User's Manual

PREFACE

Thank you for your interest in the Z380™ CPU (Central Processing Unit) and its associated family of products. This Technical Manual describes programming and operation of the Z380™ Superintegration™ Core CPU, which is found in the Z380 MPU (Microprocessor Processing Unit), and future products built around Z380™ CPU core. For the external interface and detailed descriptions of the on-chip peripherals for each Superintegration device, please refer to individual product specifications.

This Technical manual consists of the following Sections:

1. Z380™ Architectural Overview

Chapter 1 is an introductory section covering the key features and giving an overview of the architecture of the device.

2. Address Spaces

Chapter 2 explains the address spaces the Z380 CPU can handle. Also, this chapter includes a brief description of the on-chip registers.

3. Native/Extended Mode, Word/Long Word Mode of Operation, and Decoder Directives

This chapter provides a detailed explanation on the Z380's unique features, operation modes, and the Decoder Directives.

4. Addressing Modes and Data Types

Chapter 4 describes the Addressing mode and data types which the Z380 can handle.

5. Instruction Set

Chapter 5 contains an overview of the instruction set; as well as a detailed instruction-by-instruction description in alphabetical order.

6. Interrupts and Traps

Chapter 6 explains the interrupts and traps features of the Z380.

7. Reset

Chapter 7 describes the Reset function.

CHAPTER 1

Z380™ ARCHITECTURAL OVERVIEW

1.1 INTRODUCTION

The Z380 CPU incorporates advanced architectural features that allow fast and efficient throughput and increased memory addressing capabilities while maintaining Z80® CPU and Z180® MPU object-code compatibility. The Z380 CPU core provides a continuing growth path for present Z80- or Z180®-based designs and offers the following key features:

- Full Static CMOS Design with Low Power Standby Mode Support
- DC to 18 MHz Operating Frequency @ 5 Volts V_{CC}
- DC to 10 MHz Operating Frequency @ 33 Volts V_{CC}
- Enhanced Instruction Set that Maintains Object-Code Compatibility with Z80 and Z180 Microprocessors
- 16-Bit (64K) or 32-Bit (4G) Linear Address Space
- 16-Bit Internal Data Bus
- Two Clock Cycle Instruction Execution (Minimum)
- Multiple On-Chip Register Files (Z380 MPU has Four Banks)
- BC/DE/HL/IX/IY Registers are Augmented by 16-Bit Extended Registers (BCz/DEz/HLz/IXz/IYz), PC/SP/I Registers are Augmented by Extended Registers (PCz/SPz/Iz) for 32-Bit Addressing Capability.
- Newly Added IX' and IY' Registers with Extended Registers (IXz'/IYz')
- Enhanced Interrupt Capabilities, Including 16-Bit Vector
- Undefined Opcode Trap for Full Z380 CPU Instruction Set

The Z380 CPU, an enhanced version of the Z80 CPU, retains the Z80 CPU instruction set to maintain complete binary-code compatibility with present Z80 and Z180 codes. The basic addressing modes of the Z80 microprocessor have been augmented with Stack Pointer Relative loads and stores, 16-bit and 24-bit Indexed offsets, and increased Indirect register addressing flexibility, with all of the addressing modes allowing access to the entire 32-bit address space. Significant additions have been made to the instruction set incorporating 16-bit arithmetic and logical operations, 16-bit I/O operations, multiply and divide, a complete set of register-to-register loads and exchanges, plus 32-bit load and exchange, and 32-bit arithmetic operation for address calculation.

The basic register file of the Z80 microprocessor is expanded to include alternate register versions of the IX and IY registers. There are four sets of this basic Z80 microprocessor register file present in the Z380 MPU, along with the necessary resources to manage switching between the different register sets. All of the register pairs and index registers in the basic Z80 microprocessor register file are expanded to 32 bits.

The Z380 CPU expands the basic 64 Kbyte Z80 and Z180 address space to a full 4 Gbyte (32-bit) address space. This address space is linear and completely accessible to the user program. The external I/O address space is similarly expanded to a full 4 Gbyte (32-bit) range, and 16-bit I/O, both simple and block move are included. A 256 byte-wide internal I/O space has been added. This space will be used to access on-chip I/O resources on future Superintegration implementation of this CPU core.

Figure 1-1 provides a detailed description of the basic register architecture of the Z380 CPU with the size of the register banks shown at four each, however, the Z380 CPU architecture allows future expansion of up to 128 sets of each.

1.2 CPU ARCHITECTURE

The Z380 CPU is a binary-compatible extension of the Z80 CPU and the Z180 CPU architecture. High throughput rates are achieved by a high clock rate, high bus bandwidth, and instruction fetch/execute overlap. Communicating to the external world through an 8-bit or 16-bit data bus, the Z380 CPU is a full 32-bit machine internally, with a 32-bit ALU and 32-bit registers.

1.2.1 Modes of Operation

To maintain compatibility with the Z80/Z180 CPU while having the capability to manipulate 4 Gbytes of memory address range, the Z380 CPU has two bits in the Select Register (SR) to control the modes of operation. One bit controls the address manipulation mode: Native mode or Extended mode; and the other bit controls the data manipulation mode: Word mode or Long Word mode. In result, the Z380 CPU has four modes of operation. On reset, the Z380 CPU is in Native/Word mode, which is compatible to the Z80/Z180's operation mode. For details on this subject, refer to Chapter 3, "Native/Extended Mode, Word/Long Word Mode of Operation, and Decoder Directive Instructions."

1.2.1.1 Native Mode and Extended Mode

The Z380 CPU can operate in either Native or Extended mode, as controlled by a bit in the Select Register (SR). In Native mode (the Reset configuration), all address manipulations are performed modulo 65536 (2^{16}). In this mode, the Program Counter (PC) only increments across 16 bits, all address manipulation instructions (increment, decrement, add, subtract, indexed, stack relative, and PC relative) only operate on 16 bits, and the Stack Pointer (SP) only increments and decrements across 16 bits. The PC high-order word is left at all zeros, as the high-order words of the SP and the I register. Thus, Native mode is fully compatible with the Z80 CPU's 64 Kbyte address mode. It is still possible to address memory outside of 64 Kbyte address space for data storage and retrieval in Native mode, however, since direct addresses, indirect addresses, and the high-order word of the SP, I, and the IX and IY registers may be loaded with non-zero values. Executed code and interrupt service routines must reside in the lowest 64 Kbytes of the address space.

In Extended mode, however, all address manipulation instructions operate on 32 bits, allowing access to the entire 4 Gbyte address space of the Z380 CPU. In both Native and Extended modes, the Z380 drives all 32 bits of the address onto the external address bus; only the width of the manipulated addresses distinguishes Native from Extended mode. The Z380 CPU implements one instruction to allow switching from Native to Extended mode (SETC XM); however, once in Extended mode, only Reset

will return the Z380 CPU to Native mode. This restriction applies because of the possibility of "misplacing" interrupt service routines or vector tables during the transition from Extended mode back to Native mode.

1.2.1.2 Word or Long Word Mode

In addition to Native and Extended mode, which are specific to memory space addressing, the Z380 CPU can operate in either Word or Long Word mode specific to data load and exchange operations. In Word mode (the Reset configuration), all word load and exchange operations manipulate 16-bit quantities. For example, only the low-order words of the source and destination are exchanged in an exchange operation, with the high-order words unaffected.

In the Long Word mode, all 32 bits of the source and destination are exchanged. The Z380 CPU implements two instructions plus decoder directives to allow switching between Word and Long Word mode; SETC LW (Set Control Long Word) and RESC LW (Reset Control Long Word) perform a global switch, while DDIR W, DDIR LW and their variants are decoder directives that select a particular mode only for the instruction that they precede.

Note that all word data arithmetic (as opposed to address manipulation arithmetic), rotate, shift, and logical operations are always in 16-bit quantities. They are not controlled by either the Native/Extended or Word/Long Word selections. The exceptions to the 16-bit quantities are, of course, those multiply and divide operations with 32-bit products or dividends.

All word Input/Output operations are performed on 16-bit values, regardless of Word/Long Word operation.

1.2.2 Address Spaces

Addressing spaces in the Z380 CPU include the CPU register, the CPU control register, the memory address, on-chip I/O address, and the external I/O address. The CPU register space is a superset of the Z80 CPU register set, and consists of all of the registers in the CPU register file. These CPU registers are used for data and address manipulation, and are an extension of the Z80 CPU register set, with four sets of this extended Z80 CPU register set present in the Z380 CPU. Access to these registers is specified in the instruction, with the active register set selected by bits in the Select Register (SR) in the CPU control register space.

are handled by a newly added interrupt handling mode, "Assigned Vectored Mode," which is a fixed vectored interrupt mode similar in interrupt handling to the Z180's interrupts from on-chip peripherals. For handling interrupt requests on the /INTO line, there are four modes available:

- 8080 compatible (Mode 0), in which the interrupting device provides the first instruction of the interrupt routine.
- Dedicated interrupts (Mode 1), in which the CPU jumps to a dedicated address when an interrupt occurs.
- Vectored interrupt mode (Mode 2), in which the interrupting peripheral device provides a vector into a table of jump address.
- Enhanced vectored interrupt mode (Mode 3), wherein the CPU expects 16-bit vector, instead of 8-bit interrupt vectors in Mode 2.

The first three modes are compatible with Z80 interrupt modes; the fourth mode provides more flexibility.

Traps are synchronous events that trigger a special CPU response when an undefined instruction is executed. It can be used to increase system reliability, or used as a "software trap instruction."

Hardware resets occur when the /RESET line is activated and override all other conditions. A /RESET causes certain CPU control registers to be initialized.

For details on this subject, refer to Chapter 6, "Interrupts and Traps."

1.3 BENEFITS OF THE ARCHITECTURE

The Z380 CPU architecture provides several significant benefits, including increased program throughput achieved by higher bus bandwidth (16-bit wide bus), reduction to two clocks/basic machine cycle (vs four clocks/cycle on the Z80 CPU), prefetch cue, access to the larger linear addressing space, enhanced instructions/new addressing mode, data/address manipulation in 16/32 bits, and faster context switching by utilizing multiple register banks.

1.3.1 High Throughput

Very high throughput rates can be achieved with the Z380 CPU, due to the basic machine cycle's reduction to two clocks/cycle from four clocks/cycle on the Z80 CPU, fine tuned four staged pipeline with prefetch cue. This well designed pipeline and prefetch cue are both totally transparent to the user, thus maximizing the efficiency of the pipeline all the time. The Z380 CPU implemented onto the Z380 MPU is configured with a 16-bit wide data bus, which doubles the bus bandwidth. These architectural features result in two clocks/instructions execution minimum, three clocks/instruction on average. The high clock rates (up to 40 MHz) achievable with this processor. Make the overall performance of the Z380 CPU more than ten times that of the Z80.

1.3.2 Linear Memory Address Space

Z380 CPU architecture has 4 Gbytes of linear memory address space. The Z80 CPU architecture allows 64 Kbytes of memory addressing space. This was more than sufficient when the Z80 CPU was first developed. But as

the technology improved over time, applications started to demand more complicated processing, multitasking, faster processing, etc., with the high level language needed to develop software. As a result, 64 Kbytes of memory addressing space is not enough for some Z80 CPU based applications. In order to handle more than 64 Kbytes of memory, the Z80 CPU requires a Memory Banking scheme, or MMU (Memory Management Unit), like the Z180 MPU or Z280 MPU. These provide the overhead to access more than 64 Kbytes of memory.

The Z380 CPU architecture allows access to a full 4 Gbytes (2^{32}) of memory addressing space as well as 4 Gbytes of I/O addressing area, without using a Memory Banking scheme, or MMU.

1.3.3. Enhanced Instruction Set with 16-Bit and 32-Bit Manipulation Capability

The Z380 CPU instruction set is 100% upward compatible to the Z80 CPU instruction set; that is all the Z80 instructions have been preserved at the binary level. New instructions added to the Z380 CPU include:

- Less restricted operand source/destination combinations.
- More flexible register exchange instructions.
- Stack Pointer Relative addressing mode.

CHAPTER 2

ADDRESS SPACES

2.1 INTRODUCTION

The Z380 CPU supports five address spaces corresponding to the different types of locations that can be addressed and the method by which the logical addresses are formed. These five address spaces are:

- **CPU Register Space.** This consists of all the register addresses in the CPU register file.
- **CPU Control Register Space.** This consists of the Select Register (SR).
- **Memory Address Space.** This consists of the addresses of all locations in the main memory.

- **External I/O Address Space.** This consists of all external I/O ports addresses through which peripheral devices are accessed.
- **On-Chip I/O Address Space.** This consists of all internal I/O port addresses through which peripheral devices are accessed. Also, this addressing space contains registers to control the functionality of the device, giving status information.

2

2.2 CPU REGISTER SPACE

The Z380 register file is illustrated in Figure 2-1. Note that this figure shows the configuration of the register on the Z380 CPU, and the number of the register files may vary on future Superintegration devices. The Z380 CPU contains abundant register resources. At any given time, the program has immediate access to both primary and alternate registers in the selected register set. Changing register sets is a simple matter of an LDCTL instruction to program the Select Register (SR).

The CPU register file is divided into five groups of registers (an apostrophe indicates a register in the auxiliary registers).

- Four sets of Flag and Accumulator registers (F, A, F', A')
- Four sets of Primary and Working registers (B, C, D, E, H, L, B', C', D', E', H', L')

- Four sets of Index registers (IX, IY, IX', IY')
- Stack Pointer (SP)
- Program Counter, Interrupt register, Refresh register (PC, I, R)

Register addresses are either specified explicitly in the instruction or are implied by the semantics of the instruction.

2.2.1 Primary and Working Registers

The working register set is divided into two register files: the primary file and the alternate file (designated by prime (')). Each file contains an 8-bit accumulator (A), a Flag register (F), and six 8-bit general-purpose registers (B, C, D, E, H, and L) with their Extended registers. Only one file can be active at any given time, although data in the inactive file can still be accessed by using EX R, R' instructions for the byte-wide registers, EX RR, RR' instructions for register pairs (either in 16-bit or 32-bit wide depending on the LW status). Exchange instructions allow the programmer to exchange the active file with the inactive file. The EX AF, AF', EXX, or EXALL instructions changes the register files in use. Upon reset, the primary register file in register set 0 is active. Changing register sets is a simple matter of an LDCTL instruction to program SR.

The accumulator is the destination register for 8-bit arithmetic and logical operations. The six general-purpose registers can be paired (BC, DE, and HL), and are extended to 32 bits by the extension to the register (with suffix "z"; BCz/DEz/HLz), to form three 32-bit general-purpose registers. The HL register serves as the 16-bit or 32-bit accumulator for word operations. Access to the Extended portion of the registers is possible using the SWAP instruction or word Load instructions in Long Word operation mode.

The Flag register contains eight status flags. Four can be individually used for control of program branching, two are used to support decimal arithmetic, and two are reserved. These flags are set or reset by various CPU operations. For details on Flag operations, refer to Section 5.2, "Flag Register."

2.2.2. Index Registers

The four index registers, IX, IX', IY, and IY', are extended to 32 bits by the extension to the register (with suffix "z"; IXz/IYz), to form 32-bit index registers. To access the Extended portion of the registers use the SWAP instruction or word Load instructions in Long Word operation mode. These Index registers hold a 32-bit base address that is used in the Index addressing mode.

Only one register of each can be active at any given time, although data in the inactive file can still be accessed by using EX IX, IX' and EX IY, IY' (either in 16-bit or 32-bit wide depending on the LW bit status). Index registers can also function as general-purpose registers with the upper and lower bytes of the lower 16 bits being accessed individually. These byte registers are called IXU, IXU', IXL, and IXL'

for the IX and IX' registers, and IYU, IYU', IYL, and IYL' for the IY and IY' registers.

Selection of primary or auxiliary Index registers can be made by EXXX, EXXY, or EXALL instructions, or programming of SR. Upon reset, the primary registers in register set 0 is active. Changing register sets is a simple matter of an LDCTL instruction to program SR.

2.2.3. Interrupt Register

The Interrupt register (I) is used in interrupt modes 2 and 3 for /INT0 to generate a 32-bit indirect address to an interrupt service routine. The I register supplies the upper 24 or 16 bits of the indirect address and the interrupting peripheral supplies the lower eight or 16 bits. In Assigned Vectors mode for /INT3-/INT1, the upper 16 bits of the vector are supplied by the I register; bits 15-9 are supplied from the Assigned Vector Base register, and bits 8-0 are the assigned vector unique to each of /INT3-/INT1.

2.2.4. Program Counter

The Program Counter (PC) is used to sequence through instructions in the currently executing program and to generate relative addresses. The PC contains the 32-bit address of the current instruction being fetched from memory. In Native mode, the PC is effectively only 16 bits long, since the upper word [PC31-PC16] of the PC is forced to zero, and when carried from bit 15 to bit 16 (Lower word [PC15-PC0] to Upper word [PC31-PC16]) are inhibited in this mode. In Extended mode, the PC is allowed to increment across all 32 bits.

2.2.5. R Register

The R register can be used as a general-purpose 8-bit read/write register. The R register is not associated with the refresh controller and its contents are changed only by the user.

2.2.6. Stack Pointer

The Stack Pointer (SP) is used for saving information when an interrupt or trap occurs and for supporting subroutine calls and returns. Stack Pointer relative addressing allows parameter passing using the SP. The SP is 16 bits wide, but is extended by the SPz register to 32 bits wide.

CHAPTER 3

NATIVE EXTENDED MODE, WORD/LONG WORD MODE OF OPERATIONS AND DECODER DIRECTIONS

3.1 INTRODUCTION

The Z380™ CPU architecture allows access to 4 Gbytes (2^{32}) of memory addressing space, and 4G locations of I/O. It offers 16/32-bit manipulation capability while maintaining object-code compatibility with the Z80 CPU. In order to implement these capabilities and new instruction sets, it has two modes of operation for address manipulation (Native or Extended mode), two modes of operation for data manipulation (Word or Long Word mode), and a special set of new Decoder Directives.

On Reset, the Z380 CPU defaults in Native mode and Word mode. In this condition, it behaves exactly the same as the Z80 CPU, even though it has access to the entire 4 Gbytes of memory for data access and 4G locations of I/O space,

access to the newly added registers which includes Extended registers and register banks, and the capability of executing all the Z380 instructions.

As described below, the Z380 CPU can be switched between Word mode and Long Word mode during operation through the SETC LW and RESC LW instructions, or Decoder Directives. The Native and Extended modes are a key exception—it defaults up in Native mode, and can be set to Extended mode by the instruction. Only Reset can return it to Native mode. Figure 3-1 illustrates the relationship between these modes of operation.

