To provide the most up-to-date information, the revision of our documents on the World Wide Web will be the most current. Your printed copy may be an earlier revision. To verify you have the latest information available, refer to:

http://freescale.com/

The following revision history table summarizes changes contained in this document.

Revision History

Date	Revision Level	Description
September, 2005	01.00	new book
September, 2005	01.01	added MC3S12R64 corrected MC3S12RG128 block diagram
October, 2005	01.02	updated SCIV2 chapter corrected MC3S12R64 memory map diagram, added warning about 8K RAM mapping
November, 2005	01.03	updated MSCANV2 chapter added MC3S12RB128
February, 2006	01.04	updated ROM64KX16, SCI chapters updated electrical specification
November, 2006	01.05	updated ATD10B8C, IIC chapters corrected duplicated offsets in device register map removed references to the INITEE register and marked it as “reserved” (there is no EEPROM on this device)
December, 2006	01.06	fixed text formats and PDF bookmarks for ATD10B8C chapter

Chapter 1
Device Overview (MC3S12RG128V1)

1.1 Introduction

The MC3S12RG128 microcontroller unit (MCU) is a 16-bit device composed of standard on-chip peripherals including a 16-bit central processing unit (CPU12), up to 128K bytes of ROM, 8K bytes of RAM, two asynchronous serial communications interfaces (SCI), two serial peripheral interfaces (SPI), IIC-bus, an enhanced capture timer (ECT), two 8-channel 10-bit analog-to-digital converters (ADC), an eight-channel pulse-width modulator (PWM), and up to two CAN 2.0 A, B software compatible modules (MSCAN12). There is no integrated EEPROM on the MC3S12RG128. The MC3S12RG128 has full 16-bit data paths throughout. However, the external bus can operate in an 8-bit narrow mode so single 8-bit wide memory can be interfaced for lower cost systems. The inclusion of a PLL circuit allows power consumption and performance to be adjusted to suit operational requirements.

1.1.1 Features

- HCS12 Core
  - 16-bit HCS12 CPU
    - Upward compatible with M68HC11 instruction set
    - Interrupt stacking and programmer’s model identical to M68HC11
    - 20-bit ALU
    - Instruction queue
    - Enhanced indexed addressing
  - MEBI (Multiplexed External Bus Interface)
  - MMC (Module Mapping Control)
  - INT (Interrupt control)
  - BKP (Breakpoints)
  - BDM (Background Debug Module)
- CRG (Clock and Reset Generator)
  - Choice of low current Colpitts oscillator or standard Pierce oscillator
  - PLL
  - COP watchdog
  - Real time interrupt
  - Clock monitor
- 8-bit and 4-bit ports with interrupt functionality
  - Digital filtering

- Programmable rising and falling edge trigger
- Memory Options:
  - 128K Byte or 64K Byte ROM
  - 8K Byte RAM
- Two 8-channel Analog-to-Digital Converters
  - 10-bit resolution
  - External conversion trigger capability
- Two 1M bit per second, CAN 2.0 A, B software compatible modules
  - Five receive and three transmit buffers
  - Flexible identifier filter programmable as 2 x 32 bit, 4 x 16 bit or 8 x 8 bit
  - Four separate interrupt channels for Rx, Tx, error and wake-up
  - Low-pass filter wake-up function
  - Loop-back for self test operation
- Enhanced Capture Timer
  - 16-bit main counter with 7-bit prescaler
  - 8 programmable input capture or output compare channels
  - Four 8-bit or two 16-bit pulse accumulators
- 8 PWM channels
  - Programmable period and duty cycle
  - 8-bit 8-channel or 16-bit 4-channel
  - Separate control for each pulse width and duty cycle
  - Center-aligned or left-aligned outputs
  - Programmable clock select logic with a wide range of frequencies
  - Fast emergency shutdown input
  - Usable as interrupt inputs
- Serial interfaces
  - Two asynchronous Serial Communications Interfaces (SCI)
  - Two Synchronous Serial Peripheral Interface (SPI)
- Inter-IC Bus (IIC)
  - Compatible with I^2C Bus standard
  - Multi-master operation
  - Software programmable for one of 256 different serial clock frequencies
- Internal 2.5V Regulator
  - Supports an input voltage range from 2.97V to 5.5V
  - Low power mode capability
  - Includes low voltage reset (LVR) circuitry
  - Includes low voltage interrupt (LVI) circuitry
- 112-Pin LQFP and 80-Pin QFP package options
  - I/O lines with 5V input and drive capability

  - 5V A/D converter inputs
  - Operation at 66 MHz equivalent to 33 MHz Bus Speed (single-chip modes only)
  - Operation at 50 MHz equivalent to 25 MHz Bus Speed (expanded modes)
- Development support
  - Single-wire background debug™ mode (BDM)
  - On-chip hardware breakpoints

1.1.2 Modes of Operation

User modes:

- Normal and Emulation Operating Modes
  - Normal Single-Chip Mode
  - Normal Expanded Wide Mode
  - Normal Expanded Narrow Mode
  - Emulation Expanded Wide Mode
  - Emulation Expanded Narrow Mode
- Special Operating Modes
  - Special Single-Chip Mode with active Background Debug Mode
  - Special Test Mode (**Freescale use only**)
  - Special Peripheral Mode (**Freescale use only**)

Low power modes:

- Stop Mode
- Pseudo Stop Mode
- Wait Mode

1.1.3 Block Diagram

Figure 1-1 shows a block diagram of the MC3S12RG128 device.

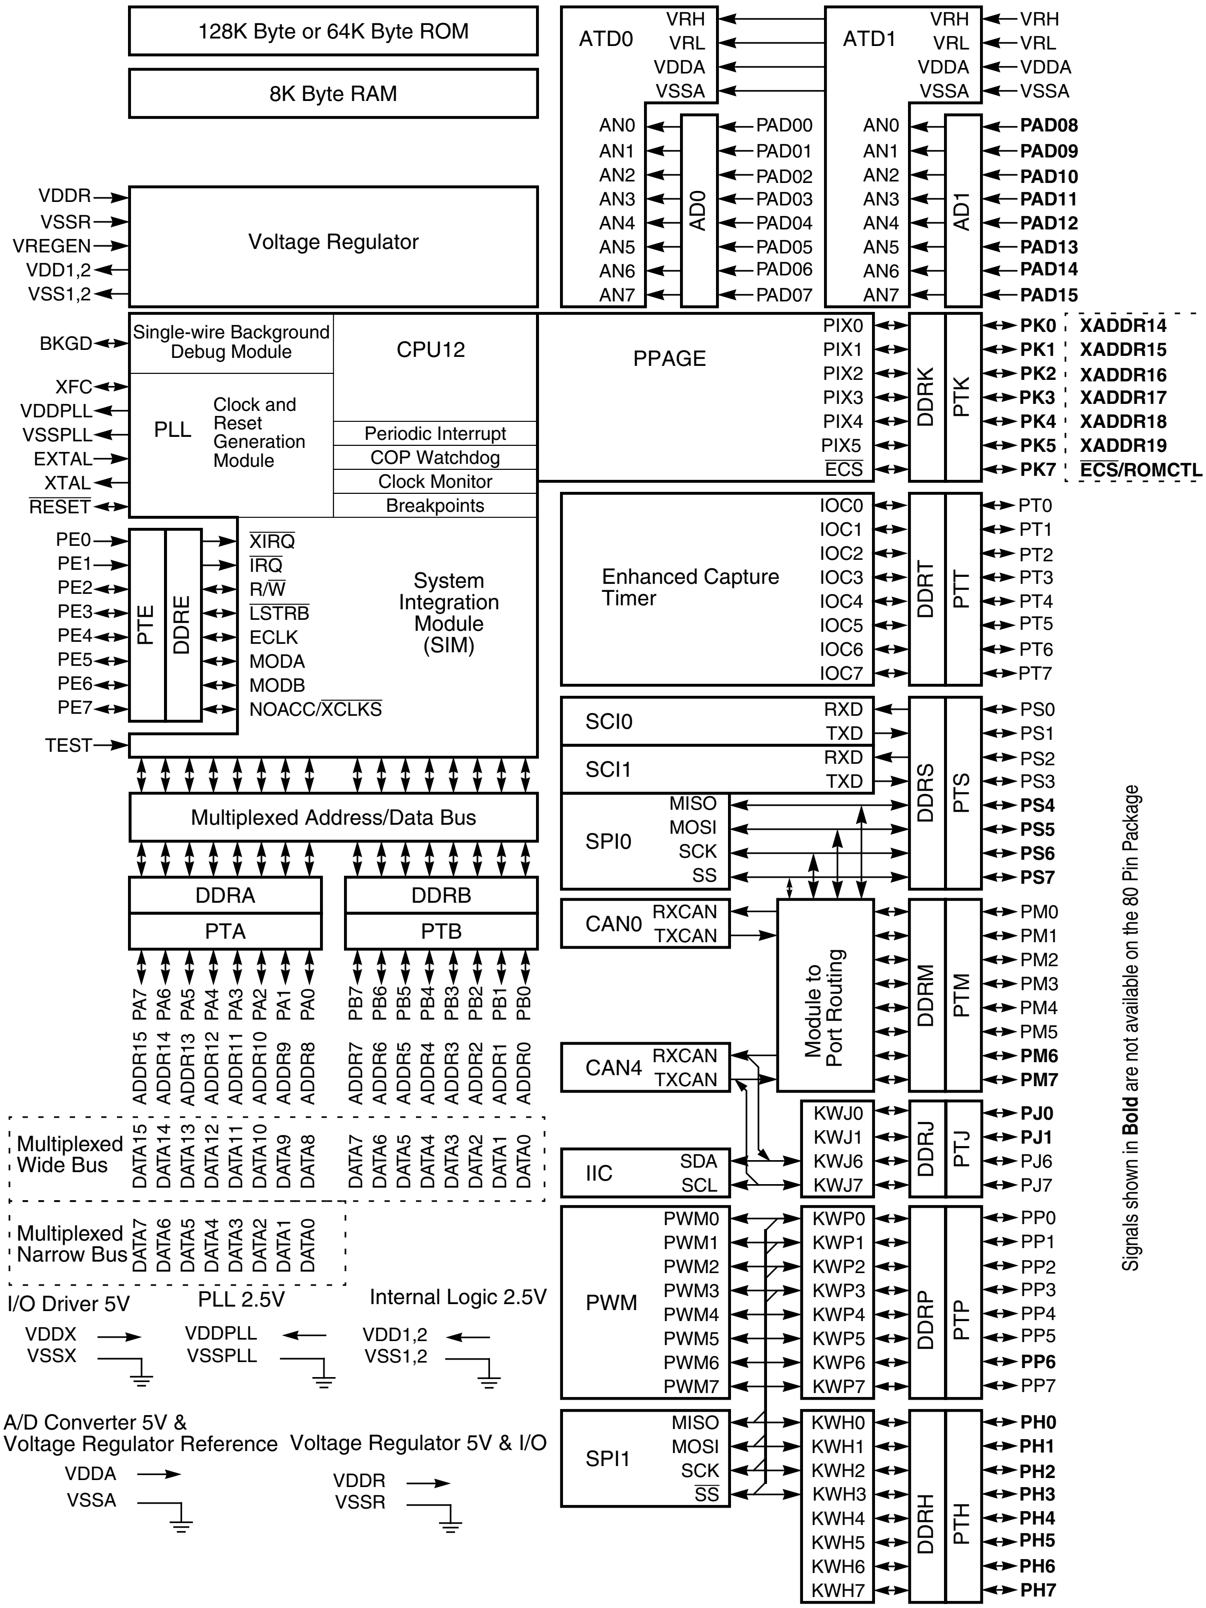

Figure 1-1. MC3S12RG128 Block Diagram

1.1.4 Device Memory Map

Table 1-1 shows the device register memory map of the MC3S12RG128 after reset. Note that after reset the bottom 1K Bytes of RAM ($0000 - $03FF) are hidden by the register space.

Table 1-1. Device Memory Map

Address	Module	Size (Bytes)
0x0000–0x0017	CORE (Ports A, B, E, Modes, Inits, Test)	24
0x0018	Reserved	1
0x0019	Voltage Regulator (VREG3V3)	1
0x001A–0x001B	Device ID register (PARTID)	2
0x001C–0x001F	CORE (MEMSIZ, IRQ, HPRIO)	4
0x0020–0x0027	Reserved	8
0x0028–0x002F	CORE (Background Debug Module)	8
0x0030–0x0033	CORE (PPAGE, Port K)	4
0x0034–0x003F	Clock and Reset Generator (PLL, RTI, COP)	12
0x0040–0x007F	Enhanced Capture Timer 16-bit 8 channels	64
0x0080–0x009F	Analog to Digital Converter 10-bit 8 channels (ATD0)	32
0x00A0–0x00C7	Pulse Width Modulator 8-bit 8 channels (PWM)	40
0x00C8–0x00CF	Serial Communications Interface (SCI0)	8
0x00D0–0x00D7	Serial Communications Interface (SCI1)	8
0x00D8–0x00DF	Serial Peripheral Interface (SPI0)	8
0x00E0–0x00E7	Inter IC Bus	8
0x00E8–0x00EF	Reserved	8
0x00F0–0x00F7	Serial Peripheral Interface (SPI1)	8
0x00F8–0x00FF	Reserved	8
0x0100–0x010F	ROM Control/Status Registers	16
0x0110–0x011B	Reserved	12
0x011C–0x011F	Reserved	4
0x0120–0x013F	Analog to Digital Converter 10-bit 8 channels (ATD1)	32
0x0140–0x017F	Motorola Scalable CAN (CAN0)	64
0x0180–0x01BF	Reserved	64
0x01C0–0x01FF	Reserved	64
0x0200–0x023F	Reserved	64
0x0240–0x027F	Port Integration Module (PIM)	64
0x0280–0x02BF	Motorola Scalable CAN (CAN4)	64
0x02C0–0x02FF	Reserved	64
0x0300–0x035F	Reserved	96
0x0360–0x03FF	Reserved	160
0x0000–0x1FFF	RAM array	8192

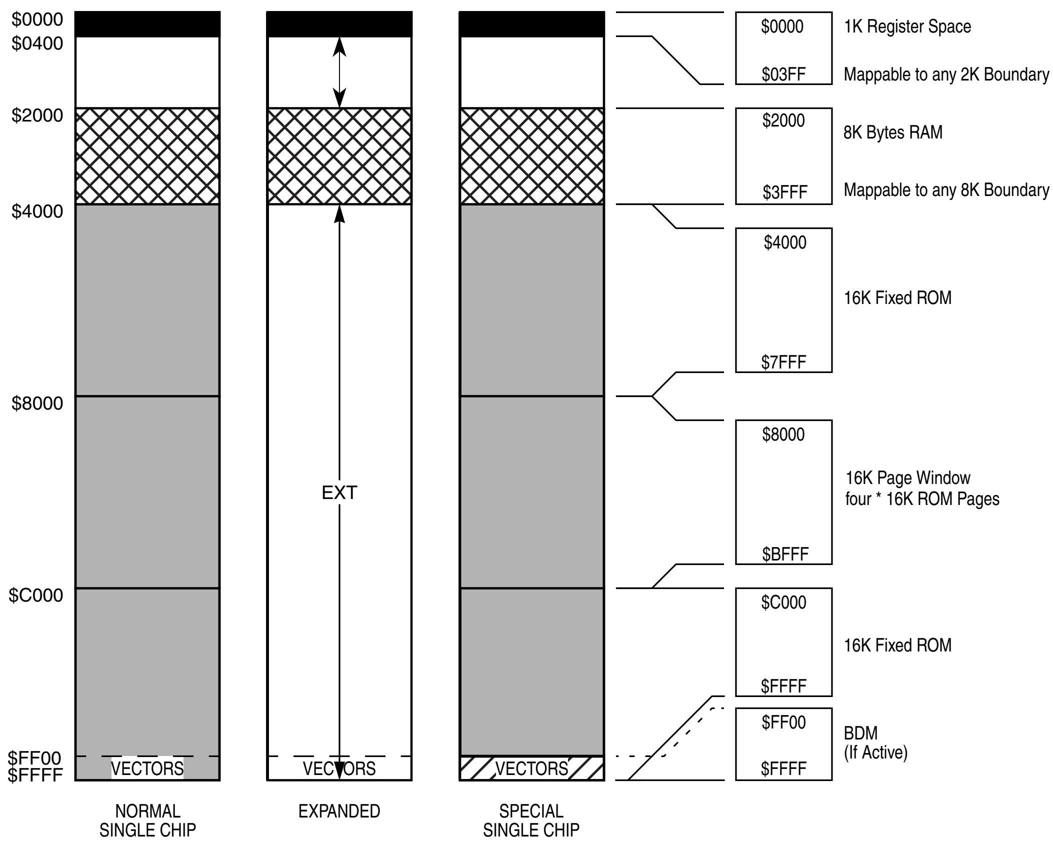
Table 1-1. Device Memory Map

Address	Module	Size (Bytes)
0x4000–0x7FFF	Fixed ROM array	16384
0x8000–0xBFFF	ROM Page Window	16384
0xC000–0xFFFF	Fixed ROM array incl. 256 bytes of Vector Space at $FF80 – $FFFF	16384

NOTE

Reserved register space shown in Table 1-1 is not allocated to any module. Writing to these locations has no effect. Read access to these locations returns zero.

1.1.5 Logical Address Map



The figure shows a useful map, which is not the map out of reset. After reset the map is:

$0000 - $03FF: Register Space
$0000 - $1FFF: 8K RAM

Figure 1-2. MC3S12RG128 Memory Map (also applies to MC3S12RB128)

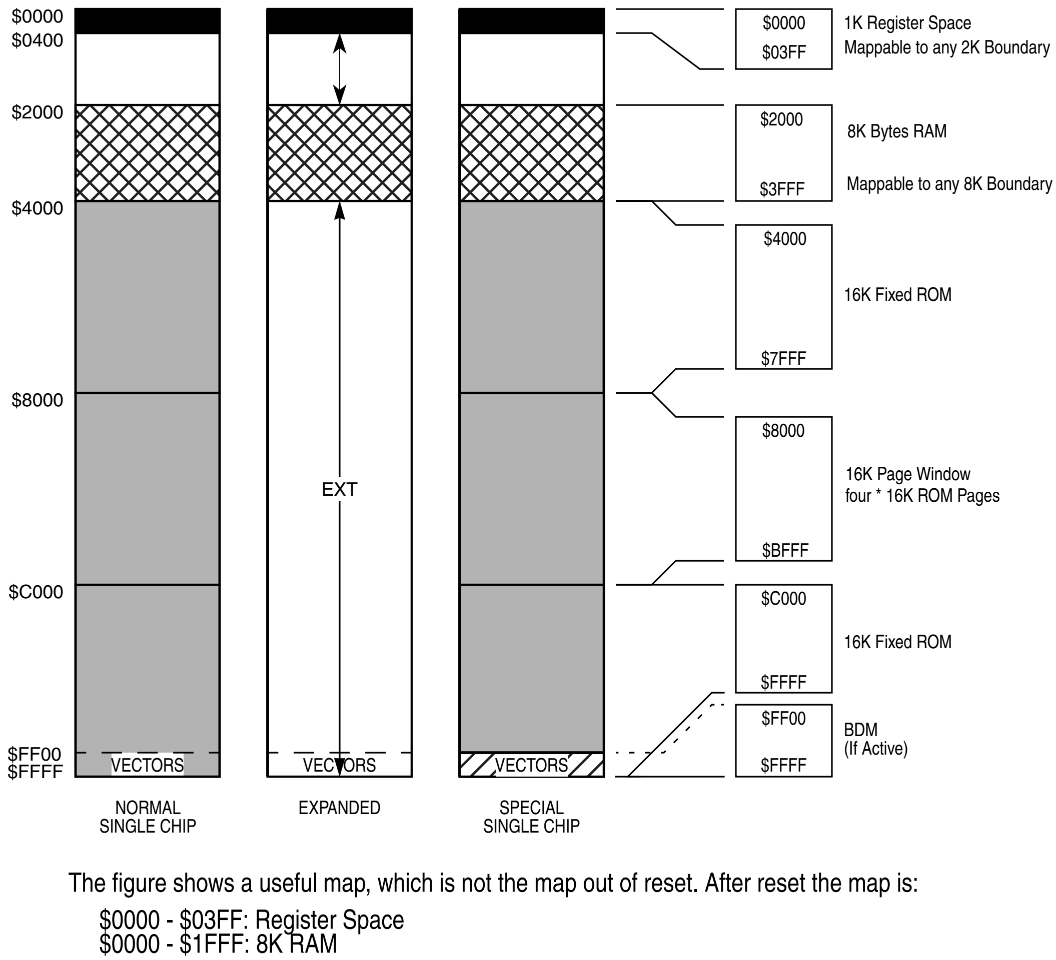


Figure 1-3. MC3S12R64 Memory Map

NOTE

To ensure compatibility with the MC9S12D64 FLASH devices, the internal RAM should not be remapped to a location outside of the first 16K page ($0000–$3FFF) in the memory map.
The internal RAM of the MC9S12D64 device and the MC3S12R64 device differ in size (4K vs. 8K). Therefore re-mapping the internal RAM outside of the first 16K page results in different sizes of visible FLASH or ROM space: a 4K RAM will leave 12K of a 16K page unmasked while the 8K RAM will only leave 8K of a 16K page unmasked.

1.1.6 Device Register Map

The following tables show the detailed register map of the MC3S12RG128 device.

0x0000–0x000F MEBI map 1 of 3 (HCS12 Multiplexed External Bus Interface

1.1.7 Part ID Assignments

The part ID is located in two 8-bit registers PARTIDH and PARTIDL (addresses 0x001A and 0x001B after reset). The read-only value is a unique part ID for each revision of the chip. Table 1-2 shows the assigned part ID number and Mask Set number.

Table 1-2. Assigned Part ID Numbers

Device	Mask Set Number	Part ID[1]
MC3S12RG128	2M38B	0x0682

[1] The coding is as follows:
Bit 15-12: Major family identifier
Bit 11-8: Minor family identifier
Bit 7-4: Major mask set revision number including FAB transfers
Bit 3-0: Minor — non full — mask set revision

The device memory sizes are located in two 8-bit registers MEMSIZ0 and MEMSIZ1 (addresses $001C and $001D after reset). Table 1-3 shows the read-only values of these registers. Refer to HCS12 Module Mapping Control (MMC) Block Guide for further details.

Table 1-3. Memory size registers

Register name	Constant value
MEMSIZ0	0x03
MEMSIZ1	0x80

1.2 Signal Description

This section describes signals that connect off chip. It includes a pinout diagram, a table of signal properties, and detailed discussion of signals. It is built from the signal description sections of the Block Guides of the individual IP Blocks contained in the system.

1.2.1 Device Pinout

The MC3S12RG128 and its derivatives are available in a 112-pin low profile quad flat pack (LQFP) and in a 80-pin quad flat pack (QFP). Most pins perform two or more functions, as described in the Signal Descriptions. Figure 1-4 and Figure 1-5 show the pin assignments for different packages. For pins not available in 80 pin QFP please refer to Table 1-4 in section 1.2.2 Signal Properties Summary.

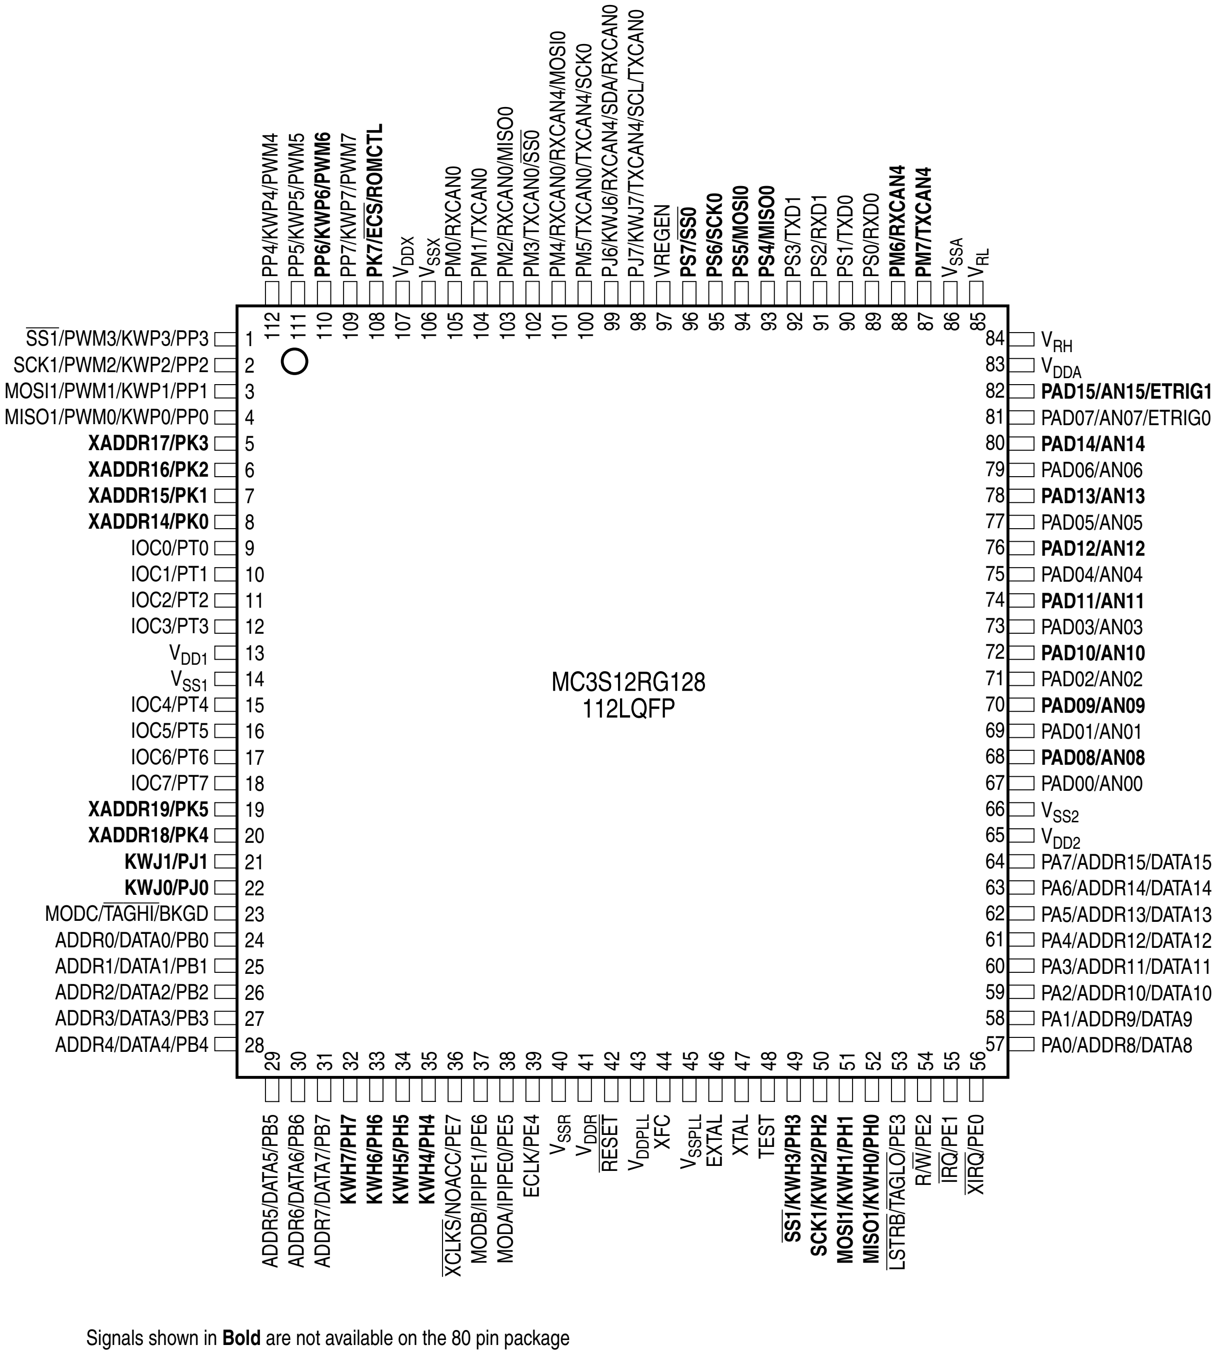

Figure 1-4. Pin assignments in 112 LQFP for MC3S12RG128

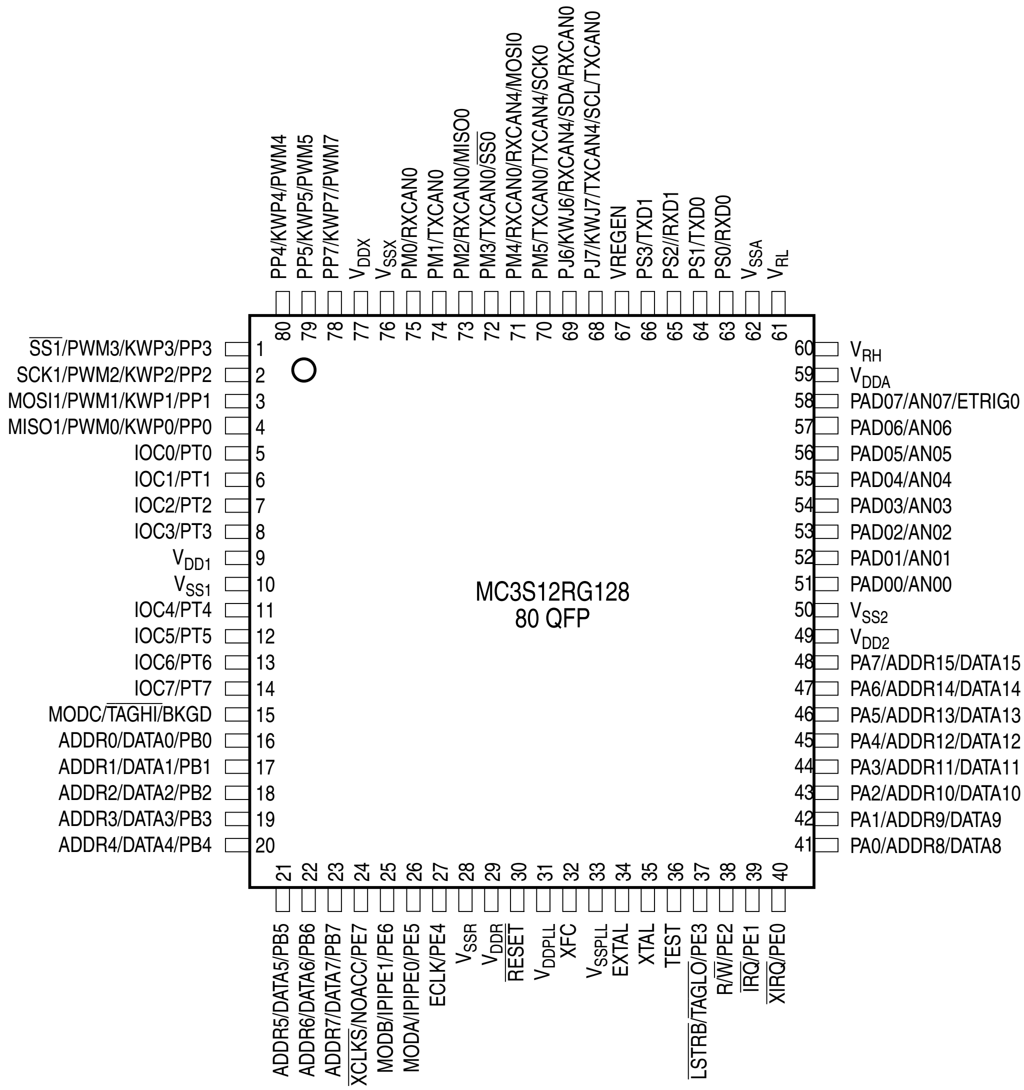

Figure 1-5. Pin assignments in 80 QFP for MC3S12RG128

1.2.2 Signal Properties Summary

Table 1-4 summarizes the pin functionality. Pin names printed in **bold** are not available in the 80 QFP package.

Table 1-4. Signal Properties Summary (Sheet 1 of 3)

Pin Name Function 1	Pin Name Function 2	Pin Name Function 3	Pin Name Function 4	Pin Name Function 5	Power Supply	Internal Pull Resistor		Description
						CTRL	Reset State	
EXTAL	—	—	—	—	V_{DDPLL}	NA	NA	Oscillator Pins
XTAL	—	—	—	—	V_{DDPLL}	NA	NA	
RESET	—	—	—	—	V_{DDR}	None	None	External Reset
TEST	—	—	—	—	V_{DDR}	None	None	Test Input
VREGEN	—	—	—	—	V_{DDX}	NA	NA	Voltage Regulator Enable Input
XFC	—	—	—	—	V_{DDPLL}	NA	NA	PLL Loop Filter
BKGD	TAGHI	MODC	—	—	V_{DDR}	Always Up	Up	Background Debug, Tag High, Mode Input
PAD[15]	**AN1[7]**	**ETRIG1**	**—**	**—**	$\mathbf{V_{DDA}}$	**None**	**None**	**Port AD Input, Analog Inputs, External Trigger Input (ATD1)**
PAD[14:8]	**AN1[6:0]**	**—**	**—**	**—**	$\mathbf{V_{DDA}}$	**None**	**None**	**Port AD Input, Analog Inputs (ATD1)**
PAD[7]	AN0[7]	ETRIG0	—	—	V_{DDA}	None	None	Port AD Input, Analog Inputs, External Trigger Input (ATD0)
PAD[6:0]	AN0[6:0]	—	—	—	V_{DDA}	None	None	Port AD Input, Analog Inputs (ATD0)
PA[7:0]	ADDR[15:8] / DATA[15:8]	—	—	—	V_{DDR}	PUCR/ PUPAE	Disabled	Port A I/O, Multiplexed Address/Data
PB[7:0]	ADDR[7:0]/ DATA[7:0]	—	—	—	V_{DDR}	PUCR/ PUPBE	Disabled	Port B I/O, Multiplexed Address/Data
PE7	NOACC	XCLKS	—	—	V_{DDR}	PUCR/ PUPEE	Mode depen-dant[1]	Port E I/O, Access, Clock Select
PE6	IPIPE1	MODB	—	—	V_{DDR}	While $\overline{RESET}$ pin low: Down		Port E I/O, Pipe Status, Mode Input
PE5	IPIPE0	MODA	—	—	V_{DDR}			Port E I/O, Pipe Status, Mode Input
PE4	ECLK	—	—	—	V_{DDR}	PUCR/ PUPEE	Mode depen-dant[1]	Port E I/O, Bus Clock Output
PE3	LSTRB	TAGLO	—	—	V_{DDR}	PUCR/ PUPEE		Port E I/O, Byte Strobe, Tag Low
PE2	R/$\overline{W}$	—	—	—	V_{DDR}	PUCR/ PUPEE		Port E I/O, R/$\overline{W}$ in expanded modes
PE1	IRQ	—	—	—	V_{DDR}	PUCR/ PUPEE	Up	Port E Input, Maskable Interrupt
PE0	XIRQ	—	—	—	V_{DDR}	PUCR/ PUPEE		Port E Input, Non Maskable Interrupt

Table 1-4. Signal Properties Summary (Sheet 2 of 3)

Pin Name Function 1	Pin Name Function 2	Pin Name Function 3	Pin Name Function 4	Pin Name Function 5	Power Supply	Internal Pull Resistor		Description
						CTRL	Reset State	
PH7	**KWH7**	—	—	—	V_{DDR}	**PERH/ PPSH**	**Disabled**	**Port H I/O, Interrupt**
PH6	**KWH6**	—	—	—	V_{DDR}	**PERH/ PPSH**	**Disabled**	**Port H I/O, Interrupt**
PH5	**KWH5**	—	—	—	V_{DDR}	**PERH/ PPSH**	**Disabled**	**Port H I/O, Interrupt**
PH4	**KWH4**	—	—	—	V_{DDR}	**PERH/ PPSH**	**Disabled**	**Port H I/O, Interrupt**
PH3	**KWH3**	**$\overline{SS}$1**	—	—	V_{DDR}	**PERH/ PPSH**	**Disabled**	**Port H I/O, Interrupt, $\overline{SS}$ of SPI1**
PH2	**KWH2**	**SCK1**	—	—	V_{DDR}	**PERH/ PPSH**	**Disabled**	**Port H I/O, Interrupt, SCK of SPI1**
PH1	**KWH1**	**MOSI1**	—	—	V_{DDR}	**PERH/ PPSH**	**Disabled**	**Port H I/O, Interrupt, MOSI of SPI1**
PH0	**KWH0**	**MISO1**	—	—	V_{DDR}	**PERH/ PPSH**	**Disabled**	**Port H I/O, Interrupt, MISO of SPI1**
PJ7	KWJ7	TXCAN4	SCL	TXCAN0	V_{DDX}	PERJ/ PPSJ	Up	Port J I/O, Interrupt, TX of CAN4, SCL of IIC
PJ6	KWJ6	RXCAN4	SDA	RXCAN0	V_{DDX}	PERJ/ PPSJ	Up	Port J I/O, Interrupt, RX of CAN4, SDA of IIC
PJ[1:0]	**KWJ[1:0]**	—	—	—	V_{DDX}	**PERJ/ PPSJ**	**Up**	**Port J I/O, Interrupts**
PK7	**ECS**	**ROMCTL**	—	—	V_{DDX}	**PUCR/ PUPKE**	**Up**	**Port K I/O, Emulation Chip Select, ROM Control**
PK[5:0]	**XADDR[19:14]**	—	—	—	V_{DDX}	**PUCR/ PUPKE**	**Up**	**Port K I/O, Extended Addresses**
PM7	**TXCAN4**	—	—	—	V_{DDX}	**PERM/ PPSM**	**Disabled**	**Port M I/O, BF slot mismatch pulse, TX of CAN4**
PM6	**RXCAN4**	—	—	—	V_{DDX}	**PERM/ PPSM**	**Disabled**	**Port M I/O, BF illegal pulse/message format error pulse, RX of CAN4**
PM5	TXCAN0	TXCAN4	SCK0	—	V_{DDX}	PERM/ PPSM	Disabled	Port M I/O, TX of CAN0, CAN4, SCK of SPI0
PM4	RXCAN0	RXCAN4	MOSI0	—	V_{DDX}	PERM/ PPSM	Disabled	Port M I/O, RX of CAN0, CAN4, MOSI of SPI0
PM3	TXCAN1	TXCAN0	SS0	—	V_{DDX}	PERM/ PPSM	Disabled	Port M I/O, CAN0, $\overline{SS}$ of SPI0
PM2	RXCAN1	RXCAN0	MISO0	—	V_{DDX}	PERM/ PPSM	Disabled	Port M I/O, CAN0, MISO of SPI0
PM1	TXCAN0	—	—	—	V_{DDX}	PERM/ PPSM	Disabled	Port M I/O, TX of CAN0

Table 1-4. Signal Properties Summary (Sheet 3 of 3)

Pin Name Function 1	Pin Name Function 2	Pin Name Function 3	Pin Name Function 4	Pin Name Function 5	Power Supply	Internal Pull Resistor		Description
						CTRL	Reset State	
PM0	RXCAN0	—	—	—	V_{DDX}	PERM/ PPSM	Disabled	Port M I/O, RX of CAN0
PP7	KWP7	PWM7	—	—	V_{DDX}	PERP/ PPSP	Disabled	Port P I/O, Interrupt, Channel 7 of PWM
PP6	**KWP6**	**PWM6**	**—**	**—**	V_{DDX}	**PERP/ PPSP**	**Disabled**	**Port P I/O, Interrupt, Channel 6 of PWM**
PP5	KWP5	PWM5	—	—	V_{DDX}	PERP/ PPSP	Disabled	Port P I/O, Interrupt, Channel 5 of PWM
PP4	KWP4	PWM4	—	—	V_{DDX}	PERP/ PPSP	Disabled	Port P I/O, Interrupt, Channel 4 of PWM
PP3	KWP3	PWM3	SS1	—	V_{DDX}	PERP/ PPSP	Disabled	Port P I/O, Interrupt, Channel 3 of PWM, $\overline{SS}$ of SPI1
PP2	KWP2	PWM2	SCK1	—	V_{DDX}	PERP/ PPSP	Disabled	Port P I/O, Interrupt, Channel 2 of PWM, SCK of SPI1
PP1	KWP1	PWM1	MOSI1	—	V_{DDX}	PERP/ PPSP	Disabled	Port P I/O, Interrupt, Channel 1 of PWM, MOSI of SPI1
PP0	KWP0	PWM0	MISO1	—	V_{DDX}	PERP/ PPSP	Disabled	Port P I/O, Interrupt, Channel 0 of PWM, MISO of SPI1
PS7	**SS0**	**—**	**—**	**—**	V_{DDX}	**PERS/ PPSS**	**Up**	**Port S I/O, $\overline{SS}$ of SPI0**
PS6	**SCK0**	**—**	**—**	**—**	V_{DDX}	**PERS/ PPSS**	**Up**	**Port S I/O, SCK of SPI0**
PS5	**MOSI0**	**—**	**—**	**—**	V_{DDX}	**PERS/ PPSS**	**Up**	**Port S I/O, MOSI of SPI0**
PS4	**MISO0**	**—**	**—**	**—**	V_{DDX}	**PERS/ PPSS**	**Up**	**Port S I/O, MISO of SPI0**
PS3	TXD1	—	—	—	V_{DDX}	PERS/ PPSS	Up	Port S I/O, TXD of SCI1
PS2	RXD1	—	—	—	V_{DDX}	PERS/ PPSS	Up	Port S I/O, RXD of SCI1
PS1	TXD0	—	—	—	V_{DDX}	PERS/ PPSS	Up	Port S I/O, TXD of SCI0
PS0	RXD0	—	—	—	V_{DDX}	PERS/ PPSS	Up	Port S I/O, RXD of SCI0
PT[7:0]	IOC[7:0]	—	—	—	V_{DDX}	PERT/ PPST	Disabled	Port T I/O, Timer channels

[1] Refer to PEAR register description in HCS12 Multiplexed External Bus Interface (MEBI) Block Guide.

