## 1. GENERAL DESCRIPTION

The W29N08GV (8G-bit) NAND Flash memory provides a storage solution for embedded systems with limited space, pins and power. It is ideal for code shadowing to RAM, solid state applications and storing media data such as, voice, video, text and photos. The device operates on a single 2.7V to 3.6V power supply with active current consumption as low as 25mA and 10uA for CMOS standby current.

The memory array totals 1,107,296bytes, and organized into 8,192 erasable blocks. Each block consists of 64 programmable pages of 2,112-bytes (1056 words) each. Each page consists of 2,048-bytes (1024 words) for the main data storage area and 64-bytes (32words) for the spare data area (The spare area is typically used for error management functions).

The W29N08GV is double chip stack of W29N04GV. Then, this document shows specified features, functions of W29N08GV. Detail functions, commands operation, AC, DC characteristics and restrictions refer to W29N04GV datasheet.

2. PACKAGE TYPES AND PIN CONFIGURATIONS

2.1 W29N08GVSIAA Pin assignment 48-pin TSOP1

Figure 1 Pin Assignment 48-pin TSOP1 1CE Type (Package code S)

2.2 W29N08GVSIAD Pin assignment 48-pin TSOP1

Figure 2 Pin Assignment 48-pin TSOP1 2CE Type (Package code S)

Note:

1. These pins might not be connected in the package. Winbond recommends connecting these pins to the designed external sources for ONFI compatibility.

3 <sup>rd</sup> cycle	A19	A18	A17	A16	A15	A14	A13	A12
4 <sup>th</sup> cycle	A27	A26	A25	A24	A23	A22	A21	A20
5 <sup>th</sup> cycle	L	L	L	L	L	A30 <sup>4</sup>	A29	A28

Table 2 Addressing

**Notes:**

1. "L" indicates a low condition, which must be held during the address cycle to insure correct processing.
2. A0 to A11 during the 1st and 2nd cycles are column addresses. A12 to A30 during the 3rd, 4th and 5th cycles are row addresses, A18 is plane address, A19 to the last address are block addresses.
3. The device ignores any additional address inputs that exceed the device's requirement.
4. The last address of W29N08GVxIAA (8Gb-1CE type) is A30.

**4. DEVICE ID**

Table 5 DC Electrical Characteristics

**Note:**

1. V<sub>OH</sub> and V<sub>OL</sub> may need to be relaxed if I/O drive strength is not set to full.
2. I<sub>OL</sub> (R<sub>Y</sub>/#B<sub>Y</sub>) may need to be relaxed if R<sub>Y</sub>/#B<sub>Y</sub> pull-down strength is not set to full

## 7. INVALID BLOCKS

The W29N08GV may have initial invalid blocks when it ships from factory. Also, additional invalid blocks may develop during the use of the device. Nvb represents the minimum number of valid blocks in the total number of available blocks (See Table 5). An invalid block is defined as blocks that contain one or more bad bits. Block 0, block address 00h is guaranteed to be a valid block at the time of shipment.

<b>Parameter</b>	<b>Symbol</b>	<b>Min</b>	<b>Max</b>	<b>Unit</b>
Valid block number	Nvb	8032	8192	blocks

## 1. GENERAL DESCRIPTION

The W29N04GV (4G-bit) NAND Flash memory provides a storage solution for embedded systems with limited space, pins and power. It is ideal for code shadowing to RAM, solid state applications and storing media data such as, voice, video, text and photos. The device operates on a single 2.7V to 3.6V power supply with active current consumption as low as 25mA at 3V and 10uA for CMOS standby current.

The memory array totals 553,648,128bytes, and organized into 4,096 erasable blocks of 135,168 bytes. Each block consists of 64 programmable pages of 2,112-bytes each. Each page consists of 2,048-bytes for the main data storage area and 64-bytes for the spare data area (The spare area is typically used for error management functions).

The W29N04GV supports the standard NAND flash memory interface using the multiplexed 8-bit bus to transfer data, addresses, and command instructions. The five control signals, CLE, ALE, #CE, #RE and #WE handle the bus interface protocol. Also, the device has two other signal pins, the #WP (Write Protect) and the RY/#BY (Ready/Busy) for monitoring the device status.

## 2. FEATURES

### • Basic Features

- Density : 4Gbit (Single chip solution)
- Vcc : 2.7V to 3.6V
- Bus width : x8
- Operating temperature
  - Industrial: -40°C to 85°C

### • Single-Level Cell (SLC) technology.

### • Organization

- Density: 4G-bit/512M-byte
- Page size
  - 2,112 bytes (2048 + 64 bytes)
- Block size
  - 64 pages (128K + 4K bytes)

### • Highest Performance

- Read performance (Max.)
  - Random read: 25us
  - Sequential read cycle: 25ns
- Write Erase performance
  - Page program time: 250us(typ.)
  - Block erase time: 2ms(typ.)
- Endurance 100,000 Erase/Program Cycles<sup>(1)</sup>
- 10-years data retention

### • Command set

- Standard NAND command set
- Additional command support
  - Sequential Cache Read
  - Random Cache Read
  - Cache Program
  - Copy Back
  - Two-plane operation
- Contact Winbond for OTP feature
- Contact Winbond for Block Lock feature

### Note:

1. Endurance specification is based on 1bit/528 byte ECC (Error Correcting Code).

### **3. PIN DESCRIPTIONS**

#### **3.1 Chip Enable (#CE)**

#CE pin enables and disables device operation. When #CE is high the device is disabled and the I/O pins are set to high impedance and enters into standby mode if not busy. When #CE is set low the device will be enabled, power consumption will increase to active levels and the device is ready for Read and Write operations.

#### **3.2 Write Enable (#WE)**

#WE pin enables the device to control write operations to input pins of the device. Such as, command instructions, addresses and data that are latched on the rising edge of #WE.

#### **3.3 Read Enable (#RE)**

#RE pin controls serial data output from the pre-loaded Data Register. Valid data is present on the I/O bus after the tREA period from the falling edge of #RE. Column addresses are incremented for each #RE pulse.

#### **3.4 Address Latch Enable (ALE)**

ALE pin controls address input to the address register of the device. When ALE is active high, addresses are latched via the I/O pins on the rising edge of #WE.

#### **3.5 Command Latch Enable (CLE)**

CLE pin controls command input to the command register of the device. When CLE is active high, commands are latched into the command register via I/O pins on the rising edge of #WE.

#### **3.6 Write Protect (#WP)**

#WP pin can be used to prevent the inadvertent program/erase to the device. When #WP pin is active low, all program/erase operations are disabled.

#### **3.7 Ready/Busy (RY/#BY)**

RY/#BY pin indicates the device status. When RY/#BY output is low, it indicates that the device is processing either a program, erase or read operations. When it returns to high, those operations have completed. RY/#BY pin is an open drain.

#### **3.8 Input and Output (I/Ox)**

I/Ox bi-directional pins are used for the following; command, address and data operations.

