High Definition Audio Codec

PRODUCT FEATURES

- **High Definition Audio Codec**
 - Intel High Definition Audio Specification Rev.1.0 Compliant
- **High Audio Quality**
 - Exceeds Microsoft Windows Logo Program (WLP) Requirements
 - High-performance ADCs with 98 dB SNR, DACs with 95 dB SNR
- **Various Output Format**
 - 4 Stereo DACs Output Pairs supporting 16/24-bit, 48/ 96/ 192/ 44.1/ 88.2 kHz sample rate
 - 2 Stereo ADCs supporting 16/24-bit, 44.1/ 48/ 96/ 192 kHz sample rate
 - 16/24-bit S/PDIF TX supports 48/ 96 / 44.1/ 88.2 kHz sample rate
 - 16/24-bit S/PDIF RX supports 32/ 48/ 96/ 44.1/ 88.2 kHz sample rate
- **Others**
 - HPF In ADC Path for DC Removal
 - Two Jack Detection Pins
 - Two GPO and Two GPI Pins for Customized Use
- **Power Supply**
 - Digital: 3.3V
 - Analog: 5V
 - Supports External Amplifier Power Down (EPAD)
 - Power Management and Enhanced Power Saving Features
- **Package**
 - Available in 48-Pin LQFP Lead-Free Package
- **Applications**

 - Laptop PCs

OVERVIEW

The VIA VT1708B is a quality High Definition Audio Codec designed for desktop and laptop PCs. It conforms to Intel High Definition Audio Specification Rev. 1.0 and delivers excellent audio performance that exceeds Microsoft Windows Logo Program (WLP) Requirements. VT1708B supports 98-dB ADC SNR and 95-dB DAC SNR. VT1708B features four 16-, 24-bit stereo digital-to-analog converter (DAC) output-pair channels, supporting audio sampling rates of 48 kHz, 96 kHz, 192 kHz, 44.1 kHz, 88.2 kHz, and two 16-, 24-bit stereo analog-to-digital converter (ADC) channels, supporting audio sampling rates of 44.1 kHz, 48 kHz, 96 kHz, and 192 kHz. VT1708B is capable of supporting various audio output stream formats.

VT1708B also features the 16-, 24-bit S/PDIF TX that supports sampling rates of 48 kHz, 96 kHz, 44.1 kHz, and 88.2 kHz, and the 16-, 24-bit S/PDIF RX that supports sampling rates of 32 kHz, 48 kHz, 96 kHz, 44.1 kHz, and 88.2 kHz. In addition, VT1708B features high-pass-filter (HPF) in analog-to-digital converter (ADC) path for removing DC offset signals. The two Jack Detection pins allow to sense if an audio device is plugged in. VT1708B provides two general-purpose-output (GPO) pins and two general-purpose-input (GPI) pins for customized configurations. VT1708B is available in the 48-Pin LQFP lead-free and RoHS compliant package. Figure 1 shows the functional block diagram of VT1708B High Definition Audio Codec.

HIGH DEFINITION AUDIO LINK PROTOCOL

Link Signaling

The link protocol defines the digital serial interface that connects High Definition Audio codec to the audio controller, and is not compatible with the previous AC97 protocol. The link is controller synchronous, based on a fixed 24MHz BITCLK and is purely isochronous without any flow control.

Figure 3. High Definition Audio Link Conceptual View

Signal Definitions

Table 3. Link Signal Description

Signal Name	Source	Type	Description
BITCLK	Controller	I	24 MHz clock
SYNC	Controller	I	Global 48 kHz Frame Sync and outbound tag signal
SDO	Controller	I	Bussed serial data output from controller
SDI	Codec & controller	I/O	Point-to-point serial data. Controller has a weak pull down
RESETN	Controller	I	Global active low reset signal

BITCLK is the 24 MHz clock sourced from the controller and connecting to all codec on the link.

SYNC marks input and output frame boundaries (Frame Sync) as well as identifying outbound data streams (stream tags). SYNC is always sourced from the controller and connects to all codec on the link.