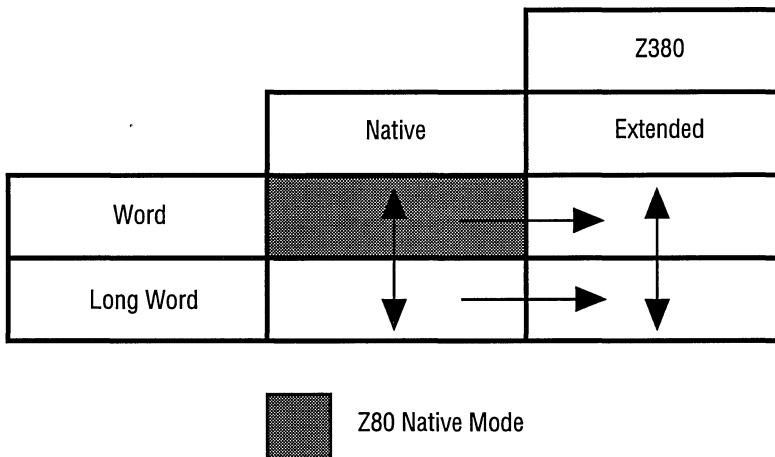

Figure 3-1. Z380™ CPU Operation Modes

For the instructions which work with the DDIR instructions, refer to Appendix D and E.

The Z380 CPU implements one instruction to switch to Extended mode from Native mode; SETC XM (set Extended mode) places the Z380 CPU in Extended mode.

Once in Extended mode, only Reset can return it to Native mode. On Reset, the Z380 is in Native mode. Refer to Sections 4 and 5 for more examples.

3.4 WORD AND LONG WORD MODE OF OPERATION

The Z380 CPU can operate in either Word or Long Word mode. In Word mode (the Reset configuration), all word operations manipulate 16-bit quantities, and are compatible with the Z80 CPU 16-bit operations. In the Long Word mode, all word operations can manipulate 32-bit quantities. Note that the Native/Extended and Word/Long Word selections are independent of one another, as Word/Long Word pertains to data and operand address manipulation only. The Z380 CPU implements two instructions and two decoder directives to allow switching between these two modes; SETC LW (Set Long Word) and RESC LW (Reset Long Word) perform a global switch, while DDIR LW and DDIR W are decoder directives that select a particular mode only for the instruction that they precede.

Examples:

1. Effect of Word mode and Long Word mode

```
DDIR W
LD BC, (HL)
```

Loads BC15-BC0 from the location (HL) and (HL+1), and BCz (BC31-BC16) remains unchanged.

```
DDIR LW
LD BC, (HL)
```

Loads BC31-BC0 from the locations (HL) to (HL+3).

2. Immediate data load with DDIR instructions

```
DDIR IW,LW
LD HL,12345678H
Loads 12345678H into HL31-HL0.
```

```
DDIR IB,LW
LD HL,123456H
```

Loads 00123456H into HL31-HL0. 00H is appended as the Most significant byte as HL31-HL24.

```
DDIR LW
LD HL,1234H
```

Loads 00001234H into HL31-HL0. 0000H is appended as the HL31-HL16 portion.

CHAPTER 4

ADDRESSING MODES AND DATA TYPES

4.1 INSTRUCTION

An instruction is a consecutive list of one or more bytes in memory. Most instructions act upon some data; the term operand refers to the data to be operated upon. For Z380™ CPU instructions, operands can reside in CPU registers, memory locations, or I/O ports (internal or external). The method used to designate the location of the operands for

an instruction are called addressing modes. The Z380 CPU supports seven addressing modes; Register, Immediate, Indirect Register, Direct Address, Indexed, Program Counter Relative Address, and Stack Pointer Relative. A wide variety of data types can be accessed using these addressing modes.

4.2 ADDRESSING MODE DESCRIPTIONS

The following pages contain descriptions of the addressing modes for the Z380 CPU. Each description explains how the operand's location is calculated, indicates which address spaces can be accessed with that particular addressing mode, and gives an example of an instruction using that mode, illustrating the assembly language format for the addressing modes.

4.2.1 Register (R, RX)

When this addressing mode is used, the instruction processes data taken from one of the 8-bit registers A, B, C, D, E, H, L, IXU, IXL, IYU, IYL, one of the 16-bit registers BC, DE, HL, IX, IY, SP, or one of the special byte registers I or R.

Storing data in a register allows shorter instructions and faster execution that occur with instructions that access memory.

Instruction
OPERATION REGISTER → OPERAND

The operand value is the contents of the register.

The operand is always in the register address space. The register length (byte or word) is specified by the instruction opcode. In the case of Long Word register operation, it is specified either through the SETC LW instruction or the DDIR LW decoder directive.

Example of R mode:

1. Load register in Word mode.

DDIR W ;Next instruction in Word mode
LD BC,HL ;Load the contents of HL into BC

	<u>BCz</u>	<u>BC</u>	<u>HLz</u>	<u>HL</u>
Before instruction execution	1234	5678	9ABC	DEF0
After instruction execution	1234	DEF0	9ABC	DEF0

2. Load register in Long Word mode.

DDIR LW ;Next instruction in Long Word mode
LD BC,HL ;Load the contents of HL into BC

	<u>BCz</u>	<u>BC</u>	<u>HLz</u>	<u>HL</u>
Before instruction execution	1234	5678	9ABC	DEF0
After instruction execution	9ABC	DEF0	9ABC	DEF0

4.2.2 Immediate (IM)

When the Immediate addressing mode is used, the data processed is in the instruction.

The Immediate addressing mode is the only mode that does not indicate a register or memory address as the source operand.

4.2.4 Direct Address (DA)

When Direct Address mode is used, the data processed is at the location whose memory or I/O port address is in the instruction.

Instruction		Memory or
OPERATION		I/O Port
ADDRESS	→	OPERAND

The operand value is the contents of the location whose address is in the instruction.

Depending on the instruction, the operand specified by DA mode is either in the I/O address space (I/O instruction) or memory address space (all other instructions).

This mode is also used by Jump and Call instructions to specify the address of the next instruction to be executed. (The address serves as an immediate value that is loaded into the program counter.)

Also, DDIR Immediate Data Directives are used to expand the direct address to 24 or 32 bits. Operand width is affected by LW bit status for the load and exchange instructions.

Example of DA mode:

1. Load BC register from memory location 00005E22H in Word mode

```
LD BC, (5E22H) ;Load BC with the data in address
                ;00005E22H
```

	<u>BC</u>	
Before instruction execution	1234	
After instruction execution	0301	
Memory location	00005E22	01
	00005E23	03

2. Load BC register from memory location 12345E22H in Word mode

```
DDIR IW ;extend direct address by one word
LD BC, (12345E22H) ;Load BC with the data in address
                  ;12345E22H
```

	<u>BC</u>	
Before instruction execution	1234	
After instruction execution	0301	
Memory location	12345E22	01
	12345E23	03

3. Load BC register from memory location 12345E22H in Long Word mode

```
DDIR IW,LW ;extend direct address by one word,
            ;and operation in Long Word
LD BC, (12345E22H) ;Load BC with the data in address
                  ;12345E22H
```

	<u>BCz</u>	<u>BC</u>	
Before instruction execution	1234	5678	
After instruction execution	0705	0301	
Memory location	12345E22	01	
	12345E23	03	
	12345E24	05	
	12345E25	07	

2. Load accumulator from location (IX-1) in Extended mode

```

SETC XM      ;Set Extended mode
LD  A, (IX-1) ;Load into the accumulator the
              ;contents of the memory location
              ;whose address is one less than
              ;the contents of IX
    
```

	A	IXz	IX
Before instruction execution	01	0001	0000
After instruction execution	23	0001	0000
Memory location	0000FFFF	23	

Address calculation: In Extended mode, 0FFH encoding in the instruction is sign extended to a 32-bit value before the address calculation, but calculation is done in modulo 2^{32} and takes into account the index register's extended portion.

```

00010000
+ FFFFFFFF
0000FFFF
    
```

4.2.6 Program Counter Relative Mode (RA)

The Program Counter Relative Addressing mode is used by certain program control instructions to specify the address of the next instruction to be executed (specifically, the sum of the Program Counter value and the displacement value is loaded into the Program Counter). Relative addressing allows reference forward or backward from the current Program Counter value; it is used for program control instructions such as Jumps and Calls that access constants in the memory.

Note that computation of the effective address is affected by the mode of operation (Native or Extended). In Native mode, address computation is done in modulo 2^{16} , and the PC Extend (PC31-PC16) is forced to 0 and will not affect this portion. In Extended mode, address computation is done in modulo 2^{32} , and will affect the contents of PC extend if there is a carry or borrow operation.

4

As a displacement, an 8-bit, 16-bit, or 24-bit value can be used. The address to be loaded into the Program Counter is computed by adding the two's complement signed displacement specified in the instruction to the current Program Counter.

Also, in Native mode,

```

Instruction  PC      MEMORY
OPERATION  ADDRESS  →+  OPERAND
DISPLACEMENT  —↑
    
```

Example of RA mode:

1. Jump relative in Native mode, 8-bit displacement

```

JR    $-2    ;Jumps to the location
              ;(Current PC value) - 2
              ;'$' represents for current PC value
              ;This instruction jumps to itself.
              ;since after the execution of this instruction,
              ;PC points to the next instruction.
    
```

4.2.7 Stack Pointer Relative Mode (SR)

For Stack Pointer Relative addressing mode, the data processed is at the location whose address is the contents of the Stack Pointer, offset by an 8-bit displacement in the instruction.

The Stack Pointer Relative address is computed by adding the 8-bit two's complement signed displacement specified in the instruction to the contents of the SP, also specified by the instruction. Stack Pointer Relative addressing mode is used to specify data items to be found in the stack, such as parameters passed to procedures.

Offset portion can be expanded to 16 or 24 bits by using DDIR immediate instructions (DDIR IB for a 16-bit offset, DDIR IW for a 24-bit offset).

Note that computation of the effective address is affected by the operation mode (Native or Extended). In Native mode, address computation is done in modulo 2^{16} , meaning computation is done in 16-bit and does not affect upper half of the SP portion for calculation (wrap around within the 16-bit). In Extended mode, address computation is done in modulo 2^{32} .

Also, the size of the data transfer is affected by the LW mode bit. In Word mode, transfer is done in 16 bits, and in Long Word mode, transfer is done in 32 bits.

Instruction	SP		
OPERATION	ADDRESS	—	MEMORY
DISPLACEMENT		—+	OPERAND

Example of SR mode:

1. Load HL from location (SP – 4) in Native mode, Word mode

```
LD HL, (SP-4) ;Load into the HL from the
               ;contents of the memory location
               ;whose address is four less than
               ;the contents of SP.
               ;Assume it is in Native/Word mode.
```

	HLz	HL	SPz	SP
Before instruction execution	1234	5678	07FF	7F00
After instruction execution	EFCD	AB89	07FF	7F00
Memory location	07FF7EFC	89		
	07FF7EFD	AB		

Address calculation: In Native mode, FCH (–4 in Decimal) encoding in the instruction is sign extended to a 16-bit value before the address calculation. Calculation is done in modulo 2^{16} and does not take into account the Stack Pointer's extended portion.

	7F00

	7EFC

4.3 DATA TYPES

The Z380 CPU can operate on bits, binary-coded decimal (BCD) digits (four bits), bytes (eight bits), words (16 bits or 32 bits), byte strings, and word strings. Bits in registers can be set, cleared, and tested.

The basic data type is a byte, which is also the basic accessible element in the register, memory, and I/O address space. The 8-bit load, arithmetic, logical, shift, and rotate instructions operate on bytes in registers or memory. Bytes can be treated as logical, signed numeric, or unsigned numeric value.

Words are operated on in a similar manner by the word load, arithmetic, logical, and shift and rotate instructions.

Operation on 2-byte words is also supported. Sixteen-bit load and arithmetic instructions operate on words in registers or memory; words can be treated as signed or unsigned numeric values. I/O reads and writes can be 8-bit or 16-bit operations. Also, the Z380 CPU architecture supports operation in Long Word mode to handle a 32-bit address manipulation. For that purpose, 16-bit wide registers originally on the Z80 have been expanded to 32 bits wide, along with the support of the arithmetic instruction needed for a 32-bit address manipulation.

Bits are fully supported and addressed by number within a byte (see Figure 2-2). Bits within byte registers or memory locations can be tested, set, or cleared.

Operation on binary-coded decimal (BCD) digits are supported by Decimal Adjust Accumulator (DAA) and Rotate Digit (RLD and RRD) instructions. BCD digits are stored in byte registers or memory locations, two per byte. The DAA instruction is used after a binary addition or subtraction of BCD numbers. Rotate Digit instructions are used to shift BCD digit strings in memory.

Strings of up to 65536 (64K) bytes of Byte data or Word data can be manipulated by the Z380 CPU's block move, block search, and block I/O instructions. The block move instructions allow strings of bytes/words in memory to be moved from one location to another. Block search instructions provide for scanning strings of bytes/words in memory to locate a particular value. Block I/O instructions allow strings of bytes or words to be transferred between memory and a peripheral device.

Arrays are supported by Indexed mode (with 8-bit, 16-bit, or 24-bit displacement). Stack is supported by the Indexed and the Stack Pointer Relative addressing modes, and by special instructions such as Call, Return, Push, and Pop.

CHAPTER 5 INSTRUCTION SET

5.1 INTRODUCTION

The Z380™ CPU instruction set is a superset of the Z80 CPU and the Z180 MPU; the Z380 CPU is opcode compatible with the Z80 CPU/Z180 MPU. Thus, a Z80/Z180 program can be executed on a Z380 CPU without modification. The instruction set is divided into 12 groups by function:

- 8-Bit Load/Exchange Group
- 16/32-Bit Load, Exchange, SWAP and Push/Pop Group
- Block Transfers, and Search Group
- 8-Bit Arithmetic and Logic Operations
- 16/32-Bit Arithmetic Operations
- 8-Bit Bit Manipulation, Rotate and Shift Group
- 16-Bit Rotates and Shifts

- Program Control Group
- Input and Output Operations for External I/O Space
- Input and Output Operations for Internal I/O Space
- CPU Control Group
- Decoder Directives

This chapter describes the instruction set of the Z380 CPU. Flags and condition codes are discussed in relation to the instruction set. Then, the interpretability of instructions and trap are discussed. The last part of this chapter is a detailed description of each instruction, listed in alphabetical order by mnemonic. This section is intended as a reference for Z380 CPU programmers. The entry for each instruction contains a complete description of the instruction, including addressing modes, assembly language mnemonics, and instruction opcode formats.

5.2 PROCESSOR FLAGS

The Flag register contains six bits of status information that are set or cleared by CPU operations (Figure 5-1). Four of these bits are testable (C, P/V, Z, and S) for use with conditional jump, call, or return instructions. Two flags are not testable (H and N) and are used for binary-coded decimal (BCD) arithmetic.

The Flag register provides a link between sequentially executed instructions, in that the result of executing one instruction may alter the flags, and the resulting value of the flags can be used to determine the operation of a subsequent instruction. The program control instructions, whose operation depends on the state of the flags, are the Jump, Jump Relative, subroutine Call, Call Relative, and subroutine Return instructions; these instructions are referred to as conditional instructions.

Figure 5-1. Flag Register

5.2.7 Condition Codes

The Carry, Zero, Sign, and Parity/Overflow flags are used to control the operation of the conditional instructions. The operation of these instructions is a function of the state of one of the flags. Special mnemonics called condition codes are used to specify the flag setting to be tested during execution of a conditional instruction; the condition codes are encoded into a 3-bit field in the instruction opcode itself.

Table 5-1 lists the condition code mnemonic, the flag setting it represents, and the binary encoding for each condition code.

Table 5-1. Condition codes

Condition Codes for Jump, Call, and Return Instructions			
Mnemonic	Meaning	Flag Setting	Binary Code
NZ	Not Zero*	Z = 0	000
Z	Zero*	Z = 1	001
NC	No Carry*	C = 0	010
C	Carry*	C = 1	011
NV	No Overflow	V = 0	100
PO	Parity Odd	V = 0	100
V	Overflow	V = 1	101
PE	Parity Even	V = 1	101
NS	No Sign	S = 0	110
P	Plus	S = 0	110
S	Sign	S = 1	111
M	Minus	S = 1	111

*Abbreviated set

Condition Codes for Jump Relative and Call Relative Instructions			
Mnemonic	Meaning	Flag Setting	Binary Code
NZ	Not Zero	Z = 0	100
Z	Zero	Z = 1	101
NC	No Carry	C = 0	110
C	Carry	C = 1	111

5.3.8. Long Word Mode (LW)

This bit controls the Long Word/Word mode selection for the Z380 CPU. This bit is set by the SETC LW instruction and cleared by the RESC LW instruction. When this bit is set, the Z380 CPU is in Long Word mode; when this bit is cleared the Z380 CPU is in Word mode. Reset clears this bit. Note that individual Word load and exchange instructions may be executed in either Word or Long Word mode using the DDIR W and DDIR LW decoder directives.

5.3.9. Interrupt Enable Flag (IEF)

This bit is the master Interrupt Enable for the Z380 CPU. This bit is set by the EI instruction and cleared by the DI instruction, or on acknowledgment of an interrupt request. When this bit is set, interrupts are enabled; when this bit is cleared, interrupts are disabled. Reset clears this bit.

5.3.10. Interrupt Mode (IM)

This 2-bit field controls the interrupt mode for the /INT0 interrupt request. These bits are controlled by the IM instructions (00 = IM 0, 01 = IM 1, 10 = IM 2, 11 = IM 3). Reset clears both of these bits, selecting Interrupt Mode 0.

5.4 INSTRUCTION EXECUTION AND EXCEPTIONS

Three types of exception conditions—interrupts, trap, and Reset—can alter the normal flow of program execution. Interrupts are asynchronous events generated by a device external to the CPU; peripheral devices use interrupts to request service from the CPU. Trap is a synchronous event generated internally in the CPU by executing undefined instructions. Reset is an asynchronous event generated by outside circuits. It terminates all current activities and puts the CPU into a known state. Interrupts and Traps are discussed in detail in Chapter 6, and Reset is discussed in detail in Chapter 7. This section examines the relationship between instructions and the exception conditions.

5.4.1 Instruction Execution and Interrupts

When the CPU receives an interrupt request, and it is enabled for interrupts of that class, the interrupt is normally processed at the end of the current instruction. However, the block transfer and search instructions are designed to be interruptible so as to minimize the length of time it takes the CPU to respond to an interrupt. If an interrupt request is received during a block move, block search, or block I/O instruction, the instruction is suspended after the current iteration. The address of the instruction itself, rather than the address of the following instruction, is saved on the stack, so that the same instruction is executed again when the interrupt handler executes an interrupt return

5.3.11. Lock (LCK)

This bit controls the Lock/Unlock status of the Z380 CPU. This bit is set by the SETC LCK instruction and cleared by the RESC LCK instruction. When this bit is set, no bus requests will be accepted, providing exclusive access to the bus by the Z380 CPU. When this bit is cleared, the Z380 CPU will grant bus requests in the normal fashion. Reset clears this bit.

5.3.12. AF or AF' Register Select (AF')

This bit controls and reports whether AF or AF' is the currently active pair of registers. AF is selected when this bit is cleared, and AF' is selected when this bit is set. Reset clears this bit, selecting AF.

instruction. The contents of the repetition counter and the registers that index into the block operands are such that, after each iteration, when the instruction is reissued upon returning from an interrupt, the effect is the same as if the instruction were not interrupted. This assumes, of course, that the interrupt handler preserves the registers.

