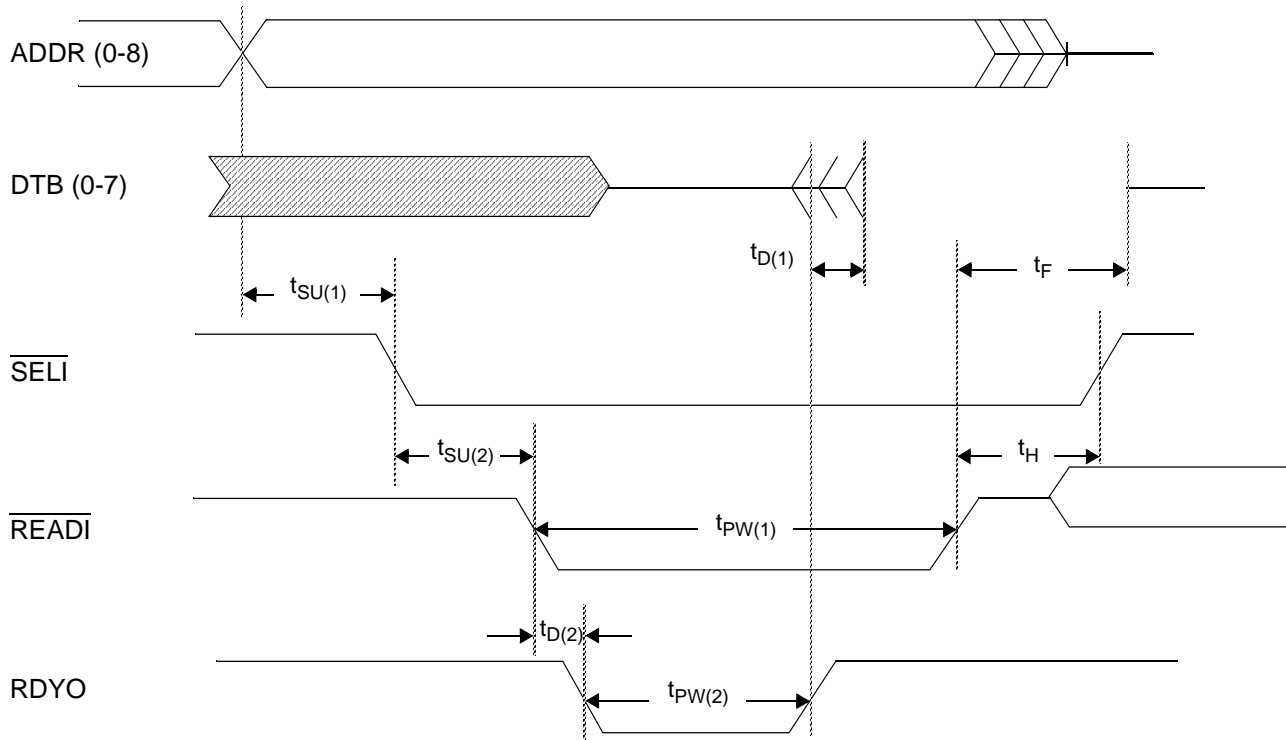

Note: n = 1 - 7

Parameter	Symbol	Min	Typ	Max	Unit
LRCLKn period	t_{CYC}	560	648		ns
Delay - LRCLKn ^{1,2} to RGCO n	$t_{D(1)}$	0.0		10	ns
Delay - \downarrow LRCLKn ^{1,2} to RSYNCn if Output	$t_{D(2)}$			50	ns
Fall Time (90% - 10%) ³ - RGCO n, and LRCLKn or RSYNCn if Outputs	t_F			6.0	ns
Hold - RPOSn or RSYNCn if input after \uparrow LRCLKn ^{1,2}	t_H	50			ns
LRCLKn or RGCO High time	t_{PWH}	240			ns
LRCLKn or RGCO Low time	t_{PWL}	240			ns
Rise Time (10% - 90%) ³ - RGCO n, and LRCLKn or RSYNCn if Outputs	t_R			6.0	ns
Set-up - RPOSn or RSYNCn if input to \uparrow LRCLKn ^{1,2}	t_{SU}	50			ns

Notes:

1. LRCLKn active edge may be inverted via control bit RCAE (bit 6) in register 007H; as shown RCAE = 1. RPOSn, RNEGn, RSIGLn, RSYNCn and RCv n are clocked in on the falling edge of LRCLKn. For true byte-synchronous mode of operation (control bits MODE0 and MODE1 = 01), LRCLKn and RSYNCn are outputs. RSYNCn is output delayed from the rising edge of LRCLKn when control bit RCAE = 0.
2. LRCLKn shown with RCAE set to a 1.
3. 25 pF load.

OPERATION

GENERAL MAPPER APPLICATION OVERVIEW

The DS1MX7 can be used in a wide variety of applications (see Figures 48 through 49) that require either an asynchronous mapping of a DS1 signal into and out of a SONET or SDH payload in which the input clock and data are replicated at the output, or a byte-synchronous mapping of a DS1 signal into or out of a SONET or SDH payload in which not only is the input clock and data replicated at the output, but DS0 visibility and signaling information is replicated at the output. When used in an asynchronous application the DS1 side of the mapper connects to the line through DS1 Line Interface Units (LIUs) that recover the 1.544 MHz from the data, provide clock and data to the DS1MX7, input clock and data from the DS1MX7 and format a line signal for transmission. A port is provided to control up to 7 LIUs from the DS1MX7. When used in byte-synchronous applications, DS1 framers may be inserted between the LIUs and the DS1MX7 to delineate the DS0s, extract and insert signaling, process DS0 and DS1 alarms, etc. The byte-synchronous applications may also be used for direct interface to sources of DS0s (e.g., time slot interchangers, PCM codecs) or to data sources like fractional T1 with HDLC protocol on N x DS0 channels. The DS1MX7 provides complete clock recovery of DS1 signals through a two stage digital filter, eliminating the need for special external de-jitter buffers. The DS1MX7 provides complete SONET or SDH low order path termination and origination functions (VT1.5/ TU-11) with alarm mapping to and from the DS1 line. On the system side, all that is required is a high order section, line and path termination origination function. The Telecom Bus provided in the DS1MX7 allows for multiple devices to be connected seamlessly to a TranSwitch SOT-1E or SOT-3 device, both of which supply these high order functions. A separate port is provided for access to optional overhead bytes. For redundant and ring applications a ring I/O port is provided as well as special alarm output and DS1 isolation input. A microprocessor port is provided to configure the DS1MX7 as well as to provide interrupts for device wide/ Telecom Bus alarms as well as VT1.5/ TU-11 or DS1 alarms. One second shadow registers are provided to assist in the preparation of performance monitoring information. An IEEE 1149.1 boundary scan function and an internal PRBS generator/ analyzer are provided for manufacturing support.

LINE INTERFACE SELECTION

Each of the seven DS1MX7 channels can be individually programmed for asynchronous mode, byte-synchronous mode as clock master, or a modified byte-synchronous mode where the DS1MX7 channel is a clock slave in which pointer movements are generated as needed to map the incoming DS1 signal to the SONET/ SDH payload. The table below details the options present at the Line Interface.

Mode of Operation	Line Code	RNEGn	TNEGn	MODE1	MODE0	LCODE	ENCOD	DATA COM
				X+00 bit 1	X+00 bit 0	X+00 bit 3	X+00 bit 2	X+00 bit 5
Asynchronous	AMI	Data	Data	0	X	0	1	X
Asynchronous	B8ZS	Data	Data	0	X	1	1	X
Asynchronous	NRZ	RCVn	Low	0	X	0	0	X
Asynchronous	NRZ	RCVn	High	0	X	1	0	X
Byte-synchronous LRCLK/RSYNCn out	NRZ	RSIGLn input	TSIGLn output	1	0	X	X	0
Byte-synchronous (Datacom) LRCLK/RSYNCn out	NRZ	RGCON output	TGCON output	1	0	X	X	1
Modified byte-synchronous LRCLK/RSYNCn in	NRZ	RSIGLn input	TSIGLn output	1	1	X	X	0

Asynchronous Operation with the Line Interface

Each of the seven mappers in the DS1MX7 can be programmed to provide either a dual unipolar interface or a NRZ interface. The dual unipolar interface is selected when a 1 is written into control bit ENCOD (bit 2) in the control register located at address X+00H in the memory map. The X is (n x 040H), where n is the number of the mapper selected (1-7), as explained in the Memory Map section. The B8ZS line or AMI coder/decoder (CODEC) feature can be selected for the dual unipolar interface. The B8ZS CODEC is selected by writing a 1 to control bit LCODE (bit 3) in the register X+00H. A 0 will select an AMI CODEC. The B8ZS stands for Bipolar with Eight Zero Substitution, which is described in ANSI Document ANSI T1.102-1993 and other Bellcore documents.

The clock polarity of the input and output line clocks is selectable by writing the sense required to global control bits TCAE and RCAE (bits 7 and 6) in register 007H. When a mapper is configured for the dual unipolar mode, the line signal is monitored for loss of signal (LOS). LOS is detected if no transitions are present for 175 ± 75 pulse positions. Recovery occurs when a ones density of 12.5% or more is detected in 175 ± 75 pulse positions. A status bit LOSS (bit 5) in register X+10H indicates this condition. A mask, LOSM, a latched value, LOSE, a PM value, LOSPM and a FM value, LOSFM are available (bit 5) at register locations X+08H, X+14H, X+18H and X+1CH respectively. Coding violations are counted in a 12-bit performance counter located at register locations X+22H and X+23H with shadow value in registers X+2AH and X+2BH. A counter overflow bit CVOS (bit 0) in register X+10H is provided. A mask, CVOM, a latched value, CVOE, a PM value, CVOPM and a FM value, CVOFM are available (bit 0) at register locations X+08H, X+14H, X+18H and X+1CH respectively. Excessive zeros (8 or more for B8ZS or 16 or more for AMI) are included if control bit ENZC (bit 4) in register X+00H is set to a 1. An AIS indication is provided which checks to see if more than 99.9% ones occur in a 3 to 75 millisecond period or if less than 99.9% ones occur in a 3 to 75 millisecond period. Status bit DAISS (bit 3) in register X+10H indicates the AIS condition. A mask, DAISM, a latched value, DAISE, a PM value, DAISPM and a FM value, DAISFM are available (bit 3) at register locations X+08H, X+14H, X+18H and X+1CH respectively. The LOS condition can also be used to generate an AIS (DS1 payload all-ones will be mapped in place of the received signal) if control bit LOS2AIS (bit 6) in register X+01H is set to a 1.

The Coder block provides an AMI/B8ZS encoder. This block provides AIS generation either from the Microprocessor Interface by control bit SDAISL (bit 3) in register X+03H when set to a 1 or optionally from various system conditions (VT AIS/LOP, Signal Label Mismatch or Unequipped) all of which are individually enabled by control bits VAIS2AIS (bit 3 at X+01H), SLM2AIS (bit 2 at X+02H) and UNE2AIS (bit 0 at X+02H) being set to a 1. A high level signal failure input on pin DFAIL will cause DS1 AIS for all seven mappers. A 'transmit all-zeros' capability is provided to conserve power in an external Line Transceiver when AIS is not required by setting control bit SDAISL (bit 3) in register X+03H to a 0 when control bit TBRVAL (bit 7) in register X+04H is also set to a 0 (Drop slot not assigned). The connections between a DS1MX7 mapper and external line interface transceivers are shown in Figure 21 for dual unipolar mode.

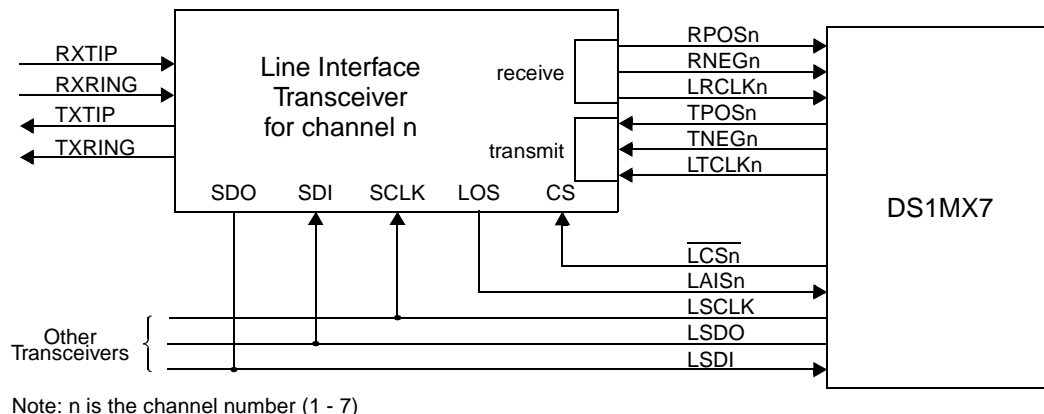

Figure 21. Line Interface for Dual Unipolar Mode

The NRZ interface is selected when a 0 is written into control bit ENCOD (bit 2) in register X+00H. The clock polarity of the line input and output clocks is selectable by writing to global control bits TCAE and RCAE (bits 7 and 6) in register 007H. Options are provided for inverting the polarity of the transmit and receive data pins. A 1 written to control bit TXNRZP (bit 0) in global register 007H inverts the polarity of the transmit data signal, TPOSn, while a 1 written to control bit RXNRZP (bit 4) in the same register inverts the polarity of the receive data signal RPOSn. In NRZ mode, the RNEGn pin may be used to input an external indication of coding violations (RCVn). External coding violations are counted in the same 12-bit performance counter as described above. Coding violations are counted when the input is high for rising edges of the line clock LRCLKn. The same AIS detector as described above for bipolar is available in NRZ mode. LOS can be detected only externally and input on pin LAISn. By setting control bit EXPLOS (bit 6) in register X+00H to a 1, LOSS status plus latched event, mask, PM and FM functions are provided as described above.

In the transmit direction, when the NRZ mode is selected, the TNEGn pin becomes a spare drive pin. When control bit ENCOD (bit 2) in register X+00H is a 0, the output state of TNEGn is defined by the value written to bit LCODE (bit 3) in register X+00H (LCODE set to a 0 is a low on TNEGn and LCODE set to a 1 is a high on TNEGn). A typical interface between a mapper in the DS1MX7 and an external line transceiver is shown in Figure 22 below for the NRZ mode. TNEGn, for example, may be used to select the encoding mode for the LIU.

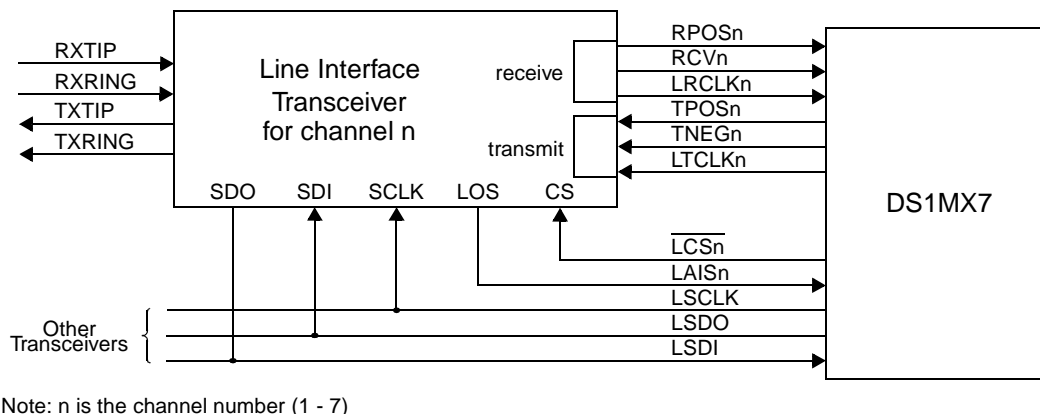

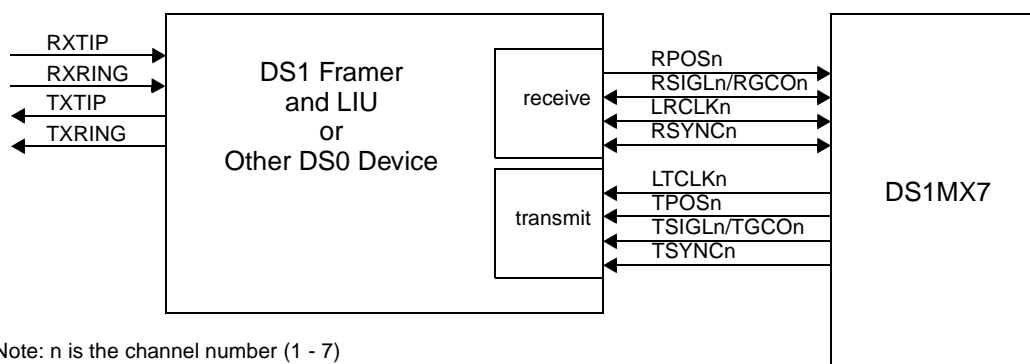

Figure 22. Line Interface for NRZ Mode

Byte-synchronous Operation with the Line Interface

For byte-synchronous operation the line interface operates in the NRZ mode with RSIGLn and TSIGLn carrying the signaling information from/to an external framer using the negative polarity input and output pins. Figure 23 is the basic byte-synchronous setup. Typical applications are shown in Figures 48 and 49. In byte-synchronous applications where signaling is not used, a Dacom option is provided for connections to HDLC controllers or other devices that operate over the DS1 payload only. TGCO and RGCO are gapped clock outputs for clocking out or in data on TPOSn and RPOSn. The clock is gapped during the frame bit time every 125 ms. This option is available by setting control bit DATACOM (bit 5) in register X+00H to a 1.

For byte-synchronous applications that require DS1-based performance monitoring (control bits MODE1, 0 =10 in register X+00H bits 1 and 0 only), CRC-6 is generated optionally for each superframe of data presented on RPOSn and inserted in the Cn frame bit locations of the following superframe to be mapped. When control bit CRC6 (bit 4) in register X+01H is set to a 1 CRC-6 is both inserted and checked. After demapping CRC-6 is checked. CRC-6 errors share the 12-bit line code violation counter shadow register and overflow indications to support performance monitoring. CRC-6 errors are counted in the 12-bit performance counter located at register locations X+22H and X+23H with shadow value in registers X+2AH and X+2BH. Each ESF superframe in which a calculated CRC-6 value does not match the received CRC-6 value increments the counter by one. A counter overflow bit CVOS (bit 0) in register X+10H is provided. A mask, CVOM, a latched value, CVOE, a PM value, CVOPM and a FM value, CVOFM are available (bit 0) at register locations X+08H, X+14H, X+18H and X+1CH respectively.

**Figure 23. Byte-synchronous Interface to a DS1 Framer****Receive Data and Signaling Highway Operation**

The receive highway carries information from the framer to the DS1MX7. The highway is sub-divided into two time division multiplexed buses, one for the data (RPOSn), and one for signaling, frame bit and alarms (RSIGLn). These two buses are synchronous with the signals LRCLKn and RSYNCn, a 1.544 MHz clock and a 3 millisecond synchronization signal driven from the framer or the DS1MX7 depending on the mode of byte-synchronous operation. If the DS1MX7 operates in the modified byte-synchronous mode, receive clock and synchronization are inputs to the DS1MX7; if the DS1MX7 operates in true byte-synchronous mode, receive clock and synchronization are outputs of the DS1MX7. The data highway is a single-bit serial bus organized into 193-bit groups called frames. Each frame consists of a spare bit position followed by twenty-four 8-bit data samples representing the 24 DS0s. 24 frames form a multiframe, the beginning of which is identified by a synchronization pulse, RSYNCn. The RSYNCn high pulse occurs one bit time before the first frame of the multiframe and every 24 frames after that. The signaling highway, RSIGLn, is also divided into 193-bit frames. Each frame consists of a frame bit followed by 192 bits of signaling and alarm information for the 24 data channels on the data highway. The frame bit pattern tracks the signaling bit pattern received from the system. The alarm

**DS1MX7
TXC-04201B**

DATA SHEET

bits in the signaling highway follow the signaling bits. In each frame of 193 bits, four signaling bits are transmitted followed by a RAI (Yellow) alarm bit position. The bit positions coincident with DS0 3 through DS0 24 are all used for the AIS alarm bit. Signaling bits A1 through A4 occur in frame number one, followed by A5 through A8 in frame number two, and so on, ending with D21 through D24 in frame number 24, corresponding to the ESF mode with 16-state signaling. For two-state or four-state signaling the B, C and D bits or the C and D bits are replaced by A bits or A and B bits respectively, as shown in the following table. The receive framing format and signaling format are shown in Figures 24 and 25. The signaling information is stored in the RX Signaling Store block for mapping. The alarm information (DS1 AIS and DS1 RAI-Yellow) is stored in the RX Alarm Control block and can be enabled to generate VT AIS or RFI automatically. Control bit SH2VAIS (bit 7) in register X+01H, when set to a 1, causes the AIS alarm bits on the signaling highway to activate VT AIS generation for the affected channel. When control bit YEL2RFI (bit 1) in register X+01H is set to a 1, the RAI-Yellow alarm bit on the signaling highway causes the DS1MX7 mapper channel to send a VT RFI in the V5 byte. The status of these two signaling highway alarm bits is available as SHDAIS and SHYEL (bits 7 and 6) in register X+20H as status only. When control bit AIS2VAIS (bit 0) in register X+01H is set to a 1, the DS1MX7 will cause VT AIS to be generated if the DS1 AIS condition as defined above for the asynchronous mode of operation is detected. When control bit DATACOM (bit 5) in register X+00H is set to a 1, RSIGLn input becomes RGCO output, which is a gapped LRCLKn clock with a gap of one LRCLKn cycle wide occurring at the frame bit time of RPOSn every 125 microseconds.

Figure 24. System Interface Receive Framing Format

Figure 25. System Interface Receive Signaling Format

Transmit Data and Signaling Highway Operation

The transmit highway carries information from the DS1MX7 to the framer. The highway is sub-divided into two time division multiplexed buses, one for the data (TPOS_n) and one for signaling, frame bits and alarms (TSIGL_n). These two buses are synchronous with the signal LTCLK_n, a 1.544 MHz clock that is driven from the DS1MX7. The data highway is a single bit-serial bus that is organized into 193-bit groups called frames. Each frame consists of a frame bit followed by twenty-four 8-bit data samples. Each of the 8-bit data samples represents a single DS0 on the receive highway. The 193-bit frames are grouped into a 24-frame multiframe. In order to help locate the beginning of a frame and extract signaling information, the DS1MX7 sources a synchronization signal, TSYNC_n. In byte synchronous mode only; TSYNC_n is present if a standard compliant P₁P₀ pattern is present in the VT1.5 or TU-11 as shown in Figure 2. The TSYNC_n high pulse occurs one bit time before the first frame in the multiframe and every 24 frames after that. The signaling highway, TSIGL_n, is also divided into 193-bit frames and is organized in an identical fashion to RSIGL_n (see the table above for signaling bit assignments). The alarm bits in the signaling highway follow the signaling bits. In each frame of 193 bits, four signaling bits are transmitted followed by a RAI (Yellow) alarm bit position. The bit positions coincident with DS0 3 through DS0 24 are all used for the AIS alarm bit. Signaling bits A1 through A4 occur in frame number one followed by A5 through A8 in frame number two ending with D21 through D24 in frame number 24, corresponding to the ESF mode with 16-state signaling. For two-state or four-state signaling the B, C and D bits or the C and D bits are replaced by A bits or A and B bits respectively, as shown in the table above. AIS or Yellow alarm sourced by the DS1MX7 are output in the same positions as on RSIGL_n. These alarm bits may be used to force DS1 Yellow or DS1 AIS automatically in the QT1F-Plus. Control bit VAIS2AIS (bit 3) in register X+01H, when set to a 1, causes the detection of VT-LOP or VT AIS to set the AIS bits on TSIGL_n unless control bit DATACOM (bit 5) in register X+00H is set to a 1. Similarly, if control bits SLM2AIS (bit 2) and UNE2AIS (bit 0) in register X+02H are set to a 1, and if either a Signal Label Mismatch or Unequipped condition exists, the AIS bits on the signaling highway are set to a 1 unless control bit DATACOM is set to a 1. Setting control bit SDAISL (bit 3) in register X+03H to a 1 will also set the AIS bits in TSIGL_n unless control bit DATACOM is set to a 1. Control bit SDAISL set to a 1 or control bits VAIS2AIS, SLM2AIS or UNE2AIS set to a 1 and the condition VT LOP/AIS, Signal Label Mismatch or Unequipped occurs will cause an all-ones signal to be generated on TPOS_n without regard for control bits DATACOM or MODE1. Likewise, the Yellow alarm bit on the signaling highway may be set if control bit RFI2YEL (bit 2) in register X+01H and an RFI alarm is detected, or if control bit SYELL (bit 2) in register X+03H is set to a 1 when control bit MODE1 (bit 1) in register X+00H is set to a 1 indicating byte-synchronous operation and DATACOM (bit 5) in the same register is set to a 0 indicating TSIGL_n is not used for gapped clock output. The frame bits received from the VT1.5/ TU-11 are available on TSIGL_n as well; they track the signaling bits and may be used for FDL extraction.

When control bit DATACOM (bit 5) in register X+00H is set to a 1, TSIGL_n output becomes TGCON output, which is a gapped LTCLK_n clock with a gap one LTCLK_n cycle wide occurring at the frame bit time of TPOS_n every 125 microseconds. System interface transmit framing format and signaling format are shown in Figures 26 and 27.

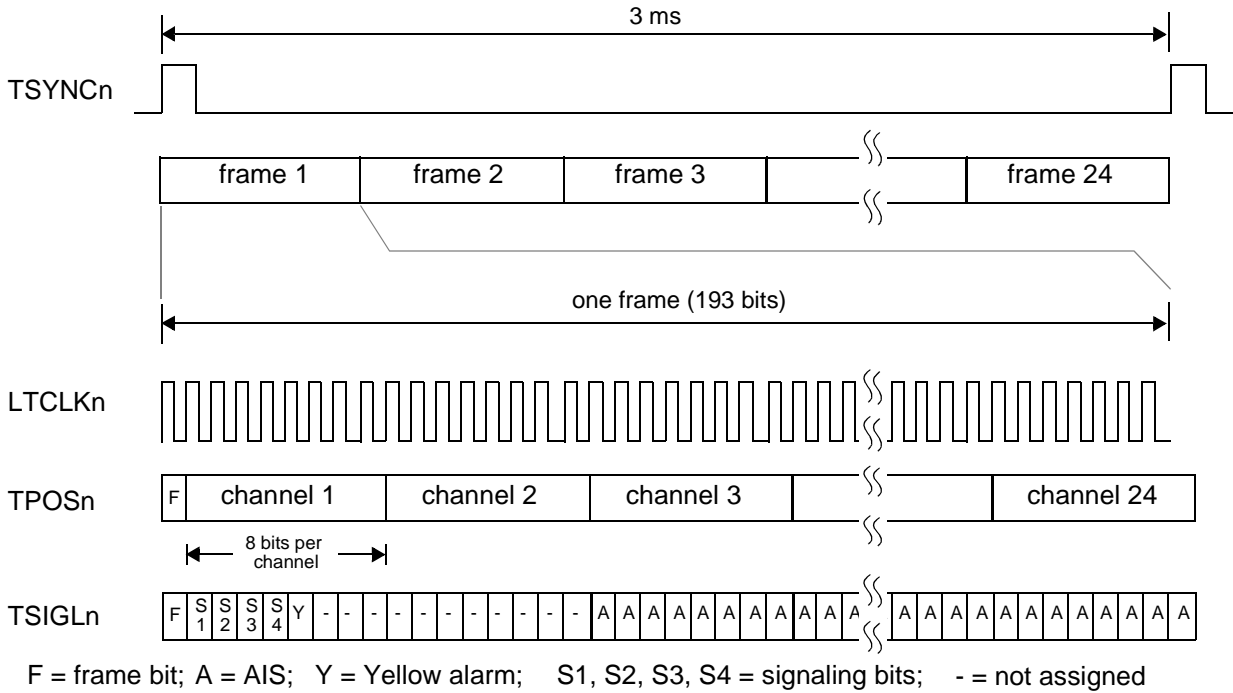

Figure 26. System Interface Transmit Framing Format

Figure 27. System Interface Transmit Signaling Format

The TX Signaling Store and the TX Alarm Control blocks buffer the signaling and alarm information to be sent on the signaling highway. The signaling bits are output as shown in the table above as well as in Figure 27. To support certain protection schemes, pin $\overline{CS0}$ when tied low will cause the transmit line interface leads (LTCLKn, TNEGn/TSIGLn/TGCON, TPOSn, and TSYNCn) to be driven to a logic low.