SDO is driven by the controller to all codec on the link. Compared with AC97, the SDO is double pumped with respect to both rising and falling edges of BITCLK in order to increase the bandwidth required for High Definition Audio link.

SDI is a point-to-point data signal driven by the codec to the controller. Because the bandwidth requirement is not that high compared to SDO, data is single pumped with respect to only the rising edge of BITCLK. The controller is required to implement weak pull-down on all SDI signals.

RESETN is sourced from the controller and connects to all codec on the link. Assertion of RESETN results installation link interface logic being reset to default power on state.

Figure 6 shows that SID may only be toggled with respect to the rising edge of BITCLK. In particular, bit cell n+1 is driven by the codec on SDI with respect to rising clock edge #2 and is sampled by the controller with respect to the subsequent rising clock edge, #3 and so forth.

Figure 6. SDI Timing Relative to BITCLK

Signaling Topology

The following diagram shows a typical system with one controller and its associated codec.

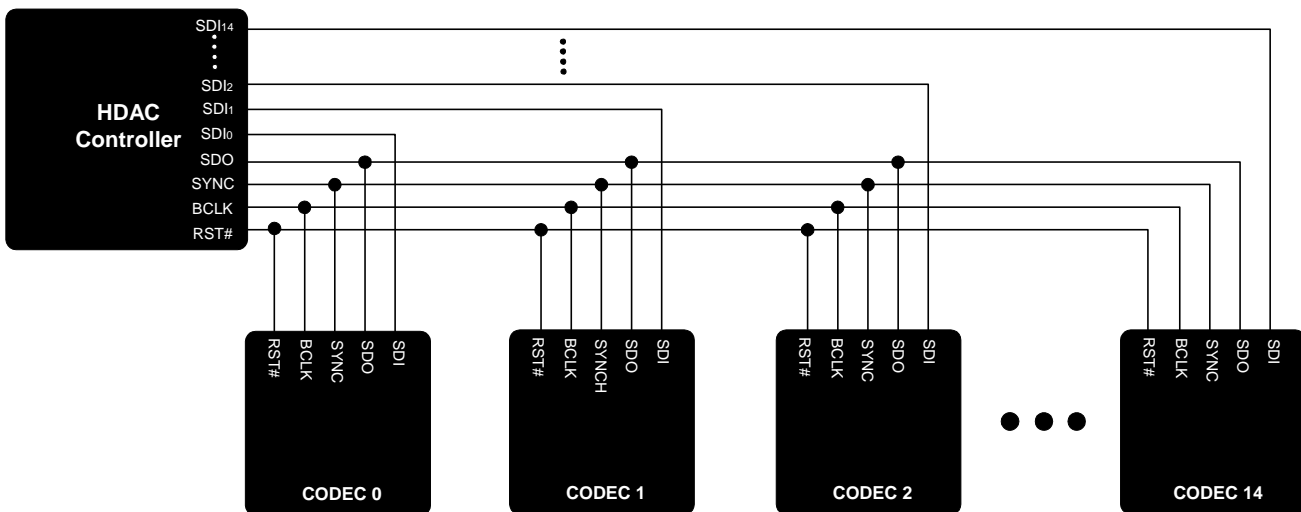

Figure 7. Basic High Definition Audio System

Frame Composition

A frame is defined as a 20.833us window of time marked by the falling edge of the Frame Sync marker, which identifies the start of each frame. The controller is responsible for generating the Frame Sync marker, which is a high-going pulse on SYNC, exactly four BITCLK in width.