5.4.2 Instruction Execution and Trap

The Z380 MPU generates a Trap when an undefined opcode is encountered. The action of the CPU in response to Trap is to jump to address 00000000H with the status bit(s) set. This response is similar to the Z180 MPU's action on execution of an undefined instruction. The Trap is enabled immediately after reset, and it is not maskable. This feature can be used to increase software reliability or to implement "extended" instructions. An undefined opcode can be fetched from the instruction stream, or it can be returned as a vector in an interrupt acknowledge transaction in Interrupt mode 0.

Since it jumps to address 00000000H, it is necessary to have a Trap handling routine at the beginning of the program if processing is to proceed. Otherwise, it behaves just like a reset for the CPU. For a detailed description, refer to Chapter 6.

5.5.2 16-Bit and 32-Bit Load, Exchange, SWAP, and PUSH/POP Group

This group of load, exchange, and PUSH/POP instructions (Table 5-4) allows one or two words of data (two bytes equal one word) to be transferred between registers and memory.

The exchange instructions (Table 5-5) allow for switching between the primary and alternate register files, exchanging the contents of two register files, exchanging the contents of an addressing register with the top word on the stack. For possible combinations of the word exchange instructions, refer to Table 5-5. The 16-bit and 32-bit loads include transfer between registers and memory and immediate loads of registers or memory. The Push and Pop stack instructions are also included in this group. None of these instructions affect the CPU flags, except for EX AF, AF'.

Table 5-6 has the supported source/destination combination for the 16-bit and 32-bit load instructions. The transfer size, 16-bit or 32-bit, is determined by the status of LW bit in SR, or by DDIR Decoder Directives.

PUSH/POP instructions are used to save/restore the contents of a register onto the stack. It can be used to exchange data between procedures, save the current register file on context switching, or manipulate data on the stack, such as return addresses. Supported sources are listed in Table 5-7.

Swap instructions allows swapping of the contents of the Word wide register (BC, DE, HL, IX, or IY) with its Extended portion. These instructions are useful to manipulate the upper word of the register to be set in Word mode. For example, when doing data accesses, other than 00000000H-0000FFFFH address range, use this instruction to set "data frame" addresses.

This group of instructions is affected by the status of the LW bit in SR (Select Register), and Decoder Directives which specifies the operation mode in Word or Long Word.

Table 5-4. 16-Bit and 32-Bit Load, Exchange, PUSH/POP Group Instructions

Instruction Name	Format	Note
Exchange Word/Long Word Registers	EX dst,src	See Table 5-5
Exchange Byte/Word Registers with Alternate Bank	EXX	
Exchange Register Pair with Alternate Bank	EX RR,RR'	RR = AF, BC, DE, or HL
Exchange Index Register with Alternate Bank	EXXX EXXY

PUSH	PUSH src	See Table 5-7
Swap Contents of D31-D16 and D15-D0	SWAP dst	dst = BC, DE, HL, IX, or IY

Table 5-5. Supported Source and Destination Combination for 16-Bit and 32-Bit Exchange Instructions

Destination	Source				
	BC	DE	HL	IX	IY
BC	√	√	√	√	
DE		√	√	√	
HL			√	√	
IX				√	
(SP)		√	√	√	

Note: √ are supported combinations. The exchange instructions which designate IY register as destination are covered by the other combinations. These Exchange Word instructions are affected by Long Word mode.

has to be an even number (D0 = 0) in Word mode transfer, and a multiple of four in Long Word mode (D1 and D0 are both 0). Also, in Word or Long Word Block transfer, memory pointer values are recommended to be even numbers so the number of the transactions will be minimized.

Note that regardless of the Z380's operation mode, Native or Extended, memory pointer increment/decrement will be done in modulo 2³². For example, if the operation is LDI and HL31-HL0 (HLz and HL) hold 0000FFFF, after the operation the value in the HL31-HL0 will be 0010000.

Load, Increment and Repeat in Word/Long Word	LDIRW

5.5.4 8-bit Arithmetic and Logical Group

This group of instructions (Table 5-9) perform 8-bit arithmetic and logical operations. The Add, Add with Carry, Subtract, Subtract with Carry, AND, OR, Exclusive OR, and Compare takes one input operand from the accumulator and the other from a register, from immediate data in the instruction itself, or from memory. For memory addressing modes, follows are supported—Indirect Register, Indexed, and Direct Address—except multiplies, which returns the 16-bit result to the same register by multiplying the upper and lower bytes of one of the register pair (BC, DE, HL, or SP).

The Increment and Decrement instructions operate on data in a register or in memory; all memory addressing modes are supported. These instructions operate only on the accumulator—Decimal Adjust, Complement, and Negate. The final instruction in this group, Extend Sign, sets the CPU flags according to the computed result.

The EXTS instruction extends the sign bit and leaves the result in the HL register. If it is in Long Word mode, HLz (HL31-HL16) portion is also affected.

The TST instruction is a nondestructive AND instruction. It ANDs "A" register and source, and changes flags according to the result of operation. Both source and destination values will be preserved.

Table 5-9. Supported Source/Destination for 8-Bit Arithmetic and Logic Group

Instruction Name	Format	src/ dst	src/ dst															
			A	B	C	D	E	H	L	IXH	IXL	IYH	IYL	n	(HL)	(IX+d)	(IY+x)

Note 1: dst = BC, DE, HL, or SP.

5.5.6 8-Bit Manipulation, Rotate and Shift Group

Instructions in this group (Table 5-11) test, set, and reset bits within bytes, and rotate and shift byte data one bit position. Bits to be manipulated are specified by a field within the instruction. Rotate can optionally concatenate the Carry flag to the byte to be manipulated. Both left and right shifting is supported. Right shifts can either shift 0 into bit 7 (logical shifts), or can replicate the sign in bits 6 and 7 (arithmetic shifts). All these instructions, Set Bit and Reset Bit, set the CPU flags according to the calculated result; the operand can be a register or a memory location

specified by the Indirect Register or Indexed addressing mode.

The RLD and RRD instructions are provided for manipulating strings of BCD digits; these rotate 4-bit quantities in memory specified by the Indirect Register. The low-order four bits of the accumulator are used as a link between rotation of successive bytes.

Table 5-11. Bit Set/Reset/Test, Rotate and Shift Group

5.5.7 16-Bit Manipulation, Rotate and Shift Group

Instructions in this group (Table 5-12) rotate and shift word data one bit position. Rotate can optionally concatenate the Carry flag to the word to be manipulated. Both left and right shifting is supported. Right shifts can either shift 0 into

bit 15 (logical shifts), or can replicate the sign in bits 14 and 15 (arithmetic shifts). The operand can be a register pair or memory location specified by the Indirect Register or Indexed addressing mode, as shown below.

Table 5-12. 16-Bit Rotate and Shift Group.

Instruction Name	Format	Destination

5.5.9 External Input/Output Instruction Group

This group of instructions (Table 5-14) are used for transferring a byte, a word, or string of bytes or words between peripheral devices and the CPU registers or memory. Byte I/O port addresses transfer bytes on D7-D0 only. These 8-bit peripherals in a 16-bit data bus environment must be connected to data line D7-D0. In an 8-bit data bus environment, word I/O instructions to external I/O peripherals should not be used; however, on-chip peripherals which is external to the CPU core and assigned as word I/O device can still be accessed by word I/O instructions.

The instructions for transferring a single byte (IN, OUT) can transfer data between any 8-bit CPU register or memory address specified in the instruction and the peripheral port specified by the contents of the C register. The IN instruction sets the CPU flags according to the input data; however, special instructions restricted to using the CPU accumulator and Direct Address mode and do not affect the CPU flags. Another variant tests an input port specified by the contents of the C register and sets the CPU flags without modifying CPU registers or memory.

The instructions for transferring a single word (INW, OUTW) can transfer data between the register pair and the peripheral port specified by the contents of the C register. For Word I/O, the contents of B, D, or H appear on D7-D0 and

the contents of C, E, or L appear D15-D7. These instructions do not affect the CPU flags.

Also, there are I/O instructions available which allow to specify 16-bit absolute I/O address (with DDIR decoder directives, a 24-bit or 32-bit address is specified) is available. These instructions do not affect the CPU flags.

The remaining instructions in this group form a powerful and complete complement of instructions for transferring blocks of data between I/O ports and memory. The operation of these instructions is very similar to that of the block move instructions described earlier, with the exception that one operand is always an I/O port whose address remains unchanged while the address of the other operand (a memory location) is incremented or decremented. In Word mode of transfer, the counter (i.e., BC register) holds the number of transfers, rather than number of bytes to transfer in memory-to-memory word block transfer. Both byte and word forms of these instructions are available. The automatically repeating forms of these instructions are interruptible, like memory-to-memory transfer.

The I/O addresses output on the address bus is dependant on the I/O instruction, as listed in Table 2-1.

5.5.10 Internal I/O Instruction Group

This group (Table 5-15) of instructions is used to access on-chip I/O addressing space on the Z380 CPU. This group consists of instructions for transferring a byte from/to Internal I/O locations and the CPU registers or memory, or a blocks of bytes from the memory to the same size of Internal I/O locations for initialization purposes. These instructions are originally assigned as newly added I/O instructions on the Z180 MPU to access Page 0 I/O addressing space. There is 256 Internal I/O locations, and all of them are byte-wide. When one of these I/O instructions is executed, the Z380 MPU outputs the register address being accessed in a pseudo transaction of two BUSCLK durations cycle, with the address signals A31-A8 at 0. In the pseudo transactions, all bus control signals are at their inactive state.

The instructions for transferring a single byte (IN0, OUT0) can transfer data between any 8-bit CPU register and the Internal I/O address specified in the instruction. The IN0 instruction sets the CPU flags according to the input data; however, special instructions which do not have a destina-

tion in the instruction with Direct Address (IN0 (n)), do not affect the CPU register, but alters flags accordingly. Another variant, the TSTIO instruction, does a logical AND to the instruction operand with the internal I/O location specified by the C register and changes the CPU flags without modifying CPU registers or memory.

The remaining instructions in this group form a powerful and complete complement of instructions for transferring blocks of data from memory to Internal I/O locations. The operation of these instructions is very similar to that of the block move instructions described earlier, with the exception that one operand is always an Internal I/O location whose address also increments or decrements by one automatically. Also, the address of the other operand (a memory location) is incremented or decremented. Since Internal I/O space is byte-wide, only byte forms of these instructions are available. Automatically repeating forms of these instructions are interruptible, like memory-to-memory transfer.

Table 5-15. Internal I/O Instruction Group

Instruction Name	Format
Input from Internal I/O Location	IN0 dst,(n) dst=A, B, C, D, E, H or L
Input from Internal I/O Location(Nondestructive)	IN0 (n)
Test I/O	TSTIO n
Output to Internal I/O Location	OUT0 (n),src src=A, B, C, D, E, H or L
Output to Internal I/O and Decrement	OTDM
Output to Internal I/O and Increment	OTIM
Output to Internal I/O, Decrement and Repeat	OTDMR
Output to Internal I/O, Increment and Repeat	OTIMR

Currently, the Z380 CPU core has the following registers as a part of the CPU core:

Register Name	Internal I/O address
Interrupt Enable Register	16H
Assigned Vector Base Register	17H
Trap Register	18H
Chip Version ID Register	0FFH

Chip Version ID register returns one byte data, which indicates the version of the CPU, or the specific implementation of the Z380 CPU based Superintegration device. Currently, the value 00H is assigned to the Z380 MPU, and other values are reserved.

Also, the Z380 MPU has registers to control chip selects, refresh, waits, and I/O clock divide to Internal I/O address 00H to 10H. For these register, refer to Z380 MPU Product specification.

For the other three registers, refer to Chapter 6, "Interrupt and Trap."

5.5.12 Decoder Directives

The Decoder Directives (Table 5-17) are a special instructions to expand the Z80 instruction set to handle the Z380's 4 Gbytes of linear memory addressing space. For details on this instruction, refer to Chapter 3.

Table 5-17. Decoder Directive Instructions

DDIR W	Word Mode
DDIR IB,W	Immediate Byte, Word Mode
DDIR IW,W	Immediate Word, Word Mode
DDIR IB	Immediate Byte
DDIR LW	Long Word Mode
DDIR IB,LW	Immediate Byte, Long Word Mode
DDIR IW,LW	Immediate Word, Long Word Mode
DDIR IW	Immediate Word

5.6 NOTATION AND BINARY ENCODING

The rest of this chapter consists of a detailed description of the Z380 CPU instructions, arranged in alphabetical order by mnemonic. This section describes the notational conventions used in the instruction descriptions and the binary encoding for register fields within the instruction's operation codes (opcodes).

The description of each instruction begins on a new page. The instruction mnemonic and name are printed in bold letters at the top of each page to enable the reader to easily locate a desired description. The assembly language syntax is then given in a single generic form that covers all the variants of the instruction, along with a list of applicable addressing modes. This is followed by a description of the operation performed by the instruction in "pseudo Pascal" fashion, a detailed description, a listing of all the flags that are affected by the instruction, and illustrations of the opcodes for all variants of the instruction.

Symbols. The following symbols are used to describe the instruction set.

n	An 8-bit constant
nn	A 16-bit constant
d	An 8-bit offset. (two's complement)
src	Source of the instruction
dst	Destination of the instruction
SR	Select Register
R	Any register. In Word operation, any register pair. Any 8-bit register (A, B, C, D, E, H, or L) for Byte operation.
IR	Indirect register
RX	Indexed register (IX or IY) in Word operation, IXH, IXL, IYH, or IYL for Byte operation.
SP	Current Stack Pointer
(C)	I/O Port pointed by C register
cc	Condition Code
[]	Optional field
()	Indirect Address Pointer or Direct Address

Assignment of a value is indicated by the symbol "←". For example,

dst ← dst + src

indicates that the source data is added to the destination data and the result is stored in the destination location.

The symbol "↔" indicates that the source and destination is swapping. For example,

dst ↔ src

indicates that the source data is swapped with the data in the destination; after the operation, data at "src" is in the "dst" location, and data in "dst" is in the "src" location.

The notation "dst (b)" is used to refer to bit "b" of a given location, "dst(m-n)" is used to refer to bit location m to n of the destination. For example,

HL(7) specifies bit 7 of the destination.

and

HL(23-16) specifies bit location 23 to 16 of the HL register.

Flags. The F register contains the following flags followed by symbols.

S	Sign Flag
Z	Zero Flag
H	Half Carry Flag
P/V	Parity/Overflow Flag
N	Add/Subtract Flag
C	Carry Flag

Table 5-18. Execution Time

Operation	Byte	Word	Word	Long	Long	Long	Long	Long
Sequence	B	W	B/B	W/W	W/B/B	B/W/B	B/B/W	B/B/B/B

8X External I/O Write	1-9	1-9	N/A	N/A	N/A	N/A	N/A	N/A

Note: Units are in Clocks. "N/A" is not applicable for that particular transaction.

ADC ADD WITH CARRY (WORD)

ADC HL,src dst = HL
 src = BC, DE, HL, SP

Operation: HL(15-0) ← HL(15-0) + src(15-0) + C

The source operand together with the Carry flag is added to the HL register and the sum is stored in the HL register. The contents of the source are unaffected. Two's complement addition is performed.

Flags:

- S: Set if the result is negative; cleared otherwise
- Z: Set if the result is zero; cleared otherwise
- H: Set if there is a carry from bit 11 of the result; cleared otherwise
- V: Set if arithmetic overflow occurs, that is, if both operands are of the same sign and the result is of the opposite sign; cleared otherwise
- N: Cleared
- C: Set if there is a carry from the most significant bit of the result; cleared otherwise

Addressing Mode	Syntax	Instruction Format	Execute Time	Note
R:	ADC HL,R	11101101 01rr1010	2	

Field Encodings: rr: 00 for BC, 01 for DE, 10 for HL, 11 for SP

ADD ADD (BYTE)

ADD A,src src = R, RX, IM, IR, X

Operation: $A \leftarrow A + \text{src}$

The source operand is added to the accumulator and the sum is stored in the accumulator. The contents of the source are unaffected. Two's complement addition is performed.

Flags:

- S: Set if the result is negative; cleared otherwise
- Z: Set if the result is zero; cleared otherwise
- H: Set if there is a carry from bit 3 of the result; cleared otherwise
- V: Set if arithmetic overflow occurs, that is, if both operands are of the same sign and the result is of the opposite sign; cleared otherwise
- N: Cleared
- C: Set if there is a carry from the most significant bit of the result; cleared otherwise

Addressing

Mode	Syntax	Instruction Format	Execute Time	Note
R:	ADD A,R	10000-r-	2	
RX:	ADD A,RX	11y11101 1000010w	2	
IM:	ADD A,n	11000110 —n—	2	
IR:	ADD A,(HL)	10000110	2+r	
X:	ADD A,(XY+d)	11y11101 10000110 —d—	4+r	1

Field Encodings:

- r: per convention
- y: 0 for IX, 1 for IY
- w: 0 for high byte, 1 for low byte

ADD ADD TO STACK POINTER (WORD)

ADD SP,src src = IM

Operation: if (XM) then begin
 SP(31-0) ← SP(31-0) + src(31-0)
 end
 else begin
 SP(15-0) ← SP(15-0) + src(15-0)
 end

The source operand is added to the SP register and the sum is stored in the SP register. This has the effect of allocating or allocating space on the stack. Two's complement addition is performed.

Flags: S: Unaffected
 Z: Unaffected
 H: Set if there is a carry from bit 11 of the result; cleared otherwise
 V: Unaffected
 N: Cleared
 C: Set if there is a carry from the most significant bit of the result; cleared otherwise

Addressing Mode	Syntax	Instruction Format	Execute Time	Note
IM:	ADD SP,n	11101101 10000010 -n(low)- n(high)	2	I, X

AND AND (BYTE)

AND [A,]src src = R, RX, IM, IR, X

Operation: A ← A AND src

A logical AND operation is performed between the corresponding bits of the source operand and the accumulator and the result is stored in the accumulator. A 1 is stored wherever the corresponding bits in the two operands are both 1s; otherwise a 0 is stored. The contents of the source are unaffected.

Flags:

- S: Set if the most significant bit of the result is set; cleared otherwise
- Z: Set if all bits of the result are zero; cleared otherwise
- H: Set
- P: Set if the parity is even; cleared otherwise
- N: Cleared
- C: Cleared

Addressing Mode	Syntax	Instruction Format	Execute Time	Note
R:	AND [A,]R	10100-r-	2	
RX:	AND [A,]RX	11y11101 1010010w	2	
IM:	AND [A,]n	11100110 —n—	2	
IR:	AND [A,](HL)	10100110	2+r	
X:	AND [A,](XY+d)	11y11101 10100110—d—	4+r	

Field Encodings:

- r: per convention
- y: 0 for IX, 1 for IY
- w: 0 for high byte, 1 for low byte

BIT BIT TEST

BIT b,dst dst = R, IR, X

Operation: Z ← NOT dst(b)

The specified bit b within the destination operand is tested, and the Zero flag is set to 1 if the specified bit is 0, otherwise the Zero flag is cleared to 0. The contents of the destination are unaffected. The bit to be tested is specified by a 3-bit field in the instruction; this field contains the binary encoding for the bit number to be tested. The bit number b must be between 0 and 7.