1.2.3 Detailed Signal Descriptions

1.2.3.1 EXTAL, XTAL — Oscillator Pins

EXTAL and XTAL are the crystal driver and external clock pins. On reset all the device clocks are derived from the EXTAL input frequency. XTAL is the crystal output.

1.2.3.2 $\overline{\text{RESET}}$ — External Reset Pin

An active low bidirectional control signal, it acts as an input to initialize the MCU to a known start-up state, and an output when an internal MCU function causes a reset.

1.2.3.3 TEST — Test Pin

This input only pin is reserved for test.

NOTE

The TEST pin must be tied to VSS in all applications.

1.2.3.4 XFC — PLL Loop Filter Pin

PLL loop filter. Please ask your Freescale representative for the interactive application note to compute PLL loop filter elements. Any current leakage on this pin must be avoided.

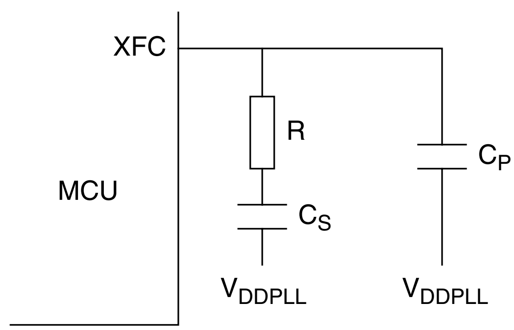

Figure 1-6. PLL Loop Filter Connections

1.2.3.5 BKGD / $\overline{\text{TAGHI}}$ / MODC — Background Debug, Tag High, and Mode Pin

The BKGD/$\overline{\text{TAGHI}}$/MODC pin is used as a pseudo-open-drain pin for the background debug communication. In MCU expanded modes of operation when instruction tagging is on, an input low on this pin during the falling edge of E-clock tags the high half of the instruction word being read into the instruction queue. It is used as an MCU operating mode select pin during reset. The state of this pin is latched to the MODC bit at the rising edge of $\overline{\text{RESET}}$. This pin has a permanently enabled pull-up device.

1.2.3.6 PAD[15] / AN1[7] / ETRIG1 — Port AD Input Pin [15]

PAD15 is a general purpose input pin and analog input of the analog to digital converter ATD1. It can act as an external trigger input for the ATD1.

1.2.3.7 PAD[14:8] / AN1[6:0] — Port AD Input Pins [14:8]

PAD14 - PAD8 are general purpose input pins and analog inputs of the analog to digital converter ATD1.

1.2.3.8 PAD[7] / AN0[7] / ETRIG0 — Port AD Input Pin [7]

PAD7 is a general purpose input pin and analog input of the analog to digital converter ATD0. It can act as an external trigger input for the ATD0.

1.2.3.9 PAD[6:0] / AN0[6:0] — Port AD Input Pins [6:0]

PAD6 - PAD8 are general purpose input pins and analog inputs of the analog to digital converter ATD0.

1.2.3.10 PA[7:0] / ADDR[15:8] / DATA[15:8] — Port A I/O Pins

PA7-PA0 are general purpose input or output pins. In MCU expanded modes of operation, these pins are used for the multiplexed external address and data bus.

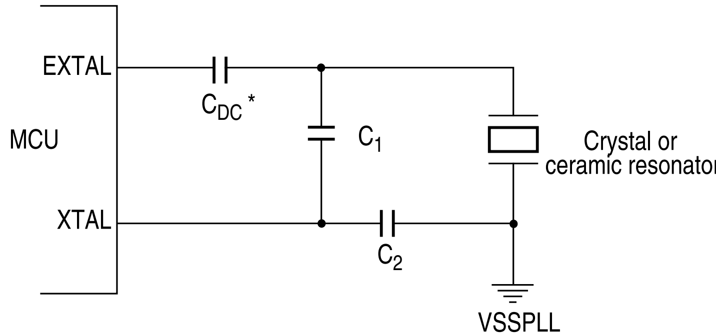
1.2.3.11 PB[7:0] / ADDR[7:0] / DATA[7:0] — Port B I/O Pins

PB7-PB0 are general purpose input or output pins. In MCU expanded modes of operation, these pins are used for the multiplexed external address and data bus.

1.2.3.12 PE7 / NOACC / $\overline{\text{XCLKS}}$ — Port E I/O Pin 7

PE7 is a general purpose input or output pin. During MCU expanded modes of operation, the NOACC signal, when enabled, is used to indicate that the current bus cycle is an unused or “free” cycle. This signal will assert when the CPU is not using the bus.

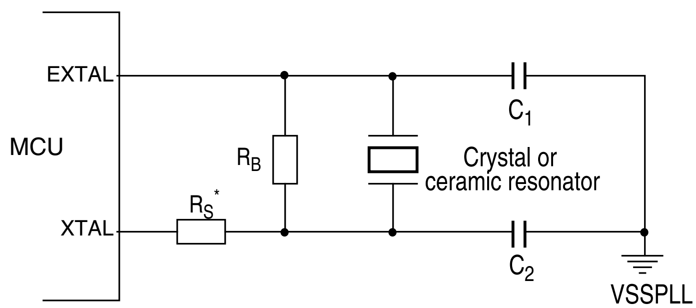
The $\overline{\text{XCLKS}}$ is an input signal which controls whether a crystal in combination with the internal Colpitts (low power) oscillator is used or whether Pierce oscillator/external clock circuitry is used. The state of this pin is latched at the rising edge of $\overline{\text{RESET}}$. If the input is a logic low the EXTAL pin is configured for an external clock drive. If input is a logic high an oscillator circuit is configured on EXTAL and XTAL. Since this pin is an input with a pull-up device during reset, if the pin is left floating, the default configuration is an oscillator circuit on EXTAL and XTAL.



* Due to the nature of a translated ground Colpitts oscillator a DC voltage bias is applied to the crystal

Please contact the crystal manufacturer for crystal DC bias conditions and recommended capacitor value C_{DC}.

Figure 1-7. Colpitts Oscillator Connections (PE7=1)



* Rs can be zero (shorted) when used with higher frequency crystals. Refer to manufacturer's data.

Figure 1-8. Pierce Oscillator Connections (PE7=0)

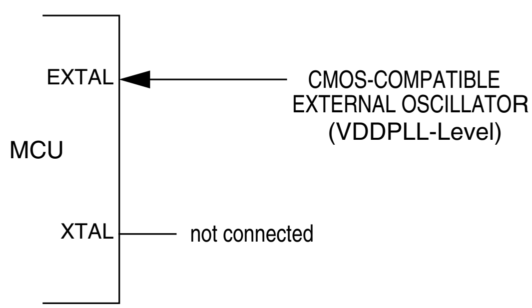


Figure 1-9. External Clock Connections (PE7=0)

1.2.3.13 PE6 / MODB / IPIPE1 — Port E I/O Pin 6

PE6 is a general purpose input or output pin. It is used as an MCU operating mode select pin during reset. The state of this pin is latched to the MODB bit at the rising edge of $\overline{\text{RESET}}$. This pin is shared with the instruction queue tracking signal IPIPE1. This pin is an input with a pull-down device which is only active when $\overline{\text{RESET}}$ is low.

1.2.3.14 PE5 / MODA / IPIPE0 — Port E I/O Pin 5

PE5 is a general purpose input or output pin. It is used as an MCU operating mode select pin during reset. The state of this pin is latched to the MODA bit at the rising edge of $\overline{\text{RESET}}$. This pin is shared with the instruction queue tracking signal IPIPE0. This pin is an input with a pull-down device which is only active when $\overline{\text{RESET}}$ is low.

1.2.3.15 PE4 / ECLK — Port E I/O Pin 4

PE4 is a general purpose input or output pin. It can be configured to drive the internal bus clock ECLK. ECLK can be used as a timing reference.

1.2.3.16 PE3 / $\overline{\text{LSTRB}}$ / $\overline{\text{TAGLO}}$ — Port E I/O Pin 3

PE3 is a general purpose input or output pin. In MCU expanded modes of operation, $\overline{\text{LSTRB}}$ can be used for the low-byte strobe function to indicate the type of bus access and when instruction tagging is on, $\overline{\text{TAGLO}}$ is used to tag the low half of the instruction word being read into the instruction queue.

1.2.3.17 PE2 / R/$\overline{\text{W}}$ — Port E I/O Pin 2

PE2 is a general purpose input or output pin. In MCU expanded modes of operations, this pin drives the read/write output signal for the external bus. It indicates the direction of data on the external bus.

1.2.3.18 PE1 / $\overline{\text{IRQ}}$ — Port E Input Pin 1

PE1 is a general purpose input pin and the maskable interrupt request input that provides a means of applying asynchronous interrupt requests. This will wake up the MCU from STOP or WAIT mode.

1.2.3.19 PE0 / $\overline{\text{XIRQ}}$ — Port E Input Pin 0

PE0 is a general purpose input pin and the non-maskable interrupt request input that provides a means of applying asynchronous interrupt requests. This will wake up the MCU from STOP or WAIT mode.

1.2.3.20 PH7 / KWH7 — Port H I/O Pin 7

PH7 is a general purpose input or output pin. It can be configured to generate an interrupt causing the MCU to exit STOP or WAIT mode.

1.2.3.21 PH6 / KWH6 — Port H I/O Pin 6

PH6 is a general purpose input or output pin. It can be configured to generate an interrupt causing the MCU to exit STOP or WAIT mode.

1.2.3.22 PH5 / KWH5 — Port H I/O Pin 5

PH5 is a general purpose input or output pin. It can be configured to generate an interrupt causing the MCU to exit STOP or WAIT mode.

1.2.3.23 PH4 / KWH4 — Port H I/O Pin 2

PH4 is a general purpose input or output pin. It can be configured to generate an interrupt causing the MCU to exit STOP or WAIT mode.

1.2.3.24 PH3 / KWH3 / $\overline{\text{SS1}}$ — Port H I/O Pin 3

PH3 is a general purpose input or output pin. It can be configured to generate an interrupt causing the MCU to exit STOP or WAIT mode. It can be configured as slave select pin $\overline{\text{SS}}$ of the Serial Peripheral Interface 1 (SPI1).

1.2.3.25 PH2 / KWH2 / SCK1 — Port H I/O Pin 2

PH2 is a general purpose input or output pin. It can be configured to generate an interrupt causing the MCU to exit STOP or WAIT mode. It can be configured as serial clock pin SCK of the Serial Peripheral Interface 1 (SPI1).

1.2.3.26 PH1 / KWH1 / MOSI1 — Port H I/O Pin 1

PH1 is a general purpose input or output pin. It can be configured to generate an interrupt causing the MCU to exit STOP or WAIT mode. It can be configured as master output (during master mode) or slave input pin (during slave mode) MOSI of the Serial Peripheral Interface 1 (SPI1).

1.2.3.27 PH0 / KWH0 / MISO1 — Port H I/O Pin 0

PH0 is a general purpose input or output pin. It can be configured to generate an interrupt causing the MCU to exit STOP or WAIT mode. It can be configured as master input (during master mode) or slave output (during slave mode) pin MISO of the Serial Peripheral Interface 1 (SPI1).

1.2.3.28 PJ7 / KWJ7 / TXCAN4 / SCL / TXCAN0 — PORT J I/O Pin 7

PJ7 is a general purpose input or output pin. It can be configured to generate an interrupt causing the MCU to exit STOP or WAIT mode. It can be configured as the transmit pin TXCAN for the Motorola Scalable Controller Area Network controller 0 or 4 (CAN0, CAN4) or the serial clock pin SCL of the IIC module.

1.2.3.29 PJ6 / KWJ6 / RXCAN4 / SDA / RXCAN0 — PORT J I/O Pin 6

PJ6 is a general purpose input or output pin. It can be configured to generate an interrupt causing the MCU to exit STOP or WAIT mode. It can be configured as the receive pin RXCAN for the Motorola Scalable Controller Area Network controller 0 or 4 (CAN0, CAN4) or the serial data pin SDA of the IIC module.

1.2.3.30 PJ[1:0] / KWJ[1:0] — Port J I/O Pins [1:0]

PJ1 and PJ0 are general purpose input or output pins. They can be configured to generate an interrupt causing the MCU to exit STOP or WAIT mode.

1.2.3.31 PK7 / $\overline{\text{ECS}}$ / ROMCTL — Port K I/O Pin 7

PK7 is a general purpose input or output pin. During MCU expanded modes of operation, this pin is used as the emulation chip select output ($\overline{\text{ECS}}$). While configurating MCU expanded modes, this pin is used to enable the ROM memory in the memory map (ROMCTL). At the rising edge of $\overline{\text{RESET}}$, the state of this pin is latched to the ROMON bit. For a complete list of modes refer to 1.4 Chip Configuration Summary.

1.2.3.32 PK[5:0] / XADDR[19:14] — Port K I/O Pins [5:0]

PK5-PK0 are general purpose input or output pins. In MCU expanded modes of operation, these pins provide the expanded address XADDR[19:14] for the external bus.

1.2.3.33 PM7 / TXCAN4 — Port M I/O Pin 7

PM7 is a general purpose input or output pin. It can be configured as the transmit pin TXCAN of the Motorola Scalable Controller Area Network controllers 4 (CAN4).

1.2.3.34 PM6 / RXCAN4 — Port M I/O Pin 6

PM6 is a general purpose input or output pin. It can be configured as the receive pin RXCAN of the Motorola Scalable Controller Area Network controllers 4 (CAN4).

1.2.3.35 PM5 / TXCAN0 / TXCAN4 / SCK0 — Port M I/O Pin 5

PM5 is a general purpose input or output pin. It can be configured as the transmit pin TXCAN of the Motorola Scalable Controller Area Network controllers 0 or 4 (CAN0 or CAN4). It can be configured as the serial clock pin SCK of the Serial Peripheral Interface 0 (SPI0).

1.2.3.36 PM4 / RXCAN0 / RXCAN4/ MOSI0 — Port M I/O Pin 4

PM4 is a general purpose input or output pin. It can be configured as the receive pin RXCAN of the Motorola Scalable Controller Area Network controllers 0 or 4 (CAN0 or CAN4). It can be configured as the master output (during master mode) or slave input pin (during slave mode) MOSI for the Serial Peripheral Interface 0 (SPI0).

1.2.3.37 PM3 / TXCAN0 / $\overline{\text{SS0}}$ — Port M I/O Pin 3

PM3 is a general purpose input or output pin. It can be configured as the transmit pin TXCAN of the Motorola Scalable Controller Area Network controller 0 (CAN0). It can be configured as the slave select pin $\overline{\text{SS}}$ of the Serial Peripheral Interface 0 (SPI0).

1.2.3.38 PM2 / RXCAN0 / MISO0 — Port M I/O Pin 2

PM2 is a general purpose input or output pin. It can be configured as the receive pin RXCAN of the Motorola Scalable Controller Area Network controller 0 (CAN0). It can be configured as the master input (during master mode) or slave output pin (during slave mode) MISO for the Serial Peripheral Interface 0 (SPI0).

1.2.3.39 PM1 / TXCAN0 — Port M I/O Pin 1

PM1 is a general purpose input or output pin. It can be configured as the transmit pin TXCAN of the Motorola Scalable Controller Area Network controller 0 (CAN0).

1.2.3.40 PM0 / RXCAN0 — Port M I/O Pin 0

PM0 is a general purpose input or output pin. It can be configured as the receive pin RXCAN of the Motorola Scalable Controller Area Network controller 0 (CAN0).

1.2.3.41 PP7 / KWP7 / PWM7 — Port P I/O Pin 7

PP7 is a general purpose input or output pin. It can be configured to generate an interrupt causing the MCU to exit STOP or WAIT mode. It can be configured as Pulse Width Modulator (PWM) channel 7 output.

1.2.3.42 PP6 / KWP6 / PWM6 — Port P I/O Pin 6

PP6 is a general purpose input or output pin. It can be configured to generate an interrupt causing the MCU to exit STOP or WAIT mode. It can be configured as Pulse Width Modulator (PWM) channel 6 output.

1.2.3.43 PP5 / KWP5 / PWM5 — Port P I/O Pin 5

PP5 is a general purpose input or output pin. It can be configured to generate an interrupt causing the MCU to exit STOP or WAIT mode. It can be configured as Pulse Width Modulator (PWM) channel 5 output.

1.2.3.44 PP4 / KWP4 / PWM4 — Port P I/O Pin 4

PP4 is a general purpose input or output pin. It can be configured to generate an interrupt causing the MCU to exit STOP or WAIT mode. It can be configured as Pulse Width Modulator (PWM) channel 4 output.

1.2.3.45 PP3 / KWP3 / PWM3 / $\overline{\text{SS1}}$ — Port P I/O Pin 3

PP3 is a general purpose input or output pin. It can be configured to generate an interrupt causing the MCU to exit STOP or WAIT mode. It can be configured as Pulse Width Modulator (PWM) channel 3 output. It can be configured as slave select pin $\overline{\text{SS}}$ of the Serial Peripheral Interface 1 (SPI1).

1.2.3.46 PP2 / KWP2 / PWM2 / SCK1 — Port P I/O Pin 2

PP2 is a general purpose input or output pin. It can be configured to generate an interrupt causing the MCU to exit STOP or WAIT mode. It can be configured as Pulse Width Modulator (PWM) channel 2 output. It can be configured as serial clock pin SCK of the Serial Peripheral Interface 1 (SPI1).

1.2.3.47 PP1 / KWP1 / PWM1 / MOSI1 — Port P I/O Pin 1

PP1 is a general purpose input or output pin. It can be configured to generate an interrupt causing the MCU to exit STOP or WAIT mode. It can be configured as Pulse Width Modulator (PWM) channel 1 output. It can be configured as master output (during master mode) or slave input pin (during slave mode) MOSI of the Serial Peripheral Interface 1 (SPI1).

1.2.3.48 PP0 / KWP0 / PWM0 / MISO1 — Port P I/O Pin 0

PP0 is a general purpose input or output pin. It can be configured to generate an interrupt causing the MCU to exit STOP or WAIT mode. It can be configured as Pulse Width Modulator (PWM) channel 0 output. It can be configured as master input (during master mode) or slave output (during slave mode) pin MISO of the Serial Peripheral Interface 1 (SPI1).

1.2.3.49 PS7 / $\overline{\text{SS0}}$ — Port S I/O Pin 7

PS7 is a general purpose input or output pin. It can be configured as the slave select pin $\overline{\text{SS}}$ of the Serial Peripheral Interface 0 (SPI0).

1.2.3.50 PS6 / SCK0 — Port S I/O Pin 6

PS6 is a general purpose input or output pin. It can be configured as the serial clock pin SCK of the Serial Peripheral Interface 0 (SPI0).

1.2.3.51 PS5 / MOSI0 — Port S I/O Pin 5

PS5 is a general purpose input or output pin. It can be configured as master output (during master mode) or slave input pin (during slave mode) MOSI of the Serial Peripheral Interface 0 (SPI0).

1.2.3.52 PS4 / MISO0 — Port S I/O Pin 4

PS4 is a general purpose input or output pin. It can be configured as master input (during master mode) or slave output pin (during slave mode) MOSI of the Serial Peripheral Interface 0 (SPI0).

1.2.3.53 PS3 / TXD1 — Port S I/O Pin 3

PS3 is a general purpose input or output pin. It can be configured as the transmit pin TXD of Serial Communication Interface 1 (SCI1).

1.2.3.54 PS2 / RXD1 — Port S I/O Pin 2

PS2 is a general purpose input or output pin. It can be configured as the receive pin RXD of Serial Communication Interface 1 (SCI1).

1.2.3.55 PS1 / TXD0 — Port S I/O Pin 1

PS1 is a general purpose input or output pin. It can be configured as the transmit pin TXD of Serial Communication Interface 0 (SCI0).

1.2.3.56 PS0 / RXD0 — Port S I/O Pin 0

PS0 is a general purpose input or output pin. It can be configured as the receive pin RXD of Serial Communication Interface 0 (SCI0).

1.2.3.57 PT[7:0] / IOC[7:0] — Port T I/O Pins [7:0]

PT7-PT0 are general purpose input or output pins. They can be configured as input capture or output compare pins IOC7-IOC0 of the Enhanced Capture Timer (ECT).

1.2.4 Power Supply Pins

MC3S12RG128 power and ground pins are described below.

Table 1-5. MC3S12RG128 Power and Ground Connection Summary

Mnemonic	Pin Number	Nominal Voltage	Description
	112-pin QFP		
$V_{DD1,2}$	13, 65	2.5V	Internal power and ground generated by internal regulator
$V_{SS1,2}$	14, 66	0V	
V_{DDR}	41	5.0V	External power and ground, supply to pin drivers and internal voltage regulator.
V_{SSR}	40	0V	
V_{DDX}	107	5.0V	External power and ground, supply to pin drivers.
V_{SSX}	106	0V	
V_{DDA}	83	5.0V	Operating voltage and ground for the analog-to-digital converters and the reference for the internal voltage regulator, allows the supply voltage to the A/D to be bypassed independently.
V_{SSA}	86	0V	
V_{RL}	85	0V	Reference voltages for the analog-to-digital converter.
V_{RH}	84	5.0V	
V_{DDPLL}	43	2.5V	Provides operating voltage and ground for the Phased-Locked Loop. This allows the supply voltage to the PLL to be bypassed independently. Internal power and ground generated by internal regulator.
V_{SSPLL}	45	0V	
VREGEN	97	5V	Internal Voltage Regulator enable/disable

NOTE

All VSS pins must be connected together in the application.

1.2.4.1 V_{DDX},V_{SSX} — Power & Ground Pins for I/O Drivers

External power and ground for I/O drivers. Because fast signal transitions place high, short-duration current demands on the power supply, use bypass capacitors with high-frequency characteristics and place them as close to the MCU as possible. Bypass requirements depend on how heavily the MCU pins are loaded.

1.2.4.2 V_{DDR}, V_{SSR} — Power & Ground Pins for I/O Drivers & for Internal Voltage Regulator

External power and ground for I/O drivers and input to the internal voltage regulator. Because fast signal transitions place high, short-duration current demands on the power supply, use bypass capacitors with high-frequency characteristics and place them as close to the MCU as possible. Bypass requirements depend on how heavily the MCU pins are loaded.

1.2.4.3 V_{DD1}, V_{DD2}, V_{SS1}, V_{SS2} — Internal Logic Power Supply Pins

Power is supplied to the MCU by the internal voltage regulator (if enabled) through V_{DD1}/V_{DD2} and V_{SS1}/V_{SS2}. Because fast signal transitions place high, short-duration current demands on the power supply, use bypass capacitors with high-frequency characteristics and place them as close to the MCU as possible. This 2.5V supply is derived from the internal voltage regulator. There is no static load on those pins allowed. The internal voltage regulator is turned off, if VREGEN is tied to ground.

NOTE

No load allowed except for bypass capacitors.

1.2.4.4 V_{DDA}, V_{SSA} — Power Supply Pins for ATD and VREG

V_{DDA}, V_{SSA} are the power supply and ground input pins for the voltage regulator and the analog to digital converter. It also provides the reference for the internal voltage regulator. This allows the supply voltage to the ATD and the reference voltage to be bypassed independently.

1.2.4.5 V_{RH}, V_{RL} — ATD Reference Voltage Input Pins

V_{RH} and V_{RL} are the reference voltage input pins for the analog to digital converter.

1.2.4.6 V_{DDPLL}, V_{SSPLL} — Power Supply Pins for PLL

Provides operating voltage and ground for the Oscillator and the Phased-Locked Loop. This allows the supply voltage to the Oscillator and PLL to be bypassed independently.This 2.5V voltage is generated by the internal voltage regulator.

NOTE

No load allowed except for bypass capacitors and/or XFC filter components (please refer A.6.3.1 XFC Component Selection for details).

1.2.4.7 VREGEN — On Chip Voltage Regulator Enable

Enables the internal 5V to 2.5V voltage regulator. If this pin is tied low, $V_{DD1,2}$ and V_{DDPLL} must be supplied externally.

1.3 System Clock Description

The Clock and Reset Generator provides the internal clock signals for the core and all peripheral modules. Figure 1-10 shows the clock connections from the CRG to all modules.

Consult the CRG Block User Guide for details on clock generation.

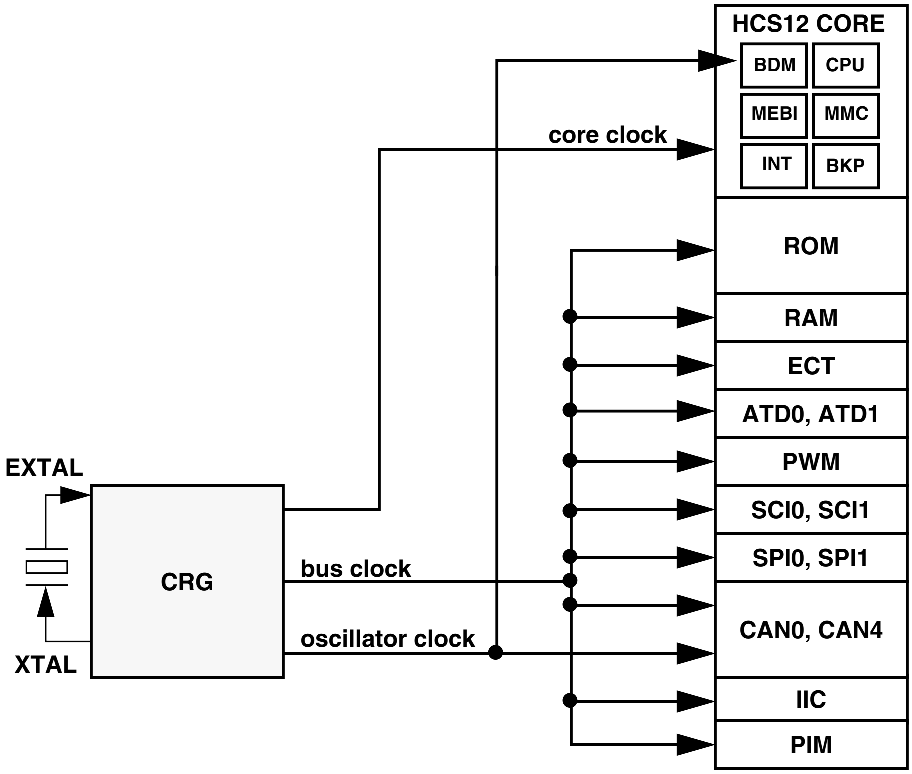

Figure 1-10. Clock Connections

1.4 Chip Configuration Summary

Eight possible modes determine the operating configuration of the MC3S12RG128. Each mode has an associated default memory map and external bus configuration controlled by a further pin.

Three low power modes exist for the device.

The operating mode out of reset is determined by the states of the MODC, MODB, and MODA pins during reset (Table 1-6). The MODC, MODB, and MODA bits in the MODE register show the current operating mode and provide limited mode switching during operation. The states of the MODC, MODB, and MODA pins are latched into these bits on the rising edge of the reset signal. The ROMCTL signal allows the setting of the ROMON bit in the MISC register thus controlling whether the internal ROM is visible in the memory map. ROMON = 1 mean the ROM is visible in the memory map. The state of the ROMCTL pin is latched into the ROMON bit in the MISC register on the rising edge of the reset signal.

Table 1-6. Mode Selection

BKGD = MODC	PE6 = MODB	PE5 = MODA	PK7 = ROMCTL[1]	ROMON Bit	Mode Description
0	0	0	X	1	Special Single Chip, BDM allowed and ACTIVE. BDM is allowed in all other modes but a serial command is required to make BDM active.
0	0	1	0	1	Emulation Expanded Narrow, BDM allowed
			1	0	
0	1	0	X	0	Special Test (Expanded Wide), BDM allowed
0	1	1	0	1	Emulation Expanded Wide, BDM allowed
			1	0	
1	0	0	X	1	Normal Single Chip, BDM allowed
1	0	1	0	0	Normal Expanded Narrow, BDM allowed
			1	1	
1	1	0	X	1	Special Peripheral; BDM allowed but bus operations would cause bus conflicts (must not be used)
1	1	1	0	0	Normal Expanded Wide, BDM allowed
			1	1	

[1] This pin is not available in the 80 pin package. It is pulled to ‘1’ by an internal pull-up resistor.

For further explanation on the modes refer to the HCS12 Multiplexed External Bus Interface Block Guide.

Table 1-7. Clock Selection Based on PE7

PE7 = $\overline{XCLKS}$	Description
1	Colpitts Oscillator selected
0	Pierce Oscillator/external clock selected

Table 1-8. Voltage Regulator VREGEN

VREGEN	Description
1	Internal Voltage Regulator enabled
0	Internal Voltage Regulator disabled, $V_{DD1,2}$ and V_{DDPLL} must be supplied externally with 2.5V

1.4.1 Security

The device will make available a security feature preventing the unauthorized read and write of the memory contents. This feature allows:

- Protection of the contents of ROM,
- Operation in single-chip mode, No BDM possible

The user must be reminded that part of the security must lie with the user’s code. An extreme example would be user’s code that dumps the contents of the internal program. This code would defeat the purpose of security. At the same time the user may also wish to put a back door in the user’s program.

1.4.1.1 Securing the Microcontroller

The status of security of the part is determined by the security bits located in the ROM module. These non-volatile bits will keep the part secured through resetting the part and through powering down the part.

The security byte resides in a portion of the ROM array.

Check the ROM Block User Guide for more details on the security configuration.

1.4.1.2 Operation of the Secured Microcontroller

1.4.1.2.1 Normal Single Chip Mode

This will be the most common usage of the secured part. Everything will appear the same as if the part was not secured with the exception of BDM operation. The BDM operation will be blocked.

1.4.1.2.2 Executing from External Memory

Disabling the internal ROM will unsecure the microcontroller and will also unblock the BDM. As a consequence, executing from external space with a secured microcontroller is not possible. Please note that in the 80 pin package the ROMCTL pin is not accessable externally but is pulled to ‘1’ internally by a pull-up resistor.

1.4.1.3 Unsecuring the Microcontroller

In order to unsecure the microcontroller, the internal ROM must be disabled. This can be done by selecting expanded mode or by starting in special single chip mode. Unsecuring is also possible via the Backdoor Key Access. Refer to ROM Block Guide for details.

If a secure part is reset to special single chip mode, BDM firmware will disable the ROM by clearing the ROMON bit (Bit0 in the MISC register). The BDM software commands are unblocked and the part can be used in unsecure mode. In this state (secured ROM disabled, part unsecured) setting the ROMON bit again has no effect on the memory map, i.e. ROM remains disabled until next reset.

1.5 Modes of Operation

1.5.1 User Modes

1.5.1.1 Normal Expanded Wide Mode

Ports A, B and K are configured as a 23-bit address bus during the address phase, port A and B are configured as 16-bit data bus during the data-phase, and port E provides bus control and status signals. This mode allows 16-bit external memory and peripheral devices to be interfaced to the system.

1.5.1.2 Normal Expanded Narrow Mode

Ports A, B and K are configured as a 23-bit address bus during the address phase, port B is configured as a 8-bit data bus during the data phase, and port E provides bus control and status signals. This mode allows 8-bit external memory and peripheral devices to be interfaced to the system.

1.5.1.3 Normal Single-Chip Mode

There is no external bus in this mode. The processor program is executed from internal memory. Ports A, B, K, and most pins of port E are available as general-purpose I/O.

1.5.1.4 Special Single-Chip Mode

This mode is used for debugging single-chip operation, boot-strapping, or security related operations. The background debug module BDM is active in this mode. The CPU executes a monitor program located in an on-chip ROM. BDM firmware is waiting for additional serial commands through the BKGD pin. There is no external bus after reset in this mode.

1.5.1.5 Emulation of Expanded Wide Mode

Developers use this mode for emulation systems in which the users target application is normal expanded wide mode. Code is executed from external memory or from internal memory depending on the state of ROMON bit. In this mode the internal operation is visible on external bus interface.

1.5.1.6 Emulation of Expanded Narrow Mode

Developers use this mode for emulation systems in which the users target application is normal expanded narrow mode. Code is executed from external memory or from internal memory depending on the state of ROMON bit. In this mode the internal operation is visible on external bus interface.

1.5.1.7 Special Test Mode

Freescale internal use only.

1.5.1.8 Special Peripheral Mode

Freescale internal use only.

1.5.2 Low Power Modes

The microcontroller features three main low power modes. Consult the respective Block User Guide for information on the module behavior in Stop, Pseudo Stop, and Wait Mode. An important source of information about the clock system is the Clock and Reset Generator User Guide (CRG).

1.5.2.1 Stop

Executing the CPU STOP instruction stops all clocks and the oscillator thus putting the chip in fully static mode. Wake up from this mode can be done via reset or external interrupts.

1.5.2.2 Pseudo Stop

This mode is entered by executing the CPU STOP instruction. In this mode the oscillator is still running and the Real Time Interrupt (RTI) or Watchdog (COP) sub module can stay active. Other peripherals are turned off. This mode consumes more current than the full STOP mode, but the wake up time from this mode is significantly shorter.

1.5.2.3 Wait

This mode is entered by executing the CPU WAI instruction. In this mode the CPU will not execute instructions. The internal CPU signals (address and databus) will be fully static. All peripherals stay active. To further reduce the power consumption the peripherals can turn off their local clocks individually.

1.5.2.4 Run

Although this is not a low power mode, unused peripheral modules should not be enabled in order to save power.

1.6 Resets and Interrupts

Consult the Exception Processing section of the S12 CPU Reference Manual for information on resets and interrupts.

1.6.1 Vectors

Table 1-9 lists interrupt sources and vectors in default order of priority.

Table 1-9. Interrupt Vector Locations

Vector Address	Interrupt Source	CCR Mask	Local Enable	HPRIO Value to Elevate
0xFFFE, 0xFFFF	Reset	None	None	–
0xFFFC, 0xFFFD	Clock Monitor fail reset	None	COPCTL (CME, FCME)	–
0xFFFA, 0xFFFB	COP failure reset	None	COP rate select	–
0xFFF8, 0xFFF9	Unimplemented instruction trap	None	None	–
0xFFF6, 0xFFF7	SWI	None	None	–
0xFFF4, 0xFFF5	XIRQ	X-Bit	None	–
0xFFF2, 0xFFF3	IRQ	I-Bit	INTCR (IRQEN)	0xF2
0xFFF0, 0xFFF1	Real Time Interrupt	I-Bit	CRGINT (RTIE)	0xF0
0xFFEE, 0xFFEF	Enhanced Capture Timer channel 0	I-Bit	TIE (C0I)	0xEE
0xFFEC, 0xFFED	Enhanced Capture Timer channel 1	I-Bit	TIE (C1I)	0xEC
0xFFEA, 0xFFEB	Enhanced Capture Timer channel 2	I-Bit	TIE (C2I)	0xEA
0xFFE8, 0xFFE9	Enhanced Capture Timer channel 3	I-Bit	TIE (C3I)	0xE8
0xFFE6, 0xFFE7	Enhanced Capture Timer channel 4	I-Bit	TIE (C4I)	0xE6
0xFFE4, 0xFFE5	Enhanced Capture Timer channel 5	I-Bit	TIE (C5I)	0xE4
0xFFE2, 0xFFE3	Enhanced Capture Timer channel 6	I-Bit	TIE (C6I)	0xE2
0xFFE0, 0xFFE1	Enhanced Capture Timer channel 7	I-Bit	TIE (C7I)	0xE0
0xFFDE, 0xFFDF	Enhanced Capture Timer overflow	I-Bit	TSCR2 (TOF)	0xDE

0xFFDC, 0xFFDD	Pulse accumulator A overflow	I-Bit	PACTL (PAOVI)	0xDC
0xFFDA, 0xFFDB	Pulse accumulator input edge	I-Bit	PACTL (PAI)	0xDA
0xFFD8, 0xFFD9	SPI0	I-Bit	SPICR1 (SPIE, SPTIE)	0xD8
0xFFD6, 0xFFD7	SCI0	I-Bit	SCICR2 (TIE, TCIE, RIE, ILIE)	0xD6
0xFFD4, 0xFFD5	SCI1	I-Bit	SCICR2 (TIE, TCIE, RIE, ILIE)	0xD4
0xFFD2, 0xFFD3	ATD0	I-Bit	ATDCTL2 (ASCIE)	0xD2
0xFFD0, 0xFFD1	ATD1	I-Bit	ATDCTL2 (ASCIE)	0xD0
0xFFCE, 0xFFCF	Port J	I-Bit	PIEJ (PIEJ7, PIEJ6, PIEJ1, PIEJ0)	0xCE
0xFFCC, 0xFFCD	Port H	I-Bit	PIEH (PIEH7-0)	0xCC
0xFFCA, 0xFFCB	Modulus Down Counter underflow	I-Bit	MCCTL (MCZI)	0xCA
0xFFC8, 0xFFC9	Pulse Accumulator B Overflow	I-Bit	PBCTL (PBOVI)	0xC8
0xFFC6, 0xFFC7	CRG PLL lock	I-Bit	PLLCR (LOCKIE)	0xC6
0xFFC4, 0xFFC5	CRG Self Clock Mode	I-Bit	PLLCR (SCMIE)	0xC4
0xFFC2, 0xFFC3	Reserved			
0xFFC0, 0xFFC1	IIC Bus	I-Bit	IBCR (IBIE)	0xC0
0xFFBE, 0xFFBF	SPI1	I-Bit	SPICR1 (SPIE, SPTIE)	0xBE
0xFFBC, 0xFFBD	Reserved			
0xFFBA, 0xFFBB	Reserved			
0xFFB8, 0xFFB9	Reserved			
0xFFB6, 0xFFB7	CAN0 wake-up	I-Bit	CANRIER (WUPIE)	0xB6
0xFFB4, 0xFFB5	CAN0 errors	I-Bit	CANRIER (CSCIE, OVRIE)	0xB4
0xFFB2, 0xFFB3	CAN0 receive	I-Bit	CANRIER (RXFIE)	0xB2
0xFFB0, 0xFFB1	CAN0 transmit	I-Bit	CANTIER (TXEIE[2:0])	0xB0
0xFFAE, 0xFFAF	Reserved			
0xFFAC, 0xFFAD	Reserved			
0xFFAA, 0xFFAB	Reserved			
0xFFA8, 0xFFA9	Reserved			
0xFFA6, 0xFFA7	Reserved			
0xFFA4, 0xFFA5	Reserved			
0xFFA2, 0xFFA3	Reserved			
0xFFA0, 0xFFA1	Reserved			
0xFF98, 0xFF9F	Reserved			
0xFF96, 0xFF97	CAN4 wake-up	I-Bit	CANRIER (WUPIE)	0x96
0xFF94, 0xFF95	CAN4 errors	I-Bit	CANRIER (CSCIE, OVRIE)	0x94
0xFF92, 0xFF93	CAN4 receive	I-Bit	CANRIER (RXFIE)	0x92
0xFF90, 0xFF91	CAN4 transmit	I-Bit	CANTIER (TXEIE[2:0])	0x90
0xFF8E, 0xFF8F	Port P Interrupt	I-Bit	PIEP (PIEP7-0)	0x8E
0xFF8C, 0xFF8D	PWM Emergency Shutdown	I-Bit	PWMSDN (PWMIE)	0x8C
0xFF8A, 0xFF8B	VREG Low Voltage Interrupt	I-Bit	VREGCTRL (LVIE)	0x8A
0xFF80 to 0xFF89	Reserved			

1.6.2 Effects of Reset

When a reset occurs, MCU registers and control bits are changed to known start-up states. Refer to the respective module Block User Guides for register reset states.

1.6.2.1 I/O pins

Refer to the HCS12 Multiplexed External Bus Interface (MEBI) Block Guide for mode dependent pin configuration of port A, B, E and K out of reset.

Refer to the PIM Block User Guide for reset configurations of all peripheral module ports.

NOTE

For devices assembled in 80-pin QFP packages all non-bonded out pins should be configured as outputs after reset in order to avoid current drawn from floating inputs. Refer to Table 1-4 for affected pins.

1.6.2.2 Memory

Refer to Figure 1-2 for locations of the memories depending on the operating mode after reset.

The content of the RAM array is not automatically initialized out of reset.

Chapter 2
Port Integration Module (PIM3RG128V1) Block Description

2.1 Introduction

The Port Integration Module establishes the interface between the peripheral modules and the I/O pins for all ports.