Figure 8. Frames Demarcation

Both inbound and outbound frames are made up of three major components, specifically:

- A single Command / Response Field
- Zero or more Stream Packets
- A Null Field to fill out the frame

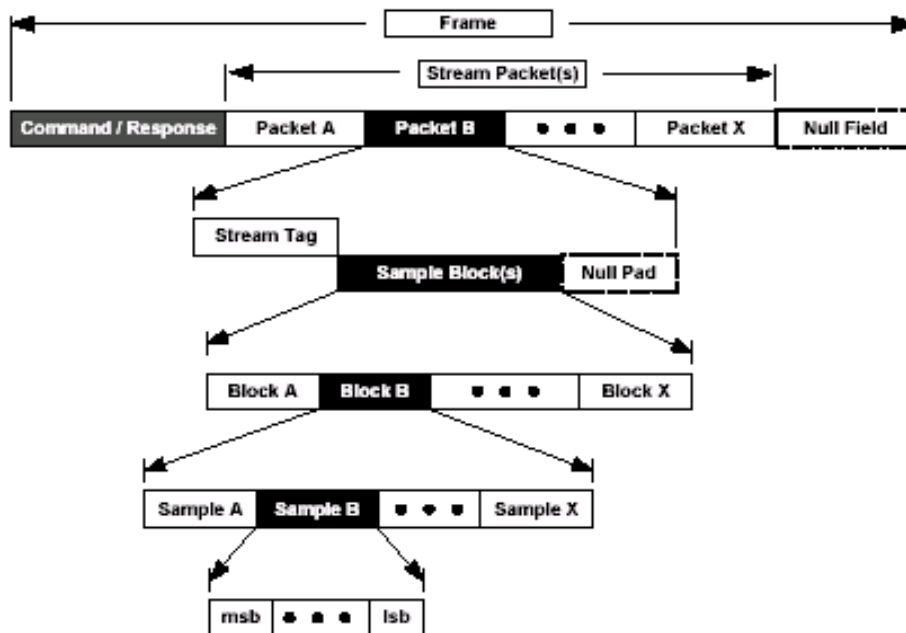

Figure 9. Frame Composition

Command / Response Field is used for link and codec management. One of these fields appears exactly once per frame, MSB first, and is always the first field in the frame. It is composed of a 40-bit Command Field on each outbound frame from the controller and a 36-bit Response Field on each inbound frame from the codec.

Stream Tag is the label at the beginning of each stream packet that provides the associated stream ID. All data in one stream packet belongs to a single stream.

Sample Block is a set of one or more samples, the number of which is specified by the “Channels” field of the Stream Descriptor Format registers. Samples in a given sample block are associated with a single given stream, have the same sample size and have the same time reference. And no padding is permitted between samples.

Ordering of samples within a block is always the same for all blocks in a given stream.

Sample is a set of bits providing a single sample point of a single analog waveform.

Null Field is used to fill up the remainder of the bits in each frame that are not used for Command/Response or packets. A null field must be transmitted as logical 0’s.

Output Frame

Stream Tags

Outbound stream tags are 8 bits in length and are transmitted at a double pumped rate as side band information on SYNC. It is composed of a 4-bit preamble which is signaled as three SDO bit times high followed by one SDO bit time low. This is immediately followed by a 4-bit Stream ID. Outbound stream tags are transmitted on SYNC so as to align with the last eight data bits of the preceding stream packet or Command Field.

Figure 10. Outbound Stream Tag Format and Transmission

Outbound Frames

Outbound frames start and end between the falling edges of successive Frame Syncs. The first 40 bits are dedicated for the Command field and are used to send commands to codec. The controller transmits the tag for the first outbound packet on SYNC during the last eight bit times of the Command field. The sample blocks for the first packet are transmitted on SDO immediately following the Command field. There is no proscribed order in which the different stream packets are to be transmitted. Controllers are required to transmit a null field for the remaining bits within an outbound frame when the transmission of the stream packets completes before the end of the frame.

Figure 11. Outbound Frame with Null Field

Input Frame

Stream Tags

An inbound stream tag is 10 bits in length, and is transmitted “in-line” at a single pumped rate on SDI, immediately preceding the associated inbound sample blocks. It is composed of a 4-bit stream ID, followed by a 6-bit data length field that provides the length, in bytes, of all sample blocks with the given stream packet.

