Ordering number : EN5350A
Wideband Output Module (Video Pack)

SANYO

VP553

CRT Display Video Output Amplifier

Features

- Active load circuits
- Wide bandwidth and high output voltage. Optimal for use in f_H (horizontal deflection frequency) = 90 kHz class ultrahigh precision monitors.
- Single 15-pin SIP molded package houses three channels.

Package Dimensions

unit: mm
2127A

[VP553]

Specifications

Absolute Maximum Ratings at Ta = 25°C

Parameter	Symbol	Conditions	Ratings	Unit
Maximum supply voltage	V_{CC} max		90	V
Allowable power dissipation	Pd max	With an ideal heat sink at Ta = 25°C	25	W
Maximum junction temperature	Tj max		150	°C
Maximum case temperature	Tc max		100	°C
Storage temperature	Tstg		−20 to +110	°C

Operating Conditions at Ta = 25°C

Parameter	Symbol	Conditions	Ratings	Unit
Recommended supply voltage	V_{CC}		80	V

Electrical Characteristics at Ta = 25°C (For a single channel, with Rin = 680 Ω, Rip = 22 Ω, Cip = 56 pF)

Parameter	Symbol	Conditions	Ratings min	Ratings typ	Ratings max	Unit
Clock frequency bandwidth (−3 dB)	f (clock)	V_{CC} = 80 V, C_L = 10 pF		160		MHz
Frequency bandwidth (−3 dB)	f_c	V_{IN} (DC) = 2.0 V, V_{OUT} (p-p) = 40 V		80		MHz
Pulse response	t_r	V_{CC} = 80 V, C_L = 10 pF		4.8		ns
	t_f	V_{IN} (DC) = 2.0 V, V_{OUT} (p-p) = 40 V		4.5		ns
Voltage gain	VG (DC)		13	15	17	Double
Current drain	$I_{CC}(1)$	V_{CC} = 80 V, V_{IN} (DC) = 2.0 V, f = 10 MHz clock, C_L = 10 pF, V_{OUT} (p-p) = 40 V		32		mA
	$I_{CC}(2)$	V_{CC} = 80 V, V_{IN} (DC) = 2.0 V, f = 100 MHz clock, C_L = 10 pF, V_{OUT} (p-p) = 40 V		75		mA

Thermal Design

Thermal design requires that the two conditions Tj (max) $\leq 150°C$ and $Tc \leq 100°C$ be met.

(a) Concerning Tj (max), the chip temperature Tj for each transistor is given by equation (1).

$$Tj = (Tri) = \theta j–c\ (Tri) \times P_C\ (Tri) + \Delta Tc + Ta\ (°C) ....(1)$$

$\theta j–c$ (Tri): The thermal resistance of each transistor chip itself

P_C (Tri): The collector loss for each transistor

ΔTc: Increase in the case temperature

Ta: Ambient temperature

$\theta j–c$ (Tri) for each chip will be:

$$\theta j–c\ (Tr1)\ to\ (Tr4) = 35°C/W ....(2)$$

The loss in transistors in a video pack varies with frequency. The loss increases with the frequency.

For example, if the maximum frequency will be 100 MHz (clock), then the transistors with the largest losses will be transistors 3 and 4 in the emitter-follower (EF) stage. From the Pd – f (clock) figure, we see that that loss will be 25% of the total for a single channel. That is:

$$P_C\ (EF\ stage)_{f = 100\ MHz} = Pd\ (1ch)_{f = 100\ MHz} \times 0.25\ [W]...................................(3)$$

The thermal design must assure that Tj does not exceed 150°C at this time.

(b) Concerning Tc (max), the relationship between θh and ΔTc is:

$$\Delta Tc = Pd\ (total) \times \theta h ....(4)$$

Taking the increase due to Ta into account, the condition the thermal design must meet becomes $Tc = \Delta Tc + Ta < 100°C$.

Next we design thermal conditions for the VP553 that meet the conditions in sections (a) and (b) above.

VP553

Sample Thermal Design for the VP553

Conditions: For an $f_H = 90$ kHz class monitor, $f_V = 100$ MHz (clock).

$V_{CC} = 80$ V, $V_{OUT} = 40$ Vp-p ($C_L = 10$ pF)

Here we consider the case where such a monitor is to be operated at ambient temperatures up to Ta = 60°C and at a maximum frequency of f = 100 MHz (clock).

As mentioned previously, the chips with the maximum loss will be transistors 3 and 4 in the emitter-follower stage. Equation (5) follows from deriving that value from the figure below and equation (3).

$$P_C (Tr3, 4)_{f = 100\ MHz} = 6.2 \times 0.25 \approx 1.55\ [W] \dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots(5)$$

However, the actual usage conditions include a blanking period. If we calculate the power during this period approximately at a 1-MHz power ratio, from Pd – f (clock) and P_C (Tri)Ratio – f (clock) figures, we see that P_C (BLK) for transistors 3 and 4 will be:

$$P_C\ BLK\ (Tr3, 4) = 2.2 \times 0.08 = 0.18\ [W]\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots(6)$$

If the blanking period is 20% of the total, from the data of equation (5) and formula (6) we see that the loss in transistors 3 and 4 will be:

$$P_C (Tr3, 4) = P_C (Tr3, 4)_{f = 100\ MHz} \times 0.8 + P_C BLK (Tr3, 4) \times 0.2 \approx 1.28\ [W]\dots(7)$$

Next, applying the value of θj–c to equation (7), shows ΔTj to be:

$$\Delta Tj = 1.28 \times 35 \approx 45\ [°C]$$

Since $\Delta Tj \leq 50°C$, it suffices to only consider the Tc ≤ 100°C condition in the thermal design. That is, in the thermal design we design θh so that Tc will be under 100°C when Pd (total) = Pd (1ch) × 3 for the time when all three channels are operating at their maximum levels.

$$\Delta Tc\ will\ be:\ \Delta Tc = 100 – 60 = 40°C$$

$$θh = \Delta Tc \div Pd\ (total) = 40 \div \{(6.2 \times 0.8 + 2.2 \times 0.2) \times 3\} = 2.5$$

Thus:

$$θh = 2.5°C/W$$

In actual use, due to the actual ambient temperature, the operating conditions, and other factors, it will be possible to use a heat sink smaller than the one required by the above design. Users should design an optimal heat sink using the data presented above and their actual conditions.