NOTE

Port A, B, E, and K are related to the core logic and multiplexed bus interface. Refer to the HCS12 Core User Guide for details.

This section covers:

- Port T connected to the timer module
- The serial port S associated with 2 SCI and 1 SPI modules
- Port M associated with 2 CAN and 1 SPI modules
- Port P connected to the PWM and 1 SPI modules, which also can be used as an external interrupt source
- The standard I/O ports H and J associated with the first and fifth CAN module and the IIC interface. These ports can also be used as external interrupt sources.

Each I/O pin can be configured by several registers in order to select data direction and drive strength, to enable and select pull-up or pull-down resistors. On certain pins also interrupts can be enabled which result in status flags.

The I/O's of two CAN and all two SPI modules can be routed from their default location to determined pins.

The implementation of the Port Integration Module is device dependent.

2.1.1 Features

A standard port pin has the following minimum features:

- Input/output selection
- 5-V output drive with two selectable drive strengths
- 5-V digital and analog input
- Input with selectable pull-up or pull-down device

Optional features:

- Open drain for wired-OR connections
- Interrupt inputs with glitch filtering

2.1.2 Block Diagram

Figure 2-1 is a block diagram of the PIM3RG128.

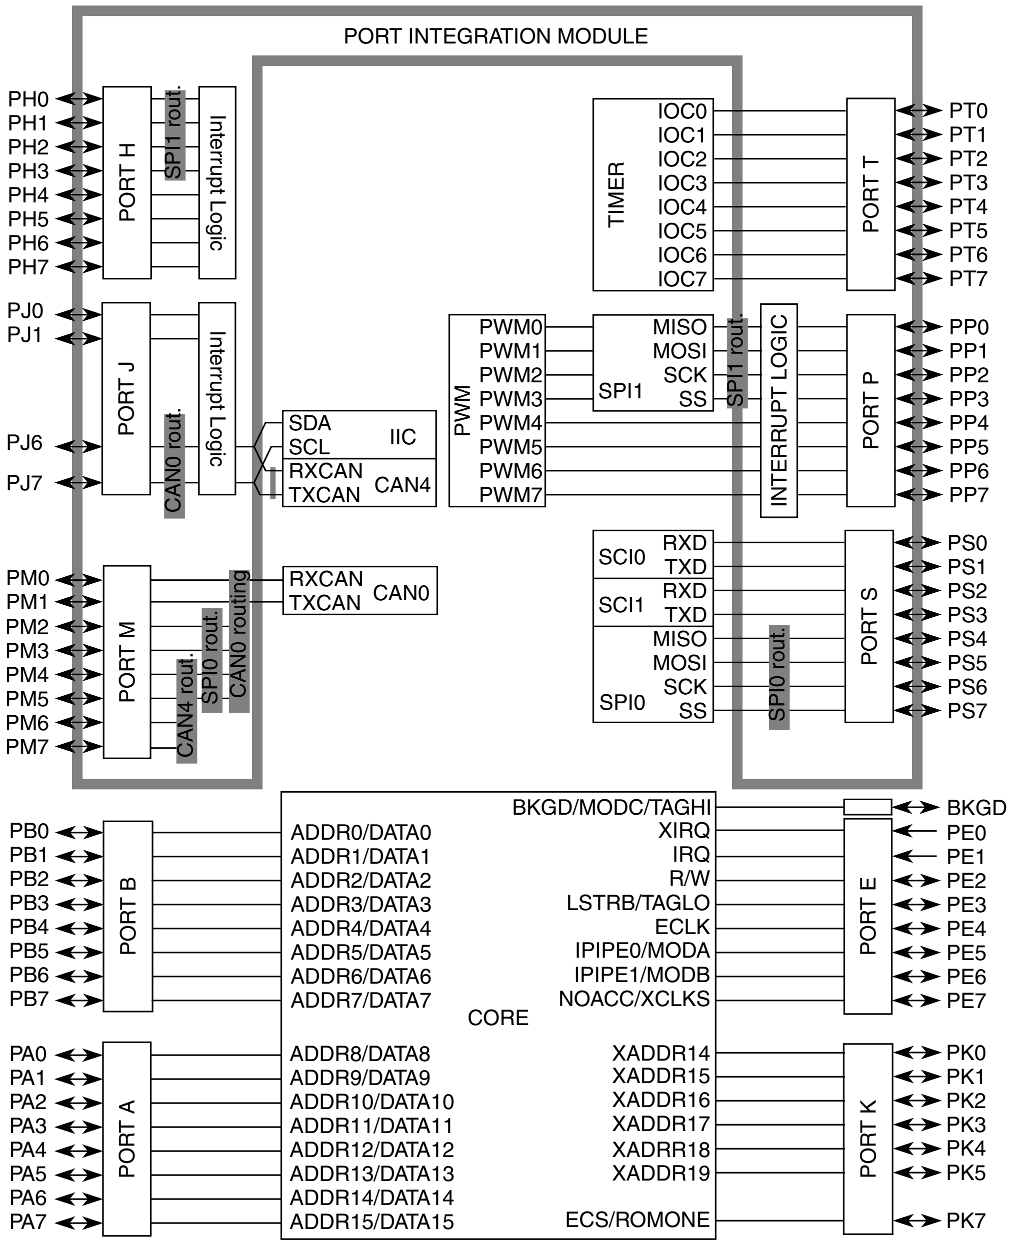

Figure 2-1. PIM3RG128 Block Diagram

2.2 External Signal Description

This section lists and describes the signals that do connect off-chip.

2.2.1 Signal Properties

Table 2-1shows all the pins and their functions that are controlled by the PIM3RG128. If there is more than one function associated with a pin, the priority is indicated by the position in the table from top (highest priority) to down (lowest priority).

Table 2-1. Pin Functions and Priorities (Sheet 1 of 4)

Port	Pin Name	Pin Function and Priority	Description	Pin Function after Reset
Port T	PT[7:0]	IOC[7:0]	Enhanced Capture Timer Channels 7 to 0	GPIO
		GPIO	General-purpose I/O	
Port S	PS7	SS0	Serial Peripheral Interface 0 slave select output in master mode, input in slave mode or master mode.	GPIO
		GPIO	General-purpose I/O	
	PS6	SCK0	Serial Peripheral Interface 0 serial clock pin	
		GPIO	General-purpose I/O	
	PS5	MOSI0	Serial Peripheral Interface 0 master out/slave in pin	
		GPIO	General-purpose I/O	
	PS4	MISO0	Serial Peripheral Interface 0 master in/slave out pin	
		GPIO	General-purpose I/O	
	PS3	TXD1	Serial Communication Interface 1 transmit pin	
		GPIO	General-purpose I/O	
	PS2	RXD1	Serial Communication Interface 1 receive pin	
		GPIO	General-purpose I/O	
	PS1	TXD0	Serial Communication Interface 0 transmit pin	
		GPIO	General-purpose I/O	
	PS0	RXD0	Serial Communication Interface 0 receive pin	
		GPIO	General-purpose I/O	

Table 2-1. Pin Functions and Priorities (Sheet 2 of 4)

Port	Pin Name	Pin Function and Priority	Description	Pin Function after Reset
Port M	PM7	TXCAN4	MSCAN4 transmit pin	GPIO
		GPIO	General-purpose I/O	
	PM6	RXCAN4	MSCAN4 receive pin	
		GPIO	General-purpose I/O	
	PM5	TXCAN0	MSCAN0 transmit pin	
		TXCAN4	MSCAN4 transmit pin	
		SCK0	Serial Peripheral Interface 0 serial clock pin	
		GPIO	General-purpose I/O	
	PM4	RXCAN0	MSCAN0 receive pin	
		RXCAN4	MSCAN4 receive pin	
		MOSI0	Serial Peripheral Interface 0 master out/slave in pin	
		GPIO	General-purpose I/O	
	PM3	TXCAN0	MSCAN0 transmit pin	
		$\overline{\text{SS0}}$[1]	Serial Peripheral Interface 0 slave select output in master mode, input for slave mode or master mode.	
		GPIO	General-purpose I/O	
	PM2	RXCAN0	MSCAN0 receive pin	
		MISO0<f-helvetica><st-superscript>	Serial Peripheral Interface 0 master in/slave out pin	
		GPIO	General-purpose I/O	
	PM1	TXCAN0	MSCAN0 transmit pin	
		GPIO	General-purpose I/O	
	PM0	RXCAN0	MSCAN0 receive pin	
		GPIO	General-purpose I/O	

Table 2-1. Pin Functions and Priorities (Sheet 3 of 4)

Port	Pin Name	Pin Function and Priority	Description	Pin Function after Reset
Port P	PP7	PWM7	Pulse Width Modulator channel 7	GPIO
		GPIO/KWP7	General-purpose I/O with interrupt	
	PP6	PWM6	Pulse Width Modulator channel 6	
		GPIO/KWP6	General-purpose I/O with interrupt	
	PP5	PWM5	Pulse Width Modulator channel 5	
		GPIO/KWP5	General-purpose I/O with interrupt	
	PP4	PWM4	Pulse Width Modulator channel 4	
		GPIO/KWP4	General-purpose I/O with interrupt	
	PP3	PWM3	Pulse Width Modulator channel 3	
		SS1	Serial Peripheral Interface 1 slave select output in master mode, input for slave mode or master mode.	
		GPIO/KWP3	General-purpose I/O with interrupt	
	PP2	PWM2	Pulse Width Modulator channel 2	
		SCK1	Serial Peripheral Interface 1 serial clock pin	
		GPIO/KWP2	General-purpose I/O with interrupt	
	PP1	PWM1	Pulse Width Modulator channel 1	
		MOSI1	Serial Peripheral Interface 1 master out/slave in pin	
		GPIO/KWP1	General-purpose I/O with interrupt	
	PP0	PWM0	Pulse Width Modulator channel 0	
		MISO1	Serial Peripheral Interface 1 master in/slave out pin	
		GPIO/KWP0	General-purpose I/O with interrupt	
Port H	PH7	GPIO/KWH7	General-purpose I/O with interrupt	GPIO
	PH6	GPIO/KWH6	General-purpose I/O with interrupt	
	PH5	GPIO/KWH5	General-purpose I/O with interrupt	
	PH4	GPIO/KWH4	General-purpose I/O with interrupt	
	PH3	SS1	Serial Peripheral Interface 1 slave select output in master mode, input for slave mode or master mode.	
		GPIO/KWH3	General-purpose I/O with interrupt	
	PH2	SCK1	Serial Peripheral Interface 1 serial clock pin	
		GPIO/KWH2	General-purpose I/O with interrupt	
	PH1	MOSI1	Serial Peripheral Interface 1 master out/slave in pin	
		GPIO/KWH1	General-purpose I/O with interrupt	
	PH0	MISO1	Serial Peripheral Interface 1 master in/slave out pin	
		GPIO/KWH0	General-purpose I/O with interrupt	

Table 2-1. Pin Functions and Priorities (Sheet 4 of 4)

Port	Pin Name	Pin Function and Priority	Description	Pin Function after Reset
Port J	PJ7	TXCAN4	MSCAN4 transmit pin	GPIO
		SCL	Inter Integrated Circuit serial clock line	
		TXCAN0	MSCAN0 transmit pin	
		GPIO/KWJ7	General-purpose I/O with interrupt	
	PJ6	RXCAN4	MSCAN4 receive pin	
		SDA	Inter Integrated Circuit serial data line	
		RXCAN0	MSCAN0 receive pin	
		GPIO/KWJ6	General-purpose I/O with interrupt	
	PJ[1:0]	GPIO/KWJ[1:0]	General-purpose I/O with interrupt	

[1] If CAN0 is routed to PM[3:2] the SPI0 can still be used in bidirectional master mode. *Refer to SPI Block Guide for details.*

2.3 Memory Map and Registers

This section provides a detailed description of all registers.

2.3.1 Module Memory Map

Figure 2-2 shows the register map of the Port Integration Module.

Address	Name		Bit 7	6	5	4	3	2	1	Bit 0
0x0000	PTT	R W	PTT7	PTT6	PTT5	PTT4	PTT3	PTT2	PTT1	PTT0

Figure 2-2. PIM Register Summary (Sheet 3 of 3)

NOTE

Register Address = Base Address + Address Offset, where the Base Address is defined at the MCU level and the Address Offset is defined at the module level.

2.3.2 Register Descriptions

Table 2-2 summarizes the effect on the various configuration bits, data direction (DDR), output level (I/O), reduced drive (RDR), pull enable (PE), pull select (PS) and interrupt enable (IE) for the ports. The configuration bit PS is used for two purposes:

1. Configure the sensitive interrupt edge (rising or falling), if interrupt is enabled.
2. Select either a pull-up or pull-down device if PE is active.

Table 2-2. Pin Configuration Summary

DDR	IO	RDR	PE	PS	IE[1]	Function	Pull Device	Interrupt
0	X	X	0	X	0	Input	Disabled	Disabled
0	X	X	1	0	0	Input	Pull Up	Disabled
0	X	X	1	1	0	Input	Pull Down	Disabled
0	X	X	0	0	1	Input	Disabled	Falling edge
0	X	X	0	1	1	Input	Disabled	Rising edge
0	X	X	1	0	1	Input	Pull Up	Falling edge
0	X	X	1	1	1	Input	Pull Down	Rising edge
1	0	0	X	X	0	Output, full drive to 0	Disabled	Disabled
1	1	0	X	X	0	Output, full drive to 1	Disabled	Disabled
1	0	1	X	X	0	Output, reduced drive to 0	Disabled	Disabled
1	1	1	X	X	0	Output, reduced drive to 1	Disabled	Disabled
1	0	0	X	0	1	Output, full drive to 0	Disabled	Falling edge
1	1	0	X	1	1	Output, full drive to 1	Disabled	Rising edge
1	0	1	X	0	1	Output, reduced drive to 0	Disabled	Falling edge
1	1	1	X	1	1	Output, reduced drive to 1	Disabled	Rising edge

[1] Applicable only on port P, H and J.

NOTE

All bits of all registers in this module are completely synchronous to internal clocks during a register read.

2.3.2.1 Port T Registers

2.3.2.1.1 Port T I/O Register (PTT)

Module Base + 0x_0000

	7	6	5	4	3	2	1	0
R W	PTT7	PTT6	PTT5	PTT4	PTT3	PTT2	PTT1	PTT0
ECT:	IOC7	IOC6	IOC5	IOC4	IOC3	IOC2	IOC1	IOC0
Reset	0	0	0	0	0	0	0	0

Figure 2-3. Port T I/O Register (PTT)

Read: Anytime.

Write: Anytime.

If the data direction bits of the associated I/O pins are set to 1, a read returns the value of the port register, otherwise the value at the pins is read.

2.3.2.1.2 Port T Input Register (PTIT)

Module Base + 0x_0001

	7	6	5	4	3	2	1	0
R	PTIT7	PTIT6	PTIT5	PTIT4	PTIT3	PTIT2	PTIT1	PTIT0
W								
Reset	—	—	—	—	—	—	—	—

= Unimplemented or Reserved

Figure 2-4. Port T Input Register (PTIT)

Read: Anytime.

Write: Never, writes to this register have no effect.

This register always reads back the status of the associated pins. This can also be used to detect overload or short circuit conditions on output pins.

2.3.2.1.3 Port T Data Direction Register (DDRT)

Module Base + 0x_0002

	7	6	5	4	3	2	1	0
R W	DDRT7	DDRT6	DDRT5	DDRT4	DDRT3	DDRT2	DDRT1	DDRT0
Reset	0	0	0	0	0	0	0	0

Figure 2-5. Port T Data Direction Register (DDRT)

Read: Anytime.

Write: Anytime.

This register configures each port T pin as either input or output.

- The ECT forces the I/O state to be an output for each timer port associated with an enabled output compare. In these cases the data direction bits will not change.
- The DDRT bits revert to controlling the I/O direction of a pin when the associated timer output compare is disabled.
- The timer input capture always monitors the state of the pin.

Table 2-3. DDRT Field Descriptions

Field	Description
7–0 DDRT[7:0]	**Data Direction Port T Bits** 0 Associated pin is configured as input. 1 Associated pin is configured as output. **Note:** Due to internal synchronization circuits, it can take up to two bus cycles until the correct value is read on PTT or PTIT registers, when changing the DDRT register.

2.3.2.1.4 Port T Reduced Drive Register (RDRT)

Module Base + 0x_0003

	7	6	5	4	3	2	1	0
R W	RDRT7	RDRT6	RDRT5	RDRT4	RDRT3	RDRT2	RDRT1	RDRT0
Reset	0	0	0	0	0	0	0	0

Figure 2-6. Port T Reduced Drive Register (RDRT)

Read: Anytime.

Write: Anytime.

This register configures the drive strength of each port T output pin as either full or reduced. If the port is used as input this bit is ignored.

Table 2-4. RDRT Field Descriptions

Field	Description
7–0 RDRT[7:0]	**Reduced Drive Port T Bits** 0 Full drive strength at output. 1 Associated pin drives at about 1/3 of the full drive strength.

2.3.2.1.5 Port T Pull Device Enable Register (PERT)

Module Base + 0x_0004

	7	6	5	4	3	2	1	0
R W	PERT7	PERT6	PERT5	PERT4	PERT3	PERT2	PERT1	PERT0
Reset	0	0	0	0	0	0	0	0

Figure 2-7. Port T Pull Device Enable Register (PERT)

Read: Anytime.

Write: Anytime.

This register configures whether a pull-up or a pull-down device is activated, if the port is used as input. This bit has no effect if the port is used as output. Out of reset no pull device is enabled.

Table 2-5. PERT Field Descriptions

Field	Description
7–0 PERT[7:0]	**Pull Device Enable Port T Bits** 0 Pull-up or pull-down device is disabled. 1 Either a pull-up or pull-down device is enabled.

2.3.2.1.6 Port T Polarity Select Register (PPST)

Module Base + 0x_0005

	7	6	5	4	3	2	1	0
R W	PPST7	PPST6	PPST5	PPST4	PPST3	PPST2	PPST1	PPST0
Reset	0	0	0	0	0	0	0	0

Figure 2-8. Port T Polarity Select Register (PPST)

Read: Anytime.

Write: Anytime.

This register selects whether a pull-down or a pull-up device is connected to the pin.

Table 2-6. PPST Field Descriptions

Field	Description
7–0 PPST[7:0]	**Pull Select Port T Bits** 0 A pull-up device is connected to the associated port T pin, if enabled by the associated bit in register PERT and if the port is used as input. 1 A pull-down device is connected to the associated port T pin, if enabled by the associated bit in register PERT and if the port is used as input.

2.3.2.2 Port S Registers

2.3.2.2.1 Port S I/O Register (PTS)

Module Base + 0x_0008

	7	6	5	4	3	2	1	0
R W	PTS7	PTS6	PTS5	PTS4	PTS3	PTS2	PTS1	PTS0
	$\overline{SS0}$	SCK0	MOSI0	MISO0	TXD1	RXD1	TXD0	RXD0
Reset	0	0	0	0	0	0	0	0

Figure 2-9. Port S I/O Register (PTS)

Read: Anytime.

Write: Anytime.

If the data direction bits of the associated I/O pins are set to 1, a read returns the value of the port register, otherwise the value at the pins is read.

- The SPI pins (PS[7:4]) configuration is determined by several status bits in the SPI module. *Refer to SPI Block Guide for details*.
- The SCI ports associated with transmit pins 3 and 1 are configured as outputs if the transmitter is enabled.
- The SCI ports associated with receive pins 2 and 0 are configured as inputs if the receiver is enabled. *Refer to SCI Block Guide for details*.

2.3.2.2.2 Port S Input Register (PTIS)

Module Base + 0x_0009

	7	6	5	4	3	2	1	0
R	PTIS7	PTIS6	PTIS5	PTIS4	PTIS3	PTIS2	PTIS1	PTIS0
W								
Reset	—	—	—	—	—	—	—	—

= Unimplemented or Reserved

Figure 2-10. Port S Input Register (PTIS)

Read: Anytime.

Write: Never, writes to this register have no effect.

This register always reads back the status of the associated pins. This also can be used to detect overload or short circuit conditions on output pins.

2.3.2.2.3 Port S Data Direction Register (DDRS)

Module Base + 0x_000A

	7	6	5	4	3	2	1	0
R W	DDRS7	DDRS6	DDRS5	DDRS4	DDRS3	DDRS2	DDRS1	DDRS0
Reset	0	0	0	0	0	0	0	0

Figure 2-11. Port S Data Direction Register (DDRS)

Read: Anytime.

Write: Anytime.

This register configures each port S pin as either input or output.

- If SPI is enabled, the SPI determines the pin direction. *Refer to SPI Block Guide for details.*
- If the associated SCI transmit or receive channel is enabled this register has no effect on the pins. The pin is forced to be an output if a SCI transmit channel is enabled, it is forced to be an input if the SCI receive channel is enabled.
- The DDRS bits revert to controlling the I/O direction of a pin when the associated channel is disabled.

Table 2-7. DDRS Field Descriptions

Field	Description
7–0 DDRS[7:0]	**Data Direction Port S Bits** 0 Associated pin is configured as input. 1 Associated pin is configured as output. **Note:** Due to internal synchronization circuits, it can take up to two bus cycles until the correct value is read on PTS or PTIS registers, when changing the DDRS register.

2.3.2.2.4 Port S Reduced Drive Register (RDRS)

Module Base + 0x_000B

	7	6	5	4	3	2	1	0
R W	RDRS7	RDRS6	RDRS5	RDRS4	RDRS3	RDRS2	RDRS1	RDRS0
Reset	0	0	0	0	0	0	0	0

Figure 2-12. Port S Reduced Drive Register (RDRS)

Read: Anytime.

Write: Anytime.

This register configures the drive strength of each port S output pin as either full or reduced. If the port is used as input this bit is ignored.

Table 2-8. RDRS Field Descriptions

Field	Description
7–0 RDRS[7:0]	**Reduced Drive Port S Bits** 0 Full drive strength at output. 1 Associated pin drives at about 1/3 of the full drive strength.

2.3.2.2.5 Port S Pull Device Enable Register (PERS)

Module Base + 0x_000C

	7	6	5	4	3	2	1	0
R W	PERS7	PERS6	PERS5	PERS4	PERS3	PERS2	PERS1	PERS0
Reset	1	1	1	1	1	1	1	1

Figure 2-13. Port S Pull Device Enable Register (PERS)

Read: Anytime.

Write: Anytime.

This register configures whether a pull-up or a pull-down device is activated, if the port is used as input or as output in wired-OR (open drain) mode. This bit has no effect if the port is used as push-pull output. Out of reset a pull-up device is enabled.

Table 2-9. PERS Field Descriptions

Field	Description
7–0 PERS[7:0]	**Pull Device Enable Port S Bits** 0 Pull-up or pull-down device is disabled. 1 Either a pull-up or pull-down device is enabled.

2.3.2.2.6 Port S Polarity Select Register (PPSS)

Module Base + 0x_000D

	7	6	5	4	3	2	1	0
R W	PPSS7	PPSS6	PPSS5	PPSS4	PPSS3	PPSS2	PPSS1	PPSS0
Reset	0	0	0	0	0	0	0	0

Figure 2-14. Port S Polarity Select Register (PPSS)

Read: Anytime.

Write: Anytime.

This register selects whether a pull-down or a pull-up device is connected to the pin.

Table 2-10. PPSS Field Descriptions

Field	Description
7–0 PPSS[7:0]	**Pull Select Port S Bits** 0 A pull-up device is connected to the associated port S pin, if enabled by the associated bit in register PERS and if the port is used as input or as wired-OR output. 1 A pull-down device is connected to the associated port S pin, if enabled by the associated bit in register PERS and if the port is used as input.

2.3.2.2.7 Port S Wire-OR Mode Register (WOMS)

Module Base + 0x_000E

	7	6	5	4	3	2	1	0
R W	WOMS7	WOMS6	WOMS5	WOMS4	WOMS3	WOMS2	WOMS1	WOMS0
Reset	0	0	0	0	0	0	0	0

Figure 2-15. Port S Wired-OR Mode Register (WOMS)

Read: Anytime.

Write: Anytime.

This register configures the output pins as wired-OR. If enabled the output is driven active low only (open-drain). A logic level of “1” is not driven. It applies also to the SPI and SCI outputs and allows a multipoint connection of several serial modules. This bit has no influence on pins used as inputs.

Table 2-11. WOMS Field Descriptions

Field	Description
7–0 WOMS[7:0]	**Wired-OR Mode Port S Bits** 0 Output buffers operate as push-pull outputs. 1 Output buffers operate as open-drain outputs.

2.3.2.3 Port M Registers

2.3.2.3.1 Port M I/O Register (PTM)

Module Base + 0x_0010

Figure 2-24. Port P I/O Register (PTP)

Read: Anytime.

Write: Anytime.

If the data direction bits of the associated I/O pins are set to 1, a read returns the value of the port register, otherwise the value at the pins is read.

- The PWM function takes precedence over the general purpose I/O function if the associated PWM channel is enabled. While channels 6-0 are output only if the respective channel is enabled, channel 7 can be PWM output or input if the shutdown feature is enabled. *Refer to PWM Block Guide for details.*
- The SPI function takes precedence over the general purpose I/O function associated with if enabled. *Refer to SPI Block Guide for details.*
- If both PWM and SPI are enabled the PWM functionality takes precedence.

2.3.2.5.2 Port P Input Register (PTIP)

Module Base + 0x_0019

	7	6	5	4	3	2	1	0
R	PTIP7	PTIP6	PTIP5	PTIP4	PTIP3	PTIP2	PTIP1	PTIP0

Read: Anytime.

Write: Anytime.

Each flag is set by an active edge on the associated input pin. This could be a rising or a falling edge based on the state of the PPSJ register. To clear this flag, write “1” to the corresponding bit in the PIFJ register. Writing a “0” has no effect.

Table 2-41. PIFJ Field Descriptions

Field	Description
7, 6, 1, 0 PIFJ[7:6] PIFJ[1:0]	**Interrupt Flags Port J Bits** 0 No active edge pending. Writing a “0” has no effect. 1 Active edge on the associated bit has occurred (an interrupt will occur if the associated enable bit is set). Writing a “1” clears the associated flag.

2.4 Functional Description

Each pin can act as general purpose I/O. In addition the pin can act as an output from a peripheral module or an input to a peripheral module.

A set of configuration registers is common to all ports. All registers can be written at any time; however a specific configuration might not become active.

Example:

> Selecting a pull-up resistor. This resistor does not become active while the port is used as a push-pull output.

2.4.1 I/O Register

This register holds the value driven out to the pin if the port is used as a general purpose I/O.

Writing to this register has only an effect on the pin if the port is used as general purpose output. When reading this address, the value of the pins is returned if the data direction register bits are set to 0.

If the data direction register bits are set to 1, the contents of the I/O register is returned. This is independent of any other configuration (Figure 2-48).

2.4.2 Input Register

This is a read-only register and always returns the value of the pin (Figure 2-48).

2.4.3 Data Direction Register

This register defines whether the pin is used as an input or an output.

If a peripheral module controls the pin the contents of the data direction register is ignored (Figure 2-48).

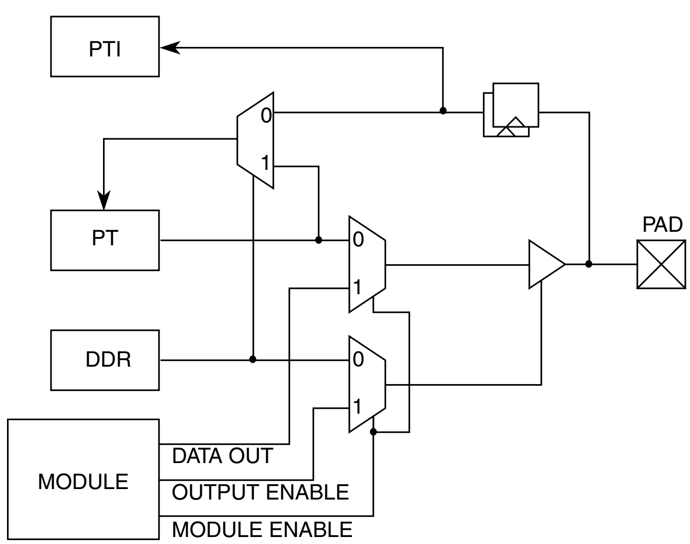

Figure 2-48. Illustration of I/O Pin Functionality

2.4.4 Reduced Drive Register

If the port is used as an output the register allows the configuration of the drive strength.

2.4.5 Pull Device Enable Register

This register turns on a pull-up or pull-down device. It becomes active only if the pin is used as an input or as a wired-OR output.

2.4.6 Polarity Select Register

This register selects either a pull-up or pull-down device if enabled. It becomes active only if the pin is used as an input. A pull-up device can be activated if the pin is used as a wired-OR output.

2.4.7 Port T

This port is associated with the ECT module.

Port T pins PT[7:0] can be used for either general-purpose I/O, or with the channels of the Enhanced Capture Timer. During reset, port T pins are configured as high-impedance inputs.

2.4.8 Port S

This port is associated with SCI0, SCI1, and SPI0.

Port S pins PS[7:0] can be used either for general-purpose I/O, or with the SCI and SPI subsystems. During reset, port S pins are configured as inputs with pull-up.

The SPI0 pins can be re-routed. Refer to Figure 2-23.

2.4.9 Port M

This port is associated with the CAN4, CAN0, and SPI0.

Port M pins PM[7:0] can be used for either general purpose I/O, or with the CAN and SPI subsystems. During reset, port M pins are configured as high-impedance inputs.

The CAN0, CAN4, and SPI0 pins can be re-routed. Refer to Figure 2-23.

2.4.9.1 Module Routing Register

This register allows to re-route the CAN0, CAN4, SPI0, and SPI1 pins to predefined pins.

NOTE

The purpose of the Module Routing Register is to provide maximum flexibility for future derivatives of the MC3S12RG128 with a lower number of MSCAN and SPI modules.

Table 2-42. Implemented Modules on Derivatives

Number of Modules	MSCAN Modules		SPI Modules	
	CAN0	CAN4	SPI0	SPI1
2	X	X	X	X
1	X	—	X	—

2.4.10 Port P

This port is associated with the PWM and SPI1.

Port P pins PP[7:0] can be used for either general purpose I/O, or with the PWM and SPI subsystems.

The pins are shared between the PWM channels and the SPI1 module. If the PWM is enabled the pins become PWM output channels with the exception of pin 7 which can be PWM input or output. If SPI1 is enabled and PWM is disabled, the respective pin configuration is determined by several status bits in the SPI1 module. During reset, port P pins are configured as high-impedance inputs.

The SPI1 pins can be re-routed. Refer to Figure 2-23.

Port P offers eight I/O pins with edge triggered interrupt capability in wired-OR fashion. The interrupt enable as well as the sensitivity to rising or falling edges can be individually configured on per pin basis. All eight bits/pins share the same interrupt vector. Interrupts can be used with the pins configured as inputs or outputs.

An interrupt is generated when a bit in the port interrupt flag register and its corresponding port interrupt enable bit are both set. This external interrupt feature is capable to wake up the CPU when it is in Stop or Wait mode.

A digital filter on each pin prevents pulses (Figure 2-50) shorter than a specified time from generating an interrupt. The minimum time varies over process conditions, temperature and voltage (Figure 2-49 and Table 2-43).

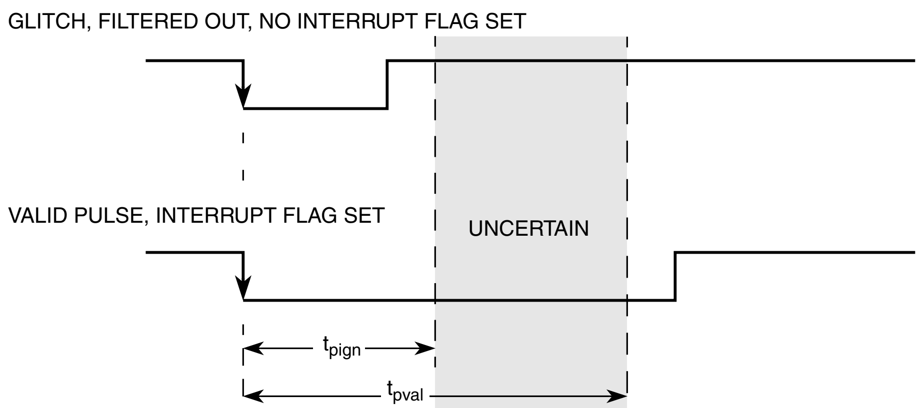

Figure 2-49. Interrupt Glitch Filter on Port P, H, and J (PPS = 0)

Table 2-43. Pulse Detection Criteria

Pulse	Mode		
	STOP		STOP[1]
		Unit	
Ignored	$t_{pulse} \leq 3$	Bus clocks	$t_{pulse} \leq t_{pign}$
Uncertain	$3 < t_{pulse} < 4$	Bus clocks	$t_{pign} < t_{pulse} < t_{pval}$
Valid	$t_{pulse} \geq 4$	Bus clocks	$t_{pulse} \geq t_{pval}$

[1] These values include the spread of the oscillator frequency over temperature, voltage and process.

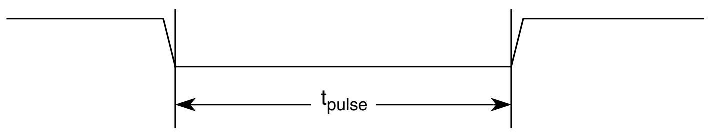

Figure 2-50. Pulse Illustration

A valid edge on an input is detected if four consecutive samples of a passive level are followed by four consecutive samples of an active level directly or indirectly.

The filters are continuously clocked by the bus clock in Run and Wait mode. In Stop mode the clock is generated by a single RC oscillator in the Port Integration Module. To maximize current saving the RC oscillator runs only if the following condition is true on any pin:

Sample count <= 4 and port interrupt enabled (PIE = 1) and port interrupt flag not set (PIF = 0).

2.4.11 Port H

This port is associated with the SPI1.

Port H pins PH[7:0] can be used for either general purpose I/O, or with the SPI subsystems. During reset, port H pins are configured as high-impedance inputs.

Port H pins can be used with the routed SPI1 module. Refer to Figure 2-23.

Port H offers eight I/O ports with the same interrupt features as port P.

2.4.12 Port J

This port is associated with the CAN4, CAN0, and the IIC.

Port J pins PJ[7:6] and PJ[1:0] can be used for either general purpose I/O, or with the CAN and IIC subsystems. During reset, port J pins are configured as inputs with pull-up. If IIC takes precedence the pins become IIC open-drain output pins.

The CAN4 pins can be re-routed. Refer to Figure 2-23. Port J pins can be used with the routed CAN0 modules. Refer to Figure 2-23.

Port J offers four I/O ports with the same interrupt features as port P.

2.4.13 Port A, B, E, K, and BKGD Pin

All port and pin logic is located in the core module. Refer to *MEBI in HCS12 Core User Guide* for details.

2.4.14 External Pin Descriptions

All ports start up as general-purpose inputs on reset.

2.4.15 Low-Power Options

2.4.15.1 Run Mode

No low-power options exist for this module in run mode.

2.4.15.2 Wait Mode

No low-power options exist for this module in wait mode.

2.4.15.3 Stop Mode

All clocks are stopped. There are asynchronous paths to generate interrupts from STOP on port P, H, and J.

Chapter 3
Module Mapping Control (MMCV5) Block Description

3.1 Introduction

This section describes the functionality of the module mapping control (MMC) sub-block of the S12 core platform.

The block diagram of the MMC is shown in Figure 3-1.

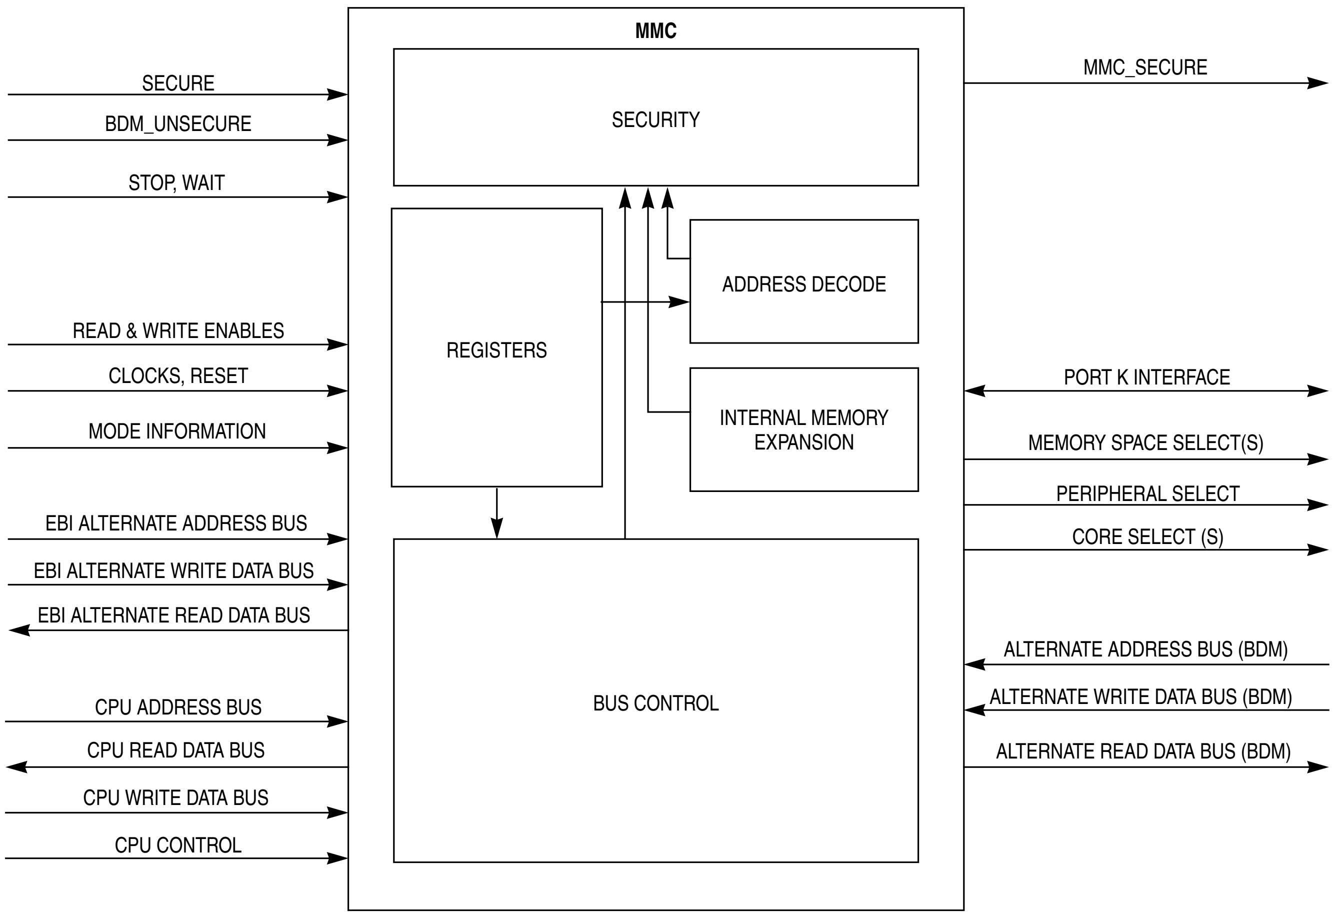

Figure 3-1. MMC Block Diagram

The MMC is the sub-module which controls memory map assignment and selection of internal resources and external space. Internal buses between the core and memories and between the core and peripherals is controlled in this module. The memory expansion is generated in this module.

3.1.1 Features

- Registers for mapping of address space for on-chip RAM, EEPROM, and FLASH (or ROM) memory blocks and associated registers
- Memory mapping control and selection based upon address decode and system operating mode
- Core address bus control
- Core data bus control and multiplexing
- Core security state decoding
- Emulation chip select signal generation ($\overline{\text{ECS}}$)
- External chip select signal generation ($\overline{\text{XCS}}$)
- Internal memory expansion
- External stretch and ROM mapping control functions via the MISC register
- Reserved registers for test purposes
- Configurable system memory options defined at integration of core into the system-on-a-chip (SoC).

3.1.2 Modes of Operation

Some of the registers operate differently depending on the mode of operation (i.e., normal expanded wide, special single chip, etc.). This is best understood from the register descriptions.

3.2 External Signal Description

All interfacing with the MMC sub-block is done within the core, it has no external signals.

3.3 Memory Map and Register Definition

A summary of the registers associated with the MMC sub-block is shown in Figure 3-2. Detailed descriptions of the registers and bits are given in the subsections that follow.

3.3.1 Register Descriptions

Name		Bit 7	6	5	4	3	2	1	Bit 0
0x0010 INITRM	R	RAM15	RAM14	RAM13	RAM12	RAM11	0	0	RAMHAL

Figure 3-2. MMC Register Summary

3.3.1.1 Initialization of Internal RAM Position Register (INITRM)

Module Base + 0x0010
Starting address location affected by INITRG register setting.