4. BLOCK DIAGRAM

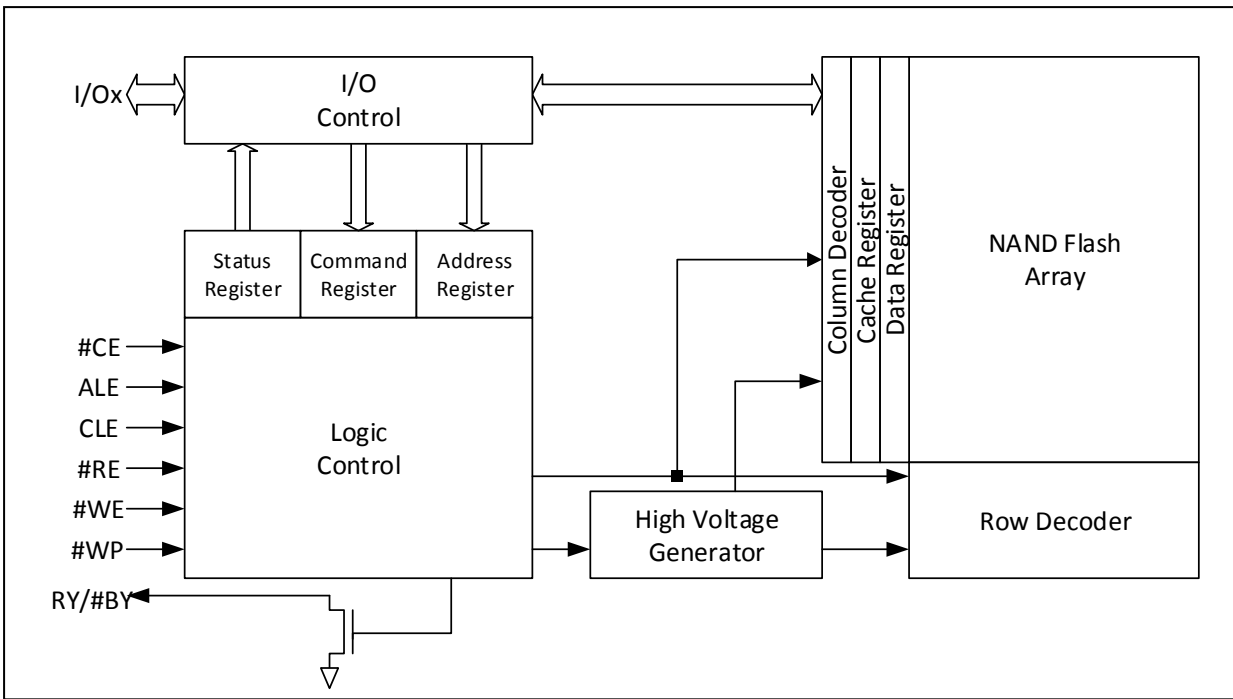

Figure 4-1 NAND Flash Memory Block Diagram

## 6. MODE SELECTION TABLE

MODE		CLE	ALE	#CE	#WE	#RE	#WP
Read mode	Command input	H	L	L		H	X
	Address input	L	H	L		H	X
Program Erase mode	Command input	H	L	L		H	H
	Address input	L	H	L		H	H
Data input		L	L	L		H	H
Sequential Read and Data output		L	L	L	H		X
During read (busy)		X	X	X	X	H	X
During program (busy)		X	X	X	X	X	H
During erase (busy)		X	X	X	X	X	H
Write protect		X	X	X	X	X	L
Standby		X	X	H	X	X	0V/Vcc

Table 6-1 Mode Selection

**Notes:**

1. "H" indicates a HIGH input level, "L" indicates a LOW input level, and "X" indicates a Don't Care Level.
2. #WP should be biased to CMOS HIGH or LOW for standby.

## 7. COMMAND TABLE

COMMAND	1 <sup>ST</sup> CYCLE	2 <sup>ND</sup> CYCLE	3 <sup>rd</sup> CYCLE	4 <sup>th</sup> CYCLE	Acceptable during busy
PAGE READ	00h	30h			
READ for COPY BACK	00h	35h

TWO PLANE CACHE PROGRAM(END)(TRADITIONAL)	80h	11h	81h	10h	
TWO PLANE CACHE PROGRAM(END)(ONFI)	80h	11h	80h	10h	
TWO PLANE PROGRAM FOR COPY BACK(TRADITIONAL)	85h	11h	81h	10h	
TWO PLANE PROGRAM FOR COPY BACK(ONFI)	85h	11h	85h	10h	

TWO PLANE BLOCK ERASE(TRADITIONAL)	60h	60h	D0h		
TWO PLANE BLOCK ERASE(ONFI)	60h	D1h	60h	D0h	

Table 7-1 Command Table

**Notes:**

1. **RANDOM DATA INPUT and RANDOM DATA OUTPUT command is only to be used within a page.**
2. **Any commands that are not in the above table are considered as undefined and are prohibited as inputs.**
3. **Do not cross plane address boundaries when using Copy Back Read and Program for copy back.**

## 8. DEVICE OPERATIONS

### 8.1 READ operation

#### 8.1.1 PAGE READ (00h-30h)

When the device powers on, 00h command is latched to command register. Therefore, system only issues five address cycles and 30h command for initial read from the device. This operation can also be entered by writing 00h command to the command register, and then write five address cycles, followed by writing 30h command. After writing 30h command, the data is transferred from NAND array to Data Register during  $t_R$ . Data transfer progress can be done by monitoring the status of the RY/#BY signal output. RY/#BY signal will be LOW during data transfer. Also, there is an alternate method by using the READ STATUS (70h) command. If the READ STATUS command is issued during read operation, the Read (00h) command must be re-issued to read out the data from Data Register. When the data transfer is complete, RY/#BY signal goes HIGH, and the data can be read from Data Register by toggling #RE. Read is sequential from initial column address to the end of the page. (See Figure 9-1)

Figure 8-1 Page Read Operations

#### 8.1.2 CACHE READ OPERATIONS

To obtain a higher degree of performance read operations, the device's Cache and Data Register can be used independent of each other. Data can be read out from the Cache Register, while array data is transferred from the NAND Array to the Data Register.

The CACHE READ mode starts with issuing a PAGE READ command (00h-30h) to transfer a page of data from NAND array to the Cache Register. RY/#BY signal will go LOW during data transfer indicating a busy status. Copying the next page of data from the NAND array to the Data Register while making the Cache Register page data available is done by issuing either a SEQUENTIAL CACHE READ (31h) or RANDOM CACHE READ (00h-31h) command. The SEQUENTIAL CACHE READ mode will copy the next page of data in sequence from the NAND array to the Data Register or use the RANDOM CACHE READ mode (00h-31h) to copy a random page of data from NAND array to the Data Register. The RY/#BY signal goes LOW for a period of  $t_{RCBSY}$  during the page data transfer from NAND array to the Data Register. When RY/#BY goes HIGH, this means that the

Cache Register data is available and can be read out of the Cache Register by with toggling #RE, which starts at address column 0. If it is desired to start at a different column address, a RANDOM DATA OUTPUT (05h-E0h) command can be used to change the column address to read out the data.

At this point in the procedure when completing the read of the desired number of bytes, one of two things can be chosen. Continue CACHE READ (31h or 00h-31h) operations or end the CACHE READ mode with a LAST ADDRESS CACHE READ (3Fh) command.

To continue with the read operations, execute the CACHE READ (31h or 00h-31h) command. The RY/#BY signal goes LOW for the period of tRCBSY while data is copied from Data Register to the Cache Register and the next page of data starts being copied from the NAND array to the Data Register. When RY/#BY signal goes HIGH signifying that the Cache Register data is available, at this time #RE can start toggling to output the desired data starting at column 0 address or using the RANDOM DATA OUPUT command for random column address access.

To terminate the CACHE READ operations a LAST ADDRESS CACHE READ (3Fh) command is issued, RY/#BY signal goes LOW and the Data Register contents is copied to the Cache Register. At the completion of the Data Register to Cache Register transfer, RY/#BY goes HIGH indicating data is available at the output of the Cache Register. At this point Data can be read by toggling #RE starting at column address 0 or using the RANDOM DATA OUPUT command for random column address access. The device NAND array is ready for next command set.

**8.1.2.1. SEQUENTIAL CACHE READ (31h)**

The SEQUENTIAL CACHE READ (31h) copies the next page of data in sequence within block to the Data Register while the previous page of data in the Cache Register is available for output. This is done by issuing the command (31h), RY/#BY signal goes LOW and the STATUS REGISTER bits 6 and 5 = "00" for the period of tRCBSY. When RY/#BY signal goes HIGH and STATUS REGISTER bits 6 and 5 = "10", data at the Cache Register is available. The data can be read out from the Cache Register by toggling #RE, starting address is column 0 or by using the RANDOM DATA OUTPUT command for random column address access.

