

256MB – 2x16Mx64 DDR SDRAM UNBUFFERED

FEATURES

- DDR266 and DDR333
- Double-data-rate architecture
- Bi-directional data strobes (DQS)
- Differential clock inputs (CK & CK#)
- Programmable Read Latency 2,2.5 (clock)
- Programmable Burst Length (2,4,8)
- Programmable Burst type (sequential & interleave)
- Edge aligned data output, center aligned data input.
- Auto and self refresh
- Serial presence detect
- Dual Rank
- Power supply: 2.5V ± 0.2V
- JEDEC 184 pin DIMM package
- JD3 PCB height: 30.48 (1.20")

DESCRIPTION

The W3EG6433S is a 2x16Mx64 Double Data Rate SDRAM memory module based on 256Mb DDR SDRAM component. The module consists of sixteen 16Mx8 DDR SDRAMs in 66 pin TSOP packages mounted on a 184 pin FR4 substrate.

Synchronous design allows precise cycle control with the use of system clock. Data I/O transactions are possible on both edges and Burst Lengths allow the same device to be useful for a variety of high bandwidth, high performance memory system applications.

Output High Current(Half strength driver); V _{OUT} = V _{TT} = 0.45V	V _{OL}	9		uA	

NOTES:

- V_{REF} is expected to be equal to 0.5*V_{CCQ} of the transmitting device, and to track variations in the dc level of same. Peak-to-peak noise on V_{REF} may not exceed +/-2% of the dc value.
- V_{TT} is not applied directly to the device. V_{TT} is a system supply for signal termination resistors, is expected to be set equal to V_{REF}, and must track variations in the DC level of V_{REF}.
- V_{ID} is the magnitude of the difference between the input level on CK and the input level on CK#.
- The ratio of the pullup current to the pulldown current is specified for the same temperature and voltage, over the entire temperature and voltage range, for device drain to source voltages from 0.25V to 1.0V. For a given output, it represents the maximum difference between pullup and pulldown drivers due to process variation. The full variation in the ratio of the maximum to minimum pullup and pulldown current will not exceed 1/7 for device drain to source voltages from 0.1 to 1.0.

Notes

1. t_{HZ} and t_{LZ} transitions occur in the same access time windows as valid data transitions. These parameters are not referenced to a specific voltage level but specify when the device output in no longer driving (HZ), or begins driving (LZ).
2. The maximum limit for this parameter is not a device limit. The device will operate with a greater value for this parameter, but system performance (bus turnaround) will degrade accordingly.
3. The specific requirement is that DQS be valid (HIGH, LOW, or at some point on a valid transition) on or before this CK edge. A valid transition is defined as monotonic and meeting the input slew rate specifications of the device. When no writes were previously in progress on the bus, DQS will be transitioning from High- Z to logic LOW. If a previous write was in progress, DQS could be HIGH, LOW, or transitioning from HIGH to LOW at this time, depending on t_{DQS} .
4. A maximum of eight AUTO REFRESH commands can be posted to any given DDR SDRAM device.
5. For command/address input slew rate ≥ 1.0 V/ns.
6. For command/address input slew rate ≥ 0.5 V/ns and > 1.0 V/ns
7. For CK & CK# slew rate ≥ 1.0 V/ns.
8. These parameters guarantee device timing, but they are not necessarily tested on each device. They may be guaranteed by device design or tester correlation.
9. Slew Rate is measured between $V_{OH(ac)}$ and $V_{OL(ac)}$.
10. Min (t_{CL} , t_{CH}) refers to the smaller of the actual clock low time and the actual clock high time as provided to the device (i.e. this value can be greater than the minimum specification limits for t_{CL} and t_{CH} . For example, t_{CL} and t_{CH} are = 50% of the period, less the half period jitter ($t_{JIT(HP)}$) of the clock source, and less the half period jitter due to crosstalk ($t_{JIT(crosstalk)}$) into the clock traces.
11. $t_{QH} = t_{HP} - t_{QHS}$, where:
 t_{HP} = minimum half clock period for any given cycle and is defined by clock high or clock low (t_{CH} , t_{CL}). t_{QHS} accounts for 1) The pulse duration distortion of on-chip clock circuits; and 2) The worst case push-out of DQS on one transition followed by the worst case pull-in of DQ on the next transition, both of which are, separately, due to data pin skew and output pattern effects, and p-channel to n-channel variation of the output drivers.
12. t_{DQSQ}
Consists of data pin skew and output pattern effects and p-channel to n-channel variation of the output drivers for any given cycle.
13. $t_{DAL} = (t_{WR}/t_{CK}) + (t_{RP}/t_{CK})$
For each of the terms above, if not already an integer, round to the next highest integer. Example: For DDR266 at $CL=2.5$ and $t_{CK}=7.5$ ns $t_{DAL} = (15 \text{ ns} / 7.5 \text{ ns}) + (20 \text{ ns} / 7.5 \text{ ns}) = (2) + (3) t_{DAL} = 5$ clocks

Part Number	Speed	CAS Latency	t _{RC} D	t _{RP}	Height*
W3EG6433S335D3	166MHz/333Mb/s	2.5	3	3	30.48 (1.20")
W3EG6433S262D3	133MHz/266Mb/s	2	2	2	30.48 (1.20")
W3EG6433S263D3	133MHz/266Mb/s	2	3	3	30.48 (1.20")
W3EG6433S265D3	133MHz/266Mb/s	2.5	3	3	30.48 (1.20")

- NOTES:
- Consult Factory for availability of RoHS compliant products. (G = RoHS Compliant)
 - Vendor specific part numbers are used to provide memory components source control. The place holder for this is shown as lower case "x" in the part numbers above and is to be replaced with the respective vendors code. Consult factory for qualified sourcing options. (M = Micron, S = Samsung & consult factory for others)
 - Consult factory for availability of industrial temperature (-40°C to 85°C) option