Figure 12. Inbound Tag Format and Transmission

Inbound Frames

Inbound frames start and end between the falling edges of successive Frame Syncs. The first 36 bits of an inbound frame are dedicated for the Response Field, which codec use for sending responses to controller commands. The codec transmits the first stream packet on SID immediately following the Response Field. A stream tag indicating a packet length of zero must immediately follow the last stream packet to be transmitted. Such a stream tag marks the completion of data transmission within that frame, and the remaining valid bit positions are set to the null field. In the event there are less than 10 valid bit positions remaining in the frame after the last stream packet, then no termination tag is transmitted, and the remaining bits are the null field.

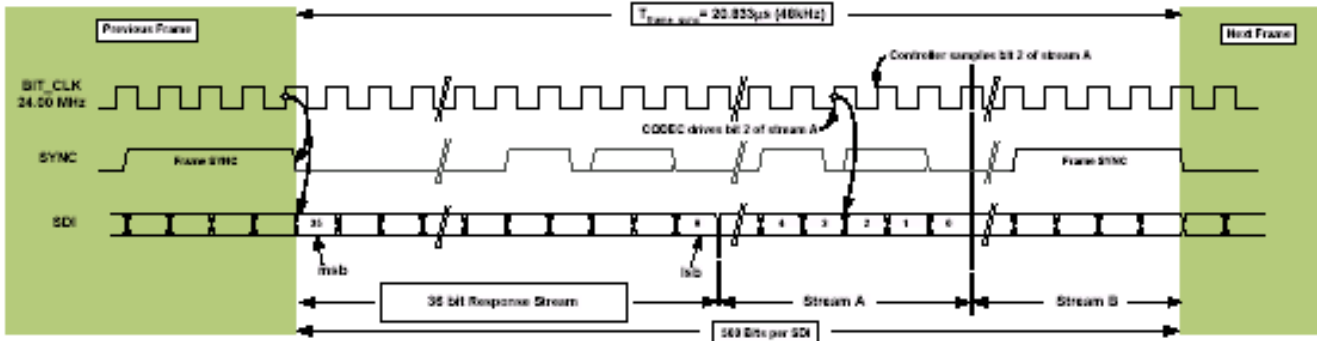

Figure 13. Inbound Frame with No Null Field

Reset and Initialization

Link Reset

A link reset is signaled on the link by assertion of the RESETN signal, and results in all Link interface logic in both codec and controller, including registers, being initialized to their default state. The controller drives all SDO and SYNC outputs low when entering or exiting link reset. A controller may only initiate the link reset entry sequence after completing any currently pending initialization or state change requests.

Figure 14. Link Reset Entry Sequence

Codec Initialization

With immediately following the completion of Link Reset sequence (or Function_Reset verb, if enabled by the vendor-defined verb), VT1708B proceeds through a codec initialization sequence, which provides each codec with a unique address by which it can thereafter be referenced with Commands on the SDO signal. During this sequence, the controller provides each requesting codec with a unique address using its attached SDI signals.

Figure 16. Codec Initialization Sequence

The codec initialization sequence occurs across three contiguous frames immediately following any reset sequence. During these three frames, codec are required to ignore all outbound traffic present on SYNC & SDO. These three frames, labeled “Connect Frame”, “Turnaround Frame” and “Address Frame”, are described below.

Connect and Turnaround Frames

In the Connect and Turnaround Frames, the codec signals its request for initialization on SDI and then releases SDI (turnaround) to be driven by the controller in the subsequent address frame.

Figure 17. Connect and Turnaround Frames

The codec signals an initialization request by synchronously driving SDI high during last bit clock cycle of Frame Sync. SDI must be asserted for the entire BITCLK cycle and be synchronously de-asserted on the same rising edge of BITCLK as the de-assertion of the Frame Sync. Codec are only permitted to signal an initialization request on a null input frame, in which no response stream or input streams are being sent.

In the Turnaround Frame, codec and controllers are required to turn SDI around upon the completion of the Connect Frame. To do this, the codec actively drives SDI low for one BITCLK cycle immediately following the de-assertion of SYNC at the end of the Connect Frame. The codec then puts its SDI drivers in a high impedance state at the end of the first BITCLK cycle in the Turnaround Frame. Four BITCLK cycles before the end of the Turnaround Frame, SYNC and SID are driven high by the controller. The SDI remains driven high through the end of the Turnaround Frame in preparation for the subsequent address frame.