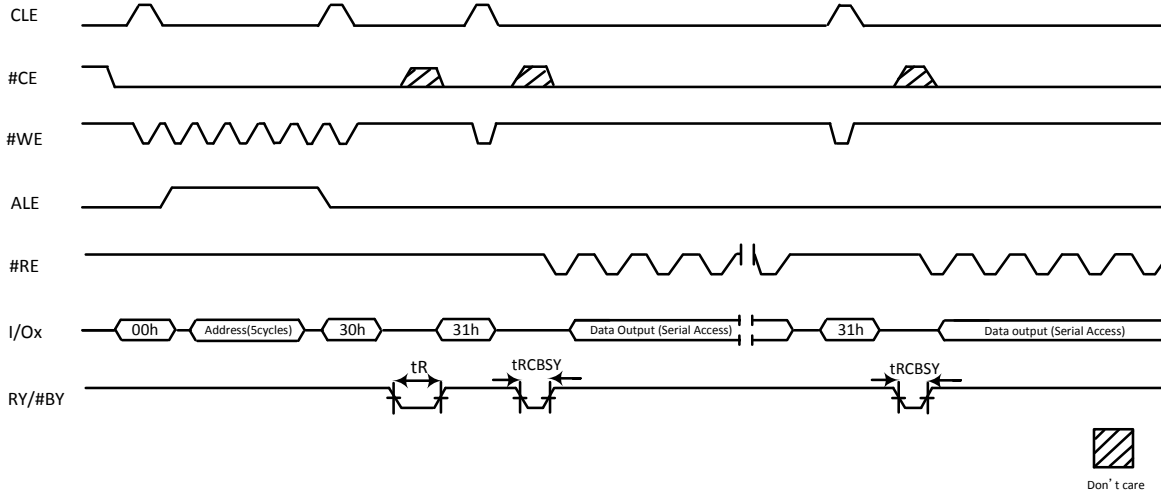

Figure 8-2 Sequential Cache Read Operations

**8.1.2.2. RANDOM CACHE READ (00h-31h)**

The RANDOM CACHE READ (00h-31h) will copy a particular page from NAND array to the Data Register while the previous page of data is available at the Cache Register output. Perform this function by first issuing the 00h command to the Command Register, then writing the five address cycles for the desired page of data to the Address Register. Then write the 31h command to the Command Register. Note; the column address bits are ignored.

After the RANDOM CACHE READ command is issued, RY/#BY signal goes LOW and STATUS REGISTER bits 6 and 5 equal "00" for the period of tRCBSY. When RY/#BY signal goes HIGH and STATUS REGISTER bits 6 and 5 equal "10", the page data in the Cache Register is available. The data can read out from the Cache Register by toggling #RE, the starting column address will be 0 or use the RANDOM DATA OUTPUT (05h-E0h) command change the column address to start reading out the data.

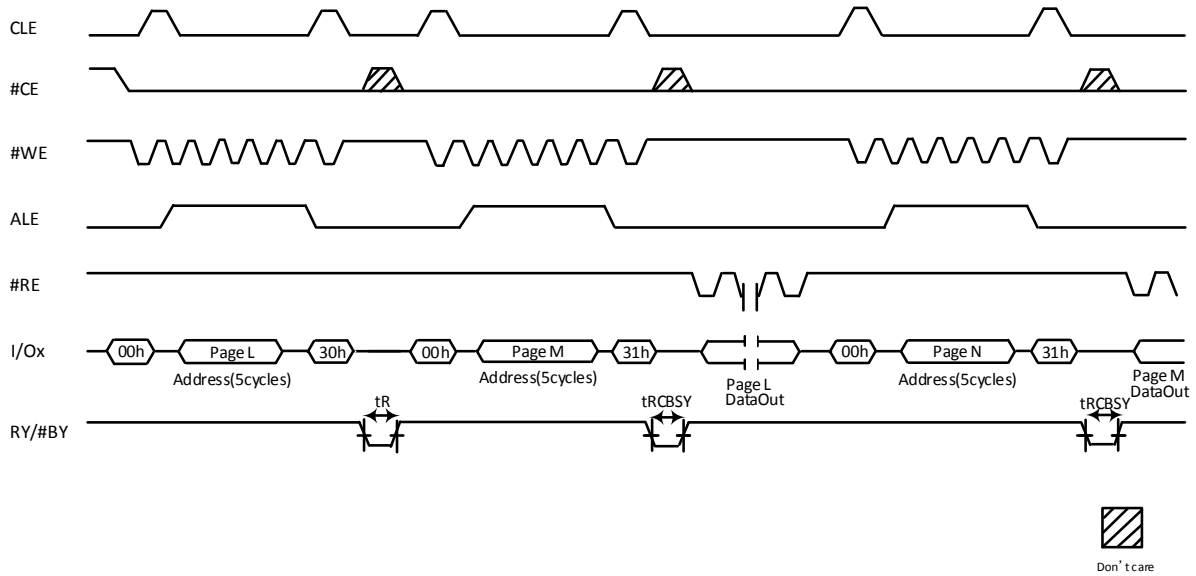

Figure 8-3 Random Cache Read Operation

### 8.1.2.3. LAST ADDRESS CACHE READ (3Fh)

The LAST ADDRESS CACHE READ (3Fh) copies a page of data from the Data Register to the Cache Register without starting the another cache read. After writing the 3Fh command, RY/#BY signal goes LOW and STATUS REGISTER bits 6 and 5 equals "00" for the period of tRCBSY. When RY/#BY signal goes HIGH and STATUS REGISTER bits 6 and 5 equals "11", the Cache Register data is available, and the device NAND array is in ready state. The data can read out from the Cache Register by toggling #RE, starting at address column 0 or us RANDOM DATA OUTPUT (05h-E0h) command to change the column address to read out the data.

Figure 8-4 Last Address Cache Read Operation

### 8.1.3 TWO PLANE READ (00h-00h-30h)

TWO PLANE READ (00h-00h-30h) transfers two pages data from the NAND array to the data registers. Each page address have to be indicated different plane address.

To set the TWO PLANE READ mode, write the 00h command to the command register, and then write five address cycles for plane 0. Secondly, write the 00h command to the command register, and five address cycles for plane 1. Finally, the 30h command is issued. The first-plane and second-plane addresses must be identical for all of issued address except plane address.

After the 30h command is written, page data is transferred from both planes to their respective data registers in tR. RY/#BY goes LOW While these are transferred,. When the transfers are complete, RY/#BY goes HIGH. To read out the data, at first, system writes TWO PLANE RANDM DATA READ (06h-E0h) command to select a plane, next, repeatedly pulse #RE to read out the data from selected plane. To change the plane address, issues TWO PLANE RANDOM DATA READ (06h-E0h) command to select the another plane address, then repeatedly pulse #RE to read out the data from the selected plane data register.

Alternatively, data transfers can be monitored by the READ STATUS (70h). When the transfers are complete, status register bit 6 is set to 1. To read data from the first of the two planes even when

READ STATUS ENHANCED (78h) command is used, the system must issue the TWO PLANE RANDOM DATA READ (06h-E0h) command at first and pulse #RE repeatedly.

Write a TWO PLANE RANDOM DATA READ (06h-E0h) command to select the other plane ,after the data cycle is complete. pulse #RE repeatedly to output the data beginning at the specified column address,

During TWO PLANE READ operation,the READ STATUS ENHANCED (78h) command is prohibited .

Figure 8-5 Two Plane Read Page (00h-00h-30h) Operation

#### 8.1.4 RANDOM DATA OUTPUT (05h-E0h)

The RANDOM DATA OUTPUT allows the selection of random column addresses to read out data from a single or multiple of addresses. The use of the RANDOM DATA OUTPUT command is available after the PAGE READ (00h-30h) sequence by writing the 05h command following by the two cycle column address and then the E0h command. Toggling #RE will output data sequentially. The RANDOM DATA OUTPUT command can be issued multiple times, but limited to the current loaded page.

Figure 8-6 Random Data Output

##### 8.1.4.1. TWO PLANE RANDOM DATA OUTPUT (06h-E0h)

TWO PLANE RANDOM DATA READ (06h-E0h) command can indicate to specified plane and column address on cache register. This command is accepted by a device when it is ready.

Issuing 06h to the command register, two column address cycles, three row address cycles, E0h are followed, this enables data output mode on the address device's cache register at the specified column address. After the E0h command, the host have to wait at least  $t_{WHR}$  before requesting data output. The selected device is in data output mode until another valid command is issued.

The TWO PLANE RANDOM DATA READ (06h-E0h) command is used to select the cache register to be enabled for data output. When the data output is complete on the selected plane, the command can be issued again to start data output on another plane.

If there is a need to update the column address without selecting a new cache register, the RANDOM DATA READ (05h-E0h) command can be used instead.

Figure 8-7 Two Plane Random Data Read (06h-E0h) Operation

**8.1.5 READ ID (90h)**

READ ID command is comprised of two modes determined by the input address, device (00h) or ONFI (20h) identification information. To enter the READ ID mode, write 90h to the Command Register followed by a 00h address cycle, then toggle #RE for 5 single byte cycles, W29N04GV. The pre-programmed code includes the Manufacturer ID, Device ID, and Product-Specific Information (see Table 9.1). If the READ ID command is followed by 20h address, the output code includes 4 single byte cycles of ONFI identifying information (See Table 9.2). The device remains in the READ ID Mode until the next valid command is issued.