	7	6	5	4	3	2	1	0
R	RAM15	RAM14	RAM13	RAM12	RAM11	0	0	RAMHAL
W								
Reset	0	0	0	0	1	0	0	1

= Unimplemented or Reserved

Figure 3-3. Initialization of Internal RAM Position Register (INITRM)

Read: Anytime

Write: Once in normal and emulation modes, anytime in special modes

NOTE

Writes to this register take one cycle to go into effect.

This register initializes the position of the internal RAM within the on-chip system memory map.

Table 3-1. INITRM Field Descriptions

Field	Description
7:3 RAM[15:11]	**Internal RAM Map Position** — These bits determine the upper five bits of the base address for the system's internal RAM array.
0 RAMHAL	**RAM High-Align** — RAMHAL specifies the alignment of the internal RAM array. 0 Aligns the RAM to the lowest address (0x0000) of the mappable space 1 Aligns the RAM to the higher address (0xFFFF) of the mappable space

3.3.1.2 Initialization of Internal Registers Position Register (INITRG)

Module Base + 0x0011
Starting address location affected by INITRG register setting.

	7	6	5	4	3	2	1	0
R	0	REG14	REG13	REG12	REG11	0	0	0
W								
Reset	0	0	0	0	0	0	0	0

= Unimplemented or Reserved

Figure 3-4. Initialization of Internal Registers Position Register (INITRG)

Read: Anytime

Write: Once in normal and emulation modes and anytime in special modes

This register initializes the position of the internal registers within the on-chip system memory map. The registers occupy either a 1K byte or 2K byte space and can be mapped to any 2K byte space within the first 32K bytes of the system's address space.

Table 3-2. INITRG Field Descriptions

Field	Description
6:3 REG[14:11]	**Internal Register Map Position** — These four bits in combination with the leading zero supplied by bit 7 of INITRG determine the upper five bits of the base address for the system's internal registers (i.e., the minimum base address is 0x0000 and the maximum is 0x7FFF).

3.3.1.3 Miscellaneous System Control Register (MISC)

Module Base + 0x0013
Starting address location affected by INITRG register setting.

	7	6	5	4	3	2	1	0
R	0	0	0	0	EXSTR1	EXSTR0	ROMHM	ROMON
W								
Reset: Expanded or Emulation	0	0	0	0	1	1	0	—[1]
Reset: Peripheral or Single Chip	0	0	0	0	1	1	0	1
Reset: Special Test	0	0	0	0	1	1	0	0

1. The reset state of this bit is determined at the chip integration level.

= Unimplemented or Reserved

Figure 3-5. Miscellaneous System Control Register (MISC)

Read: Anytime

Write: As stated in each bit description

NOTE

Writes to this register take one cycle to go into effect.

This register initializes miscellaneous control functions.

Table 3-3. MISC Field Descriptions

Field	Description
3:2 EXSTR[1:0]	**External Access Stretch Bits 1 and 0** Write: once in normal and emulation modes and anytime in special modes This two-bit field determines the amount of clock stretch on accesses to the external address space as shown in Table 3-4. In single chip and peripheral modes these bits have no meaning or effect.
1 ROMHM	**FLASH EEPROM or ROM Only in Second Half of Memory Map** Write: once in normal and emulation modes and anytime in special modes 0 The fixed page(s) of FLASH EEPROM or ROM in the lower half of the memory map can be accessed. 1 Disables direct access to the FLASH EEPROM or ROM in the lower half of the memory map. These physical locations of the FLASH EEPROM or ROM remain accessible through the program page window.
0 ROMON	**ROMON — Enable FLASH EEPROM or ROM** Write: once in normal and emulation modes and anytime in special modes This bit is used to enable the FLASH EEPROM or ROM memory in the memory map. 0 Disables the FLASH EEPROM or ROM from the memory map. 1 Enables the FLASH EEPROM or ROM in the memory map. **Note:** Removing the Mask-ROM from the memory map in a secured Mask-ROM device unsecures the device. This can be either achieved by writing a '0' to the ROMON bit or by starting up with the Mask-ROM disabled using the external ROMCTL pin. A secured Mask-ROM cannot be re-enabled once the device was unsecured using this method. Writing a '1' to the ROMON bit will not have any effect. Re-enabling a secured Mask-ROM requires a system reset. Additionally, when starting in special single chip mode, the BDM firmware in a Mask-ROM device will disable a secured ROM automatically before BDM access to the device is enabled.

Table 3-4. External Stretch Bit Definition

Stretch Bit EXSTR1	Stretch Bit EXSTR0	Number of E Clocks Stretched
0	0	0
0	1	1
1	0	2
1	1	3

3.3.1.4 Reserved Test Register 0 (MTST0)

Module Base + 0x0014
Starting address location affected by INITRG register setting.

	7	6	5	4	3	2	1	0
R	0	0	0	0	0	0	0	0
W								
Reset	0	0	0	0	0	0	0	0

= Unimplemented or Reserved

Figure 3-6. Reserved Test Register 0 (MTST0)

3.3.1.6 Memory Size Register 0 (MEMSIZ0)

Module Base + 0x001C
Starting address location affected by INITRG register setting.

	7	6	5	4	3	2	1	0
R	REG_SW0	0	EEP_SW1	EEP_SW0	0	RAM_SW2	RAM_SW1	RAM_SW0
W								
Reset	—	—	—	—	—	—	—	—

= Unimplemented or Reserved

Figure 3-8. Memory Size Register 0 (MEMSIZ0)

Read: Anytime

Write: Writes have no effect

Reset: Defined at chip integration, see device overview section.

The MEMSIZ0 register reflects the state of the register, EEPROM and RAM memory space configuration switches at the core boundary which are configured at system integration. This register allows read visibility to the state of these switches.

Table 3-5. MEMSIZ0 Field Descriptions

Field	Description
7 REG_SW0	**Allocated System Register Space** 0 Allocated system register space size is 1K byte 1 Allocated system register space size is 2K byte
5:4 EEP_SW[1:0]	**Allocated System EEPROM Memory Space** — The allocated system EEPROM memory space size is as given in Table 3-6.
2 RAM_SW[2:0]	**Allocated System RAM Memory Space** — The allocated system RAM memory space size is as given in Table 3-7.

Table 3-6. Allocated EEPROM Memory Space

eep_sw1:eep_sw0	Allocated EEPROM Space
00	0K byte
01	2K bytes
10	4K bytes
11	8K bytes

Table 3-7. Allocated RAM Memory Space

ram_sw2:ram_sw0	Allocated RAM Space	RAM Mappable Region	INITRM Bits Used	RAM Reset Base Address[1]
000	2K bytes	2K bytes	RAM[15:11]	0x0800
001	4K bytes	4K bytes	RAM[15:12]	0x0000
010	6K bytes	8K bytes[2]	RAM[15:13]	0x0800

Table 3-7. Allocated RAM Memory Space (continued)

ram_sw2:ram_sw0	Allocated RAM Space	RAM Mappable Region	INITRM Bits Used	RAM Reset Base Address[1]
011	8K bytes	8K bytes	RAM[15:13]	0x0000
100	10K bytes	16K bytes [2]	RAM[15:14]	0x1800
101	12K bytes	16K bytes [2]	RAM[15:14]	0x1000
110	14K bytes	16K bytes [2]	RAM[15:14]	0x0800
111	16K bytes	16K bytes	RAM[15:14]	0x0000

1 The RAM Reset BASE Address is based on the reset value of the INITRM register, 0x0009.

2 Alignment of the Allocated RAM space within the RAM mappable region is dependent on the value of RAMHAL.

NOTE

As stated, the bits in this register provide read visibility to the system physical memory space allocations defined at system integration. The actual array size for any given type of memory block may differ from the allocated size. Please refer to the device overview chapter for actual sizes.

3.3.1.7 Memory Size Register 1 (MEMSIZ1)

Module Base + 0x001D
Starting address location affected by INITRG register setting.

	7	6	5	4	3	2	1	0
R	ROM_SW1	ROM_SW0	0	0	0	0	PAG_SW1	PAG_SW0
W								
Reset	—	—	—	—	—	—	—	—

= Unimplemented or Reserved

Figure 3-9. Memory Size Register 1 (MEMSIZ1)

Read: Anytime

Write: Writes have no effect

Reset: Defined at chip integration, see device overview section.

The MEMSIZ1 register reflects the state of the FLASH or ROM physical memory space and paging switches at the core boundary which are configured at system integration. This register allows read visibility to the state of these switches.

Table 3-8. MEMSIZ0 Field Descriptions

Field	Description
7:6 ROM_SW[1:0]	**Allocated System FLASH or ROM Physical Memory Space** — The allocated system FLASH or ROM physical memory space is as given in Table 3-9.
1:0 PAG_SW[1:0]	**Allocated Off-Chip FLASH or ROM Memory Space** — The allocated off-chip FLASH or ROM memory space size is as given in Table 3-10.

Table 3-9. Allocated FLASH/ROM Physical Memory Space

rom_sw1:rom_sw0	Allocated FLASH or ROM Space
00	0K byte
01	16K bytes
10	48K bytes(1)
11	64K bytes(1)

NOTES:

1. The ROMHM software bit in the MISC register determines the accessibility of the FLASH/ROM memory space. Please refer to Section 3.3.1.7, "Memory Size Register 1 (MEMSIZ1)," for a detailed functional description of the ROMHM bit.

Table 3-10. Allocated Off-Chip Memory Options

pag_sw1:pag_sw0	Off-Chip Space	On-Chip Space
00	876K bytes	128K bytes
01	768K bytes	256K bytes
10	512K bytes	512K bytes
11	0K byte	1M byte

NOTE

As stated, the bits in this register provide read visibility to the system memory space and on-chip/off-chip partitioning allocations defined at system integration. The actual array size for any given type of memory block may differ from the allocated size. Please refer to the device overview chapter for actual sizes.

3.3.1.8 Program Page Index Register (PPAGE)

Module Base + 0x0030
Starting address location affected by INITRG register setting.

	7	6	5	4	3	2	1	0
R	0	0	PIX5	PIX4	PIX3	PIX2	PIX1	PIX0
W								
Reset[1]	—	—	—	—	—	—	—	—

1. The reset state of this register is controlled at chip integration. Please refer to the device overview section to determine the actual reset state of this register.

= Unimplemented or Reserved

Figure 3-10. Program Page Index Register (PPAGE)

Read: Anytime

Write: Determined at chip integration. Generally it's: "write anytime in all modes;" on some devices it will be: "write only in special modes." Check specific device documentation to determine which applies.

Reset: Defined at chip integration as either 0x00 (paired with write in any mode) or 0x3C (paired with write only in special modes), see device overview chapter.

The HCS12 core architecture limits the physical address space available to 64K bytes. The program page index register allows for integrating up to 1M byte of FLASH or ROM into the system by using the six page index bits to page 16K byte blocks into the program page window located from 0x8000 to 0xBFFF as defined in Table 3-12. CALL and RTC instructions have special access to read and write this register without using the address bus.

NOTE

Normal writes to this register take one cycle to go into effect. Writes to this register using the special access of the CALL and RTC instructions will be complete before the end of the associated instruction.

Table 3-11. MEMSIZ0 Field Descriptions

Field	Description
5:0 PIX[5:0]	**Program Page Index Bits 5:0** — These page index bits are used to select which of the 64 FLASH or ROM array pages is to be accessed in the program page window as shown in Table 3-12.

1	1	1	1	1	1	16K page 63

3.4 Functional Description

The MMC sub-block performs four basic functions of the core operation: bus control, address decoding and select signal generation, memory expansion, and security decoding for the system. Each aspect is described in the following subsections.

3.4.1 Bus Control

The MMC controls the address bus and data buses that interface the core with the rest of the system. This includes the multiplexing of the input data buses to the core onto the main CPU read data bus and control of data flow from the CPU to the output address and data buses of the core. In addition, the MMC manages all CPU read data bus swapping operations.

3.4.2 Address Decoding

As data flows on the core address bus, the MMC decodes the address information, determines whether the internal core register or firmware space, the peripheral space or a memory register or array space is being addressed and generates the correct select signal. This decoding operation also interprets the mode of operation of the system and the state of the mapping control registers in order to generate the proper select. The MMC also generates two external chip select signals, emulation chip select ($\overline{\text{ECS}}$) and external chip select ($\overline{\text{XCS}}$).

3.4.2.1 Select Priority and Mode Considerations

Although internal resources such as control registers and on-chip memory have default addresses, each can be relocated by changing the default values in control registers. Normally, I/O addresses, control registers, vector spaces, expansion windows, and on-chip memory are mapped so that their address ranges do not overlap. The MMC will make only one select signal active at any given time. This activation is based upon the priority outlined in Table 3-13. If two or more blocks share the same address space, only the select signal for the block with the highest priority will become active. An example of this is if the registers and the RAM are mapped to the same space, the registers will have priority over the RAM and the portion of RAM mapped in this shared space will not be accessible. The expansion windows have the lowest priority. This means that registers, vectors, and on-chip memory are always visible to a program regardless of the values in the page select registers.

Table 3-13. Select Signal Priority

Priority	Address Space
Highest	BDM (internal to core) firmware or register space
...	Internal register space
...	RAM memory block
...	EEPROM memory block
...	On-chip FLASH or ROM
Lowest	Remaining external space

In expanded modes, all address space not used by internal resources is by default external memory space. The data registers and data direction registers for ports A and B are removed from the on-chip memory map and become external accesses. If the EME bit in the MODE register (see MEBI block description chapter) is set, the data and data direction registers for port E are also removed from the on-chip memory map and become external accesses.

In special peripheral mode, the first 16 registers associated with bus expansion are removed from the on-chip memory map (PORTA, PORTB, DDRA, DDRB, PORTE, DDRE, PEAR, MODE, PUCR, RDRIV, and the EBI reserved registers).

In emulation modes, if the EMK bit in the MODE register (see MEBI block description chapter) is set, the data and data direction registers for port K are removed from the on-chip memory map and become external accesses.

3.4.2.2 Emulation Chip Select Signal

When the EMK bit in the MODE register (see MEBI block description chapter) is set, port K bit 7 is used as an active-low emulation chip select signal, $\overline{\text{ECS}}$. This signal is active when the system is in emulation mode, the EMK bit is set and the FLASH or ROM space is being addressed subject to the conditions outlined in Section 3.4.3.2, "Extended Address (XAB19:14) and ECS Signal Functionality." When the EMK bit is clear, this pin is used for general purpose I/O.

3.4.2.3 External Chip Select Signal

When the EMK bit in the MODE register (see MEBI block description chapter) is set, port K bit 6 is used as an active-low external chip select signal, $\overline{\text{XCS}}$. This signal is active only when the $\overline{\text{ECS}}$ signal described above is not active and when the system is addressing the external address space. Accesses to unimplemented locations within the register space or to locations that are removed from the map (i.e., ports A and B in expanded modes) will not cause this signal to become active. When the EMK bit is clear, this pin is used for general purpose I/O.

3.4.3 Memory Expansion

The HCS12 core architecture limits the physical address space available to 64K bytes. The program page index register allows for integrating up to 1M byte of FLASH or ROM into the system by using the six page index bits to page 16K byte blocks into the program page window located from 0x8000 to 0xBFFF in the physical memory space. The paged memory space can consist of solely on-chip memory or a combination of on-chip and off-chip memory. This partitioning is configured at system integration through the use of the paging configuration switches (*pag_sw1:pag_sw0*) at the core boundary. The options available to the integrator are as given in Table 3-14 (this table matches Table 3-10 but is repeated here for easy reference).

Table 3-14. Allocated Off-Chip Memory Options

pag_sw1:pag_sw0	Off-Chip Space	On-Chip Space
00	876K bytes	128K bytes
01	768K bytes	256K bytes
10	512K bytes	512K bytes
11	0K byte	1M byte

Based upon the system configuration, the program page window will consider its access to be either internal or external as defined in Table 3-15.

Table 3-15. External/Internal Page Window Access

pag_sw1:pag_sw0	Partitioning	PIX5:0 Value	Page Window Access
00	876K off-Chip, 128K on-Chip	0x0000–0x0037	External
		0x0038–0x003F	Internal
01	768K off-chip, 256K on-chip	0x0000–0x002F	External
		0x0030–0x003F	Internal
10	512K off-chip, 512K on-chip	0x0000–0x001F	External
		0x0020–0x003F	Internal
11	0K off-chip, 1M on-chip	N/A	External
		0x0000–0x003F	Internal

NOTE

The partitioning as defined in Table 3-15 applies only to the allocated memory space and the actual on-chip memory sizes implemented in the system may differ. Please refer to the device overview chapter for actual sizes.

The PPAGE register holds the page select value for the program page window. The value of the PPAGE register can be manipulated by normal read and write (some devices don't allow writes in some modes) instructions as well as the CALL and RTC instructions.

Control registers, vector spaces, and a portion of on-chip memory are located in unpaged portions of the 64K byte physical address space. The stack and I/O addresses should also be in unpaged memory to make them accessible from any page.

The starting address of a service routine must be located in unpaged memory because the 16-bit exception vectors cannot point to addresses in paged memory. However, a service routine can call other routines that are in paged memory. The upper 16K byte block of memory space (0xC000–0xFFFF) is unpaged. It is recommended that all reset and interrupt vectors point to locations in this area.

3.4.3.1 CALL and Return from Call Instructions

CALL and RTC are uninterruptable instructions that automate page switching in the program expansion window. CALL is similar to a JSR instruction, but the subroutine that is called can be located anywhere in the normal 64K byte address space or on any page of program expansion memory. CALL calculates and stacks a return address, stacks the current PPAGE value, and writes a new instruction-supplied value to PPAGE. The PPAGE value controls which of the 64 possible pages is visible through the 16K byte expansion window in the 64K byte memory map. Execution then begins at the address of the called subroutine.

During the execution of a CALL instruction, the CPU:

- Writes the old PPAGE value into an internal temporary register and writes the new instruction-supplied PPAGE value into the PPAGE register.
- Calculates the address of the next instruction after the CALL instruction (the return address), and pushes this 16-bit value onto the stack.
- Pushes the old PPAGE value onto the stack.
- Calculates the effective address of the subroutine, refills the queue, and begins execution at the new address on the selected page of the expansion window.

This sequence is uninterruptable; there is no need to inhibit interrupts during CALL execution. A CALL can be performed from any address in memory to any other address.

The PPAGE value supplied by the instruction is part of the effective address. For all addressing mode variations except indexed-indirect modes, the new page value is provided by an immediate operand in the instruction. In indexed-indirect variations of CALL, a pointer specifies memory locations where the new page value and the address of the called subroutine are stored. Using indirect addressing for both the new page value and the address within the page allows values calculated at run time rather than immediate values that must be known at the time of assembly.

The RTC instruction terminates subroutines invoked by a CALL instruction. RTC unstacks the PPAGE value and the return address and refills the queue. Execution resumes with the next instruction after the CALL.

During the execution of an RTC instruction, the CPU:

- Pulls the old PPAGE value from the stack
- Pulls the 16-bit return address from the stack and loads it into the PC
- Writes the old PPAGE value into the PPAGE register
- Refills the queue and resumes execution at the return address

This sequence is uninterruptable; an RTC can be executed from anywhere in memory, even from a different page of extended memory in the expansion window.

The CALL and RTC instructions behave like JSR and RTS, except they use more execution cycles. Therefore, routinely substituting CALL/RTC for JSR/RTS is not recommended. JSR and RTS can be used to access subroutines that are on the same page in expanded memory. However, a subroutine in expanded memory that can be called from other pages must be terminated with an RTC. And the RTC unstacks a PPAGE value. So any access to the subroutine, even from the same page, must use a CALL instruction so that the correct PPAGE value is in the stack.

3.4.3.2 Extended Address (XAB19:14) and $\overline{\text{ECS}}$ Signal Functionality

If the EMK bit in the MODE register is set (see MEBI block description chapter) the PIX5:0 values will be output on XAB19:14 respectively (port K bits 5:0) when the system is addressing within the physical program page window address space (0x8000–0xBFFF) and is in an expanded mode. When addressing anywhere else within the physical address space (outside of the paging space), the XAB19:14 signals will be assigned a constant value based upon the physical address space selected. In addition, the active-low emulation chip select signal, $\overline{\text{ECS}}$, will likewise function based upon the assigned memory allocation. In the cases of 48K byte and 64K byte allocated physical FLASH/ROM space, the operation of the $\overline{\text{ECS}}$ signal will additionally depend upon the state of the ROMHM bit (see Section 3.3.1.3, “Miscellaneous System Control Register (MISC)”) in the MISC register. Table 3-16, Table 3-17, Table 3-18, and Table 3-19 summarize the functionality of these signals based upon the allocated memory configuration. Again, this signal information is only available externally when the EMK bit is set and the system is in an expanded mode.

Table 3-16. 0K Byte Physical FLASH/ROM Allocated

Address Space	Page Window Access	ROMHM	ECS	XAB19:14
0x0000–0x3FFF	N/A	N/A	1	0x3D

0xC000–0xFFFF	N/A	N/A	0	0x3F

A graphical example of a memory paging for a system configured as 1M byte on-chip FLASH/ROM with 64K allocated physical space is given in Figure 3-11.

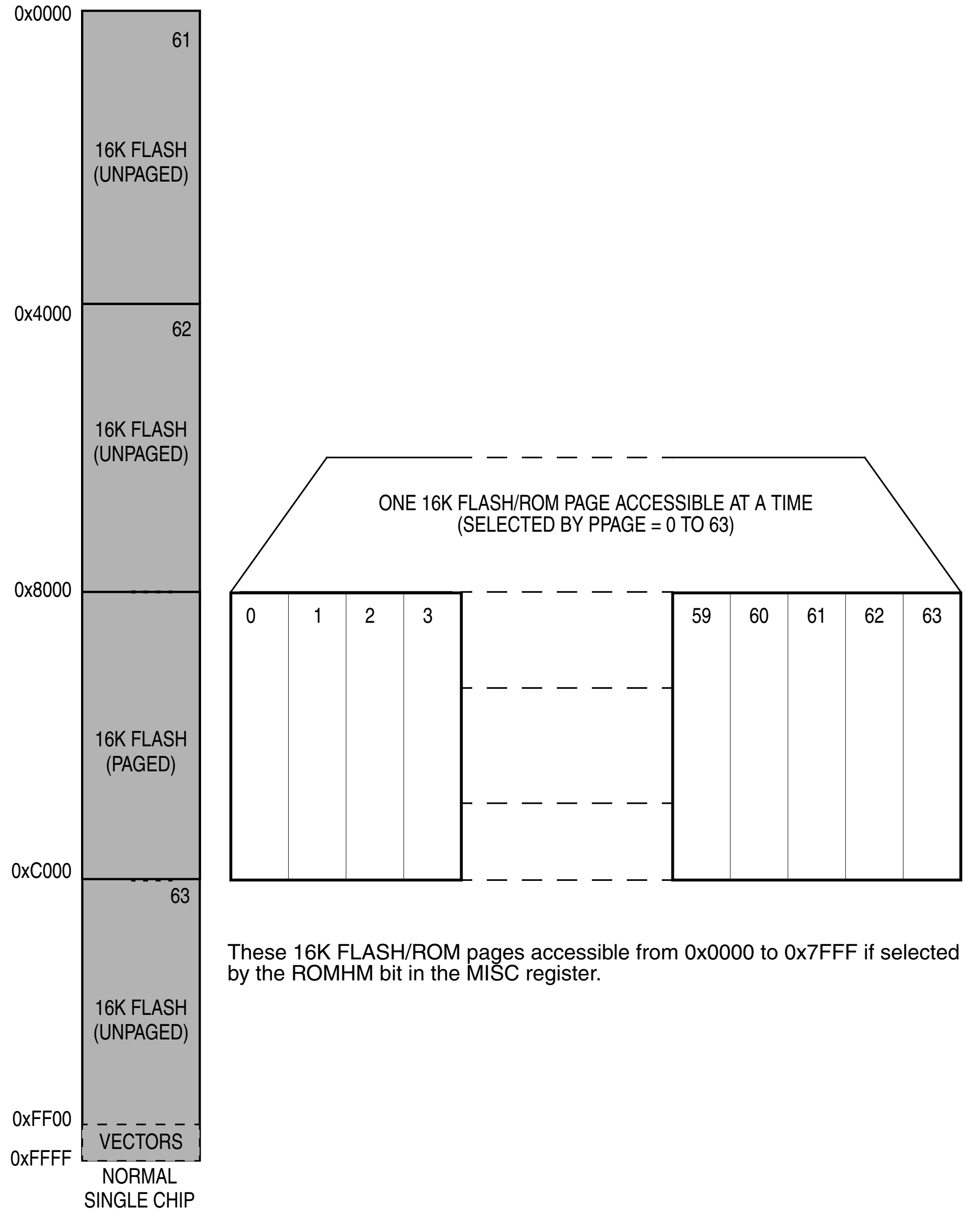

Figure 3-11. Memory Paging Example: 1M Byte On-Chip FLASH/ROM, 64K Allocation

Chapter 4
Multiplexed External Bus Interface (MEBIV3) Block Description

4.1 Introduction

This section describes the functionality of the multiplexed external bus interface (MEBI) sub-block of the S12 core platform. The functionality of the module is closely coupled with the S12 CPU and the memory map controller (MMC) sub-blocks.

Figure 4-1 is a block diagram of the MEBI. In Figure 4-1, the signals on the right hand side represent pins that are accessible externally. On some chips, these may not all be bonded out.

The MEBI sub-block of the core serves to provide access and/or visibility to internal core data manipulation operations including timing reference information at the external boundary of the core and/or system. Depending upon the system operating mode and the state of bits within the control registers of the MEBI, the internal 16-bit read and write data operations will be represented in 8-bit or 16-bit accesses externally. Using control information from other blocks within the system, the MEBI will determine the appropriate type of data access to be generated.

4.1.1 Features

The block name includes these distinctive features:

- External bus controller with four 8-bit ports A,B, E, and K
- Data and data direction registers for ports A, B, E, and K when used as general-purpose I/O
- Control register to enable/disable alternate functions on ports E and K
- Mode control register
- Control register to enable/disable pull-ups on ports A, B, E, and K
- Control register to enable/disable reduced output drive on ports A, B, E, and K
- Control register to configure external clock behavior
- Control register to configure $\overline{\text{IRQ}}$ pin operation
- Logic to capture and synchronize external interrupt pin inputs

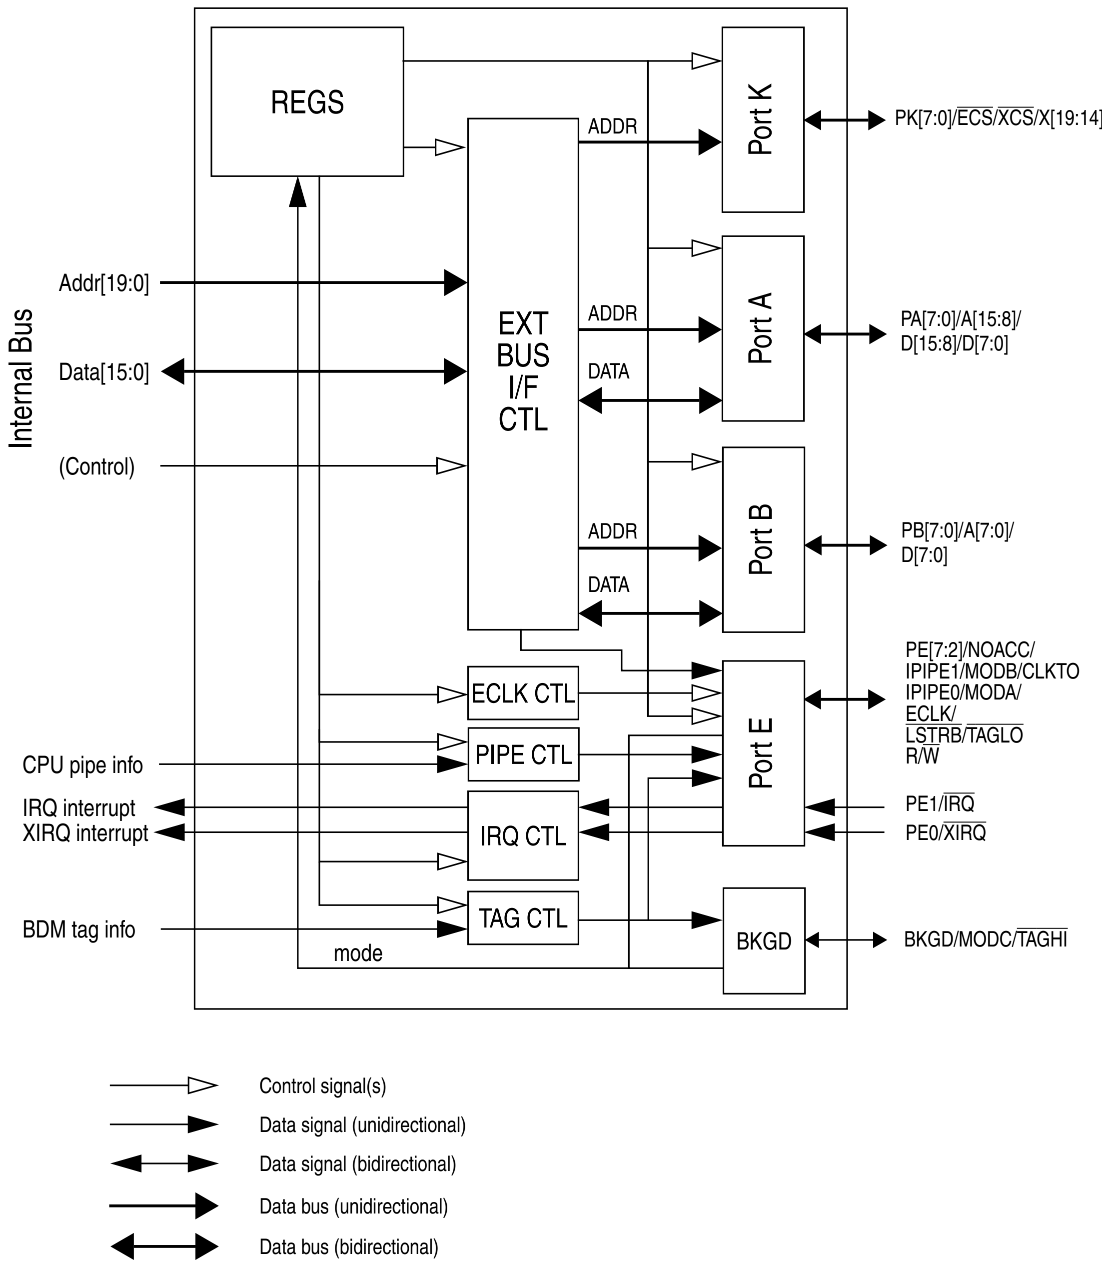

Figure 4-1. MEBI Block Diagram

4.1.2 Modes of Operation

- Normal expanded wide mode

  Ports A and B are configured as a 16-bit multiplexed address and data bus and port E provides bus control and status signals. This mode allows 16-bit external memory and peripheral devices to be interfaced to the system.
- Normal expanded narrow mode

  Ports A and B are configured as a 16-bit address bus and port A is multiplexed with 8-bit data. Port E provides bus control and status signals. This mode allows 8-bit external memory and peripheral devices to be interfaced to the system.
- Normal single-chip mode

  There is no external expansion bus in this mode. The processor program is executed from internal memory. Ports A, B, K, and most of E are available as general-purpose I/O.
- Special single-chip mode

  This mode is generally used for debugging single-chip operation, boot-strapping, or security related operations. The active background mode is in control of CPU execution and BDM firmware is waiting for additional serial commands through the BKGD pin. There is no external expansion bus after reset in this mode.
- Emulation expanded wide mode

  Developers use this mode for emulation systems in which the users target application is normal expanded wide mode.
- Emulation expanded narrow mode

  Developers use this mode for emulation systems in which the users target application is normal expanded narrow mode.
- Special test mode

  Ports A and B are configured as a 16-bit multiplexed address and data bus and port E provides bus control and status signals. In special test mode, the write protection of many control bits is lifted so that they can be thoroughly tested without needing to go through reset.
- Special peripheral mode

  This mode is intended for Freescale Semiconductor factory testing of the system. The CPU is inactive and an external (tester) bus master drives address, data, and bus control signals.

4.2 External Signal Description

In typical implementations, the MEBI sub-block of the core interfaces directly with external system pins. Some pins may not be bonded out in all implementations.

Table 4-1 outlines the pin names and functions and gives a brief description of their operation reset state of these pins and associated pull-ups or pull-downs is dependent on the mode of operation and on the integration of this block at the chip level (chip dependent).

Table 4-1. External System Pins Associated With MEBI

Pin Name	Pin Functions	Description
BKGD/MODC/ $\overline{\text{TAGHI}}$	MODC	At the rising edge on $\overline{\text{RESET}}$, the state of this pin is registered into the MODC bit to set the mode. (This pin always has an internal pullup.)
	BKGD	Pseudo open-drain communication pin for the single-wire background debug mode. There is an internal pull-up resistor on this pin.
	$\overline{\text{TAGHI}}$	When instruction tagging is on, a 0 at the falling edge of E tags the high half of the instruction word being read into the instruction queue.
PA7/A15/D15/D7 thru PA0/A8/D8/D0	PA7–PA0	General-purpose I/O pins, see PORTA and DDRA registers.
	A15–A8	High-order address lines multiplexed during ECLK low. Outputs except in special peripheral mode where they are inputs from an external tester system.
	D15–D8	High-order bidirectional data lines multiplexed during ECLK high in expanded wide modes, special peripheral mode, and visible internal accesses (IVIS = 1) in emulation expanded narrow mode. Direction of data transfer is generally indicated by R/$\overline{\text{W}}$.
	D15/D7 thru D8/D0	Alternate high-order and low-order bytes of the bidirectional data lines multiplexed during ECLK high in expanded narrow modes and narrow accesses in wide modes. Direction of data transfer is generally indicated by R/$\overline{\text{W}}$.
PB7/A7/D7 thru PB0/A0/D0	PB7–PB0	General-purpose I/O pins, see PORTB and DDRB registers.
	A7–A0	Low-order address lines multiplexed during ECLK low. Outputs except in special peripheral mode where they are inputs from an external tester system.
	D7–D0	Low-order bidirectional data lines multiplexed during ECLK high in expanded wide modes, special peripheral mode, and visible internal accesses (with IVIS = 1) in emulation expanded narrow mode. Direction of data transfer is generally indicated by R/$\overline{\text{W}}$.
PE7/NOACC	PE7	General-purpose I/O pin, see PORTE and DDRE registers.
	NOACC	CPU No Access output. Indicates whether the current cycle is a free cycle. Only available in expanded modes.
PE6/IPIPE1/ MODB/CLKTO	MODB	At the rising edge of $\overline{\text{RESET}}$, the state of this pin is registered into the MODB bit to set the mode.
	PE6	General-purpose I/O pin, see PORTE and DDRE registers.
	IPIPE1	Instruction pipe status bit 1, enabled by PIPOE bit in PEAR.
	CLKTO	System clock test output. Only available in special modes. PIPOE = 1 overrides this function. The enable for this function is in the clock module.
PE5/IPIPE0/MODA	MODA	At the rising edge on $\overline{\text{RESET}}$, the state of this pin is registered into the MODA bit to set the mode.
	PE5	General-purpose I/O pin, see PORTE and DDRE registers.
	IPIPE0	Instruction pipe status bit 0, enabled by PIPOE bit in PEAR.

Table 4-1. External System Pins Associated With MEBI (continued)

Pin Name	Pin Functions	Description
PE4/ECLK	PE4	General-purpose I/O pin, see PORTE and DDRE registers.
	ECLK	Bus timing reference clock, can operate as a free-running clock at the system clock rate or to produce one low-high clock per visible access, with the high period stretched for slow accesses. ECLK is controlled by the NECLK bit in PEAR, the IVIS bit in MODE, and the ESTR bit in EBICTL.
PE3/$\overline{\text{LSTRB}}$/ $\overline{\text{TAGLO}}$	PE3	General-purpose I/O pin, see PORTE and DDRE registers.
	$\overline{\text{LSTRB}}$	Low strobe bar, 0 indicates valid data on D7–D0.
	SZ8	In special peripheral mode, this pin is an input indicating the size of the data transfer (0 = 16-bit; 1 = 8-bit).
	$\overline{\text{TAGLO}}$	In expanded wide mode or emulation narrow modes, when instruction tagging is on and low strobe is enabled, a 0 at the falling edge of E tags the low half of the instruction word being read into the instruction queue.
PE2/R/$\overline{\text{W}}$	PE2	General-purpose I/O pin, see PORTE and DDRE registers.
	R/$\overline{\text{W}}$	Read/write, indicates the direction of internal data transfers. This is an output except in special peripheral mode where it is an input.
PE1/$\overline{\text{IRQ}}$	PE1	General-purpose input-only pin, can be read even if $\overline{\text{IRQ}}$ enabled.
	$\overline{\text{IRQ}}$	Maskable interrupt request, can be level sensitive or edge sensitive.
PE0/$\overline{\text{XIRQ}}$	PE0	General-purpose input-only pin.
	$\overline{\text{XIRQ}}$	Non-maskable interrupt input.
PK7/$\overline{\text{ECS}}$	PK7	General-purpose I/O pin, see PORTK and DDRK registers.
	$\overline{\text{ECS}}$	Emulation chip select
PK6/$\overline{\text{XCS}}$	PK6	General-purpose I/O pin, see PORTK and DDRK registers.
	$\overline{\text{XCS}}$	External data chip select
PK5/X19 thru PK0/X14	PK5–PK0	General-purpose I/O pins, see PORTK and DDRK registers.
	X19–X14	Memory expansion addresses

Detailed descriptions of these pins can be found in the device overview chapter.

4.3 Memory Map and Register Definition

A summary of the registers associated with the MEBI sub-block is shown in Figure 4-2. Detailed descriptions of the registers and bits are given in the subsections that follow. On most chips the registers are mappable. Therefore, the upper bits may not be all 0s as shown in the table and descriptions.

4.3.1 Module Memory Map

Figure 4-2. MEBI Register Summary (continued)

4.3.2 Register Descriptions

4.3.2.1 Port A Data Register (PORTA)

Module Base + 0x0000
Starting address location affected by INITRG register setting.

	7	6	5	4	3	2	1	0
R/W	Bit 7	6	5	4	3	2	1	Bit 0
Reset	0	0	0	0	0	0	0	0
Single Chip	PA7	PA6	PA5	PA4	PA3	PA2	PA1	PA0
Expanded Wide, Emulation Narrow with IVIS, and Peripheral	AB/DB15	AB/DB14	AB/DB13	AB/DB12	AB/DB11	AB/DB10	AB/DB9	AB/DB8
Expanded Narrow	AB15 and DB15/DB7	AB14 and DB14/DB6	AB13 and DB13/DB5	AB12 and DB12/DB4	AB11 and DB11/DB3	AB10 and DB10/DB2	AB9 and DB9/DB1	AB8 and DB8/DB0

Figure 4-3. Port A Data Register (PORTA)

Read: Anytime when register is in the map

Write: Anytime when register is in the map

Port A bits 7 through 0 are associated with address lines A15 through A8 respectively and data lines D15/D7 through D8/D0 respectively. When this port is not used for external addresses such as in single-chip mode, these pins can be used as general-purpose I/O. Data direction register A (DDRA) determines the primary direction of each pin. DDRA also determines the source of data for a read of PORTA.

This register is not in the on-chip memory map in expanded and special peripheral modes. Therefore, these accesses will be echoed externally.

NOTE

To ensure that you read the value present on the PORTA pins, always wait at least one cycle after writing to the DDRA register before reading from the PORTA register.

4.3.2.2 Port B Data Register (PORTB)

Module Base + 0x0001
Starting address location affected by INITRG register setting.

	7	6	5	4	3	2	1	0
R/W	Bit 7	6	5	4	3	2	1	Bit 0
Reset	0	0	0	0	0	0	0	0
Single Chip	PB7	PB6	PB5	PB4	PB3	PB2	PB1	PB0
Expanded Wide, Emulation Narrow with IVIS, and Peripheral	AB/DB7	AB/DB6	AB/DB5	AB/DB4	AB/DB3	AB/DB2	AB/DB1	AB/DB0
Expanded Narrow	AB7	AB6	AB5	AB4	AB3	AB2	AB1	AB0

Figure 4-4. Port A Data Register (PORTB)

Read: Anytime when register is in the map

Write: Anytime when register is in the map

Port B bits 7 through 0 are associated with address lines A7 through A0 respectively and data lines D7 through D0 respectively. When this port is not used for external addresses, such as in single-chip mode, these pins can be used as general-purpose I/O. Data direction register B (DDRB) determines the primary direction of each pin. DDRB also determines the source of data for a read of PORTB.

This register is not in the on-chip memory map in expanded and special peripheral modes. Therefore, these accesses will be echoed externally.

NOTE

To ensure that you read the value present on the PORTB pins, always wait at least one cycle after writing to the DDRB register before reading from the PORTB register.

4.3.2.3 Data Direction Register A (DDRA)

Module Base + 0x0002
Starting address location affected by INITRG register setting.

