

General Description

The AAT3520 series of PowerManager products is part of AnalogicTech's Total Power Management IC™ (TPMIC™) product family. These microprocessor reset circuits are ideal for monitoring voltage supplies in portable systems, where extended battery life is critical. They provide a low-cost, reliable solution by eliminating the need for external components. The AAT3520 series operates by monitoring the system power supply voltage. When the input voltage drops below a fixed threshold, the device asserts a reset signal for a fixed time period after V_{CC} has risen back above the fixed threshold; 30ms and 150ms minimum periods are available. The AAT3520 product series is guaranteed to operate down to 1.2V and is designed to ignore fast line transients appearing on V_{CC} . The AAT3520 series is available with three output stage versions: AAT3520 push-pull active high output; AAT3522 push-pull active low output; and AAT3524 open drain active low output. The quiescent supply current is extremely low, typically 1 μ A, making it ideal for portable battery-operated equipment.

The AAT3520/2/4 are available in a Pb-free, 3-pin SOT23 package and are specified over the -40°C to +85°C operating temperature range.

Features

- Input Voltage Range: 1.2V to 5.5V
- Operation Down to 1.2V
- Extremely Low Quiescent Current: <2 μ A
- High Accuracy Detection Threshold: $\pm 1.5\%$
- Monitor Power Supply Voltages
- Fixed Thresholds from 2.2V to 4.6V
- -Reset Pulse Width Options
 - Minimum 30ms or 150ms or 300ms
 - Fast Propagation Delay <20 μ s
- Available Output Configurations:
 - Open-Drain Output
 - CMOS Active High Output
 - CMOS Active Low Output
- Temperature Range: -40°C to +85°C
- 3-Pin SOT23 Package
- 4kV ESD Rating

Applications

- Cell Phones
- Embedded Systems
- Intelligent Instruments
- Notebook Computers
- Portable Electronics

Typical Application

*AAT3524 Only

Pin Descriptions

Pin #	Symbol	Function
1	GND	Ground connection.
2	RESET (AAT3520)	RESET output remains high while V_{CC} is below the reset threshold and remains so for a fixed time period after V_{CC} raises above the reset threshold.
	RESET (AAT3522, AAT3524)	$\overline{\text{RESET}}$ output remains low while V_{CC} is below the reset threshold and remains so for a fixed time period after V_{CC} raises above the reset threshold.
3	VCC	Supply voltage (+1.2V to +5.5V). Due to extremely low operating current, place a 10nF capacitor between VCC and GND.

Functional Description

General

During start-up, the reset pin on a microprocessor ensures that it is fully reset and starts up in a known condition. The AAT3520 series of microprocessor reset devices monitor the supply voltage to a microprocessor

and assert a reset signal whenever the V_{CC} voltage falls below a factory-programmed threshold. This threshold is accurate within $\pm 1.5\%$ at 25°C and within $\pm 2.5\%$ over the entire operating temperature range. The reset signal remains asserted for a fixed time period (t_{RDY}) after V_{CC} has risen above the threshold, as shown in Figure 1. See Ordering Information for available RESET active timeout periods.

Applications Information

Reset Output Options

The AAT3524 has an active low open drain output and the AAT3520/2 have a push-pull output. The AAT3524 may be used in multiple voltage systems with an external pull-up resistor. This allows the AAT3524 to interface to microprocessors with higher supply voltages up to 5.5V (Figure 3). In the event of a power down or brown-out condition, the reset signal remains valid until the V_{CC} drops below 1.2V. To ensure validity down to ground, an external 100k Ω resistor should be connected between the RESET output and GND.

Supply Voltage Transient Behavior

In some cases, fast negative transients of short duration can appear on the V_{CC} power supply. The AAT3520 series devices provide some immunity to line transients which can generate invalid reset pulses. Figure 1 shows typical behavior to short duration pulses versus RESET comparator overdrive. As shown in the Maximum Transient Duration vs. Reset Threshold Overdrive graph, when the transient voltage becomes larger, the time allowed before asserting a reset becomes shorter (i.e., typically a transient of 100mV below the reset threshold would have to present for more than 50 μ s to cause a reset). Immunity can be increased by the addition of a small bypass capacitor of 0.1 μ F connected as closely to the V_{CC} pin as possible.