Figure 8-8 Read ID

# of Byte/Cycles	1 <sup>st</sup> Byte/Cycle	2 <sup>nd</sup> Byte/Cycle	3 <sup>rd</sup> Byte/Cycle	4 <sup>th</sup> Byte/Cycle
Code	4Fh	4Eh	46h	49h

Table 8-1 ONFI identifying codes for Address 20h

### 8.1.6 READ PARAMETER PAGE (ECh)

READ PARAMETER PAGE can read out the device's parameter data structure, such as, manufacturer information, device organization, timing parameters, key features, and other pertinent device parameters. The data structure is stored with at least three copies in the device's parameter page. Figure 9-9 shows the READ PARAMETER PAGE timing. The RANDOM DATA OUTPUT (05h-E0h) command is supported during data output.

Figure 8-9 Read Parameter Page

### 8.1.7 READ STATUS (70h)

The W29N04GV has an 8-bit Status Register which can be read during device operation. Refer to Table 9.4 for specific Status Register definitions. After writing 70h command to the Command Register, read cycles will only read from the Status Register. The status can be read from I/O[7:0] outputs, as long as #CE and #RE are LOW. Note; #RE does not need to be toggled for Status Register read. The Command Register remains in status read mode until another command is issued. To change to normal read mode, issue the PAGE READ (00h) command. After the PAGE READ command is issued, data output starts from the initial column address.

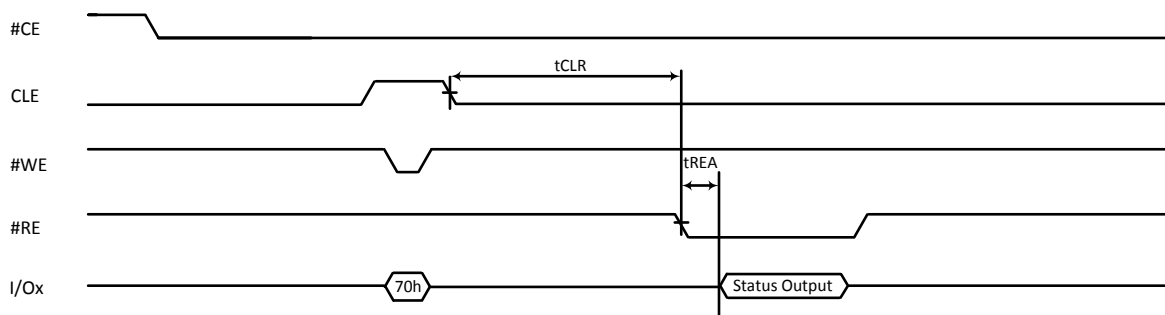

Figure 8-10 Read Status Operation

SR bit	Page Read	Cache Read	Page Program	Cache Program	Block Erase	Definition
I/O 0	Not Use	Not Use	Pass/Fail	Pass/Fail(N)	Pass/Fail	0=Successful Program/Erase 1=Error in Program/Erase
I/O 1	Not Use	Not Use	Not Use	Pass/Fail(N-1)	Not Use	0=Successful Program 1=Error in Program
I/O 2	Not Use	Not Use	Not Use	Not Use	Not Use	0
I/O 3	Not Use	Not Use	Not Use	Not Use	Not Use	0
I/O 4	Not Use	Not Use	Not Use	Not Use	Not Use	0
I/O 5	Ready/Busy	Ready/Busy <sub>1</sub>	Ready/Busy	Ready/Busy	Ready/Busy	Ready = 1 Busy = 0
I/O 6	Ready/Busy	Cache Ready/Busy <sub>2</sub>	Ready/Busy	Cache Ready/Busy	Ready/Busy	Ready = 1 Busy = 0
I/O 7	Write Protect	Write Protect	Write Protect	Write Protect	Write Protect	Unprotected = 1 Protected = 0

Table 8-2 Status Register Bit Definition

**Notes:**

1. SR bit 5 is 0 during the actual programming operation. If cache mode is used, this bit will be 1 when all internal operations are complete.
2. SR bit 6 is 1 when the Cache Register is ready to accept new data. RY/#BY follows bit 6.

### 8.1.8 READ STATUS ENHANCED (78h)

The READ STATUS ENHANCED (78h) command returns the status of the addressed plane on a target even when it is busy (SR BIT 6 = 0).

Writing 78h to the command register, followed by three row address cycles containing the page, plane and block addresses that is same as executed addresses, puts the device into read status mode. The device stays in this mode until another valid command is issued

The device status is returned when the host requests data output. The SR BIT 6 and SR bit 5 bits of the status register are shared for all planes on the device. The SR BIT 1 and SR BIT 0 (SR bit0) bits are specific to the plane specified in the row address.

The READ STATUS ENHANCED (78h) command also enables the device for data output. To begin data output following a READ operation after the device is ready (SR BIT 6 = 1), issue the READ MODE (00h) command, then begin data output. If the host needs to change the cache register that will output data, use the TWO PLANE RANDOMDATA READ (06h-E0h) command after the device is ready

Use of the READ STATUS ENHANCED (78h) command is prohibited when OTP mode is enabled. It is also prohibited following some of the other reset, identification.

Figure 8-11 Read Status Enhanced (78h) Operation

**8.1.9 READ UNIQUE ID (EDh)**

The W29N04GV NAND Flash device has a method to uniquely identify each NAND Flash device by using the READ UNIQUE ID command. The format of the ID is limitless, but the ID for every NAND Flash device manufactured, will be guaranteed to be unique.

Numerous NAND controllers typically use proprietary error correction code (ECC) schemes. In these cases Winbond cannot protect unique ID data with factory programmed ECC. However, to ensure data reliability, Winbond will program the NAND Flash devices with 16 bytes of unique ID code, starting at byte 0 on the page, immediately followed by 16 bytes of the complement of that unique ID. The combination of these two actions is then repeated 16 times. This means the final copy of the unique ID will reside at location byte 511. At this point an XOR or exclusive operation can be performed on the first copy of the unique ID and its complement. If the unique ID is good, the results should yield all the bits as 1s. In the event that any of the bits are 0 after the XOR operation, the procedure can be repeated on a subsequent copy of the unique ID data.

Figure 8-12 Read Unique ID

## 8.2 PROGRAM operation

### 8.2.1 PAGE PROGRAM (80h-10h)

The W29N04GV Page Program command will program pages sequentially within a block, from the lower order page address to higher order page address. Programming pages out of sequence is prohibited. The W29N04GV supports partial-page programming operations up to 4 times before an erase is required if partitioning a page. Note; programming a single bit more than once without first erasing it is not supported.

### 8.2.2 SERIAL DATA INPUT (80h)

Page Program operation starts with the execution of the Serial Data Input command (80h) to the Command Register, following next by inputting five address cycles and then the data is loaded. Serial data is loaded to Cache Register with each #WE cycle. The Program command (10h) is written to the Command Register after the serial data input is finished. At this time the internal write state controller automatically executes the algorithms for program and verifies operations. Once the programming starts, determining the completion of the program process can be done by monitoring the RY/#BY output or the Status Register Bit 6, which will follow the RY/#BY signal. RY/#BY will stay LOW during the internal array programming operation during the period of (tPROG). During page program operation, only two commands are available, READ STATUS (70h) and RESET (FFh). When the device status goes to the ready state, Status Register Bit 0 (I/O) indicates whether the program operation passed (Bit0=0) or failed (Bit0=1), (see Figure 9-13). The Command Register remains in read status mode until the next command is issued.

Figure 8-13 Page Program

### 8.2.3 RANDOM DATA INPUT (85h)

After the Page Program (80h) execution of the initial data has been loaded into the Cache Register, if the need for additional writing of data is required, using the RANDOM DATA INPUT (85h) command can perform this function to a new column address prior to the Program (10h) command. The RANDOM DATA INPUT command can be issued multiple times in the same page (See Figure 9-14).

Figure 8-14 Random Data Input

### 8.2.4 CACHE PROGRAM (80h-15h)

CACHE PROGEAM (80h) command is started by writing the command to the Command Register. The next writes should be five cycles of address, and then either writing a full or partial page of input data into the Cache Register. Issuing the CACHE PROGRAM (15h) command to the Command Register, starting transferring data from the Cache Register to the Data Register on the rising edge of #WE and RY/#BY will go LOW. Programming to the array starts after the data has been copied into the Data Register and RY/#BY returns to HIGH.