The Synchronizer, Mapper and Overhead Generator

The Synchronizer/Mapper block operates in three different modes, programmable on a per channel basis as described above in the Line Interface Section. The Synchronizer/Mapper is the heart of the mapping side of the device. It synchronizes the 1.544 Mb/s data stream to the SONET/SDH clock domain, it maps the data stream to the virtual tributary (VT1.5/ TU-11) and it inserts the low order path overhead for performance monitoring and administrative purposes. Figure 2 shows the result of the synchronization, mapping and overhead insertion functions to form a VT1.5/ TU-11 for asynchronous or byte-synchronous mode.

The synchronization function adjusts approximately 772 DS1 bits so that they fit into a VT1.5 / TU-11 which is 500 microseconds long. The DS1 signal, whether framed to SF or ESF formats or framed to another format, generates 193 bits every 125 microseconds. As shown in Figure 2, three opportunities are provided for 193 bits (I plus 24 bytes) and one opportunity for 192 (no St bits used for information), 193 (one St bit used for information) or 194 bits (both St bits used for information) in the VT1.5/ TU-11 for the asynchronous mode. Two stuffing control bits (C_1 and C_2) repeated twice are provided in every VT1.5/ TU-11 to indicate if a stuffing bit opportunity is to be used for information or stuff; for $C_1C_1C_1 = 000$ indicates that S_{T1} is used for an information bit and $C_1C_1C_1 = 111$ indicates that S_{T1} is used for a stuff bit. C_2 is treated likewise. This mechanism allows majority voting to be used at the desynchronizer, providing a robust solution at high bit error rates. The DS1MX7 has an input buffer that is written by the DS1 line clock and read by the SONET/ SDH clock. The stuffing control in the DS1MX7 uses the depth of this input buffer to set the value of C_1 and C_2 . Buffer overflow/underflow is a fault condition of the input caused by the input frequency being outside the stuffing range for asynchronous mapping (approximately ± 230 Hz). This condition will be passed to the Microprocessor Interface as an alarm (Map Error). Status bit MPS (bit 4) in register X+10H indicates the Map Error status; mask MPM, latched event MPE, performance value MPPM and hard fault value MPFM are all bit 4 of registers X+08H, X+14H, X+18H and X+1CH respectively. The stuffing mechanism in the DS1MX7 employs threshold modulation such that a desynchronizer will meet GR-253-CORE category I jitter requirements. This is done by using SRCLK to vary the input DS1 clock's phase for every sequential VT1.5/ TU-11 such that the stuffing pattern varies at a frequency high enough to be filtered easily by the desynchronizer. This prevents a DS1 clock that is a few Hz different from a SONET/SDH derived 1.544 MHz reference clock from generating jitter spikes when desynchronized. This feature can be turned off for testing purposes by setting global control bit TMDIS (bit 2) in register 03DH to a 1.

Byte-synchronous mapping permits full DS0 and signaling visibility as is shown in Figure 2. The 24 bytes every 125 microseconds are now 24 DS0s; the stuffing mechanism is replaced by a P_1/P_0 pattern that is used to identify different SF and ESF frame bits as well as which signaling bits are being sent and which go to what DS0s. Byte-synchronous mapping performs synchronization in two different ways. When LRCLKn and RSYNCn are outputs they are derived from signal LO, which must be sourced from the SONET/SDH payload timing (ACLK, ASPE and AC1J1V1). As such, exactly 24 DS0s, one frame bit and four signaling bits are mapped every 125 microseconds. RSYNCn output defines the start of the first of six VT superframes (the P_1/P_0 pattern goes from 11 to 00) that form a 3.0 ms multiframe. If the source of the DS1 has a different clock than at pin LO, an external slip buffer must be provided; the TranSwitch QT1F-Plus (TXC-03103) provides this function.

Since some applications do not want to have the added delay of up to two DS1 frames for slip buffering (e.g. TR-496 Objective 3-6), a modified version of byte-synchronous mapping is provided where LRCLKn and RSYNCn are inputs for floating VT1.5/ TU-11 mode. On the tributary or DS1 line side it operates from the input timing block, where data is fed into the block. On the system side it operates off of Telecom Bus SONET/SDH drop timing. DS1 line side clock and multi-frame synchronization uses the buffering supplied by this block. If the input buffer becomes too full the synchronizer requests a pointer decrement to be generated by the VT Termination block which aligns the virtual container to the virtual tributary; this will cause an extra byte of data to be read out of the input buffer in a 500 microsecond period. In Figure 2 the V3 byte will be skipped and everything will shift up one byte. Likewise, if the input buffer is too empty the synchronizer requests a pointer increment causing the V3 position to be repeated and one less byte of data will be read out of the input buffer in a 500 microsecond period. Buffer overflow/underflow is a fault condition of the input caused by the loss of frame

synchronization (if control bit LOF2VAIS (bit 5) in register X+01H is set to a 1) for this mode. This condition will be passed to the Microprocessor Interface as an alarm (Map Error). Status bit MPS (bit 4) in register X+10H indicates the Map Error status; mask MPM, latched event MPE, performance value MPPM and hard fault value MPFM are all bit 4 of registers X+08H, X+14H, X+18H and X+1CH respectively. RSYNCn input defines the start of the first of six VT superframes (the P₁/P₀ pattern goes from 11 to 00), as shown in the table below.

The Mapper takes the output of the synchronizer and adds the overhead bits and bytes to it. The O, J2, Z6 and Z7 positions are driven with the values stored in registers X+36H (O-bits), X+37H (J2 byte), X+38H (Z6/N2 byte) and X+39H (Z7/K4 byte) unless the Auxiliary Port is used. If the Auxiliary Port is used and the enable bit (OBAPEN, J2APEN, Z6APEN or Z7APEN, bits 3 - 0 in register X+0BH) for the specific byte is set to a 1, the byte is brought in from the Auxiliary Port and inserted into the overhead byte position as well as in the above register locations. For asynchronous operation only, the eight O-bits and six C₁ and C₂ bits are included as shown in Figure 2. For byte-synchronous operation the mapper also multiplexes into the payload the data from the RX Signaling Store, which contains both the ABCD signaling bits for each DS0 and also the DS1 SF or ESF frame bits. Since the signaling and framing bits in a framed DS1 take 3.0 milliseconds for a single ESF superframe, six 500-microsecond VT superframes are required to define it. The P₁/P₀ bits for the byte-synchronous mapping are coded to identify the signaling and framing bits as shown in the table below. Refer to Figure 2 for the signaling and P₁/P₀ bit positions. The signaling bits are shown for ESF; for SF or ESF with four-state signaling the CnDn bits are the AnBn bits repeated; for two-state signaling AnBnCnDn becomes AnAnAnAn in the table below. Whether the frame bits are provided or not, the DS1MX7 can be set to calculate CRC-6 over the DS0s only, inserting them in the CRC positions in the table below if control bit CRC6 (bit 4) in register X+01H is set to a 1. The TranSwitch QT1F-Plus (TXC-03103) supports the insertion of specific ABCD signaling codes for DS0 AIS and DS0 RAI via its signaling buffer write capability and it optionally forces the robbed bit positions to all 1 to support byte-synchronous GR-253-CORE signaling conditional requirements.

Signaling and Frame Bit Assignments for Byte-synchronous Modes

P ₁	P ₀	S ₁	S ₂	S ₃	S ₄	F for SF	F for ESF	Time (ms)

Legend:

An, Bn, Cn, and Dn are the signaling bits for 16-state signaling in ESF format and represent the bits robbed from DS0 'n' in frames 6, 12, 18 and 24. For 4-state signaling Cn and Dn are interpreted as An and Bn. For 2-state signaling Bn, Cn and Dn are interpreted as An.

F_{Tn} are the frame alignment bits for SF; F_{Sn} are the signaling framing bits for SF.

FPS_n are the ESF frame alignment bits; CRC_n are the CRC-6 bits in ESF;

M_n are the Facility Data Link bits in ESF.

Pointer Generation and Telecom Bus Slot Selection

In the DS1MX7 device only the VT1.5/TU-11 termination is provided. The VT Termination block accepts data, alarms and timing information from the Synchronizer/Mapper block and completes the generation of the VT1.5/TU-11 started in the Synchronizer/Mapper block.

Each mapper can add its VT1.5/ TU-11 to any one of 28 or 84 slots as shown in Figure 39 and Figure 40 below. Control bit TBTVAL (bit 7) in register X+05H must be set to a 1 for the VT1.5/ TU-11 to be added to the Telecom Bus. Bits 6-5 of the same register determine the STS-1, AU3 or TUG-3 number (one of three). Bits 4-2 in this same register determine the VT Group or TUG-2 number (one of seven) and bits 1 and 0 determine the VT1.5 or TU-11 number (one of four).

For asynchronous operation a fixed position for V5 is generated (offset of 78 with a valid V1 and V2; next VT/TU byte after V1) as shown in Figure 2 above. For the modified version of byte-synchronous operation, the VT synchronous payload envelope or virtual container (VT-SPE/ VC) moves to accommodate frequency differences as described above. The VT Termination block provides a pointer generation state machine that follows the Bellcore, ANSI and ITU rules in T1.105, GR-253-CORE and G.709 by generating no more than a single movement every four VT superframes (2.0 ms). Loss of frame or signal will cause a new start of VT superframe position when the signal recovers; this will force a New Data Flag (NDF) request of the VT Termination block. On exiting AIS the synchronizer block will re-center its buffer and request an NDF. The synchronizer block will also look for a change in the expected position of RSYNCn and indicate an NDF request upstream. Valid V1 and V2 bytes are always generated. V3 is used as a stuff opportunity when pointer decrements are done and V4 is unused. For true byte-synchronous operation a fixed position for V5 results from the fact that clock and frame synchronization are outputs which are synchronous with the SONET/SDH structure even though the pointer generation state machine is enabled. Two four-bit counters (one to count increments generated and one to count decrements generated) are provided to track frequency deviations. These counters are located at X+25H (bits 7-4 for increment and bits 3-0 for decrement) with latched shadow values located in the same bits at X+2DH. If an overflow of either counter occurs, status bit PGOS (bit 1) in register X+10H is set to a 1 and an interrupt can be generated; one second polling/clearing of this counter is recommended. A mask PGOM, latched event PGOE, performance value PGOPM and hard fault value PGOFM are all bit 1 of registers X+08H, X+14H, X+18H and X+1CH respectively.

The V5 byte is generated for all modes. V5 is formed from a bit-interleaved parity calculation, a signal label stored in register X+07H bits 2-0, and three alarm bits, REI-V, RFI-V and RDI-V. Now that the entire virtual container is formed, the BIP-2 bits are calculated and inserted in the V5 byte as shown in Figure 2 based on the previous VT-SPE/ VC; the MSB is chosen to make the sum of the odd bits of every byte in the VT-SPE even parity and the second bit is chosen to make the sum of all the even bits of every byte in the VT-SPE even. The alarm bits are mapped based on the results of demapping, DS1 Line conditions or via the Ring Port as shown in the table below. When the Ring Port is enabled, V5 only gets REI-V and RDI-V from this port. RFI-V is used in byte-synchronous modes only and comes from a microprocessor-forced value as the result of software-based failure detection (usually in the 2 to 3 second range) of a persisting line, section or high or low order path defect or via the signaling highway as the result of a DS1 RAI or Yellow alarm.

**DS1MX7
TXC-04201B**

DATA SHEET

V5 Generation Alarm Sources and Controls

Alarm	Microproc. Force	Demap Conditions	DS1 Line Conditions	Enable Controls	Ring Bit	Ring Enable
BIP-2	SBIPE = 1, reg. X+03H, bit 5. ECTL(7-0) in reg. 01DH sets number of times	none	none	FEBEIS = 1, reg. X+02H, bit 1, enables microproc. forcing. FEBEIS = 0 for normal calculation.	none	none
REI-V = 1	SFEBE = 1, reg. X+03H, bit 5. ECTL(7-0) in reg. 01DH sets number of times	One or two BIP-2 errors	none	FEBEIS = 1, reg. X+02H, bit 1, enables microproc. forcing. FEBEIS = 0 for normal calculation.	REI-V = 1	RINGEN = 1, reg. X+0BH, bit 4
RFI-V = 1	SRFI = 1, reg. X+03H, bit 1.	Software integrated failure state from LOS, LOF, AIS-L/P/V, LOP-P/V, UNEQ-P/V, & PLM-P/V	Yellow via signaling highway; Y-bit = 1	YEL2RFI = 1, reg. X+01H, bit 1.	none	none
RDI-V = 1	SRDI-VSD = 1, reg. X+02H, bit 6.	AIS-V, LOP-V	none	RDIIS = 1 reg. X+02H, bit 3 enables microproc. forcing. RDIIS = 0 for normal insertion from demap	RDI-VSD = 1	RINGEN = 1 reg. X+0BH, bit 4
	SRDI-VCD = 1, reg. X+02H, bit 5.	UNEQ-V			RDI-VCD = 1	

To support three-bit RDI, the Z7 byte is also encoded based on different demap conditions or on the three-bit RDI values supplied by the Ring Port. The unused bits in Z7/K4 are supplied from the Auxiliary Port or the internal register at X+39H; Figure 2 shows the Z7 byte usage for three-bit RDI. The table below defines the conditions that generate three-bit RDI. When the alarms occur in the Demap side of the DS1MX7 and are supplied internally or via the Ring Port, the higher priority code always replaces the lower priority code.

Z7 Three-bit RDI Generation Sources and Controls

Alarm	Microproc. Force	Demap Conditions	Z7 Code bits 5, 6, 7	Priority	Enable Controls	Ring Bit	Ring Enable
RDI-VSD = 1	SRDI-VSD = 1, reg. X+02H, bit 6.	AIS-V, LOP-V	101	1	RDIIS = 1, reg. X+02H, bit 3 enables microproc. forcing. RDIIS = 0 for normal insertion from demap	RDI-VSD = 1	RINGEN = 1, reg. X+0BH, bit 4
RDI-VCD = 1	SRDI-VCD = 1, reg. X+02H, bit 5.	UNEQ-V	110	2		RDI-VCD = 1	
RDI-VPD = 1	SRDI-VPD = 1, reg. X+02H, bit 7.	PLM-V	010	3		RDI-VPD = 1	
none	none	No defects	001	4		all 0	

VT/TU Idle and AIS Insertion are performed at this point. Microprocessor Interface controls for V5 allow either a valid V5 with an all-zeros payload to be generated for idle or an all-zeros V5 for unequipped. Control bit IDLE (bit 7) in register X+00H, when set to a 0, powers down the channel. Control bits RDIIS, FEBEIS, SBIPE, SFEBE, Transmit Signal Label, SRDI-VPD, SRDI-VSD, SRDI-VCD and Tx Z7 all have an effect on the idle signal sent. The table below provides recommended settings for idle and unassigned (but still monitored) and idle but unequipped (not monitored).

Idle Control of DS1MX7

Control Bit	Valid V5 & Z7 Payload = 0	Payload Z7 & V5 = 0
IDLE; reg. X+00H, bit 7	0	0
RDIIS; reg. X+02H, bit 3	0	1
SRDI-VPD; reg. X+02H, bit 7	X	0
SRDI-VSD; reg. X+02H, bit 6	X	0
SRDI-VCD; reg. X+02H, bit 5	X	0
FEBEIS; reg. X+02H, bit 1	0	1
SFEBE; reg. X+03H, bit 7	0	0
SBIPE; reg. X+03H, bit 5	0	0
Tx Z7; reg. X+39H, bits 7-0	00H	00H
RINGEN (if Ring Port used); reg. X+0BH, bit 4	1	0

Note: X = Don't Care

Control bits SH2VAIS, LOS2AIS, LOF2VAIS, AIS2VAIS, SDAISS and SVTAIS, together with the mapping mode control bits (MODE1, MODE0 and DATACOM) and the line decoder controls (ENCOD and EXPLOS) determine whether AIS or VT AIS is mapped. The AIS alarm bits on the signaling highway, Loss of Frame in modified byte-synchronous mode, microprocessor command, an all-ones detected in the decoder, a LOS condition detected in the decoder and the LOS condition via a signal on the LAIS pin can be used to generate an AIS (DS1 payload all-ones will be mapped in place of the received signal) or VT AIS (payload, overhead and V1 plus V2 bytes all-ones). The table below details the feature.

**DS1MX7
TXC-04201B**

DATA SHEET

AIS and VT-AIS Generation Sources and Controls

Alarm Generated	Microproc. Force	DS1Line Conditions	MODE1 reg. X+00H, bit 1	MODE0 reg. X+00H, bit 0	DATAKOM reg. X+00H, bit 5	Enable Controls

Note: X = Don't Care

VT/TU Pointer Tracking and Telecom Bus Slot Selection

In the DS1MX7 device only the VT1.5/TU-11 termination is provided. The VT Termination block accepts data, high order alarms and timing information from the Telecom Bus Interface block, tracks the VT1.5/ TUI-11 pointer and extracts the alarms. The VT Termination block also provides data, alarms and control to the Desynchronizer/Demapper block. All operations (pointer interpretation, pointer generation, VT/TU LOP detection, VT/TU AIS detection, etc.) are performed in accordance with GR-253-CORE, G.709, and G.783.

Each mapper can drop its VT1.5/ TU-11 from any one of 28 or 84 slots as shown in Figure 39 and Figure 40 below. Control bit TBRVAL (bit 7) in register X+04H must be set to a 1 for the VT1.5/ TU-11 to be dropped from the Telecom Bus. Bits 6-5 of the same register determine the STS-1, AU3 or TUG-3 number (one of three). Bits 4-2 in this same register determine the VT Group or TUG-2 number (one of seven) and bits 1 and 0 determine the VT1.5 or TU-11 number (one of four). The values chosen may be the same or different from the add bus values.

The starting location of the V1 byte is determined by the V1 pulses in the DC1J1V1 signals. The VT/TU pointer bit assignment for the V1 and V2 bytes is shown below. The alignment is necessary to determine the starting locations of the V5 byte and the other bytes that are carrying the 1544 kbit/s format.

Pointer Bytes Bit Assignment

The pointer value is a binary number with a range of 0 to 103 for the 1544 kbit/s format. It indicates the offset from the V2 byte to the first byte in the VT1.5 mapping. The pointer bytes are not counted in the offset calculation. The pointer offset arrangement for this format is shown below.

VT/TU Pointer Offset Locations

Seven independent pointer tracking state machines are used in the DS1MX7. The pointer tracking algorithm is illustrated in Figure 28. The pointer tracking state machine is based on the pointer tracking machine found in the latest ETSI requirements, and is also valid for both Bellcore and ANSI. See GR-253-CORE and G.709 for pointer processing rules. Where differences occur the GR-253-CORE rules are used; in particular, the AIS state is not exited to LOP state on invalid pointers; receipt of all-ones for a pointer is considered an invalid pointer until 3 consecutive all-ones pointers are received (considered as AIS); new pointers without NDF count toward the 3 consecutive new pointers even though an INC/DEC action is taken as the result of the new pointer mimicking an INC/DEC; the INC/DEC decision is 8 out of 10 bits. When control bit SDH (bit 5) in register 007H is set to a 1, the transition from AIS to LOP is enabled (shown dotted), which is required in ITU recommendations. Increments and decrements are forwarded to the desynchronizer for counting and use in pointer leak controls as described below.

Figure 28. VT/TU Pointer Tracking State Machine

From the Telecom Bus input, V1 and V2 are extracted by means of DC1J1V1 and DSPE. VT/TU LOP and VT/TU AIS are individually made available to the Microprocessor Interface as status bits VAISS and LOPS (bits 5 and 4) in register X+11H. Masks VAISM and LOPM, latched events VAISE and LOPE, performance values VAISPM and LOPPM and hard fault values VAISFM and LOPFM are all bits 5 and 4 of registers X+09H, X+15H, X+19H and X+1DH respectively. The logical 'OR' of these two alarms is handled as AIS for the demapped DS1 as described above in the Transmit Data and Signaling Highway section. The 'SS' bits are compared to the expected value of '11' for a VT1.5/TU-11 and are interpreted as LOP (high level signal failure input at pin DFAIL masks VTAIS, VTLOP and Signal Label Mismatch). The SS-bits are available as status only bits RXSS1 and RXSS0 (bits 4 and 3) in register X+20H.

The Demapper

The Signal Label received in the V5 Byte is extracted and sent to the Microprocessor Interface. It is stored in bits 2-0 of register X+20H. Additional processing is performed to detect a Signal Label Mismatch (compare with Expected Signal Label) and the Unequipped Code. Both conditions are reported to the Microprocessor Interface and notification of an Unequipped or Signal Label Mismatch Condition (also known as VT Path Label Mismatch or PLM-V) is handled as described herein for the mapping direction. Status bits UNES and SLMS (bits 2 and 1) in register X+11 indicate the current condition. Masks UNEM and SLMM, latched events UNEE and SLME, performance values UNEPM and SLMPM and hard fault values UNEFM and SLMFM are all bits 2 and 1 of registers X+09H, X+15H, X+19H and X+1DH respectively. A mismatch alarm is considered as 5 consecutive Signal Labels of a different condition; 5 consecutive matches will clear the alarm. The Signal Label 'Equipped - Nonspecific' (001) received is not considered a mismatch to any non-zero expected value. Also, if the Expected Signal Label is set to 'Equipped-Nonspecific' (001) any non-zero value received for the Signal Label will not cause an alarm. If an unequipped signal label is received, the DS1MX7 will generate an alarm regardless of the setting of the expected signal label (including 000). The alarm should be masked when both ends of a connection are programmed unequipped but a path exists. The table below shows the alarms based on the received versus expected value, per GR-253-CORE.

Signal Label Mismatch and Unequipped Alarms

Received Signal Label	Expected Signal Label Stored in reg. X+07H, bits 6-4								
	000	001	010	011	100	101	110	111	
000	* UNEQ								
001	M	M							
010		M	M	PLM					
011			PLM	M	PLM				
100			PLM	M	PLM				
101			PLM	M	PLM				
110			PLM	M	PLM				
111			PLM	M	PLM				
111			PLM	M	PLM				

Legend: M = match found and no alarm
 PLM = Path label mismatch and alarm, PLM-V
 UNEQ = Unequipped alarm (* DS1MX7 will generate an alarm for RX/EXP=000/000)

The V5 and Z7/K4 Bytes are further processed to extract BIP-2 Errors, VT/TU REI (FEBE) Events, and VT/TU RDI-V and VT/TU RFI Alarms. VT/TU RDI-V is de-bounced for 5 (default) or 10 (selectable) consecutive VT superframes before an alarm is declared; 5 (default) or 10 (selectable) consecutive RDI-V = 0 will clear the alarm. De-bounce control is through global register RDID10 (bit 0) in register 01EH which, when set to a 1,

causes the DS1MX7 to de-bounce all RDI bits over 10 VT superframes. RFI is de-bounced for 10 consecutive VT superframes before an alarm is declared; 10 consecutive RFI = 0 will clear the alarm. V5 byte RDI and RFI alarms are sent to the Microprocessor Interface once de-bounced, with status bits RFIS and RDI-VS (bits 3 and 0) in register X+11H. Masks RFIM and RDI-VM, latched events RFIE and RDI-VE, performance values RFIPM and RDI-VPM and hard fault values RFIFM and RDI-VFM are all bits 3 and 0 of registers X+09H, X+15H, X+19H and X+1DH respectively. The VT/TU RFI Alarm can be sent to the signaling highway as a DS1 Yellow for byte-synchronous modes only, as was described in the Transmit Data and Signaling Highway section.

BIP-2 Errors and VT/TU REI (FEBE) events are accumulated in 12-bit overflow indicating counters. Control bit SDH (bit 5) in register 007H, when set to a 1, will cause BIP-2 errors to count in blocks (count 1 error if one or both BIP-2 bits received is different than calculated). When SDH is set to a 0 each different bit counts as an error. The BIP-2 Error counter is located at location X+26H and X+27H with a shadow value located at X+2EH and X+2FH. An overflow bit BIPOS (bit 6) in register X+11H is set to a 1 if an overflow occurs. The REI (FEBE) Error counter is located at location X+28H and X+29H with a shadow value located at X+30H and X+31H. An overflow bit FEOS (bit 7) in register X+11H is set to a 1 if an overflow occurs. Masks BIPOM and FEOM, latched events BIPOE and FEOE, performance values BIPOPM and FEOPM and hard fault values BIPOFM and FEOFM are all bits 6 and 7 of registers X+09H, X+15H, X+19H and X+1DH respectively.

The DS1MX7 supports three-bit RDI using the Z7/K4 byte. Three-bit RDI is an enhanced Remote Defect Indication that provides three classes of defects: Payload Defect (Path Label Mismatch), Server Defects (Loss of Pointer or AIS) and Connectivity Defects (Unequipped). The mechanism uses a combination of V5 Bit 0, and Z7/K4 Bits 3, 2 and 1 to implement an algorithm that is compatible with the existing RDI-V (V5 Bit 0) and the new indications. When Z7/R4 Bits 2 and 1 = 00 or 11, the RDI is from old equipment. When Z7/K4 Bits 2 and 1 = 01 or 10, the RDI is from enhanced equipment. Enhanced RDI is checked for persistency for either 5 or 10 consecutive VT superframes, the same as for RDI-V. Alarms are available to the Microprocessor Interface. Status bits RDI-VPDS, RDI-VSDS and RDI-VCDS (bits 2-0) of register X+12H indicate the signals received in Z7/K4. Masks RDI-VPDM, RDI-VSDM and RDI-VCDM, latched events RDI-VPDE, RDI-VSDE and RDI-VCDE, performance values RDI-VPDPM, RDI-VSDPM and RDI-VCDPM and hard fault values RDI-VPDFM, RDI-VSDFM and RDI-VCDFM are all bits 2 through 0 of registers X+0AH, X+16H, X+1AH and X+1EH respectively.

The table below indicates the V5 and Z7/K4 bit settings the DS1MX7 uses to support both old equipment and enhanced equipment. Higher priority events (e.g., AIS) cause RDI codes to be sent that override lower priority RDI codes when both conditions occur simultaneously. The signal failure input pin, DFAIL, blocks all RDI-V detection. The DS1MX7 will automatically switch between single-bit and three-bit RDI based on the received Z7/K4 bits 2 and 1.