Address Frames

During the Address Frame, SDI is a codec input and driven by the controller beginning in the last four BITCLK periods (Frame Sync) of the Turnaround Frame. The falling edge of Frame Sync marks the start of codec address assignment. Address assignment is indicated by the controller holding each SDI high for the number of BITCLK cycles equal to the numeric ID of that particular SDI. Thus the unique address of the codec becomes the ID of its attached SDI.

Figure 18. Address Frame

Codec count from zero to fourteen starting on the rising edge of BITCKL following the de-assertion of Frame Sync, and sample the value of this count for their unique address on the first rising edge of BITCLK in which SYNC and SDI are both sampled low.

The controller must put its SDI drivers in a high impedance state by the rising edge of the 18th BITCLK of the address frame but not before driving each SDI low for at least one clock cycle. The SDI then becomes an input to the controller. Normal link operation starts on the frame following the completion of the Address Frame, and the codec is required to actively drive a valid response field and to be ready to accept commands in this and subsequent frames.

Handling Stream Independent Sample Rates

Unlike AC97, the Link is source synchronous and has no codec initiated flow control, the controller generates all sample transfer timing.

Codec Sample Rendering Timing

VT1708B supports all the multiples and submultiples of the base rates of 48 kHz and 44.1 kHz up to the maximum rate of DAC and ADC respectively. For DAC, up to 192 kHz sample rate is supported. For ADC, the maximum rate is 96 kHz.

Table 4. Sample Rates Supported

Multiple	Base Rate 48 kHz	Base Rate 44.1 kHz
1/6	8 kHz	-
1/4	-	11.025 kHz
1/3	16 kHz	-
1/2	-	22.05 kHz
2/3	32 kHz	-
1	48 kHz	44.1 kHz
2	96 kHz	88.2 kHz
4	192 kHz	176.4 kHz

Link Sample Delivering Timing

For streams whose sample rate is a natural harmonic of 48 kHz, the timing is relatively straightforward. The rates in multiple (N) of 48 kHz are containing N sample blocks in one frame. For the rates in sub-multiple (1/N) of 48 kHz, there must be one sample block transmitted every one in N frames, and the intervening N-1 frames will contain no sample for this stream.

Since the link frame rate is fixed at 48 kHz, streams using a base rate of 44.1 kHz must have samples transmitted on a cadence creating the slightly lower aggregate transmission rate to match the slightly lower rendering rate. For streams running at a sample rate of 44.1 kHz, there are occasional frames that will not contain a sample generating the following cadence:

12-11-11-12-11-11-12-11-11-12-11-11-11- (repeat)

The dashes indicate frames that do not contain a sample block. The cadence repeats continuously generating exactly 147 sample blocks every 160 frames, and avoids any long-term drift between sample delivery and rendering clock.

Sample rates that are integral multiples of 44.1 kHz apply the “12-11” cadence rule just as a 44.1 kHz sample rate would, except that the non-empty frames contain multiple (2 or 4) sample blocks instead of just one.

For a sample rate of 22.05 kHz, the transmission pattern becomes:

{12}-*{11}-*{11}-*{12}-*{11}-*{11}-*{12}-*{11}-*{11}-*{12}-*{11}-*{11}-*{11}-* (repeat)

where

{12} = 1*1*1*1*1*1*1*1*1*1*

{11} = 1*1*1*1*1*1*1*1*

and the asterisks * represent a frame in which there is no sample block.

For a sample rate of 11.025 kHz, the transmission pattern becomes:
[12].*[11].***[11].***[12].***[11].***[11].***[12].***[11].***[11].***[12].***[11].***[11].*** (repeat)**

where
[12] = 1*1***1***1***1***1***1***1***1***1***1***1***1*****
[11] = 1*1***1***1***1***1***1***1***1***1*****

and the asterisks * represent a frame in which there is no sample block.

