Silicon Carbide (SiC) Cascode JFET -
EliteSiC, Power N-Channel, D2PAK-7L,
1200 V, 23 mohm

Rev. B, January 2025

Description

The UF4SC120023B7S is a 1200V, 23mΩ G4 SiC FET. It is based on a unique ‘cascode’ circuit configuration, in which a normally-on SiC JFET is co-packaged with a Si MOSFET to produce a normally-off SiC FET device. The device’s standard gate-drive characteristics allows use of off-the-shelf gate drivers hence requiring minimal re-design when replacing Si IGBTs, Si superjunction devices or SiC MOSFETs. Available in the space-saving D²PAK-7L package which enables automated assembly, this device exhibits ultra-low gate charge and exceptional reverse recovery characteristics, making it ideal for switching inductive loads and any application requiring standard gate drive.

Features

- ♦ On-resistance $R_{DS(on)}$: 23m Ω (typ)
- ♦ Operating temperature: 175°C (max)
- ♦ Excellent reverse recovery: Q_{rr} = 243 nC
- ♦ Low body diode V_{FSD} : 1.2V
- ♦ Low gate charge: Q_G = 37.8nC
- ♦ Threshold voltage $V_{G(th)}$: 4.8V (typ) allowing 0 to 15V drive
- ♦ Low intrinsic capacitance
- ♦ ESD protected: HBM class 2 and CDM class C3
- ♦ D²PAK-7L package for faster switching, clean gate waveforms

Typical applications

- ♦ EV charging
- ♦ PV inverters
- ♦ Switch mode power supplies
- ♦ Power factor correction modules
- ♦ Induction heating

Applications Information

SiC FETs are enhancement-mode power switches formed by a high-voltage SiC depletion-mode JFET and a low-voltage silicon MOSFET connected in series. The silicon MOSFET serves as the control unit while the SiC JFET provides high voltage blocking in the off state. This combination of devices in a single package provides compatibility with standard gate drivers and offers superior performance in terms of low on-resistance ($R_{DS(on)}$), output capacitance (C_{oss}), gate charge (Q_G), and reverse recovery charge (Q_{rr}) leading to low conduction and switching losses. The SiC FETs also provide excellent reverse conduction capability eliminating the need for an external anti-parallel diode. Like other high performance power switches, proper PCB layout design to minimize circuit parasitics is strongly recommended due to the high dv/dt and di/dt rates. An external gate resistor is recommended when the FET is working in the diode mode in order to achieve the optimum reverse recovery performance. For more information on SiC FET operation, see www.unitedsic.com.

A snubber circuit with a small R_G , or gate resistor, provides better EMI suppression with higher efficiency compared to using a high R_G value. There is no extra gate delay time when using the snubber circuitry, and a small R_G will better control both the turn-off $V_{(DS)}$ peak spike and ringing duration, while a high R_G will damp the peak spike but result in a longer delay time. In addition, the total switching loss when using a snubber circuit is less than using high R_G , while greatly reducing $E_{(OFF)}$ from mid-to-full load range with only a small increase in $E_{(ON)}$. Efficiency will therefore improve with higher load current. For more information on how a snubber circuit will improve overall system performance, visit the UnitedSiC website at www.unitedsic.com