When RY/#BY returns to HIGH, the next input data can be written to the Cache Register by issuing another CACHE PROGRAM command series. The time RY/#BY goes LOW, is typical controlled by the actual programming time. The time for the first programming pass equals the time it takes to transfer the data from the Cache Register to the Data Register. On the second and subsequent programming passes, data transfer from the Cache Register to the Data Register is held until Data Register content is programming into the NAND array.

The CACHE PROGRAM command can cross block address boundaries. RANDOM DATA INPUT (85h) commands are permitted with CACHE PROGRAM operations. Status Register's Cache RY/#BY (Bit 6 or I/O6) can be read after issuing the READ STATUS (70h) command for confirming when the Cache Register is ready or busy. RY/#BY, always follows Status Register Bit 6 (I/O6). Status Register's RY/#BY Bit 5 (I/O5) can be polled to determine whether the array programming is in progress or completed for the current programming cycle.

If only RY/#BY is used for detecting programming status, the last page of the program sequence must use the PAGE PROGRAM (10h) command instead of the CACHE PROGRAM (15h) command. If the CACHE PROGRAM (15h) command is used every time, including the last page programming, Status Register's Bit 5 (I/O5) must be used to determine when programming is complete.

Status Register's Pass/Fail, Bit 1 (I/O1) returns the pass/fail status for the previous page when Status Register's Bit 6 (I/O6) equals a "1" (ready state). The pass/fail status of the current PROGRAM operation is returned with Status Register's Bit 0 (I/O0) when Bit 5 (I/O5) of the Status Register equals a "1" (ready state) as shown in Figure 9-15 and 9-16.

Note: The CACHE PROGRAM command cannot be used on blocks 0-3 if used as boot blocks.

Figure 8-15 Cache Program Start

Figure 8-16 Cache Program End

### 8.2.5 TWO PLANE PAGE PROGRAM

TWO PLANE PAGE PROGRAM command make it possible for host to input data to the addressed plane's cache register and queue the cache register to be moved to the NAND Flash array.

This command can be issued several times. Each time a new plane address is specified that plane is also queued for data transfer. To input data for the final plane and to begin the program operation for all previously queued planes, either the PAGE PROGRAM command or the CACHE PROGRAM command have to be issued. All of the queued planes will move the data to the NAND Flash array. When it is ready (SR BIT 6 = 1), this command is accepted.

At the block and page address is specified, input a page to the cache register and queue it to be moved to the NAND Flash array, the 80h is issued to the command register. Unless this command has been preceded by a TWO PLANE PAGE PROGRAM command, issuing the 80h to the command register clears all of the cache registers' contents on the selected target. Write five address cycles containing the column address and row address; data input cycles follow. Serial data is input beginning at the column address specified. At any time, while the data input cycle, the RANDOM DATA INPUT (85h) command can be issued. When data input is complete, write 11h to the command register. The device will go busy (SR BIT 6 = 0, SR BIT 5 = 0) for tDBSY.

To ascertain the progress of tDBSY, the host can monitor the target's RY/#BY signal or, the status operations (70h, 78h) can be used alternatively. When the device status shows that it is ready (SR BIT 6 = 1), additional TWO PLANE PAGE PROGRAM commands can be issued to queue additional planes for data transfer, then, the PAGE PROGRAM or CACHE PROGRAM commands can be issued.

When the PAGE PROGRAM command is used as the final command of a two plane program operation, data is transferred from the cache registers to the NAND Flash array for all of the addressed planes during tPROG. When the device is ready (SR BIT 6 = 1, SR BIT 5 = 1), the host should check the status of the SR BIT 0 for each of the planes to verify that programming completed successfully.

When the CACHE PROGRAM command is used as the final command of a program cache two plane operation, data is transferred from the cache registers to the data registers after the previous array operations completed. Then, the data is moved from the data registers to the NAND Flash array for all of the addressed planes. This occurs while tCBSY. After tCBSY, the host should check the status of the SR BIT 1 for each of the planes from the previous program cache operation, if any, to verify that programming completed successfully.

When system issues TWO PLANE PAGE PROGRAM, PAGE PROGRAM, and CACHE PROGRAM commands, READ STATUS (70h) command can confirm whether the operation(s) passed or failed. If the status after READ STATUS (70h) command indicates an error (SR BIT 0 = 1 and/or SR BIT 1 = 1), READ STATUS ENHANCED (78h) command can be determined which plane is failed.

TWO PLANE PROGRAM commands require five-cycle addresses, one address indicates the operational plane. These addresses are subject to the following requirements:

- The column address bits must be valid address for each plane
- The plane select bit, A18, must be set to "L" for 1<sup>st</sup> address input, and set to "H" for 2<sup>nd</sup> address input.
- The page address (A17-A12) and block address (A29-A19) of first input are don't care. It follows secondary inputted page address and block address.

Two plane operations must be same type operation across the planes; for example, it is not possible to perform a PROGRAM operation on one plane with an ERASE operation on another.

- 1) The same row address, except for A18, is applied to the two blocks.
- 2) Any command between 11h and 81h is prohibited except 70h, 78h, and FFh.

Figure 8-17 Two Plane Page Program

1. In this figure the Read Status Register (70h) is used, but the Read Status Enhanced (78h) can be used as well.

Figure 8-18 Two Plane Cache Program

### 8.3 COPY BACK operation

Copy Back operations require two command sets. Issue a READ for COPY BACK (00h-35h) command first, then the PROGRAM for COPY BACK (85h-10h) command. Copy back operations are only supported within a same plane.

#### 8.3.1 READ for COPY BACK (00h-35h)

The READ for COPY BACK command is used together with the PROGRAM for COPY BACK (85h-10h) command. To start execution, READ for COPY BACK (00h) command is written to the Command Register, followed by the five cycles of the source page address. To start the transfer of the selected page data from the memory array to the Cache Register, write the 35h command to the Command Register.

After execution of the READ for COPY BACK command sequence and RY/#BY returns to HIGH marking the completion of the operation, the transferred data from the source page into the Cache Register may be read out by toggling #RE. Data is output sequentially from the column address that was originally specified with the READ for COPY BACK command. RANDOM DATA OUTPUT (05h-E0h) commands can be issued multiple times without any limitation after READ for COPY BACK command has been executed (see Figures 9-19 and 9-20).

At this point the device is in ready state to accept the PROGRAM for COPY BACK command.

#### 8.3.2 PROGRAM for COPY BACK (85h-10h)

After the READ for COPY BACK command operation has been completed and RY/#BY goes HIGH, the PROGRAM for COPY BACK command can be written to the Command Register. The command results in the transfer of data from the Cache Register to the Data Register, then internal operations start programming of the new destination page. The sequence would be, write 85h to the Command Register, followed by the five cycle destination page address to the NAND array. Next write the 10h command to the Command Register; this will signal the internal controller to automatically start to program the data to new destination page. During this programming time, RY/#BY will LOW. The READ STATUS command can be used instead of the RY/#BY signal to determine when the program is complete. When Status Register Bit 6 (I/O6) equals to "1", Status Register Bit 0 (I/O0) will indicate if the operation was successful or not.

The RANDOM DATA INPUT (85h) command can be used during the PROGRAM for COPY BACK command for modifying the original data. Once the data is copied into the Cache Register using the READ for COPY BACK (00h-35h) command, follow by writing the RANDOM DATA INPUT (85h) command, along with the address of the data to be changed. The data to be changed is placed on the external data pins. This operation copies the data into the Cache Register. Once the 10h command is written to the Command Register, the original data and the modified data are transferred to the Data Register, and programming of the new page commences. The RANDOM DATA INPUT command can be issued numerous times without limitation, as necessary before starting the programming sequence with 10h command.

Since COPY BACK operations do not use external memory and the data of source page might include a bit errors, a competent ECC scheme should be developed to check the data before programming data to a new destination page.

### **8.3.3 TWO PLANE READ for COPY BACK**

To improve read through rate, TWO PLANE READ for COPY BACK operation is copied data concurrently from one or two plane to the specified cache registers.

TWO PLANE PROGRAM for COPY BACK command can move the data in two pages from the cache registers to different pages. This operation improves system performance than PROGRAM for COPY BACK operation.