Flags:

- S: Unaffected
- Z: Set if the specified bit is zero; cleared otherwise
- H: Set
- V: Unaffected
- N: Cleared
- C: Unaffected

Addressing Mode	Syntax	Instruction Format	Execute Time	Note
R:	BIT b,R	11001011 01bbb-r-	2	
IR:	BIT b,(HL)	11001011 01bbb110	2+r	
X:	BIT b,(XY+d)	11y11101 11001011 —d— 01bbb110	4+r	I

Field Encodings: r: per convention
 y: 0 for IX, 1 for IY

**CALL
CALL**

CALL [cc,]dst dst = DA

Operation: if (cc is TRUE) then begin
 if (XM) then begin
 SP ← SP - 4
 (SP) ← PC(7-0)
 (SP+1) ← PC(15-8)
 (SP+2) ← PC(23-16)
 (SP+3) ← PC(31-24)
 PC(31-0) ← dst(31-0)
 else begin
 SP ← SP - 2
 (SP) ← PC(7-0)
 (SP+1) ← PC(15-8)
 PC(15-0) ← dst(15-0)
 end
 end

A conditional Call transfers program control to the destination address if the setting of a selected flag satisfies the condition code "cc" specified in the instruction; an Unconditional Call always transfers control to the destination address. The current contents of the Program Counter (PC) are pushed onto the top of the stack; the PC value used is the address of the first instruction byte following the Call instruction. The destination address is then loaded into the PC and points to the first instruction of the called procedure. At the end of a procedure a Return instruction (RET) can be used to return to the original program.

Each of the Zero, Carry, Sign, and Overflow Flags can be individually tested and a call performed conditionally on the setting of the flag.

The operand is not enclosed in parentheses with the CALL instruction.

Flags: S: Unaffected
 Z: Unaffected
 H: Unaffected
 V: Unaffected
 N: Unaffected
 C: Unaffected

Addressing Mode	Syntax	Instruction Format	Execute Time	Note
DA:	CALL CC,addr	11-cc100 -a(low)- -a(high)	note	I, X
	CALL addr	11001101 -a(low)- -a(high)	4+w	I, X

Field Encodings: cc: 000 for NZ, 001 for Z, 010 for NC, 011 for C, 100 for PO or NV, 101 for PE or V, 110 for P or NS, 111 for M or S

Note: 2 if CC is false, 4+w if CC is true

CCF COMPLEMENT CARRY FLAG

CCF

Operation: C ← NOT C

The Carry flag is inverted.

Flags:

- S: Unaffected
- Z: Unaffected
- H: The previous state of the Carry flag
- V: Unaffected
- N: Cleared
- C: Set if the Carry flag was clear before the operation; cleared otherwise

Addressing Mode	Syntax	Instruction Format	Execute Time Note
	CCF	00111111	2

CPW COMPARE (WORD)

CPW [HL,]src src = R, RX, IM, X

Operation: HL(15-0) – src(15-0)

The source operand is compared with the HL register and the flags are set accordingly. The contents of the HL register and the source are unaffected. Two's complement subtraction is performed.

Flags:

- S: Set if the result is negative; cleared otherwise
- Z: Set if the result is zero; cleared otherwise
- H: Set if there is a borrow from bit 12 of the result; cleared otherwise
- V: Set if arithmetic overflow occurs, that is, if the operands are of different signs and the result is of the same sign as the source; cleared otherwise
- N: Set
- C: Set if there is a borrow from the most significant bit of the result; cleared otherwise

Addressing Mode	Syntax	Instruction Format	Execute Time	Note
R:	CPW [HL,]R	11101101 101111rr	2	
RX:	CPW [HL,]RX	11y11101 10111111	2	
IM:	CPW [HL,]nn	11101101 10111110 -n(low)- n(high)-	2	
X:	CPW [HL,](XY+d)	11y11101 11111110 —d—	4+r	

Field Encodings:

- rr: 00 for BC, 01 for DE, 11 for HL
- y: 0 for IX, 1 for IY

CPDR COMPARE, DECREMENT AND REPEAT (BYTE)

CPDR

Operation: Repeat until (BC=0 OR match) begin
 A - (HL)
 if (XM) then begin
 HL(31-0) ← HL(31-0) - 1
 end
 else begin
 HL(15-0) ← HL(15-0) - 1
 end
 BC(15-0) ← BC(15-0) - 1
 end

This instruction is used for searching strings of byte data. The bytes of data starting at the location addressed by the HL register are compared with the contents of the accumulator until either an exact match is found or the string length is exhausted because the BC register has decremented to zero. The Sign and Zero flags are set to reflect the result of the comparison. The contents of the accumulator and the memory bytes are unaffected. Two's complement subtraction is performed.

After each comparison, the HL register is decremented by one, thus moving the pointer to the previous element in the string.

The BC register, used as a counter, is then decremented by one. If the result of decrementing the BC register is not zero and no match has been found, the process is repeated. If the contents of the BC register are zero at the start of this instruction, a string length of 65,536 is indicated.

This instruction can be interrupted after each execution of the basic operation. The PC value at the start of this instruction is pushed onto the stack so that the instruction can be resumed.

Flags:

- S: Set if the last result is negative; cleared otherwise
- Z: Set if the last result is zero, indicating a match; cleared otherwise
- H: Set if there is a borrow from bit 4 of the last result; cleared otherwise
- V: Set if the result of decrementing BC is not equal to zero; cleared otherwise
- N: Set
- C: Unaffected

Addressing Mode	Syntax	Instruction Format	Execute Time	Note
CPDR		11101101 10111001	(3+r)n	X

CPIR

COMPARE, INCREMENT AND REPEAT (BYTE)

CPIR

Operation: Repeat until (BC=0 OR match) begin
 A - (HL)
 if (XM) then begin
 HL(31-0) ← HL(31-0) + 1
 end
 else begin
 HL(15-0) ← HL(15-0) + 1
 end
 BC(15-0) ← BC(15-0) - 1
 end

This instruction is used for searching strings of byte data. The bytes of data starting at the location addressed by the HL register are compared with the contents of the accumulator until either an exact match is found or the string length is exhausted because the BC register has decremented to zero. The Sign and Zero flags are set to reflect the result of the comparison. The contents of the accumulator and the memory bytes are unaffected. Two's complement subtraction is performed.

After each comparison, the HL register is incremented by one, thus moving the pointer to the next element in the string. The BC register, used as a counter, is then decremented by one. If the result of decrementing the BC register is not zero and no match has been found, the process is repeated. If the contents of the BC register are zero at the start of this instruction, a string length of 65,536 is indicated.

This instruction can be interrupted after each execution of the basic operation. The PC value at the start of this instruction is pushed onto the stack so that the instruction can be resumed.

Flags:

- S: Set if the last result is negative; cleared otherwise
- Z: Set if the last result is zero, indicating a match; cleared otherwise
- H: Set if there is a borrow from bit 4 of the last result; cleared otherwise
- V: Set if the result of decrementing BC is not equal to zero; cleared otherwise
- N: Set
- C: Unaffected

Addressing Mode	Syntax	Instruction Format	Execute Time	Note
	CPIR	11101101 10110001	(3+r)n	X

CPLW COMPLEMENT HL REGISTER (WORD)

CPLW [HL]

Operation: HL(15-0) ← NOT HL(15-0)

The contents of the HL register are complemented (ones complement); all 1s are changed to 0 and vice-versa.

Flags:

- S: Unaffected
- Z: Unaffected
- H: Set
- V: Unaffected
- N: Set
- C: Unaffected

Addressing Mode	Syntax	Instruction Format	Execute Time	Note
	CPLW [HL]	11011101 00101111	2	

DDIR DECODER DIRECTIVE

DDIR mode mode = W or LW, IB or IW

Operation: None, decoder directive only

This is not an instruction, but rather a directive to the instruction decoder.

The instruction decoder may be directed to fetch an additional byte or word of immediate data or address with the instruction, as well as tagging the instruction for execution in either Word or Long Word mode. All eight combinations of the two options are supported, as shown in the encoding below. Instructions which do not support decoder directives are assembled by the instruction decoder as if the decoder directive were not present.

The IB decoder directive causes the decoder to fetch an additional byte immediately after the existing immediate data or direct address, and in front of any trailing opcode bytes (with instructions starting with DD-CB or FD-CB, for example).

Likewise, the IW decoder directive causes the decoder to fetch an additional word immediately after the existing immediate data or direct address, and in front of any trailing opcode bytes.

Byte ordering within the instruction follows the usual convention; least significant byte first, followed by more significant bytes. More-significant immediate data or direct address bytes not specified in the instruction are taken as all zeros by the processor.

The W decoder directive causes the instruction decoder to tag the instruction for execution in Word mode. This is useful while the Long Word (LW) bit in the Select Register (SR) is set, but 16-bit data manipulation is required for this instruction.

The LW decoder directive causes the instruction decoder to tag the instruction for execution in Long Word mode. This is useful while the LW bit in the SR is cleared, but 32-bit data manipulation is required for this instruction.

Flags:

- S: Unaffected
- Z: Unaffected
- H: Unaffected
- V: Unaffected
- N: Unaffected
- C: Unaffected

Addressing Mode	Syntax	Instruction Format	Execute Time	Note
	DDIR mode	11w11101 110000im	0	

Field Encodings:		
wim: 000	W	Word mode
001	IB,W	Immediate byte, Word mode
010	IW,W	Immediate word, Word mode
011	IB	Immediate byte
100	LW	Long Word mode
101	IB,LW	Immediate byte, Long Word mode
110	IW,LW	Immediate word, Long Word mode
111	IW	Immediate word

DEC[W] DECREMENT (WORD)

DEC[W] dst dst = R, RX

Operation: if (XM) then begin
 dst(31-0) ← dst(31-0) - 1
 end
 else begin
 dst(15-0) ← dst(15-0) - 1
 end

The destination operand is decremented by one and the result is stored in the destination. Two's complement subtraction is performed. Note that the length of the operand is controlled by the Extended/Native mode selection, which is consistent with the manipulation of an address by the instruction.

Flags: S: Unaffected
 Z: Unaffected
 H: Unaffected
 V: Unaffected
 N: Unaffected
 C: Unaffected

Addressing Mode	Syntax	Instruction Format	Execute Time	Note
R:	DEC[W] R	00rr1011	2	X
RX:	DEC[W] RX	11y11101 00101011	2	X

Field Encodings: rr: 00 for BC, 01 for DE, 10 for HL, 11 for SP
 y: 0 for IX, 1 for IY

DIVUW DIVIDE UNSIGNED (WORD)

DIVUW [HL,]src src = R, RX, IM, X

Operation: HL(15-0) ← HL / src
 HL(31-16) ← remainder

The contents of the the HL register (dividend) are divided by the source operand (divisor) and the quotient is stored in the lower word of the HL register; the remainder is stored in the upper word of the HL register. The contents of the source are unaffected. Both operands are treated as unsigned, binary integers. There are three possible outcomes of the DIVUW instruction, depending on the division and the resulting quotient:

Case 1: If the quotient is less than 65536, then the quotient is left in the HL register, the Overflow and Sign flags are cleared to 0, and the Zero flag is set according to the value of the quotient.

Case 2: If the divisor is zero, the HL register is unchanged, the Zero and Overflow flags are set to 1, and the Sign flag is cleared to 0.

Case 3: If the quotient is greater than or equal to 65536, the HL register is unchanged, the Overflow flag is set to 1, and the Sign and Zero flags are cleared to 0.

Flags:

- S: Cleared
- Z: Set if the quotient or divisor is zero; cleared otherwise
- H: Unaffected

EI ENABLE INTERRUPTS

EI [n]

Operation:

```

if (n is present) then begin
  for i=1 to 4 begin
    if (n(i) = 1) then begin
      IER(i-1) ← 1
    end
  end
  if (n(0) = 1) then begin
    SR(5) ← 1
  end
end
else begin
  SR(5) ← 1
end
    
```

If an argument is present, enable the selected interrupts by setting the appropriate enable bits in the Interrupt Enable Register, and then set the Interrupt Enable Flag (IEF1) in the Select Register (SR) if the least-significant bit of the argument is set, enabling maskable interrupts. Bits 7-5 of the argument are ignored.

If no argument is present, IEF1 in the SR is set to 1, enabling maskable interrupts.

Note that during the execution of this instruction and the following instruction, maskable interrupts are not sampled.

EX

EXCHANGE ADDRESSING REGISTER WITH TOP OF STACK

EX (SP),dst dst = HL, IX, IY

Operation: if (LW) then begin
 (SP+3) ↔ dst(31-24)
 (SP+2) ↔ dst(23-16)
 end
 (SP+1) ↔ dst(15-8)
 (SP) ↔ dst(7-0)

The contents of the destination register are exchanged with the top of the stack. In Long Word mode this exchange is two words; otherwise it is one word.

Flags: S: Unaffected
 Z: Unaffected
 H: Unaffected
 V: Unaffected
 N: Unaffected
 C: Unaffected

Field Encodings: r: per convention

EXTS EXTEND SIGN (BYTE)

EXTS [A]

Operation:

```

L ← A
if (A(7)=0) then begin
    H ← 00h
    if (LW) then begin
        HL(31-16) ← 0000h
    end
end
else begin
    H ← FFh
    if (LW) then begin
        HL(31-16) ← FFFFh
    end
end
    
```

The contents of the accumulator, considered as a signed, two's complement integer, are sign-extended to 16 bits and the result is stored in the HL register. The contents of the accumulator are unaffected. This instruction is useful for conversion of short signed operands into longer signed operands.

Field Encodings: pp: 00 for Mode 0, 01 for Mode 3, 10 for Mode 1, 11 for Mode 2

INW INPUT (WORD)

INW dst,(C) dst = R

Operation: dst(15-0) ← (C)

The word of data from the selected peripheral is loaded into the destination register. During the I/O transaction, the contents of the 32-bit BC register are placed on the address bus.

Flags:

- S: Set if the input data is negative; cleared otherwise
- Z: Set if the input data is zero; cleared otherwise
- H: Cleared
- P: Set if the input data has even parity; cleared otherwise
- N: Cleared
- C: Unaffected

Addressing Mode	Syntax	Instruction Format	Execute Time	Note
R:	INW R,(C)	11011101 01rrr000	2+i	

Field Encodings: rrr: 000 for BC, 010 for DE, 111 for HL

INO INPUT (FROM PAGE 0)

INO dst,(n) dst = R

Operation: dst ← (n)

The byte of data from the selected on-chip peripheral is loaded into the destination register. No external I/O transaction will be generated as a result of this instruction, although the I/O address will appear on the address bus while this internal read is occurring. The peripheral address is placed on the low byte of the address bus and zeros are placed on all other address lines. When the second opcode byte is 30h no data is stored in a destination; only the flags are updated.

Flags:

- S: Set if the input data is negative; cleared otherwise
- Z: Set if the input data is zero; cleared otherwise
- H: Cleared
- P: Set if the input data has even parity; cleared otherwise
- N: Cleared
- C: Unaffected

none:	INO (n)	11101101 00110000 —n—	3+i	

Field Encodings: r: per convention

INAW INPUT DIRECT FROM PORT ADDRESS (WORD)

INAW HL,(nn)

Operation: HL(15-0) ← (nn)

The word of data from the selected peripheral is loaded into the HL register. During the I/O transaction, the peripheral address from the instruction is placed on the address bus. Any bytes of address not specified in the instruction are driven on the address lines as all zeros.

Flags:

- S: Unaffected
- Z: Unaffected
- H: Unaffected
- V: Unaffected
- N: Unaffected
- C: Unaffected

Addressing Mode	Syntax	Instruction Format	Execute Time	Note
	INAW HL,(nn)	11111101 11011011 -n(low)- n(high)	3+i	I

INC[W] INCREMENT (WORD)

INC[W] dst dst = R, RX

Operation: if (XM) then begin
 dst(31-0) < dst(31-0) + 1
 end
 else begin
 dst(15-0) ← dst(15-0) + 1
 end

The destination operand is incremented by one and the sum is stored in the destination. Two's complement addition is performed. Note that the length of the operand is controlled by the Extended/Native mode selection, which is consistent with the manipulation of an address by the instruction.

Flags: S: Unaffected
 Z: Unaffected
 H: Unaffected
 V: Unaffected
 N: Unaffected
 C: Unaffected

Addressing Mode	Syntax	Instruction Format	Execute Time	Note

Field Encodings: rr: 00 for BC, 01 for DE, 10 for HL, 11 for SP
 y: 0 for IX, 1 for IY

INDW INPUT AND DECREMENT (WORD)

INDW

Operation:

(HL)	←	(DE)
BC(15-0)	←	BC(15-0) - 1
HL	←	HL - 2

This instruction is used for block input of strings of data. During the I/O transaction the 32-bit DE register is placed on the address bus.

First the word of data from the selected peripheral is loaded into the memory location addressed by the HL register. Then the BC register, used as a counter, is decremented by one. The HL register is then decremented by two, thus moving the pointer to the next destination for the input.

Flags:

S:	Unaffected
Z:	Set if the result of decrementing BC is zero; cleared otherwise
H:	Unaffected
V:	Unaffected
N:	Set
C:	Unaffected

Addressing Mode	Syntax	Instruction Format	Execute Time	Note
	INDW	11101101 11101010	2+i+w	

INDRW INPUT, DECREMENT AND REPEAT (WORD)

INDRW

Operation: repeat until (BC=0) begin
 (HL) ← (DE)
 BC(15-0) ← BC(15-0) - 1
 HL ← HL - 2
 end

This instruction is used for block input of strings of data. The string of input data from the selected peripheral is loaded into memory at consecutive addresses, starting with the location addressed by the HL register and decreasing. During the I/O transaction the 32-bit DE register is placed on the address bus.

First the BC register, used as a counter, is decremented by one. First the word of data from the selected peripheral is loaded into the memory location addressed by the HL register. Then the BC register, used as a counter, is decremented by one. The HL register is then decremented by two, thus moving the pointer to the next destination for the input. If the result of decrementing the BC register is 0, the instruction is terminated, otherwise the sequence is repeated. If the BC register contains 0 at the start of the execution of this instruction, 65536 bytes are input.

This instruction can be interrupted after each execution of the basic operation. The Program Counter value at the start of this instruction is saved before the interrupt request is accepted, so that the instruction can be properly resumed.

Flags:
 S: Unaffected
 Z: Set if the result of decrementing BC is zero; cleared otherwise
 H: Unaffected
 V: Unaffected
 N: Set
 C: Unaffected

INIRW

INPUT, INCREMENT AND REPEAT (WORD)

INIRW

Operation: repeat until (BC=0) begin
 (HL) ← (DE)
 BC(15-0) ← BC(15-0) - 1
 HL ← HL + 2
 end

This instruction is used for block input of strings of data. The string of input data from the selected peripheral is loaded into memory at consecutive addresses, starting with the location addressed by the HL register and increasing. During the I/O transaction the 32-bit DE register is placed on the address bus.