RDI-V Bit Settings and Interpretation

Z7/K4 Bits 5, 6 and 7	V5 Bit 8	Priority of Enhanced RDI-V Codes	Trigger	Interpretation
yxx ^a	0	Not Applicable	No defects	No RDI-V defect
yxx ^a	1	Not Applicable	AIS-V, LOP-V, UNEQ-V ^b	RDI-V defect (one-bit RDI-V)
001 ^c	0 ^d	4	No defects	No RDI-V defect
010 ^c	0 ^d	3	PLM-V	RDI-V Payload defect
101 ^c	1 ^d	1	AIS-V, LOP-V	RDI-V Server defect
110 ^c	1 ^d	2	UNEQ-V	RDI-V Connectivity defect

Notes: a. These codes are transmitted by equipment that does not support enhanced RDI-V. If enhanced RDI-V is not supported, Z7 Bits 6 and 7 must be set to the same value.

- b. A signal label mismatch (PLM-V) does not cause a one-bit RDI-V
- c. This code is transmitted by equipment that supports enhanced RDI-V.
- d. V5 Bit 8 is set to the same value as Z7/K4 Bit 5 by the equipment that supports enhanced RDI-V. At the receiving equipment, V5 Bit 8 is ignored unless Z7 Bits 6 and 7 are both set to '0' or both set to '1'.

The Signal Label expected and the Signal Label to be sent in the V5 by the DS1MX7 are stored separately in register X+07H. Acceptable values for the Signal Label are as shown in the following table:

VT/TU Assignment	V5 Signal Label (Bits 5-7)
Idle/Unequipped	000
Equipped - Nonspecific	001
Asynchronous Mapping	010
Byte-synchronous Mapping	100

Desynchronization and Pointer Leak Rate Calculations

Desynchronization is performed in two stages, a pointer leak buffer and a DPLL/FIFO. Thus the DS1MX7 removes jitter from the demapped and destuffed VT1.5 or TU-11 in two steps. First the payload is sent to a pointer leak buffer which is a 10-byte deep FIFO centered at 5 bytes, allowing for up to 5 VT pointer increments or decrements in a row to be absorbed when a change in a network condition or rate adjustment for byte-synchronous mappings are translated into VT pointer movements. The pointer leak buffer converts VT pointer movements (± 8 bits) into slowly leaked single ± 1 bit adjustments to the DPLL/FIFO. The pointer leak buffer can be programmed to leak in steps of 8 milliseconds per bit. For test purposes, the pointer leak buffer may be bypassed by setting control bit BYPLB (bit 4) in register 03DH to a 1. STS-1 pointer movements have approximately one twenty-eighth of the effect of a VT pointer movement; STS-1 pointer movements, in effect, represent about one half of a stuffing bit and are handled by the DPLL in the same way as a stuffing bit.

The second filtering stage is provided by the DPLL, which operates from the '31.5 times 1.544 MHz' clock (48.636 MHz) supplied to pin SRCLK. The DPLL controls a FIFO whose depth measurement is made once every VT superframe. From the depth measurement the DPLL adjusts its output frequency to match the effects of stuffing performed for asynchronous mapping and pointer movements which have been converted to stuffing by the pointer leak buffer. The DPLL provides rate adjustments for byte-synchronous mappings as well as rate adjustments affecting both mappings in addition to asynchronous rate tracking. The DPLL has a single pole low pass filter characteristic with a 1.8 Hz corner frequency. Residual jitter without pointer movement of the demapper is approximately 0.20 UI peak to peak (p-p). Mapping and demapping jitter combined with VT pointer movements is under 1.20 UI p-p. Through delay (DA1 to or from Telecom Bus) is under 65 ms.

For testing purposes the DPLL can have its output frequency locked by setting control bit DPLLK (bit 7) in global register 03CH to a 1; control bits DPLL6- DPLL0 in the same global register are used to adjust the output frequency; this affects all seven channels. When control bit DPLLK is set to a 0, control bits DPLL6- DPLL0 can be used to change the DPLL bias offset which changes the DPLL FIFO's residual depth. Control register 03CH must be set to 00H for normal desynchronizer operation.

Since a wide range of VT pointer increment and decrement rates can occur, the DS1MX7 provides a wide range of leak rates. As was mentioned above, the pointer increments and decrements received represent a variety of sources of frequency correction relative to the SONET or SDH clock rates that can occur after a DS1 signal is mapped asynchronously (e.g., due to synchronization failures or clock noise) as well as part of the mapping function for a byte synchronously mapped DS1. A VT pointer movement represents an 8-bit instantaneous frequency correction (an 8 UI jitter spike). Such adjustments are not palatable to most traditional DS1 network equipment and may cause slips or bit errors. The DS1MX7 has a programmable pointer leak buffer

**DS1MX7
TXC-04201B**

DATA SHEET

that can be set to convert the received VT pointer movements to a rate that can match the actual DS1 payload frequency. For example, if a pointer decrement is being received once every second, the DS1 payload signal needs to be adjusted 8 Hz higher. By programming the pointer leak buffer to leak one bit every 125 milliseconds, the DPLL will automatically run 8 Hz faster continuously by receiving an extra bit in its FIFO every 125 milliseconds. If the pointer leak rate is set too slow the pointers will build up in the pointer leak buffer; at a ± 12 bit (one and a half pointers) level the pointer leak rate automatically doubles to compensate. If the pointer leak rate is set too fast the frequency will be over-corrected for a period and then return to nominal. For example, if the pointer leak rate were set to once every 63 milliseconds for the 'pointer decrement per second' case, the output frequency would run 16 Hz faster (8 Hz too high) for one half second and return to nominal (8 Hz too low) for one half second. This would cause a frequency modulation of the DS1 output signal that would result in jitter and wander. The Mean Time Interval Error (MTIE) would build up to an undesirable level relative to GR-253-CORE objectives and requirements. The table below indicates the pointer leak rate range available by setting per channel control bits PL8 - PL1 in register X+06H.

PL8 - PL1	Time between bits leaked from Pointer Leak Buffer when less than 12 bits from center	Time between bits leaked from Pointer Leak Buffer when equal to or more than 12 bits from center
00H	16 ms	8 ms
01H	32 ms	16 ms
02H ↓	48 ms ↓	24 ms ↓
FDH	4,064 ms	2,032 ms
FEH	4,080 ms	2,040 ms
FFH	4,096 ms	2,048 ms

A software-based control loop is required to program the DS1MX7 to meet MTIE requirements. The control loop is required to read the received pointer increment and decrement counters, bits 7-4 in register X+24H and bits 3-0 in register X+24H respectively for unlatched values; if the one second performance feature is used by setting control bit ENPMFM (bit 3) in register 006H to a 1 and supplying a 1 Hz ± 32 ppm clock on pin T1S1, latch pointer increment and decrement values are preferably used from bits 7-4 in register X+2CH and bits 3-0 in register X+2CH respectively. Measuring the 4-bit counters every one second is sufficient for up to 15 increments or decrements, representing up to ± 120 Hz, which is beyond the range of a byte-synchronous DS1 used as a clock source (LRCLKn as an input) handled between two add drop multiplexers experiencing a synchronization failure. To initialize the pointer leak buffer, set it to the maximum expected or possible leak rate required from the application (asynchronous, byte-synchronous, network clock stratum references along the path, etc.). The table below provides some typical settings.

Mapping	Application	Clock difference	PL8 - PL1
Asynchronous	Add Drop Mux to DCS	38 Hz [20 ppm +4.6 ppm]	01H
Byte-synchronous: LRCLKn an output	Add Drop Mux to DCS	38 Hz [20 ppm +4.6 ppm]	01H
Byte-synchronous: LRCLKn an input	Add Drop Mux to DCS with customer DS1	87 Hz [20 ppm +4.6 ppm + 32 ppm (DS1 @ Stratum 4)]	00H
Asynchronous	DCS to DCS, one stratum 2	7.1 Hz [4.6 ppm]	08H
Asynchronous	DCS to DCS, both stratum 3	14.2 Hz [9.2 ppm]	04H

From the values that are read, use the net value (increment less decrement) to form a running average over a 30 second period. This value is used to calculate the nearest applicable pointer leak rate for within 12 bits of center and written to the DS1MX7 PL8-PL1 per channel control bits. At each subsequent one-second period, the oldest value is discarded and the newest value is added; the pointer leak rate is again calculated and written to the DS1MX7 PL8-PL1 control bits. For a constant stream of pointer increments or decrements, the last pointer should be leaked out just before the next pointer arrives. Missing or additional pointer increments or

decrements in the stream will alter the average only slightly. Figure 29 below shows the general algorithm. Each time a DS1MX7 is reset, or the channel experiences an AIS, LOP, NDF or LOS, the algorithm needs to be restarted. The algorithm is independent for all seven channels and must be performed as such. The maximum range of adjustment due to pointers is when PL8 - PL1 is set to 00H. With at least one and a half residual increments or decrements, one additional or less than normal bit per 8 milliseconds will be sent to the DPLL representing, ± 125 Hz. This range supports byte-synchronous mapping for DS1 signals which are ± 50 Hz.

Notes:

1. The procedure described must be performed independently for each of the seven channels.
2. The procedure shown uses a 30-second sliding window with a 1-second resolution.
3. The initial leak rate is application dependent; however setting the PL8 - PL1 value in register X+06H to 01H will cover all asynchronous applications and setting it to 00H will cover all byte-synchronous applications where the DS1 line supplies clock (pleisiochronous).
4. Measure 30 consecutive one-second samples from the Receive Pointer Increment and Decrement Counters. If the counters overflow use a value of 16 for the overflowed counter:
 S_1 = Pointer Increment Value - Pointer Decrement Value for first one-second sample.
 S_2 = Pointer Increment Value - Pointer Decrement Value for second one-second sample, and so on.
 S_{30} = Pointer Increment Value - Pointer Decrement Value for thirtieth one-second sample.
5. Calculate the Leak Rate:
 Leak Rate = The smaller of (Hex [Integer {234/C}], Hex[INT{34/D}] if $D \geq 2$, Hex[INT{25/E}] if $E \geq 2$, Hex[INT{17/F}] if $F \geq 2$, Hex[INT{8/G}] if $G \geq 2$) where HEX is the hexadecimal value, INT is the integer value:
 C = Absolute Value [sum(S_1 to S_{30+i})], D = Absolute Value [sum (S_{27+i} to S_{30+i})], E = Absolute Value [sum(S_{28+i} to S_{30+i})], F = Absolute Value [$S_{29+i} + S_{30+i}$], G = Absolute Value [S_{30+i}], and i represents the number of times through the loop above (notes 5, 6 and 7). If the C is 0 set the Leak Rate to FFH; A pointer will be leaked before another arrives for uniform pointer arrivals for $0 \leq C \leq 234$ arrival rates. If D, E, F , or $G \geq 2$, faster pointer leaking accounts for a rapid change in pointer arrival rate (e.g. start up after a cool down sequence).
6. Set the leak rate register between 1 and 255 per note 5, and take another measurement (e.g., S_{31}).
7. Recalculate the value of 'C', 'D', 'E', 'F', and 'G' in note 5 by discarding the oldest value and adding the newest value;
 $(i = i + 1)$
8. Continue the loop in notes 5, 6 and 7 until the low order path is disrupted (e.g. VT AIS, VT LOP, reset or higher order path failure like LOP, AIS).

Figure 29. Pointer Leak Rate Algorithm

In general, the receive DPLL/FIFO in the desynchronizer should never overflow or underflow. If it does it will set status bit DMPS (bit 6) in register X+10H and recenter the FIFO. Mask DMPM, latched event DMPE, performance value DMPPM and hard fault value DMPFM are all bit 6 of registers X+08H, X+14H, X+18H and X+1CH respectively.

JITTER MEASUREMENTS

Equipment used in DS1MX7 jitter measurements:

- Hewlett Packard Digital Transmission Analyzer, HP-3784A
- Anritsu STM/SONET Analyzer, MP1560A
- DS1MX7 Test Fixture

Jitter Tolerance Test

Input jitter tolerance is defined in [GR-499] section 7.3.1 as:

The minimum amplitude of sinusoidal jitter at a given frequency that, when modulating the signal at an equipment input port, results in more than 2 errored seconds in a 30-second measurement interval.

The jitter tolerance is measured by injecting jitter at various frequencies into the DS1MX7's DS1 port by using the HP-3784A as shown in Figure 30. The VT1.5 (TU11) mapped data will be monitored on the SONET/SDH side by using the Anritsu MP1560A. The jitter tolerance limit of the device is the amount of jitter insertion allowed before a bit error is detected at the point where data is being added to the SONET/SDH data stream. Figure 31 shows the jitter tolerance requirements and the measured results for the DS1MX7 device.

Figure 30. Jitter Tolerance Test Setup

Figure 31. Jitter Tolerance Measurements

	Input Jitter Frequency	Requirement (UI pp)	Maximum Input Jitter (UI pp)
F1	10 Hz	> 5.0	12.0
	100 Hz	> 5.0	7.5
F2	500 Hz	> 5.0	11.8
	1 kHz	> 1.9	11.5
F3	8 kHz	> 0.1	11.0
	20 kHz	> 0.1	3.9
F4	40 kHz	> 0.1	1.9

Jitter Transfer Test

For this test the HP-3784A is used to inject a fixed jitter level (1.0 UI) into the DS1 interface of the DS1MX7, as shown in Figure 32. The mapped DS1 data is then looped back at the SONET/SDH interface and dropped by the same device. The dropped DS1 jitter is measured at the HP-3784A using a filter of 10Hz - 40 kHz. The actual jitter transfer measurements for the DS1MX7 device are shown in Figure 33.

Figure 32. Jitter Transfer Test Setup

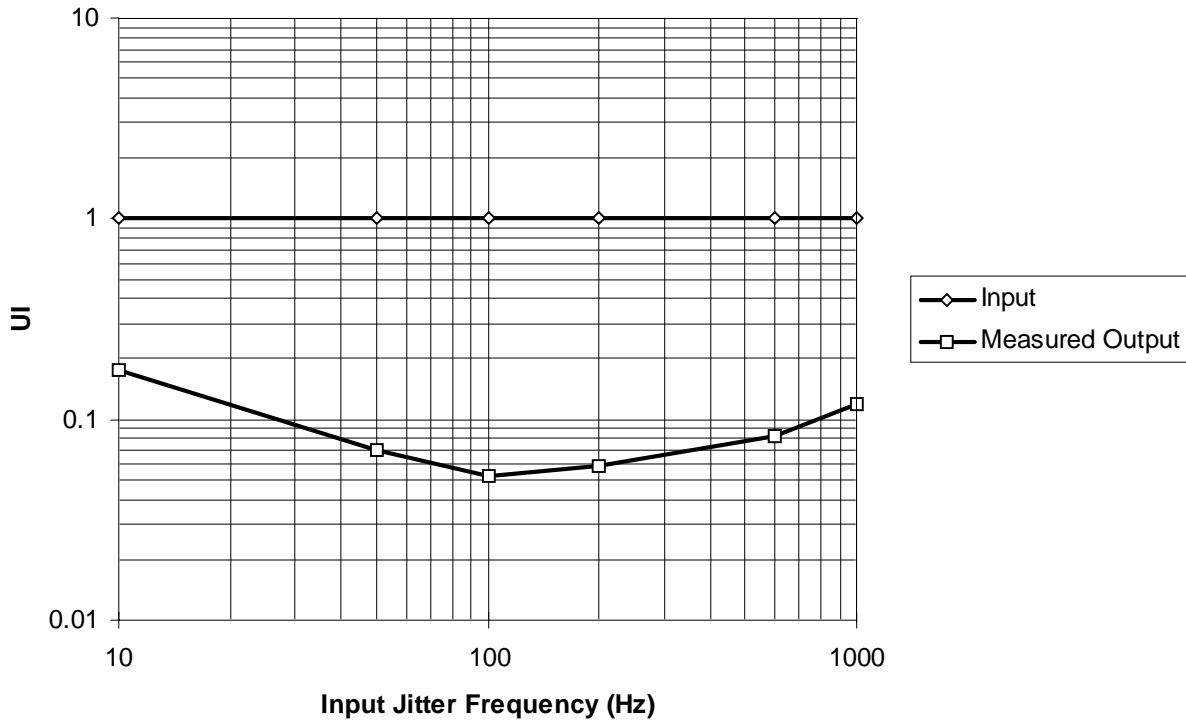

Figure 33. Jitter Transfer Measurements

Input Jitter		Filter Used	Measured Output Jitter (UI)
Frequency (Hz)	Unit Interval (UI)		
10	1.0	(f1 - f4) (10 Hz -> 40 kHz)	0.176
50	1.0		0.070
100	1.0		0.052
200	1.0		0.058
600	1.0		0.082
1000	1.0		0.119

Jitter Generation

The setup shown in Figure 34 was used for both the mapping and combined jitter measurements described below.

Figure 34. Jitter Generation Test Setup

Mapping Jitter Measurement

The following table lists the mapping jitter measurements made with the test setup shown in Figure 34 in the absence of STS or VT(TU) pointer adjustments.

Interface	Filter Characteristics	Maximum Output Jitter (UI pp)		
		Requirement		Measured
		Per G.783 (Note 1)	Per Bellcore (Note 2)	
DS1	(f1) (f4) 10 Hz -> 40 kHz	(Note 3)	≤ 0.7	0.031
	(f3) (f4) 10 Hz -> 40 kHz	≤ 0.1	≤ 0.7	0.015

Notes:

1. Per Recommendation ITU-T G.783 (04/97).
2. Per Bellcore GR-253-CORE Issue 2 Dec. 95: Rev 2 Jan. 99.
3. These values are for further study.

Combined Jitter Measurement

This table lists the combined jitter measurements made with the test setup shown in Figure 34 with STS-1 and VT 1.5 (TU-11) pointer adjustments as indicated in the first column and shown in Figure 35.

Pointer Test Sequence	Filter	Leak Rate Value (Hex) (Note 3)	Maximum Output Jitter (UI pp)		
			Requirement		Measured
			G.783 (Note 1)	Bellcore (Note 2)	
Single Pointer Adjustment $T = 30$ s	(f1) (f4) 10 Hz -> 40 kHz	10H	≤ 1.5	$\leq A_o + 0.60$ (Note 4)	0.22
Periodic VT1.5 Pointer Adjustment (26-1 Pattern) $T = 0.2$ s		01H or 02H	≤ 1.5	≤ 1.3	0.64
Periodic VT1.5 Pointer Adjustment (Continuous Pattern) $T = 0.2$ s		01H or 02H	≤ 1.5	≤ 1.3	0.60
Periodic VT1.5 Pointer Adjustment (Continuous Pattern Plus Add) $T = 1$ s $t = 30$ ms		02H	≤ 1.5	≤ 1.9	0.78

Notes:

1. Per Recommendation ITU-T G.783.
2. Per Bellcore GR-253-CORE Issue 2 Dec. 95: Rev 2 Jan. 99.
3. These are values written into the desynchronizer Pointer Leak Rate register for mapper port n (register address X+06) Normally the Pointer Leak Rate Register is controlled by the external microprocessor through the implementation of the pointer leak rate algorithm shown in Figure 29.
4. A_o is the mapping jitter generated by the device under test. Please see Mapping Jitter Measurement on the previous page.

Figure 35. Standard Pointer Test Sequences

DATA SHEET

TRANSWITCH

MICROPROCESSOR INTERFACE AND COMMON CONTROL/STATUS I/O

The Microprocessor Interface and Common Control/Status I/O block allows access and control for each of the seven DS1 mappers. It also provides common control and status of the entire DS1MX7. Alarm information detected by the mappers can be read as current status (which may not persist long enough to be easily observed in some cases like counter overflows) and is also latched in event registers which are write to clear. Either the arrival or the departure of a condition can be individually enabled to set the event register. To facilitate either interrupt or polled systems, global interrupt masks, per channel interrupt masks, global event and global polling registers are provided. To assist in the collection of performance parameters, shadow registers and counter latching are provided in addition to latched value and raw value registers. Two forms of shadow registers (performance-PM and fault logic-FM) and counter latching are provided at separate locations and are triggered by an external one second clock input pin (T1SI), as is described below. The configuration of each mapper is provided by this interface. The Serial Port Control block is also controlled by the Microprocessor Interface and Common Control/Status I/O. The microprocessor bus supports both Intel and Motorola style processors with a minimum amount of interface logic. An external pin (MOTOI) configures the type of bus supported. The data bus is an 8-bit, bidirectional, 3-state port. The internal control and status registers are accessed through this port. When not accessed, this port is in a high impedance state. The address bus is a 9-bit input port. These address pins select individual control and status registers within the mapper. SELI is the microprocessor port select signal. WRI and READI/READI/WRI are the microprocessor port write and read/write input pins (only the latter is used for the Motorola interface). The RDYO/DTACKO output is used to delay microprocessor access, if required to access internal registers. The INTO/IRQO output is the microprocessor port interrupt line. The RSTI input is the overall device reset line that resets all counters, state machines and the configuration. PCKI is a high speed processor clock input signal that is used by all blocks.

Alarms

The nineteen per channel alarms have been covered in the above sections. To facilitate a quick microprocessor location of an alarm that has been programmed to generate an interrupt, global event and mask registers are provided as well as an activity register. Global masks are provided at register locations 015H and 016H. Setting any of these to a 1 will prevent that condition from generating an interrupt; for example, if the DS1MX7 is programmed for asynchronous operation, setting GRFIM (bit 3) in register 016H to a 1 would prevent RFI alarms (used in byte-synchronous mappings) from causing spurious interrupts. Global event registers are provided at locations 013H and 014H. These registers are the logical 'or' of all seven like per channel registers; for example, GLOSE (bit 5) in register 013H is the logical 'or' of all seven LOSE per channel event registers. Note that GRDIE and GRDIM provide a global event indication and mask for all RDI conditions (RDI-VE; V5 bit 8 and RDI-VPDE, RDI-VSDE, RDI-VCDE; Z7 bits 5, 6 and 7). To facilitate polling, an activity register is provided at location 011H; each bit CH1 to CH7 (bits 0 to 6) represents a mapper channel (1 to 7). Each bit CHn is the logical 'or' of all 19 event bits for mapper channel 'n'. To disable all interrupts to pin INTO/IRQO, control bit GIM (bit 7) in register 006H can be set to a 1; polling may be done instead to detect alarm events. The interrupt polarity may be inverted by setting control bit IPOL (bit 4) in register 006H to a 1.

Events may be latched into the event registers (global registers 00CH and 00DH or per channel registers X+14H, X+15H and X+16H) either on the onset of the condition, the exit of the condition or both. Control bit RISE (bit 6) in register 006H, when set to a 1, will cause the associated event bit to be set when a status bit changes from 0 to 1. Likewise, control bit FALL (bit 5) in register 006H, when set to a 1, will cause the associated event bit to be set when a status bit changes from 1 to 0. By setting both RISE and FALL to a 1, both the onset of an alarm and the clearing of an alarm will cause an interrupt if the event register is cleared after the onset of the alarm.

Assuming all mask bits are set to a 0, asynchronous mode is used, and both RISE and FALL are set to a 1, the following scenario would apply if mapper channel 2 (X=080H) detected a LOS condition for 2 seconds at its line decoder. First, bit 5 of register 090H (LOSS) would be set to a 1. Bit 5 of register 094H (LOSE) would be set to a 1 on the rising edge of LOSS. This would set bit 5 of register 013H (GLOSE) to a 1, set bit 1 of register 011H (CH2) to a 1 and cause an interrupt to be asserted on pin INTO/IRQO. The software in the attached microprocessor would respond by reading registers 011H, 013H and 014H. Analysis would indicate an LOS

change at channel 2. The software in the attached microprocessor would then respond by reading registers 090H and 094H, followed by clearing register 094H by writing 00H to it. This writing to clear will automatically clear the interrupt, bit 5 of register 013H (GLOSE) and bit 1 of register 011H (CH2). At the end of 2 seconds, bit 5 of register 090H (LOSS) will clear. Bit 5 of register 094H (LOSE) would be set on the falling edge of LOSS. This would set bit 5 of register 013H (GLOSE) to a 1, set bit 1 of register 011H (CH2) to a 1 and cause an interrupt to be asserted on pin INTO/IRQO. The software in the attached microprocessor would respond by reading registers 011H, 013H and 014H. Analysis would indicate an LOS change at channel 2. The software in the attached microprocessor would then respond by reading registers 090H and 094H followed by clearing register 094H by writing 00H to it. This writing to clear will automatically clear the interrupt, bit 5 of register 013H (GLOSE) and bit 1 of register 011H (CH2).

To provide for operational security and fault localization, system clocks and reference signals are optionally monitored for lack of transitions and alarmed to the Microprocessor Interface and the internal alarm output in $\overline{\text{IAO}}$. Status bits TBRCKS, TBRSNS and TBRPAS (bits 7 through 5) in register 00AH indicate a failure of DCLK, DC1J1V1 or DSPE, if set to a 1, respectively. Mask bits MTBRCF, MTBRSF and MTBRPF, latched event bits TBRCKE, TBRSE and TBRPAE, performance values TBRCKPM, TBRSNPM and TBRPAPM, and fault values TBRCKFM, TBRSNFM and TBRPAFM are all bits 7, 6 and 5 of registers 008H, 00CH, 00EH and 03EH respectively. Status bits TBTCKS, TBTSNS and TBTPAS (bits 2 through 0) in register 00AH indicate a failure of ACLK, AC1J1V1 or ASPE, if set to a 1, respectively. Mask bits MTBTCF, MTBTSE and MTBTPE, latched event bits TBTCKE, TBTSE and TBTPE, performance values TBTCKPM, TBTSNPM and TBTAPM, and fault values TBTCKFM, TBTSNFM and TBTAPM are all bits 2 through 0 of registers 008H, 00CH, 00EH and 03EH respectively. Status bit MCKS (bit 3) in register 00AH indicates a failure of SRCLK if set to a 1. Mask bit MMCKF, latched event bit MCKE, performance value MCKPM, and fault value MCKFM are all bit 3 of registers 008H, 00CH, 00EH and 03EH respectively.

In addition, internal checks are made in the Telecom Bus Interface block to determine if two or more channels of a DS1MX7 device attempt to drive the same bus slot; if multiple channel drive attempts are detected an internal alarm event is indicated by status bit TBIES (bit 1) in register 00BH being set to a 1. Mask bit MTBIE, latched event bit TBIEE, performance value TBIEPM, and fault value TBIEFM are all bit 1 of registers 009H, 00DH, 00FH and 03FH respectively. Similarly, if two or more DS1MX7s attempt to drive the Telecom Bus simultaneously, an external alarm is declared by status bit TBXES (bit 0) in register 00BH being set to a 1; this is implemented by connecting the AADD output of each DS1MX7 to one of the three BUSCHK inputs of the other DS1MX7s (up to 4 DS1MX7s are supported without external logic). Mask bit MTBXE, latched event bit TBXEE, performance value TBXEPM, and fault value TBXEFM are all bit 0 of registers 009H, 00DH, 00FH and 03FH respectively. Parity errors are monitored on the Drop Telecom Bus for all active slots from which signals are dropped. Control bit TBPIS (bit 3) in register 007H includes DC1J1V1 and DSPE in the parity check if set to a 1. Control bit TBPE (bit 2) in the same register selects even parity if set to a 1. Status bit TBRPYS (bit 3) in register 00BH is set to a 1 whenever a parity error is detected. Mask bit MTBRPY, latched event bit TBRPYE, performance value TBRPYPM, and fault value TBRPYFM are all bit 3 of registers 009H, 00DH, 00FH and 03FH respectively. Bad parity may be forced onto the Add Telecom bus by setting control bit FTBTPE (bit 6) in register 01EH to a 1.

