GP3406

1.5MHz, 700mA Synchronous Step-Down Converter

GENERAL DESCRIPTION

The GP3406 is a 1.5MHz constant frequency, slope compensated current mode PWM step-down converter. The device integrates a main switch and a synchronous rectifier for high efficiency without an external Schottky diode. It is ideal for powering portable equipment that runs from a single cell lithium-Ion (Li+) battery. The GP3406 can supply 700mA of load current from a 2.5V to 5.5V input voltage. The output voltage can be regulated as low as 0.6V. The GP3406 can also run at 100% duty cycle for low dropout operation, extending battery life in portable system. Pulse Skipping Mode operation at light loads provides very low output ripple voltage for noise sensitive applications.

The GP3406 is offered in a low profile (1mm) 5-pin,SOT package, and is available with an adjustable version and fixed output voltage of 1.2V,1.5V and 1.8V or customer-specific versions.

APPLICATIONS

- Cellular and Smart Phones
- Microprocessors and DSP Core Supplies
- Wireless and DSL Modems
- PDAs
- Portable Media players / MP3 Players
- Digital Still and Video Cameras
- Portable Instruments

FEATURES

- High Efficiency: Up to 96%
- 1.5MHz Constant Switching Frequency
- 700mA Output Current at V_{IN}=3V
- Integrated Main switch and synchronous rectifier. No Schottky Diode Required
- 2.5V to 5.5V Input Voltage Range
- Output Voltage as Low as 0.6V
- 100% Duty Cycle Dropout Operation
- 270uA Typical Quiescent Current
- Slope Compensated Current Mode Control for Excellent Line and Load Transient Response
- Short Circuit Protection
- Thermal Fault Protection
- <1µA Shutdown Current
- Space Saving 5-Pin Thin SOT23 package

Typical Application

Figure 1. Basic Application Circuit with GP3406 adjustable version, Vout = 1.8V

Efficiency vs. Output Current

Pin Descriptions

Pin #	Symbol	Function
1	RUN	Enable pin. Active high. In shutdown, all functions are disabled drawing <1µA supply current. Do not leave EN floating.
2	GND	Ground pin.
3	SW	Switching node. Connect the output inductor to this pin. Connects to the drains of the internal P- and N-channel MOSFET switches.
4	V_{IN}	Supply input pin. Must be closely decoupled to GND with a 2.2µF or larger ceramic capacitor.
5	V_{FB}/ V_{OUT}	V_{FB} (GP3406ICB-ADJ)**:** Feedback input pin. Connect V_{FB} to the center point of the external resistor divider. The feedback threshold voltage is 0.6V.
		V_{OUT} : Output voltage pin for Fixed Output Versions.

Pin Configuration

TSOT23-5

Functional Block Diagram

Figure 2. GP3406 Block Diagram
Operation

GP3406 is a monolithic switching mode Step-Down DC-DC converter. It utilizes internal MOSFETs to achieve high efficiency and can generate very low output voltage by using internal reference at 0.6V. It operates at a fixed switching frequency, and uses the slope compensated current mode architecture. This Step-Down DC-DC Converter supplies 700mA output current at VIN = 3V with input voltage range from 2.5V to 5.5V.

Current Mode PWM Control

Slope compensated current mode PWM control provides stable switching and cycle-by-cycle current limit for excellent load and line responses and protection of the internal main switch (P-Ch MOSFET) and synchronous rectifier (N-CH MOSFET). During normal operation, the internal P-Ch MOSFET is turned on for a certain time to ramp the inductor current at each rising edge of the internal oscillator, and switched off when the peak inductor current is above the error voltage. The current comparator, I_{COMP}, limits the peak inductor current. When the main switch is off, the synchronous rectifier will be turned on immediately and stay on until either the inductor current starts to reverse, as indicated by the current reversal comparator, I_{ZERO}, or the beginning of the next clock cycle. The OVDET comparator controls output transient overshoots by turning the main switch off and keeping it off until the fault is no longer present.

Pulse Skipping Mode Operation

At very light loads, the GP3406 automatically enters Pulse Skipping Mode. In the Pulse Skipping Mode, the inductor current may reach zero or reverse on each pulse. The PWM control loop will automatically skip pulses to maintain output regulation. The bottom MOSFET is turned off by the current reversal comparator, I_{ZERO}, and the switch voltage will ring. This is discontinuous mode operation, and is normal behavior for the switching regulator.