	7	6	5	4	3	2	1	0
R W	Bit 7	6	5	4	3	2	1	Bit 0
Reset	0	0	0	0	0	0	0	0

Figure 4-5. Data Direction Register A (DDRA)

Read: Anytime when register is in the map

Write: Anytime when register is in the map

This register controls the data direction for port A. When port A is operating as a general-purpose I/O port, DDRA determines the primary direction for each port A pin. A 1 causes the associated port pin to be an output and a 0 causes the associated pin to be a high-impedance input. The value in a DDR bit also affects the source of data for reads of the corresponding PORTA register. If the DDR bit is 0 (input) the buffered pin input state is read. If the DDR bit is 1 (output) the associated port data register bit state is read.

This register is not in the on-chip memory map in expanded and special peripheral modes. Therefore, these accesses will be echoed externally. It is reset to 0x00 so the DDR does not override the three-state control signals.

Table 4-2. DDRA Field Descriptions

Field	Description
7:0 DDRA	**Data Direction Port A** 0 Configure the corresponding I/O pin as an input 1 Configure the corresponding I/O pin as an output

4.3.2.4 Data Direction Register B (DDRB)

Module Base + 0x0003
Starting address location affected by INITRG register setting.

	7	6	5	4	3	2	1	0
R/W	Bit 7	6	5	4	3	2	1	Bit 0
Reset	0	0	0	0	0	0	0	0

Figure 4-6. Data Direction Register B (DDRB)

Read: Anytime when register is in the map

Write: Anytime when register is in the map

This register controls the data direction for port B. When port B is operating as a general-purpose I/O port, DDRB determines the primary direction for each port B pin. A 1 causes the associated port pin to be an output and a 0 causes the associated pin to be a high-impedance input. The value in a DDR bit also affects the source of data for reads of the corresponding PORTB register. If the DDR bit is 0 (input) the buffered pin input state is read. If the DDR bit is 1 (output) the associated port data register bit state is read.

This register is not in the on-chip memory map in expanded and special peripheral modes. Therefore, these accesses will be echoed externally. It is reset to 0x00 so the DDR does not override the three-state control signals.

= Unimplemented or Reserved   u = Unaffected by reset

Figure 4-11. Port E Data Register (PORTE)

Read: Anytime when register is in the map

Write: Anytime when register is in the map

Port E is associated with external bus control signals and interrupt inputs. These include mode select (MODB/IPIPE1, MODA/IPIPE0), E clock, size ($\overline{\text{LSTRB}}$/$\overline{\text{TAGLO}}$), read/write (R/$\overline{\text{W}}$), $\overline{\text{IRQ}}$, and $\overline{\text{XIRQ}}$. When not used for one of these specific functions, port E pins 7:2 can be used as general-purpose I/O and pins 1:0 can be used as general-purpose input. The port E assignment register (PEAR) selects the function of each pin and DDRE determines whether each pin is an input or output when it is configured to be general-purpose I/O. DDRE also determines the source of data for a read of PORTE.

Some of these pins have software selectable pull-ups (PE7, ECLK, $\overline{\text{LSTRB}}$, R/$\overline{\text{W}}$, $\overline{\text{IRQ}}$, and $\overline{\text{XIRQ}}$). A single control bit enables the pull-ups for all of these pins when they are configured as inputs.

This register is not in the on-chip map in special peripheral mode or in expanded modes when the EME bit is set. Therefore, these accesses will be echoed externally.

NOTE

It is unwise to write PORTE and DDRE as a word access. If you are changing port E pins from being inputs to outputs, the data may have extra transitions during the write. It is best to initialize PORTE before enabling as outputs.

NOTE

To ensure that you read the value present on the PORTE pins, always wait at least one cycle after writing to the DDRE register before reading from the PORTE register.

4.3.2.7 Data Direction Register E (DDRE)

Module Base + 0x0009
Starting address location affected by INITRG register setting.

	7	6	5	4	3	2	1	0
R	Bit 7	6	5	4	3	Bit 2	0	0
W								
Reset	0	0	0	0	0	0	0	0

(shaded) = Unimplemented or Reserved

Figure 4-12. Data Direction Register E (DDRE)

Read: Anytime when register is in the map

Write: Anytime when register is in the map

Data direction register E is associated with port E. For bits in port E that are configured as general-purpose I/O lines, DDRE determines the primary direction of each of these pins. A 1 causes the associated bit to be an output and a 0 causes the associated bit to be an input. Port E bit 1 (associated with $\overline{\text{IRQ}}$) and bit 0 (associated with $\overline{\text{XIRQ}}$) cannot be configured as outputs. Port E, bits 1 and 0, can be read regardless of whether the alternate interrupt function is enabled. The value in a DDR bit also affects the source of data for reads of the corresponding PORTE register. If the DDR bit is 0 (input) the buffered pin input state is read. If the DDR bit is 1 (output) the associated port data register bit state is read.

This register is not in the on-chip memory map in expanded and special peripheral modes. Therefore, these accesses will be echoed externally. Also, it is not in the map in expanded modes while the EME control bit is set.

Table 4-4. DDRE Field Descriptions

Field	Description
7:2 DDRE	**Data Direction Port E** 0 Configure the corresponding I/O pin as an input 1 Configure the corresponding I/O pin as an output **Note:** It is unwise to write PORTE and DDRE as a word access. If you are changing port E pins from inputs to outputs, the data may have extra transitions during the write. It is best to initialize PORTE before enabling as outputs.

Read: Anytime (provided this register is in the map).

Write: Each bit has specific write conditions. Please refer to the descriptions of each bit on the following pages.

Port E serves as general-purpose I/O or as system and bus control signals. The PEAR register is used to choose between the general-purpose I/O function and the alternate control functions. When an alternate control function is selected, the associated DDRE bits are overridden.

The reset condition of this register depends on the mode of operation because bus control signals are needed immediately after reset in some modes. In normal single-chip mode, no external bus control signals are needed so all of port E is configured for general-purpose I/O. In normal expanded modes, only the E clock is configured for its alternate bus control function and the other bits of port E are configured for general-purpose I/O. As the reset vector is located in external memory, the E clock is required for this access. R/$\overline{W}$ is only needed by the system when there are external writable resources. If the normal expanded system needs any other bus control signals, PEAR would need to be written before any access that needed the additional signals. In special test and emulation modes, IPIPE1, IPIPE0, E, $\overline{LSTRB}$, and R/$\overline{W}$ are configured out of reset as bus control signals.

This register is not in the on-chip memory map in expanded and special peripheral modes. Therefore, these accesses will be echoed externally.

Table 4-5. PEAR Field Descriptions

Field	Description
7 NOACCE	**CPU No Access Output Enable** Normal: write once Emulation: write never Special: write anytime 1 The associated pin (port E, bit 7) is general-purpose I/O. 0 The associated pin (port E, bit 7) is output and indicates whether the cycle is a CPU free cycle. This bit has no effect in single-chip or special peripheral modes.
5 PIPOE	**Pipe Status Signal Output Enable** Normal: write once Emulation: write never Special: write anytime. 0 The associated pins (port E, bits 6:5) are general-purpose I/O. 1 The associated pins (port E, bits 6:5) are outputs and indicate the state of the instruction queue This bit has no effect in single-chip or special peripheral modes.
4 NECLK	**No External E Clock** Normal and special: write anytime Emulation: write never 0 The associated pin (port E, bit 4) is the external E clock pin. External E clock is free-running if ESTR = 0 1 The associated pin (port E, bit 4) is a general-purpose I/O pin. External E clock is available as an output in all modes.
3 LSTRE	**Low Strobe ($\overline{\text{LSTRB}}$) Enable** Normal: write once Emulation: write never Special: write anytime. 0 The associated pin (port E, bit 3) is a general-purpose I/O pin. 1 The associated pin (port E, bit 3) is configured as the $\overline{\text{LSTRB}}$ bus control output. If BDM tagging is enabled, $\overline{\text{TAGLO}}$ is multiplexed in on the rising edge of ECLK and $\overline{\text{LSTRB}}$ is driven out on the falling edge of ECLK. This bit has no effect in single-chip, peripheral, or normal expanded narrow modes. **Note:** $\overline{\text{LSTRB}}$ is used during external writes. After reset in normal expanded mode, $\overline{\text{LSTRB}}$ is disabled to provide an extra I/O pin. If $\overline{\text{LSTRB}}$ is needed, it should be enabled before any external writes. External reads do not normally need $\overline{\text{LSTRB}}$ because all 16 data bits can be driven even if the system only needs 8 bits of data.
2 RDWE	**Read/Write Enable** Normal: write once Emulation: write never Special: write anytime 0 The associated pin (port E, bit 2) is a general-purpose I/O pin. 1 The associated pin (port E, bit 2) is configured as the R/$\overline{\text{W}}$ pin This bit has no effect in single-chip or special peripheral modes. **Note:** R/$\overline{\text{W}}$ is used for external writes. After reset in normal expanded mode, R/$\overline{\text{W}}$ is disabled to provide an extra I/O pin. If R/$\overline{\text{W}}$ is needed it should be enabled before any external writes.

4.3.2.9 Mode Register (MODE)

Module Base + 0x000B
Starting address location affected by INITRG register setting.

	7	6	5	4	3	2	1	0
R	MODC	MODB	MODA	0	IVIS	0	EMK	EME
W

Special Test	0	1	0	0	1	0	0	0
Emulation Expanded Wide	0	1	1	0	1	0	1	1
Normal Single Chip	1	0	0	0	0	0	0	0
Normal Expanded Narrow	1	0	1	0	0	0	0	0
Peripheral	1	1	0	0	0	0	0	0
Normal Expanded Wide	1	1	1	0	0	0	0	0

= Unimplemented or Reserved

Figure 4-14. Mode Register (MODE)

Read: Anytime (provided this register is in the map).

Write: Each bit has specific write conditions. Please refer to the descriptions of each bit on the following pages.

The MODE register is used to establish the operating mode and other miscellaneous functions (i.e., internal visibility and emulation of port E and K).

In special peripheral mode, this register is not accessible but it is reset as shown to system configuration features. Changes to bits in the MODE register are delayed one cycle after the write.

This register is not in the on-chip memory map in expanded and special peripheral modes. Therefore, these accesses will be echoed externally.

Table 4-6. MODE Field Descriptions

Field	Description
7:5 MOD[C:A]	**Mode Select Bits** — These bits indicate the current operating mode. If MODA = 1, then MODC, MODB, and MODA are write never. If MODC = MODA = 0, then MODC, MODB, and MODA are writable with the exception that you cannot change to or from special peripheral mode If MODC = 1, MODB = 0, and MODA = 0, then MODC is write never. MODB and MODA are write once, except that you cannot change to special peripheral mode. From normal single-chip, only normal expanded narrow and normal expanded wide modes are available. See Table 4-7 and Table 4-15.
3 IVIS	**Internal Visibility (for both read and write accesses)** — This bit determines whether internal accesses generate a bus cycle that is visible on the external bus. Normal: write once Emulation: write never Special: write anytime 0 No visibility of internal bus operations on external bus. 1 Internal bus operations are visible on external bus.
1 EMK	**Emulate Port K** Normal: write once Emulation: write never Special: write anytime 0 PORTK and DDRK are in the memory map so port K can be used for general-purpose I/O. 1 If in any expanded mode, PORTK and DDRK are removed from the memory map. In single-chip modes, PORTK and DDRK are always in the map regardless of the state of this bit. In special peripheral mode, PORTK and DDRK are never in the map regardless of the state of this bit.
0 EME	**Emulate Port E** Normal and Emulation: write never Special: write anytime 0 PORTE and DDRE are in the memory map so port E can be used for general-purpose I/O. 1 If in any expanded mode or special peripheral mode, PORTE and DDRE are removed from the memory map. Removing the registers from the map allows the user to emulate the function of these registers externally. In single-chip modes, PORTE and DDRE are always in the map regardless of the state of this bit.

Table 4-7. MODC, MODB, and MODA Write Capability[1]

MODC	MODB	MODA	Mode	MODx Write Capability
0	0	0	Special single chip	MODC, MODB, and MODA write anytime but not to 110[2]
0	0	1	Emulation narrow	No write
0	1	0	Special test	MODC, MODB, and MODA write anytime but not to 110[(2)]
0	1	1	Emulation wide	No write
1	0	0	Normal single chip	MODC write never, MODB and MODA write once but not to 110
1	0	1	Normal expanded narrow	No write
1	1	0	Special peripheral	No write
1	1	1	Normal expanded wide	No write

1 No writes to the MOD bits are allowed while operating in a secure mode. For more details, refer to the device overview chapter.

2 If you are in a special single-chip or special test mode and you write to this register, changing to normal single-chip mode, then one allowed write to this register remains. If you write to normal expanded or emulation mode, then no writes remain.

4.3.2.10 Pull-Up Control Register (PUCR)

Module Base + 0x000C
Starting address location affected by INITRG register setting.

NOTES:
1. The default value of this parameter is shown. Please refer to the device overview chapter to determine the actual reset state of this register.

= Unimplemented or Reserved

Figure 4-15. Pullup Control Register (PUCR)

Read: Anytime (provided this register is in the map).

Write: Anytime (provided this register is in the map).

This register is used to select pull resistors for the pins associated with the core ports. Pull resistors are assigned on a per-port basis and apply to any pin in the corresponding port that is currently configured as an input. The polarity of these pull resistors is determined by chip integration. Please refer to the device overview chapter to determine the polarity of these resistors.

This register is not in the on-chip memory map in expanded and special peripheral modes. Therefore, these accesses will be echoed externally.

NOTE

These bits have no effect when the associated pin(s) are outputs. (The pull resistors are inactive.)

Table 4-8. PUCR Field Descriptions

Field	Description
7 PUPKE	**Pull-Up Port K Enable** 0 Port K pull resistors are disabled. 1 Enable pull resistors for port K input pins.
4 PUPEE	**Pull-Up Port E Enable** 0 Port E pull resistors on bits 7, 4:0 are disabled. 1 Enable pull resistors for port E input pins bits 7, 4:0. **Note:** Pins 5 and 6 of port E have pull resistors which are only enabled during reset. This bit has no effect on these pins.
1 PUPBE	**Pull-Up Port B Enable** 0 Port B pull resistors are disabled. 1 Enable pull resistors for all port B input pins.
0 PUPAE	**Pull-Up Port A Enable** 0 Port A pull resistors are disabled. 1 Enable pull resistors for all port A input pins.

4.3.2.11 Reduced Drive Register (RDRIV)

Module Base + 0x000D
Starting address location affected by INITRG register setting.

	7	6	5	4	3	2	1	0

= Unimplemented or Reserved

Figure 4-16. Reduced Drive Register (RDRIV)

Read: Anytime (provided this register is in the map)

Write: Anytime (provided this register is in the map)

This register is used to select reduced drive for the pins associated with the core ports. This gives reduced power consumption and reduced RFI with a slight increase in transition time (depending on loading). This feature would be used on ports which have a light loading. The reduced drive function is independent of which function is being used on a particular port.

This register is not in the on-chip memory map in expanded and special peripheral modes. Therefore, these accesses will be echoed externally.

Table 4-9. RDRIV Field Descriptions

Field	Description
7 RDRK	**Reduced Drive of Port K** 0 All port K output pins have full drive enabled. 1 All port K output pins have reduced drive enabled.
4 RDPE	**Reduced Drive of Port E** 0 All port E output pins have full drive enabled. 1 All port E output pins have reduced drive enabled.
1 RDPB	**Reduced Drive of Port B** 0 All port B output pins have full drive enabled. 1 All port B output pins have reduced drive enabled.
0 RDPA	**Reduced Drive of Ports A** 0 All port A output pins have full drive enabled. 1 All port A output pins have reduced drive enabled.

4.3.2.12 External Bus Interface Control Register (EBICTL)

Module Base + 0x000E

Figure 4-20. Port K Data Register (PORTK)

Read: Anytime

Write: Anytime

This port is associated with the internal memory expansion emulation pins. When the port is not enabled to emulate the internal memory expansion, the port pins are used as general-purpose I/O. When port K is operating as a general-purpose I/O port, DDRK determines the primary direction for each port K pin. A 1 causes the associated port pin to be an output and a 0 causes the associated pin to be a high-impedance input. The value in a DDR bit also affects the source of data for reads of the corresponding PORTK register. If the DDR bit is 0 (input) the buffered pin input is read. If the DDR bit is 1 (output) the output of the port data register is read.

This register is not in the map in peripheral or expanded modes while the EMK control bit in MODE register is set. Therefore, these accesses will be echoed externally.

When inputs, these pins can be selected to be high impedance or pulled up, based upon the state of the PUPKE bit in the PUCR register.

Table 4-12. PORTK Field Descriptions

Field	Description
7 Port K, Bit 7	**Port K, Bit 7** — This bit is used as an emulation chip select signal for the emulation of the internal memory expansion, or as general-purpose I/O, depending upon the state of the EMK bit in the MODE register. While this bit is used as a chip select, the external bit will return to its de-asserted state (V_{DD}) for approximately 1/4 cycle just after the negative edge of ECLK, unless the external access is stretched and ECLK is free-running (ESTR bit in EBICTL = 0). See the MMC block description chapter for additional details on when this signal will be active.
6 Port K, Bit 6	**Port K, Bit 6** — This bit is used as an external chip select signal for most external accesses that are not selected by $\overline{\text{ECS}}$ (see the MMC block description chapter for more details), depending upon the state the of the EMK bit in the MODE register. While this bit is used as a chip select, the external pin will return to its de-asserted state (V_{DD}) for approximately 1/4 cycle just after the negative edge of ECLK, unless the external access is stretched and ECLK is free-running (ESTR bit in EBICTL = 0).
5:0 Port K, Bits 5:0	**Port K, Bits 5:0** — These six bits are used to determine which FLASH/ROM or external memory array page is being accessed. They can be viewed as expanded addresses XAB19–XAB14 of the 20-bit address used to access up to1M byte internal FLASH/ROM or external memory array. Alternatively, these bits can be used for general-purpose I/O depending upon the state of the EMK bit in the MODE register.

4.3.2.16 Port K Data Direction Register (DDRK)

Module Base + 0x0033
Starting address location affected by INITRG register setting.

	7	6	5	4	3	2	1	0
R W	Bit 7	6	5	4	3	2	1	Bit 0
Reset	0	0	0	0	0	0	0	0

Figure 4-21. Port K Data Direction Register (DDRK)

Read: Anytime

Write: Anytime

This register determines the primary direction for each port K pin configured as general-purpose I/O. This register is not in the map in peripheral or expanded modes while the EMK control bit in MODE register is set. Therefore, these accesses will be echoed externally.

Table 4-13. EBICTL Field Descriptions

Field	Description
7:0 DDRK	**Data Direction Port K Bits** 0 Associated pin is a high-impedance input 1 Associated pin is an output **Note:** It is unwise to write PORTK and DDRK as a word access. If you are changing port K pins from inputs to outputs, the data may have extra transitions during the write. It is best to initialize PORTK before enabling as outputs. **Note:** To ensure that you read the correct value from the PORTK pins, always wait at least one cycle after writing to the DDRK register before reading from the PORTK register.

4.4 Functional Description

4.4.1 Detecting Access Type from External Signals

The external signals $\overline{\text{LSTRB}}$, R/$\overline{\text{W}}$, and AB0 indicate the type of bus access that is taking place. Accesses to the internal RAM module are the only type of access that would produce $\overline{\text{LSTRB}}$ = AB0 = 1, because the internal RAM is specifically designed to allow misaligned 16-bit accesses in a single cycle. In these cases the data for the address that was accessed is on the low half of the data bus and the data for address + 1 is on the high half of the data bus. This is summarized in Table 4-14.

Table 4-14. Access Type vs. Bus Control Pins

$\overline{\text{LSTRB}}$	AB0	R/$\overline{\text{W}}$	Type of Access
1	0	1	8-bit read of an even address
0	1	1	8-bit read of an odd address
1	0	0	8-bit write of an even address
0	1	0	8-bit write of an odd address

Table 4-14. Access Type vs. Bus Control Pins

$\overline{LSTRB}$	AB0	R/$\overline{W}$	Type of Access
0	0	1	16-bit read of an even address
1	1	1	16-bit read of an odd address (low/high data swapped)
0	0	0	16-bit write to an even address
1	1	0	16-bit write to an odd address (low/high data swapped)

4.4.2 Stretched Bus Cycles

In order to allow fast internal bus cycles to coexist in a system with slower external memory resources, the HCS12 supports the concept of stretched bus cycles (module timing reference clocks for timers and baud rate generators are not affected by this stretching). Control bits in the MISC register in the MMC sub-block of the core specify the amount of stretch (0, 1, 2, or 3 periods of the internal bus-rate clock). While stretching, the CPU state machines are all held in their current state. At this point in the CPU bus cycle, write data would already be driven onto the data bus so the length of time write data is valid is extended in the case of a stretched bus cycle. Read data would not be captured by the system until the E clock falling edge. In the case of a stretched bus cycle, read data is not required until the specified setup time before the falling edge of the stretched E clock. The chip selects, and R/$\overline{W}$ signals remain valid during the period of stretching (throughout the stretched E high time).

NOTE

The address portion of the bus cycle is not stretched.

4.4.3 Modes of Operation

The operating mode out of reset is determined by the states of the MODC, MODB, and MODA pins during reset (Table 4-15). The MODC, MODB, and MODA bits in the MODE register show the current operating mode and provide limited mode switching during operation. The states of the MODC, MODB, and MODA pins are latched into these bits on the rising edge of the reset signal.

Table 4-15. Mode Selection

MODC	MODB	MODA	Mode Description
0	0	0	Special Single Chip, BDM allowed and ACTIVE. BDM is allowed in all other modes but a serial command is required to make BDM active.
0	0	1	Emulation Expanded Narrow, BDM allowed
0	1	0	Special Test (Expanded Wide), BDM allowed
0	1	1	Emulation Expanded Wide, BDM allowed
1	0	0	Normal Single Chip, BDM allowed
1	0	1	Normal Expanded Narrow, BDM allowed
1	1	0	Peripheral; BDM allowed but bus operations would cause bus conflicts (must not be used)
1	1	1	Normal Expanded Wide, BDM allowed

There are two basic types of operating modes:

1. Normal modes: Some registers and bits are protected against accidental changes.
2. Special modes: Allow greater access to protected control registers and bits for special purposes such as testing.

A system development and debug feature, background debug mode (BDM), is available in all modes. In special single-chip mode, BDM is active immediately after reset.

Some aspects of Port E are not mode dependent. Bit 1 of Port E is a general purpose input or the $\overline{\text{IRQ}}$ interrupt input. $\overline{\text{IRQ}}$ can be enabled by bits in the CPU's condition codes register but it is inhibited at reset so this pin is initially configured as a simple input with a pull-up. Bit 0 of Port E is a general purpose input or the $\overline{\text{XIRQ}}$ interrupt input. $\overline{\text{XIRQ}}$ can be enabled by bits in the CPU's condition codes register but it is inhibited at reset so this pin is initially configured as a simple input with a pull-up. The ESTR bit in the EBICTL register is set to one by reset in any user mode. This assures that the reset vector can be fetched even if it is located in an external slow memory device. The PE6/MODB/IPIPE1 and PE5/MODA/IPIPE0 pins act as high-impedance mode select inputs during reset.

The following paragraphs discuss the default bus setup and describe which aspects of the bus can be changed after reset on a per mode basis.

4.4.3.1 Normal Operating Modes

These modes provide three operating configurations. Background debug is available in all three modes, but must first be enabled for some operations by means of a BDM background command, then activated.

4.4.3.1.1 Normal Single-Chip Mode

There is no external expansion bus in this mode. All pins of Ports A, B and E are configured as general purpose I/O pins Port E bits 1 and 0 are available as general purpose input only pins with internal pull-ups enabled. All other pins of Port E are bidirectional I/O pins that are initially configured as high-impedance inputs with internal pull-ups enabled. Ports A and B are configured as high-impedance inputs with their internal pull-ups disabled.

The pins associated with Port E bits 6, 5, 3, and 2 cannot be configured for their alternate functions IPIPE1, IPIPE0, $\overline{\text{LSTRB}}$, and R/$\overline{\text{W}}$ while the MCU is in single chip modes. In single chip modes, the associated control bits PIPOE, LSTRE, and RDWE are reset to zero. Writing the opposite state into them in single chip mode does not change the operation of the associated Port E pins.

In normal single chip mode, the MODE register is writable one time. This allows a user program to change the bus mode to narrow or wide expanded mode and/or turn on visibility of internal accesses.

Port E, bit 4 can be configured for a free-running E clock output by clearing NECLK=0. Typically the only use for an E clock output while the MCU is in single chip modes would be to get a constant speed clock for use in the external application system.

4.4.3.1.2 Normal Expanded Wide Mode

In expanded wide modes, Ports A and B are configured as a 16-bit multiplexed address and data bus and Port E bit 4 is configured as the E clock output signal. These signals allow external memory and peripheral devices to be interfaced to the MCU.

Port E pins other than PE4/ECLK are configured as general purpose I/O pins (initially high-impedance inputs with internal pull-up resistors enabled). Control bits PIPOE, NECLK, LSTRE, and RDWE in the PEAR register can be used to configure Port E pins to act as bus control outputs instead of general purpose I/O pins.

It is possible to enable the pipe status signals on Port E bits 6 and 5 by setting the PIPOE bit in PEAR, but it would be unusual to do so in this mode. Development systems where pipe status signals are monitored would typically use the special variation of this mode.

The Port E bit 2 pin can be reconfigured as the $R/\overline{W}$ bus control signal by writing “1” to the RDWE bit in PEAR. If the expanded system includes external devices that can be written, such as RAM, the RDWE bit would need to be set before any attempt to write to an external location. If there are no writable resources in the external system, PE2 can be left as a general purpose I/O pin.

The Port E bit 3 pin can be reconfigured as the $\overline{LSTRB}$ bus control signal by writing “1” to the LSTRE bit in PEAR. The default condition of this pin is a general purpose input because the $\overline{LSTRB}$ function is not needed in all expanded wide applications.

The Port E bit 4 pin is initially configured as ECLK output with stretch. The E clock output function depends upon the settings of the NECLK bit in the PEAR register, the IVIS bit in the MODE register and the ESTR bit in the EBICTL register. The E clock is available for use in external select decode logic or as a constant speed clock for use in the external application system.

4.4.3.1.3 Normal Expanded Narrow Mode

This mode is used for lower cost production systems that use 8-bit wide external EPROMs or RAMs. Such systems take extra bus cycles to access 16-bit locations but this may be preferred over the extra cost of additional external memory devices.

Ports A and B are configured as a 16-bit address bus and Port A is multiplexed with data. Internal visibility is not available in this mode because the internal cycles would need to be split into two 8-bit cycles.

Since the PEAR register can only be written one time in this mode, use care to set all bits to the desired states during the single allowed write.

The PE3/$\overline{LSTRB}$ pin is always a general purpose I/O pin in normal expanded narrow mode. Although it is possible to write the LSTRE bit in PEAR to “1” in this mode, the state of LSTRE is overridden and Port E bit 3 cannot be reconfigured as the $\overline{LSTRB}$ output.

It is possible to enable the pipe status signals on Port E bits 6 and 5 by setting the PIPOE bit in PEAR, but it would be unusual to do so in this mode. LSTRB would also be needed to fully understand system activity. Development systems where pipe status signals are monitored would typically use special expanded wide mode or occasionally special expanded narrow mode.

The PE4/ECLK pin is initially configured as ECLK output with stretch. The E clock output function depends upon the settings of the NECLK bit in the PEAR register, the IVIS bit in the MODE register and the ESTR bit in the EBICTL register. In normal expanded narrow mode, the E clock is available for use in external select decode logic or as a constant speed clock for use in the external application system.

The PE2/R/W pin is initially configured as a general purpose input with a pull-up but this pin can be reconfigured as the R/$\overline{\text{W}}$ bus control signal by writing “1” to the RDWE bit in PEAR. If the expanded narrow system includes external devices that can be written such as RAM, the RDWE bit would need to be set before any attempt to write to an external location. If there are no writable resources in the external system, PE2 can be left as a general purpose I/O pin.

4.4.3.1.4 Emulation Expanded Wide Mode

In expanded wide modes, Ports A and B are configured as a 16-bit multiplexed address and data bus and Port E provides bus control and status signals. These signals allow external memory and peripheral devices to be interfaced to the MCU. These signals can also be used by a logic analyzer to monitor the progress of application programs.

The bus control related pins in Port E (PE7/NOACC, PE6/MODB/IPIPE1, PE5/MODA/IPIPE0, PE4/ECLK, PE3/$\overline{\text{LSTRB}}$/$\overline{\text{TAGLO}}$, and PE2/R/$\overline{\text{W}}$) are all configured to serve their bus control output functions rather than general purpose I/O. Notice that writes to the bus control enable bits in the PEAR register in emulation mode are restricted.

4.4.3.1.5 Emulation Expanded Narrow Mode

Expanded narrow modes are intended to allow connection of single 8-bit external memory devices for lower cost systems that do not need the performance of a full 16-bit external data bus. Accesses to internal resources that have been mapped external (i.e. PORTA, PORTB, DDRA, DDRB, PORTE, DDRE, PEAR, PUCR, RDRIV) will be accessed with a 16-bit data bus on Ports A and B. Accesses of 16-bit external words to addresses which are normally mapped external will be broken into two separate 8-bit accesses using Port A as an 8-bit data bus. Internal operations continue to use full 16-bit data paths. They are only visible externally as 16-bit information if IVIS=1.

Ports A and B are configured as multiplexed address and data output ports. During external accesses, address A15, data D15 and D7 are associated with PA7, address A0 is associated with PB0 and data D8 and D0 are associated with PA0. During internal visible accesses and accesses to internal resources that have been mapped external, address A15 and data D15 is associated with PA7 and address A0 and data D0 is associated with PB0.

The bus control related pins in Port E (PE7/NOACC, PE6/MODB/IPIPE1, PE5/MODA/IPIPE0, PE4/ECLK, PE3/$\overline{\text{LSTRB}}$/$\overline{\text{TAGLO}}$, and PE2/R/$\overline{\text{W}}$) are all configured to serve their bus control output functions rather than general purpose I/O. Notice that writes to the bus control enable bits in the PEAR register in emulation mode are restricted.

The main difference between special modes and normal modes is that some of the bus control and system control signals cannot be written in emulation modes.

4.4.3.2 Special Operating Modes

There are two special operating modes that correspond to normal operating modes. These operating modes are commonly used in factory testing and system development.

4.4.3.2.1 Special Single-Chip Mode

When the MCU is reset in this mode, the background debug mode is enabled and active. The MCU does not fetch the reset vector and execute application code as it would in other modes. Instead the active background mode is in control of CPU execution and BDM firmware is waiting for additional serial commands through the BKGD pin. When a serial command instructs the MCU to return to normal execution, the system will be configured as described below unless the reset states of internal control registers have been changed through background commands after the MCU was reset.

There is no external expansion bus after reset in this mode. Ports A and B are initially simple bidirectional I/O pins that are configured as high-impedance inputs with internal pull-ups disabled; however, writing to the mode select bits in the MODE register (which is allowed in special modes) can change this after reset. All of the Port E pins (except PE4/ECLK) are initially configured as general purpose high-impedance inputs with pull-ups enabled. PE4/ECLK is configured as the E clock output in this mode.

The pins associated with Port E bits 6, 5, 3, and 2 cannot be configured for their alternate functions IPIPE1, IPIPE0, $\overline{\text{LSTRB}}$, and R/$\overline{\text{W}}$ while the MCU is in single chip modes. In single chip modes, the associated control bits PIPOE, LSTRE and RDWE are reset to zero. Writing the opposite value into these bits in single chip mode does not change the operation of the associated Port E pins.

Port E, bit 4 can be configured for a free-running E clock output by clearing NECLK=0. Typically the only use for an E clock output while the MCU is in single chip modes would be to get a constant speed clock for use in the external application system.

4.4.3.2.2 Special Test Mode

In expanded wide modes, Ports A and B are configured as a 16-bit multiplexed address and data bus and Port E provides bus control and status signals. In special test mode, the write protection of many control bits is lifted so that they can be thoroughly tested without needing to go through reset.

4.4.3.3 Test Operating Mode

There is a test operating mode in which an external master, such as an I.C. tester, can control the on-chip peripherals.

4.4.3.3.1 Peripheral Mode

This mode is intended for factory testing of the MCU. In this mode, the CPU is inactive and an external (tester) bus master drives address, data and bus control signals in through Ports A, B and E. In effect, the whole MCU acts as if it was a peripheral under control of an external CPU. This allows faster testing of on-chip memory and peripherals than previous testing methods. Since the mode control register is not accessible in peripheral mode, the only way to change to another mode is to reset the MCU into a different mode. Background debugging should not be used while the MCU is in special peripheral mode as internal bus conflicts between BDM and the external master can cause improper operation of both functions.

4.4.4 Internal Visibility

Internal visibility is available when the MCU is operating in expanded wide modes or emulation narrow mode. It is not available in single-chip, peripheral or normal expanded narrow modes. Internal visibility is enabled by setting the IVIS bit in the MODE register.

If an internal access is made while E, R/$\overline{\text{W}}$, and $\overline{\text{LSTRB}}$ are configured as bus control outputs and internal visibility is off (IVIS=0), E will remain low for the cycle, R/$\overline{\text{W}}$ will remain high, and address, data and the $\overline{\text{LSTRB}}$ pins will remain at their previous state.

When internal visibility is enabled (IVIS=1), certain internal cycles will be blocked from going external. During cycles when the BDM is selected, R/$\overline{\text{W}}$ will remain high, data will maintain its previous state, and address and $\overline{\text{LSTRB}}$ pins will be updated with the internal value. During CPU no access cycles when the BDM is not driving, R/$\overline{\text{W}}$ will remain high, and address, data and the $\overline{\text{LSTRB}}$ pins will remain at their previous state.

NOTE

When the system is operating in a secure mode, internal visibility is not available (i.e., IVIS = 1 has no effect). Also, the IPIPE signals will not be visible, regardless of operating mode. IPIPE1–IPIPE0 will display 0es if they are enabled. In addition, the MOD bits in the MODE control register cannot be written.

4.4.5 Low-Power Options

The MEBI does not contain any user-controlled options for reducing power consumption. The operation of the MEBI in low-power modes is discussed in the following subsections.

4.4.5.1 Operation in Run Mode

The MEBI does not contain any options for reducing power in run mode; however, the external addresses are conditioned to reduce power in single-chip modes. Expanded bus modes will increase power consumption.

4.4.5.2 Operation in Wait Mode

The MEBI does not contain any options for reducing power in wait mode.

4.4.5.3 Operation in Stop Mode

The MEBI will cease to function after execution of a CPU STOP instruction.

Figure 4-22.

Chapter 5
Interrupt (INTV1) Block Description

5.1 Introduction

This section describes the functionality of the interrupt (INT) sub-block of the S12 core platform.

A block diagram of the interrupt sub-block is shown in Figure 5-1.

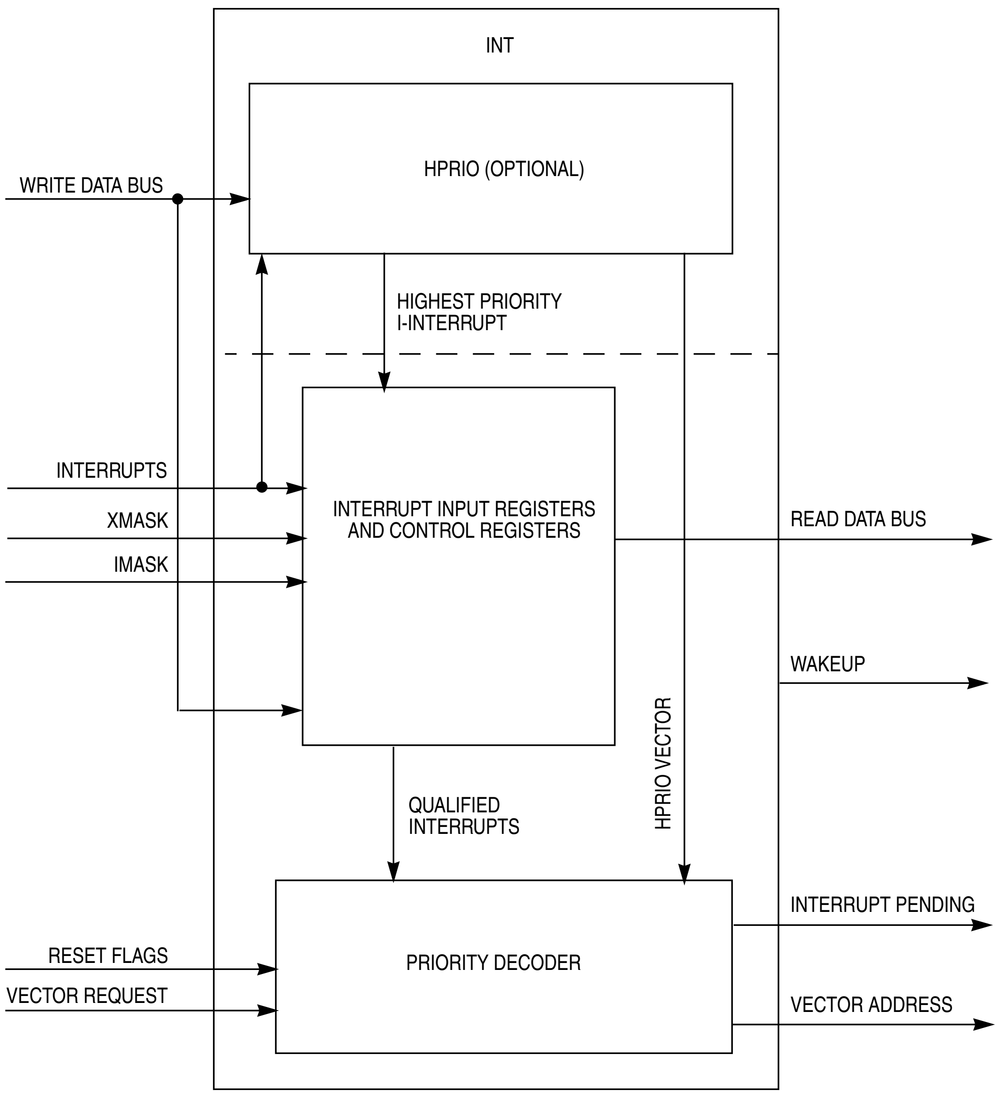

Figure 5-1. INT Block Diagram

The interrupt sub-block decodes the priority of all system exception requests and provides the applicable vector for processing the exception. The INT supports I-bit maskable and X-bit maskable interrupts, a non-maskable unimplemented opcode trap, a non-maskable software interrupt (SWI) or background debug mode request, and three system reset vector requests. All interrupt related exception requests are managed by the interrupt sub-block (INT).

5.1.1 Features

The INT includes these features:

- Provides two to 122 I-bit maskable interrupt vectors (0xFF00–0xFFF2)
- Provides one X-bit maskable interrupt vector (0xFFF4)
- Provides a non-maskable software interrupt (SWI) or background debug mode request vector (0xFFF6)
- Provides a non-maskable unimplemented opcode trap (TRAP) vector (0xFFF8)
- Provides three system reset vectors (0xFFFA–0xFFFE) (reset, CMR, and COP)
- Determines the appropriate vector and drives it onto the address bus at the appropriate time
- Signals the CPU that interrupts are pending
- Provides control registers which allow testing of interrupts
- Provides additional input signals which prevents requests for servicing I and X interrupts
- Wakes the system from stop or wait mode when an appropriate interrupt occurs or whenever $\overline{\text{XIRQ}}$ is active, even if $\overline{\text{XIRQ}}$ is masked
- Provides asynchronous path for all I and X interrupts, (0xFF00–0xFFF4)
- (Optional) selects and stores the highest priority I interrupt based on the value written into the HPRIO register

5.1.2 Modes of Operation

The functionality of the INT sub-block in various modes of operation is discussed in the subsections that follow.

- **Normal operation**
  The INT operates the same in all normal modes of operation.
- **Special operation**
  Interrupts may be tested in special modes through the use of the interrupt test registers.
- **Emulation modes**
  The INT operates the same in emulation modes as in normal modes.
- **Low power modes**
  See Section 5.4.1, “Low-Power Modes,” for details

5.2 External Signal Description

Most interfacing with the interrupt sub-block is done within the core. However, the interrupt does receive direct input from the multiplexed external bus interface (MEBI) sub-block of the core for the $\overline{IRQ}$ and $\overline{XIRQ}$ pin data.

5.3 Memory Map and Register Definition

Detailed descriptions of the registers and associated bits are given in the subsections that follow.

5.3.1 Module Memory Map

Name		Bit 7	6	5	4	3	2	1	Bit 0

Figure 5-3. Interrupt Test Control Register (ITCR)

Read: See individual bit descriptions

Write: See individual bit descriptions

Table 5-1. ITCR Field Descriptions

Field	Description
4 WRTINT	**Write to the Interrupt Test Registers** Read: anytime Write: only in special modes and with I-bit mask and X-bit mask set. 0 Disables writes to the test registers; reads of the test registers will return the state of the interrupt inputs. 1 Disconnect the interrupt inputs from the priority decoder and use the values written into the ITEST registers instead. **Note:** Any interrupts which are pending at the time that WRTINT is set will remain until they are overwritten.
3:0 ADR[3:0]	**Test Register Select Bits** Read: anytime Write: anytime These bits determine which test register is selected on a read or write. The hexadecimal value written here will be the same as the upper nibble of the lower byte of the vector selects. That is, an “F” written into ADR[3:0] will select vectors 0xFFFE–0xFFF0 while a “7” written to ADR[3:0] will select vectors 0xFF7E–0xFF70.