Device alarms can also be enabled to a separate alarm output pin $\overline{\text{IAO}}$, which can be used as an interrupt or a board failure lead when wire "or" gated with other DS1MX7s. Control bits ETBRCF, ETBRSF, ETBRPF (bits 7 through 5) in register 01BH, when set to a 1, enable the DCLK, DC1J1V1 and DSPE failures to drive pin $\overline{\text{IAO}}$ low. Control bits ETBTSE, ETBTSE, ETBTPE (bits 2 through 0) in register 01BH, when set to a 1, enable the ACLK, AC1J1V1 and ASPE failures to drive pin $\overline{\text{IAO}}$ low. Likewise, EMCKF (bit 3) in register 01BH, when set to a 1, enables the SRCLK failure to drive pin $\overline{\text{IAO}}$ low. Control bits ETBRPY, ETBIE, ETBXE (bits 3, 1 and 0) in register 01CH, when set to a 1, enable the Parity error, internal Telecom Bus collision and external Telecom Bus collision to drive pin $\overline{\text{IAO}}$ low. The alarm output $\overline{\text{IAO}}$ is enabled by control bit ENHWM (bit 2) in register 006H being set to a 1.

To provide for masking alarms on a particular assigned VT/TU, the DFAIL input pin signal, which indicates a general signal failure, is sampled on the rising edge of DCLK and latched for the particular channel assigned to

that VT/TU column. If it is high, the data on DD(0-7) is invalid (e.g., STS-1 AIS), and any alarms generated as a result will not interrupt the microprocessor. However, some consequent actions on the data should still be properly handled (e.g., generate DS1 AIS); other actions (e.g., RDI) will not occur. DFAIL is not included in bus parity. The following tables show the masking of lower order alarms by higher order alarms provided in the DS1MX7 in both the mapping and demapping directions.

DS1MX7 Demapper Alarm Masking

Condition Reported	Signal Fail	VT AIS detected	VT LOP detected	VT Unequipped detected	Signal Label Mismatch detected	VT RDI detected	VT RFI detected	Demap Error
Signal Failure	X							
VT AIS		X						
VT LOP			X					
VT Uneq.				X				
Sig Label Mismatch					X			
VT RDI						X		
VT RFI							X	
Demap Error								X

The shaded area indicates which detectors are blocked for which condition. For example, VT AIS blocks VT LOP, VT Unequipped, Signal Label Mismatch, VT RDI, VT RFI and Demap errors.

DS1MX7 Demapper Alarm Masking

Condition	LOS	AIS	OOF	Yellow	Map error
LOS	x				
DS1 AIS		x			
OOF			x		
Other					

Figure 36 illustrates the operation of the shadow registers for a loss of signal (LOSS) alarm for any one of the seven mappers. The behavior shown in the diagram also applies to the other alarms in the same registers (AIS, LOP, RDI, etc.) for per channel alarms. Global control bit ENPMFM (bit 3) in register 006H is assumed to be set to a 1. Global alarms (e.g., Master Clock Fail - MCKS, MCKE, etc.) are handled slightly differently in that the T1SI pulse does not clear the event value as it does for per channel alarms. This figure assumes that control bits RISE and FALL (bits 6 and 5) in the Global Configuration Register 006H are set to 10 (latched event set on a positive transition only). Please note that the LOS alarm causes a latched status indication LOSE (bit 5) in register X+14H, and that the latched bit is reset by the rising edge of the T1SI pulse. The LOSPM status bit (bit 5) in register X+18H is a 1 whenever there is a transition to LOS during the last one-second interval or LOS is present at the end of the last one-second interval. The LOSFM status bit (bit 5) in register X+1CH is a 1 if the LOS alarm is active but did not become active during the previous one-second interval.

Note 1: For this example, latched events are set only on positive event transitions.

Note 2: LOSPM = LOSS + LOSE evaluated at one-second boundaries (where '+' is a logical or).

Note 3: LOSFM = LOSS & $\overline{\text{LOSE}}$ evaluated at one-second boundaries (where '&' is a logical and, and \overline{X} is a logical inversion).

Figure 36. Shadow Register Operation

SERIAL PORT CONTROL INTERFACE

The Serial Port Control Interface block is a serial interface that can be used to control and manage the external analog line transceivers operating in the 'host mode'. This allows the system processor to have complete control of the line transceivers through the DS1MX7 Microprocessor Interface. The interface consists of a data input pin (LSDI), a data output pin (LSDO), and a serial clock output pin (LSCLK) that are shared among all the transceivers. The source of LSCLK is the signal present on input pin LO. In addition, there is an individual chip select ($\overline{\text{LCSn}}$) for each transceiver, and an individual input (LAISn) from each transceiver that may be used to generate a maskable interrupt; status bit XPS (bit 7) in register X+10H indicates the signal on this pin. A mask XPM, a latched event value XPE, a PM value XPPM and a FM value XPFM are available (bit 7) at register locations X+08H, X+14H, X+18H and X+1CH respectively. If desired, the signal at this pin may be used to indicate a Loss of Signal, which can be used to generate AIS (see the Line Interface section for details).

Data to be written to the external transceiver is formatted as a two-byte message. The first byte is an address/command byte and the second byte contains the data to be written or read. Figure 37 illustrates the message and control formats associated with the transceiver serial I/O timing. The format of the address/command byte depends upon the external transceiver being controlled. Please refer to the transceiver's data sheet for the command/data formats. The interface for controlling the external transceiver operates in the following way. The external transceiver selection (via $\overline{\text{LCSn}}$) is determined by the value written to three bits (bits 2, 1 and 0) in register 01AH. For example, a 000 value selects the transceiver for mapper 1. The microprocessor writes the command byte to the Line Interface Control register 017H. This is followed by writing the data byte to be written to

the selected transceiver in Line Interface Control register 018H. The serial message is sent on LSDO when a 1 is written to replace the 0 in the ENSRP bit (bit 4) in register 01AH. The ENSRP bit must be first written with a 0, followed by a 1, before another transfer can take place between the DS1MX7 and the external transceiver selected. Broadcast capability to all transceivers is enabled when the control bit BDCST (bit 7) in register 01AH is written with a 1. Eight clock cycles later, the selected transceiver will respond by sending serial data on the LSDI input pin. The data is shifted in to the Serial Port Data Input Register 019H, LSB first.

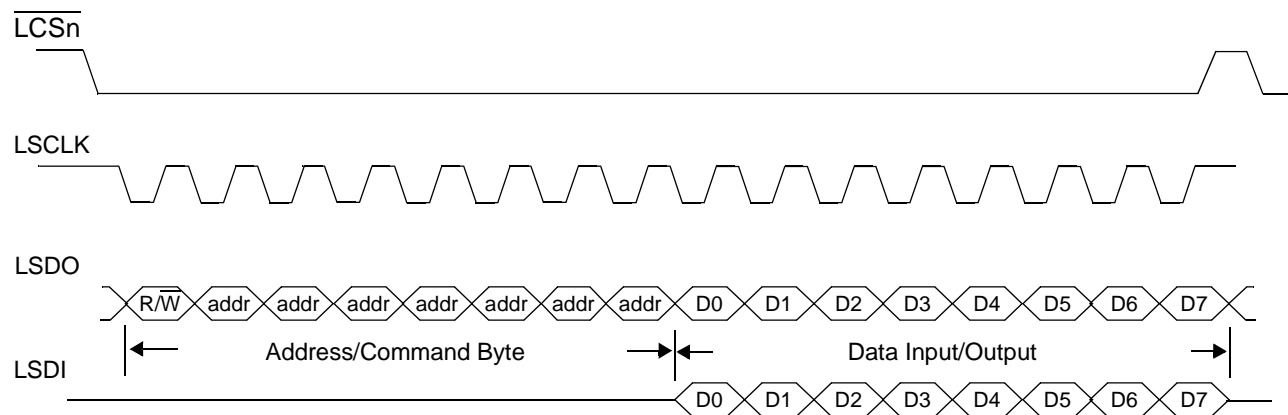

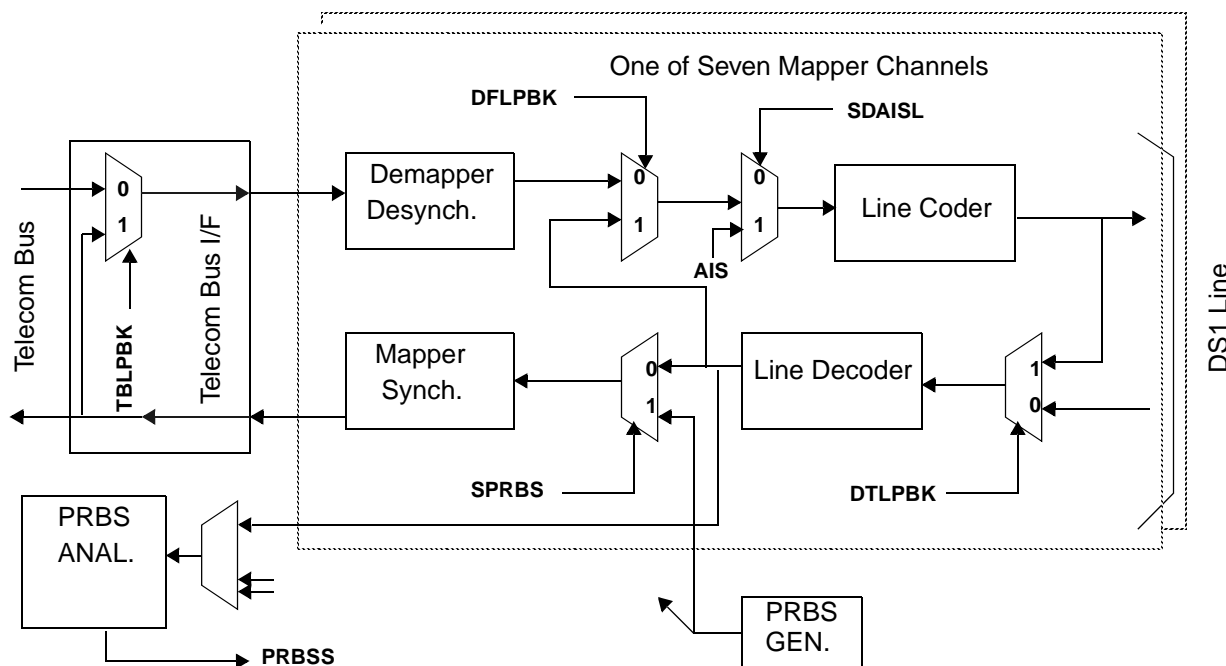

Figure 37. Serial Interface Operation

DS1MX7 Channel Testing using the PRBS Generator and Analyzer

The PRBS Generator and Analyzer block provides the ability to test each channel using the tributary and/or Telecom Bus loopback features provided. Figure 38 below shows the general configuration used for testing any one of the seven channels. Control bit TBLPBK (bit 7) in register 01EH, when set to a 1, loops back the Telecom Bus. Setting TBLPBK to a 1 should only be done if all seven channels are off line, because normal operation for the channels not under test is suspended. For the Telecom Bus loopback to function, control bits in registers X+04H and X+05H also need to be set to enable the VT1.5/ TU-11 to and from the same Telecom Bus slot. Control bit DTLPBK (bit 7) in register X+0CH, when set to a 1, loops the Line Coder output clock, signaling, synchronization pulse and data back to the Line Decoder input, providing a local loopback. This DS1 Tributary Loopback can only be used in the Asynchronous and Modified Byte Synchronous modes. The local loopback can be moved to the Line Interface Transceiver or as a distant end remote loop back. It should be noted that if AIS is to be sent to the line during a local loopback, it must be provided externally to the DS1MX7 (e.g., via a QT1F-Plus or LIU). If the distant end is a DS1MX7, control bit DFLPBK (bit 6) in register X+0CH may be set to a 1 to loop the received DS1 clock, signaling, synchronization and data to the transmit clock, signaling, synchronization and data. The PRBS pattern may be inserted into any one or more mappers in place of the line decoder output by setting control bit SPRBS (bit 4) in register X+0CH to a 1 when control bit EPRBSA (bit 5) in global register 01AH is also set to a 1. The PRBS Analyzer is assigned to a mapper channel by the same control bits used to select an LIU for the serial port, bits 2-0 in register 01AH. The analyzer monitors any one of the seven line decoder outputs. The output of the analyzer is readable by the Microprocessor Interface as status bit PRBSS (bit 2) in register 00BH with a mask MPRBSE, a latched value PRBSE, a performance value PRBSPM and a hard fault value PRBSFM, all bit 2 in registers 009H, 00DH, 00FH and 03FH respectively. The pattern is a $2^{15}-1$ bit pseudo-random binary sequence that follows the ITU O.151 recommendations, but is inverted. Control bit TXNRZP (bit 0) in register 007H, when set to a 1, will make the internal PRBS signal readable by standard test equipment connected to the DS1 line side of the DS1MX7 mapper channel. The Out of Lock alarm can be made to go to an external pin IAO, if desired, by setting control bit EPRBSE, bit 2 in register 01CH, to a 1.

Note: Control and status bits are shown in bold font

Figure 38. Loopbacks and Built-in PRBS Testing of the DS1MX7

TELECOM BUS INTERFACE

The Telecom Bus Interface contains the drivers and receivers for all the Telecom Bus signals. It multiplexes and demultiplexes all the data flowing from/to the Telecom Bus Output and Input Control blocks. It also calculates the parity for APAR and checks the parity against DPAR for any driven slot used by this DS1MX7 (both odd and even parity are selectable, and APAR may be calculated on AD(0-7) only or on the combination of AD(0-7), ASPE and AC1J1V1); slots that are not selected are skipped. Telecom Bus assignments can be used to localize parity errors. This block generates the AADD signal for any active slot driven by this DS1MX7, to permit using external buffers. AADD is generally not required as the DS1MX7 outputs are tristated; however, if an application requires bus drivers with different characteristics or with additional drive this signal is available. SPE is valid during the STS-1 or STS-3 synchronous payload. C1J1V1 defines the starting position of the VT/TUs on the bus. Note that AD(0-7) data is pre-fetched to be ready to be clocked into an external device on the rising edge of ACLK; if the column or byte is a stuff position in the STS-1 the data remains present until the slot is a valid SPE (ASPE active). For systems that use the Telecom Bus to multiplex in transport or path overhead information (e.g., H4 via the TranSwitch SOT-1E), the DATEN pin should be tied externally to ASPE so that SPE inactive bytes are not driven during the rising edge of ACLK. When the AD(0-7) signals are delayed one ACLK clock period by control bit TBDD (bit 3) in register 01EH, the ASPE signal into the DATEN must be delayed by one ACLK clock period to align with the data output to the Add bus. If required, the MASTER input pin may be grounded so that the STS-1 POH and stuff columns or bytes may be driven with idle (all-zeros with valid parity) or an assigned VT value such that bus parity errors are prevented. The following table shows which bytes are driven on the Telecom Bus in various modes; note that each STS-1 or TUG-3 is treated separately. Under Microprocessor Interface control the data, AD(0-7), may be delayed one clock period by control bit TBDD (bit 3) in register 01EH, and the active clock edges of DCLK and ACLK may be inverted by control bits TBRCI (bit 4) and TBTCL (bit 5) in the same register being set to a 1.

**DS1MX7
TXC-04201B**

DATA SHEET

DATEN and MASTER Pins	Assigned VT	Unassigned VT	POH and Stuff	TOH	TOH
Condition				Followed by assigned VT	Followed by POH or Stuff
DATEN high; MASTER high	$\frac{\text{driven}}{\text{AADD low}}$	$\frac{\text{float}}{\text{AADD high}}$	$\frac{\text{float}}{\text{AADD high}}$	driven to VT value that follows AADD low	$\frac{\text{float}}{\text{AADD high}}$
DATEN high; MASTER low	$\frac{\text{driven}}{\text{AADD low}}$	$\frac{\text{float}}{\text{AADD high}}$	driven to zero AADD high	driven to VT value that follows AADD low	driven to zero AADD high
DATEN = ASPE; MASTER high (see Note)	$\frac{\text{driven}}{\text{AADD low}}$	$\frac{\text{float}}{\text{AADD high}}$	$\frac{\text{float}}{\text{AADD high}}$	$\frac{\text{float}}{\text{AADD high}}$	$\frac{\text{float}}{\text{AADD high}}$
DATEN = ASPE; MASTER low (see Note)	$\frac{\text{driven}}{\text{AADD low}}$	$\frac{\text{float}}{\text{AADD high}}$	driven to zero AADD high	$\frac{\text{float}}{\text{AADD high}}$	$\frac{\text{float}}{\text{AADD high}}$
DATEN low	$\frac{\text{float}}{\text{AADD high}}$	$\frac{\text{float}}{\text{AADD high}}$	$\frac{\text{float}}{\text{AADD high}}$	$\frac{\text{float}}{\text{AADD high}}$	$\frac{\text{float}}{\text{AADD high}}$

Note: The ASPE signal into the DATEN input must be delayed by one ACLK clock period when the Telecom Bus Data Delay, control bit TBDD (bit 3 in register 01EH) is enabled.

The Telecom Bus Interface also provides a loopback mode for device testing. Internally, the entire Telecom Bus is looped. Individual channels are tested by enabling them through the serial port select byte for the PRBS Analyzer and the per channel select bit for the PRBS Generator, as described above.

The Mapper Timing block supplies overall mapper timing to both the Synchronizer/Mapper and the Desynchronizer/Demapper blocks based on the Telecom Bus clocks, C1J1V1 and SPE signals received. SONET and SDH have different stuff column positions. In SONET format V1 is coincident with V1 #1; in SDH format for TUG-3, V1 starts six TUG-3 clock pulses early. A bit in the Common Control register is used to select this. The external clock, LO, is an independent 1.544 MHz clock for the purpose of generating a system-synchronized clock for clocking in data and signaling for byte-synchronous operation.

The DS1MX7 can operate at 6.48 MHz or 19.44 MHz, as shown in Figures 39 and 40. The bus speed is determined by the CONFIG1 pin; if tied low, the DS1MX7 operates in 19.44 MHz mode with 84 VT1.5/ TU-11 slots; if tied high, the DS1MX7 operates in 6.48 MHz mode with 28 VT1.5/ TU-11 slots. For gapped clock situations an allowance for up to 10% higher speed needs to be made. The DS1MX7 cannot account for extra columns, so SPE being inactive for extra columns must be used.

For 19.44 MHz operation in SONET or SDH AU-3 mapping, the three J1 signals can be anywhere in the STS-1 or AU-3 for both DC1J1V1 and AC1J1V1; hence separate tracking is provided for each. Control bit VC3VC4 (bit 1) in register 007H must be set to a 1. In this mode of operation there are no restrictions on the three J1 positions in AC1J1V1 for asynchronous or modified byte-synchronous applications. However, if byte-synchronous modes are used, the three J1s in AC1J1V1 cannot move with respect to each other, since LO must be locked to ACLK and AC1J1V1. If all channels are mapped to a specific STS-1, the restriction does not apply as long as the J1 reference for LO is the same STS-1.

Figure 39. Telecom Bus Structure; SONET or VC-3 SDH; Telecom Bus @ 6.48 MHz

The signals shown in Figure 39 are valid for the entire STS-1 signal, representing an overlay of all 36 rows of 90 bytes each. Each of the 28 VT1.5s occupy 3 columns (counted from the STS-1 path overhead and with the two stuff columns the same) with transport overhead (TOH) taking 3 columns (shaded), the STS-1 path overhead taking a column (J1, B3.Z5) and 2 columns of fixed stuff (crosshatched). SPE is only low during TOH. C1J1V1 is high during the 4 C1 bytes shown, the 4 J1 bytes shown and the one V1 #1 byte shown. For VT#1 of VTG#1, J2, Z6 and Z7 are also shown. Figure 41 below provides the column assignments for an STS-1 system bus. The STS-3 case is as depicted in Figure 40, with the columns of the three STS-1s byte-interleaved; in this case, the three C1 bytes occur together, but the individual J1 bytes can occur in any of the 87 columns of the STS-1 or VC-3. Fixed offset places V5s after V1s. Figure 42 below provides the column assignments for the STS-3.

Figure 40. Telecom Bus Structure; TUG-3 SDH; Telecom Bus @ 19.44 MHz

Figure 40 above shows the SDH format for three TUG-3s in a VC-4. Control bit VC3VC4 (bit 1) in register 007H must be set to a 0. Figure 43 below provides the column assignments for an STM-1. Each TUG-3 contains seven TUG-2s and each TUG-2 contains four TU-11s. The signals shown are an overlay of all 36 rows of 270 bytes each. SPE is low only for the STM-1 transport overhead (TOH), which is the first 9 columns (shaded). C1J1V1 is high for the first C1 byte of the TOH, the J1 byte of the VC-4 path overhead (POH) and the first column of each TUG-3 (null pointer indications). Fixed offset for V5 generation of 78 places system-bound V5 bytes after V1 bytes for asynchronous only. In the byte-synchronous mode (modified byte-synchronous or true byte-synchronous operation), the initial location of the V5 bytes is defined by the phase between the add bus reference, AC1J1V1, and RSYNCn. If the relationship changes slowly, V1 and V2 are incremented or decremented to track the signal. Abrupt changes in RSYNCn will cause a new value of V1 and V2 to be generated with a corresponding NDF indication in V1.

MULTIPLEX FORMAT AND MAPPING INFORMATION

STS-1 VT1.5 (1.544 Mbit/s) Multiplex Format

The following diagram and table illustrate the mapping of the 28 VT1.5s into a STS-1 SPE. Column 1 is assigned to carry the path overhead bytes.

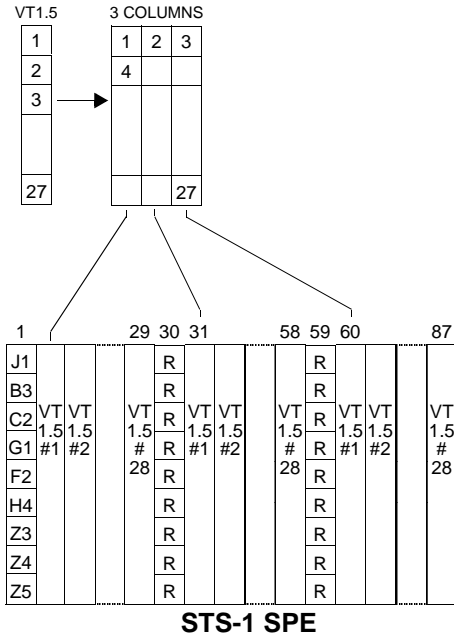

Figure 41. STS-1 SPE Mapping

28	1	0	0	1	1	0	1	1	29, 58, 87

* Note: Columns 30 and 59 carry fixed stuff bytes. Column 1 is assigned for the POH bytes.

STS-3/AU-3 VT1.5/TU-11 (1.544 Mbit/s) Multiplex Format Mapping

The following diagram and table illustrate the mapping of the VT1.5/TU-11s into a STS-3/AU-3 SPE. Each STS-3 carries three STS-1s. Column 1 in each STS-1/AU-3 is assigned to carry the path overhead bytes.

Figure 42. STS-3/AU-3 Mapping

AUXILIARY PORT

The Auxiliary Port is used to access the J2, Z6/N2, Z7/K4 bytes, and the O-bit information, contained in the VT1.5 Overhead. The Auxiliary Port consists of ten pins. The five output port pins are Output Port Clock (OAPCKO), Output Port Address Valid (OAPAVO), Output Port Address (OAPADO), Output Port Data Valid (OAPDVO), and Output Port Data (OAPDTO), all of which are output signals. The five input port pins are Input Port Clock (IAPCKO, an output), Input Port Address Valid (IAPAVO, an output), Input Port Address (IAPADO, an output), Input Port Data Valid (IAPDVO, an output), Input Port Data (IAPDTI, an input).

Figure 44 shows the Auxiliary Port operation. All signals are outputs except for IAPDTI, as noted above. Input and output operations are identical. (O/I)APCKO are continuous. An Input or Output Transfer Cycle requires 21 clock times. The cycle begins with (O/I)APAVO transitioning High. Input and Output Transfer Cycles are asynchronous to each other. As indicated by the dotted lines, Transfer Cycles may overlap, i.e., Address information can be output while data is being output or input. The minimum time between Transfer Cycles is one clock time. OAPCKO and IAPCKO are 'divide by 2' derivatives of DCLK and ACLK, respectively. Data bytes are formatted with MSB first.

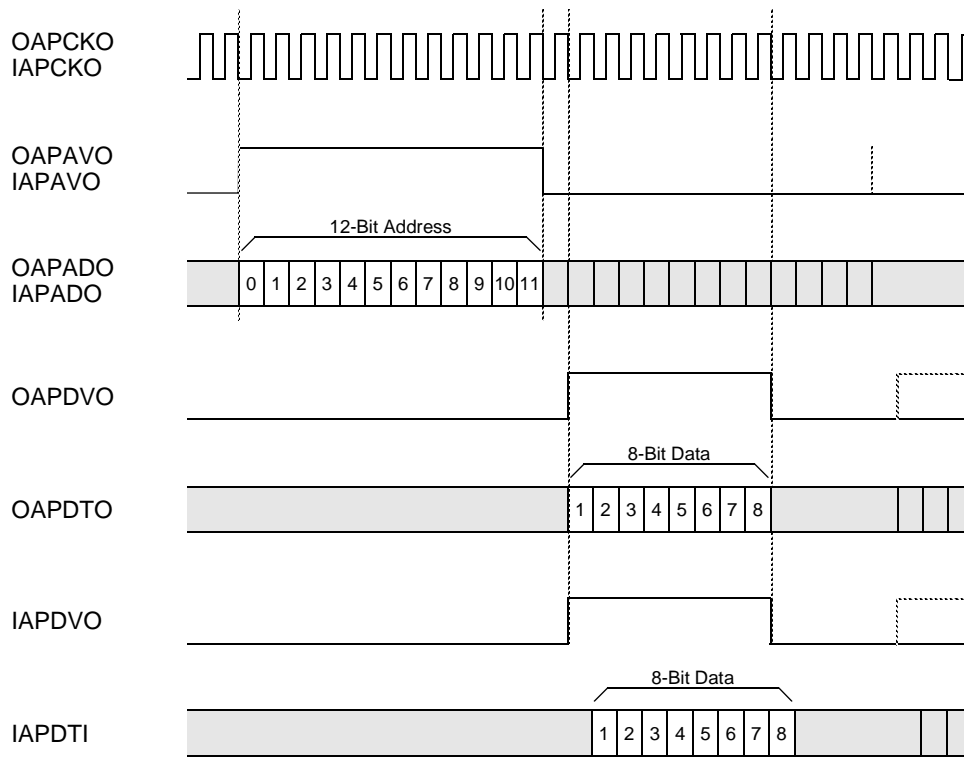

Figure 44. Auxiliary Port Operation

Input and output accesses require that Telecom Bus slots have been assigned to a specific channel; TBTVAL (bit 7) in control register X+05H and TBRVAL (bit 7) in control register X+04H are set to 1, and that the appropriate control bits in register X+0BH for the overhead bytes are enabled.

The 12-bit address identifies the information that will be output or input during the Transfer Cycle. Figure 45 details the address fields. The O-bits are output or input eight bits at a time (per VT Super frame basis) where:

1. the first four O-bits (Byte following J2, Bits 3, 4, 5 and 6) are placed in Bits 3, 2, 1 and 0
2. the second four O-bits (Byte following Z6/N2, Bits 3, 4, 5 and 6) are placed in Bits 7, 6, 5 and 4

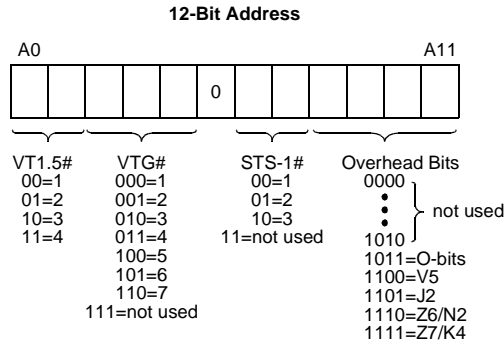

Figure 45. Auxiliary Port Address Designation

The remaining bytes are mapped to the Auxiliary Port on a bit-for-bit basis.