First the word of data from the selected peripheral is loaded into the memory location addressed by the HL register. Then the BC register, used as a counter, is decremented by one. The HL register is then incremented by two, thus moving the pointer to the next destination for the input. If the result of decrementing the BC register is 0, the instruction is terminated, otherwise the sequence is repeated. If the BC register contains 0 at the start of the execution of this instruction, 65536 bytes are input.

This instruction can be interrupted after each execution of the basic operation. The Program Counter value at the start of this instruction is saved before the interrupt request is accepted, so that the instruction can be properly resumed.

Flags:

Addressing Mode	Syntax	Instruction Format	Execute Time	Note
	INIRW	11101101 11110010	n X (2+i+w)	

JR JUMP RELATIVE

JR [cc,]dst dst = RA

Operation: if (cc is TRUE) then begin
 dst ← SIGN EXTEND dst
 if (XM) then begin
 PC(31-0) ← PC(31-0) + dst(31-0)
 end
 else begin
 PC(15-0) ← PC(15-0) + dst(15-0)
 end
 end

A conditional Jump transfers program control to the destination address if the setting of a selected flag satisfies the condition code "cc" specified in the instruction; an unconditional Jump always transfers control to the destination address. Either the Zero or Carry flag can be tested for the conditional Jump. If the jump is taken, the Program Counter (PC) is loaded with the destination address; otherwise the instruction following the Jump Relative instruction is executed.

The destination address is calculated using relative addressing. The displacement in the instruction is added to the PC value for the instruction following the JR instruction, not the value of the PC for the JR instruction.

These instructions employ either an 8-bit, 16-bit, or 24-bit signed, two's complement displacement from the PC to permit jumps within a range of -126 to +129 bytes, -32,765 to +32,770 bytes, or -8,388,604 to +8,388,611 bytes from the location of this instruction.

LDDW LOAD AND DECREMENT (WORD)

LDDW

Operation: if (LW) then begin
 (DE) ← (HL)
 (DE+1) ← (HL+1)
 (DE+2) ← (HL+2)
 (DE+3) ← (HL+3)
 DE ← DE - 4
 HL ← HL - 4
 BC(15-0) ← BC(15-0) - 4
 end
 else begin
 (DE) ← (HL)
 (DE+1) ← (HL+1)
 DE ← DE - 2
 HL ← HL - 2
 BC(15-0) ← BC(15-0) - 2
 end

This instruction is used for block transfers of words of data. The word of data at the location addressed by the HL register is loaded into the location addressed by the DE register. Both the DE and HL registers are then decremented by two or four, thus moving the pointers to the preceding words in the array. The BC register, used as a byte counter, is then decremented by two or four.

Both DE and HL should be even, to allow word transfers on the bus. BC must be even, transferring an even number of bytes, or the operation is undefined.

Flags:

- S: Unaffected
- Z: Unaffected
- H: Cleared
- V: Set if the result of decrementing BC is not equal to zero; cleared otherwise
- N: Cleared
- C: Unaffected

LDDRW LOAD, DECREMENT AND REPEAT (WORD)

LDDRW

Operation: repeat until (BC=0) begin
 if (LW) then begin
 (DE) ← (HL)
 (DE+1) ← (HL+1)
 (DE+2) ← (HL+2)
 (DE+3) ← (HL+3)
 DE ← DE - 4
 HL ← HL - 4
 BC(15-0) ← BC(15-0) - 4
 end
 else begin
 (DE) ← (HL)
 (DE+1) ← (HL+1)
 DE ← DE - 2
 HL ← HL - 2
 BC(15-0) ← BC(15-0) - 2
 end
 end

This instruction is used for block transfers of strings of data. The words of data at the location addressed by the HL register are loaded into memory starting at the location addressed by the DE register. The number of words moved is determined by the contents of the BC register. If the BC register contains zero when this instruction is executed, 65,536 words are transferred. The effect of decrementing the pointers during the transfer is important if the source and destination strings overlap with the source string starting at a lower memory address. Placing the pointers at the highest address of the strings and decrementing the pointers ensures that the source string is copied without destroying the overlapping area.

This instruction can be interrupted after each execution of the basic operation. The Program Counter value of the start of this instruction is saved before the interrupt request is accepted, so that the instruction can be properly resumed.

LDIW LOAD AND INCREMENT (WORD)

LDIW

Operation: if (LW) then begin
 (DE) ← (HL)
 (DE+1) ← (HL+1)
 (DE+2) ← (HL+2)
 (DE+3) ← (HL+3)
 DE ← DE + 4
 HL ← HL + 4
 BC(15-0) ← BC(15-0) - 4
 end
 else begin
 (DE) ← (HL)
 (DE+1) ← (HL+1)
 DE ← DE + 2
 HL ← HL + 2
 BC(15-0) ← BC(15-0) - 2
 end

This instruction is used for block transfers of words of data. The word of data at the location addressed by the HL register is loaded into the location addressed by the DE register. Both the DE and HL registers are then incremented by two or four, thus moving the pointers to the succeeding words in the array. The BC register, used as a byte counter, is then decremented by two or four.

Both DE and HL should be even, to allow word transfers on the bus. BC must be even, transferring an even number of bytes, or the operation is undefined.

Flags: S: Unaffected
 Z: Unaffected
 H: Cleared
 V: Set if the result of decrementing BC is not equal to zero; cleared otherwise

LDIRW LOAD, INCREMENT AND REPEAT (WORD)

LDIRW

Operation: repeat until (BC=0) begin
 if (LW) then begin
 (DE) ← (HL)
 (DE+1) ← (HL+1)
 (DE+2) ← (HL+2)
 (DE+3) ← (HL+3)
 DE ← DE + 4
 HL ← HL + 4
 BC(15-0) ← BC(15-0) - 4
 end
 else begin
 (DE) ← (HL)
 (DE+1) ← (HL+1)
 DE ← DE + 2
 HL ← HL + 2
 BC(15-0) ← BC(15-0) - 2
 end
 end

This instruction is used for block transfers of strings of data. The words of data at the location addressed by the HL register are loaded into memory starting at the location addressed by the DE register. The number of words moved is determined by the contents of the BC register. If the BC register contains zero when this instruction is executed, 65,536 words are transferred. The effect of incrementing the pointers during the transfer is important if the source and destination strings overlap with the source string starting at a higher memory address. Placing the pointers at the lowest address of the strings and incrementing the pointers ensures that the source string is copied without destroying the overlapping area.

This instruction can be interrupted after each execution of the basic operation. The Program Counter value of the start of this instruction is save before the interrupt request is accepted,so that the instruction can be properly resumed.

MTEST MODE TEST

MTEST

Operation: S ← SR(7)
Z ← SR(6)
C ← SR(1)

The three mode control bits in the Select Register (SR) are transferred to the flags. This allows the program to determine the state of the machine.

Flags: S: Set if Extended mode is in effect; cleared otherwise
Z: Set if Long word mode is in effect; cleared otherwise
H: Unaffected
V: Unaffected
N: Unaffected
C: Set if Lock mode is in effect; cleared otherwise

Addressing Mode	Syntax	Instruction Format	Execute Time	Note
	MTEST	11011101 11001111	2	

MULTUW MULTIPLY UNSIGNED (WORD)

MULTUW [HL,]src src = R, RX, IM, X

Operation: HL(31-0) ← HL(15-0) x src(15-0)

The contents of the HL register are multiplied by the source operand and the product is stored in the HL register. The contents of the source are unaffected. Both operands are treated as unsigned, binary integers.

The initial contents of the HL register are overwritten by the result. The Carry flag is set to indicate that the upper word of the HL register is required to represent the result; if the Carry flag is cleared, the product can be correctly represented in 16 bits and the upper word of the HL register merely holds zero.

Flags:

- S: Cleared
- Z: Set if the result is zero; cleared otherwise
- H: Unaffected
- V: Cleared
- N: Unaffected
- C: Set if the product is greater than or equal to 65536; cleared otherwise

NEGW NEGATE HL REGISTER (WORD)

NEGW [HL]

Operation: HL(15-0) ← -HL(15-0)

The contents of the HL register are negated, that is replaced by its two's complement value. Note that 8000h is, replaced by itself, because in two's complement representation the negative number with the greatest magnitude has no positive counterpart; for this case, the Overflow flag is set to 1.

Flags:

- S: Set if the result is negative; cleared otherwise
- Z: Set if the result is zero; cleared otherwise
- H: Set if there is a borrow from bit 4 of the result; cleared otherwise
- V: Set if the content of the HL register was 8000h before the operation; cleared otherwise
- N: Set
- C: Set if the content of the HL register was not 0000h before the operation; cleared if the content of the HL register was 0000h

	NEGW [HL]	111011101 01010100	2	

OR OR (BYTE)

OR [A,]src src = R, RX, IM, IR, X

Operation: A ← A OR src

A logical OR operation is performed between the corresponding bits of the source operand and the accumulator and the result is stored in the accumulator. A 1 bit is stored wherever either of the corresponding bits in the two operands is 1; otherwise a 0 bit is stored. The contents of the source are unaffected.

Flags:

- S: Set if the most significant bit of the result is set; cleared otherwise
- Z: Set if all bits of the result are zero; cleared otherwise
- H: Cleared
- P: Set if the parity is even; cleared otherwise
- N: Cleared
- C: Cleared

OTDM OUTPUT DECREMENT MEMORY

OTDM

Operation:

(C) ← (HL)
 C ← C - 1
 B ← B - 1
 HL ← HL - 1

This instruction is used for block output of strings of data to on-chip peripherals. No external I/O transaction will be generated as a result of this instruction, although the I/O address will appear on the address bus and the write data will appear on the data bus while this internal write is occurring. The peripheral address is placed on the low byte of the address bus and zeros are placed on all other address lines. The byte of data from the memory location addressed by the HL register is loaded to the on-chip I/O port addressed by the C register. The C register, holding the port address, is decremented by one to select the next output port. The B register, used as a counter, is then decremented by one. The HL register is then decremented by one, thus moving the pointer to the next source for the output.

Flags:

S: Set if the result of decrementing B is negative; cleared otherwise
 Z: Set if the result of decrementing B is zero; cleared otherwise
 H: Set if there is a borrow from bit 4 during the decrement of the B register; cleared otherwise
 P: Set if the result of the decrement of the B register is even; cleared otherwise
 N: Set if the most significant bit of the byte transferred was a 1; cleared otherwise
 C: Set if there is a borrow from the most significant bit during the decrement of the B register; cleared otherwise

Addressing Mode	Syntax	Instruction Format	Execute Time	Note
	OTDM	11101101 10001011	2+T+0	

OTDR OUTPUT, DECREMENT AND REPEAT (BYTE)

OTDR

Operation: repeat until (B=0) begin
 B ← B - 1
 (C) ← (HL)
 HL ← HL - 1
 end

This instruction is used for block output of strings of data. The string of output data is loaded into the selected peripheral from memory at consecutive addresses, starting with the location addressed by the HL register and decreasing. During the I/O transaction the 32-bit BC register is placed on the address bus. Note that the B register contains the loop count for this instruction so that A(15-8) are not useable as part of a fixed port address. The decremented B register is used in the address.

First the B register, used as a counter, is decremented by one. The byte of data from the memory location addressed by the HL register is loaded into the selected peripheral. The HL register is then decremented by one, thus moving the pointer to the next source for the output. If the result of decrementing the B register is 0, the instruction is terminated, otherwise the sequence is repeated. If the B register contains 0 at the start of the execution of this instruction, 256 bytes are output.

This instruction can be interrupted after each execution of the basic operation. The Program Counter value at the start of this instruction is saved before the interrupt request is accepted, so that the instruction can be properly resumed.

Flags:

- S: Unaffected
- Z: Set if the result of decrementing B is zero; cleared otherwise
- H: Unaffected
- V: Unaffected
- N: Set
- C: Unaffected

Addressing Mode	Syntax	Instruction Format	Execute Time	Note

OTIM OUTPUT INCREMENT MEMORY

OTIM

Operation: (C) ← (HL)
 C ← C + 1
 B ← B - 1
 HL ← HL + 1

This instruction is used for block output of strings of data to on-chip peripherals. No external I/O transaction will be generated as a result of this instruction, although the I/O address will appear on the address bus and the write data will appear on the data bus while this internal write is occurring. The peripheral address is placed on the low byte of the address bus and zeros are placed on all other address lines. The byte of data from the memory location addressed by the HL register is loaded to the on-chip I/O port addressed by the C register. The C register, holding the port address, is incremented by one to select the next output port. The B register, used as a counter, is then decremented by one. The HL register is then incremented by one, thus moving the pointer to the next source for the output.

Flags:

- S: Set if the result of decrementing B is negative; cleared otherwise
- Z: Set if the result of decrementing B is zero; cleared otherwise
- H: Set if there is a borrow from bit 4 during the decrement of the B register; cleared otherwise
- P: Set if the result of the decrement of the B register is even; cleared otherwise
- N: Set if the most significant bit of the byte transferred was a 1; cleared otherwise
- C: Set if there is a borrow from the most significant bit during the decrement of the B register; cleared otherwise

OTIR

OUTPUT, INCREMENT AND REPEAT (BYTE)

OTIR

Operation: repeat until (B=0) begin
 B ← B - 1
 (C) ← (HL)
 HL ← HL + 1
 end

This instruction is used for block output of strings of data. The string of output data is loaded into the selected peripheral from memory at consecutive addresses, starting with the location addressed by the HL register and increasing. During the I/O transaction the 32-bit BC register is placed on the address bus. Note that the B register contains the loop count for this instruction so that A(15-8) are not useable as part of a fixed port address. The decremented B register is used in the address.

First the B register, used as a counter, is decremented by one. The byte of data from the memory location addressed by the HL register is loaded into the selected peripheral. The HL register is then incremented by one, thus moving the pointer to the next source for the output. If the result of decrementing the B register is 0, the instruction is terminated, otherwise the sequence is repeated. If the B register contains 0 at the start of the execution of this instruction, 256 bytes are output.

This instruction can be interrupted after each execution of the basic operation. The Program Counter value at the start of this instruction is saved before the interrupt request is accepted, so that the instruction can be properly resumed.

Flags:

POP POP ACCUMULATOR

POP dst dst = AF

Operation:

```

F ← (SP)
A ← (SP+1)
SP ← SP + 2
if (LW) then begin
    SP ← SP + 2
end
    
```

The contents of the memory location addressed by the Stack Pointer (SP) are loaded into the destination in ascending byte order from ascending address memory locations. For this instruction, the Flag register is the least significant byte, followed by the Accumulator. The SP is then incremented by two (by four in the Long Word mode). Note that in the Long Word mode only one word is read from memory, although the SP is in fact incremented by four.

Flags:

```

S:  Loaded from (SP)
Z:  Loaded from (SP)
H:  Loaded from (SP)
V:  Loaded from (SP)
N:  Loaded from (SP)
C:  Loaded from (SP)
    
```

RESC RESET CONTROL BIT

RESC mode mode = LCK, LW

Operation: if (mode = LCK) then begin
 SR(1) ← 0
 end
 else begin
 SR(6) ← 0
 end

When resetting Lock mode (LCK), the LCK bit (bit 1) in the Select Register (SR) is set to 0, enabling external bus requests. Note that these requests cannot be granted until after the instruction has been executed, and that one or more of the succeeding instructions may also have been fetched for decoding before this instruction has been executed.

When resetting Long Word mode (LW), the LW bit (bit 6) in the SR is set to 0, selecting 16-bit words. When using 16-bit words, all word load operations transfer 16 bits.

Flags:

- S: Unaffected

RETB RETURN FROM BREAKPOINT

Operation: PC (31-0) ← SPC (31-0)

This instruction is used to return to a previously executing procedure at the end of a breakpoint. The contents of the Shadow Program Counter (SPC), which holds the address of the next instruction of the previously executing procedure, are loaded into the Program Counter (PC).

Note that maskable interrupts (if IEF1 is set) and non-maskable interrupt are enabled after the instruction following RETB is executed.

Flags:
 S: Unaffected
 Z: Unaffected
 H: Unaffected
 V: Unaffected
 N: Unaffected
 C: Unaffected

Addressing Mode	Syntax	Instruction Format	Execute Time	Note
	RETB	11101101 01010101	2	

RETN

RETURN FROM NONMASKABLE INTERRUPT

RETN

Operation:

```

if (XM) then begin
    PC(7-0) ← (SP)
    PC(15-8) ← (SP+1)
    PC(23-16) ← (SP+2)
    PC(31-24) ← (SP+3)
    SP ← SP + 4
end
else begin
    PC(7-0) ← (SP)
    PC(15-8) ← (SP+1)
    SP ← SP + 2
end
IEF1 ← IEF2
    
```

This instruction is used to return to a previously executing procedure at the end of a procedure entered by a nonmaskable interrupt. The contents of the location addressed by the Stack Pointer (SP) are popped into the Program Counter (PC), thereby specifying the location of the next instruction to be executed. The previous setting of the interrupt enable bit is restored by execution of this instruction.

Flags:

- S: Unaffected
- Z: Unaffected
- H: Unaffected
- V: Unaffected
- N: Unaffected
- C: Unaffected

Addressing Mode	Syntax	Instruction Format	Execute Time	Note

X:	RLW (XY+d)	11y11101 11001011 —d— 00010010	4+r	

Field Encodings: rr: 00 for BC, 01 for DE, 11 for HL
 y: 0 for IX, 1 for IY

RLC ROTATE LEFT CIRCULAR (BYTE)

RLC dst dst = R, IR, X

Operation: tmp ← dst
 C ← dst(7)
 dst(0) ← tmp(7)
 dst(n+1) ← tmp(n) for n = 0 to 6

The contents of the destination operand are rotated left one bit position. Bit 7 of the destination operand is moved to the bit 0 position and also replaces the Carry flag.

Flags: S: Set if the most significant bit of the result is set; cleared otherwise
 Z: Set if the result is zero; cleared otherwise
 H: Cleared
 P: Set if parity of the result is even; cleared otherwise
 N: Cleared
 C: Set if the bit rotated from bit 7 was a 1; cleared otherwise

Addressing Mode	Syntax	Instruction Format	Execute Time	Note
R:	RLC R	11001011 00000-r-	2	
IR:	RLC (HL)	11001011 00000110	2+r	
X:	RLC (XY+d)	11y11101 11001011 —d— 00000110	4+r	

Field Encodings: r: per convention
 y: 0 for IX, 1 for IY

RLCA ROTATE LEFT CIRCULAR (ACCUMULATOR)

RLCA

Operation: tmp ← A
 C ← A(7)
 A(0) ← tmp(7)
 A(n+1) ← tmp(n) for n = 0 to 6

The contents of the accumulator are rotated left one bit position. Bit 7 of the accumulator is moved to the bit 0 position and also replaces the Carry flag.