= Unimplemented or Reserved

Figure 5-4. Interrupt TEST Registers (ITEST)

Read: Only in special modes. Reads will return either the state of the interrupt inputs of the interrupt sub-block (WRTINT = 0) or the values written into the TEST registers (WRTINT = 1). Reads will always return 0s in normal modes.

Write: Only in special modes and with WRTINT = 1 and CCR I mask = 1.

Table 5-2. ITEST Field Descriptions

Field	Description
7:0 INT[E:0]	**Interrupt TEST Bits** — These registers are used in special modes for testing the interrupt logic and priority independent of the system configuration. Each bit is used to force a specific interrupt vector by writing it to a logic 1 state. Bits are named INTE through INT0 to indicate vectors 0xFFxE through 0xFFx0. These bits can be written only in special modes and only with the WRTINT bit set (logic 1) in the interrupt test control register (ITCR). In addition, I interrupts must be masked using the I bit in the CCR. In this state, the interrupt input lines to the interrupt sub-block will be disconnected and interrupt requests will be generated only by this register. These bits can also be read in special modes to view that an interrupt requested by a system block (such as a peripheral block) has reached the INT module. There is a test register implemented for every eight interrupts in the overall system. All of the test registers share the same address and are individually selected using the value stored in the ADR[3:0] bits of the interrupt test control register (ITCR). **Note:** When ADR[3:0] have the value of 0x000F, only bits 2:0 in the ITEST register will be accessible. That is, vectors higher than 0xFFF4 cannot be tested using the test registers and bits 7:3 will always read as a logic 0. If ADR[3:0] point to an unimplemented test register, writes will have no effect and reads will always return a logic 0 value.

5.3.2.3 Highest Priority I Interrupt (Optional)

Module Base + 0x001F
Starting address location affected by INITRG register setting.

	7	6	5	4	3	2	1	0
R	PSEL7	PSEL6	PSEL5	PSEL4	PSEL3	PSEL2	PSEL1	0
W								
Reset	1	1	1	1	0	0	1	0

= Unimplemented or Reserved

Figure 5-5. Highest Priority I Interrupt Register (HPRIO)

Read: Anytime

Write: Only if I mask in CCR = 1

Table 5-3. HPRIO Field Descriptions

Field	Description
7:1 PSEL[7:1]	**Highest Priority I Interrupt Select Bits** — The state of these bits determines which I-bit maskable interrupt will be promoted to highest priority (of the I-bit maskable interrupts). To promote an interrupt, the user writes the least significant byte of the associated interrupt vector address to this register. If an unimplemented vector address or a non I-bit masked vector address (value higher than 0x00F2) is written, IRQ (0xFFF2) will be the default highest priority interrupt.

5.4 Functional Description

The interrupt sub-block processes all exception requests made by the CPU. These exceptions include interrupt vector requests and reset vector requests. Each of these exception types and their overall priority level is discussed in the subsections below.

5.4.1 Low-Power Modes

The INT does not contain any user-controlled options for reducing power consumption. The operation of the INT in low-power modes is discussed in the following subsections.

5.4.1.1 Operation in Run Mode

The INT does not contain any options for reducing power in run mode.

5.4.1.2 Operation in Wait Mode

Clocks to the INT can be shut off during system wait mode and the asynchronous interrupt path will be used to generate the wake-up signal upon recognition of a valid interrupt or any $\overline{\text{XIRQ}}$ request.

5.4.1.3 Operation in Stop Mode

Clocks to the INT can be shut off during system stop mode and the asynchronous interrupt path will be used to generate the wake-up signal upon recognition of a valid interrupt or any $\overline{\text{XIRQ}}$ request.

5.5 Resets

The INT supports three system reset exception request types: normal system reset or power-on-reset request, crystal monitor reset request, and COP watchdog reset request. The type of reset exception request must be decoded by the system and the proper request made to the core. The INT will then provide the service routine address for the type of reset requested.

5.6 Interrupts

As shown in the block diagram in Figure 5-1, the INT contains a register block to provide interrupt status and control, an optional highest priority I interrupt (HPRIO) block, and a priority decoder to evaluate whether pending interrupts are valid and assess their priority.

5.6.1 Interrupt Registers

The INT registers are accessible only in special modes of operation and function as described in Section 5.3.2.1, “Interrupt Test Control Register,” and Section 5.3.2.2, “Interrupt Test Registers,” previously.

5.6.2 Highest Priority I-Bit Maskable Interrupt

When the optional HPRIO block is implemented, the user is allowed to promote a single I-bit maskable interrupt to be the highest priority I interrupt. The HPRIO evaluates all interrupt exception requests and passes the HPRIO vector to the priority decoder if the highest priority I interrupt is active. RTI replaces the promoted interrupt source.

5.6.3 Interrupt Priority Decoder

The priority decoder evaluates all interrupts pending and determines their validity and priority. When the CPU requests an interrupt vector, the decoder will provide the vector for the highest priority interrupt request. Because the vector is not supplied until the CPU requests it, it is possible that a higher priority interrupt request could override the original exception that caused the CPU to request the vector. In this case, the CPU will receive the highest priority vector and the system will process this exception instead of the original request.

NOTE

Care must be taken to ensure that all exception requests remain active until the system begins execution of the applicable service routine; otherwise, the exception request may not be processed.

If for any reason the interrupt source is unknown (e.g., an interrupt request becomes inactive after the interrupt has been recognized but prior to the vector request), the vector address will default to that of the last valid interrupt that existed during the particular interrupt sequence. If the CPU requests an interrupt vector when there has never been a pending interrupt request, the INT will provide the software interrupt (SWI) vector address.

5.7 Exception Priority

The priority (from highest to lowest) and address of all exception vectors issued by the INT upon request by the CPU is shown in Table 5-4.

Table 5-4. Exception Vector Map and Priority

Vector Address	Source
0xFFFE–0xFFFF	System reset
0xFFFC–0xFFFD	Crystal monitor reset
0xFFFA–0xFFFB	COP reset
0xFFF8–0xFFF9	Unimplemented opcode trap
0xFFF6–0xFFF7	Software interrupt instruction (SWI) or BDM vector request
0xFFF4–0xFFF5	$\overline{\text{XIRQ}}$ signal
0xFFF2–0xFFF3	$\overline{\text{IRQ}}$ signal
0xFFF0–0xFF00	Device-specific I-bit maskable interrupt sources (priority in descending order)

Chapter 6
Background Debug Module (BDMV4) Block Description

6.1 Introduction

This section describes the functionality of the background debug module (BDM) sub-block of the HCS12 core platform.

A block diagram of the BDM is shown in Figure 6-1.

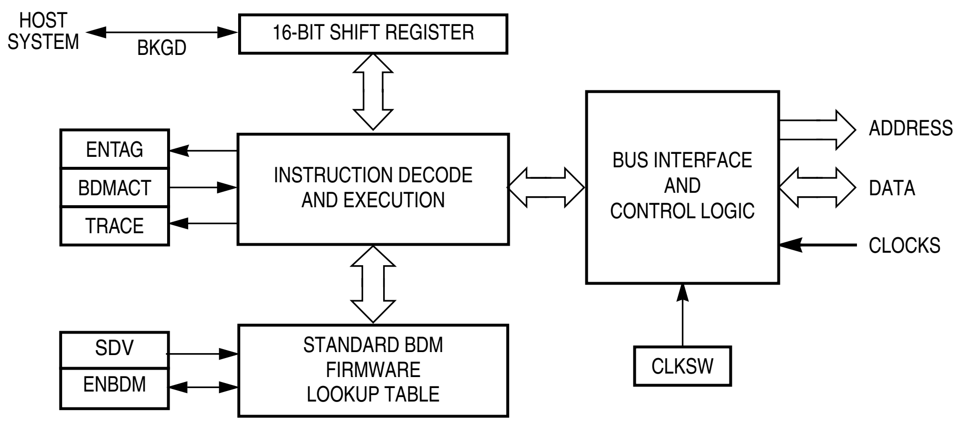

Figure 6-1. BDM Block Diagram

The background debug module (BDM) sub-block is a single-wire, background debug system implemented in on-chip hardware for minimal CPU intervention. All interfacing with the BDM is done via the BKGD pin.

BDMV4 has enhanced capability for maintaining synchronization between the target and host while allowing more flexibility in clock rates. This includes a sync signal to show the clock rate and a handshake signal to indicate when an operation is complete. The system is backwards compatible with older external interfaces.

6.1.1 Features

- Single-wire communication with host development system
- BDMV4 (and BDM2): Enhanced capability for allowing more flexibility in clock rates
- BDMV4: SYNC command to determine communication rate
- BDMV4: GO_UNTIL command
- BDMV4: Hardware handshake protocol to increase the performance of the serial communication
- Active out of reset in special single-chip mode

- Nine hardware commands using free cycles, if available, for minimal CPU intervention
- Hardware commands not requiring active BDM
- 15 firmware commands execute from the standard BDM firmware lookup table
- Instruction tagging capability
- Software control of BDM operation during wait mode
- Software selectable clocks
- When secured, hardware commands are allowed to access the register space in special single-chip mode, if the FLASH and EEPROM erase tests fail.

6.1.2 Modes of Operation

BDM is available in all operating modes but must be enabled before firmware commands are executed. Some system peripherals may have a control bit which allows suspending the peripheral function during background debug mode.

6.1.2.1 Regular Run Modes

All of these operations refer to the part in run mode. The BDM does not provide controls to conserve power during run mode.

- Normal operation

  General operation of the BDM is available and operates the same in all normal modes.
- Special single-chip mode

  In special single-chip mode, background operation is enabled and active out of reset. This allows programming a system with blank memory.
- Special peripheral mode

  BDM is enabled and active immediately out of reset. BDM can be disabled by clearing the BDMACT bit in the BDM status (BDMSTS) register. The BDM serial system should not be used in special peripheral mode.
- Emulation modes

  General operation of the BDM is available and operates the same as in normal modes.

6.1.2.2 Secure Mode Operation

If the part is in secure mode, the operation of the BDM is reduced to a small subset of its regular run mode operation. Secure operation prevents access to FLASH or EEPROM other than allowing erasure.

6.2 External Signal Description

A single-wire interface pin is used to communicate with the BDM system. Two additional pins are used for instruction tagging. These pins are part of the multiplexed external bus interface (MEBI) sub-block and all interfacing between the MEBI and BDM is done within the core interface boundary. Functional descriptions of the pins are provided below for completeness.

- BKGD — Background interface pin
- $\overline{\text{TAGHI}}$ — High byte instruction tagging pin
- $\overline{\text{TAGLO}}$ — Low byte instruction tagging pin
- BKGD and $\overline{\text{TAGHI}}$ share the same pin.
- $\overline{\text{TAGLO}}$ and $\overline{\text{LSTRB}}$ share the same pin.

NOTE

Generally these pins are shared as described, but it is best to check the device overview chapter to make certain. All MCUs at the time of this writing have followed this pin sharing scheme.

6.2.1 BKGD — Background Interface Pin

Debugging control logic communicates with external devices serially via the single-wire background interface pin (BKGD). During reset, this pin is a mode select input which selects between normal and special modes of operation. After reset, this pin becomes the dedicated serial interface pin for the background debug mode.

6.2.2 $\overline{\text{TAGHI}}$ — High Byte Instruction Tagging Pin

This pin is used to tag the high byte of an instruction. When instruction tagging is on, a logic 0 at the falling edge of the external clock (ECLK) tags the high half of the instruction word being read into the instruction queue.

6.2.3 $\overline{\text{TAGLO}}$ — Low Byte Instruction Tagging Pin

This pin is used to tag the low byte of an instruction. When instruction tagging is on and low strobe is enabled, a logic 0 at the falling edge of the external clock (ECLK) tags the low half of the instruction word being read into the instruction queue.

6.3 Memory Map and Register Definition

A summary of the registers associated with the BDM is shown in Figure 6-2. Registers are accessed by host-driven communications to the BDM hardware using READ_BD and WRITE_BD commands. Detailed descriptions of the registers and associated bits are given in the subsections that follow.

6.3.1 Register Descriptions

Register Name		Bit 7	6	5	4	3	2	1	Bit 0
0xFF00 Reserved	R	X	X	X	X	X	X	0	0

Special peripheral mode:	0	1	0	0	0	0	0	0
All other modes:	0	1	0	0	0	0	0	0
	0	0	0	0	0	0	0	0

= Unimplemented or Reserved   = Implemented (do not alter)

Figure 6-3. BDM Status Register (BDMSTS)

Note:

1 ENBDM is read as "1" by a debugging environment in Special single-chip mode when the device is not secured or secured but fully erased (Flash and EEPROM).This is because the ENBDM bit is set by the standard firmware before a BDM command can be fully transmitted and executed.

2 UNSEC is read as "1" by a debugging environment in Special single-chip mode when the device is secured and fully erased, else it is "0" and can only be read if not secure (see also bit description).

Read: All modes through BDM operation

Write: All modes but subject to the following:

- BDMACT can only be set by BDM hardware upon entry into BDM. It can only be cleared by the standard BDM firmware lookup table upon exit from BDM active mode.
- CLKSW can only be written via BDM hardware or standard BDM firmware write commands.
- All other bits, while writable via BDM hardware or standard BDM firmware write commands, should only be altered by the BDM hardware or standard firmware lookup table as part of BDM command execution.
- ENBDM should only be set via a BDM hardware command if the BDM firmware commands are needed. (This does not apply in special single-chip mode).

Table 6-1. BDMSTS Field Descriptions

Field	Description
7 ENBDM	**Enable BDM** — This bit controls whether the BDM is enabled or disabled. When enabled, BDM can be made active to allow firmware commands to be executed. When disabled, BDM cannot be made active but BDM hardware commands are allowed. 0 BDM disabled 1 BDM enabled **Note:** ENBDM is set by the firmware immediately out of reset in special single-chip mode. In secure mode, this bit will not be set by the firmware until after the EEPROM and FLASH erase verify tests are complete.
6 BDMACT	**BDM Active Status** — This bit becomes set upon entering BDM. The standard BDM firmware lookup table is then enabled and put into the memory map. BDMACT is cleared by a carefully timed store instruction in the standard BDM firmware as part of the exit sequence to return to user code and remove the BDM memory from the map. 0 BDM not active 1 BDM active
5 ENTAG	**Tagging Enable** — This bit indicates whether instruction tagging in enabled or disabled. It is set when the TAGGO command is executed and cleared when BDM is entered. The serial system is disabled and the tag function enabled 16 cycles after this bit is written. BDM cannot process serial commands while tagging is active. 0 Tagging not enabled or BDM active 1 Tagging enabled
4 SDV	**Shift Data Valid** — This bit is set and cleared by the BDM hardware. It is set after data has been transmitted as part of a firmware read command or after data has been received as part of a firmware write command. It is cleared when the next BDM command has been received or BDM is exited. SDV is used by the standard BDM firmware to control program flow execution. 0 Data phase of command not complete 1 Data phase of command is complete
3 TRACE	**TRACE1 BDM Firmware Command is Being Executed** — This bit gets set when a BDM TRACE1 firmware command is first recognized. It will stay set as long as continuous back-to-back TRACE1 commands are executed. This bit will get cleared when the next command that is not a TRACE1 command is recognized. 0 TRACE1 command is not being executed 1 TRACE1 command is being executed

Table 6-1. BDMSTS Field Descriptions (continued)

Field	Description
2 CLKSW	**Clock Switch** — The CLKSW bit controls which clock the BDM operates with. It is only writable from a hardware BDM command. A 150 cycle delay at the clock speed that is active during the data portion of the command will occur before the new clock source is guaranteed to be active. The start of the next BDM command uses the new clock for timing subsequent BDM communications. Table 6-2 shows the resulting BDM clock source based on the CLKSW and the PLLSEL (Pll select from the clock and reset generator) bits. **Note:** The BDM alternate clock source can only be selected when CLKSW = 0 and PLLSEL = 1. The BDM serial interface is now fully synchronized to the alternate clock source, when enabled. This eliminates frequency restriction on the alternate clock which was required on previous versions. Refer to the device overview section to determine which clock connects to the alternate clock source input. **Note:** If the acknowledge function is turned on, changing the CLKSW bit will cause the ACK to be at the new rate for the write command which changes it.
1 UNSEC	**Unsecure** — This bit is only writable in special single-chip mode from the BDM secure firmware and always gets reset to zero. It is in a zero state as secure mode is entered so that the secure BDM firmware lookup table is enabled and put into the memory map along with the standard BDM firmware lookup table. The secure BDM firmware lookup table verifies that the on-chip EEPROM and FLASH EEPROM are erased. This being the case, the UNSEC bit is set and the BDM program jumps to the start of the standard BDM firmware lookup table and the secure BDM firmware lookup table is turned off. If the erase test fails, the UNSEC bit will not be asserted. 0 System is in a secured mode 1 System is in a unsecured mode **Note:** When UNSEC is set, security is off and the user can change the state of the secure bits in the on-chip FLASH EEPROM. Note that if the user does not change the state of the bits to “unsecured” mode, the system will be secured again when it is next taken out of reset.

Table 6-2. BDM Clock Sources

PLLSEL	CLKSW	BDMCLK
0	0	Bus clock
0	1	Bus clock
1	0	Alternate clock (refer to the device overview chapter to determine the alternate clock source)
1	1	Bus clock dependent on the PLL

6.3.1.2 BDM CCR Holding Register (BDMCCR)

0xFF06

	7	6	5	4	3	2	1	0
R W	CCR7	CCR6	CCR5	CCR4	CCR3	CCR2	CCR1	CCR0
Reset	0	0	0	0	0	0	0	0

Figure 6-4. BDM CCR Holding Register (BDMCCR)

Read: All modes

Write: All modes

NOTE

When BDM is made active, the CPU stores the value of the CCR register in the BDMCCR register. However, out of special single-chip reset, the BDMCCR is set to 0xD8 and not 0xD0 which is the reset value of the CCR register.

When entering background debug mode, the BDM CCR holding register is used to save the contents of the condition code register of the user's program. It is also used for temporary storage in the standard BDM firmware mode. The BDM CCR holding register can be written to modify the CCR value.

6.3.1.3 BDM Internal Register Position Register (BDMINR)

0xFF07

	7	6	5	4	3	2	1	0

Write: Never

Table 6-3. BDMINR Field Descriptions

Field	Description
6:3 REG[14:11]	**Internal Register Map Position** — These four bits show the state of the upper five bits of the base address for the system's relocatable register block. BDMINR is a shadow of the INITRG register which maps the register block to any 2K byte space within the first 32K bytes of the 64K byte address space.

6.4 Functional Description

The BDM receives and executes commands from a host via a single wire serial interface. There are two types of BDM commands, namely, hardware commands and firmware commands.

Hardware commands are used to read and write target system memory locations and to enter active background debug mode, see Section 6.4.3, "BDM Hardware Commands." Target system memory includes all memory that is accessible by the CPU.

Firmware commands are used to read and write CPU resources and to exit from active background debug mode, see Section 6.4.4, "Standard BDM Firmware Commands." The CPU resources referred to are the accumulator (D), X index register (X), Y index register (Y), stack pointer (SP), and program counter (PC).

Hardware commands can be executed at any time and in any mode excluding a few exceptions as highlighted, see Section 6.4.3, "BDM Hardware Commands." Firmware commands can only be executed when the system is in active background debug mode (BDM).

6.4.1 Security

If the user resets into special single-chip mode with the system secured, a secured mode BDM firmware lookup table is brought into the map overlapping a portion of the standard BDM firmware lookup table. The secure BDM firmware verifies that the on-chip EEPROM and FLASH EEPROM are erased. This being the case, the UNSEC bit will get set. The BDM program jumps to the start of the standard BDM firmware and the secured mode BDM firmware is turned off and all BDM commands are allowed. If the EEPROM or FLASH do not verify as erased, the BDM firmware sets the ENBDM bit, without asserting UNSEC, and the firmware enters a loop. This causes the BDM hardware commands to become enabled, but does not enable the firmware commands. This allows the BDM hardware to be used to erase the EEPROM and FLASH. After execution of the secure firmware, regardless of the results of the erase tests, the CPU registers and PPAGE will no longer be in their reset state.

6.4.2 Enabling and Activating BDM

The system must be in active BDM to execute standard BDM firmware commands. BDM can be activated only after being enabled. BDM is enabled by setting the ENBDM bit in the BDM status (BDMSTS) register. The ENBDM bit is set by writing to the BDM status (BDMSTS) register, via the single-wire interface, using a hardware command such as WRITE_BD_BYTE.

After being enabled, BDM is activated by one of the following[1]:

- Hardware BACKGROUND command
- BDM external instruction tagging mechanism
- CPU BGND instruction
- Breakpoint sub-block's force or tag mechanism[2]

When BDM is activated, the CPU finishes executing the current instruction and then begins executing the firmware in the standard BDM firmware lookup table. When BDM is activated by the breakpoint

1. BDM is enabled and active immediately out of special single-chip reset.
2. This method is only available on systems that have a a breakpoint or a debug sub-block.

sub-block, the type of breakpoint used determines if BDM becomes active before or after execution of the next instruction.

NOTE

If an attempt is made to activate BDM before being enabled, the CPU resumes normal instruction execution after a brief delay. If BDM is not enabled, any hardware BACKGROUND commands issued are ignored by the BDM and the CPU is not delayed.

In active BDM, the BDM registers and standard BDM firmware lookup table are mapped to addresses 0xFF00 to 0xFFFF. BDM registers are mapped to addresses 0xFF00 to 0xFF07. The BDM uses these registers which are readable anytime by the BDM. However, these registers are not readable by user programs.

6.4.3 BDM Hardware Commands

Hardware commands are used to read and write target system memory locations and to enter active background debug mode. Target system memory includes all memory that is accessible by the CPU such as on-chip RAM, EEPROM, FLASH EEPROM, I/O and control registers, and all external memory.

Hardware commands are executed with minimal or no CPU intervention and do not require the system to be in active BDM for execution, although they can continue to be executed in this mode. When executing a hardware command, the BDM sub-block waits for a free CPU bus cycle so that the background access does not disturb the running application program. If a free cycle is not found within 128 clock cycles, the CPU is momentarily frozen so that the BDM can steal a cycle. When the BDM finds a free cycle, the operation does not intrude on normal CPU operation provided that it can be completed in a single cycle. However, if an operation requires multiple cycles the CPU is frozen until the operation is complete, even though the BDM found a free cycle.

The BDM hardware commands are listed in Table 6-4.

Table 6-4. Hardware Commands

Command	Opcode (hex)	Data	Description
BACKGROUND	90	None	Enter background mode if firmware is enabled. If enabled, an ACK will be issued when the part enters active background mode.
ACK_ENABLE	D5	None	Enable handshake. Issues an ACK pulse after the command is executed.
ACK_DISABLE	D6	None	Disable handshake. This command does not issue an ACK pulse.
READ_BD_BYTE	E4	16-bit address 16-bit data out	Read from memory with standard BDM firmware lookup table in map. Odd address data on low byte; even address data on high byte.
READ_BD_WORD	EC	16-bit address 16-bit data out	Read from memory with standard BDM firmware lookup table in map. Must be aligned access.
READ_BYTE	E0	16-bit address 16-bit data out	Read from memory with standard BDM firmware lookup table out of map. Odd address data on low byte; even address data on high byte.
READ_WORD	E8	16-bit address 16-bit data out	Read from memory with standard BDM firmware lookup table out of map. Must be aligned access.
WRITE_BD_BYTE	C4	16-bit address 16-bit data in	Write to memory with standard BDM firmware lookup table in map. Odd address data on low byte; even address data on high byte.
WRITE_BD_WORD	CC	16-bit address 16-bit data in	Write to memory with standard BDM firmware lookup table in map. Must be aligned access.
WRITE_BYTE	C0	16-bit address 16-bit data in	Write to memory with standard BDM firmware lookup table out of map. Odd address data on low byte; even address data on high byte.
WRITE_WORD	C8	16-bit address 16-bit data in	Write to memory with standard BDM firmware lookup table out of map. Must be aligned access.

NOTE:
If enabled, ACK will occur when data is ready for transmission for all BDM READ commands and will occur after the write is complete for all BDM WRITE commands.

The READ_BD and WRITE_BD commands allow access to the BDM register locations. These locations are not normally in the system memory map but share addresses with the application in memory. To distinguish between physical memory locations that share the same address, BDM memory resources are enabled just for the READ_BD and WRITE_BD access cycle. This allows the BDM to access BDM locations unobtrusively, even if the addresses conflict with the application memory map.

6.4.4 Standard BDM Firmware Commands

Firmware commands are used to access and manipulate CPU resources. The system must be in active BDM to execute standard BDM firmware commands, see Section 6.4.2, "Enabling and Activating BDM." Normal instruction execution is suspended while the CPU executes the firmware located in the standard BDM firmware lookup table. The hardware command BACKGROUND is the usual way to activate BDM.

As the system enters active BDM, the standard BDM firmware lookup table and BDM registers become visible in the on-chip memory map at 0xFF00–0xFFFF, and the CPU begins executing the standard BDM firmware. The standard BDM firmware watches for serial commands and executes them as they are received.

The firmware commands are shown in Table 6-5.

Table 6-5. Firmware Commands

Command[1]	Opcode (hex)	Data	Description
READ_NEXT	62	16-bit data out	Increment X by 2 (X = X + 2), then read word X points to.
READ_PC	63	16-bit data out	Read program counter.
READ_D	64	16-bit data out	Read D accumulator.
READ_X	65	16-bit data out	Read X index register.
READ_Y	66	16-bit data out	Read Y index register.
READ_SP	67	16-bit data out	Read stack pointer.
WRITE_NEXT	42	16-bit data in	Increment X by 2 (X = X + 2), then write word to location pointed to by X.
WRITE_PC	43	16-bit data in	Write program counter.
WRITE_D	44	16-bit data in	Write D accumulator.
WRITE_X	45	16-bit data in	Write X index register.
WRITE_Y	46	16-bit data in	Write Y index register.
WRITE_SP	47	16-bit data in	Write stack pointer.
GO	08	None	Go to user program. If enabled, ACK will occur when leaving active background mode.
GO_UNTIL[2]	0C	None	Go to user program. If enabled, ACK will occur upon returning to active background mode.
TRACE1	10	None	Execute one user instruction then return to active BDM. If enabled, ACK will occur upon returning to active background mode.
TAGGO	18	None	Enable tagging and go to user program. There is no ACK pulse related to this command.

1 If enabled, ACK will occur when data is ready for transmission for all BDM READ commands and will occur after the write is complete for all BDM WRITE commands.

2 Both WAIT (with clocks to the S12 CPU core disabled) and STOP disable the ACK function. The GO_UNTIL command will not get an Acknowledge if one of these two CPU instructions occurs before the "UNTIL" instruction. This can be a problem for any instruction that uses ACK, but GO_UNTIL is a lot more difficult for the development tool to time-out.

6.4.5 BDM Command Structure

Hardware and firmware BDM commands start with an 8-bit opcode followed by a 16-bit address and/or a 16-bit data word depending on the command. All the read commands return 16 bits of data despite the byte or word implication in the command name.

NOTE

8-bit reads return 16-bits of data, of which, only one byte will contain valid data. If reading an even address, the valid data will appear in the MSB. If reading an odd address, the valid data will appear in the LSB.

NOTE

16-bit misaligned reads and writes are not allowed. If attempted, the BDM will ignore the least significant bit of the address and will assume an even address from the remaining bits.

For hardware data read commands, the external host must wait 150 bus clock cycles after sending the address before attempting to obtain the read data. This is to be certain that valid data is available in the BDM shift register, ready to be shifted out. For hardware write commands, the external host must wait 150 bus clock cycles after sending the data to be written before attempting to send a new command. This is to avoid disturbing the BDM shift register before the write has been completed. The 150 bus clock cycle delay in both cases includes the maximum 128 cycle delay that can be incurred as the BDM waits for a free cycle before stealing a cycle.

For firmware read commands, the external host should wait 44 bus clock cycles after sending the command opcode and before attempting to obtain the read data. This includes the potential of an extra 7 cycles when the access is external with a narrow bus access (+1 cycle) and / or a stretch (+1, 2, or 3 cycles), (7 cycles could be needed if both occur). The 44 cycle wait allows enough time for the requested data to be made available in the BDM shift register, ready to be shifted out.

NOTE

This timing has increased from previous BDM modules due to the new capability in which the BDM serial interface can potentially run faster than the bus. On previous BDM modules this extra time could be hidden within the serial time.

For firmware write commands, the external host must wait 32 bus clock cycles after sending the data to be written before attempting to send a new command. This is to avoid disturbing the BDM shift register before the write has been completed.

The external host should wait 64 bus clock cycles after a TRACE1 or GO command before starting any new serial command. This is to allow the CPU to exit gracefully from the standard BDM firmware lookup table and resume execution of the user code. Disturbing the BDM shift register prematurely may adversely affect the exit from the standard BDM firmware lookup table.

NOTE

If the bus rate of the target processor is unknown or could be changing, it is recommended that the ACK (acknowledge function) be used to indicate when an operation is complete. When using ACK, the delay times are automated.

Figure 6-6 represents the BDM command structure. The command blocks illustrate a series of eight bit times starting with a falling edge. The bar across the top of the blocks indicates that the BKGD line idles in the high state. The time for an 8-bit command is 8×16 target clock cycles.[1]

1. Target clock cycles are cycles measured using the target MCU's serial clock rate. See Section 6.4.6, "BDM Serial Interface," and Section 6.3.1.1, "BDM Status Register (BDMSTS)," for information on how serial clock rate is selected.

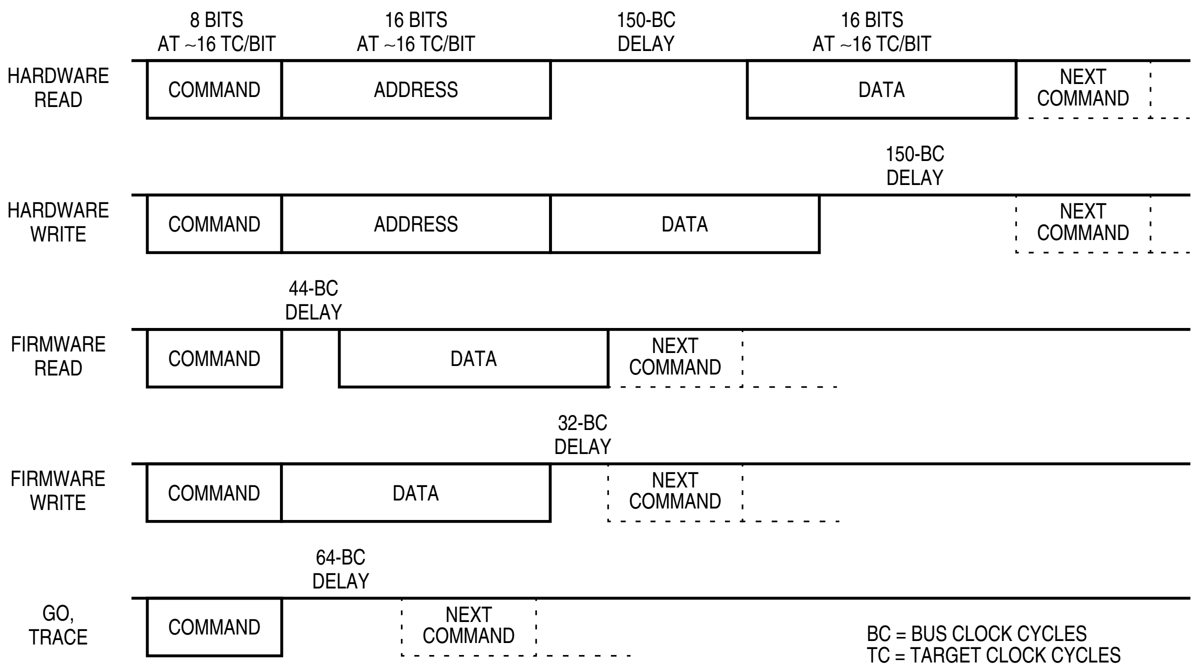

Figure 6-6. BDM Command Structure

6.4.6 BDM Serial Interface

The BDM communicates with external devices serially via the BKGD pin. During reset, this pin is a mode select input which selects between normal and special modes of operation. After reset, this pin becomes the dedicated serial interface pin for the BDM.

The BDM serial interface is timed using the clock selected by the CLKSW bit in the status register see Section 6.3.1.1, "BDM Status Register (BDMSTS)." This clock will be referred to as the target clock in the following explanation.

The BDM serial interface uses a clocking scheme in which the external host generates a falling edge on the BKGD pin to indicate the start of each bit time. This falling edge is sent for every bit whether data is transmitted or received. Data is transferred most significant bit (MSB) first at 16 target clock cycles per bit. The interface times out if 512 clock cycles occur between falling edges from the host.

The BKGD pin is a pseudo open-drain pin and has an weak on-chip active pull-up that is enabled at all times. It is assumed that there is an external pull-up and that drivers connected to BKGD do not typically drive the high level. Because R-C rise time could be unacceptably long, the target system and host provide brief driven-high (speedup) pulses to drive BKGD to a logic 1. The source of this speedup pulse is the host for transmit cases and the target for receive cases.

The timing for host-to-target is shown in Figure 6-7 and that of target-to-host in Figure 6-8 and Figure 6-9. All four cases begin when the host drives the BKGD pin low to generate a falling edge. Because the host and target are operating from separate clocks, it can take the target system up to one full clock cycle to recognize this edge. The target measures delays from this perceived start of the bit time while the host measures delays from the point it actually drove BKGD low to start the bit up to one target clock cycle earlier. Synchronization between the host and target is established in this manner at the start of every bit time.

Figure 6-7 shows an external host transmitting a logic 1 and transmitting a logic 0 to the BKGD pin of a target system. The host is asynchronous to the target, so there is up to a one clock-cycle delay from the host-generated falling edge to where the target recognizes this edge as the beginning of the bit time. Ten target clock cycles later, the target senses the bit level on the BKGD pin. Internal glitch detect logic requires the pin be driven high no later that eight target clock cycles after the falling edge for a logic 1 transmission.

Because the host drives the high speedup pulses in these two cases, the rising edges look like digitally driven signals.

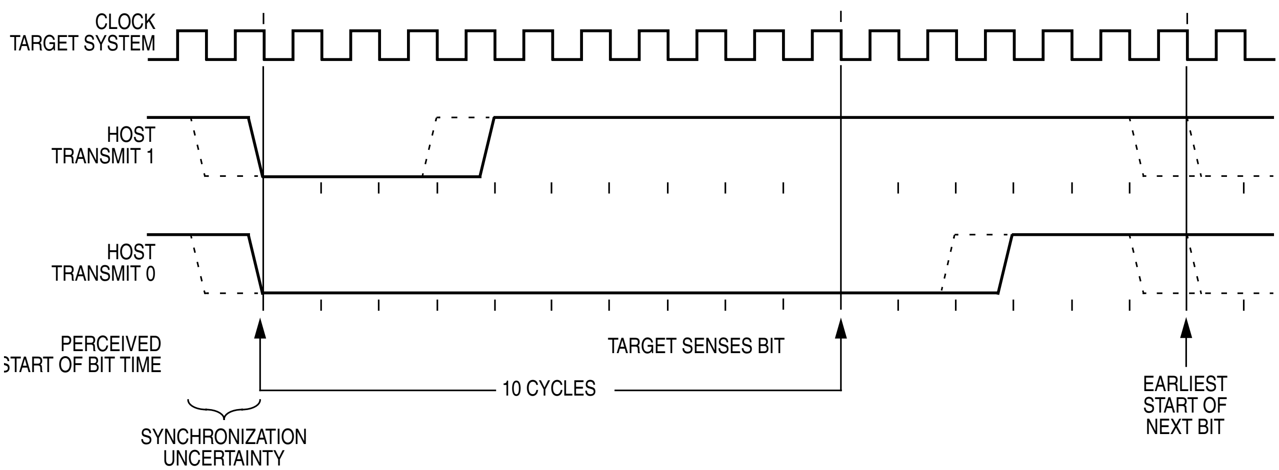

Figure 6-7. BDM Host-to-Target Serial Bit Timing

The receive cases are more complicated. Figure 6-8 shows the host receiving a logic 1 from the target system. Because the host is asynchronous to the target, there is up to one clock-cycle delay from the host-generated falling edge on BKGD to the perceived start of the bit time in the target. The host holds the BKGD pin low long enough for the target to recognize it (at least two target clock cycles). The host must release the low drive before the target drives a brief high speedup pulse seven target clock cycles after the perceived start of the bit time. The host should sample the bit level about 10 target clock cycles after it started the bit time.

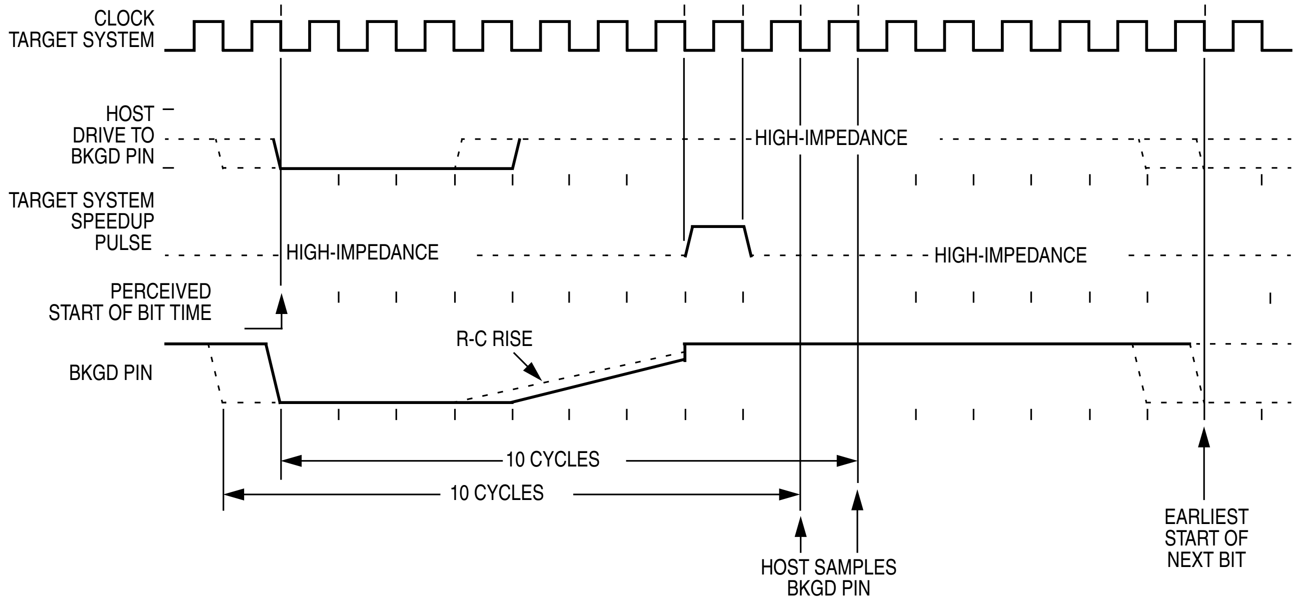

Figure 6-8. BDM Target-to-Host Serial Bit Timing (Logic 1)

Figure 6-9 shows the host receiving a logic 0 from the target. Because the host is asynchronous to the target, there is up to a one clock-cycle delay from the host-generated falling edge on BKGD to the start of the bit time as perceived by the target. The host initiates the bit time but the target finishes it. Because the target wants the host to receive a logic 0, it drives the BKGD pin low for 13 target clock cycles then briefly drives it high to speed up the rising edge. The host samples the bit level about 10 target clock cycles after starting the bit time.