All five indicated bytes are output from information input on DD(0-7). In addition, the O-bits, J2, Z6/N2, and Z7/K4 information will be written in the Per Channel Memory Map, for access by the microprocessor. Register X+32H stores the received O-bits, X+33H is used to store the last received J2 byte, X+34H is used to store the last received Z6/N2 byte and X+35H is used to store the last received Z7/K4 byte.

The Input Port will accept the O-bits, J2, Z6/N2, and Z7/K4 Bytes. The V5 Byte will not be requested. Four Per Channel Memory Locations will be used for storage of outgoing O-bit, J2, Z6/N2 and Z7/K4 information. These locations will be available to the microprocessor to read the data collected by the Auxiliary Port. If an overhead byte is not to be input to the Auxiliary Port, these same memory locations can be used by the microprocessor to write a desired value which will be transmitted in the overhead byte location. Control bit OBAPEN (bit 3) in register X+0BH, when set to a 0, enables the O-bits for mapper channel n to be accessed from register X+36H and input to the correct position per Figure 2 for inclusion in the VT1.5/ TU-11; when OBAPEN is set to a 1, the O-bits for mapper channel n are requested at the Auxiliary Port input, written to the correct position per Figure 2 for inclusion in the VT1.5/ TU-11, and also stored in register X+36H. Control bit J2APEN (bit 2) in register X+0BH, when set to a 0, enables the J2 byte for mapper channel n to be accessed from register X+37H and input to the correct position per Figure 2 for inclusion in the VT1.5/ TU-11; when J2APEN is set to a 1, the J2 byte for mapper channel n is requested at the Auxiliary Port input, written to the correct position per Figure 2 for inclusion in the VT1.5/ TU-11, and also stored in register X+37H. Control bit Z6APEN (bit 1) in register X+0BH, when set to a 0, enables the Z6/N2 byte for mapper channel n to be accessed from register X+38H and input to the correct position per Figure 2 for inclusion in the VT1.5/ TU-11; when Z6APEN is set to a 1, the Z6/N2 byte for mapper channel n is requested at the Auxiliary Port input, written to the correct position per Figure 2 for inclusion in the VT1.5/ TU-11, and also stored in register X+38H. Control bit Z7APEN (bit 0) in register X+0BH, when set to a 0, enables the Z7/K4 byte for mapper channel n to be accessed from register X+39H and input to the correct position per Figure 2 for inclusion in the VT1.5/ TU-11; when Z7APEN is set to a 1, the Z7/K4 byte for mapper channel n is requested at the Auxiliary Port input, written to the correct position per Figure 2 for inclusion in the VT1.5/ TU-11, and also stored in register X+39H. It should be noted that bits 3, 2 and 1 of Z7/K4 are used for 3-bit RDI and will be overwritten with the appropriate values prior to transmission to the Telecom Bus.

RING PORT

The Ring Port is used in USHR/P Ring applications to communicate REI (FEBE) and RDI Information between mated DS1MX7s. The Ring Port consists of six pins, three outputs and three inputs. The output port pins are Output Port Clock (ORPCKO), Output Port Frame (ORPFMO), Output Port Data (ORPDTO) and the input port pins are Input Port Clock (IRPCKI), Input Port Frame (IRPFMI), Input Port Data (IRPDTI).

Figure 46 shows the ring port operation and Figure 49 shows an application. The information consists of seven eight-bit fields, one for each channel. The first four bits are REI-V (FEBE), RDI-VPD, RDI-VSD, and RDI-VCD. The last four bits are not used. The information is accumulated for all seven channels and sent as a burst of 56 bits. The ORPCKO is a 'divide by ten' derivative of DCLK. Ring operation is enabled with the control bit RINGEN (bit 4) in register X+0BH. When set to zero, normal operations are performed. When set to one, Ring Mode is enabled. The information incoming on IRPDTI is stored in register X+3AH, Bits 3-0 for access by the microprocessor. The designation for these bits is RGFEBE-V (bit 3), RGRDI-VPD (bit 2), RGRDI-VSD (bit 1), and RGRDI-VCD (bit 0). The four remaining bits will be designated "Unused".

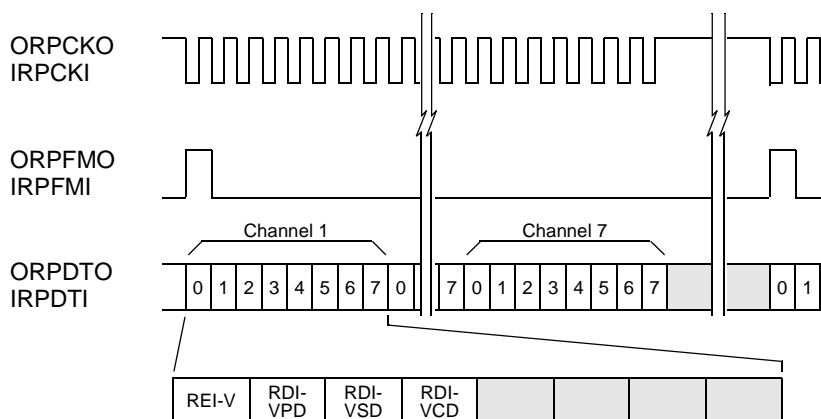

Figure 46. Ring Port Operation

TEST ACCESS PORT

Introduction

The IEEE 1149.1 Standard defines the requirements of a boundary scan architecture that has been specified by the IEEE Joint Test Action Group (JTAG). Boundary scan is a specialized scan architecture that provides observability and controllability for the interface pins of the device. The Test Access Port block, which implements the boundary scan functions, consists of a Test Access Port (TAP) controller, instruction and test data registers, and a boundary scan register path bordering the input and output pins, as illustrated in Figure 47. The boundary scan test bus interface consists of four input signals (i.e., the Test Clock (TCK), Test Mode Select (TMS), Test Data Input (TDI) and Test Reset (TRS) input signals) and a Test Data Output (TDO) output signal. A brief description of boundary scan operation is provided below; further information is available in the IEEE Standard document.

The TAP controller receives external control information via a Test Clock (TCK) signal, a Test Mode Select (TMS) signal, and a Test Reset ($\overline{\text{TRS}}$) signal, and it sends control signals to the internal scan paths. The scan path architecture consists of a three-bit serial instruction register and two or more serial test data registers. The instruction and data registers are connected in parallel between the serial Test Data Input (TDI) and Test Data Output (TDO) signals. The Test Data Input (TDI) signal is routed to both the instruction and test data registers and is used to transfer serial data into a register during a scan operation. The Test Data Output (TDO) is selected to send data from either register during a scan operation.

When boundary scan testing is not being performed, the boundary scan register is transparent, allowing the input and output signals at the device pins to pass to and from the DS1MX7 device's internal logic, as illustrated in Figure 47. During boundary scan testing, the boundary scan register disables the normal flow of input and output signals to allow the device to be controlled and observed via scan operations. A timing diagram for the boundary scan feature is provided in Figure 20.

Boundary Scan Support

The maximum frequency the DS1MX7 device will support for boundary scan is 10 MHz. The DS1MX7 device performs the following boundary scan test instructions:

- EXTEST (000)
- SAMPLE/PRELOAD (010)
- BYPASS (111)

It should be noted that the Capture - IR State (INSTRUCTION_CAPTURE attribute of BSDL) is 011.

EXTEST Test Instruction:

One of the required boundary scan tests is the external boundary test (EXTEST) instruction. When this instruction is shifted in, the DS1MX7 device is forced into an off-line test mode. While in this test mode, the test bus can shift data through the boundary scan registers to control the external DS1MX7 input and output leads.

SAMPLE/PRELOAD Test Instruction:

When the SAMPLE/PRELOAD instruction is shifted in, the DS1MX7 device remains fully operational. While in this test mode, DS1MX7 input data, and data destined for device outputs, can be captured and shifted out for inspection. The data is captured in response to control signals sent to the TAP controller.

BYPASS Test Instruction:

When the BYPASS instruction is shifted in, the DS1MX7 device remains fully operational. While in this test mode, a scan operation will transfer serial data from the TDI input, through an internal scan cell, to the TDO pin. The purpose of this instruction is to abbreviate the scan path through the circuits that are not being tested to only a single clock delay.

Boundary Scan Reset

Specific control of the $\overline{\text{TRS}}$ lead is required in order to ensure that the boundary scan logic does not interfere with normal device operation. This lead must either be held low, asserted low, or asserted low then high (pulsed low), to asynchronously reset the Test Access Port (TAP) controller during power-up of the DS1MX7. If boundary scan testing is to be performed and the lead is held low, then a pull-down resistor value should be chosen which will allow the tester to drive this lead high, but still meet the V_{IL} requirements listed in the 'Input, Output and Input/Output Parameters' section of this Data Sheet for worst case leakage currents of all devices sharing this pull-down resistor.

Note: Pin locations are shown for illustration only, and do not correspond to the physical device pins.

DATA SHEET**Boundary Scan Chain**

There are 200 scan cells in the DS1Mx7 boundary scan chain. Bidirectional device pins require two scan cells. Additional scan cells are used for direction control as needed. The following table shows the listed order of the scan cells and their functions. Cells that are not associated with a pin are marked "NA". Scan cell number 0 is defined as the cell nearest the TDO pin and is therefore the first to be shifted out. The last scan cell to be shifted out is number 199. A Boundary Scan Description Language (BSDL) file for the DS1Mx7 device is available on the "Products" page of the TranSwitch Web site (www.transwitch.com).

DEVICE RESET PROCEDURE

After power-up the DS1MX7 requires a hardware reset. This reset will reset all the per channel registers in the memory map. It will also reset all of the global registers at addresses 04H through 03FH. A low placed on the RSTI lead for at least 10 cycles of PCKI after all clocks become stable will accomplish the hardware reset.

A global software reset is also available and should be applied at least 10 ms after power-up. This resets the internal state machines. It does not change the state of any of the control registers, performance counters and latched shadow registers. Writing a 91H to control byte RESET in register 005H places the DS1MX7 in a reset state. Writing a value other than 91H to control byte RESET will take the DS1MX7 out of the reset state. The RESET register can be read to determine the reset state of the DS1MX7. A value of 01H in the RESET register indicates the DS1MX7 is in a reset state; a value of 00H indicates the DS1MX7 is not in reset. A per channel version of this function is available by writing a 1 to control bit RSTCH (bit 5) in register X0CH followed by writing a 0 to control bit RSTCH.

Changing the mode of operation of a mapper should be followed by a per channel software reset (RSTCH). The mode bits can be found in mapper per channel registers X+00H through X+02H (EXPLOS, DATACOM, ENZC, LCODE, ENCOD, MODE1, MODE0 and CRC6). Not resetting the mapper after changing other mode control bits will have minimal effect.

If all 7 channels of the DS1MX7 are not implemented in an application, the channels that are not used should be powered down (control bit IDLE, bit 7 in register X+00H is set to a 0) and all interrupts masked (registers X+09H through X+0BH set to FFH).

DATA SHEET

MEMORY MAP DESCRIPTIONS

COMMON MEMORY MAP

Component ID

Address	Bit	Symbol	Description
000	7-0	MI7-MI0	Manufacturer Identity: Read-only register containing the seven least significant bits of the component manufacturer's identity (107 decimal) followed by a 1 in bit 0 (D7 Hex).
001	7-4	PN3-PN0	Part Number: Read-only register containing the four least significant bits of the component part number (9 Hex).
	3-0	MI11-MI8	Manufacturer Identity: Read-only register containing the four most significant bits of the component manufacturer's identity (0 Hex).
002	7-0	PN11-PN4	Part Number: Read-only register containing the middle eight bits of the component part number (06 Hex).
003	7-4	V3-V0	Version: Read-only register containing the component version number (2 Hex).
	3-0	PN15-PN12	Part Number: Read-only register containing the four most significant bits of the component part number (1 Hex).
004	7-0	Notebook	User Register: Read/write register for end-user application. The content of this register will have no effect on the operation of the device.
005	7-0	RESET	Software Reset: Writing a 91 Hex into this location will generate a software reset to the component (all but configuration registers are reset). Writing other than 91 Hex will remove the DS1MX7 from the reset state. Reading this location will return a 00 Hex if the DS1MX7 is not in reset and 01 Hex if the DS1MX7 is in reset. The DS1MX7 will default to reset on application of external hardware reset (\overline{RSTI}).

Global Registers

Address	Bit	Symbol	Description
006	7	GIM	Global Interrupt Mask: When cleared (this bit set to zero), the external interrupt output ($\overline{INTO/IRQO}$, pin 32) will be asserted when an internal interrupt event occurs. The internal interrupt status may still be polled by software to detect interrupt events when this bit is set to one.
	6	RISE	Rising Edge Interrupt: When set to one, a status change will be registered as a one in the latched value bits on the start of an event.
	5	FALL	Falling Edge Interrupt: When set to one, a status change will be registered as a one in the latched value bits on the end of an event.
	4	IPOL	Interrupt Polarity: When set to one, the polarity of the interrupt pin will be inverted at the pin.

DATA SHEET

DS1MX7
TXC-04201B

Address	Bit	Symbol	Description
006 (cont.)	3	ENPMFM	Enable PM/FM function: When set to one, the Performance and Fault Monitoring function is in the PM/FM registers (00E/F, 03E/F, X+18H to X+1EH) and the latched counters (X+2AH to X+31H); latching takes place after T1SI rising edge. Both RISE and FALL must be set to one.
	2	ENHWM	Enable Hardware Mask: When set to one, global errors (e.g., DCLK fails; TBRCKS = 1) may be used to generate an active low internal alarm output on pin IAO, if enabled (e.g., control bit ETBRCF = 1). When set to zero, pin IAO will remain high.
	1-0	R	Reserved: These bits must be set to zero.
007	7	TCAE	Tributary Transmit Clock Active Edge: If this bit is set to one, the TPOS _n , TNEG _n /TSIGL _n and TSYNC _n signals are clocked out of the DS1MX7 on the rising edge of LTCLK _n . When set to zero, they are clocked out on the falling edge of LTCLK _n .
	6	RCAE	Tributary Receive Clock Active Edge: If this bit is set to one, the RPOS _n , RNEG _n /RSIGL _n /RCV _n and RSYNC _n signals are clocked into the DS1MX7 on the rising edge of LRCLK _n and out of the DS1MX7 on the falling edge of LRCLK _n . When set to zero, they are clocked in or out on the falling/rising edge of LRCLK _n respectively.
	5	SDH	SDH functions: When this bit is set to one, the pointer tracking state machine will transition from the AIS state to the LOP state on receipt of eight Invalid pointers and a block count of BIP-2 errors will be recorded by the BIP-2 error counter. This is used in SDH applications. When set to zero, the pointer tracking state machine will not include the AIS state to the LOP state transition and the actual number of BIP-2 errors will be recorded by the BIP-2 error counter. This setting is used in SONET applications.
	4	RXNRZP	Receive NRZ Polarity: When set to one, the polarity of the data received at RPOS _n and LAIS _n will be inverted at these pins; a low will be interpreted as a logic one.
	3	TBPIS	Telecom Bus Parity Includes Sync.: When set to one, the signals AC1J1V1 and ASPE are included with AD(0-7) in the parity calculation for APAR. When set to zero, APAR includes parity calculated for AD(0-7) only.
	2	TBPE	Telecom Bus Parity Even/Odd: When set to one, even parity is calculated for APAR and checked for DPAR. When set to zero, odd parity is calculated for APAR and checked for DPAR.
	1	VC3VC4	VC3 / VC4 Telecom Bus Operation: When set to one, the Telecom Bus operates with stuffing per SONET requirements and SDH requirements for a TU-11 in a TUG-2, VC-3, AU-3 at either 6.48 or 19.44 MHz. When set to zero, the Telecom Bus operates with stuffing per SDH requirements for a TU-11 in a TUG-2 via a TUG-3, VC-3, AU-4 at 19.44 MHz only. Pin CONFIG1 must be set to low if SDH stuffing is required.
	0	TXNRZP	Transmit NRZ Polarity: When set to one, the polarity of the data transmitted at TPOS _n will be inverted at the pin; a logic one will generate a low output signal.

TXC-04201B

DATA SHEET

Address	Bit	Symbol	Description
008	7	MTBRCF	Mask Telecom Bus Receive Clock Fail: When set to one, the fault detector for DCLK is masked from generating an interrupt (status and event not affected).
	6	MTBRSF	Mask Telecom Bus Receive Sync. Fail: When set to one, the fault detector for DC1J1V1 is masked from generating an interrupt (status and event not affected).
	5	MTBRPF	Mask Telecom Bus Receive Payload Indicator Fail: When set to one, the fault detector for DSPE is masked from generating an interrupt (status and event not affected).
	4	R	Reserved: This bit must be set to zero.
	3	MMCKF	Mask Master Clock Fail: When set to one, the fault detector for SRCLK is masked from generating an interrupt (status and event not affected).
	2	MTBTCF	Mask Telecom Bus Transmit Clock Fail: When set to one, the fault detector for ACLK is masked from generating an interrupt (status and event not affected).
	1	MTBTSE	Mask Telecom Bus Transmit Sync. Fail: When set to one, the fault detector for AC1J1V1 is masked from generating an interrupt (status and event not affected).
	0	MTBTPE	Mask Telecom Bus Transmit Payload Indicator Fail: When set to one, the fault detector for ASPE is masked from generating an interrupt (status and event not affected).
009	7-4	R	Reserved: These bits must be set to zeros.
	3	MTBRPY	Mask Telecom Bus Receive Parity Error: When set to one, the parity error detector for the received Telecom Bus is masked from generating an interrupt (status and event not affected).
	2	MPRBSE	Mask PRBS Out of Lock Events: When set to one, the PRBS analyzer out of lock output is masked from generating an interrupt (status and event not affected).
	1	MTBIE	Mask Telecom Bus Internal Error: When set to one, the fault detector for Telecom Bus transmit internal collisions is masked from generating an interrupt (status and event not affected).
	0	MTBXE	Mask Telecom Bus External Error: When set to one, the fault detector for Telecom Bus transmit external collisions is masked from generating an interrupt (status and event not affected).

DATA SHEET

DS1MX7
TXC-04201B

Address	Bit	Symbol	Description
00A	7	TBRCKS	Telecom Bus Receive Clock Fail Status: When set to one, the fault detector for DCLK is currently detecting loss of transitions. This bit is set to a 1 when no DCLK transitions are detected for a time between 32 and 64 cycles of PCKI. This bit is cleared to 0 when DCLK transitions are present for between 32 and 64 cycles of PCKI.
	6	TBRSNS	Telecom Bus Receive Sync. Fail Status: When set to one, the fault detector for DC1J1V1 is currently detecting loss of transitions. Detection time is 2000 ± 500 microseconds; clear time is a single transition of DC1J1V1.
	5	TBRPAS	Telecom Bus Receive Payload Indicator Fail Status: When set to one, the fault detector for DSPE is currently detecting loss of transitions. Minimum detection time is 35 microseconds; clear time is a single transition of DSPE.
	4	R	Reserved: This bit reads out as zero.
	3	MCKS	Master Clock Fail Status: When set to one, the fault detector for SRCLK is currently detecting loss of transitions. Detection time is 2.0 ± 0.5 microseconds (32 cycles of PCKI @ 16 MHz); This bit is cleared to zero when SRCLK is present for 32 cycles of PCKI.
	2	TBTCKS	Telecom Bus Transmit Clock Fail Status: When set to one, the fault detector for ACLK is currently detecting loss of transitions. This bit is set to a 1 when no ACLK transitions are detected for a time between 32 and 64 cycles of PCKI. This bit is cleared to 0 when ACLK transitions are present for between 32 and 64 cycles of PCKI.
	1	TBTSNS	Telecom Bus Transmit Sync. Fail Status: When set to one, the fault detector for AC1J1V1 is currently detecting loss of transitions. Detection time is 2000 ± 500 microseconds; clear time is a single transition of AC1J1V1.
	0	TBTPAS	Telecom Bus Transmit Payload Indicator Fail Status: When set to one, the fault detector for ASPE is currently detecting loss of transitions. Minimum detection time is 49 microseconds; clear time is a single transition of ASPE.
00B	7-4	R	Reserved: These bits read out as zeros.
	3	TBRPYS	Telecom Bus Receive Parity Error Status: When set to one, the parity error detector for the received Telecom Bus is detecting a parity error.
	2	PRBSS	PRBS Out of Lock Status: When set to one, the PRBS analyzer is out of lock.
	1	TBIES	Telecom Bus Internal Error Status: When set to one, the fault detector for Telecom Bus transmit internal collisions is detecting simultaneous bus slot access (i.e., two or more channel registers at X+05H set to same slot).
	0	TBXES	Telecom Bus External Error Status: When set to one, the fault detector for Telecom Bus transmit external collisions is detecting simultaneous bus slot access as determined by the AADD and BUSCHK pin levels.

DATA SHEET

Address	Bit	Symbol	Description
00C	7	TBRCKE	Telecom Bus Receive Clock Fail Latched Event: This bit will be set to one when the active edge, as selected by RISE and FALL, has occurred for DCLK loss of clock. If not masked, an interrupt and/or internal alarm is generated when this bit is set. This bit is cleared only by writing it to zero.
	6	TBR SNE	Telecom Bus Receive Sync. Fail Latched Event: This bit will be set to one when the active edge, as selected by RISE and FALL, has occurred for DC1J1V1 loss of signal. If not masked, an interrupt and/or internal alarm is generated when this bit is set. This bit is cleared only by writing it to zero.
	5	TBRPAE	Telecom Bus Receive Payload Indicator Fail Latched Event: This bit will be set to one when the active edge, as selected by RISE and FALL, has occurred for DSPE loss of signal. If not masked, an interrupt and/or internal alarm is generated when this bit is set. This bit is cleared only by writing it to zero.
	4	R	Reserved: This bit must be set to zero.
	3	MCKE	Master Clock Fail Latched Event: This bit will be set to one when the active edge, as selected by RISE and FALL, has occurred for SRCLK loss of clock. If not masked, an interrupt and/or internal alarm is generated when this bit is set. This bit is cleared only by writing it to zero.
	2	TBTCKE	Telecom Bus Transmit Clock Fail Latched Event: This bit will be set to one when the active edge, as selected by RISE and FALL, has occurred for ACLK loss of clock. If not masked, an interrupt and/or internal alarm is generated when this bit is set. This bit is cleared only by writing it to zero.
	1	TBTSNE	Telecom Bus Transmit Sync. Fail Latched Event: This bit will be set to one when the active edge, as selected by RISE and FALL, has occurred for AC1J1V1 loss of signal. If not masked, an interrupt and/or internal alarm is generated when this bit is set. This bit is cleared only by writing it to zero.
	0	TBTPAE	Telecom Bus Transmit Payload Indicator Fail Latched Event: This bit will be set to one when the active edge, as selected by RISE and FALL, has occurred for ASPE loss of signal. If not masked, an interrupt and/or internal alarm is generated when this bit is set. This bit is cleared only by writing it to zero.

DATA SHEET

DS1MX7
TXC-04201B

Address	Bit	Symbol	Description
00D	7-4	R	Reserved: These bits must be set to zeros.
	3	TBRPYE	Telecom Bus Receive Parity Error Latched Event: This bit will be set to one when the active edge, as selected by RISE and FALL, has occurred for a parity error. If not masked, an interrupt and/or internal alarm is generated when this bit is set. This bit is cleared only by writing it to zero.
	2	PRBSE	PRBS Out of Lock Latched Event: This bit will be set to one when the active edge, as selected by RISE and FALL, has occurred for a PRBS out of lock condition. If not masked, an interrupt and/or internal alarm is generated when this bit is set. This bit is cleared only by writing it to zero.
	1	TBIEE	Telecom Bus Internal Error Latched Event: This bit will be set to one when the active edge, as selected by RISE and FALL, has occurred for an internal bus error. If not masked, an interrupt and/or internal alarm is generated when this bit is set. This bit is cleared only by writing it to zero.
	0	TBXEE	Telecom Bus External Error Latched Event: This bit will be set to one when the active edge, as selected by RISE and FALL, has occurred for an external bus error. If not masked, an interrupt and/or internal alarm is generated when this bit is set. This bit is cleared only by writing it to zero.
00E	7	TBRCKPM	Telecom Bus Receive Clock Performance Monitor: This bit will be set to one if DCLK loss of clock has occurred at any time in the last one-second interval as defined by T1SI. This bit is cleared by writing it to zero or by T1SI rising edge if the condition no longer exists and event bit TBRCKE has been cleared.
	6	TBRSNPM	Telecom Bus Receive Sync. Performance Monitor: This bit will be set to one if DC1J1V1 loss of signal has occurred at any time in the last one-second interval as defined by T1SI. This bit is cleared by writing it to zero or by T1SI rising edge if the condition no longer exists and event bit TBRSE has been cleared.
	5	TBRPAPM	Telecom Bus Receive Payload Indicator Performance Monitor: This bit will be set to one if DSPE loss of signal has occurred at any time in the last one-second interval as defined by T1SI. This bit is cleared by writing it to zero or by T1SI rising edge if the condition no longer exists and event bit TBRPAE has been cleared.
	4	R	Reserved: This bit must be set to zero.
	3	MCKPM	Master Clock Performance Monitor: This bit will be set to one if SRCLK loss of clock has occurred at any time in the last one-second interval as defined by T1SI. This bit is cleared by writing it to zero or by T1SI rising edge if the condition no longer exists and event bit MCKE has been cleared.
	2	TBTCKPM	Telecom Bus Transmit Clock Performance Monitor: This bit will be set to one if ACLK loss of clock has occurred at any time in the last one-second interval as defined by T1SI. This bit is cleared by writing it to zero or by T1SI rising edge if the condition no longer exists and event bit TBTCKE has been cleared.

DATA SHEET

Address	Bit	Symbol	Description
00E (cont.)	1	TBTSNPM	Telecom Bus Transmit Sync. Performance Monitor: This bit will be set to one if AC1J1V1 loss of signal has occurred at any time in the last one-second interval as defined by T1SI. This bit is cleared by writing it to zero or by T1SI rising edge if the condition no longer exists and event bit TBTSNE has been cleared.
	0	TBTPAPM	Telecom Bus Transmit Payload Indicator Performance Monitor: This bit will be set to one if ASPE loss of clock has occurred at any time in the last one-second interval as defined by T1SI. This bit is cleared by writing it to zero or by T1SI rising edge if the condition no longer exists and event bit TBTPAE has been cleared.
00F	7-4	R	Reserved: These bits must be set to zeros.
	3	TBRPYPM	Telecom Bus Receive Parity Error Performance Monitor: This bit will be set to one if a parity error has occurred at any time in the last one-second interval as defined by T1SI. This bit is cleared by writing it to zero or by T1SI rising edge if the condition no longer exists and event bit TBRPYE has been cleared.
	2	PRBSPM	PRBS Out of Lock Performance Monitor: This bit will be set to one if a PRBS out of lock has occurred at any time in the last one-second interval as defined by T1SI. This bit is cleared by writing it to zero or by T1SI rising edge if the condition no longer exists and event bit PRBSE has been cleared.
	1	TBIEPM	Telecom Bus Internal Error Performance Monitor: This bit will be set to one if an internal bus collision has occurred at any time in the last one-second interval as defined by T1SI. This bit is cleared by writing it to zero or by T1SI rising edge if the condition no longer exists and event bit TBXIE has been cleared.
	0	TBXEPM	Telecom Bus External Error Performance Monitor: This bit will be set to one if an external bus collision has occurred at any time in the last one-second interval as defined by T1SI. This bit is cleared by writing it to zero or by T1SI rising edge if the condition no longer exists and event bit TBXEE has been cleared.
010	7-0	SPARE	Spare: This register should not be accessed.
011	7	R	Reserved: This bit reads out as zero.
	6-0	CH7 - CH1	Channel Activity: A bit is set to one for any channel that has one or more pending events. It is used as a polling register to identify channels in need of service or to locate channels that have generated an interrupt.
012	7-0	SPARE	Spare: This register should not be accessed.