These framing sequences apply only to the outbound (SDO) data from the controller. Inbound (SDI) data transmitted by the codec is permitted to deviate for minimizing codec buffer management.

Power Management

Whenever the Link is commanded to enter a low power state, it enters the link-reset state. This state is only exited in response to a software command and follows all link rules for exiting the link-reset state.

The Audio Function Group and the analog input / output converter widgets support power control. The whole chip power states can be controlled through the Audio Function Group, while individual DACs and ADCs can also be controlled through the corresponding power state control verbs. The definitions of the power states are described in the following table.

Table 5. Power States Definitions

FUNCTION DESCRIPTIONS

Clock Control

- One of the major differences between High Definition Audio and AC97 is the clock source. The High Definition Audio controller provides a 24 MHz clock (BITCLK). An internal PLL (PLL1) in the codec uses BITCLK (24 MHz) as the reference clock and generates 49.152 MHz clocks for internal use. A second PLL (PLL2) also takes the 24 MHz BITCLK and generates 22.5792 MHz clock for 44.1 kHz based rates. The PLLs can be powered down by the Power Widget for power management.
- The interface signals between digital block and the 2 PLLs are listed below.

PLL1 (49.152 MHz)		
Pin Name	Direction (from PLL)	Pin Description
REFCLK	I	Connects to a 24-MHz clock input.
CLK49152	O	49.152-MHz clock output.
RST	I	When RST is high , the PLL enters a low power mode and all internal states are reset.
PWRPD	I	When PWRPD is high , the PLL enters a power-down mode.
VDD	I/O	Digital power supply for PFD and Dividers. Nominally 3.3V.
GND	I/O	Ground for PFD and Dividers.
VCOPWR	I/O	Analog power supply for VCO. Nominally 3.3V.
VCOGND	I/O	Ground for VCO.
CHGPPWR	I/O	Analog power supply for Bias and Charge Pump. Nominally 3.3V.
CHGPGND	I/O	Ground for Bias and Charge Pump.
PLL2 (22.5792 MHz)		
Pin Name	Direction (from PLL)	Pin Description
REFCLK	I	Connects to a 24-MHz clock input.
CLK225792	O	22.5792-MHz clock output.
RST	I	When RST is high , the PLL enters a low power mode and all internal states are reset.
PWRPD	I	When PWRPD is high , the PLL enters a power-down mode.
VDD	I/O	Digital power supply for PFD and Dividers. Nominally 3.3V.
GND	I/O	Ground for PFD and Dividers.
VCOPWR	I/O	Analog power supply for VCO. Nominally 3.3V.
VCOGND	I/O	Ground for VCO.
CHGPPWR	I/O	Analog power supply for Bias and Charge Pump. Nominally 3.3V.
CHGPGND	I/O	Ground for Bias and Charge Pump.

HPF for ADC DC Removal

- The built-in high-pass filter for each ADC can remove the DC component in the ADC data.

Audio Jack Detection Circuits

- Based on the jack detection circuit defined in the High Definition Audio specification, the figure below summarizes the equivalent resistance values to the SENSE pin in different scenario.

Figure 19. Jack Detect Circuit

Internal Loopback and Peak Detection for Low Cost Production Test

- Internal loopback paths can be used to test all DACs and ADCs functions. The output of each DAC can be routed back to the input of the ADC. The ADC output data is analyzed by a specially designed block to detect the zero-crossing point and the peak values. These information can be read back to decide whether the digital and analog functions are normal. Refer to the descriptions in the Vendor-Defined Verbs in the Audio Function Group.

Absolute Maximum Ratings

Symbol	Condition	Min	Max	Unit
T _S	Storage Temperature	-55	+125	°C
T _A	Ambient Operating Temperature	0	+85	°C
VESD	Electrostatic Discharge (Human Body)	-	2	kV

Note: Stress above the conditions listed may cause permanent damage to the device. Functional operation of this device should be restricted to the conditions described under operating conditions.