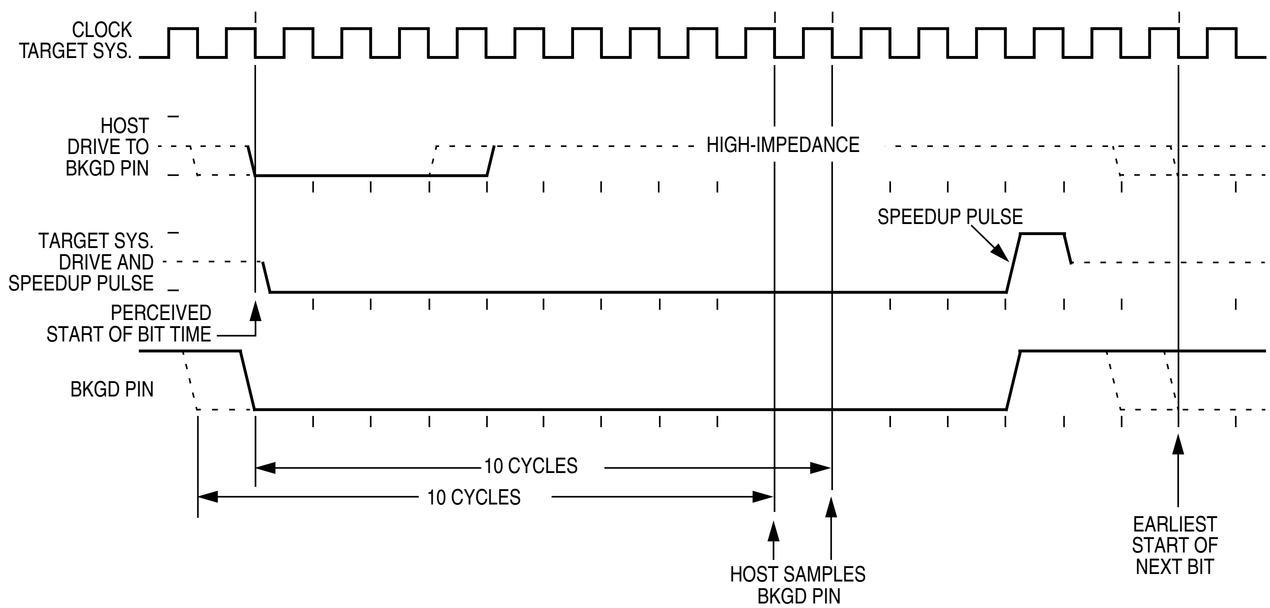

Figure 6-9. BDM Target-to-Host Serial Bit Timing (Logic 0)

6.4.7 Serial Interface Hardware Handshake Protocol

BDM commands that require CPU execution are ultimately treated at the MCU bus rate. Because the BDM clock source can be asynchronously related to the bus frequency, when CLKSW = 0, it is very helpful to provide a handshake protocol in which the host could determine when an issued command is executed by the CPU. The alternative is to always wait the amount of time equal to the appropriate number of cycles at the slowest possible rate the clock could be running. This sub-section will describe the hardware handshake protocol.

The hardware handshake protocol signals to the host controller when an issued command was successfully executed by the target. This protocol is implemented by a 16 serial clock cycle low pulse followed by a brief speedup pulse in the BKGD pin. This pulse is generated by the target MCU when a command, issued by the host, has been successfully executed (see Figure 6-10). This pulse is referred to as the ACK pulse. After the ACK pulse has finished: the host can start the bit retrieval if the last issued command was a read command, or start a new command if the last command was a write command or a control command (BACKGROUND, GO, GO_UNTIL, or TRACE1). The ACK pulse is not issued earlier than 32 serial clock cycles after the BDM command was issued. The end of the BDM command is assumed to be the 16th tick of the last bit. This minimum delay assures enough time for the host to perceive the ACK pulse. Note also that, there is no upper limit for the delay between the command and the related ACK pulse, because the command execution depends upon the CPU bus frequency, which in some cases could be very slow compared to the serial communication rate. This protocol allows a great flexibility for the POD designers, because it does not rely on any accurate time measurement or short response time to any event in the serial communication.

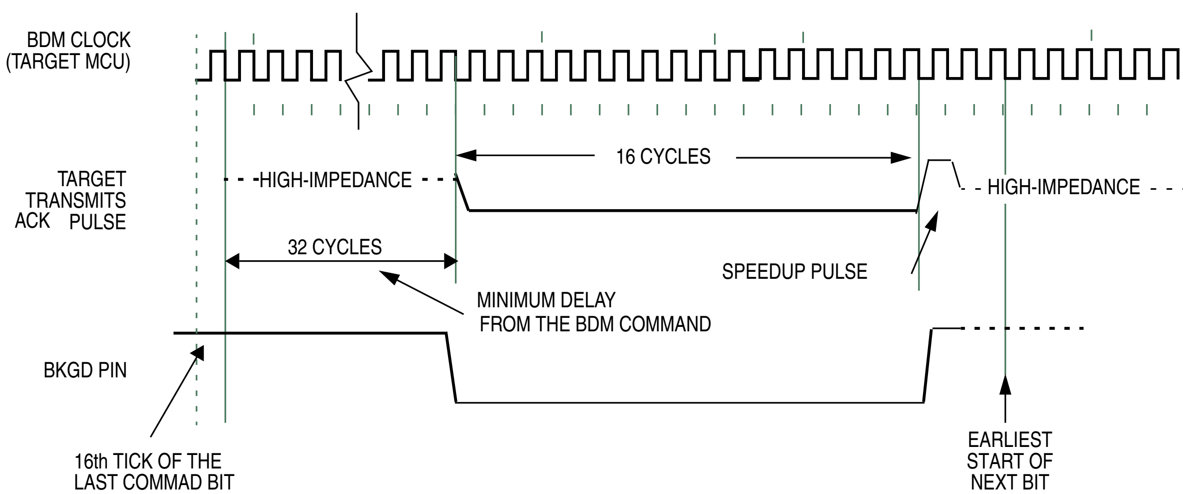

Figure 6-10. Target Acknowledge Pulse (ACK)

NOTE

If the ACK pulse was issued by the target, the host assumes the previous command was executed. If the CPU enters WAIT or STOP prior to executing a hardware command, the ACK pulse will not be issued meaning that the BDM command was not executed. After entering wait or stop mode, the BDM command is no longer pending.

Figure 6-11 shows the ACK handshake protocol in a command level timing diagram. The READ_BYTE instruction is used as an example. First, the 8-bit instruction opcode is sent by the host, followed by the address of the memory location to be read. The target BDM decodes the instruction. A bus cycle is grabbed (free or stolen) by the BDM and it executes the READ_BYTE operation. Having retrieved the data, the BDM issues an ACK pulse to the host controller, indicating that the addressed byte is ready to be retrieved. After detecting the ACK pulse, the host initiates the byte retrieval process. Note that data is sent in the form of a word and the host needs to determine which is the appropriate byte based on whether the address was odd or even.

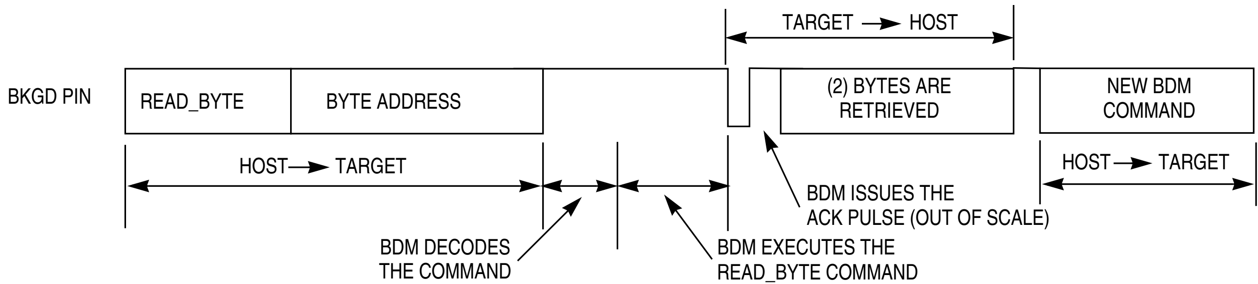

Figure 6-11. Handshake Protocol at Command Level

Differently from the normal bit transfer (where the host initiates the transmission), the serial interface ACK handshake pulse is initiated by the target MCU by issuing a falling edge in the BKGD pin. The hardware handshake protocol in Figure 6-10 specifies the timing when the BKGD pin is being driven, so the host should follow this timing constraint in order to avoid the risk of an electrical conflict in the BKGD pin.

NOTE

The only place the BKGD pin can have an electrical conflict is when one side is driving low and the other side is issuing a speedup pulse (high). Other "highs" are pulled rather than driven. However, at low rates the time of the speedup pulse can become lengthy and so the potential conflict time becomes longer as well.

The ACK handshake protocol does not support nested ACK pulses. If a BDM command is not acknowledge by an ACK pulse, the host needs to abort the pending command first in order to be able to issue a new BDM command. When the CPU enters WAIT or STOP while the host issues a command that requires CPU execution (e.g., WRITE_BYTE), the target discards the incoming command due to the WAIT or STOP being detected. Therefore, the command is not acknowledged by the target, which means that the ACK pulse will not be issued in this case. After a certain time the host should decide to abort the ACK sequence in order to be free to issue a new command. Therefore, the protocol should provide a mechanism in which a command, and therefore a pending ACK, could be aborted.

NOTE

Differently from a regular BDM command, the ACK pulse does not provide a time out. This means that in the case of a WAIT or STOP instruction being executed, the ACK would be prevented from being issued. If not aborted, the ACK would remain pending indefinitely. See the handshake abort procedure described in Section 6.4.8, "Hardware Handshake Abort Procedure."

6.4.8 Hardware Handshake Abort Procedure

The abort procedure is based on the SYNC command. In order to abort a command, which had not issued the corresponding ACK pulse, the host controller should generate a low pulse in the BKGD pin by driving it low for at least 128 serial clock cycles and then driving it high for one serial clock cycle, providing a speedup pulse. By detecting this long low pulse in the BKGD pin, the target executes the SYNC protocol, see Section 6.4.9, "SYNC — Request Timed Reference Pulse," and assumes that the pending command and therefore the related ACK pulse, are being aborted. Therefore, after the SYNC protocol has been completed the host is free to issue new BDM commands.

Although it is not recommended, the host could abort a pending BDM command by issuing a low pulse in the BKGD pin shorter than 128 serial clock cycles, which will not be interpreted as the SYNC command. The ACK is actually aborted when a falling edge is perceived by the target in the BKGD pin. The short abort pulse should have at least 4 clock cycles keeping the BKGD pin low, in order to allow the falling edge to be detected by the target. In this case, the target will not execute the SYNC protocol but the pending command will be aborted along with the ACK pulse. The potential problem with this abort procedure is when there is a conflict between the ACK pulse and the short abort pulse. In this case, the target may not perceive the abort pulse. The worst case is when the pending command is a read command (i.e., READ_BYTE). If the abort pulse is not perceived by the target the host will attempt to send a new command after the abort pulse was issued, while the target expects the host to retrieve the accessed memory byte. In this case, host and target will run out of synchronism. However, if the command to be aborted is not a read command the short abort pulse could be used. After a command is aborted the target assumes the next falling edge, after the abort pulse, is the first bit of a new BDM command.

NOTE

The details about the short abort pulse are being provided only as a reference for the reader to better understand the BDM internal behavior. It is not recommended that this procedure be used in a real application.

Because the host knows the target serial clock frequency, the SYNC command (used to abort a command) does not need to consider the lower possible target frequency. In this case, the host could issue a SYNC very close to the 128 serial clock cycles length. Providing a small overhead on the pulse length in order to assure the SYNC pulse will not be misinterpreted by the target. See Section 6.4.9, "SYNC — Request Timed Reference Pulse."

Figure 6-12 shows a SYNC command being issued after a READ_BYTE, which aborts the READ_BYTE command. Note that, after the command is aborted a new command could be issued by the host computer.

NOTE

Figure 6-12 does not represent the signals in a true timing scale

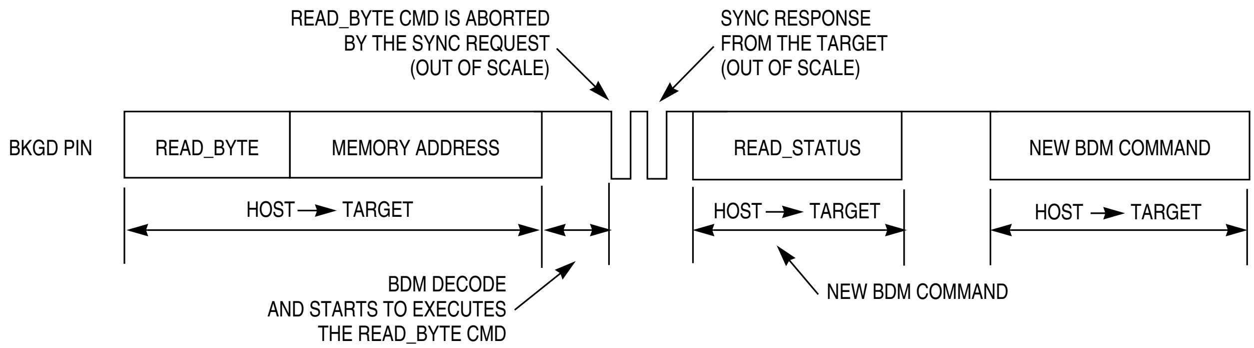

Figure 6-12. ACK Abort Procedure at the Command Level

Figure 6-13 shows a conflict between the ACK pulse and the SYNC request pulse. This conflict could occur if a POD device is connected to the target BKGD pin and the target is already in debug active mode. Consider that the target CPU is executing a pending BDM command at the exact moment the POD is being connected to the BKGD pin. In this case, an ACK pulse is issued along with the SYNC command. In this case, there is an electrical conflict between the ACK speedup pulse and the SYNC pulse. Because this is not a probable situation, the protocol does not prevent this conflict from happening.

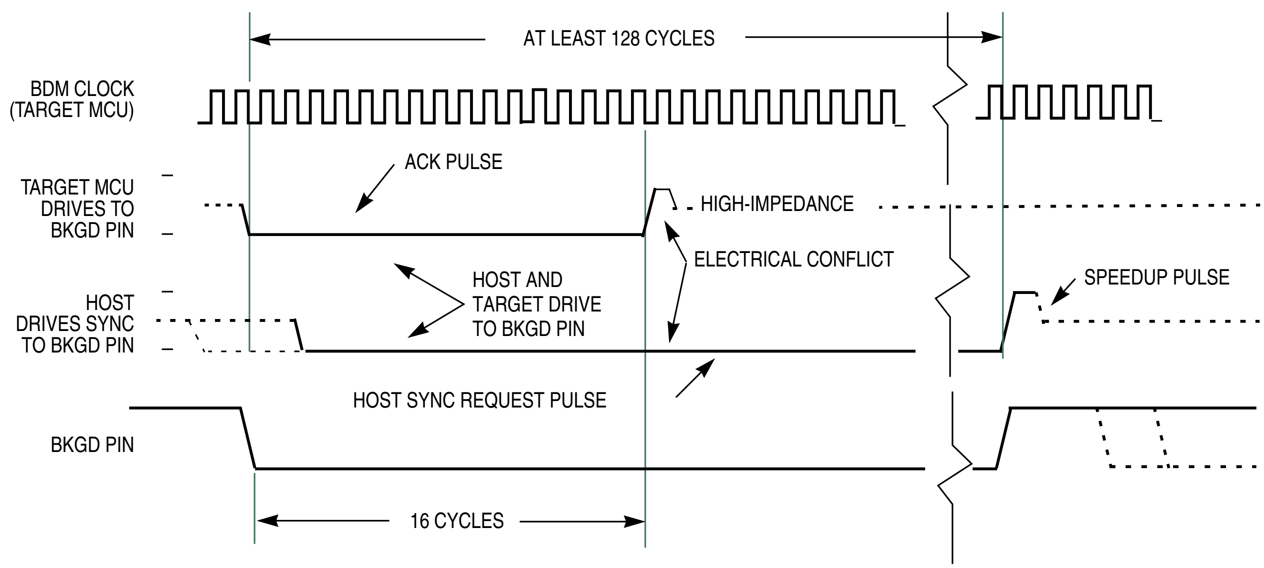

Figure 6-13. ACK Pulse and SYNC Request Conflict

NOTE

This information is being provided so that the MCU integrator will be aware that such a conflict could eventually occur.

The hardware handshake protocol is enabled by the ACK_ENABLE and disabled by the ACK_DISABLE BDM commands. This provides backwards compatibility with the existing POD devices which are not able to execute the hardware handshake protocol. It also allows for new POD devices, that support the hardware handshake protocol, to freely communicate with the target device. If desired, without the need for waiting for the ACK pulse.

The commands are described as follows:

- ACK_ENABLE — enables the hardware handshake protocol. The target will issue the ACK pulse when a CPU command is executed by the CPU. The ACK_ENABLE command itself also has the ACK pulse as a response.
- ACK_DISABLE — disables the ACK pulse protocol. In this case, the host needs to use the worst case delay time at the appropriate places in the protocol.

The default state of the BDM after reset is hardware handshake protocol disabled.

All the read commands will ACK (if enabled) when the data bus cycle has completed and the data is then ready for reading out by the BKGD serial pin. All the write commands will ACK (if enabled) after the data has been received by the BDM through the BKGD serial pin and when the data bus cycle is complete. See Section 6.4.3, "BDM Hardware Commands," and Section 6.4.4, "Standard BDM Firmware Commands," for more information on the BDM commands.

The ACK_ENABLE sends an ACK pulse when the command has been completed. This feature could be used by the host to evaluate if the target supports the hardware handshake protocol. If an ACK pulse is issued in response to this command, the host knows that the target supports the hardware handshake protocol. If the target does not support the hardware handshake protocol the ACK pulse is not issued. In this case, the ACK_ENABLE command is ignored by the target because it is not recognized as a valid command.

The BACKGROUND command will issue an ACK pulse when the CPU changes from normal to background mode. The ACK pulse related to this command could be aborted using the SYNC command.

The GO command will issue an ACK pulse when the CPU exits from background mode. The ACK pulse related to this command could be aborted using the SYNC command.

The GO_UNTIL command is equivalent to a GO command with exception that the ACK pulse, in this case, is issued when the CPU enters into background mode. This command is an alternative to the GO command and should be used when the host wants to trace if a breakpoint match occurs and causes the CPU to enter active background mode. Note that the ACK is issued whenever the CPU enters BDM, which could be caused by a breakpoint match or by a BGND instruction being executed. The ACK pulse related to this command could be aborted using the SYNC command.

The TRACE1 command has the related ACK pulse issued when the CPU enters background active mode after one instruction of the application program is executed. The ACK pulse related to this command could be aborted using the SYNC command.

The TAGGO command will not issue an ACK pulse because this would interfere with the tagging function shared on the same pin.

6.4.9 SYNC — Request Timed Reference Pulse

The SYNC command is unlike other BDM commands because the host does not necessarily know the correct communication speed to use for BDM communications until after it has analyzed the response to the SYNC command. To issue a SYNC command, the host should perform the following steps:

1. Drive the BKGD pin low for at least 128 cycles at the lowest possible BDM serial communication frequency (the lowest serial communication frequency is determined by the crystal oscillator or the clock chosen by CLKSW.)
2. Drive BKGD high for a brief speedup pulse to get a fast rise time (this speedup pulse is typically one cycle of the host clock.)
3. Remove all drive to the BKGD pin so it reverts to high impedance.
4. Listen to the BKGD pin for the sync response pulse.

Upon detecting the SYNC request from the host, the target performs the following steps:

1. Discards any incomplete command received or bit retrieved.
2. Waits for BKGD to return to a logic 1.
3. Delays 16 cycles to allow the host to stop driving the high speedup pulse.
4. Drives BKGD low for 128 cycles at the current BDM serial communication frequency.
5. Drives a one-cycle high speedup pulse to force a fast rise time on BKGD.
6. Removes all drive to the BKGD pin so it reverts to high impedance.

The host measures the low time of this 128 cycle SYNC response pulse and determines the correct speed for subsequent BDM communications. Typically, the host can determine the correct communication speed within a few percent of the actual target speed and the communication protocol can easily tolerate speed errors of several percent.

As soon as the SYNC request is detected by the target, any partially received command or bit retrieved is discarded. This is referred to as a soft-reset, equivalent to a time-out in the serial communication. After the SYNC response, the target will consider the next falling edge (issued by the host) as the start of a new BDM command or the start of new SYNC request.

Another use of the SYNC command pulse is to abort a pending ACK pulse. The behavior is exactly the same as in a regular SYNC command. Note that one of the possible causes for a command to not be acknowledged by the target is a host-target synchronization problem. In this case, the command may not have been understood by the target and so an ACK response pulse will not be issued.

6.4.10 Instruction Tracing

When a TRACE1 command is issued to the BDM in active BDM, the CPU exits the standard BDM firmware and executes a single instruction in the user code. As soon as this has occurred, the CPU is forced to return to the standard BDM firmware and the BDM is active and ready to receive a new command. If the TRACE1 command is issued again, the next user instruction will be executed. This facilitates stepping or tracing through the user code one instruction at a time.

If an interrupt is pending when a TRACE1 command is issued, the interrupt stacking operation occurs but no user instruction is executed. Upon return to standard BDM firmware execution, the program counter points to the first instruction in the interrupt service routine.

6.4.11 Instruction Tagging

The instruction queue and cycle-by-cycle CPU activity are reconstructible in real time or from trace history that is captured by a logic analyzer. However, the reconstructed queue cannot be used to stop the CPU at a specific instruction. This is because execution already has begun by the time an operation is visible outside the system. A separate instruction tagging mechanism is provided for this purpose.

The tag follows program information as it advances through the instruction queue. When a tagged instruction reaches the head of the queue, the CPU enters active BDM rather than executing the instruction.

NOTE

Tagging is disabled when BDM becomes active and BDM serial commands are not processed while tagging is active.

Executing the BDM TAGGO command configures two system pins for tagging. The $\overline{\text{TAGLO}}$ signal shares a pin with the $\overline{\text{LSTRB}}$ signal, and the $\overline{\text{TAGHI}}$ signal shares a pin with the BKGD signal.

Table 6-6 shows the functions of the two tagging pins. The pins operate independently, that is the state of one pin does not affect the function of the other. The presence of logic level 0 on either pin at the fall of the external clock (ECLK) performs the indicated function. High tagging is allowed in all modes. Low tagging is allowed only when low strobe is enabled (LSTRB is allowed only in wide expanded modes and emulation expanded narrow mode).

Table 6-6. Tag Pin Function

$\overline{\text{TAGHI}}$	$\overline{\text{TAGLO}}$	Tag
1	1	No tag
1	0	Low byte
0	1	High byte
0	0	Both bytes

6.4.12 Serial Communication Time-Out

The host initiates a host-to-target serial transmission by generating a falling edge on the BKGD pin. If BKGD is kept low for more than 128 target clock cycles, the target understands that a SYNC command was issued. In this case, the target will keep waiting for a rising edge on BKGD in order to answer the SYNC request pulse. If the rising edge is not detected, the target will keep waiting forever without any time-out limit.

Consider now the case where the host returns BKGD to logic one before 128 cycles. This is interpreted as a valid bit transmission, and not as a SYNC request. The target will keep waiting for another falling edge marking the start of a new bit. If, however, a new falling edge is not detected by the target within 512 clock cycles since the last falling edge, a time-out occurs and the current command is discarded without affecting memory or the operating mode of the MCU. This is referred to as a soft-reset.

If a read command is issued but the data is not retrieved within 512 serial clock cycles, a soft-reset will occur causing the command to be disregarded. The data is not available for retrieval after the time-out has occurred. This is the expected behavior if the handshake protocol is not enabled. However, consider the behavior where the BDC is running in a frequency much greater than the CPU frequency. In this case, the command could time out before the data is ready to be retrieved. In order to allow the data to be retrieved even with a large clock frequency mismatch (between BDC and CPU) when the hardware handshake protocol is enabled, the time out between a read command and the data retrieval is disabled. Therefore, the host could wait for more then 512 serial clock cycles and continue to be able to retrieve the data from an issued read command. However, as soon as the handshake pulse (ACK pulse) is issued, the time-out feature is re-activated, meaning that the target will time out after 512 clock cycles. Therefore, the host needs to retrieve the data within a 512 serial clock cycles time frame after the ACK pulse had been issued. After that period, the read command is discarded and the data is no longer available for retrieval. Any falling edge of the BKGD pin after the time-out period is considered to be a new command or a SYNC request.

Note that whenever a partially issued command, or partially retrieved data, has occurred the time out in the serial communication is active. This means that if a time frame higher than 512 serial clock cycles is observed between two consecutive negative edges and the command being issued or data being retrieved is not complete, a soft-reset will occur causing the partially received command or data retrieved to be disregarded. The next falling edge of the BKGD pin, after a soft-reset has occurred, is considered by the target as the start of a new BDM command, or the start of a SYNC request pulse.

6.4.13 Operation in Wait Mode

The BDM cannot be used in wait mode if the system disables the clocks to the BDM.

There is a clearing mechanism associated with the WAIT instruction when the clocks to the BDM (CPU core platform) are disabled. As the clocks restart from wait mode, the BDM receives a soft reset (clearing any command in progress) and the ACK function will be disabled. This is a change from previous BDM modules.

6.4.14 Operation in Stop Mode

The BDM is completely shutdown in stop mode.

There is a clearing mechanism associated with the STOP instruction. STOP must be enabled and the part must go into stop mode for this to occur. As the clocks restart from stop mode, the BDM receives a soft reset (clearing any command in progress) and the ACK function will be disabled. This is a change from previous BDM modules.

Chapter 7
Breakpoint Module (BKPV1) Block Description

7.1 Introduction

This block guide describes the functionality of the Breakpoint (BKP) sub-block of the HCS12 Core Platform.

The Breakpoint contains three main sub-blocks:

- Register Block
- Compare Block
- Control Block

The Register Block consists of the eight registers that make up the Breakpoint register space. The Compare Block performs all required address and data signal comparisons. The Control Block generates the signals for the CPU for the tag high, tag low, force SWI, and force BDM functions. In addition, it generates the register read and write signals and the comparator block enable signals.

NOTE

There is a two-cycle latency for address compares and for forces, a two-cycle latency for write data compares, and a three-cycle latency for read data compares.

The Breakpoint sub-block of the Core Platform provides for hardware breakpoints that are used to debug software on the CPU by comparing actual address and data values to predetermine data in setup registers. A successful comparison will place the CPU in Background Debug Mode or initiate a software interrupt (SWI). The choice between Background Debug Mode and SWI is software selectable.

There are two types of breakpoints, forced and tagged. Forced breakpoints occur at the next instruction boundary if a match occurs and tagged breakpoints allow for breaking just before a specific instruction executes. Tagged breakpoints will only occur on addresses of program fetches. Tagging on data is not allowed; however, if this occurs nothing will happen within the BKP.

The range function of the BKP allows breaking within a 256-byte address range. The page function allows breaking within expanded memory. In data matching operations, 8-bit or 16-bit data can be matched. Forced breakpoints are mainly used on a read or a write cycle, but can be used on any bus cycle.

7.1.1 Features

- Full or Dual Breakpoint Mode
  - — Compare on address and data (Full)
  - — Compare on either of two addresses (Dual)
- BDM or SWI Breakpoint
  - — Enter BDM on breakpoint (BDM)
  - — Execute SWI on breakpoint (SWI)
- Tagged or Forced Breakpoint
  - — Break just before a specific instruction will begin execution (TAG)
  - — Break on the first instruction boundary after a match occurs (Force)
- Single, Range, or Page address compares
  - — Compare on address (Single)
  - — Compare on address 256 byte (Range)
  - — Compare on any 16K Page (Page)
- Compare address on read or write on forced breakpoints
- High and/or low byte data compares

7.1.2 Modes of Operation

The Breakpoint sub-block contains two modes of operation:

1. Dual Address Mode, where a match on either of two addresses will cause the system to enter Background Debug Mode or initiate a Software Interrupt (SWI).
2. Full Breakpoint Mode, where a match on address and data will cause the system to enter Background Debug Mode or initiate a Software Interrupt (SWI).

7.1.3 Block Diagram

A block diagram of the Breakpoint sub-block is shown in Figure 7-1.

7.2 External Signal Description

The breakpoint sub-module relies on the external bus interface (generally the MEBI) when the breakpoint is matching on the external bus.

The tag pins in Table 7-1 (part of the MEBI) may also be a part of the breakpoint operation.

Table 7-1. External System Pins Associated With Breakpoint and MEBI

Pin Name	Pin Functions	Description
BKGD/MODC/ $\overline{\text{TAGHI}}$	$\overline{\text{TAGHI}}$	When instruction tagging is on, a 0 at the falling edge of PE4/ECLK tags the high half of the instruction word being read into the instruction queue.
PE3/ $\overline{\text{LSTRB}}$/ $\overline{\text{TAGLO}}$	$\overline{\text{TAGLO}}$	In expanded wide mode or emulation narrow modes, when instruction tagging is on and low strobe is enabled, a 0 at the falling edge of PE4/ECLK tags the low half of the instruction word being read into the instruction queue.

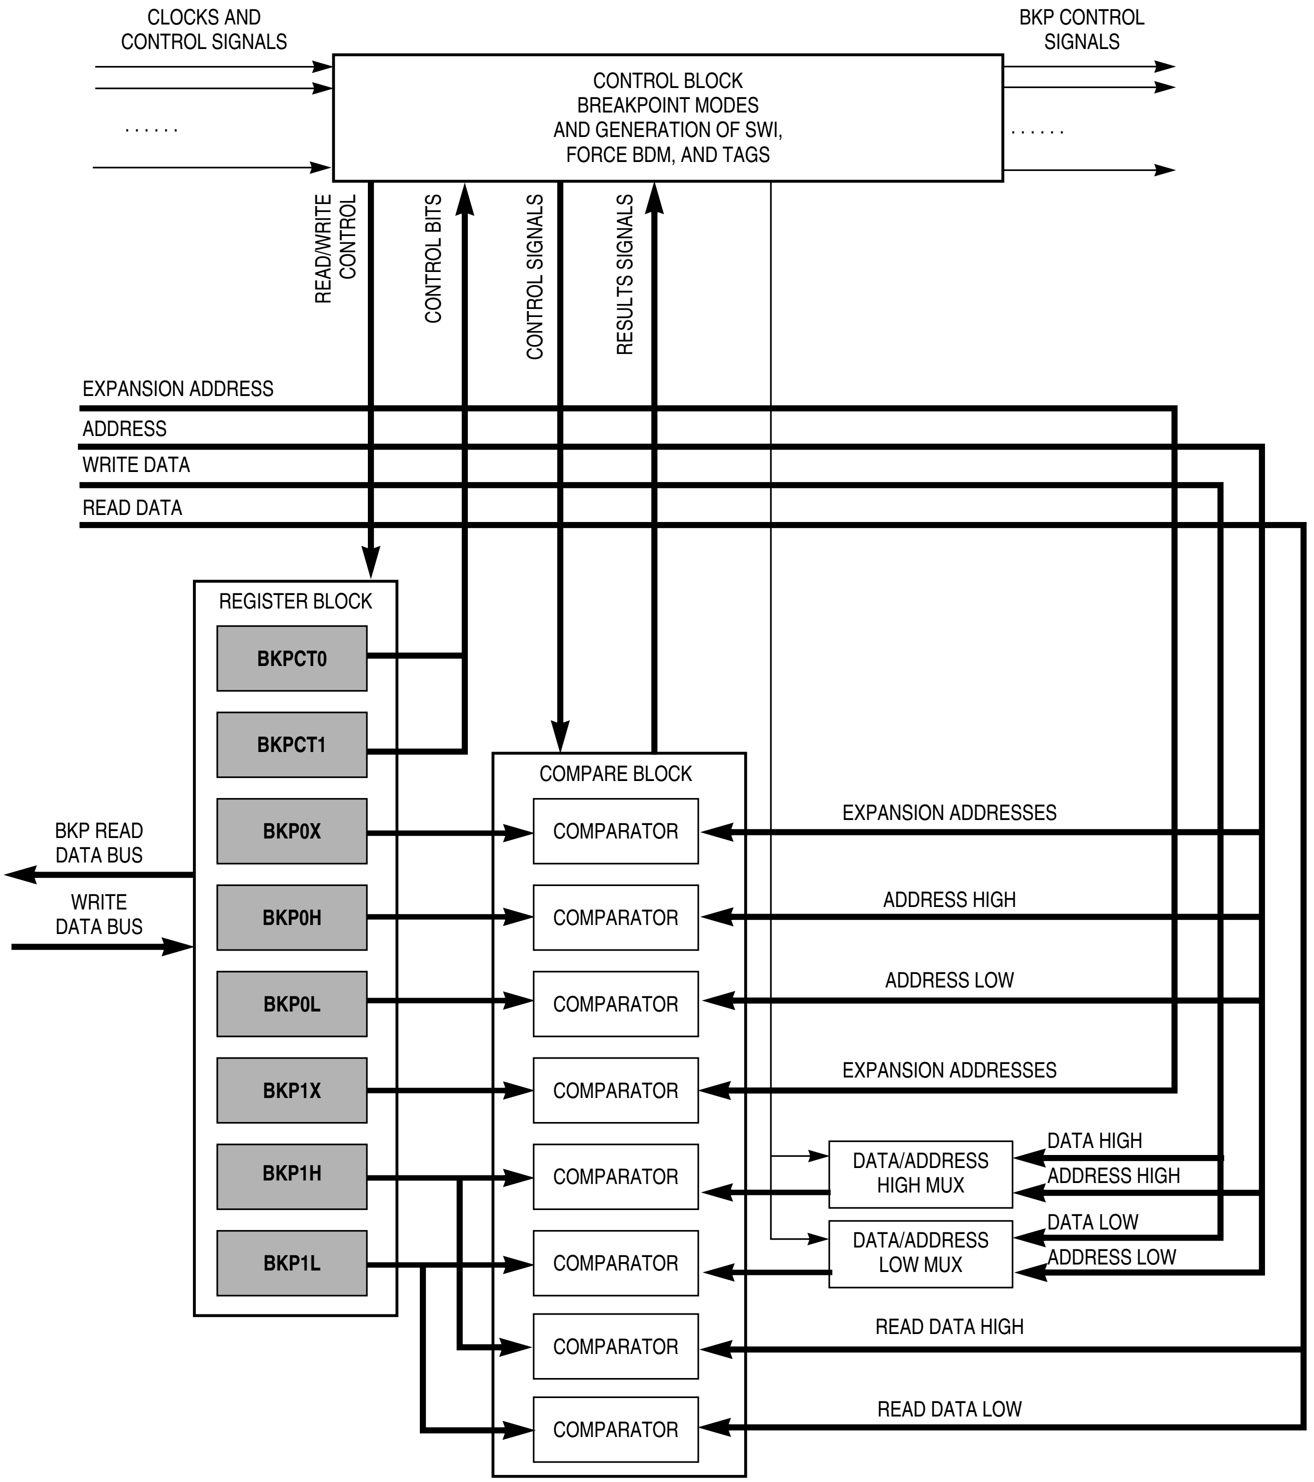

Figure 7-1. Breakpoint Block Diagram

7.3 Memory Map and Registers

This section provides a detailed description of all memory and registers.

7.3.1 Module Memory Map

A summary of the registers associated with the Breakpoint sub-block is shown in Figure 7-2. Detailed descriptions of the registers and bits are given in the subsections that follow.

This register is used to configure the functionality of the Breakpoint sub-block within the Core.

Table 7-3. BKPCT1 Field Descriptions

Field	Description
7–6 BK0MBH BK0MBL	**Breakpoint Mask High Byte and Low Byte for First Address** — In Dual or Full Mode, these bits may be used to mask (disable) the comparison of the high and low bytes of the first address breakpoint. The functionality is as given in Table 7-4 below. The x:0 case is for a Full Address Compare. When a program page is selected, the full address compare will be based on bits for a 20-bit compare. The registers used for the compare are {BKP0X[5:0], BKP0H[5:0], BKP0L[7:0]}. When a program page is not selected, the full address compare will be based on bits for a 16-bit compare. The registers used for the compare are {BKP0H[7:0], BKP0L[7:0]}. The 1:0 case is not sensible because it would ignore the high order address and compare the low order and expansion addresses. Logic forces this case to compare all address lines (effectively ignoring the BK0MBH control bit). The 1:1 case is useful for triggering a breakpoint on any access to a particular expansion page. This only makes sense if a program page is being accessed so that the breakpoint trigger will occur only if BKP0X compares.
5–4 BK1MBH BK1MBL	**Breakpoint Mask High Byte and Low Byte of Data (Second Address)** — In Dual Mode, these bits may be used to mask (disable) the comparison of the high and/or low bytes of the second address breakpoint. The functionality is as given in Table 7-5. The x:0 case is for a Full Address Compare. When a program page is selected, the full address compare will be based on bits for a 20-bit compare. The registers used for the compare are {BKP1X[5:0], BKP1H[5:0], BKP1L[7:0]}. When a program page is not selected, the full address compare will be based on bits for a 16-bit compare. The registers used for the compare are {BKP1H[7:0], BKP1L[7:0]}. The 1:0 case is not sensible because it would ignore the high order address and compare the low order and expansion addresses. Logic forces this case to compare all address lines (effectively ignoring the BK1MBH control bit). The 1:1 case is useful for triggering a breakpoint on any access to a particular expansion page. This only makes sense if a program page is being accessed so that the breakpoint trigger will occur only if BKP1X compares. In Full Mode, these bits may be used to mask (disable) the comparison of the high and/or low bytes of the data breakpoint. The functionality is as given in Table 7-6.
3 BK0RWE	**R/$\overline{\text{W}}$ Compare Enable** — Enables the comparison of the R/$\overline{\text{W}}$ signal for first address breakpoint. This bit is not useful in tagged breakpoints. 0 R/$\overline{\text{W}}$ is not used in the comparisons 1 R/$\overline{\text{W}}$ is used in comparisons

Table 7-3. BKPCT1 Field Descriptions (continued)

Field	Description
2 BK0RW	**R/$\overline{W}$ Compare Value** — When BK0RWE = 1, this bit determines the type of bus cycle to match on first address breakpoint. When BK0RWE = 0, this bit has no effect. 0 Write cycle will be matched 1 Read cycle will be matched
1 BK1RWE	**R/$\overline{W}$ Compare Enable** — In Dual Mode, this bit enables the comparison of the R/$\overline{W}$ signal to further specify what causes a match for the second address breakpoint. This bit is not useful on tagged breakpoints or in Full Mode and is therefore a don't care. 0 R/$\overline{W}$ is not used in comparisons 1 R/$\overline{W}$ is used in comparisons
0 BK1RW	**R/$\overline{W}$ Compare Value** — When BK1RWE = 1, this bit determines the type of bus cycle to match on the second address breakpoint.When BK1RWE = 0, this bit has no effect. 0 Write cycle will be matched 1 Read cycle will be matched

7.4 Functional Description

The Breakpoint sub-block supports two modes of operation: Dual Address Mode and Full Breakpoint Mode. Within each of these modes, forced or tagged breakpoint types can be used. Forced breakpoints occur at the next instruction boundary if a match occurs and tagged breakpoints allow for breaking just before a specific instruction executes. The action taken upon a successful match can be to either place the CPU in Background Debug Mode or to initiate a software interrupt.

7.4.1 Modes of Operation

The Breakpoint can operate in Dual Address Mode or Full Breakpoint Mode. Each of these modes is discussed in the subsections below.

7.4.1.1 Dual Address Mode

When Dual Address Mode is enabled, two address breakpoints can be set. Each breakpoint can cause the system to enter Background Debug Mode or to initiate a software interrupt based upon the state of the BKBDM bit in the BKPCT0 Register being logic one or logic zero, respectively. BDM requests have a higher priority than SWI requests. No data breakpoints are allowed in this mode.

The BKTAG bit in the BKPCT0 register selects whether the breakpoint mode is forced or tagged. The BKxMBH:L bits in the BKPCT1 register select whether or not the breakpoint is matched exactly or is a range breakpoint. They also select whether the address is matched on the high byte, low byte, both bytes, and/or memory expansion. The BKxRW and BKxRWE bits in the BKPCT1 register select whether the type of bus cycle to match is a read, write, or both when performing forced breakpoints.

7.4.1.2 Full Breakpoint Mode

Full Breakpoint Mode requires a match on address and data for a breakpoint to occur. Upon a successful match, the system will enter Background Debug Mode or initiate a software interrupt based upon the state of the BKBDM bit in the BKPCT0 Register being logic one or logic zero, respectively. BDM requests have a higher priority than SWI requests. $R/\overline{W}$ matches are also allowed in this mode.

The BKTAG bit in the BKPCT0 register selects whether the breakpoint mode is forced or tagged. If the BKTAG bit is set in BKPCT0, then only address is matched, and data is ignored. The BK0MBH:L bits in the BKPCT1 register select whether or not the breakpoint is matched exactly, is a range breakpoint, or is in page space. The BK1MBH:L bits in the BKPCT1 register select whether the data is matched on the high byte, low byte, or both bytes. The BK0RW and BK0RWE bits in the BKPCT1 register select whether the type of bus cycle to match is a read or a write when performing forced breakpoints. BK1RW and BK1RWE bits in the BKPCT1 register are not used in Full Breakpoint Mode.

7.4.2 Breakpoint Priority

Breakpoint operation is first determined by the state of BDM. If BDM is already active, meaning the CPU is executing out of BDM firmware, Breakpoints are not allowed. In addition, while in BDM trace mode, tagging into BDM is not allowed. If BDM is not active, the Breakpoint will give priority to BDM requests over SWI requests. This condition applies to both forced and tagged breakpoints.

In all cases, BDM related breakpoints will have priority over those generated by the Breakpoint sub-block. This priority includes breakpoints enabled by the $\overline{\text{TAGLO}}$ and $\overline{\text{TAGHI}}$ external pins of the system that interface with the BDM directly and whose signal information passes through and is used by the Breakpoint sub-block.