DATA SHEET

DS1MX7
TXC-04201B

Address	Bit	Symbol	Description
013	7	GXPE	Global External LAIS Pin Event: This bit will be set to one if an active signal is present (XPE is one) in any of the channels for LAIS. This bit will be cleared when all LAIS events have been cleared in the individual channel event registers.
	6	GDMPE	Global Demap Error Event: This bit will be set to one if a demap error event (DMPE) is present in any of the channels. This bit will be cleared when all demap error events have been cleared in the individual channel event registers.
	5	GLOSE	Global LOS Event: This bit will be set to one if a DS1 loss of signal event (LOSE) is present in any of the channels. This bit will be cleared when all DS1 loss of signal events have been cleared in the individual channel event registers.
	4	GMPE	Global Map Error Event: This bit will be set to one if a map error event (MPE) is present in any of the channels. This bit will be cleared when all map error events have been cleared in the individual channel event registers.
	3	GDAISE	Global DS1 AIS Event: This bit will be set to one if a DS1 AIS event (DAISE) is present in any of the channels. This bit will be cleared when all DS1 AIS events have been cleared in the individual channel event registers.
	2	GRPOE	Global Received Pointer Justification Counter Overflow Event: This bit will be set to one if a received pointer justification counter overflow event (RPOE) is present in any of the channels. This bit will be cleared when all receive pointer counter overflow events have been cleared in the individual channel event registers.
	1	GPGOE	Global Generated Pointer Justification Counter Overflow Event: This bit will be set to one if a generated pointer justification counter overflow event (PGOE) is present in any of the channels. This bit will be cleared when all pointer generation counter overflow events have been cleared in the individual channel event registers.
	0	GCVOE	Global Code Violation Counter/CRC-6 Error Counter Overflow Event: This bit will be set to one if a code violation counter/CRC-6 error counter overflow event (CVOE) is present in any of the channels. This bit will be cleared when all code violation counter/CRC-6 error counter overflow events have been cleared in the individual channel event registers.

DS1MX7
TXC-04201B

DATA SHEET

Address	Bit	Symbol	Description
014	7	GFEOE	Global REI (FEBE) Counter Overflow Event: This bit will be set to one if a REI (FEBE) counter overflow event (FEOE) is present in any of the channels. This bit will be cleared when all REI (FEBE) counter overflow events have been cleared in the individual channel event registers.
	6	GBIPOE	Global BIP-2 Error Counter Overflow Event: This bit will be set to one if a BIP-2 error counter overflow event (BIPOE) is present in any of the channels. This bit will be cleared when all BIP-2 error counter overflow events have been cleared in the individual channel event registers.
	5	GVAISE	Global VT AIS Event: This bit will be set to one if a VT AIS event (VAISE) is present in any of the channels. This bit will be cleared when all VT AIS events have been cleared in the individual channel event registers.
	4	GLOPE	Global Loss of Pointer Event: This bit will be set to one if a loss of pointer event (LOPE) is present in any of the channels. This bit will be cleared when all loss of pointer events have been cleared in the individual channel event registers.
	3	GRFIE	Global RFI Event: This bit will be set to one if a remote failure indication event (RFIE) is present in any of the channels. This bit will be cleared when all RFI events have been cleared in the individual channel event registers.
	2	GUNEE	Global Unequipped Event: This bit will be set to one if an unequipped event (UNEE) is present in any of the channels. This bit will be cleared when all unequipped events have been cleared in the individual channel event registers.
	1	GSLME	Global Signal Label Mismatch Event: This bit will be set to one if a signal label mismatch event (SLME) is present in any of the channels. This bit will be cleared when all signal label mismatch events have been cleared in the individual channel event registers.
	0	GRDIE	Global RDI Event: This bit will be set to one if a remote defect indication event (RDI-VE, RDI-VPDE, RDI-VSDE or RDI-VCDE) is present in any of the channels. This bit will be cleared when all RDI events have been cleared in the individual channel event registers.

DATA SHEET

DS1MX7
TXC-04201B

Address	Bit	Symbol	Description
015	7	GXPM	Global External LAIS Pin Event Mask: When set to one, all per channel LAIS events (XPE) are masked from generating interrupts (overrides per channel mask when set).
	6	GDMPM	Global Demap Error Event Mask: When set to one, all per channel demap error events (DMPE) are masked from generating interrupts (overrides per channel mask when set).
	5	GLOSM	Global LOS Event Mask: When set to one, all per channel LOS events (LOSE) are masked from generating interrupts (overrides per channel mask when set).
	4	GMPM	Global Map Error Event Mask: When set to one, all per channel map error events (MPE) are masked from generating interrupts (overrides per channel mask when set).
	3	GDAISM	Global DS1 AIS Event Mask: When set to one, all per channel DS1 AIS events (DAISE) are masked from generating interrupts (overrides per channel mask when set).
	2	GRPOM	Global Received Pointer Justification Counter Overflow Event Mask: When set to one, all received pointer justification counter overflow events (RPOE) are masked from generating interrupts (overrides per channel mask when set).
	1	GPGOM	Global Generated Pointer Justification Counter Overflow Event Mask: When set to one, all per channel generated pointer justification counter overflow events (PGOE) are masked from generating interrupts (overrides per channel mask when set).
	0	GCVOM	Global Code Violation Counter/CRC-6 Error Counter Overflow Event Mask: When set to one, all per channel code violation counter/CRC-6 error counter overflow events (CVOE) are masked from generating interrupts (overrides per channel mask when set).

DS1MX7
TXC-04201B

DATA SHEET

Address	Bit	Symbol	Description
016	7	GFEOM	Global REI (FEBE) Counter Overflow Event Mask: When set to one, all per channel REI (FEBE) counter overflow events (FEOE) are masked from generating interrupts (overrides per channel mask when set).
	6	GBIPOM	Global BIP-2 Error Counter Overflow Event Mask: When set to one, all per channel BIP-2 error counter overflow events (BIPOE) are masked from generating interrupts (overrides per channel mask when set).
	5	GVAISM	Global VT AIS Event Mask: When set to one, all per channel VT AIS events (VAISE) are masked from generating interrupts (overrides per channel mask when set).
	4	GLOPM	Global Loss of Pointer Event Mask: When set to one, all per channel LOP events (LOPE) are masked from generating interrupts (overrides per channel mask when set).
	3	GRFIM	Global RFI Event Mask: When set to one, all per channel RFI events (RFIE) are masked from generating interrupts (overrides per channel mask when set).
	2	GUNEM	Global Unequipped Event Mask: When set to one, all per channel unequipped events (UNEE) are masked from generating interrupts (overrides per channel mask when set).
	1	GSLMM	Global Signal Label Mismatch Event Mask: When set to one, all per channel signal label mismatch events (SLME) are masked from generating interrupts (overrides per channel mask when set).
	0	GRDIM	Global RDI Event Mask: When set to one, all per channel RDI events (RDI-VE, RDI-VPDE, RDI-VSDE or RDI-VCDE) are masked from generating interrupts (overrides per channel mask when set).
017	7-0	D7-D0	Command Byte: This register contains the command byte for the serial port. The definitions of the bits will depend on the external device that is selected. The serial port control logic does not depend on the values in this register for operation. This byte is shifted out LSB (D0) first and represents the first byte sent out at pin LSDO.
018	7-0	D7-D0	Line Interface Serial Data Output: This register contains the serial data to be written to the selected line interface transceiver. The data is shifted out LSB (D0) first and represents the second byte sent out at pin LSDO.
019	7-0	D7-D0	Line Interface Serial Data Input: This register contains the read back data from the line interface transceiver when a read operation is performed. The data is shifted in LSB (D0) first (see pin LSDI).

DATA SHEET

DS1MX7
TXC-04201B

Address	Bit	Symbol	Description
01A	7	BDCST	Broadcast: When this bit is set to one, serial port command and data output registers are broadcast to all seven line interface transceivers.
	6	R	Reserved: This bit must be set to zero.
	5	EPRBSA	PRBS Enable: When set to one, both the internal PRBS analyzer and PRBS generator are enabled. Bits 2, 1 and 0 of this register select which channel's line decoder output is connected to the analyzer. The analyzer's output is a one for bits PRBSS, PRBSE, PRBSPM and PRBSFM as controlled by bits MPRBSE and EPRBSE. When this bit is set to zero or when the PRBS analyzer is in lock, a zero is present in PRBSS, PRBSE, PRBSPM and PRBSFM. To operate with an ITU-T O.151 compliant $2^{15} - 1$ signal, the output of the PRBS generator and/or the input to the PRBS analyzer must be inverted. This is controlled by setting either or both TXNRZP and RXNRZP in the global registers to a 1.
	4	ENSRP	Enable Serial Port: When set to one, a single transfer takes place to the selected device (single or broadcast) in serial port mode. This bit must be toggled to zero before setting it to one for another transfer.
	3	R	Reserved: This bit must be set to zero.
	2-0		DS1 Channel Number (0-6): When decoded with bit 0 as least significant bit the value (N=0-6) selected drives the active low chip select pin, LCS(N+1). BDCST causes all seven LCSn pins to be selected in serial port mode. In PRBS operation these bits select the channel to be monitored by the PRBS analyzer.
01B	7	ETBRCF	Enable Telecom Bus Receive Clock Fail: When set to one, the fault detector for DCLK is enabled to drive pin IAO if DCLK fails.
	6	ETBRSF	Enable Telecom Bus Receive Sync. Fail: When set to one, the fault detector for DC1J1V1 is enabled to drive pin IAO if DC1J1V1 fails.
	5	ETBRPF	Enable Telecom Bus Receive Payload Indicator Fail: When set to one, the fault detector for DSPE is enabled to drive pin IAO if DSPE fails.
	4	R	Reserved: This bit must be set to zero.
	3	EMCKF	Enable Master Clock Fail: When set to one, the fault detector for SRCLK is enabled to drive pin IAO if SRCLK fails.
	2	ETBTCF	Enable Telecom Bus Transmit Clock Fail: When set to one, the fault detector for ACLK is enabled to drive pin IAO if ACLK fails.
	1	ETBTSF	Enable Telecom Bus Transmit Sync. Fail: When set to one, the fault detector for AC1J1V1 is enabled to drive pin IAO if AC1J1V1 fails.
	0	ETBTPF	Enable Telecom Bus Transmit Payload Indicator Fail: When set to one, the fault detector for ASPE is enabled to drive pin IAO if ASPE fails.

DATA SHEET

DS1MX7
TXC-04201B

Address	Bit	Symbol	Description
01E	7	TBLPBK	Telecom Bus Loopback: When set to one, internally the Telecom Bus is placed in loopback with all 28 or 84 timeslots out of the mappers connected to the 28 or 84 timeslots of the demappers. ACLK is the only Telecom Bus signal used in Telecom Bus Loopback; payload and reference signals are internally generated. This is an off-line test for the entire DS1MX7 with invalid data sent to the Telecom Bus; individual channels may be tested with the PRBS generator / analyzer in this mode.
	6	FTBTPE	Force Telecom Bus Transmit Parity Error: When set to one, the parity to the Telecom Bus (APAR) is inverted, forcing continuous parity errors.
	5	TBTCI	Telecom Bus Transmit Clock Inversion: This bit controls the active edge of the Add Bus Clock (ACLK). When set to a zero, the Add Bus input signals ASPE and AC1J1V1 are sampled on the rising edge of ACLK. The AD(0-7), APAR and AADD output signals are clocked out to the Add Bus on the falling edge of the ACLK. When set to a one, ASPE and AC1J1V1 are sampled on the falling edge of ACLK and AD(0-7), APAR and AADD are clocked out on the rising edge.
	4	TBRCI	Telecom Bus Receive Clock Inversion: When set to zero, the active edge of DCLK is the rising edge. When set to one, the active edge of DCLK is the falling edge.
	3	TBDD	Telecom Bus Data Delay: When set to zero, AD(0-7) and APAR are pre-fetched and made available on the active edge of ACLK as defined by ASPE and AC1J1V1 (as shown in Figure 10 and Figure 11) with drive control as determined by drive pins DATEN and MASTER (as described in the Block Diagram Description and Operation-Telecom Bus Interface section). When set to one, AD(0-7) and APAR are delayed by one full clock period of ACLK; DATEN input must be delayed externally by one ACLK period if it is to be used (e.g., DATEN controlled by ASPE).
	2-1	R	Reserved: These bits must be set to zeros.
	0	RDID10	RDI De-bouncing equals 10: When set to zero, RDI is de-bounced for 5 VT superframes. This means it must be set for 5 VT superframes in a row to be declared as RDI for a channel and it must be cleared for 5 VT superframes in a row to be cleared. When set to one, RDI is de-bounced for 10 VT superframes.
01F - 03B	7-0	SPARE	Spare: These registers should not be accessed.
03C	7	DPLLLK	Digital Phase Lock Loop Lock: When set to one, the DPLL FIFO depth is determined by the value of DPLL(6-0) in this register. This forces a constant frequency from all DPLLs (LTCLKn). When set to zero, the DPLL bias offset is determined by DPLL(6-0). For normal DS1MX7 operation set DPLLLK to zero. This control bit is for test purposes.
	6-0	DPLL6 - DPLL0	Digital Phase Lock Loop Control: When DPLLLK is set to zero, the value of DPLL(6-0) is the ones complement of the DPLL bias offset; for DPLL(6-0) = 00 Hex, the nominal design value is chosen. When DPLLLK is set to one, DPLL(6-0) determines the FIFO depth. For normal operation, set to zero. These control bits are for test purposes.

DS1MX7
TXC-04201B

DATA SHEET

TRANSWITCH
X

Address	Bit	Symbol	Description
03D	7-5	R	Reserved: These bits must be set to zeros.
	4	BYPLB	Bypass Pointer Leak Buffer: When set to zero, the pointer leak buffer is enabled in all channels. When set to one, the pointer leak buffer is bypassed. For normal operation, set this bit to zero. This control bit is for test purposes.
	3	PRBSCK	PRBS Clock: When set to zero, SRCLK is selected as the source of PRBS clock. This bit is used for manufacturing tests; do not set it to a 1.
	2	TMDIS	Threshold Modulator Disable: When set to zero, the threshold modulator is enabled. When set to one, the threshold modulator is disabled. For normal operation this bit should be set to zero. This control bit is for test purposes and may not be available in future versions.
	1, 0	C2PH(1-0)	C2 Stuff Bit Phase: When both bits are set to zero, normal threshold modulator phase is chosen for the C2 stuff bits. Setting either or both of these bits to one chooses an alternate phase for the threshold modulator. For normal operation, both of these bits should be set to zero. These control bits are for test purposes and may not be available in future versions.
03E	7	TBRCKFM	Telecom Bus Receive Clock Fault Monitor: This bit will be set to one if DCLK loss of clock is present but the transition to this state did not occur in the last one-second interval as defined by T1SI. This bit is cleared by writing it to zero or by T1SI rising edge if the condition no longer exists and event bit TBRCKE has been cleared.
	6	TBRSNFM	Telecom Bus Receive Sync. Fault Monitor: This bit will be set to one if DC1J1V1 loss of signal is present, but the transition to this state did not occur in the last one-second interval as defined by T1SI. This bit is cleared by writing it to zero or by T1SI rising edge if the condition no longer exists and event bit TBRSE has been cleared.
	5	TBRPAFM	Telecom Bus Receive Payload Indicator Fault Monitor: This bit will be set to one if DSPE loss of signal is present, but the transition to this state did not occur in the last one-second interval as defined by T1SI. This bit is cleared by writing it to zero or by T1SI rising edge if the condition no longer exists and event bit TBRPAE has been cleared.
	4	R	Reserved: This bit must be set to zero.
	3	MCKFM	Master Clock Fault Monitor: This bit will be set to one if SRCLK loss of clock is present, but the transition to this state did not occur in the last one-second interval as defined by T1SI. This bit is cleared by writing it to zero or by T1SI rising edge if the condition no longer exists and event bit MCKE has been cleared.
	2	TBTCKFM	Telecom Bus Transmit Clock Fault Monitor: This bit will be set to one if ACLK loss of clock is present, but the transition to this state did not occur in the last one-second interval as defined by T1SI. This bit is cleared by writing it to zero or by T1SI rising edge if the condition no longer exists and event bit TBTCKE has been cleared.

Address	Bit	Symbol	Description
03E (cont.)	1	TBTSNFM	Telecom Bus Transmit Sync. Fault Monitor: This bit will be set to one if AC1J1V1 loss of signal is present, but the transition to this state did not occur in the last one-second interval as defined by T1SI. This bit is cleared by writing it to zero or by T1SI rising edge if the condition no longer exists and event bit TBTSNE has been cleared.
	0	TBTPAFM	Telecom Bus Transmit Payload Indicator Fault Monitor: This bit will be set to one if ASPE loss of clock is present, but the transition to this state did not occur in the last one-second interval as defined by T1SI. This bit is cleared by writing it to zero or by T1SI rising edge if the condition no longer exists and event bit TBTPAE has been cleared.
03F	7-4	R	Reserved: These bits must be set to zeros.
	3	TBRPYFM	Telecom Bus Receive Parity Error Fault Monitor: This bit will be set to one if a parity error is present, but the transition to this state did not occur in the last one-second interval as defined by T1SI. This bit is cleared by writing it to zero or by T1SI rising edge if the condition no longer exists and event bit TBRPYE has been cleared.
	2	PRBSFM	PRBS Out of Lock Fault Monitor: This bit will be set to one if a PRBS out of lock is present, but the transition to this state did not occur in the last one-second interval as defined by T1SI. This bit is cleared by writing it to zero or by T1SI rising edge if the condition no longer exists and event bit PRBSE has been cleared.
	1	TBIEFM	Telecom Bus Internal Error Fault Monitor: This bit will be set to one if an internal bus collision is present, but the transition to this state did not occur in the last one-second interval as defined by T1SI. This bit is cleared by writing it to zero or by T1SI rising edge if the condition no longer exists and event bit TBIEE has been cleared.
	0	TBXEFM	Telecom Bus External Error Fault Monitor: This bit will be set to one if an external bus collision is present, but the transition to this state did not occur in the last one-second interval as defined by T1SI. This bit is cleared by writing it to zero or by T1SI rising edge if the condition no longer exists and event bit TBXEE has been cleared.

DS1MX7
TXC-04201B

DATA SHEET

PER CHANNEL CONTROL REGISTERS

*Note: In the address, X= 040H for DS1 channel 1; 080H for DS1 channel 2; 0C0H for DS1 channel 3; 100H for DS1 channel 4; 140H for DS1 channel 5; 180H for DS1 channel 6; 1C0H for DS1 channel 7.

Address*	Bit	Symbol	Description																									
X+00	7	IDLE	Set the Channel to Idle: When set to zero, the channel is powered down; all-zeros are substituted for the payload and overhead bytes except V5. Either an all-zeros V5 may be sent, indicating an unequipped condition, or a valid V5 may be sent (unassigned); V5 is determined by per channel control bits RDIIS, FEBEIS, SFEFE, SRDI and Transmit Signal Label. For normal operation, including sending VT AIS, this bit should be set to one. Note that for proper idle operation register TXZ7 (reg. X+39H) should also be set to 00H.																									
	6	EXPLOS	External Pin enables LOS: When set to one, LAIS active (as determined by RXNRZP) is treated as LOS from the decoder. Set this bit to one if using an external decoder or external Loss of Clock detector. Set this bit to zero if LAIS pin is unused or used for another purpose (e.g., interrupt from an external line transceiver). See SH2AIS and LOS2AIS below for logic (register X+01H).																									
	5	DATA COM	Datacom Mode: This bit, in conjunction with MODE0 and MODE1, enables Datacom Mode. If MODE1 is set to zero, this bit is disregarded. See MODE0, MODE1 in this register.																									
	4	ENZC	Enable Excess Zeros Count: When set to one, this bit will enable the BPV counter to also count excess zeros. When B8ZS transcoding is enabled, 8 or more consecutive zeros is an error. When B8ZS transcoding is disabled, 16 or more consecutive zeros is an error.																									
	3	LCODE	Line Code Select: When set to one and ENCOD is set to one, B8ZS is selected for coding and decoding. When set to zero and ENCOD is set to one, AMI is selected for coding and decoding. When ENCOD is set to zero, this bit selects the signal level on TNEGn. <table border="1" style="margin-left: auto; margin-right: auto;"> <thead> <tr> <th>ENCOD</th> <th>LCODE</th> <th>MODE1</th> <th>Line Code</th> <th>TNEGn</th> </tr> </thead> <tbody> <tr> <td>1</td> <td>0</td> <td>0</td> <td>AMI</td> <td>per codec</td> </tr> <tr> <td>1</td> <td>1</td> <td>0</td> <td>B8ZS</td> <td>per codec</td> </tr> <tr> <td>0</td> <td>0</td> <td>0,1</td> <td>NRZ</td> <td>logic low</td> </tr> <tr> <td>0</td> <td>1</td> <td>0,1</td> <td>NRZ</td> <td>logic high</td> </tr> </tbody> </table>	ENCOD	LCODE	MODE1	Line Code	TNEGn	1	0	0	AMI	per codec	1	1	0	B8ZS	per codec	0	0	0,1	NRZ	logic low	0	1	0,1	NRZ	logic high
	ENCOD	LCODE	MODE1	Line Code	TNEGn																							
1	0	0	AMI	per codec																								
1	1	0	B8ZS	per codec																								
0	0	0,1	NRZ	logic low																								
0	1	0,1	NRZ	logic high																								
2	ENCOD	Enable Codec: When set to one, the line coder and decoder are enabled if MODE1 is set to zero with the code selected by LCODE. When set to zero, or if MODE1 is set to one, NRZ is selected.

TXC-04201B

DATA SHEET

Address*	Bit	Symbol	Description
X+01 (cont.)	5	LOF2VAIS	Enable Loss of Frame to VT AIS and Map Error: When set to one, the loss of multiframe synchronization signal (RSYNCn) maps to VT AIS and is indicated as a map error (see SH2VAIS for logic).
	4	CRC6	Enable CRC-6 generation: When set to one in the True Byte Sync mode only, CRC-6 is generated into the transmit VT payload. CRC-6 is calculated on the Received VT payload and compared with the received CRC-6 code.
	3	VAIS2AIS	<p>Enable VT AIS to DS1 AIS: When set to one, VT AIS received in V1 and V2 is mapped to DS1 AIS.</p>
	2	RFI2YEL	<p>Enable RFI to DS1 Yellow: When set to one, RFI received in V5 is mapped to DS1 Yellow on the signaling highway. If DATACOM is set to one, this bit is disregarded.</p>
1	YEL2RFI	Enable DS1 Yellow to RFI: When set to one, DS1 Yellow on the signaling highway maps to RFI in V5 (see RFI2YEL for logic). If DATACOM is set to one, this bit is disregarded.	
0	AIS2VAIS	Enable DS1 AIS to VT AIS: When set to one, DS1 AIS detected in the decoder (99.9% or more ones) maps to VT AIS in the byte sync. mode (see SH2VAIS for logic). If DATACOM is set to one, this bit is disregarded.	

DATA SHEET

DS1MX7
TXC-04201B

Address*	Bit	Symbol	Description
X+02	7	SRDI-VPD*	Send RDI-VPD: When set to one, RDI-VPD is sent continuously if RDIIS is also set to one. See RDIIS below for logic. Set to zero if this channel is programmed unequipped.
	6	SRDI-VSD*	Send RDI-VSD: When set to one, RDI-VSD is sent continuously if RDIIS is also set to one. See RDIIS below for logic. Set to zero if this channel is programmed unequipped.
	5	SRDI-VCD*	Send RDI-VCD: When set to one, RDI-VCD is sent continuously if RDIIS is also set to one. See RDIIS below for logic. Set to zero if this channel is programmed unequipped.
	4	R	Reserved: This bit must be set to zero.
	3	RDIIS	<p>RDI Insert Select: When set to zero, RDI-Vxx is generated autonomously from either internally detected faults or from values input at the Ring Port. When set to one RDI-Vxx is sent continuously if SRDI-Vxx is set to one.</p> <p>Note: "W:XYZ" = V5, Bit 8: Z7, Bits 5, 6, 7</p> <p>Set to one if this channel is programmed unequipped.</p>
2	SLM2AIS	Enable Signal Label Mismatch to AIS: When set to one, a Signal Label Mismatch detected maps to DS1 AIS (see VAIS2AIS above for logic). This bit should be set to one if this channel is programmed unequipped.	

* Note: When forcing by microprocessor selection, set only one of the bits SRDI-VPD, SRDI-VSD and SRDI-VCD to one at any given time, to retain proper alarm priority.

DS1MX7
TXC-04201B

DATA SHEET

Address*	Bit	Symbol	Description
X+02 (cont)	1	FEBEIS	<p>REI (FEBE) Insert Select: When set to zero, REI (FEBE) is generated from received BIP-2 errors or from the Ring Port Input. When set to one, REI (FEBE) or BIP-2 errors can be created with SFEBE or SPIBE. The required REI (FEBE) value is always output at the Ring Port (RGFEBE-V). The REI (FEBE) value appearing in the outgoing V5, Bit 3 results from received BIP-2 errors if RINGEN is set to zero or from the Input Ring Port value, RGFEBE-V, if RINGEN is set to one.</p>
	0	UNE2AIS	<p>Enable Unequipped to DS1 AIS: When set to one, an Unequipped Signal Label received is mapped to DS1 AIS (see VAIS2AIS for logic). This bit should be set to a zero if this channel is unequipped. Use SDAIS to force AIS to DS1 line if required when UNE2AIS is set to zero.</p>
X+03	7	SFEBE	<p>Send REI (FEBE): When set to one, REI (FEBE) is sent the number of times specified by ECTL(0-7) if control bit FEBEIS is set to one, control bit IDLE is set to one and if control bit RINGEN is set to zero. When set to one, REI (FEBE) is sent continuously if control bit FEBEIS is set to one, control bit IDLE is set to zero and if control bit RINGEN is set to zero. If RINGEN is set to one, the FEBEs from the ring port are placed in the outgoing V5, Bit 3.</p>
	6	SDAISS	<p>Send DS1 AIS to System: When set to one, DS1 AIS (all-ones) is used for the VT1.5 or TU-11 payload in the map direction.</p>
	5	SBIPE	<p>Send BIP-2 Errors: When set to one, inverted BIP-2 is sent the number of times specified by ECTL(0-7) if FEBEIS is set to one. This bit must be cleared to zero and set again to send a second set of inverted BIP-2.</p>
	4	R	<p>Reserved: This bit must be set to zero.</p>
	3	SDAISL	<p>Send DS1 AIS to the DS1 Line: When set to one, DS1 AIS is sent out of the coder using nominal timing (derived from SRCLK by dividing by 31.5).</p>
	2	SYELL	<p>Send DS1 Yellow: When set to one, DS1 Yellow is sent on the signaling highway (TSIGLn) in byte-synchronous mode. If DATACOM is set to one, this bit is disregarded.</p>
	1	SRFI	<p>Send RFI: When set to one, the RFI bit is set in V5.</p>
	0	SVTAIS	<p>Send VT AIS: When set to one, VT AIS is generated in the mapping direction by generating an all-ones VT1.5 or TU-11.</p>

DATA SHEET

Address*	Bit	Symbol	Description
X+08	7	XPM	External LAIS Pin Event Mask: When set to one, this channel's LAIS events (XPE) are masked from generating interrupts (status and event not affected).
	6	DMPM	Demap Error Event Mask: When set to one, this channel's demap error events (DMPE) are masked from generating interrupts (status and event not affected).
	5	LOSM	LOS Event Mask: When set to one, this channel's LOS events (LOSE) are masked from generating interrupts (status and event not affected).
	4	MPM	Map Error Event Mask: When set to one, this channel's map error events (MPE) are masked from generating interrupts (status and event not affected).
	3	DAISM	DS1 AIS Event Mask: When set to one, this channel's DS1 AIS events (DAISE) are masked from generating interrupts (status and event not affected).
	2	RPOM	Received Pointer Justification Counter Overflow Event Mask: When set to one, received pointer justification counter overflow events (RPOE) from this channel are masked from generating interrupts (status and event not affected).
	1	PGOM	Generated Pointer Justification Counter Overflow Event Mask: When set to one, this channel's generated pointer justification counter overflow events (PGOE) are masked from generating interrupts (status and event not affected).
	0	CVOM	Code Violation Counter/CRC-6 Error Counter Overflow Event Mask: When set to one, this channel's code violation counter/CRC-6 error counter overflow events (CVOE) are masked from generating interrupts (status and event not affected).
X+09	7	FEOM	REI (FEBE) Counter Overflow Event Mask: When set to one, this channel's REI (FEBE) counter overflow events (FEOE) are masked from generating interrupts (status and event not affected).
	6	BIPOM	BIP-2 Error Counter Overflow Event Mask: When set to one, this channel's BIP-2 error counter overflow events (BIPOE) are masked from generating interrupts (status and event not affected).
	5	VAISM	VT AIS Event Mask: When set to one, this channel's VT AIS events (VAISE) are masked from generating interrupts (status and event not affected).
	4	LOPM	Loss of Pointer Event Mask: When set to one, this channel's LOP events (LOPE) are masked from generating interrupts (status and event not affected).
	3	RFIM	RFI Event Mask: When set to one, this channel's RFI events (RFIE) are masked from generating interrupts (status and event not affected).
	2	UNEM	Unequipped Event Mask: When set to one, this channel's unequipped events (UNEE) are masked from generating interrupts (status and event not affected). Set to one when this channel is programmed unequipped.