### **8.3.4 TWO PLANE PROGRAM for COPY BACK**

Function of TWO PLANE PROGRAM for COPY BACK command is equal to TWO-PLANE PAGE PROGRAM command, except that when 85h is written to the command register, then cache register contents are not cleared. Refer to TWO-PLANE PAGE PROGRAM for more details features.

Figure 8-19 Program for copy back Operation

Figure 8-20 Copy Back Operation with Random Data Input

Figure 8-21 Two Plane Copy Back

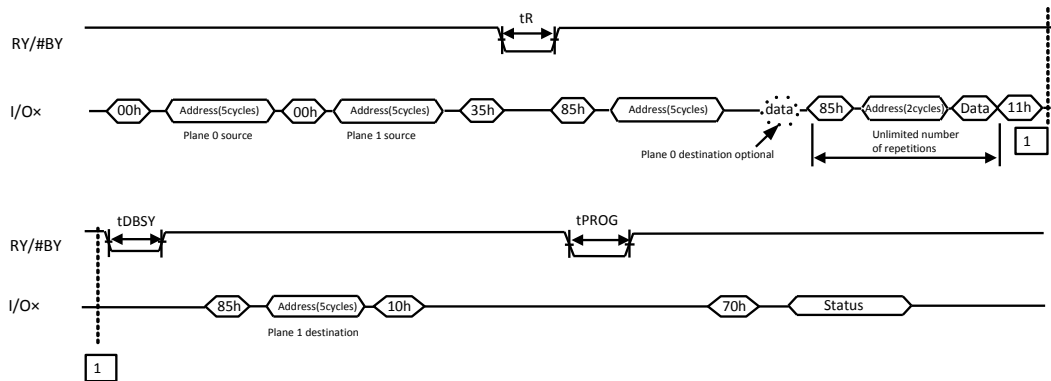

Figure 8-22 Two Plane Copy Back with Random Data Input

Single plane copy back read can be used to two plane operation.

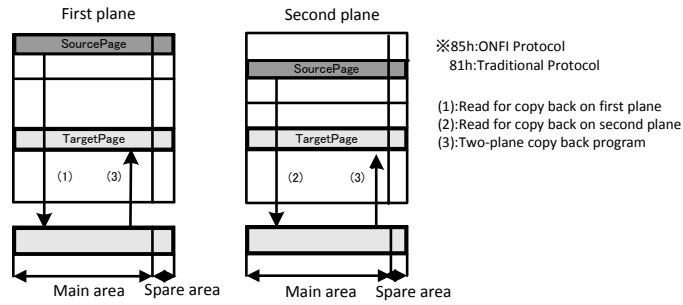

Figure 8-23 Two Plane Program for Copy Back

## 8.4 BLOCK ERASE operation

### 8.4.1 BLOCK ERASE (60h-D0h)

Erase operations happen at the architectural block unit. This W29N04GV has 2048 erase blocks. Each block is organized into 64 pages (x8:2112 bytes/page), 132K bytes (x8:128K + 4K bytes)/block. The BLOCK ERASE command operates on a block by block basis.

Erase Setup command (60h) is written to the Command Register. Next, the three cycle block address is written to the device. The page address bits are loaded during address block address cycle, but are ignored. The Erase Confirm command (D0h) is written to the Command Register at the rising edge of #WE, RY/#BY goes LOW and the internal controller automatically handles the block erase sequence of operation. RY/#BY goes LOW during Block Erase internal operations for a period of tBERS,

The READ STATUS (70h) command can be used for confirm block erase status. When Status Register Bit6 (I/O6) becomes to "1", block erase operation is finished. Status Register Bit0 (I/O0) will indicate a pass/fail condition (see Figure 9-24).

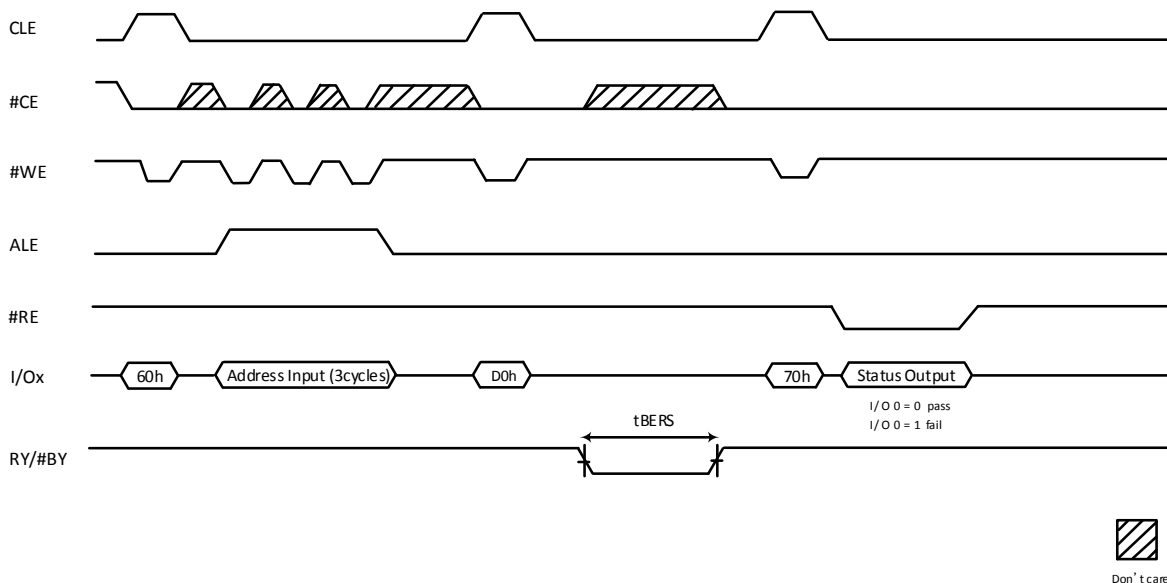

Figure 8-24 Block Erase Operation

**8.4.2 TWO PLANE BLOCK ERASE**

TWO PLANE BLOCK ERASE (60h-D1h) command indicates two blocks in the specified plane that is to be erased. To start ERASE operation for indicated blocks in the specified plane, write the BLOCK ERASE (60h-D0h) command.

To indicate a block to be erased, writing 60h to the command register, then, write three address cycles containing the row address, the page address is ignored. By writing D1h command to command register, the device will go busy (SR BIT 6 = 0, SR BIT 5 = 0) for tDBSY.

To confirm busy status during tDBSY, the host can monitor RY/#BY signal. Instead, system can use READ STATUS (70h) or READ STATUS ENHANCED (78h) commands. When the status shows ready (SR BIT 6 = 1, SR BIT 5 = 1), additional TWO PLANE BLOCK ERASE commands can be issued for erasing two blocks in a specified plane.

When system issues TWO PLANE BLOCK ERASE (60h-D1h), and BLOCK ERASE (60h-D0h) commands, READ STATUS (70h) command can confirm whether the operation(s) passed or failed. If the status after READ STATUS (70h) command indicates an error (SR BIT 0 = 1), READ STATUS ENHANCED (78h) command can be determined which plane is failed.

TWO PLANE BLOCK ERASE commands require three cycles of row addresses; one address indicates the operational plane. These addresses are subject to the following requirements:

- The plane select bit, A18, must be set to “L” for 1<sup>st</sup> address input, and set to “H” for 2<sup>nd</sup> address input.
- The block address (A29-A19) of first address input is don’t care. It follows secondary inputted block address.

Two plane operations must be same type operation across the planes; for example, it is not possible to perform a PROGRAM operation on one plane with an ERASE operation on another.