Recommended Operating Conditions

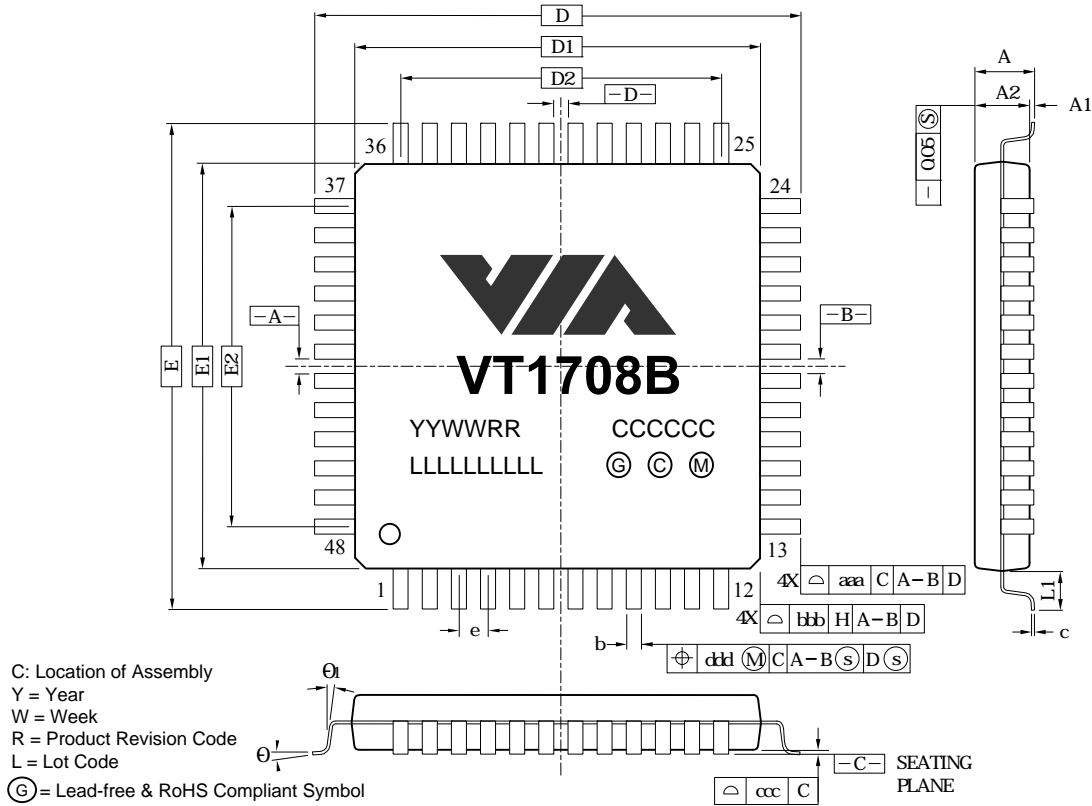

Symbol	Condition	Min	Typ	Max	Unit
DVDD	Digital Power Supplies	3.135	3.3	3.465	V
AVDD	Analog Power Supplies (preferred)	-	5	-	V
AVDD	Analog Power Supplies (for low-power apps)	-	3.3	-	V

MECHANICAL SPECIFICATIONS

- NOTES :
- DIMENSIONS D1 AND E1 DO NOT INCLUDE MOLD PROTRUSION. ALLOWABLE PROTRUSION IS 0.25mm PER SIDE. D1 AND E1 ARE MAXIMUM PLASTIC BODY SIZE DIMENSIONS INCLUDING MOLD MISMATCH
 - DIMENSION b DOES NOT INCLUDE DAMBAR PROTRUSION. ALLOWABLE DAMBAR PROTRUSION SHALL NOT CAUSE THE LEAD WIDTH TO EXCEED THE MAXIMUM b DIMENSION BY MORE THAN 0.08mm. DAMBAR CAN NOT BE LOCATED ON THE LOWER RADIUS OR THE FOOT. MINIMUM SPACE BETWEEN PROTRUSION AND AN ADJACENT LEAD IS 0.07mm

CONTROL DIMENSIONS ARE IN MILLIMETERS.