DATA SHEET

DS1MX7
TXC-04201B

Address*	Bit	Symbol	Description
X+09 (cont)	1	SLMM	Signal Label Mismatch Event Mask: When set to one, this channel's signal label mismatch events (SLME) are masked from generating interrupts (status and event not affected). Set to one when this channel is programmed unequipped.
	0	RDIM	RDI Event Mask: When set to one, this channel's RDI events (RDI_VE) are masked from generating interrupts (status and event not affected).
X+0A	7-3	R	Reserved: These bits must be set to zeros.
	2	RDI-VPDM	RDI-VPD Event Mask: When set to one, this channels's RDI-VPD events (RDI-VPDE) are masked from generating interrupts (status and event not affected).
	1	RDI-VSDM	RDI-VSD Event Mask: When set to one, this channels's RDI-VSD events (RDI-VSDE) are masked from generating interrupts (status and event not affected).
	0	RDI-VCDM	RDI-VCD Event Mask: When set to one, this channels's RDI-VCD events (RDI-VCDE) are masked from generating interrupts (status and event not affected).
X+0B	7-5	R	Reserved: These bits must be set to zeros.
	4	RINGEN	Ring Port Enable: When set to one, the outgoing V5 REI (FEBE) and RDI-Vxx values are accepted from the Ring Port Input. See RDIIS and FEBEIS above for logic. Information input at the Ring Port is readable by the microprocessor in register X+3AH.
	3	OBAPEN	O-bits Auxiliary Port Enable: When set to zero, register X+36H contains microprocessor-written data that will appear on AD(0-7). When set to one, the O-bit incoming at the Auxiliary Port will appear on AD(0-7) and will also be written in register X+36H for access by the microprocessor.
	2	J2APEN	J2 Auxiliary Port Enable: When set to zero, register X+37H contains microprocessor-written data that will appear on AD(0-7). When set to one, the J2 Byte incoming at the Auxiliary Port will appear on AD(0-7) and will also be written in register X+37H for access by the microprocessor.
	1	Z6APEN	Z6/N2 Auxiliary Port Enable: When set to zero, register X+38H contains microprocessor-written data that will appear on AD(0-7). When set to one, the Z6/N2 Byte incoming at the Auxiliary Port will appear on AD(0-7) and will also be written in register X+38H for access by the microprocessor.
	0	Z7APEN	Z7/K4 Auxiliary Port Enable: When set to zero, register X+39H contains microprocessor-written data that will appear on AD(0-7). When set to one, the Z7/K4 Byte incoming at the Auxiliary Port will appear on AD(0-7) and will also be written in register X+39H for access by the microprocessor. When RINGEN is set to one, RDI insert is from the ring port even if this bit is set to one.

DS1MX7
TXC-04201B

DATA SHEET

Address*	Bit	Symbol	Description
X+0C	7	DTLPBK	DS1 Tributary Loopback: When set to one, the output of the line coder is looped to the input of the line decoder. Clock, multiframe synchronization and signaling are also looped back. This loopback is useful for DS1MX7 self test with the PRBS generator and analyzer. The DS1 Tributary Loopback can only be used in the Asynchronous and Modified Byte Synchronous modes.
	6	DFLPBK	DS1 Remote Facility Loopback: When set to one, the output of the decoder is looped to the input of the coder. Clock, multiframe synchronization and signaling are also looped back. This loopback is used to provide remote facility loopback testing.
	5	RSTCH	Reset Channel: When this bit is set to one, this channel is held in reset; it provides the same function that the RESET register (005H) provides for all channels.
	4	SPRBS	Send PRBS: When set to one, the output of the PRBS generator is substituted for the output of the decoder for this channel. This bit, used in conjunction with DTLPBK (DS1 facility loopback), bit 7 in this register, TBLPBK (Telecom bus loopback) at register 01EH bit 7, EPRBSA (enable PRBS Generator/Analyzer) at register 01AH bit 5, which must be set to one, and the DS1 Channel number, provides a self test of this channel.
	3-0	R	Reserved: These bits must be set to zeros.
X+0D - X+0F	7-0	R	Reserved: These registers should not be accessed.

PER CHANNEL STATUS REGISTERS

Address*	Bit	Symbol	Description
X+10	7	XPS	External Pin Status: When this bit is a one, the external pin (LAIS) for this channel is active per RXNRZP (LAIS is high if RXNRZP is zero or LAIS is low if RXNRZP is one).
	6	DMP5	Demap Error Status: When this bit is a one, a fault (e.g. internal FIFO overflow/underflow) is occurring in the desynchronizer for this channel.
	5	LOSS	Loss of Signal Status: When this bit is a one, LOS is currently being detected in this channel. Detection of LOS is based on no pulses being a logic low on both the RPOS _n and RNEG _n pins for 175 ± 75 contiguous clock cycles of LRCLK _n . LOS exits on 12.5% or greater ones density for 175 ± 75 contiguous pulse positions. LOS does not function in NRZ mode.
	4	MPS	Map Error Status: When this bit is a one, a map error is occurring in this channel. If bit LOF2VAIS is one, this bit represents a loss of multiframe input in byte-synchronous operation.
	3	DAISS	DS1 AIS Status: When this bit is a one, DS1 AIS is being detected in the line decoder for this channel. DS1 AIS is declared if 99.9% ones are detected for between 3 and 75 milliseconds. AIS exits on less than 99.9% all-ones for between 3 and 75 milliseconds.
	2	RPOS	Received Pointer Justification Counter Overflow Status: When this bit is a one, the received pointer justification counter for this channel has overflowed.
	1	PGOS	Generated Pointer Justification Counter Overflow Status: When this bit is a one, the generated pointer justification counter has overflowed for this channel.
	0	CVOS	Code Violation Counter/CRC-6 Error Counter Overflow Status: When this bit is a one, the code violation counter/CRC-6 error counter for this channel has overflowed.

DS1MX7
TXC-04201B

DATA SHEET

Address*	Bit	Symbol	Description
X+11	7	FEOS	REI (FEBE) Counter Overflow Status: When this bit is a one, the REI (FEBE) counter for this channel has overflowed.
	6	BIPOS	BIP-2 Error Counter Overflow Status: When this bit is a one, the BIP-2 error counter for this channel has overflowed.
	5	VAISS	VT AIS Status: When this bit is a one, VT AIS is currently being detected for this channel. VT AIS is declared if 3 consecutive V1 and V2 bytes are all-ones. VT AIS is removed when a valid VT pointer is received with valid SS-bits, with a NDF, or with 3 consecutive VT superframes having a valid VT pointer and valid SS-bits with no NDF.
	4	LOPS	LOP Status: When this bit a one, loss of pointer is currently being detected for this channel. LOP is entered with 8 consecutive NDF enables or invalid pointers. LOP is exited to normal if 3 consecutive valid VT pointers are received with valid SS-bits. LOP is exited to AIS if 3 consecutive all-ones pointers are received.
	3	RFIS	RFI Status: When this bit is a one, the receive failure indication has been de-bounced for 10 consecutive V5 bytes and is set for this channel. RFI is only a valid indication in byte-synchronous modes of operation. This bit will clear if RFI is reset in 10 consecutive V5 bytes.
	2	UNES	Unequipped Status: This bit reflects the current status of the receive signal label for this channel (de-bounced for 5 consecutive V5 bytes) with respect to unequipped (signal label = 000). When this bit is a one, the incoming VT1.5 or TU-11 is unequipped. This bit will clear if 5 consecutive V5 bytes do not have an all-zero signal label.
	1	SLMS	Signal Label Mismatch Status: When this bit is set to a one, a mismatch has been de-bounced and detected for 5 consecutive V5 bytes between the expected signal label and the received signal label for this channel. A received or expected value of 'equipped non-specific' (signal label = 001) is not a mismatch for any non-zero signal label. This bit will clear if 5 consecutive V5 bytes match. An unequipped signal label (signal label = 000) received will cause this bit to be set unless the expected signal label (bits 6-4 of register X+07H) is set to unequipped.
	0	RDI-VS	RDI-V Status: When this bit is a one, a remote defect indication (from equipment that does not support Enhanced RDI) has been de-bounced for 5 or 10 consecutive V5 bytes and detected for this channel. This bit will clear if RDI is reset for 5 or 10 consecutive V5 bytes. RDID10 selects the de-bounce period.

DATA SHEET

DS1MX7
TXC-04201B

Address*	Bit	Symbol	Description
X+12	7-3	R	Reserved: These bits have indeterminate status on read.
	2	RDI-VPDS	RDI-VPD Status: When this bit is set to one, a VT Remote Payload Defect Indication has been de-bounced for 5 or 10 consecutive Z7/K4 Bytes and detected for this channel. This bit will clear if RDI-VPD is not received for 5 or 10 consecutive Z7/K4 Bytes. RDID10 selects the de-bounce period.
	1	RDI-VSDS	RDI-VSD Status: When this bit is set to one, a VT Remote Server Defect Indication has been de-bounced for 5 or 10 consecutive Z7/K4 Bytes and detected for this channel. This bit will clear if RDI-VSD is not received for 5 or 10 consecutive Z7/K4 Bytes. RDID10 selects the de-bounce period.
	0	RDI-VCDS	RDI-VCD Status: When this bit is set to one, a VT Remote Connectivity Defect Indication has been de-bounced for 5 or 10 consecutive Z7/K4 Bytes and detected for this channel. This bit will clear if RDI-VCD is not received for 5 or 10 consecutive Z7/K4 Bytes. RDID10 selects the de-bounce period.
X+13	7-0	SPARE	Spare: This register should not be accessed.
X+14	7	XPE	External Pin Event: This bit will be set to one by the DS1MX7 when the active edge of the external pin (LAIS) for this channel (XPS), as determined by RISE and FALL, and the sense as determined by RXNRZP, has occurred. This bit is cleared by writing a zero to this bit location or by T1SI if ENPMFM is set to one.
	6	DMPE	Demap Error Event: This bit will be set to one by the DS1MX7 when the active edge of a demap error for this channel (DMPS), as determined by RISE and FALL, has occurred. This bit is cleared by writing a zero to this bit location or by T1SI if ENPMFM is set to one.
	5	LOSE	Loss of Signal Event: This bit will be set to one by the DS1MX7 when the active edge of an LOS for this channel (LOSS), as determined by RISE and FALL, has occurred. This bit is cleared by writing a zero to this bit location or by T1SI if ENPMFM is set to one.
	4	MPE	Map Error Event: This bit will be set to one by the DS1MX7 when the active edge of a map error for this channel (MPS), as determined by RISE and FALL, has occurred. This bit is cleared by writing a zero to this bit location or by T1SI if ENPMFM is set to one.
	3	DAISE	DS1 AIS Event: This bit will be set to one by the DS1MX7 when the active edge of a DS1 AIS for this channel (DAISS), as determined by RISE and FALL, has occurred. This bit is cleared by writing a zero to this bit location or by T1SI if ENPMFM is set to one.
	2	RPOE	Received Pointer Justification Counter Overflow Event: This bit will be set to one by the DS1MX7 when the active edge of a received pointer justification counter overflow for this channel (RPOS), as determined by RISE and FALL, has occurred. This bit is cleared by writing a zero to this bit location or by T1SI if ENPMFM is set to one.

DS1MX7
TXC-04201B

DATA SHEET

Address*	Bit	Symbol	Description
X+14 (cont.)	1	PGOE	Generated Pointer Justification Counter Overflow Event: This bit will be set to one by the DS1MX7 when the active edge of a generated pointer justification counter overflow for this channel (PGOS), as determined by RISE and FALL, has occurred. This bit is cleared by writing a zero to this bit location or by T1SI if ENPMFM is set to one.
	0	CVOE	Code Violation Counter/CRC-6 Error Counter Overflow Event: This bit will be set to one by the DS1MX7 when the active edge of a code violation counter/CRC-6 Error counter overflow for this channel (CVOS), as determined by RISE and FALL, has occurred. This bit is cleared by writing a zero to this bit location or by T1SI if ENPMFM is set to one.
X+15	7	FEOE	REI (FEBE) Counter Overflow Event: This bit will be set to one by the DS1MX7 when the active edge of a REI (FEBE) counter overflow for this channel (FEOS), as determined by RISE and FALL, has occurred. This bit is cleared by writing a zero to this bit location or by T1SI if ENPMFM is set to one.
	6	BIPOE	BIP-2 Error Counter Overflow Event: This bit will be set to one by the DS1MX7 when the active edge of a BIP-2 error counter overflow for this channel (BIPOS), as determined by RISE and FALL, has occurred. This bit is cleared by writing a zero to this bit location or by T1SI if ENPMFM is set to one.
	5	VAISE	VT AIS Event: This bit will be set to one by the DS1MX7 when the active edge of a VT AIS for this channel (VAISS), as determined by RISE and FALL, has occurred. This bit is cleared by writing a zero to this bit location or by T1SI if ENPMFM is set to one.
	4	LOPE	LOP Event: This bit will be set to one by the DS1MX7 when the active edge of a LOP for this channel (LOPS), as determined by RISE and FALL, has occurred. This bit is cleared by writing a zero to this bit location or by T1SI if ENPMFM is set to one.
	3	RFIE	RFI Event: This bit will be set to one by the DS1MX7 when the active edge of an RFI for this channel (RFIS), as determined by RISE and FALL, has occurred. This bit is cleared by writing a zero to this bit location or by T1SI if ENPMFM is set to one.
	2	UNEE	Unequipped Event: This bit will be set to one by the DS1MX7 when the active edge of an unequipped signal label for this channel (UNES), as determined by RISE and FALL, has occurred. This bit is cleared by writing a zero to this bit location or by T1SI if ENPMFM is set to one.
	1	SLME	Signal Label Mismatch Event: This bit will be set to one by the DS1MX7 when the active edge of a signal label mismatch for this channel (SLMS), as determined by RISE and FALL, has occurred. This bit is cleared by writing a zero to this bit location or by T1SI if ENPMFM is set to one.
	0	RDI-VE	RDI-V Event: This bit will be set to one by the DS1MX7 when the active edge of an RDI for this channel (RDI-VS), as determined by RISE and FALL, has occurred. This bit is cleared by writing a zero to this bit location or by T1SI if ENPMFM is set to one.

DATA SHEET

DATA SHEET

Address*	Bit	Symbol	Description
X+18 (cont.)	0	CVOPM	Code Violation Counter/CRC-6 Error Counter Overflow Performance Monitor: This bit will be set to one by the DS1MX7 if a code violation counter/CRC-6 error counter overflow event (CVOE) has occurred in the last one-second interval as defined by T1SI, if ENPMFM is set to one. This bit may be cleared by writing it to a zero.
X+19	7	FEOPM	REI (FEBE) Counter Overflow Performance Monitor: This bit will be set to one by the DS1MX7 if a REI (FEBE) counter overflow event (FEOE) has occurred in the last one-second interval as defined by T1SI, if ENPMFM is set to one. This bit may be cleared by writing it to a zero.
	6	BIOPM	BIP-2 Error Counter Overflow Performance Monitor: This bit will be set to one by the DS1MX7 if a BIP-2 counter overflow event (BIPOE) has occurred in the last one-second interval as defined by T1SI, if ENPMFM is set to one. This bit may be cleared by writing it to a zero.
	5	VAISPM	VT AIS Performance Monitor: This bit will be set to one by the DS1MX7 if a VT AIS event (VAISE) has occurred in the last one-second interval as defined by T1SI, if ENPMFM is set to one. This bit may be cleared by writing it to a zero.
	4	LOPPM	LOP Performance Monitor: This bit will be set to one by the DS1MX7 if an LOP event (LOPE) has occurred in the last one-second interval as defined by T1SI, if ENPMFM is set to one. This bit may be cleared by writing it to a zero.
	3	RFIPM	RFI Performance Monitor: This bit will be set to one by the DS1MX7 if an RFI event (RFIE) has occurred in the last one-second interval as defined by T1SI, if ENPMFM is set to one. This bit may be cleared by writing it to a zero.
	2	UNEPM	Unequipped Performance Monitor: This bit will be set to one by the DS1MX7 if an unequipped signal label event (UNEE) has occurred in the last one-second interval as defined by T1SI, if ENPMFM is set to one. This bit may be cleared by writing it to a zero.
	1	SLMPM	Signal Label Mismatch Performance Monitor: This bit will be set to one by the DS1MX7 if a signal label mismatch event (SLME) has occurred in the last one-second interval as defined by T1SI, if ENPMFM is set to one. This bit may be cleared by writing it to a zero.
	0	RDI-VPM	RDI-V Performance Monitor: This bit will be set to one by the DS1MX7 if an RDI event (RDI-VE) has occurred in the last one-second interval as defined by T1SI, if ENPMFM is set to one. This bit may be cleared by writing it to a zero.

DATA SHEET

DS1MX7
TXC-04201B

Address*	Bit	Symbol	Description
X+1A	7-3	R	Reserved: These bits must be set to zeros.
	2	RDI-VPDPM	RDI-VPD Performance Monitor: This bit will be set to one, if an RDI-VPD event (RDI-VPDE) has occurred in the last one-second interval as defined by T1SI, if ENPMFM is set to one. This bit may be cleared by writing it to a zero.
	1	RDI-VSDPM	RDI-VSD Performance Monitor: This bit will be set to one, if an RDI-VSD event (RDI-VSDE) has occurred in the last one-second interval as defined by T1SI, if ENPMFM is set to one. This bit may be cleared by writing it to a zero.
	0	RDI-VCDPM	RDI-VCD Performance Monitor: This bit will be set to one, if an RDI-VCD event (RDI-VCDE) has occurred in the last one-second interval as defined by T1SI, if ENPMFM is set to one. This bit may be cleared by writing it to a zero.
X+1B	7-0	SPARE	Spare: This register should not be accessed.
X+1C	7	XPFM	External Pin Fault Monitor: This bit will be set to one by the DS1MX7 if an external pin event (XPE) is active but the transition to the active state has not occurred in the last one-second interval as defined by T1SI, if ENPMFM is set to one. This bit may be cleared by writing it to a zero.
	6	DMPFM	Demap Error Fault Monitor: This bit will be set to one by the DS1MX7 if a demap error event (DMPE) is active but the transition to the active state has not occurred in the last one-second interval as defined by T1SI, if ENPMFM is set to one. This bit may be cleared by writing it to a zero.
	5	LOSFM	Loss of Signal Fault Monitor: This bit will be set to one by the DS1MX7 if an LOS event (LOSE) is active but the transition to the active state has not occurred in the last one-second interval as defined by T1SI, if ENPMFM is set to one. This bit may be cleared by writing it to a zero.
	4	MPFM	Map Error Fault Monitor: This bit will be set to one by the DS1MX7 if a map error event (MPE) is active but the transition to the active state has not occurred in the last one-second interval as defined by T1SI, if ENPMFM is set to one. This bit may be cleared by writing it to a zero.
	3	DAISFM	DS1 AIS Fault Monitor: This bit will be set to one by the DS1MX7 if a DS1 AIS event (DAISE) is active but the transition to the active state has not occurred in the last one-second interval as defined by T1SI, if ENPMFM is set to one. This bit may be cleared by writing it to a zero.
	2	RPOFM	Received Pointer Justification Counter Overflow Fault Monitor: This bit will be set to one by the DS1MX7 if a received pointer justification counter overflow event (RPOE) is active but the transition to the active state has not occurred in the last one-second interval as defined by T1SI, if ENPMFM is set to one. This bit may be cleared by writing it to a zero.
	1	PGOFM	Generated Pointer Justification Counter Overflow Fault Monitor: This bit will be set to one by the DS1MX7 if a generated pointer justification counter overflow event (PGOE) is active but the transition to the active state has not occurred in the last one-second interval as defined by T1SI, if ENPMFM is set to one. This bit may be cleared by writing it to a zero.

DATA SHEET

Address*	Bit	Symbol	Description
X+1C (cont.)	0	CVOFM	Code Violation Counter/CRC-6 Error Counter Overflow Fault Monitor: This bit will be set to one by the DS1MX7 if a code violation counter/CRC-6 error counter overflow event (CVOE) is active but the transition to the active state has not occurred in the last one-second interval as defined by T1SI, if ENPMFM is set to one. This bit may be cleared by writing it to a zero.
X+1D	7	FEOFM	REI (FEBE) Counter Overflow Fault Monitor: This bit will be set to one by the DS1MX7 if a REI (FEBE) counter overflow event (FEOE) is active but the transition to the active state has not occurred in the last one-second interval as defined by T1SI, if ENPMFM is set to one. This bit may be cleared by writing it to a zero.
	6	BIPOFM	BIP-2 Error Counter Overflow Fault Monitor: This bit will be set to one by the DS1MX7 if a BIP-2 error counter overflow event (BIPOE) is active but the transition to the active state has not occurred in the last one-second interval as defined by T1SI, if ENPMFM is set to one. This bit may be cleared by writing it to a zero.
	5	VAISFM	VT AIS Fault Monitor: This bit will be set to one by the DS1MX7 if a VT AIS event (VAISE) is active but the transition to the active state has not occurred in the last one-second interval as defined by T1SI, if ENPMFM is set to one. This bit may be cleared by writing it to a zero.
	4	LOPFM	LOP Fault Monitor: This bit will be set to one by the DS1MX7 if a LOP event (LOPE) is active but the transition to the active state has not occurred in the last one-second interval as defined by T1SI, if ENPMFM is set to one. This bit may be cleared by writing it to a zero.
	3	RFIFM	RFI Fault Monitor: This bit will be set to one by the DS1MX7 if an RFI event (RFIE) is active but the transition to the active state has not occurred in the last one-second interval as defined by T1SI, if ENPMFM is set to one. This bit may be cleared by writing it to a zero.
	2	UNEFM	Unequipped Fault Monitor: This bit will be set to one by the DS1MX7 if an unequipped signal label event (UNEE) is active but the transition to the active state has not occurred in the last one-second interval as defined by T1SI, if ENPMFM is set to one. This bit may be cleared by writing it to a zero.
	1	SLMFM	Signal Label Mismatch Fault Monitor: This bit will be set to one by the DS1MX7 if a signal label mismatch event (SLME) is active but the transition to the active state has not occurred in the last one-second interval as defined by T1SI, if ENPMFM is set to one. This bit may be cleared by writing it to a zero.
	0	RDI-VFM	RDI-V Fault Monitor: This bit will be set to one by the DS1MX7 if an RDI event (RDI-VE) is active but the transition to the active state has not occurred in the last one-second interval as defined by T1SI, if ENPMFM is set to one. This bit may be cleared by writing it to a zero.

DATA SHEET

DS1MX7
TXC-04201B

Address*	Bit	Symbol	Description
X+1E	7-3	Reserved	Reserved: These bits must be set to zeros.
	2	RDI-VPDFM	RDI-VPD Fault Monitor: This bit will be set to one if an RDI-VPD event (RDI-VPDE) is active but the transition to the active state has not occurred in the last one-second interval as defined by T1SI, if ENPMFM is set to one. This bit may be cleared by writing it to a zero.
	1	RDI-VSDFM	RDI-VSD Fault Monitor: This bit will be set to one if an RDI-VSD event (RDI-VSDE) is active but the transition to the active state has not occurred in the last one-second interval as defined by T1SI, if ENPMFM is set to one. This bit may be cleared by writing it to a zero.
	0	RDI-VCDFM	RDI-VCD Fault Monitor: This bit will be set to one if an RDI-VCD event (RDI-VCDE) is active but the transition to the active state has not occurred in the last one-second interval as defined by T1SI, if ENPMFM is set to one. This bit may be cleared by writing it to a zero.
X+1F	7-0	SPARE	Spare: This register should not be accessed.
X+20	7	SHDAIS	Signaling Highway DS1 AIS Status: This bit is a one if a DS1 AIS indication is received from the signaling highway in byte-synchronous mode only.
	6	SHYEL	Signaling Highway Yellow: This bit is a one if a DS1 Yellow indication is received from the signaling highway in byte-synchronous mode only.
	5	R	Reserved: This bit reads out as zero.
	4, 3	RXSS1, RXSS0	Received SS-bits: These two bits represent the SS-bits (SS-bit 1 and SS-bit 0 respectively) received from the VT1.5 or TU-11 V1 and V2 bytes.
	2-0	RX Signal Label (2-0)	Receive Signal Label: These bits represent the signal label received from the V5 byte for this channel. Bits 2 through 0 correspond to bits 5 through 7 respectively of the V5 byte received from the Telecom Bus.
X+21	7-0	SPARE	Spare: This register should not be accessed.
X+22	7-0	CVC (7-0)/ CRC6(7-0)	Line Code Violation Counter/CRC-6 Error Counter: This is the lower byte of a 12-bit free running counter which will increment by one for each received line code violation. If excessive zeros counting is enabled (ENZC is set to one) they will also be counted with the line code errors. This counter can be cleared by writing its value to zero. If the counter overflows the CVOS and CVOE bits (plus CVOPM and CVOFM bits if ENPMFM is set) will be set. If ENPMFM is set, this counter's latched value is updated every one-second at LVCV(7-0) and this counter is subsequently cleared for the next one-second interval. When CRC-6 (X+01H, bit 4) is set, this counter is used as the CRC-6 error counter lower byte in byte-synchronous modes only.