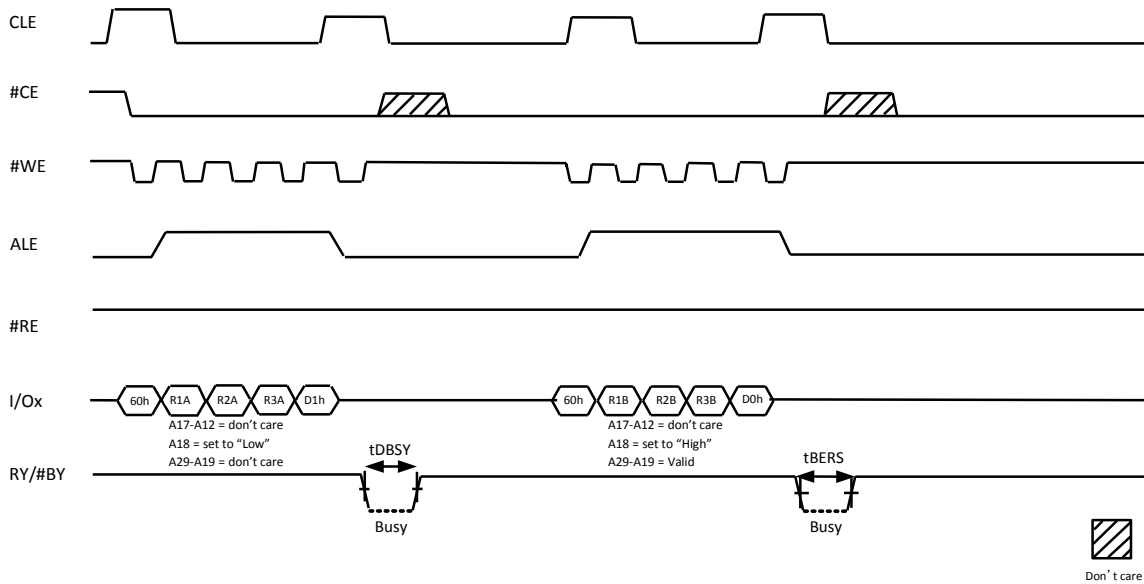

Figure 8-25 Two Plane Block Erase Operation

## 8.5 RESET operation

### 8.5.1 RESET (FFh)

READ, PROGRAM, and ERASE commands can be aborted by the RESET (FFh) command during the time the W29N04GV is in the busy state. The Reset operation puts the device into known status. The data that is processed in either the programming or erasing operations are no longer valid. This means the data can be partially programmed or erased and therefore data is invalid. The Command Register is cleared and is ready to accept next command. The Data Register and Cache Register contents are marked invalid.

The Status Register indicates a value of E0h when #WP is HIGH; otherwise a value of 60h is written when #WP is LOW. After RESET command is written to the command register, RY/#BY goes LOW for a period of  $t_{RST}$  (see Figure 9-26).

Figure 8-26 Reset Operation

## 8.6 FEATURE OPERATION

The GET FEATURES (EEh) and SET FEATURES (EFh) commands are used to change the NAND Flash device behavior from the default power on settings. These commands use a one-byte feature address to determine which feature is to be read or modified. A range of 0 to 255 defines all features; each is described in the features table (see Table 9.5 thru 9.7). The GET FEATURES (EEh) command reads 4-Byte parameter in the features table (See [GET FEATURES function](#)). The SET FEATURES (EFh) command places the 4-Byte parameter in the features table (See [SET FEATURES function](#)).

When a feature is set, meaning it remains active by default until the device is powered off. The set feature remains the set even if a RESET (FFh) command is issued.

Feature address	Description
00h	N.A
02h-7Fh	Reserved
80h	Vendor specific parameter : Programmable I/O drive strength
81h	Vendor specific parameter : Programmable RY/#BY pull-down strength
82h-FFh	Reserved

Table 8-3 Features

Feature Address 80h: Programmable I/O Drive Strength

Sub feature parameter	Options	I/O7	I/O6	I/O5	I/O4	I/O3	I/O2	I/O1	I/O0	Value	Notes

Table 8-4 Feature Address 80h

**Note:**

1. The default drive strength setting is Full strength. The Programmable I/O Drive Strength mode is used to change from the default I/O drive strength. Drive strength should be selected based on expected loading of the memory bus. This table shows the four supported output drive-strength settings. The device returns to the default drive strength mode when a power cycle has occurred. AC timing parameters may need to be relaxed if I/O drive strength is not set to full.

Feature Address 81h: Programmable RY/#BY Pull-down Strength

Sub feature parameter	Options	I/O7	I/O6	I/O5	I/O4	I/O3	I/O2	I/O1	I/O0	Value	Notes
P1											
RY/#BY pull-down strength	Full (default)	Reserved (0)						0	0	00h	1
	Three-quarters	Reserved (0)						0	1	01h	
	One-half	Reserved (0)						1	0	02h	
	One-quarter	Reserved (0)						1	1	03h	
P2											
		Reserved (0)								00h	
P3											
		Reserved (0)								00h	
P4											
		Reserved (0)								00h	

Table 8-5 Feature Address 81h

**Note:**

1. The default programmable RY/#BY pull-down strength is set to Full strength. The pull-down strength is used to change the RY/#BY pull-down strength. RY/#BY pull-down strength should be selected based on expected loading of RY/#BY. The four supported pull-down strength settings are shown. The device returns to the default pull-down strength when a power cycle has occurred.

**8.6.1 GET FEATURES (EEh)**

The GET FEATURES command returns the device feature settings including those previously set by the SET FEATURES command. To use the Get Feature mode write the command (EEh) to the Command Register followed by the single cycle byte Feature Address. RY/#BY will go LOW for the period of tFEAT. If Read Status (70h) command is issued for monitoring the process completion status, Read Command (00h) has to be executed to re-establish data output mode. Once, RY/#BY goes HIGH, the device feature settings can be read by toggling #RE. The device remains in Feature Mode until another valid command is issued to Command Register. See Figure 9-27.

Figure 8-27 Get Feature Operation

**8.6.2 SET FEATURES (EFh)**

The SET FEATURES command sets the behavior parameters by selecting a specified feature address. To change device behavioral parameters, execute Set Feature command by writing EFh to the Command Register, followed by the single cycle feature address. Each feature parameter (P1-P4) is latched at the rising edge of each #WE. The RY/#BY signal will go LOW during the period of tFEAT while the four feature parameters are stored. The Read Status (70h) command can be issued for monitoring the progress status of this operation. The parameters are stored in device until the device goes through a power on cycle. The device remains in feature mode until another valid command is issued to Command Register.

Figure 8-28 Set Feature Operation

### **8.7 ONE TIME PROGRAMMABLE (OTP) area**

The device has One-Time Programmable (OTP) memory area comprised of a number of pages (2112 bytes/page) (1056words/page). This entire range of pages is functionally guaranteed. Only the OTP commands can access the OTP area. When the device ships from Winbond, the OTP area is in an erase state (all bits equal "1"). The OTP area cannot be erased, therefore protecting the area only prevent further programming. Contact to Winbond for using this feature.

**8.8 WRITE PROTECT**

#WP pin can enable or disable program and erase commands preventing or allowing program and erase operations. Figure 9-29 to 9-34 shows the enabling or disabling timing with #WP setup time ( $t_{WW}$ ) that is from rising or falling edge of #WP to latch the first commands. After first command is latched, #WP pin must not toggle until the command operation is complete and the device is in the ready state. (Status Register Bit5 (I/O5) equal 1)

Figure 8-29 Erase Enable

Figure 8-30 Erase Disable

Figure 8-31 Program Enable

Figure 8-32 Program Disable

Figure 8-33 Program for Copy Back Enable

Figure 8-34 Program for Copy Back Disable

## **8.9 BLOCK LOCK**

The device has block lock feature that can protect the entire device or user can indicate a ranges of blocks from program and erase operations. Using this feature offers increased functionality and flexibility data protection to prevent unexpected program and erase operations. Contact to Winbond for using this feature.

## 9. ELECTRICAL CHARACTERISTICS

### 9.1 Absolute Maximum Ratings (3.3V)

PARAMETERS	SYMBOL	CONDITIONS	RANGE	UNIT
Supply Voltage	VCC		-0.6 to +4.6	V
Voltage Applied to Any Pin	VIN	Relative to Ground	-0.6 to +4.6	V
Storage Temperature	TSTG		-65 to +150	°C
Short circuit output current, I/Os			5	mA

Table 9-1 Absolute Maximum Ratings

**Notes:**

1. Minimum DC voltage is -0.6V on input/output pins. During transitions, this level may undershoot to -2.0V for periods <30ns.
2. Maximum DC voltage on input/output pins is Vcc+0.3V which, during transitions, may overshoot to Vcc+2.0V for periods <20ns.
3. This device has been designed and tested for the specified operation ranges. Proper operation outside of these levels is not guaranteed. Exposure to absolute maximum ratings may affect device reliability. Exposure beyond absolute maximum ratings may cause permanent damage.