Flags: S: Unaffected
 Z: Unaffected
 H: Cleared
 P: Unaffected
 N: Cleared
 C: Set if the bit rotated from bit 7 was a 1; cleared otherwise

Addressing Mode	Syntax	Instruction Format	Execute Time	Note
	RLCA	00000111	2	

RR ROTATE RIGHT (BYTE)

RR dst dst = R, IR, X

Operation:

```

tmp ← dst
dst(7) ← C
C ← dst(0)
dst(n) ← tmp(n+1) for n = 0 to 6
    
```

The contents of the destination operand are concatenated with the Carry flag and together they are rotated right one bit position. Bit 0 of the destination operand is moved to the Carry flag and the Carry flag is moved to bit 7 of the destination.

Flags:

- S: Set if the most significant bit of the result is set; cleared otherwise
- Z: Set if the result is zero; cleared otherwise
- H: Cleared
- P: Set if parity of the result is even; cleared otherwise
- N: Cleared
- C: Set if the bit rotated from bit 0 was a 1; cleared otherwise

Addressing Mode	Syntax	Instruction Format	Execute Time	Note
R:	RR R	11001011 00011-r-	2	
IR:	RR (HL)	11001011 00011110	2+r	
X:	RR (XY+d)	11y11101 11001011 —d— 00011110	4+r	I

Field Encodings:

- r: per convention
- y: 0 for IX, 1 for IY

RRA ROTATE RIGHT (ACCUMULATOR)

RRA

Operation: tmp ← A
 A(7) ← C
 C ← A(0)
 A(n) ← tmp(n+1) for n = 0 to 6

The contents of the accumulator are concatenated with the Carry flag and together they are rotated right one bit position. Bit 0 of the accumulator is moved to the Carry flag and the Carry flag is moved to bit 7 of the accumulator.

Flags: S: Unaffected
 Z: Unaffected
 H: Cleared
 P: Unaffected
 N: Cleared
 C: Set if the bit rotated from bit 0 was a 1; cleared otherwise

Addressing Mode	Syntax	Instruction Format	Execute Time	Note
	RRA	00011111	2	

RRCW ROTATE RIGHT CIRCULAR (WORD)

RRCW dst dst = R, RX, IR, X

Operation: tmp ← dst
 C ← dst(0)
 dst(15) ← tmp(0)
 dst(n) ← tmp(n+1) for n = 0 to 14

The contents of the destination operand are rotated right one bit position. Bit 0 of the destination operand is moved to the most significant bit position and also replaces the Carry flag.

Flags: S: Set if the most significant bit of the result is set; cleared otherwise
 Z: Set if the result is zero; cleared otherwise
 H: Cleared
 P: Set if parity of the result is even; cleared otherwise
 N: Cleared
 C: Set if the bit rotated from bit 0 was a 1; cleared otherwise

Addressing Mode	Syntax	Instruction Format	Execute Time	Note
R:	RRCW R	11101101 11001011 000010rr	2	
RX:	RRCW RX	11101101 11001011 0000110y	2	
IR:	RRCW (HL)	11101101 11001011 00001010	2+r	
X:	RRCW (XY+d)	11y11101 11001011 —d— 00001010	4+r	I

Field Encodings: rr: 00 for BC, 01 for DE, 11 for HL
 y: 0 for IX, 1 for IY

RRD ROTATE RIGHT DIGIT

RRD

Operation:

```

tmp(3-0) ← A(3-0)
A(3-0)   ← dst(3-0)
dst(3-0) ← dst(7-4)
dst(7-4) ← tmp(3-0)
    
```

The low digit of the accumulator is logically concatenated to the destination byte whose memory address is in the HL register. The resulting three-digit quantity is rotated to the right by one BCD digit (four bits). The upper digit of the source is moved to the lower digit of the source; the lower digit of the source is moved to the lower digit of the accumulator, and the lower digit of the accumulator is moved to the upper digit of the source. The upper digit of the accumulator is unaffected. In multiple-digit BCD arithmetic, this instruction can be used to shift to the right a string of BCD digits, thus dividing it by a power of ten. The accumulator serves to transfer digits between successive bytes of the string. This is analogous to the use of the Carry flag in multiple-precision shifting using the RR instruction.

Flags:

- S: Set if the accumulator is negative after the operation; cleared otherwise
- Z: Set if the accumulator is zero after the operation; cleared otherwise
- H: Cleared
- P: Set if the parity of the accumulator is even after the operation; cleared otherwise
- N: Cleared
- C: Unaffected

Addressing Mode	Syntax	Instruction Format	Execute Time	Note
	RRD	11101101 01100111	3+r	

SBC SUBTRACT WITH CARRY (BYTE)

SBC A,src src = R, RX, IM, IR, X

Operation: $A \leftarrow A - \text{src} - C$

The source operand together with the Carry flag is subtracted from the accumulator and the difference is stored in the accumulator. The contents of the source are unaffected. Two's complement subtraction is performed.

Flags:

- S: Set if the result is negative; cleared otherwise
- Z: Set if the result is zero; cleared otherwise
- H: Set if there is a borrow from bit 4 of the result; cleared otherwise
- V: Set if arithmetic overflow occurs, that is, if the operands are of different signs and the result is of the same sign as the source; cleared otherwise
- N: Set
- C: Set if there is a borrow from the most significant bit of the result; cleared otherwise

Addressing Mode	Syntax	Instruction Format	Execute Time	Note

- w: 0 for high byte, 1 for low byte

SBCW SUBTRACT WITH CARRY (WORD)

SBCW [HL,]src src = R, RX, IM, X

Operation: HL(15-0) ← HL(15-0) - src(15-0) - C

The source operand together with the Carry flag is subtracted from the HL register and the difference is stored in the HL register. The contents of the source are unaffected. Two's complement subtraction is performed.

Flags:

- S: Set if the result is negative; cleared otherwise
- Z: Set if the result is zero; cleared otherwise
- H: Set if there is a borrow from bit 12 of the result; cleared otherwise
- V: Set if arithmetic overflow occurs, that is, if the operands are of different signs and the result is of the same sign as the source; cleared otherwise
- N: Set
- C: Set if there is a borrow from the most significant bit of the result; cleared otherwise

 y: 0 for IX, 1 for IY

SET SET BIT

SET b, dst dst = R, IR, X

Operation: dst(b) ← 1

The specified bit b within the destination operand is set to 1. The other bits in the destination are unaffected. The bit to be set is specified by a 3-bit field in the instruction; this field contains the binary encoding for the bit number to be set. The bit number b must be between 0 and 7.

Flags:

- S: Unaffected
- Z: Unaffected
- H: Unaffected
- V: Unaffected
- N: Unaffected
- C: Unaffected

Addressing Mode	Syntax	Instruction Format	Execute Time	Note

SLA SHIFT LEFT ARITHMETIC (BYTE)

SLA dst dst = R, IR, X

Operation:

```

tmp            ← dst
C              ← dst(7)
dst(0)        ← 0
dst(n+1)      ← tmp(n) for n = 0 to 6
    
```

The contents of the destination operand are shifted left one bit position. Bit 7 of the destination operand is moved to the Carry flag and zero is shifted into bit 0 of the destination.

Flags:

- S: Set if the most significant bit of the result is set; cleared otherwise
- Z: Set if the result is zero; cleared otherwise
- H: Cleared
- P: Set if parity of the result is even; cleared otherwise
- N: Cleared
- C: Set if the bit shifted from bit 7 was a 1; cleared otherwise

SLP SLEEP

SLP

Operation: if (STBY not enabled) then
CPU Halts
else
Z380 enters Standby mode

With Standby mode disabled, this instruction is interpreted and executed as a HALT instruction.

With Standby mode enabled, executing this instruction causes all device operation to stop, thus minimizing power dissipation. The /STNBY signal is asserted to indicate this Standby mode status. /STNBY remains asserted until an interrupt or reset request is accepted, which causes the device to exit Standby mode. If the option is enabled, an external bus request also causes the devcie to exit the Standby mode.

Flags: S: Unaffected
Z: Unaffected
H: Unaffected
V: Unaffected
N: Unaffected
C: Unaffected

Addressing Mode	Syntax	Instruction Format	Execute Time	Note
	SLP	11101101 01110110	2	

SRAW SHIFT RIGHT ARITHMETIC (WORD)

SRAW dst dst = R, RX, IR, X

Operation: tmp ← dst
 C ← dst(0)
 dst(15) ← tmp(15)
 dst(n) ← tmp(n+1) for n = 0 to 14

The contents of the destination operand are shifted right one bit position. Bit 0 of the destination operand is moved to the Carry flag and the most significant bit remains unchanged.

Flags: S: Set if the result is negative; cleared otherwise
 Z: Set if the result is zero; cleared otherwise
 H: Cleared
 P: Set if parity of the result is even; cleared otherwise
 N: Cleared
 C: Set if the bit shifted from bit 0 was a 1; cleared otherwise

RX:	SRAW RX	11101101 11001011 0010110y	2	
IR:	SRAW (HL)	11101101 11001011 00101010	2+r	
X:	SRAW (XY+d)	11y11101 11001011 —d— 00101010	4+r	!

Field Encodings: rr: 00 for BC, 01 for DE, 11 for HL
 y: 0 for IX, 1 for IY

SRLW SHIFT RIGHT LOGICAL (WORD)

SRLW dst dst = R, RX, IR, X

Operation:
 tmp ← dst
 C ← dst(0)
 dst(15) ← 0
 dst(n) ← tmp(n+1) for n = 0 to 14

The contents of the destination operand are shifted right one bit position. Bit 0 of the destination operand is moved to the Carry flag and zero is shifted into the most significant bit of the destination.

Flags:
 S: Cleared
 Z: Set if the result is zero; cleared otherwise
 H: Cleared
 P: Set if parity of the result is even; cleared otherwise
 N: Cleared
 C: Set if the bit shifted from bit 0 was a 1; cleared otherwise

Addressing Mode	Syntax	Instruction Format	Execute Time	Note
R:	SRLW R	11101101 11001011 001110rr	2	
RX:	SRLW RX	11101101 11001011 0011110y	2	
IR:	SRLW (HL)	11101101 11001011 00111010	2+r	
X:	SRLW (XY+d)	11y11101 11001011 —d— 00111010	4+r	

Field Encodings: rr: 00 for BC, 01 for DE, 11 for HL
 y: 0 for IX, 1 for IY

SUB SUBTRACT (WORD)

SUB HL,src src = DA

Operation:

```
if (XM) then begin
    HL(31-0) ← HL(31-0) - src(31-0)
end
else begin
    HL(15-0) ← HL(15-0) - src(15-0)
end
```

The source operand is subtracted from the HL register and the difference is stored in the HL register. The contents of the source are unaffected. Two's complement subtraction is performed. Note that the length of the operand is controlled by the Extended/Native mode selection, which is consistent with the manipulation of an address by the instruction.

Flags:

S: Unaffected
 Z: Unaffected
 H: Set if there is a borrow from bit 12 of the result; cleared otherwise
 V: Unaffected
 N: Set
 C: Set if there is a borrow from the most significant bit of the result; cleared otherwise

Addressing

Mode	Syntax	Instruction Format	Execute Time	Note
DA:	SUB HL,(nn)	11101101 11010110 -n(low)- -n(high)	2+r	I, X

SUBW SUBTRACT (WORD)

SUBW [HL,]src src = R, RX, IM, X

Operation: HL(15-0) ← HL(15-0) - src(15-0)

The source operand is subtracted from the HL register and the difference is stored in the HL register. The contents of the source are unaffected. Two's complement subtraction is performed.

Flags:

- S: Set if the result is negative; cleared otherwise
- Z: Set if the result is zero; cleared otherwise
- H: Set if there is a borrow from bit 12 of the result; cleared otherwise
- V: Set if arithmetic overflow occurs, that is, if the operands are of different signs and the result is of the same sign as the source; cleared otherwise
- N: Set
- C: Set if there is a borrow from the most significant bit of the result; cleared otherwise

Addressing Mode	Syntax	Instruction Format	Execute Time	Note

X:	SUBW [HL,](XY+d)	11y11101 11010110 —d—	2+r	

Field Encodings: rr: 00 for BC, 01 for DE, 11 for HL
 y: 0 for IX, 1 for IY

TST TEST (BYTE)

TST src src = R, IM, IR

Operation: A AND src

A logical AND operation is performed between the corresponding bits of the source operand and the accumulator. The contents of both the accumulator and the source are unaffected; only the flags are modified as a result of this instruction.

Flags:

- S: Set if the most significant bit of the result is set; cleared otherwise
- Z: Set if all bits of the result are zero; cleared otherwise
- H: Set
- P: Set if the parity is even; cleared otherwise
- N: Cleared
- C: Cleared

CHAPTER 6

INTERRUPTS AND TRAPS

6.1 INTRODUCTION

Exceptions are conditions that can alter the normal flow of program execution. The Z380™ CPU supports three kinds of exceptions; interrupts, traps, and resets.

Interrupts are asynchronous events generated by a device external to the CPU; peripheral devices use interrupts to request service from the CPU. Traps are synchronous events generated internally in the CPU by a particular condition that can occur during the attempted execution of an instruction—in particular, when executing undefined instructions. Thus, the difference between Traps and Interrupts is their origin. A Trap condition is always reproducible by re-executing the program that created the Trap, whereas an Interrupt is generally independent of the currently executing task.

A hardware reset overrides all other conditions, including Interrupts and Traps. It occurs when the /RESET line is activated and causes certain CPU control registers to be initialized. Resets are discussed in detail in Chapter 7.

The Z380 MPU's Interrupt and Trap structure provides compatibility with the existing Z80 and Z180 MPU's with the following exception—the undefined opcode Trap occurrence is with respect to the Z380 instruction set, and its response is improved (vs the Z180) to make Trap handling easier. The Z380 MPU also offers additional features to enhance flexibility in system design.

6.2 INTERRUPTS

Of the five external Interrupt inputs provided, one is assigned as a Nonmaskable Interrupt, /NMI. The remaining inputs, /INT3-/INT0, are four asynchronous maskable Interrupt requests.

The Nonmaskable Interrupt; (NMI) is an Interrupt that cannot be disabled (masked) by software. Typically NMI is reserved for high priority external events that need immediate attention, such as an imminent power failure. Maskable Interrupts are Interrupts that can be disabled (masked) through software by cleaning the appropriate bits in the Interrupt Enable Register (IER) and IEF1 bit in the Select Register (SR).

All of these four maskable Interrupt inputs (/INT3-/INT0) are external input signals to the Z380 CPU core. The four Interrupt enable bits in the Interrupt Enable Register determine (IER; Internal I/O address: 17H) which of the requested Interrupts are accepted. Each Interrupt input has a fixed priority, with /INT0 as the highest and /INT3 as the lowest.

The Enable Interrupt (EI) instruction is used to selectively enable the maskable Interrupts (by setting the appropriate bits in the IER register and IEF1 bit in the SR register) and

the Disable Interrupt instruction is used to selectively disable interrupts (by clearing appropriate bits in the IER, and/or clearing IEF1 bit in the SR register). When an Interrupt source has been disabled, the CPU ignores any request from that source. Because maskable Interrupt requests are not retained by the CPU, the request signal on a maskable Interrupt line must be asserted until the CPU acknowledges the request.

When enabling Interrupts with the EI instruction, all maskable Interrupts are automatically disabled (whether previously enabled or not) for the duration of the execution of the EI instruction and the instruction immediately following.

Interrupts are always accepted between instructions. The block move, block search, and block I/O instructions can be interrupted after any iteration.

The Z380 CPU has four selectable modes for handling externally generated Interrupts, using the IM instruction. The first three modes extend the Z80 CPU Interrupt Modes to accommodate the Z380 CPU's additional Interrupt inputs in a compatible fashion. The fourth mode allows more flexibility in interrupt handling.

6.2.2.1 IEF1, IEF2

IEF1 controls the overall enabling and disabling of all on-chip peripheral and external maskable Interrupt requests. If IEF1 is at logic 0, all such Interrupts are disabled. The purpose of IEF2 is to correctly manage the occurrence of /NMI. When /NMI is acknowledged, the state of IEF1 is copied to IEF2 and then IEF1 is cleared to logic 0. At the

end of the /NMI interrupt service routine, execution of the Return From Nonmaskable Interrupt instruction, RETN, automatically copies the state of IEF2 back to IEF1. This is a means to restore the Interrupt enable condition existing before the occurrence of /NMI. Table 6-3 summarizes the states of IEF1 and IEF2 resulting from various operations.

Table 6-3. Operation Effects on IEF1 and IEF2

Operation	IEF1	IEF2	Comments
/RESET	0	0	Inhibits all interrupts except Trap and /NMI.
Trap	0	0	Disables interrupt nesting.
/NMI	0	IEF1	IEF1 value copied to IEF2, then IEF1 is cleared.
RETN	IEF2	NC	Returns from /NMI service routine.
/INT3-/INT0	0	0	Disables interrupt nesting.
RETI	NC	NC	Returns from Interrupt service routine, Z80 I/O device.
RET	NC	NC	Returns from service routine, or returns from Interrupt service routine for a non-Z80 I/O device.
EI	1	1	
DI	0	0	
LD A,I or LD R,I	NC	NC	IEF2 value is copied to P/V Flag.
LD HL,I or LD HL,R	NC	NC	

(NC = No Change)

6.2.2.2 I, I Extend

The 8-bit Interrupt Register and the 16-bit Interrupt Register Extension are cleared during reset.

6.2.2.3 Interrupt Enable Register

D7-D4 Reserved Read as 0, should write to as 0.
D3-D0 IE3-IE0 (Interrupt Request Enable Flags)

These flags individually indicate if /INT3, /INT2, /INT1, or /INT0 is enabled. Note that these flags are conditioned with the Enable and Disable Interrupt instructions (with arguments) (See Figure 6.1).

Figure 6-1. Interrupt Enable Register

6.2.2.4 Assigned Vectors Base Register

D7-D1 AB15-AB9 (Assigned Vectors Base). The Interrupt Register Extension, Iz, together with AB15-AB9, define the base address of the assigned Interrupt vectors table in memory space (See Figure 6-2).

D0 Reserved. Read as 0, should write to as 0.

Figure 6-2. Assigned Vectors Base Register

6.4 NONMASKABLE INTERRUPT

The Nonmaskable Interrupt Input /NMI is edge sensitive, with the Z380 MPU internally latching the occurrence of its falling edge. When the latched version of /NMI is recognized, the following operations are performed.

1. The Interrupted PC (Program Counter) value is pushed onto the stack. The size of the PC value pushed onto the stack depends on Native (one word) or Extended mode (two words) in effect.
2. The state of IEF1 is copied to IEF2, then IEF1 is cleared.
3. The Z380 MPU commences to fetch and execute instructions from address 00000066H.

6.5 INTERRUPT RESPONSE FOR MASKABLE INTERRUPT ON /INT0

The transactions caused by the Maskable Interrupt on /INT0 are different depends on the Interrupt Mode in effect at the time when the interrupt has been accepted, as described below.