DS1MX7
TXC-04201B

DATA SHEET

Address*	Bit	Symbol	Description
X+23	7-4	R	Reserved: These bits must be set to zeros.
	3-0	CVC (11-8)/ CRC6(11-8)	Line Code Violation Counter/CRC-6 Error Counter: This is the upper nibble of a 12-bit free running counter which will increment by one for each received line code violation. If excessive zeros counting is enabled (ENZC is set to one) they will also be counted with the line code errors. This counter can be cleared by writing its value to zero. If the counter overflows the CVOS and CVOE bits (plus CVOPM and CVOFM bits if ENPMFM is set) will be set. If ENPMFM is set, this counter's latched value is updated every one-second at LCVC(11-8) and this counter is subsequently cleared for the next one-second interval. When CRC-6 (X+01H, bit 4) is set, this counter is used as CRC-6 error counter upper nibble in byte-synchronous modes only.
X+24	7-4	RX Ptr. Inc. Counter	Pointer Increments Received Counter: This four-bit counter represents the number of VT pointer increments received for this channel. This counter can be cleared by writing its value to zero. If the counter overflows the RPOS and RPOE bits (plus RPOPm and RPOFM bits if ENPMFM is set) will be set. If ENPMFM is set, this counter's latched value is updated every one-second at address X+23H and this counter is subsequently cleared for the next one-second interval.
	3-0	RX Ptr. Dec. Counter	Pointer Decrements Received Counter: This four-bit counter represents the number of VT pointer decrements received for this channel. This counter can be cleared by writing its value to zero. If the counter overflows the RPOS and RPOE bits (plus RPOPm and RPOFM bits if ENPMFM is set) will be set. If ENPMFM is set, this counter's latched value is updated every one-second at address X+23H and this counter is subsequently cleared for the next one-second interval.
X+25	7-4	Ptr. Inc. Gen. Counter	Pointer Increments Generated Counter: This four-bit counter represents the number of VT pointer increments generated by this channel for byte-synchronous mode of operation. This counter can be cleared by writing its value to zero. If the counter overflows the PGOS and PGOE bits (plus PGOPM and PGOFM bits if ENPMFM is set) will be set. If ENPMFM is set, this counter's latched value is updated every one-second at address X+24H and this counter is subsequently cleared for the next one-second interval.
	3-0	Ptr Dec. Gen. Counter	Pointer Decrements Generated Counter: This four-bit counter represents the number of VT pointer decrements received for this channel. This counter can be cleared by writing its value to zero. If the counter overflows the PGOS and PGOE bits (plus PGOPM and PGOFM bits if ENPMFM is set) will be set. If ENPMFM is set, this counter's latched value is updated every one-second at address X+24H and this counter is subsequently cleared for the next one-second interval.

DATA SHEET

TXC-04201B

Address*	Bit	Symbol	Description
X+26	7-0	BEC (7-0)	BIP-2 Error Counter: This is the lower byte of a 12-bit free running counter. When control bit SDH is set to zero, it will increment by one for each BIP-2 error received. When SDH is set to one, it will increment block counts of BIP-2 errors. This counter can be cleared by writing its value to zero. If the counter overflows the BIPOS and BIPOE bits (plus BIPOPM and BIPOFM bits if ENPMFM is set) will be set. If ENPMFM is set, this counter's latched value is updated every one-second at LBEC(7-0) and this counter is subsequently cleared for the next one-second interval.
X+27	7-4	R	Reserved: These bits must be set to zeros.
	3-0	BEC (11-8)	BIP-2 Error Counter: This is the upper nibble of a 12-bit free running counter. When control SDH is set to zero, it will increment by one for each BIP-2 error received. When SDH is set to one, it will increment block counts of BIP-2 errors. This counter can be cleared by writing its value to zero. If the counter overflows the BIPOS and BIPOE bits (plus BIPOPM and BIPOFM bits if ENPMFM is set) will be set. If ENPMFM is set, this counter's latched value is updated every one-second at LBEC(11-8) and this counter is subsequently cleared for the next one-second interval.
X+28	7-0	FEC (7-0)	REI (FEBE) Counter: This is the lower byte of a 12-bit free running counter which will increment by one for each far end block error received. This counter can be cleared by writing its value to zero. If the counter overflows the FEOS and FEOE bits (plus FEOPM and FEOFM bits if ENPMFM is set) will be set. If ENPMFM is set, this counter's latched value is updated every one-second at LFEC(7-0) and this counter is subsequently cleared for the next one-second interval.
X+29	7-4	R	Reserved: These bits must be set to zeros.
	3-0	FEC (11-8)	REI (FEBE) Counter: This is the upper nibble of a 12-bit free running counter which will increment by one for each far end block error received. This counter can be cleared by writing its value to zero. If the counter overflows the FEOS and FEOE bits (plus FEOPM and FEOFM bits if ENPMFM is set) will be set. If ENPMFM is set, this counter's latched value is updated every one-second at LFEC(11-8) and this counter is subsequently cleared for the next one-second interval.
X+2A	7-0	LCVC (7-0)/ LCRC6(7-0)	Latched Line Code Violation Counter / CRC-6 Error Counter: This is the lower byte of a 12-bit shadow register which is updated from the Line Code Violation Counter once a second. The one-second interval is derived from the external one-second input, T1SI. When CRC6 (X+01H, Bit 4) is set, this counter is used as CRC-6 error counter lower byte in byte-synchronous modes only.
X+2B	7-4	R	Reserved: These bits must be set to zeros.
	3-0	LCVC (11-8)/ LCRC6(11-8)	Latched Line Code Violation Counter / CRC-6 Error Counter: This is the upper nibble of a 12-bit shadow register which is updated from the Line Code Violation Counter once a second. The one-second interval is derived from the external one-second input, T1SI. When CRC6 (X+01H, Bit 4) is set, this counter is used as CRC-6 error counter upper nibble in byte-synchronous modes only.

DATA SHEET

Address*	Bit	Symbol	Description
X+2C	7-4	Latched RX Ptr. Inc. Counter	Latched Pointer Increments Received Counter: This is the 4-bit shadow register which is updated from the pointer increments received counter once a second. The one-second interval is derived from the external one-second input, T1SI.
	3-0	Latched RX Ptr. Dec. Counter	Latched Pointer Decrements Received Counter: This is the 4-bit shadow register which is updated from the pointer decrements received counter once a second. The one-second interval is derived from the external one-second input, T1SI.
X+2D	7-4	Latched Ptr. Inc. Gen. Counter	Latched Pointer Increments Generated Counter: This is the 4-bit shadow register which is updated from the pointer increments generated counter once a second. The one-second interval is derived from the external one-second input, T1SI.
	3-0	Latched Ptr. Dec. Gen. Counter	Latched Pointer Decrements Generated Counter: This is the 4-bit shadow register which is updated from the pointer decrements generated counter once a second. The one-second interval is derived from the external one-second input, T1SI.
X+2E	7-0	LBEC (7-0)	Latched BIP-2 Error Counter: This is the lower byte of a 12-bit shadow register which is updated from the BIP-2 Error Counter once a second. The one-second interval is derived from the external one-second input, T1SI.
X+2F	7-4	R	Reserved: These bits must be set to zeros.
	3-0	LBEC (11-8)	Latched BIP-2 Error Counter: This is the upper nibble of a 12-bit shadow register which is updated from the BIP-2 Error Counter once a second. The one-second interval is derived from the external one-second input, T1SI.
X+30	7-0	LFEC (7-0)	Latched REI (FEBE) Counter: This is the lower byte of a 12-bit shadow register which is updated from the REI (FEBE) Counter once a second. The one-second interval is derived from the external one-second input, T1SI.
X+31	7-4	R	Reserved: These bits must be set to zeros.
	3-0	LFEC (11-8)	Latched REI (FEBE) Counter: This is the upper nibble of a 12-bit shadow register which is updated from the REI (FEBE) Counter once a second. The one-second interval is derived from the external one-second input, T1SI.
X+32	7-0	RXOB(7-0)	Received O-bits: Bits 3, 2, 1 and 0 are the first four O-bits (Byte following J2, Bits 3, 4, 5 and 6) incoming on DD(0-7). The second four O-bits (Byte following Z6/N2, Bits 3, 4, 5 and 6) are placed in Bits 7, 6, 5 and 4.
X+33	7-0	RXJ2(7-0)	Received J2 Byte: Bit 7 is Bit 1 of the J2 Byte incoming on DD(0-7). Bit 0 is Bit 8 of the J2 Byte.
X+34	7-0	RXZ6(7-0)	Received Z6/N2 Byte: Bit 7 is Bit 1 of the Z6/N2 Byte incoming on DD(0-7). Bit 0 is Bit 8 of the Z6/N2 Byte.
X+35	7-0	RXZ7(7-0)	Received Z7/K4 Byte: Bit 7 is Bit 1 of the Z7/K4 Byte incoming on DD(0-7). Bit 0 is Bit 8 of the Z7/K4 Byte.

DATA SHEET

DS1MX7
TXC-04201B

Address*	Bit	Symbol	Description
X+36	7-0	TXOB(7-0)	Transmit O-bits: Bits 3, 2, 1 and 0 are the first four O-bits (Byte following J2, Bits 3, 4, 5 and 6). The second four O-bits (Byte following Z6/N2, Bits 3, 4, 5 and 6) are Bits 7, 6, 5 and 4. When OBAPEN is set to zero, the microprocessor-written data, in this location is output on AD(0-7). If OBAPEN is set to one, the O-bit information is taken from the Auxiliary Port and is output on AD(0-7). It is also written here for access by the microprocessor. Control bit TBTVAL (register X+05H bit 7) must be set to a "1" to be able to read this register after it is written.
X+37	7-0	TXJ2(7-0)	Transmit J2 Byte: Bit 7 is Bit 1 of the J2 Byte and Bit 0 is the Bit 8 of the J2 Byte. When J2APEN is set to zero, the microprocessor-written data in this location, is output on AD(0-7). If J2APEN is set to one, the J2 information is taken from the Auxiliary Port and output on AD(0-7). It is also written here for access by the microprocessor. Control bit TBTVAL (register X+05H bit 7) must be set to a "1" to be able to read this register after it is written.
X+38	7-0	TXZ6(7-0)	Transmit Z6/N2 Byte: Bit 7 is Bit 1 of the Z6/N2 Byte and Bit 0 is Bit 8 of the Z6/N2 Byte. When Z6APEN is set to zero, the microprocessor-written data, in this location, is output on AD(0-7). If Z6APEN is set to one, the Z6/N2 information is taken from the Auxiliary Port and output on AD(0-7). It is also written here for access by the microprocessor. Control bit TBTVAL (register X+05H bit 7) must be set to a "1" to be able to read this register after it is written.
X+39	7-0	TXZ7(7-0)	Transmit Z7/K4 Byte: Bit 7 is Bit 1 of the Z7/K4 Byte and Bit 0 is Bit 8 of the Z7/K4 Byte. When Z7APEN is set to zero, the microprocessor-written data, in this location, is output on AD(0-7). If Z7APEN is set to one, the Z7/K4 information is taken from the Auxiliary Port and output on AD(0-7). It is also written here for access by the microprocessor. In either case, only bits 7-4 and 0 will appear in the output. Bits 1, 2 and 3 are controlled by the Transmit RDI circuitry. For proper idle operation this register should be set to 00H. Control bit TBTVAL (register X+05H bit 7) must be set to a "1" to be able to read this register after it is written.
X+3A	7-4	R	Reserved: These bits have indeterminate status on read.
	3	RGFEBE-V	Ring Port REI (FEBE) Input: This location contains the information input at the Ring Port. Control bit RINGEN (bit 4) in register X+0BH must be set to a one.
	2	RGRDI-VPD	Ring Port Path Defect Input: This location contains the information input at the Ring Port. Control bit RINGEN (bit 4) in register X+0BH must be set to a one.
	1	RGRDI-VSD	Ring Port Server Defect Input: This location contains the information input at the Ring Port. Control bit RINGEN (bit 4) in register X+0BH must be set to a one.
	0	RGRDI-VCD	Ring Port Connectivity Defect Input: This location contains the information input at the Ring Port. Control bit RINGEN (bit 4) in register X+0BH must be set to a one.
X+3B - X+3F	7-0	Reserved	Reserved: These registers should not be accessed.

APPLICATION DIAGRAMS

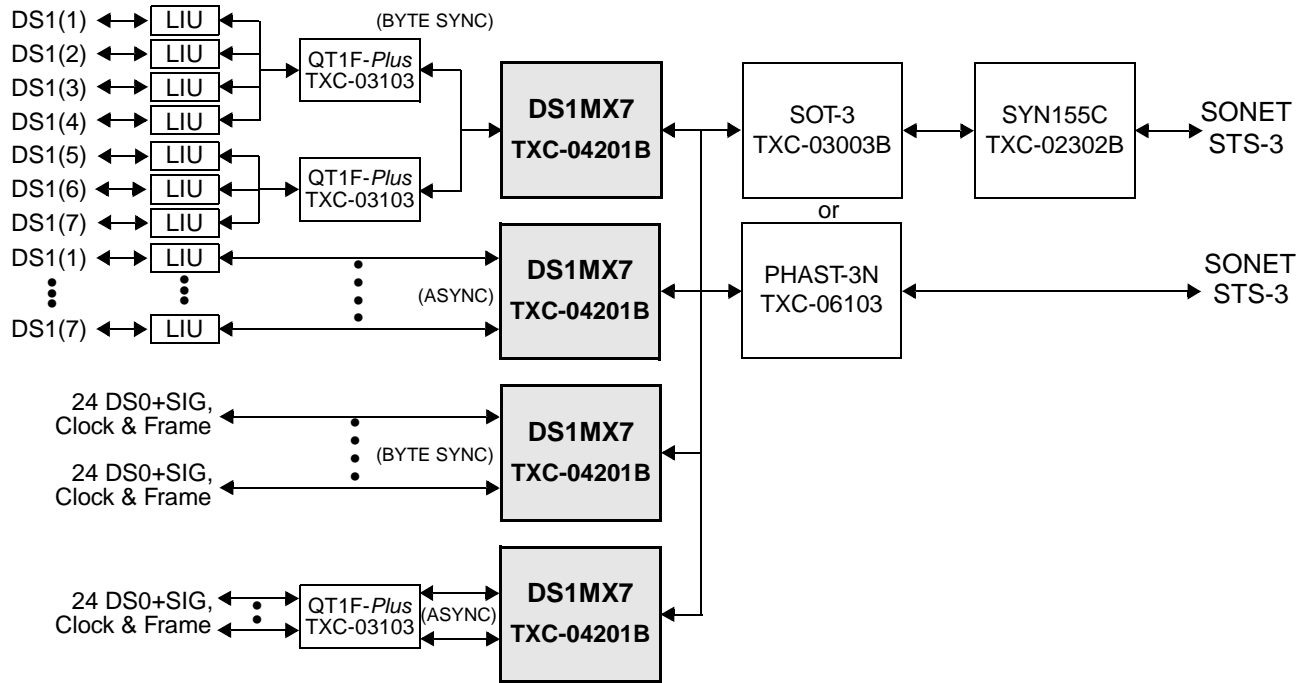

Figure 48. DS1MX7 TXC-04201B Applications

The Application diagram in Figure 48 shows four different uses for the DS1MX7. For SONET byte-synchronous application the DS1MX7 connected to the QT1F-Plus provides for mapping seven DS1s byte-synchronously. LIU control can be provided by either QT1F-Plus or DS1MX7. For asynchronous mappings the DS1MX7 can connect directly to most commercial LIU devices and control them. Direct DS0 access is available for byte-synchronous mappings (external slip buffers are required for common clocks across more than 24 DS0s). With the QT1F-Plus, DS0 access is also available from DS1s mapped asynchronously. Note that a single DS1MX7 can support all applications simultaneously.

The diagram in Figure 49 illustrates some uses of the DS1MX7 device to provide framing and DS0 access for a variety of DS1 sources. Direct control of most commercial line interface unit devices (LIUs) is provided.

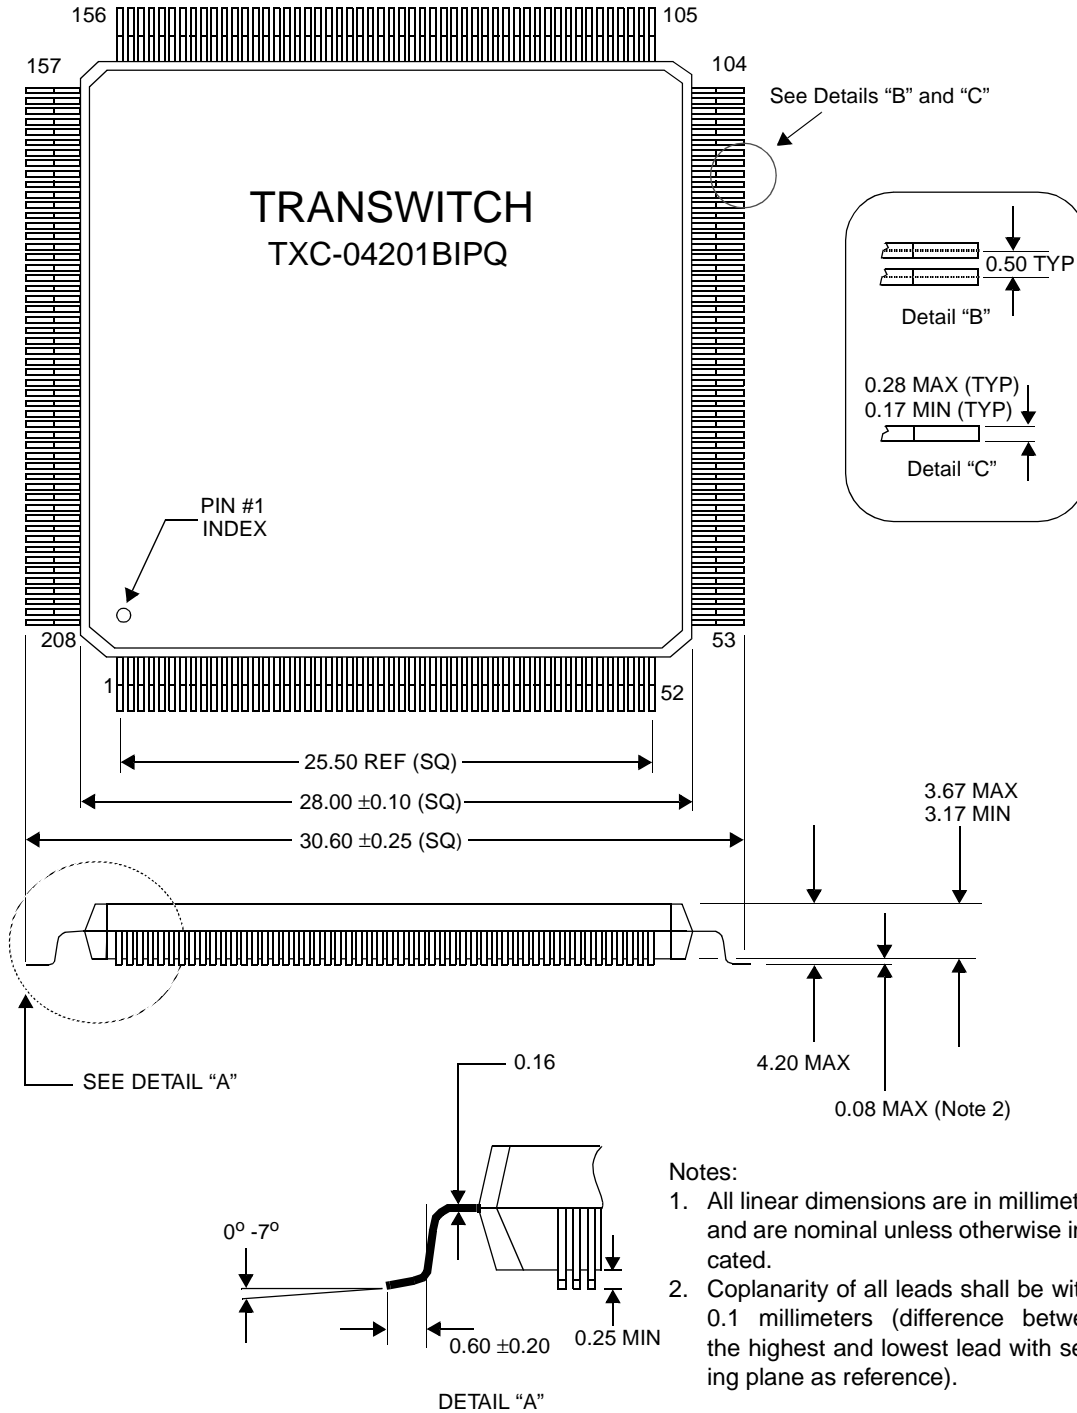

DS1MX7
TXC-04201B

DATA SHEET

PACKAGE INFORMATION

The DS1MX7 device is packaged in a 208-pin plastic quad flat package (PQFP) suitable for surface mounting, as shown in Figure 50.

- Notes:
1. All linear dimensions are in millimeters and are nominal unless otherwise indicated.
 2. Coplanarity of all leads shall be within 0.1 millimeters (difference between the highest and lowest lead with seating plane as reference).

Figure 50. DS1MX7 TXC-04201B 208-Pin Plastic Quad Flat Package

ORDERING INFORMATION

Part Number: TXC-04201BIPQ 208-Pin Plastic Quad Flat Package

RELATED PRODUCTS

TXC-02020, ART VLSI Device (Advanced STS-1/DS3 Receiver/Transmitter). ART performs the transmit and receive line interface functions required for transmission of STS-1 (51.840 Mbit/s) and DS3 (44.736 Mbit/s) signals across a coaxial interface.

TXC-02021, ARTE VLSI Device (Advanced STS-1/DS3 Receiver/Transmitter). ARTE has the same functionality as ART, plus extended features.

TXC-02302B, SYN155C VLSI Device (155-Mbit/s Synchronizer, Clock and Data Output). This device provides a complete STS-3/STM-1 frame synchronization function in a single CMOS unit.

TXC-03001B, SOT-1 VLSI Device (SONET STS-1 Overhead Terminator). Performs Section, Line, and Path Overhead processing for STS-1 SONET signals. Interfaces are provided for both Section and Line Orderwire and Datacom channels. Further, control bits in the Memory Map enable the SOT-1 to perform loopback and serial or parallel I/O.

TXC-03003B, SOT-3 VLSI Device (STM-1/STS-3/STS-3c Overhead Terminator). This is a programmable device that performs section, line and path overhead processing for STM-1/STS-3/STS-3c signals. The SOT-3 device performs pointer generation (with internal pointer justification) with respect to external clock timing in both the transmit and receive directions.

TXC-03011, SOT-1E VLSI Device (SONET STS-1 Overhead Terminator). This device provides extended features relative to the 84-lead TXC-03001B SOT-1 device, and it has a 144-lead package.

TXC-03103, QT1F-Plus VLSI Device (Quad T1 Framer-Plus). A 4-channel framer for voice and data applications. This device handles all logical interfacing functionality to a T1 line. It operates from a power supply of 3.3 volts or 5 volts.

TXC-03108, T1Fx8 VLSI Device (8-Channel T1 Framer). An 8-channel framer for voice and data communications applications. This device handles all logical interfacing functionality to a T1 line and operates from a power supply of 3.3 volts.

TXC-04251, QT1M VLSI Device (Quad DS1 to VT1.5 or TU-11 Async Mapper-Desync). Interconnects four DS1 signals with any four asynchronous mode VT1.5 or TU-11 tributaries carried in SONET STS-1 or SDH AU-3 rate payload interface.

TXC-04228, T1Mx28 VLSI Device (DS1 Mapper 28-Channel Device). The T1Mx28 maps twenty eight DS1 signals into any seven selected asynchronous or byte-synchronous mode VT1.5 or TU-11 tributaries in a SONET/SDH synchronous payload envelope. T1Mx28 is four DS1Mx7 devices combined into one package.

TXC-06101, PHAST-1 VLSI Device (SONET STS-1 Overhead Terminator). This device provides features similar to those of the TXC-03011 SOT-1E device, but it operates from a power supply of 3.3 volts rather than 5 volts.

TXC-06103, PHAST-3N VLSI Device (SONET STM-1, STS-3 or STS-3c Overhead Terminator). This PHAST-3N VLSI device provides a Telecom Bus interface for downstream devices. It operates from a power supply of 3.3 volts.

LIST OF DATA SHEET CHANGES

This change list identifies those areas within this updated DS1MX7 Data Sheet that have significant differences relative to the previous and now superseded DS1MX7 Data Sheet:

Updated DS1MX7 Data Sheet: Ed. 4, September 2001
 Previous DS1MX7 Data Sheet: Ed. 3, November 2000.

The page numbers indicated below of this updated Data Sheet include changes relative to the previous Data Sheet.

<u>Page Number of Updated Data Sheet</u>	<u>Summary of the Change</u>
All	Changed edition number and date.
11	Changed the fifth paragraph which begins "The VT termination block..."
21	For the symbol \overline{AADD} , removed Tristate designation from the I/O/P column and changed the last line of the description.
33	Changed the Min times for $t_{H(1)}$, $t_{H(2)}$, and $t_{H(3)}$ in Figure 8 to 6.0 ns.
34	Changed the Min times for $t_{H(1)}$, $t_{H(2)}$, and $t_{H(3)}$ in Figure 9 to 6.0 ns.
44	Added $t_{H(2)}$ to the timing diagram and table in Figure 19 for ADDR (0-8).
57	Changed the 9 th sentence of the third paragraph, to read "For true byte-synchronous operation....".
67	Changed the Pointer Leak Rate Algorithm description notes 5, 6, 7, and 8 in Figure 29.
82	In description for Figure 40, replaced the last sentence with four new ones.
97	For Boundary Scan Cell # 68, changed I/O from OUTPUT1 to OUTPUT.
143	In description for registers X+36 through X+39 added new last sentence.
147	Deleted last entry under Related Products (TXC-06112).
150	Replaced "List of Data Sheet Changes" section.

- NOTES -

TranSwitch reserves the right to make changes to the product(s) or circuit(s) described herein without notice. No liability is assumed as a result of their use or application. TranSwitch assumes no liability for TranSwitch applications assistance, customer product design, software performance, or infringement of patents or services described herein. Nor does TranSwitch warrant or represent that any license, either express or implied, is granted under any patent right, copyright, mask work right, or other intellectual property right of TranSwitch covering or relating to any combination, machine, or process in which such semiconductor products or services might be or are used.

DOCUMENTATION UPDATE REGISTRATION FORM

If you would like to receive updated documentation for selected devices as it becomes available, please provide the information requested below (print clearly or type) then tear out this page, fold and mail it to the Marketing Communications Department at TranSwitch. Marketing Communications will ensure that the relevant Product Information Sheets, Data Sheets, Application Notes, Technical Bulletins and other publications are sent to you. You may also choose to provide the same information by fax (203.926.9453), or by e-mail (info@txc.com), or by telephone (203.929.8810). Most of these documents will also be made immediately available for direct download as Adobe PDF files from the TranSwitch World Wide Web Site (www.transwitch.com).

Name: _____

Company: _____ Title: _____

Dept./Mailstop: _____

Street: _____

City/State/Zip: _____

If located outside U.S.A., please add - Country: _____ Postal Code: _____

Telephone: _____ Ext.: _____ Fax: _____

E-mail: _____

Please provide the following details for the managers in charge of the following departments at your company location.

<u>Department</u>	<u>Title</u>	<u>Name</u>
Company/Division	_____	_____
Engineering	_____	_____
Marketing	_____	_____

Please describe briefly your intended application(s) and indicate whether you would like to have a TranSwitch applications engineer contact you to provide further assistance:

If you are also interested in receiving updated documentation for other TranSwitch device types, please list them below rather than submitting separate registration forms:

Please fold, tape and mail this page (see other side) or fax it to Marketing Communications at 203.926.9453.

(Fold back on this line second, then tape closed, stamp and mail.)