### 9.2 Operating Ranges (3.3V)

PARAMETER	SYMBOL	CONDITIONS	SPEC		UNIT
			MIN	MAX	
Supply Voltage	VCC		2.7	3.6	V
Ambient Temperature, Operating	TA	Industrial	-40	+85	°C

Table 9-2 Operating Ranges

### 9.3 Device power-up timing

The device is designed to avoid unexpected program/erase operations during power transitions. When the device is powered on, an internal voltage detector disables all functions whenever Vcc is below about 2V at 3V device. Write Protect (#WP) pin provides hardware protection and is recommended to be kept at VIL during power up and power down. A recovery time of minimum 1ms is required before internal circuit gets ready for any command sequences (See Figure 10-1).

Figure 9-1 Power ON/OFF sequence

#### 9.4 AC Measurement Conditions (3.3V)

PARAMETER	SYMBOL	SPEC		UNIT
		MIN	MAX	
Input Capacitance <sup>(1), (2)</sup>	C <sub>IN</sub>	-	10	pF
Input/Output Capacitance <sup>(1), (2)</sup>	C <sub>IO</sub>	-	10	pF
Input Rise and Fall Times	TR/TF	-	5	ns
Input Pulse Voltages	-	0 to VCC		V
Input/Output timing Voltage	-	V <sub>CC</sub> /2		V
Output load <sup>(1)</sup>	CL	1TTL GATE and CL=30pF		-

Table 9-3 AC Measurement Conditions

**Notes:**

1. Verified on device characterization , not 100% tested
2. Test conditions TA=25°C, f=1MHz, VIN=0V

### 9.5 AC timing characteristics for Command, Address and Data Input (3.3V)

PARAMETER	SYMBOL	SPEC		UNIT
		MIN	MAX	
ALE to Data Loading Time	tADL	70	-	ns
ALE Hold Time	tALH	5	-	ns
ALE setup Time	tALS	10	-	ns
#CE Hold Time	tCH	5	-	ns
CLE Hold Time	tCLH	5	-	ns
CLE setup Time	tCLS	10	-	ns
#CE setup Time	tCS	15	-	ns
Data Hold Time	tDH	5	-	ns
Data setup Time	tDS	10	-	ns
Write Cycle Time	tWC	25	-	ns
#WE High Hold Time	tWH	10	-	ns
#WE Pulse Width	tWP	12	-	ns
#WP setup Time	tWW	100	-	ns

Table 9-4 AC timing characteristics for Command, Address and Data Input

**Note:**

1. tADL is the time from the #WE rising edge of final address cycle to the #WE rising edge of first data cycle.

AC timing characteristics for Operation (3.3V)

### 9.6 AC timing characteristics for Operation (3.3V)

PARAMETER	SYMBOL	SPEC		UNIT
		MIN	MAX	
ALE to #RE Delay	tAR	10	-	ns
#CE Access Time	tCEA	-	25	ns
#CE HIGH to Output High-Z <sup>(1)</sup>	tCHZ	-	30	ns
CLE to #RE Delay	tCLR	10	-	ns
#CE HIGH to Output Hold	tCOH	15	-	ns
Cache Busy in Cache Read mode	tRCBSY	-	25	μs
Output High-Z to #RE LOW	tIR	0	-	ns
Data Transfer from Cell to Data Register	tR	-	25	μs
READ Cycle Time	tRC	25	-	ns
#RE Access Time	tREA	-	20	ns
#RE HIGH Hold Time	tREH	10	-	ns
#RE HIGH to Output Hold	tRHOH	15	-	ns
#RE HIGH to #WE LOW	tRHW	100	-	ns
#RE HIGH to Output High-Z <sup>(1)</sup>	tRHZ	-	100	ns
#RE LOW to output hold	tRLOH	5	-	ns
#RE Pulse Width	tRP	12	-	ns
Ready to #RE LOW	tRR	20	-	ns
Reset Time (READ/PROGRAM/ERASE) <sup>(2)</sup>	tRST	-	5/10/500	μs
#WE HIGH to Busy <sup>(3)</sup>	tWB	-	100	ns
#WE HIGH to #RE LOW	tWHR	60	-	ns

Table 9-5 AC timing characteristics for Operation

**Notes:** AC characteristics may need to be relaxed if I/O drive strength is not set to “full.”

1. Transition is measured  $\pm 200\text{mV}$  from steady-state voltage with load. This parameter is sampled and not 100 % tested.
2. Do not issue new command during tWB, even if RY/#BY is ready.

## 9.7 Program and Erase Characteristics

PARAMETER	SYMBOL	SPEC		UNIT
		TYP	MAX	
Number of partial page programs	NoP	-	4	cycles
Page Program time	tPROG	250	700	μs
Busy Time for Cache program <sup>(1)</sup>	tCBSY	3	700	μs
Busy Time for SET FEATURES /GET FEATURES	tFEAT	-	1	μs
Busy Time for program/erase at locked block	tLBSY	-	3	μs
Busy Time for OTP program when OTP is protected	tOBSY	-	30	μs
Block Erase Time	tBERS	2	10	ms
Last Page Program time <sup>(2)</sup>	tLPROG	-	-	-
Busy Time for Two Plane page program and Two Plane Block Erase	tDBSY	0.5	1	μs

Table 9-6 Program and Erase Characteristics

**Note:**

1. tCBSY maximum time depends on timing between internal program complete and data-in.
2. tLPROG = Last Page program time (tPROG) + Last -1 Page program time (tPROG) – Last page Address, Command and Data load time.

## 11. INVALID BLOCK MANAGEMENT

### 11.1 Invalid blocks

The W29N04GV may have initial invalid blocks when it ships from factory. Also, additional invalid blocks may develop during the use of the device. Nvb represents the minimum number of valid blocks in the total number of available blocks (See Table 12.1). An invalid block is defined as blocks that contain one or more bad bits. Block 0, block address 00h is guaranteed to be a valid block at the time of shipment.

Parameter	Symbol	Min	Max	Unit
Valid block number	Nvb	4016	4096	blocks

Table 11-1 Valid Block Number

### 11.2 Initial invalid blocks

Initial invalid blocks are defined as blocks that contain one or more invalid bits when shipped from factory.

Although the device contains initial invalid blocks, a valid block of the device is of the same quality and reliability as all valid blocks in the device with reference to AC and DC specifications. The W29N04GV has internal circuits to isolate each block from other blocks and therefore, the invalid blocks will not affect the performance of the entire device.

Before the device is shipped from the factory, it will be erased and invalid blocks are marked. All initial invalid blocks are marked with non-FFh at the first byte of spare area on the 1<sup>st</sup> or 2<sup>nd</sup> page. The initial invalid block information cannot be recovered if inadvertently erased. Therefore, software should be created to initially check for invalid blocks by reading the marked locations before performing any program or erase operation, and create a table of initial invalid blocks as following flow chart

Figure 11-1 Flow chart of create initial invalid block table

### 11.3 Error in operation

Additional invalid blocks may develop in the device during its life cycle. Following the procedures herein is required to guarantee reliable data in the device.

After each program and erase operation, check the status read to determine if the operation failed. In case of failure, a block replacement should be done with a bad-block management algorithm. The system has to use a minimum 1-bit ECC per 528 bytes of data to ensure data recovery.

Operation	Detection and recommended procedure
Erase	Status read after erase → Block Replacement
Program	Status read after program → Block Replacement
Read	Verify ECC → ECC correction

Table 11-2 Block failure

Figure 11-2 Bad block Replacement

**Note:**

1. An error happens in the nth page of block A during program or erase operation.
2. Copy the data in block A to the same location of block B which is valid block.
3. Copy the nth page data of block A in the buffer memory to the nth page of block B
4. Creating or updating bad block table for preventing further program or erase to block A

#### 11.4 Addressing in program operation

The pages within the block have to be programmed sequentially from LSB (least significant bit) page to the MSB (most significant bit) within the block. The LSB is defined as the start page to program, does not need to be page 0 in the block. Random page programming is prohibited.

## 12. REVISION HISTORY

VERSION	DATE	PAGE	DESCRIPTION
0.1	11/19/14		New Create as Preliminary
0.2	02/01/16	27, 55	Update Parameter Page Output Value Update Notes of Absolute Maximum Ratings
A	06/01/16		Remove "Preliminary"
B	02/09/17	44	Change A18 address input requirement of Two Plane Block Erase operation
C	12/12/17	10	Change description of DNU
N/A	12/13/17		Modified for W29N08GV