6.5.1 Interrupt Mode 0 Response for Maskable Interrupt /INT0

This mode is similar to the 8080 CPU Interrupt response mode. During the Interrupt acknowledge transaction, the external I/O device being acknowledged is expected to output a vector onto the upper portion of the data bus, D15-D8. The Z380 MPU interprets the vector as an instruction opcode. IEF1 and IEF2 are reset to logic 0, disabling all further maskable interrupt requests. Note that unlike the other interrupt responses, the PC is not automatically pushed onto the stack. Typically, a Restart instruction (RST) is used, since the Restart opcode is only one byte long, meaning that the interrupting peripheral needs to supply only one byte of information. For this case, it pushes the interrupted PC (Program Counter) value onto the stack and resumes execution at a fixed memory location. Alternatively, a 3-byte call to any location can be executed.

Note that a Trap occurs if an undefined opcode is supplied by the I/O device as a vector.

6.5.2 Interrupt Mode 1 Response for Maskable Interrupt /INT0

In Interrupt Mode 1, the Z380 CPU automatically executes a Restart to a fixed location (00000038H) when an interrupt occurs. An Interrupt acknowledge transaction is generated, during which the data bus contents are ignored by the Z380 MPU. The interrupted PC value is pushed onto the stack. The size of the PC value pushed onto the stack is depends on Native (one word) or Extended mode (two words) in effect. The IEF1 and IEF2 are reset to logic 0 so as to disable further maskable interrupt requests. Instruction fetching and execution restarts at memory location 00000038H.

6.5.3 Interrupt Mode 2 Response for Maskable Interrupt /INT0

Interrupt Mode 2 is a vectored Interrupt response mode, wherein the interrupting device identifies the starting location of service routine using an 8-bit vector read by the CPU during the Interrupt acknowledge cycle.

During the Interrupt acknowledge transaction, the external I/O device being acknowledged is expected to output a vector onto the upper portion of the data bus, D15-D8. The interrupted PC value is pushed onto the stack and IEF1 and IEF2 are reset to logic 0 so as to disable further maskable interrupt requests. The size of the PC value pushed onto the stack is depends on Native (one word) or Extended mode (two words) in effect. The Z380 MPU then reads an entry from a table residing in memory and loads it into the PC to resume execution. The address of the table entry is composed of the I Extend (Iz) contents as A31-A16, the I Register contents as A15-A8 and the vector supplied by the I/O device as A7-A0. Note that the table entry is effectively the starting address of the interrupt service routine designed for the I/O device being acknowledged, and the table composing of starting addresses for all the Interrupt Mode 2 service routines can be referred to as the Interrupt Mode 2 vector table. Each table entry should be word-sized if the Z380 MPU is in the Native mode and Long Word-sized if in the Extended mode, in either case even-aligned (least significant byte with address A0 = 0), meaning 128 different vectors can be used in the Native mode, and 64 different vectors can be used in Extended mode.

6.5.4 Interrupt Mode 3 Response for Maskable Interrupt /INT0

Interrupt Mode 3 is similar to mode 2 except that a 16-bit vector is expected to be placed on the data bus D15-D0 by the I/O device during the Interrupt acknowledge transaction. The interrupted PC is pushed onto the stack. The size of the PC value pushed onto the stack depends on the

CHAPTER 7

RESET

7.1 INTRODUCTION

The Z380 CPU is placed in a dormant state when the $\overline{\text{RESET}}$ input is asserted. All its operations are terminated, including any interrupt, bus request, or bus transaction that may be in progress. On the Z380 MPU, the IOCLK goes Low on the next BUSCLK rising edge and enters into the BUSCLK divided-by-eight mode. The address and data buses are tri-stated, and the bus control signals are driven to their inactive states. The effect of $\overline{\text{RESET}}$ on the Z380 CPU and related internal I/O registers is depicted in Table 7-1.

The $\overline{\text{RESET}}$ input may be asynchronous to BUSCLK, though it is sampled internally at BUSCLK's falling edges. For proper initialization of the Z380 CPU, V_{DD} must be within operating specifications and the CLK input must be stable for more than five cycles with $\overline{\text{RESET}}$ held Low.

The Z380 CPU proceeds to fetch the first instruction 3.5 BUSCLK cycles after $\overline{\text{RESET}}$ is deasserted, provided such deassertion meets the proper setup and hold times

with reference to the falling edge of BUSCLK. On the Z380 MPU implementation, with the proper setup and hold times being met, IOCLK's first rising edge is 11.5 BUSCLK cycles after the $\overline{\text{RESET}}$ deassertion, preceded by a minimum of four BUSCLK cycles when IOCLK is at Low.

Note that if $\overline{\text{BREQ}}$ is active when $\overline{\text{RESET}}$ is deasserted, the Z380 MPU would relinquish the bus instead of fetching its first instruction. IOCLK synchronization would still take place as described before.

Requirements to reset the device, and the initial state after reset might be different depending on the particular implementation of the Z380 CPU on the individual Superintegration version of the device. For $\overline{\text{RESET}}$ effects and requirements, refer to the individual product specification.

Z380™ BENCHMARKING

This application note compares the performance and program memory requirements among the new 16-bit CPU from Zilog Z80380 and several competing processors, including the Intel 80186, 80960 and Motorola 68020 and CPU32.

INTRODUCTION

Zilog's new Z380™ Central Processing Unit is a high performance CPU engine designed to meet today's application requirements. The Z380 CPU incorporates advanced architectural features that allow fast and efficient throughput and increased memory addressing capability while maintaining Z80®/Z180® object code compatibility.

The Z380 CPU is an enhanced version of the Z80 CPU. The Z80 instruction set has been retained, adding a full compliment of 16-bit arithmetic and logical operations, multiply and divide, a complete set of register-to-register loads and exchanges, plus 32-bit load and exchange, and 32-bit arithmetic operations for address calculations.

The addressing modes of the Z80 have been enhanced with Stack pointer relative loads and stores, 16-bit and 24-bit indexed offsets, and more flexible indirect register addressing. All of the addressing modes allow access to the entire 32-bit addressing space.

The register set of the Z80 microprocessor is expanded to 32 bits, and has been replicated four times to allow for fast context switching among tasks in a dedicated control environment.

The following are the key features of the Z380:

- Full static CMOS design with low power standby mode support
- 32-bit internal data paths and ALU
- 16-bit (64K) or 32-bit (4G) linear addressing space
- 16-bit internal data bus
- Two clock cycle minimum instruction execution
- Two clock cycle Memory bus
- Programmable I/O bus protocols and clock rates
- Four banks of 32-bit registers
- Enhanced interrupt capabilities, including 16-bit vectors and four external Interrupt inputs
- Undefined opcode trap for full Z380 CPU instruction set

The Z380 block diagram is shown in Figure 1. For a detailed description of the Z380 please refer to the Z380 Technical Manual, DC #8297-00, and the Z380 Preliminary Product Specification DC #6003-02 from Zilog.

BENCHMARKS AMONG EMBEDDED PROCESSORS

In response to a recent microprocessor selection process by a major customer, Zilog's Datacom Marketing group compared the performance and program memory requirements among the new Z80380 and several compet-

ing processors, including the Intel 80186 and 80960 and the Motorola 68020 and CPU32. (The CPU32 is the heart of the Motorola's 803xx series of integrated products.)

METHOD

Benchmarking consisted of selecting four code fragments judged to be typical of embedded applications, coding the four fragments in assembly language for each of the four processors, and calculating the execution time for each fragment on each processor, at 16, 25, and 40 MHz clock rates as applicable to each.

The results were then tabulated in a spreadsheet that first normalized them to the figure for the 25 MHz 80380, and then averaged the normalized values for memory code size and execution time, as well as an overall "figure of merit".

The code fragments were called "I/O Loop", "Signed Byte Handling", "Multiply/Accumulate", and "Interrupt". Since the execution time for I/O Loop is a function of the number of times through the loop, and because it was felt to be the most typical of user requirements, it was counted twice toward the composite performance and merit figures, once for a single iteration and once for eight times through the loop. Finally, a fifth performance category was included, the time required for memory-to-memory block movement of data. This made six performance values that were averaged with four program-size values for the overall Figure of Merit, an imbalance that "felt right" in terms of the way we think many users view the value of an embedded microprocessor.

ASSUMPTIONS

Because execution time can be a complex matter for today's pipelined processors, our benchmarks made several assumptions that simplified performance evaluation. The most presumptive was that the memory on all processors was fast enough that there would be NO WAIT STATES. (In many cases this would mandate fast Static RAM rather than larger, more economical Dynamic RAM, which makes sense for some applications but not others.)

A second assumption was that all operands were ALIGNED to the natural boundaries for their size: data accessed 16 bits at a time was located at an address that was a multiple of two bytes, while data to be accessed 32 bits at a time was located at an address that's a multiple of 4 bytes. This characteristic can be guaranteed by many high-level-language compilers, and is questionable only for the Block Move operations.

For processors that include a cache (the 68020 and 80960), the timing was calculated such that the first access to each instruction was a cache miss, and any subsequent accesses were cache hits. In other words, we assumed that these code fragments were not part of a central loop, but were executed in response to specific events that were sufficiently infrequency that the code was superseded in the cache between events.

DESCRIPTION OF THE CODE FRAGMENTS

I/O Loop

This code fragment reads received data, two bytes at a time, from a 16C30 Universal Serial Controller (USC), and stores the data in a memory buffer for each frame. The USC is the successor to Zilog's popular SCC, and has a 32-byte FIFO capacity. First, each sequence sets up whatever registers are needed to access the USC, the memory buffer, and a current pointer into the buffer named "rxl".

At the start of each loop, the code reads the number of bytes currently in the receive FIFO, from the MSbyte of a USC register called RICR. It also reads a 16-bit status register called RCSR.

If there are no bytes left in the FIFO, the code exits from the fragment. If there is one byte in the RxFIFO, the code checks the status to see if the byte is either the last one of a frame, or is the byte at which a Receive Overrun condition occurred. If neither of these is the case, the code leaves the byte in the RxFIFO for the future, and exits from the fragment. Otherwise, or if there are two or more bytes in the FIFO, the code:

1. ensures that no interrupt can occur between the following steps,
2. reads two bytes from the FIFO via the USC register called RDR
(the USC will only provide one if there's only one in the FIFO)
3. stores the data in memory at the address in the pointer "rxl",
4. increments rxl by 2,
5. stores rxl back in memory, and
6. enables interrupts to occur again.

After these operations the code tests the status obtained earlier from RCSR, and if the data just stored didn't represent the end of a frame, it goes back to the start of the loop described above. The following code calls an end-of-frame-handling subroutine called "_Handle_RxStatus_" this part of the fragment counts toward the code memory required but not toward the execution time, because a frame ends only once in many executions of the loop.

Signed Byte Handling

This code fragment originally came from a customer code in the hard disk field. It examines three 8-bit variables in memory called NORM, Q, and K2. Actually NORM can range from -256 to +255 and is implemented as a 16-bit variable. It computes an eight-bit result in any of six ways,

depending on the sign of NORM and how it compares to that of Q, as described in the comments at the top of each page of code.

First the code may access some or all of the three input variables and/or set up registers to point to one or more of them. Then it tests the sign of NORM, branching to the second "half" of the code fragment if it's positive. In each "half", the code compares NORM and Q and branches around in a tree-structured fashion to compute the result dictated by relative values of NORM and Q.

To evaluate the overall execution time of the fragment, we computed the execution time for each of the six result cases, and averaged them.

This may be the least clear code fragment as to its cosmic purpose, but it is a reasonable example of the kind of decision-tree processing that's typical of many I/O handling and control systems.

Multiply/Accumulate

This code fragments is also taken from a customer code in a hard-disk application. It uses four 16-bit input values in memory, CURSEC, POSN_ERR, S_GRAT, and K_GRAT, plus two memory tables of 16-bit values called S_TABLE and C_TABLE, each as large as the largest possible values of CURSEC. From these the code extracts S_TABLE (CURSEC) and saves the result in a memory variable S_VALUE, and similarly extracts C_TABLE (CUSEC) and saves it in K_VALUE. The code also multiplies each value by POSN_ERR, scales/divides each result by 64, and adds the results into memory variables S_ACCUM and K_ACCUM respectively. Finally it calculates $R_CP = (S_VALUE * S_GRAT + K_VALUE * K_GRAT) / 32$.

This code includes four 16x16 multiplications and 32-bit scale/shift operations. For all the processors except the CPU32, the fragment is coded to loop back once to minimize memory requirements, by taking advantage of the similarity of the computations for the "S" and "K" values.

Interrupt

These code fragments service a "receive status" interrupt from a Zilog 16C30 Universal Serial Controller (USC). The actual code size and execution time are reduced from a full-blown ISR, by evaluating for the case of a "Receive Overrun" event, and by isolating the details of handling an End of Frame event in a separate subroutine. This is done

SUMMARY (Continued)

Of course there's something a little out of line about including the 80960KA in this comparison, which

* costs far more than any of the other processors,

* entails added system-level expense because of its 32-bit data path and required memory width (also true of the 68020), and

* requires special "block transfer" memory design techniques

In fact, Intel has another member of its 80960 that is more like the other processors herein, the 8096KA. This device has a 16-bit data bus like the 80380 and 80186, and a more compact package that lowers its cost into a more competitive range. Unfortunately we were unable to obtain any timing information for the 80960SA in the time frame required for this benchmarking.

However, we did find an Intel brochure that allows the 80960SA to participate in these results in a small way. It showed a "Dhrystone" (fixed point) figure for the 80960SA of 12145, compared to 19740 for the 960KA. Multiplying the performance figures for the 960KA by 19740/12145 (smaller is better in our figures while larger is better for the Dhrystone) yielded the results shown in the third-last and last lines. For the last line that combines code size and execution time into a final figure of Merit, only the execution time values were scaled by Intel's Dhrystone results.

To wrap up, considering both code density and execution time for these code fragments, the new Zilog 80380 blows away other 16-bit processors including the 80960SA, and comes out about equal to the much more expensive 32-bit 80960KA if skewed by one speed grade (25 MHz 380 vs. 16 MHz 960, 40 MHz 380 vs. 25 MHz 960).

SIGNED BYTE HANDLING: 80960KA

```

# the following 80960KA code handles signed bytes.
# there are 3 signed byte variables in memory, Q, K2, and NORM.
# Actually NORM can range from -256 to +255, so we test the
# MSbyte of a 16-bit NORM but use only the LSbyte otherwise.
# The result is as follows
# if    NORM < 0 then
#     if NORM > -Q then result := NORM
#     else if NORM > Q then result := -2*K2-NORM
#     else result := Q - K2
# else if NORM <= Q then result := NORM
#     else if NORM <= -Q then result := 2*K2-NORM
#     else result := K2 - Q
# Routines can leave the result wherever is most convenient.
# this code is not warranted to be correct nor operative, and is
# intended for performance benchmarking purposes only
    
```