Dropout Operation

When the input voltage decreases toward the value of the output voltage, the GP3406 allows the main switch to remain on for more than one switching cycle and increases the duty cycle [Note 5] until it reaches 100%. The output voltage then is the input voltage minus the voltage drop across the main switch and the inductor. At low input supply voltage, the $R_{DS(ON)}$ of the P-Channel MOSFET increases, and the efficiency of the converter decreases. Caution must be exercised to ensure the heat dissipated not to exceed the maximum junction temperature of the IC.

Note 5: The duty cycle D of a step-down converter is defined as:

$$D = T_{ON} \times f_{OSC} \times 100\% \approx \frac{V_{OUT}}{V_{IN}} \times 100\%$$

Where T_{ON} is the main switch on time and f_{OSC} is the oscillator frequency (1.5Mhz).

Maximum Load Current

The GP3406 will operate with input supply voltage as low as 2.5V, however, the maximum load current decreases at lower input due to large IR drop on the main switch and synchronous rectifier. The slope compensation signal reduces the peak inductor current as a function of the duty cycle to prevent sub-harmonic oscillations at duty cycles greater than 50%. Conversely the current limit increases as the duty cycle decreases.

Layout Guidance

When laying out the PC board, the following suggestions should be taken to ensure proper operation of the GP3406. These items are also illustrated graphically in Figure 3.

1. The power traces, including the GND trace, the SW trace and the VIN trace should be kept short, direct and wide to allow large current flow. Put enough multiply-layer pads when they need to change the trace layer.
2. Connect the input capacitor C1 to the VIN pin as closely as possible to get good power filter effect.

3. Keep the switching node, SW, away from the sensitive FB node.

4. Do not trace signal line under inductor.

APPLICATIONS INFORMATION

Figure 4 below shows the basic application circuit with GP3406 fixed output versions.

Figure 4. Basic Application Circuit with fixed output versions

Setting the Output Voltage

Figure 1 above shows the basic application circuit with GP3406 adjustable output version. The external resistor sets the output voltage according to the following equation:

$$V_{OUT} = 0.6V \times \left(1 + \frac{R2}{R1}\right)$$

Table 1 Resistor select for output voltage setting

V_{OUT}	R1(R3)	R2(R4)
1.2V	316k	316k
1.5V	316k	470k
1.8V	316k	634k
2.5V	316k	1000k

Inductor Selection

For most designs, the GP3406 operates with inductors of 1µH to 4.7µH. Low inductance values are physically smaller but require faster switching, which results in some efficiency loss. The inductor value can be derived from the following equation:

$$L = \frac{V_{OUT} \times (V_{IN} - V_{OUT})}{V_{IN} \times \Delta I_L \times f_{OSC}}$$

Where ΔI_L is inductor Ripple Current. Large value inductors lower ripple current and small value inductors result in high ripple currents. Choose inductor ripple current approximately 35% of the maximum load current 600mA, or ΔI_L=210mA.

efficiency is important, the minimum recommended inductor is 2.2µH. For optimum voltage-positioning load transients, choose an inductor with DC series resistance in the 50mΩ to 150mΩ range. For higher efficiency at heavy loads (above 200mA), or minimal load regulation (but some transient overshoot), the resistance should be kept below 100mΩ. The DC current rating of the inductor should be at least equal to the maximum load current plus half the ripple current to prevent core saturation (600mA+105mA). Table 2 lists some typical surface mount inductors that meet target applications for the GP3406.

Table 2. Typical Surface Mount Inductors

Input Capacitor Selection

The input capacitor reduces the surge current drawn from the input and switching noise from the device. The input capacitor impedance at the switching frequency shall be less than input source impedance to prevent high frequency switching current passing to the input. A low ESR input capacitor sized for maximum RMS current must be used. Ceramic capacitors with X5R or X7R dielectrics are highly recommended because of their low ESR and small temperature coefficients. A 4.7µF ceramic capacitor for most applications is sufficient.

Output Capacitor Selection

The output capacitor is required to keep the output voltage ripple small and to ensure regulation loop stability. The output capacitor must have low impedance at the switching frequency. Ceramic capacitors with X5R or X7R dielectrics are recommended due to their low
ESR and high ripple current. The output ripple V_{OUT} is determined by:

$$\Delta V_{OUT} \leq \frac{V_{OUT} \times (V_{IN} - V_{OUT})}{V_{IN} \times f_{OSC} \times L} \times \left(ESR + \frac{1}{8 \times f_{osc} \times C3} \right)$$
