**NEC Microcomputers, Inc.****4096 BIT DYNAMIC RAMS****DESCRIPTION**

The  $\mu$ PD411A Family consists of four 4096 words by 1 bit dynamic N-channel MOS RAMs. They are designed for memory applications where very low cost and large bit storage are important design objectives. The  $\mu$ PD411A Family is designed using dynamic circuitry which reduces the standby power dissipation.

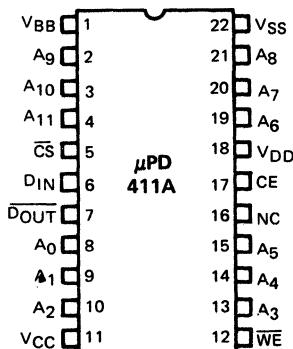

Reading information from the memory is non-destructive. Refreshing is easily accomplished by performing one read cycle on each of the 64 row addresses. Each row address must be refreshed every two milliseconds. The memory is refreshed whether Chip Select is a logic high or a logic low.

**FEATURES**

- Low Standby Power
- 4096 words x 1 bit Organization
- A single low-capacitance high level clock input with solid  $\pm 1$  volt margins.
- Inactive Power 0.7 mW (Typ.)
- Power Supply +12, +5, -5V
- Easy System Interface
- TTL Compatible (Except CE)
- Address Registers on the Chip
- Simple Memory Expansion by Chip Select
- Three State Output and TTL Compatible
- 22 pin Plastic Dual-in-Line Package
- Replacement for INTEL's 2107B, TI's 4060 and Equivalent Devices.
- 3 Performance Ranges:

	ACCESS TIME	R/W CYCLE	RMW CYCLE	REFRESH TIME
$\mu$ PD411A	300 ns	470 ns	650 ns	2 ms
$\mu$ PD411A-1	250 ns	430 ns	600 ns	2 ms
$\mu$ PD411A-2	200 ns	400 ns	520 ns	2 ms

**PIN CONFIGURATION****PIN NAMES**

A0 - A11	Address Inputs
A0 - A5	Refresh Addresses
CE	Chip Enable
CS	Chip Select
DIN	Data Input
DOUT	Data Output
WE	Write Enable
VDD	Power (+12V)
VCC	Power (+5V)
VSS	Ground
VBB	(Power: -5V)
NC	No Connection

## **CE Chip Enable**

A single external clock input is required. All read, write, refresh and read-modify-write operations take place when chip enable input is high. When the chip enable is low, the memory is in the low power standby mode. No read/write operations can take place because the chip is automatically precharging.

## **FUNCTIONAL DESCRIPTION**

### **CS Chip Select**

The chip select terminal affects the data in, data out and read/write inputs. The data input and data output terminals are enabled when chip select is low. The chip select input must be low on or before the rising edge of the chip enable and can be driven from standard TTL circuits. A register for the chip select input is provided on the chip to reduce overhead and simplify system design.

### **WE Write Enable**

The read or write mode is selected through the write enable input. A logic high on the WE input selects the read mode and a logic low selects the write mode. The WE terminal can be driven from standard TTL circuits. The data input is disabled when the read mode is selected.

### **A0-A11 Addresses**

All addresses must be stable on or before the rising edge of the chip enable pulse. All address inputs can be driven from standard TTL circuits. Address registers are provided on the chip to reduce overhead and simplify system design.

### **DIN Data Input**

Data is written during a write or read-modify-write cycle while the chip enable is high. The data in terminal can be driven from standard TTL circuits. There is no register on the data in terminal.

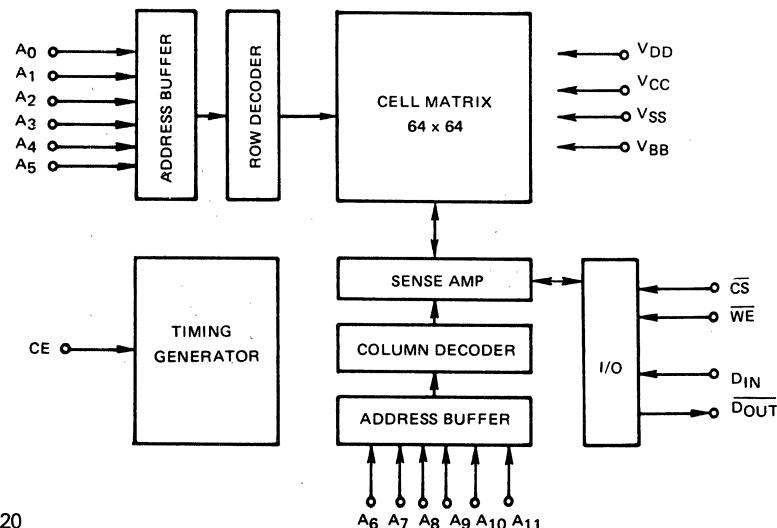

### **DOUT Data Output**

The three state output buffer provides direct TTL compatibility with a fan-out of two TTL gates. The output is in the high-impedance (floating) state when the chip enable is low or when the Chip Select input is high. Data output is inverted from data in.

### **Refresh**

Refresh must be performed every two milliseconds by cycling through the 64 addresses of the lower-order-address inputs A<sub>0</sub> through A<sub>5</sub> or by addressing every row within any 2-millisecond period. Addressing any row refreshes all 64 bits in that row.

The chip does not need to be selected during the refresh. If the chip is refreshed during a write mode, the chip select must be high.