MULTIPLY/ACCUMULATE: 80380

```

; this 80380 code performs a 16-bit multiply/accumulate:
; several 16-bit variables pre-exist in memory, including
; CURSEC, POSN_ERR, S_GRAT, and K_GRAT. In addition,
; two tables S_TABLE and C_TABLE are of a size equal to
; the possible range of values of CURSEC. 16-bit results
; of this calculation in memory include S_VALUE, K_VALUE,
; R_CP, and two accumulators S_ACCUM and K_ACCUM:

; S_VALUE := S_TABLE(CURSEC)
; K_VALUE := C_TABLE(CURSEC)
; S_ACCUM := S_ACCUM + ((S_VALUE*POSN_ERR)/64)
; K_ACCUM := K_ACCUM + ((K_VALUE*POSN_ERR)/64)
; R_CP := (S_VALUE*S_GRAT + K_VALUE*K_GRAT) / 32

; to optimize memory accessing, all routines may assume
; that variables S_VALUE, S_GRAT, S_ACCUM, K_VALUE, K_GRAT,
; K_ACCUM are consecutive in memory in whatever order is
; optimal for their instruction set, while CURSEC, POSN_ERR,
; S_TABLE, and C_TABLE are at unrelated locations. R_CP
; can be in either place.

; the order in this version in S_VALUE, S_ACCUM, S_GRAT, K_VALUE,
; K_ACCUM, K_GRAT, R_CP.

; this code is not warranted to be correct nor operative, and is
; intended for performance benchmarking purposes only
; this code assumes that the global LW and XM bits are cleared.

Z380™ Questions & Answers

9

Z380™

QUESTIONS AND ANSWERS

GENERAL OVERVIEW

- Q:** What is currently assigned as the value in the Chip ID version register?
- A:** Currently the value 00H is assigned to the Z380 MPU, and other values are reserved. Note that the internal I/O address for this register is OFFH.
- Q:** Can data be accessed in the memory space beyond the 64K boundary in Native mode?
- A:** Yes. The Z380 in Native/Word mode behaves exactly like the Z80, but has access to the entire 4 Gbytes of memory for data and 4G locations of I/O space because the upper 16 bits of all CPU registers (except the PC) are still accessible to the software using new Z380 instructions. Note that the program must reside within the first 64K of memory because the upper word of the PC is not accessible in Native mode and is always all zeros in this mode.
- Q:** Z380 is binary code compatible with which processor?
- A:** The Z80 and Z180. Please note that the Z380 is not binary code compatible with the Z280.
- Q:** What are the two modes that Z380 can operate in?
- A:** The Z380 can operate in Native mode or Extended mode. In Native mode all of the address manipulations operate on 16-bit quantities whereas in Extended mode all of the address manipulations operate on 32-bit quantities.
- Q:** What are the specifics of the Z380 PC in Extended mode?
- A:** In extended mode the PC increments across all 32 bits since the entire 4G Byte of addressing capability is in use.
- Q:** How would one determine during a memory read, whether or not the cycle is instruction fetch or data?
- A:** There is a Fetch signal available in the PGA version that goes active during an instruction fetch.
- Q:** What are the Interrupt acknowledge and I/O transactions timings relative to?
- A:** All of the Interrupt Acknowledge and I/O transactions are in reference to the I/O clock which is a program controlled divided-down version of the BUSCLK.
- Q:** How can the Z380 return from Extended to Native mode of operation?
- A:** Hardware Reset is the ONLY way that one can go back to Native mode.
- Q:** Is the Z380 an Intel based architecture or Motorola based?
- A:** The Z380, being compatible with the original Z80, is Intel based. Intel based means the memory organization is the "LSbyte first followed by MSbytes" whereas the Motorola architecture has "MSbyte first followed by LSbytes".

RESET

Q: What is the effect of the reset on the Z380?

A: Reset will cause the address and data lines to float. All of the control lines will go to the inactive state.

Q: What is the status of the memory chip select signals during Reset?

A: They are all tri-stated, since the Address bus is tri-stated.

Q: Will reset affect all of the registers on Z380?

A: Not all of the registers are effected by Reset. CPU registers are not affected by Reset. Please refer to Product spec DC#6003-02 page 102 for the effect of Reset on Z380 CPU and related I/O registers.

Q: How long do one need to have the /RESET line active for proper operation?

A: The /RESET line must be kept Low for a minimum of 10 BUSCLK cycles. The /RESET signal does not need to be synchronized to BUSCLK.

Q: When is the /RESET signal be internally by the CPU?

A: The /RESET input signal may be asynchronous to BUSCLK, though it is sampled internally by the falling edge of BUSCLK. For proper initialization of the MPU V_{DD} must be within operating specification and BUSCLK must be stable for more than 10 cycles with /RESET held low.

Q: Does the /RESET input include a Schmitt-trigger buffer?

A: Yes. The /RESET input on Z380 includes a Schmitt-trigger buffer to facilitate power-on reset generation through a simple RC network.

Q: How are the devices external to the Z380 MPU that are clocked by IOCLK affected by /RESET pulse width?

A: This depends on the specific device, but in general they will require a /RESET pulse width that spans several IOCLK cycles for proper initialization.

Q: How many BUSCLK cycles after the deassertion of /RESET will the Z380 proceed to fetch the first instruction?

A: The first memory read, for an instruction fetch, will start 3.5 BUSCLK cycles after the deassertion of /RESET, providing that the proper setup and hold times are met with respect to the BUSCLK falling edge.

Q: When is the first IOCLK rising edge after deassertion of /RESET signal?

A: The first rising edge of IOCLK occurs 11.5 BUSCLK cycles after the deassertion of /RESET, providing that the proper setup and hold times are met with respect to the BUSCLK falling edge. This first rising edge on IOCLK is preceded by a minimum of 4 BUSCLK cycles where IOCLK is Low.

Q: What happens if the /BREQ signal is active when /RESET is deasserted?

A: In this case the Z380 will relinquish the bus instead of fetching the first instruction, but the IOCLK synchronization will still take place as it normally does.

POWER DOWN MODE

- Q:** What are the status of the output drivers when the CPU is in power down situation?
- A:** When the Z380 is without the power the output drivers appear to be in a high impedance state.
- Q:** How many ways are available to exit the Standby mode?
- A:** One can exit standby mode by: /BREQ, /RESET, /NMI, or /INT0-3. Note that /BREQ can be disabled as a Standby mode exit condition with a bit in the Standby Mode Control Register (SMCR) at internal I/O address 00000016H. Also, /INT0-3 will only cause an exit from the Standby mode if interrupts were globally enabled (with the IEF1 flag) when the Standby mode was entered.
- Q:** How could a user select the warm-up time appropriate for the crystal being used?
- A:** The WM2-WM0 bits in the Standby Mode Control Register (SMCR) at internal I/O address 00000016H control the warm-up time for the crystal oscillator when exiting the Standby mode.
- Q:** If the Standby mode option is not enabled, how does the Z380 interpret the SLP (Sleep) instruction?
- A:** In this case the SLP instruction is interpreted and executed identically to the HALT instruction, stopping the Z380 from further instruction execution.
- Q:** In the above case what would happen to /HALT signal?
- A:** In this case the /HALT signal goes to active (Low) to indicate that the Z380 is in the Halt state.

INTERRUPT SECTION

- Q:** What is the state of the IEF1 and IEF2 flags after execution of the DI (Disable Interrupt) instruction for the Z380?
- A:** Both IEF1 and IEF2 are set to zero by the DI instruction.
- Q:** What are the specifics of /INT0 Mode 3 for the Z380?
- A:** Mode 3 is similar to Mode 2 (as in the Z180 or Z80) except that a 16-bit interrupt vector is expected from the peripherals.
- Q:** How can the user take advantage of INT0 mode 3 with 8-bit I/O devices?
- A:** All of the upper 8 bits of the data bus need to be pulled either High or Low with external resistors.
- Q:** How many clocks are required for the Interrupt sequence in Interrupt mode 2 on the Z380?
- A:** With no wait states and a 1X I/O bus, the time from /INT0 assertion to the start of first service routine instruction fetch (Interrupt Mode 2) is 18 clocks.
- Q:** Is there a problem with interrupt vectors in Extended mode?
- A:** In Extended mode the Interrupt Vector in Interrupt Mode 2 has the two least significant bits both "0". This can cause a problem when connecting to Z80/Z8500 peripherals if the vector includes status from those devices. This is because most of these devices modify the vector starting with the bit just after the least-significant bit. Thus in certain cases this bit may be returned as a "1" from the interrupting device.
- Q:** How would the user access the Iz register (the Interrupt Register Extension)?
- A:** The LD I,HL and LD HL,I instructions (in Long Word mode) will transfer 32 bits to or from the I register.

APPENDIX A

Z380™ CPU INSTRUCTION FORMATS

Four formats are used to generate the machine language bit encoding for the Z380 CPU instructions. Also, the Z380 CPU has eight Decoder Directives which work as a special escape sequence to the certain instructions, to expand its capability as explained in Chapter 3.

The bit encoding of the Z380 CPU instructions are partitioned into bytes. Every instructions encoding contains one byte dedicated to specifying the type of operation to be performed; this byte is referred to as the instruction's operation code, or opcode. Besides specifying a particular operation, opcode typically include bit encoding specifying the operand addressing mode for the instruction and identifying any general purpose registers used by the instruction. Along with the opcode, instruction encoding may include bytes that contain an address, displacement, and/or immediate value used by the instruction, and special bytes called "escape codes" that determine the meaning of the opcode itself.

By themselves, one byte opcode would allow the encoding of only 256 unique instructions. Therefore, special "escape codes" that precede the opcode in the instruction encoding are used to expand the number of possible instructions. There are two types of escape codes; addressing mode and opcode. Escape codes for the Z80 original instructions are one bytes in length, and the escape codes used to expand the Z380 instructions are one or two bytes in length.

These instruction formats are differentiated by the opcode escape value used. Format 1 is for instructions without an opcode escape byte(s), Format 2 is for instructions with an opcode escape byte. Format 3 is for instructions whose opcode escape byte has the value 0CBH, and Format 4 is for instructions whose escape bytes are 0ED, followed by 0CBH.

For the opcode escape byte, the Z380 CPU uses 0DDH and 0FDH as well, which on the Z80 CPU, these are used only as an address escape byte.

In Format 2 and 4, the opcode escape byte immediately precedes the opcode byte itself.

In Format 3, a 1-byte displacement may be between the opcode escape byte and opcode itself. Opcode escape bytes are used to distinguish between two different instructions with the same opcode bytes, thereby allowing more than 256 unique instructions. For example, the 01H opcode, when alone, specifies a form of a Load Register Word instruction; when proceeded by 0CBH escape code, the opcode 01H specifies a Rotate Left Circular instruction.

Format 3 instructions with DDIR Immediate data Decoder Directives, 1 to 3 bytes of displacement is between the opcode escape byte and opcode itself.

Format 4 instructions are proceeded by 0EDH, 0CBH, and a opcode. Optionally, with immediate word field follows.

Addressing mode escape codes are used to determine the type of encoding for the addressing mode field within an instruction's opcode, and can be used in instructions with and without opcode escape value. An addressing mode escape byte can have the value of 0DDH or 0FDH. The addressing mode escape byte, if present, is always the first byte of the instruction's machine code, and is immediately followed by either the opcode (Format 1), or the opcode escape byte (Format 2 and 3). For example, the 46H opcode, when alone, specifies a Load B register from memory location pointed by (HL) register; when proceeded by the 0DDH escape byte, the opcode 46H specifies a Load B register from the memory location pointed by (IX+d).

APPENDIX B

Z380™ INSTRUCTIONS IN ALPHABETIC ORDER

This Appendix contains a quick reference guide when programming.

It has the Z380 instructions sorted by alphabetic order.

The column "Mode" indicates whether the instruction is affected by DDIR immediate Decoder Directives, Extended mode or Native mode of operation, and Word or Long Word

mode of operation; "I" means the instruction can be used with DDIR IM to expand its immediate constant, "X" means that the operation of the instruction is affected by the XM status bit, and "L" means that the instruction is affected by LW status bit, or can be used with DDIR LW or DDIR W. The Native/Extended modes, Word/Long Word modes and Decoder Directives are discussed in Chapter 3 in this manual.

APPENDIX C

Z380™ INSTRUCTION IN NUMERIC ORDER

The following Appendix has the Z380 instructions sorted by numeric order.

The column "Mode" indicates whether the instruction is affected by DDIR immediate Decoder Directives, Extended mode or Native mode of operation, and Word or Long Word Mode of operation; "I" means the instruction can be used with DDIR IM to expand its immediate constant, "X" means

that the operation of the instruction is affected by the XM status bit, and "L" means that the instruction is affected by LW status bit, or can be used with DDIR LW or DDIR W. The Native/Extended modes, Word/Long Word modes and Decoder Directives are discussed in Chapter 3 in this manual.

INSTRUCTIONS AFFECTED BY NORMAL/ EXTENDED MODE, AND LONG WORD MODE

This Appendix has two sets of tables. Each table is a subset of the Table in the Appendix B. The Table D-1 has the instructions which works differently in the Native and

Extended mode of operation, and the Table D-2 has the instructions which works differently in Word/Long Word mode of operation.

APPENDIX E

INSTRUCTIONS AFFECTED BY DDIR IM INSTRUCTIONS

This Appendix has instructions which can be used with the Decoder Directive(s) Extend Immediate. There are eight tables (E1-E8) which are the subset of the Table A, sorted by the category of the instruction.

Note that the instructions listed here does not have the DDIR Decoder Directive in front of the instructions listed below, and notation used here may be different by the assembler to be used.

Table E-1. Valid with DDIR IB in Extended mode. LW bit status does not affect the operation

INDEX

Symbols

/INT3-/INT0	6-1
/NMI	6-1
/RESET	1-5
8-Bit Load/Exchange Group	5-6
8080 compatible (Mode 0)	1-5

A

ADC Add with Carry (Word)	5-21
Add (Byte)	5-23
Add (Word)	5-24
Add to Stack Pointer (Word)	5-25
Add/Subtract flag	5-2
Address manipulation	3-1
Address space	1-1
Addressing mode	A-1
Addressing mode escape byte	A-1
Addressing mode escape bytes, addresses	A-2
Addressing Modes	1-4,4-1
AF or AF' Register Select	5-5
AND (Byte)	5-27
AND (Word)	5-28
Arithmetic and Logical Group	5-9
Arithmetic Operation	5-10
Assembly language format	4-1
Assigned Vector Base Register	5-15,6-3,6-6
Assigned Vectors Base	6-4

B

Bank Test	5-30
Bank Test instructions	5-16
BC/DE/HL or BC'/DE'/HL' Register Select	5-4
Binary-coded decimal	4-10,5-1
Bit Test	5-29
Block I/O	5-5
Block move	5-5
Block move, block search, and block I/O instruction	6-1
Block search	5-2, 5-5
Block Transfer and Search Group	5-1,5-8
Block transfer	5-2, 5-8
Bus bandwidth	1-5
Byte ordering	3-2
Byte strings	4-10

C

Call and Restart	5-12
Call Relative	5-1, 5-12
Call Relative	5-32
Call, Return, Push, and Pop	4-10
Carry flag	5-2
Carry or borrow operation	4-6
Chip Version ID Register	2-6,5-15
Compare (Byte)	5-34
Compare (Word)	5-35
Compare and Decrement (Byte)	5-36
Compare and Increment (Byte)	5-38
Compare, Decrement and Repeat (Byte)	5-37
Compare, Increment and Repeat (Byte)	5-39
Complement Accumulator	5-40
Complement Carry flag	5-33
Complement HL Register (Word)	5-41
Condition Codes	5-3
Conditional instructions	5-1
Conditional Return instruction	5-12
Context Switching	1-5,1-6
CPU Control Group	5-16
CPU Control Register Space	2-1
CPU Register Space	2-1

D

Data frame	5-7
Data manipulation	3-1
Data Types	4-1, 4-10
DDIR	3-1
DDIR IB Immediate Byte	3-2
DDIR IB,LW Immediate Byte, Long Word Mode	3-2
DDIR IB,W Immediate Byte, Word Mode	3-2
DDIR IW,LW Immediate Word, Long Word Mode	3-2
DDIR IW,W Immediate Word, Word Mode	3-2
DDIR LW	1-3
DDIR LW Long Word Mode	3-2
DDIR W	1-3
DDIR W Word Mode	3-2
Decimal Adjust Accumulator	4-10,5-2, 5-42
Decoder Directive	3-2, 5-17, 5-43, A-1
Decrement (Byte)	5-44
Decrement (Word)	5-45

Interrupt mode	6-1,6-2, 6-3, 6-5
Interrupt Priority Ranking	6-2
Interrupt Register	2-3
Interrupt Register Extension	6-2
Interrupt service routines	1-3
Interrupt Vectors Mode	6-6
Interrupt vectors	6-2
interrupt return instruction	5-5
Interrupts	6-1
Interrupts, traps, and resets	1-4,6-1
IW decoder directive	3-2
IX Bank Select	5-4
IX or IX' Register Select	5-4
IY Bank Select	5-4
IY or IY' Register Select	5-4

J

JP	5-80
Jump	5-1,5-80
Jump and Call instructions	4-3
Jump Relative	5-1, 5-81

L

Linear Memory Address Space	1-5
Load Accumulator	5-82
Load Accumulator from R or I register	5-16
Load and Decrement (Byte)	5-96
Load and Decrement (Word)	5-97
Load and Increment (Byte)	5-100
Load and Increment (Word)	5-101
Load B register	A-1
Load Control Register (Byte)	5-93
Load from Control Register (Word)	5-94
Load from I or R Register (Byte)	5-90
Load I Register (Word)	5-92
Load Immediate (Byte)	5-83
Load Immediate (Word)	5-84
Load into Control Register (Word)	5-95
Load into I or R Register (Byte)	5-91
Load Register (Byte)	5-86
Load Register (Word)	5-87,5-88, A-1
Load Stack Pointer	5-89
Load, Decrement and Repeat (Byte)	5-98
Load, Decrement and Repeat (Word)	5-99
Load, Exchange, SWAP and Push/Pop Group	5-1
Load, Exchange, SWAP, and PUSH/POP Group	5-7
Load, Increment and Repeat (Byte)	5-102
Load, Increment and Repeat (Word)	5-103
load, arithmetic, logical, shift, and rotate	4-10
Load/Exchange Group	5-1
Lock	5-5
Lock/Unlock status	5-5
Logical, signed numeric, or unsigned	4-10
Long Word Mode	5-5
LW decoder directive	3-2

M

Machine language bit	A-1
Main Bank Select	5-4
Maskable Interrupt	6-5
Memory Address Space	2-1
Memory Banking scheme	1-5
memory addressing modes	5-9
Mode Test	5-105
Mode Test instructions	5-16
Multiple register banks	1-5
Multiply (Word)	5-106
Multiply Unsigned (Byte)	5-104
Multiply Unsigned (Word)	5-107

N

NATIVE MODE AND EXTENDED MODE	3-2
Native or Extended mode	6-2
Native/Extended	1-3
Negate Accumulator	5-108
Negate HL instruction	5-10
Negate HL Register (Word)	5-109
No Operation	5-110
No Operation instruction	5-16
NONMASKABLE INTERRUPT	6-5
Nonmaskable Interrupt (NMI)	6-1

O

Object-code compatibility	1-1
ON-CHIP I/O ADDRESS SPACE	2-6
On-Chip I/O Address Space	2-1
On-Chip Register Files	1-1
Opcode Trap	1-1
Operand	4-1
OR (Byte)	5-111
OR (Word)	5-112
Output (Byte)	5-121
Output (to Page 0)	5-124
Output (Word)	5-122
Output Accumulator	5-123
Output and Decrement (Byte)	5-127
Output and Decrement (Word)	5-128
Output and Increment (Byte)	5-129
Output and Increment (Word)	5-130
Output Decrement Memory	5-113
Output Direct to Port Address (Byte)	5-125
Output Direct to Port Address (Word)	5-126
Output Increment Memory	5-117
Output, Decrement and Repeat (Byte)	5-115
Output, Decrement and Repeat (Word)	5-116
Output, Decrement Memory Repeat	5-114
Output, Increment and Repeat (Byte)	5-119
Output, Increment and Repeat (Word)	5-120
Output, Increment Memory Repeat	5-118

T

Test (Byte)	5-176
Test I/O Port	5-177
TRAP INTERRUPT	6-4
Trap and Break Register	2-6, 6-4
Trap handling routine	5-5
Trap on Instruction Fetch	6-4
Trap on Interrupt Vector	6-4
Trap Register	5-15, 6-4
TST instruction	5-9
TSTIO instruction	5-15

U

Ump relative/Call relative	1-6
Unsigned divide instruction	5-10

V

Vectored interrupt mode (Mode 2)	1-5
--	-----

W

W decoder directive	3-2
Word or Long Word block transfer	5-8
Word strings	4-10
Word/Long Word	1-3

Z

Zero byte input	5-2
Zero flag	5-2

Z8® MICROCONTROLLERS - CONSUMER FAMILY OF PRODUCTS

Databooks By Market Niche	Part No	Unit Cost
Z8® Microcontrollers Databook	DC-8305-02	\$ 5.00

Product Specifications

- Z86C07 CMOS Z8 8-Bit Microcontroller
- Z86C08 CMOS Z8 8-Bit Microcontroller
- Z86E08 CMOS Z8 8-Bit OTP Microcontroller
- Z86C11 CMOS Z8 Microcontroller
- Z86C12 CMOS Z8 In-Circuit Microcontroller Emulator
- Z86C21 8K ROM Z8 CMOS Microcontroller
- Z86E21 CMOS Z8 8K OTP Microcontroller
- Z86C61/62/96 CMOS Z8 Microcontroller
- Z86C63/64 32K ROM Z8 CMOS Microcontroller
- Z86C91 CMOS Z8 ROMless Microcontroller
- Z86C93 CMOS Z8 Multiply/Divide Microcontroller

Support Product Specifications

- Z0860000ZCO Development Kit
- Z86C0800ZCO Applications Board
- Z86C0800ZDP Adaptor Board
- Z86E2100ZDF Adaptor Kit
- Z86E2100ZDP Adaptor Kit
- Z86E2100ZDV Adaptor Kit
- Z86E2100ZDV Adaptor Kit
- Z86E2101ZDF Conversion Kit
- Z86E2101ZDV Conversion Kit
- Z86C6100TSC Z86C61/63 MCU OTP Emulation Board
- Z86C6200ZEM In-Circuit Emulator
- Z86C1200ZEM Z8® In-Circuit Emulator -C12
- Z8® S Series Emulators, Base Units and Pods

LITERATURE GUIDE

ORDERING INFORMATION

Complete the attached literature order form. Be sure to enclose the proper payment or supply a purchase order. Please reference specific order requirements.

MINIMUM ORDER REQUIREMENTS

Orders under \$300.00 must be prepaid by check, money order or credit card. Canadian and foreign orders must be accompanied by a cashier's check in U.S. dollars, drawn on a correspondent U.S. bank only.
Orders over \$300.00 may be submitted with a Purchase Order.

SHIPMENT

Orders will be shipped after your check is cashed or credit is checked via the most economical method. Please allow four weeks for delivery.

RETURNS ARE NOT ACCEPTED.

PLEASE PRINT OR TYPE