NOTE

BDM should not be entered from a breakpoint unless the BKEN bit is set in the BDM. Even if the ENABLE bit in the BDM is negated, the CPU actually executes the BDM firmware code. It checks the ENABLE and returns if enable is not set. If the BDM is not serviced by the monitor then the breakpoint would be re-asserted when the BDM returns to normal CPU flow.

There is no hardware to enforce restriction of breakpoint operation if the BDM is not enabled.

Chapter 8
Analog-to-Digital Converter (ATD10B8CV3)

8.1 Introduction

The ATD10B8C is an 8-channel, 10-bit, multiplexed input successive approximation analog-to-digital converter. Refer to device electrical specifications for ATD accuracy.

8.1.1 Features

- 8/10-bit resolution
- 7 μsec, 10-bit single conversion time
- Sample buffer amplifier
- Programmable sample time
- Left/right justified, signed/unsigned result data
- External trigger control
- Conversion completion interrupt generation
- Analog input multiplexer for 8 analog input channels
- Analog/digital input pin multiplexing
- 1-to-8 conversion sequence lengths
- Continuous conversion mode
- Multiple channel scans
- Configurable external trigger functionality on any AD channel or any of four additional external trigger inputs. The four additional trigger inputs can be chip external or internal. Refer to the device overview chapter for availability and connectivity.
- Configurable location for channel wrap around (when converting multiple channels in a sequence).

8.1.2 Modes of Operation

8.1.2.1 Conversion Modes

There is software programmable selection between performing single or continuous conversion on a single channel or multiple channels.

8.1.2.2 MCU Operating Modes

- Stop mode

  Entering stop mode causes all clocks to halt and thus the system is placed in a minimum power standby mode. This aborts any conversion sequence in progress. During recovery from stop mode, there must be a minimum delay for the stop recovery time t_{SR} before initiating a new ATD conversion sequence.
- Wait mode

  Entering wait mode the ATD conversion either continues or aborts for low power depending on the logical value of the AWAIT bit.
- Freeze mode

  In freeze mode the ATD will behave according to the logical values of the FRZ1 and FRZ0 bits. This is useful for debugging and emulation.

8.1.3 Block Diagram

Figure 8-1 shows a block diagram of the ATD.

8.2 External Signal Description

This section lists all inputs to the ATD block.

8.2.1 AN*x* (*x* = 7, 6, 5, 4, 3, 2, 1, 0) — Analog Input Pin

This pin serves as the analog input channel *x*. It can also be configured as general purpose digital port pin and/or external trigger for the ATD conversion.

8.2.2 ETRIG3, ETRIG2, ETRIG1, and ETRIG0 — External Trigger Pins

These inputs can be configured to serve as an external trigger for the ATD conversion.

Refer to the device overview chapter for availability and connectivity of these inputs.

8.2.3 V_{RH} and V_{RL} — High and Low Reference Voltage Pins

V_{RH} is the high reference voltage and V_{RL} is the low reference voltage for ATD conversion.

8.2.4 V_{DDA} and V_{SSA} — Power Supply Pins

These pins are the power supplies for the analog circuitry of the ATD block.

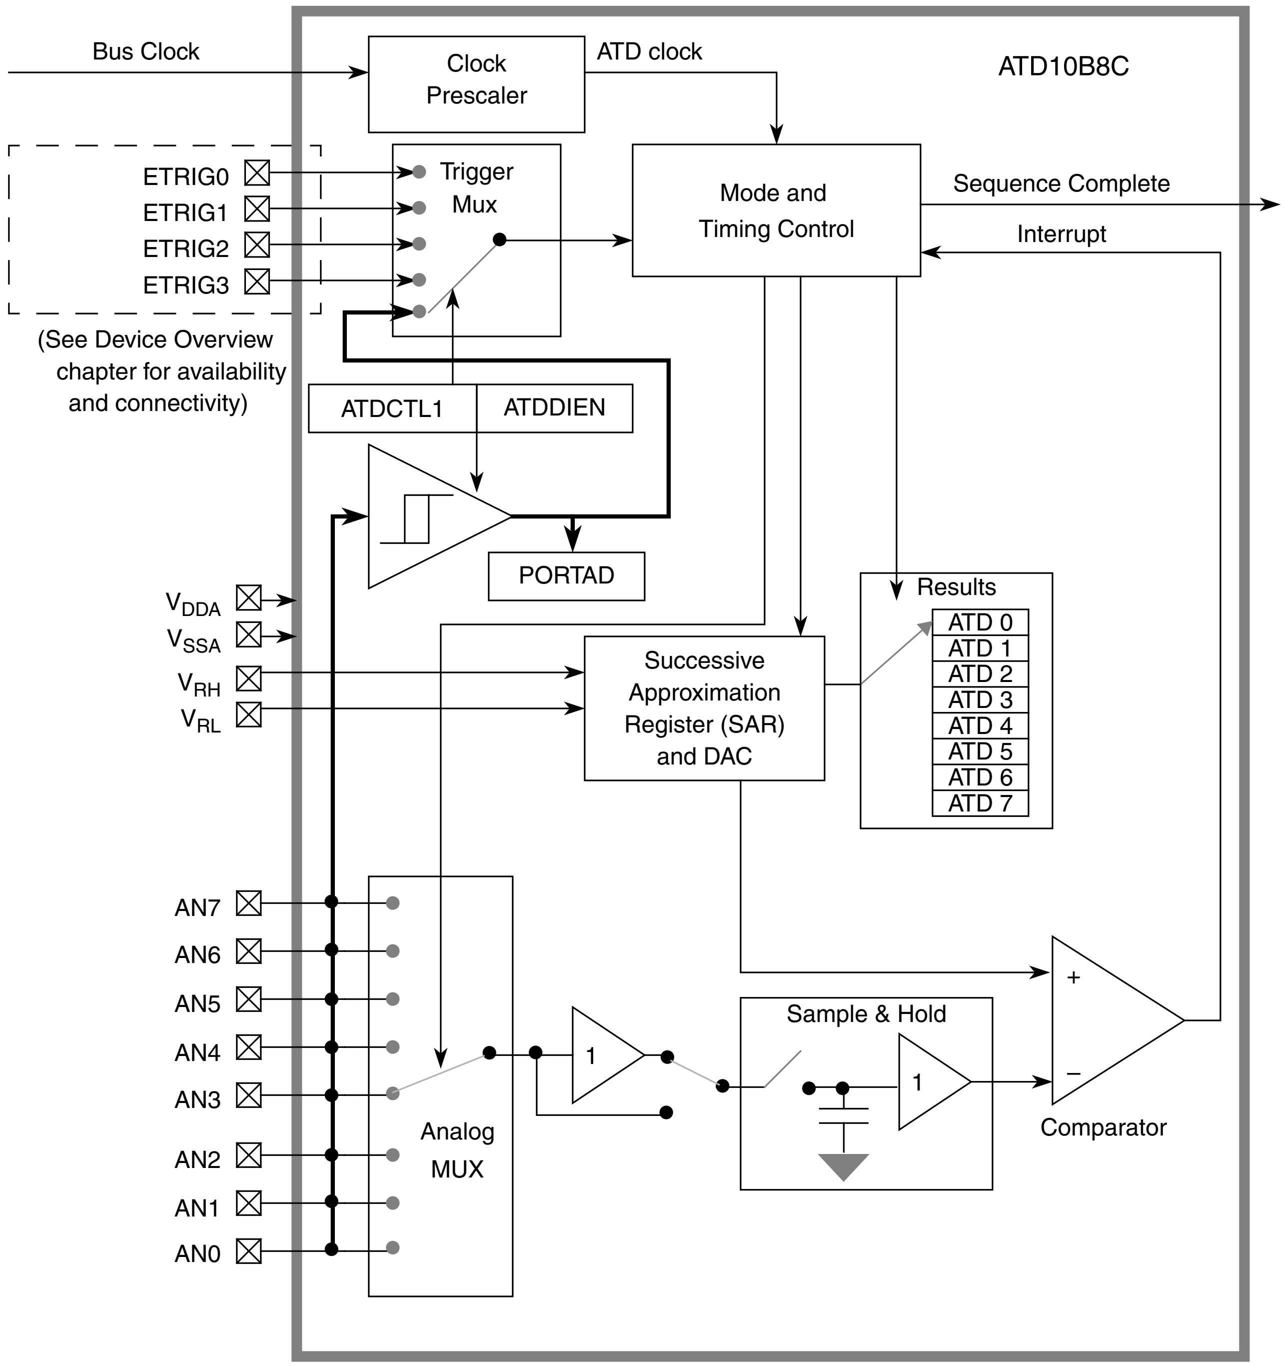

Figure 8-1. ATD Block Diagram

8.3 Memory Map and Register Definition

This section provides a detailed description of all registers accessible in the ATD.

8.3.1 Module Memory Map

Figure 8-2 gives an overview of all ATD registers.

NOTE

Register Address = Base Address + Address Offset, where the Base Address is defined at the MCU level and the Address Offset is defined at the module level.

8.3.2 Register Descriptions

This section describes in address order all the ATD registers and their individual bits.

Register Name		Bit 7	6	5	4	3	2	1	Bit 0

Table 8-3. ATDCTL1 Field Descriptions

Field	Description
7 ETRIGSEL	**External Trigger Source Select** — This bit selects the external trigger source to be either one of the AD channels or one of the ETRIG3–0 inputs. See the device overview chapter for availability and connectivity of ETRIG3–0 inputs. If ETRIG3–0 input option is not available, writing a 1 to ETRISEL only sets the bit but has not effect, that means still one of the AD channels (selected by ETRIGCH2–0) is the source for external trigger. The coding is summarized in Table 8-4.
2–0 ETRIGCH[2:0]	**External Trigger Channel Select** — These bits select one of the AD channels or one of the ETRIG3–0 inputs as source for the external trigger. The coding is summarized in Table 8-4.

Table 8-4. External Trigger Channel Select Coding

ETRIGSEL	ETRIGCH2	ETRIGCH1	ETRIGCH0	External trigger source is
0	0	0	0	AN0
0	0	0	1	AN1
0	0	1	0	AN2
0	0	1	1	AN3
0	1	0	0	AN4
0	1	0	1	AN5
0	1	1	0	AN6
0	1	1	1	AN7
1	0	0	0	ETRIG0[1]
1	0	0	1	ETRIG1[1]
1	0	1	0	ETRIG2[1]
1	0	1	1	ETRIG3[1]
1	1	X	X	Reserved

[1] Only if ETRIG3–0 input option is available (see device overview chapter), else ETRISEL is ignored, that means external trigger source is still on one of the AD channels selected by ETRIGCH2–0

8.3.2.3 ATD Control Register 2 (ATDCTL2)

This register controls power down, interrupt and external trigger. Writes to this register will abort current conversion sequence but will not start a new sequence.

Module Base + 0x0002

(shaded) = Unimplemented or Reserved

Figure 8-5. ATD Control Register 2 (ATDCTL2)

Read: Anytime

Write: Anytime

Table 8-5. ATDCTL2 Field Descriptions

Field	Description
7 ADPU	**ATD Power Up** — This bit provides on/off control over the ATD block allowing reduced MCU power consumption. Because analog electronic is turned off when powered down, the ATD requires a recovery time period after ADPU bit is enabled. 0 Power down ATD. Flags (SCF, CCFx, ETORF, FIFOR) can not be cleared. 1 Normal ATD functionality
6 AFFC	**ATD Fast Flag Clear All** 0 ATD flag clearing operates normally (read the status register ATDSTAT1 before reading the result register to clear the associate CCF flag). 1 Changes all ATD conversion complete flags to a fast clear sequence. Any access to a result register will cause the associate CCF flag to clear automatically.
5 AWAI	**ATD Power Down in Wait Mode** — When entering wait mode this bit provides on/off control over the ATD block allowing reduced MCU power. Because analog electronic is turned off when powered down, the ATD requires a recovery time period after exit from Wait mode. 0 ATD continues to run in Wait mode 1 Halt conversion and power down ATD during wait mode After exiting wait mode with an interrupt conversion will resume. But due to the recovery time the result of this conversion should be ignored.
4 ETRIGLE	**External Trigger Level/Edge Control** — This bit controls the sensitivity of the external trigger signal. See Table 8-6 for details.
3 ETRIGP	**External Trigger Polarity** — This bit controls the polarity of the external trigger signal. See Table 8-6 for details.
2 ETRIGE	**External Trigger Mode Enable** — This bit enables the external trigger on one of the AD channels or one of the ETRIG3–0 inputs as described in Table 8-4. If external trigger source is one of the AD channels, the digital input buffer of this channel is enabled. The external trigger allows to synchronize sample and ATD conversions processes with external events. 0 Disable external trigger 1 Enable external trigger **Note:** If using one of the AD channel as external trigger (ETRIGSEL = 0) the conversion results for this channel have no meaning while external trigger mode is enabled.

Table 8-5. ATDCTL2 Field Descriptions (continued)

Field	Description
1 ASCIE	**ATD Sequence Complete Interrupt Enable** 0 ATD Sequence Complete interrupt requests are disabled. 1 ATD Interrupt will be requested whenever ASCIF = 1 is set.
0 ASCIF	**ATD Sequence Complete Interrupt Flag** — If ASCIE = 1 the ASCIF flag equals the SCF flag (see Section 8.3.2.7, "ATD Status Register 0 (ATDSTAT0)"), else ASCIF reads zero. Writes have no effect. 0 No ATD interrupt occurred 1 ATD sequence complete interrupt pending

Table 8-6. External Trigger Configurations

ETRIGLE	ETRIGP	External Trigger Sensitivity
0	0	Falling edge
0	1	Rising edge
1	0	Low level
1	1	High level

8.3.2.4 ATD Control Register 3 (ATDCTL3)

This register controls the conversion sequence length, FIFO for results registers and behavior in freeze mode. Writes to this register will abort current conversion sequence but will not start a new sequence.

Module Base + 0x0003

	7	6	5	4	3	2	1	0
R	0	S8C	S4C	S2C	S1C	FIFO	FRZ1	FRZ0
W								
Reset	0	0	0	0	0	0	0	0

= Unimplemented or Reserved

Figure 8-6. ATD Control Register 3 (ATDCTL3)

Read: Anytime

Write: Anytime

Table 8-7. ATDCTL3 Field Descriptions

Field	Description
6–3 S8C, S4C, S2C, S1C	**Conversion Sequence Length** — These bits control the number of conversions per sequence. Table 8-8 shows all combinations. At reset, S4C is set to 1 (sequence length is 4). This is to maintain software continuity to HC12 Family.

Table 8-7. ATDCTL3 Field Descriptions (continued)

Field	Description
2 FIFO	**Result Register FIFO Mode** — If this bit is zero (non-FIFO mode), the A/D conversion results map into the result registers based on the conversion sequence; the result of the first conversion appears in the first result register, the second result in the second result register, and so on. If this bit is one (FIFO mode) the conversion counter is not reset at the beginning or ending of a conversion sequence; sequential conversion results are placed in consecutive result registers. In a continuously scanning conversion sequence, the result register counter will wrap around when it reaches the end of the result register file. The conversion counter value (CC2-0 in ATDSTAT0) can be used to determine where in the result register file, the current conversion result will be placed. Aborting a conversion or starting a new conversion by write to an ATDCTL register (ATDCTL5-0) clears the conversion counter even if FIFO=1. So the first result of a new conversion sequence, started by writing to ATDCTL5, will always be place in the first result register (ATDDDR0). Intended usage of FIFO mode is continuos conversion (SCAN=1) or triggered conversion (ETRIG=1). Finally, which result registers hold valid data can be tracked using the conversion complete flags. Fast flag clear mode may or may not be useful in a particular application to track valid data. 0 Conversion results are placed in the corresponding result register up to the selected sequence length. 1 Conversion results are placed in consecutive result registers (wrap around at end).
1–0 FRZ[1:0]	**Background Debug Freeze Enable** — When debugging an application, it is useful in many cases to have the ATD pause when a breakpoint (Freeze Mode) is encountered. These 2 bits determine how the ATD will respond to a breakpoint as shown in Table 8-9. Leakage onto the storage node and comparator reference capacitors may compromise the accuracy of an immediately frozen conversion depending on the length of the freeze period.

Table 8-8. Conversion Sequence Length Coding

S8C	S4C	S2C	S1C	Number of Conversions per Sequence
0	0	0	0	8
0	0	0	1	1
0	0	1	0	2
0	0	1	1	3
0	1	0	0	4
0	1	0	1	5
0	1	1	0	6
0	1	1	1	7
1	X	X	X	8

Table 8-9. ATD Behavior in Freeze Mode (Breakpoint)

FRZ1	FRZ0	Behavior in Freeze Mode
0	0	Continue conversion
0	1	Reserved
1	0	Finish current conversion, then freeze
1	1	Freeze Immediately

8.3.2.5 ATD Control Register 4 (ATDCTL4)

This register selects the conversion clock frequency, the length of the second phase of the sample time and the resolution of the A/D conversion (i.e.: 8-bits or 10-bits). Writes to this register will abort current conversion sequence but will not start a new sequence.

Module Base + 0x0004

	7	6	5	4	3	2	1	0
R W	SRES8	SMP1	SMP0	PRS4	PRS3	PRS2	PRS1	PRS0
Reset	0	0	0	0	0	1	0	1

Figure 8-7. ATD Control Register 4 (ATDCTL4)

Read: Anytime

Write: Anytime

Table 8-10. ATDCTL4 Field Descriptions

Field	Description
7 SRES8	**A/D Resolution Select** — This bit selects the resolution of A/D conversion results as either 8 or 10 bits. The A/D converter has an accuracy of 10 bits; however, if low resolution is required, the conversion can be speeded up by selecting 8-bit resolution. 0 10-bit resolution 8-bit resolution
6–5 SMP[1:0]	**Sample Time Select** — These two bits select the length of the second phase of the sample time in units of ATD conversion clock cycles. Note that the ATD conversion clock period is itself a function of the prescaler value (bits PRS4–0). The sample time consists of two phases. The first phase is two ATD conversion clock cycles long and transfers the sample quickly (via the buffer amplifier) onto the A/D machine's storage node. The second phase attaches the external analog signal directly to the storage node for final charging and high accuracy. Table 8-11 lists the lengths available for the second sample phase.
4–0 PRS[4:0]	**ATD Clock Prescaler —** These 5 bits are the binary value prescaler value PRS. The ATD conversion clock frequency is calculated as follows: $ATDclock = \frac{[BusClock]}{[PRS + 1]} \times 0.5$ **Note:** The maximum ATD conversion clock frequency is half the bus clock. The default (after reset) prescaler value is 5 which results in a default ATD conversion clock frequency that is bus clock divided by 12. Table 8-12 illustrates the divide-by operation and the appropriate range of the bus clock.

Table 8-11. Sample Time Select

SMP1	SMP0	Length of 2nd Phase of Sample Time
0	0	2 A/D conversion clock periods
0	1	4 A/D conversion clock periods
1	0	8 A/D conversion clock periods
1	1	16 A/D conversion clock periods

Table 8-12. Clock Prescaler Values

Prescale Value	Total Divisor Value	Max. Bus Clock[1]	Min. Bus Clock[2]
00000	Divide by 2	4 MHz	1 MHz
00001	Divide by 4	8 MHz	2 MHz

Table 8-13. ATDCTL5 Field Descriptions

Field	Description
7 DJM	**Result Register Data Justification** — This bit controls justification of conversion data in the result registers. See Section 8.3.2.13, "ATD Conversion Result Registers (ATDDRx)," for details. 0 Left justified data in the result registers 1 Right justified data in the result registers
6 DSGN	**Result Register Data Signed or Unsigned Representation** — This bit selects between signed and unsigned conversion data representation in the result registers. Signed data is represented as 2's complement. Signed data is not available in right justification. See Section 8.3.2.13, "ATD Conversion Result Registers (ATDDRx)," for details. 0 Unsigned data representation in the result registers 1 Signed data representation in the result registers Table 8-14 summarizes the result data formats available and how they are set up using the control bits. Table 8-15 illustrates the difference between the signed and unsigned, left justified output codes for an input signal range between 0 and 5.12 Volts.
5 SCAN	**Continuous Conversion Sequence Mode** — This bit selects whether conversion sequences are performed continuously or only once. 0 Single conversion sequence 1 Continuous conversion sequences (scan mode)
4 MULT	**Multi-Channel Sample Mode** — When MULT is 0, the ATD sequence controller samples only from the specified analog input channel for an entire conversion sequence. The analog channel is selected by channel selection code (control bits CC/CB/CA located in ATDCTL5). When MULT is 1, the ATD sequence controller samples across channels. The number of channels sampled is determined by the sequence length value (S8C, S4C, S2C, S1C). The first analog channel examined is determined by channel selection code (CC, CB, CA control bits); subsequent channels sampled in the sequence are determined by incrementing the channel selection code. 0 Sample only one channel 1 Sample across several channels
2–0 CC, CB, CA	**Analog Input Channel Select Code** — These bits select the analog input channel(s) whose signals are sampled and converted to digital codes. Table 8-16 lists the coding used to select the various analog input channels. In the case of single channel scans (MULT = 0), this selection code specified the channel examined. In the case of multi-channel scans (MULT = 1), this selection code represents the first channel to be examined in the conversion sequence. Subsequent channels are determined by incrementing channel selection code; selection codes that reach the maximum value wrap around to the minimum value.

Table 8-14. Available Result Data Formats

SRES8	DJM	DSGN	Result Data Formats Description and Bus Bit Mapping
1	0	0	8-bit / left justified / unsigned — bits 8–15
1	0	1	8-bit / left justified / signed — bits 8–15
1	1	X	8-bit / right justified / unsigned — bits 0–7
0	0	0	10-bit / left justified / unsigned — bits 6–15
0	0	1	10-bit / left justified / signed — bits 6–15
0	1	X	10-bit / right justified / unsigned — bits 0–9

Figure 8-9. ATD Status Register 0 (ATDSTAT0)

Read: Anytime

Write: Anytime (No effect on (CC2, CC1, CC0))

Table 8-17. ATDSTAT0 Field Descriptions

Field	Description
7 SCF	**Sequence Complete Flag** — This flag is set upon completion of a conversion sequence. If conversion sequences are continuously performed (SCAN = 1), the flag is set after each one is completed. This flag can be cleared when ADPU=1 and one of the following occurs: A) Write “1” to SCF B) Write to ATDCTL5 (a new conversion sequence is started) C) If AFFC=1 and read of a result register 0 Conversion sequence not completed 1 Conversion sequence has completed
5 ETORF	**External Trigger Overrun Flag** — While in edge trigger mode (ETRIGLE = 0), if additional active edges are detected while a conversion sequence is in process the overrun flag is set. This flag can be cleared when ADPU=1 and one of the following occurs: A) Write “1” to ETORF B) Write to ATDCTL2, ATDCTL3 or ATDCTL4 (a conversion sequence is aborted) C) Write to ATDCTL5 (a new conversion sequence is started) 0 No External trigger over run error has occurred 1 External trigger over run error has occurred
4 FIFOR	**FIFO Over Run Flag** — This bit indicates that a result register has been written to before its associated conversion complete flag (CCF) has been cleared. This flag is most useful when using the FIFO mode because the flag potentially indicates that result registers are out of sync with the input channels. However, it is also practical for non-FIFO modes, and indicates that a result register has been over written before it has been read (i.e., the old data has been lost). This flag can be cleared when ADPU=1 and one of the following occurs: A) Write “1” to FIFOR B) Start a new conversion sequence (write to ATDCTL5 or external trigger) 0 No over run has occurred 1 An over run condition exists
2–0 CC[2:0]	**Conversion Counter** — These 3 read-only bits are the binary value of the conversion counter. The conversion counter points to the result register that will receive the result of the current conversion. E.g. CC2 = 1, CC1 = 1, CC0 = 0 indicates that the result of the current conversion will be in ATD result register 6. If in non-FIFO mode (FIFO = 0) the conversion counter is initialized to zero at the begin and end of the conversion sequence. If in FIFO mode (FIFO = 1) the register counter is not initialized. The conversion counters wraps around when its maximum value is reached. Aborting a conversion or starting a new conversion by write to an ATDCTL register (ATDCTL5-0) clears the conversion counter even if FIFO=1.

8.3.2.8 Reserved Register (ATDTEST0)

Module Base + 0x0008

Table 8-20. ATDSTAT1 Field Descriptions

Field	Description
7–0 CCF[7:0]	**Conversion Complete Flag x (x = 7, 6, 5, 4, 3, 2, 1, 0)** — A conversion complete flag is set at the end of each conversion in a conversion sequence. The flags are associated with the conversion position in a sequence (and also the result register number). Therefore, CCF0 is set when the first conversion in a sequence is complete and the result is available in result register ATDDR0; CCF1 is set when the second conversion in a sequence is complete and the result is available in ATDDR1, and so forth. A flag CCFx (x = 7, 6, 5, 4, 3, 2,1, 70) is cleared when ADPU=1 and one of the following occurs: A) Write to ATDCTL5 (a new conversion sequence is started) B) If AFFC=0 and read of ATDSTAT1 followed by read of result register ATDDRx C) If AFFC=1 and read of result register ATDDRx In case of a concurrent set and clear on CCFx: The clearing by method A) will overwrite the set. The clearing by methods B) or C) will be overwritten by the set. 0 Conversion number x not completed 1 Conversion number x has completed, result ready in ATDDRx

8.3.2.11 ATD Input Enable Register (ATDDIEN)

Module Base + 0x000D

Write: Anytime

Table 8-21. ATDDIEN Field Descriptions

Field	Description
7–0 IEN[7:0]	**ATD Digital Input Enable on channel x (x = 7, 6, 5, 4, 3, 2, 1, 0)** — This bit controls the digital input buffer from the analog input pin (ANx) to PTADx data register. 0 Disable digital input buffer to PTADx 1 Enable digital input buffer to PTADx. **Note:** Setting this bit will enable the corresponding digital input buffer continuously. If this bit is set while simultaneously using it as an analog port, there is potentially increased power consumption because the digital input buffer maybe in the linear region.

8.3.2.12 Port Data Register (PORTAD)

The data port associated with the ATD can be configured as general-purpose I/O or input only, as specified in the device overview. The port pins are shared with the analog A/D inputs AN7–0.

Module Base + 0x000F

	7	6	5	4	3	2	1	0

Write: Anytime, no effect

The A/D input channels may be used for general purpose digital input.

Table 8-22. PORTAD Field Descriptions

Field	Description
7–0 PTAD[7:0]	**A/D Channel x (ANx) Digital Input (x = 7, 6, 5, 4, 3, 2, 1, 0)** — If the digital input buffer on the ANx pin is enabled (IENx = 1) or channel x is enabled as external trigger (ETRIGE = 1,ETRIGCH[2–0] = x,ETRIGSEL = 0) read returns the logic level on ANx pin (signal potentials not meeting V_{IL} or V_{IH} specifications will have an indeterminate value). If the digital input buffers are disabled (IENx = 0) and channel x is not enabled as external trigger, read returns a “1”. Reset sets all PORTAD0 bits to “1”.

8.3.2.13 ATD Conversion Result Registers (ATDDRx)

The A/D conversion results are stored in 8 read-only result registers. The result data is formatted in the result registers based on two criteria. First there is left and right justification; this selection is made using the DJM control bit in ATDCTL5. Second there is signed and unsigned data; this selection is made using the DSGN control bit in ATDCTL5. Signed data is stored in 2’s complement format and only exists in left justified format. Signed data selected for right justified format is ignored.

Figure 8-18. Right Justified, ATD Conversion Result Register, Low Byte (ATDDRxL)

8.4 Functional Description

The ATD is structured in an analog and a digital sub-block.

8.4.1 Analog Sub-Block

The analog sub-block contains all analog electronics required to perform a single conversion. Separate power supplies V_{DDA} and V_{SSA} allow to isolate noise of other MCU circuitry from the analog sub-block.

8.4.1.1 Sample and Hold Machine

The sample and hold (S/H) machine accepts analog signals from the external surroundings and stores them as capacitor charge on a storage node.

The sample process uses a two stage approach. During the first stage, the sample amplifier is used to quickly charge the storage node.The second stage connects the input directly to the storage node to complete the sample for high accuracy.

When not sampling, the sample and hold machine disables its own clocks. The analog electronics still draw their quiescent current. The power down (ADPU) bit must be set to disable both the digital clocks and the analog power consumption.

The input analog signals are unipolar and must fall within the potential range of V_{SSA} to V_{DDA}.

8.4.1.2 Analog Input Multiplexer

The analog input multiplexer connects one of the 8 external analog input channels to the sample and hold machine.

8.4.1.3 Sample Buffer Amplifier

The sample amplifier is used to buffer the input analog signal so that the storage node can be quickly charged to the sample potential.

8.4.1.4 Analog-to-Digital (A/D) Machine

The A/D Machine performs analog to digital conversions. The resolution is program selectable at either 8 or 10 bits. The A/D machine uses a successive approximation architecture. It functions by comparing the stored analog sample potential with a series of digitally generated analog potentials. By following a binary search algorithm, the A/D machine locates the approximating potential that is nearest to the sampled potential.

When not converting the A/D machine disables its own clocks. The analog electronics still draws quiescent current. The power down (ADPU) bit must be set to disable both the digital clocks and the analog power consumption.

Only analog input signals within the potential range of V_{RL} to V_{RH} (A/D reference potentials) will result in a non-railed digital output codes.

8.4.2 Digital Sub-Block

This subsection explains some of the digital features in more detail. See register descriptions for all details.

8.4.2.1 External Trigger Input

The external trigger feature allows the user to synchronize ATD conversions to the external environment events rather than relying on software to signal the ATD module when ATD conversions are to take place. The external trigger signal (out of reset ATD channel 7, configurable in ATDCTL1) is programmable to be edge or level sensitive with polarity control. Table 8-23 gives a brief description of the different combinations of control bits and their effect on the external trigger function.

Table 8-23. External Trigger Control Bits

ETRIGLE	ETRIGP	ETRIGE	SCAN	Description
X	X	0	0	Ignores external trigger. Performs one conversion sequence and stops.
X	X	0	1	Ignores external trigger. Performs continuous conversion sequences.
0	0	1	X	Falling edge triggered. Performs one conversion sequence per trigger.
0	1	1	X	Rising edge triggered. Performs one conversion sequence per trigger.
1	0	1	X	Trigger active low. Performs continuous conversions while trigger is active.
1	1	1	X	Trigger active high. Performs continuous conversions while trigger is active.

During a conversion, if additional active edges are detected the overrun error flag ETORF is set.

In either level or edge triggered modes, the first conversion begins when the trigger is received. In both cases, the maximum latency time is one bus clock cycle plus any skew or delay introduced by the trigger circuitry.

NOTE

The conversion results for the external trigger ATD channel 7 have no meaning while external trigger mode is enabled.

Once ETRIGE is enabled, conversions cannot be started by a write to ATDCTL5, but rather must be triggered externally.

If the level mode is active and the external trigger both de-asserts and re-asserts itself during a conversion sequence, this does not constitute an overrun; therefore, the flag is not set. If the trigger is left asserted in level mode while a sequence is completing, another sequence will be triggered immediately.

8.4.2.2 General Purpose Digital Input Port Operation

The input channel pins can be multiplexed between analog and digital data. As analog inputs, they are multiplexed and sampled to supply signals to the A/D converter. As digital inputs, they supply external input data that can be accessed through the digital port register PORTAD (input-only).

The analog/digital multiplex operation is performed in the input pads. The input pad is always connected to the analog inputs of the ATD. The input pad signal is buffered to the digital port registers. This buffer can be turned on or off with the ATDDIEN register. This is important so that the buffer does not draw excess current when analog potentials are presented at its input.

8.4.2.3 Low Power Modes

The ATD can be configured for lower MCU power consumption in 3 different ways:

1. Stop mode: This halts A/D conversion. Exit from stop mode will resume A/D conversion, but due to the recovery time the result of this conversion should be ignored.
2. Wait mode with AWAI = 1: This halts A/D conversion. Exit from wait mode will resume A/D conversion, but due to the recovery time the result of this conversion should be ignored.
3. Writing ADPU = 0 (Note that all ATD registers remain accessible.): This aborts any A/D conversion in progress.

Note that the reset value for the ADPU bit is zero. Therefore, when this module is reset, it is reset into the power down state.

8.5 Initialization/Application Information

8.5.1 Setting up and starting an A/D conversion

The following describes a typical setup procedure for starting A/D conversions. It is highly recommended to follow this procedure to avoid common mistakes.

Each step of the procedure will have a general remark and a typical example

8.5.1.1 Step 1

Power up the ATD and concurrently define other settings in ATDCTL2
Example: Write to ATDCTL2: ADPU=1 -> powers up the ATD, ASCIE=1 enable interrupt on finish of a conversion sequence.

8.5.1.2 Step 2

Wait for the ATD Recovery Time t_{REC} before you proceed with Step 3.

Example: Use the CPU in a branch loop to wait for a defined number of bus clocks.

8.5.1.3 Step 3

Configure how many conversions you want to perform in one sequence and define other settings in ATDCTL3.

Example: Write S4C=1 to do 4 conversions per sequence.

8.5.1.4 Step 4

Configure resolution, sampling time and ATD clock speed in ATDCTL4.

Example: Use default for resolution and sampling time by leaving SRES8, SMP1 and SMP0 clear. For a bus clock of 40MHz write 9 to PR4-0, this gives an ATD clock of 0.5*40MHz/(9+1) = 2MHz which is within the allowed range for f_{ATDCLK}.

8.5.1.5 Step 5

Configure starting channel, single/multiple channel, continuous or single sequence and result data format in ATDCTL5. Writing ATDCTL5 will start the conversion, so make sure your write ATDCTL5 in the last step.

Example: Leave CC,CB,CA clear to start on channel AN0. Write MULT=1 to convert channel AN0 to AN3 in a sequence (4 conversion per sequence selected in ATDCTL3).

8.5.2 Aborting an A/D conversion

8.5.2.1 Step 1

Write to ATDCTL4. This will abort any ongoing conversion sequence.

(Do not use write to other ATDCTL registers to abort, as this under certain circumstances might not work correctly.)

8.5.2.2 Step 2

Disable the ATD Interrupt by writing ASCIE=0 in ATDCTL2.

It is important to clear the interrupt enable at this point, prior to step 3, as depending on the device clock gating it may not always be possible to clear it or the SCF flag once the module is disabled (ADPU=0).

8.5.2.3 Step 3

Clear the SCF flag by writing a 1 in ATDSTAT0.

(Remaining flags will be cleared with the next start of a conversions, but SCF flag should be cleared to avoid SCF interrupt.)

8.5.2.4 Step 4

Power down ATD by writing ADPU=0 in ATDCTL2.

8.6 Resets

At reset the ATD is in a power down state. The reset state of each individual bit is listed within the Register Description section (see Section 8.3, “Memory Map and Register Definition”), which details the registers and their bit-field.

8.7 Interrupts

The interrupt requested by the ATD is listed in Table 8-24. Refer to the device overview chapter for related vector address and priority.

Table 8-24. ATD Interrupt Vectors

Interrupt Source	CCR Mask	Local Enable
Sequence complete interrupt	I bit	ASCIE in ATDCTL2

See register descriptions for further details.

Chapter 9
Clocks and Reset Generator (CRGV4) Block Description

9.1 Introduction

This specification describes the function of the clocks and reset generator (CRG).

9.1.1 Features

The main features of this block are:

- Phase-locked loop (PLL) frequency multiplier
  - Reference divider
  - Automatic bandwidth control mode for low-jitter operation
  - Automatic frequency lock detector
  - CPU interrupt on entry or exit from locked condition
  - Self-clock mode in absence of reference clock
- System clock generator
  - Clock quality check
  - Clock switch for either oscillator- or PLL-based system clocks
  - User selectable disabling of clocks during wait mode for reduced power consumption
- Computer operating properly (COP) watchdog timer with time-out clear window
- System reset generation from the following possible sources:
  - Power-on reset
  - Low voltage reset
    Refer to the device overview section for availability of this feature.
  - COP reset
  - Loss of clock reset
  - External pin reset
- Real-time interrupt (RTI)

9.1.2 Modes of Operation

This subsection lists and briefly describes all operating modes supported by the CRG.

- Run mode

  All functional parts of the CRG are running during normal run mode. If RTI or COP functionality is required the individual bits of the associated rate select registers (COPCTL, RTICTL) have to be set to a nonzero value.
- Wait mode

  This mode allows to disable the system and core clocks depending on the configuration of the individual bits in the CLKSEL register.
- Stop mode

  Depending on the setting of the PSTP bit, stop mode can be differentiated between full stop mode (PSTP = 0) and pseudo-stop mode (PSTP = 1).
  - Full stop mode

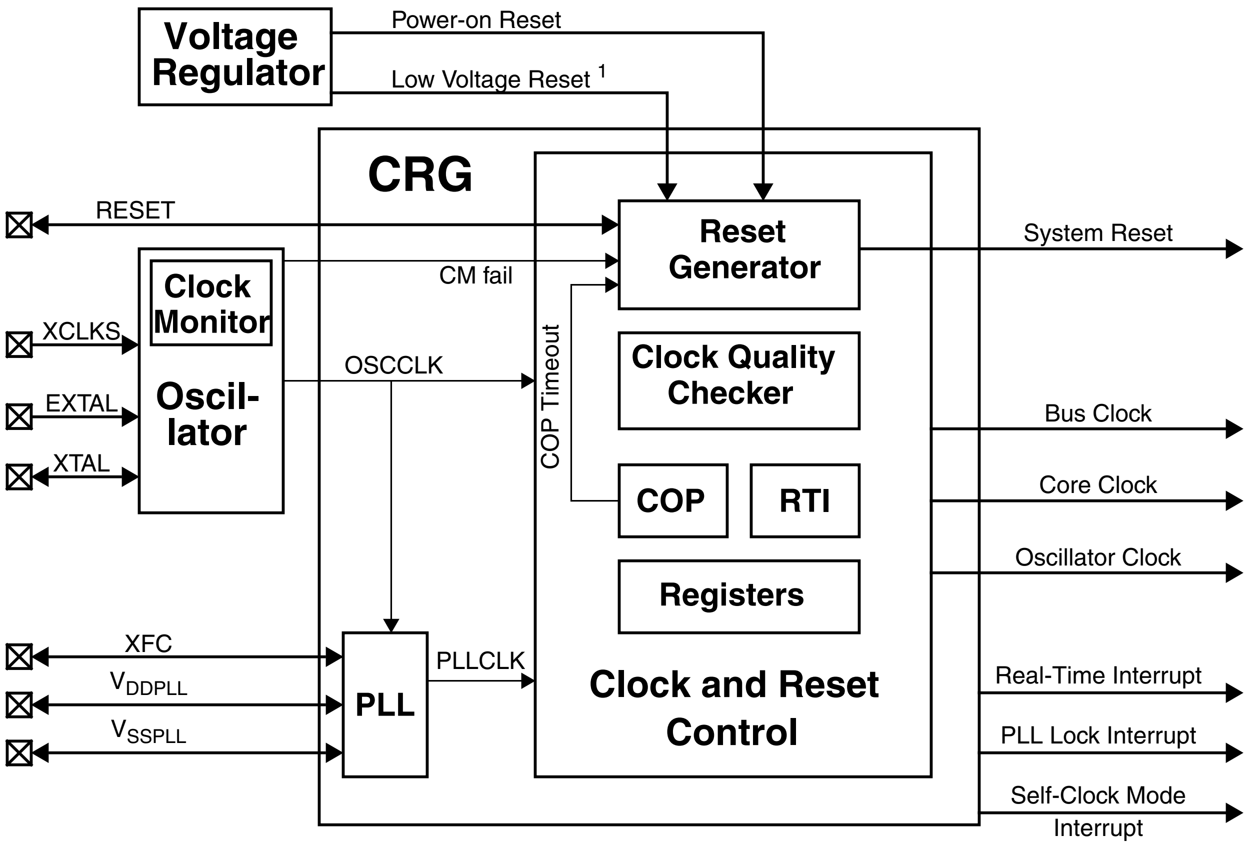
    The oscillator is disabled and thus all system and core clocks are stopped. The COP and the RTI remain frozen.
  - Pseudo-stop mode

    The oscillator continues to run and most of the system and core clocks are stopped. If the respective enable bits are set the COP and RTI will continue to run, else they remain frozen.
- Self-clock mode

  Self-clock mode will be entered if the clock monitor enable bit (CME) and the self-clock mode enable bit (SCME) are both asserted and the clock monitor in the oscillator block detects a loss of clock. As soon as self-clock mode is entered the CRG starts to perform a clock quality check. Self-clock mode remains active until the clock quality check indicates that the required quality of the incoming clock signal is met (frequency and amplitude). Self-clock mode should be used for safety purposes only. It provides reduced functionality to the MCU in case a loss of clock is causing severe system conditions.

9.1.3 Block Diagram

Figure 9-1 shows a block diagram of the CRG.



[1] Refer to the device overview section for availability of the low-voltage reset feature.

Figure 9-1. CRG Block Diagram

9.2 External Signal Description

This section lists and describes the signals that connect off chip.

9.2.1 V_{DDPLL}, V_{SSPLL} — PLL Operating Voltage, PLL Ground

These pins provides operating voltage (V_{DDPLL}) and ground (V_{SSPLL}) for the PLL circuitry. This allows the supply voltage to the PLL to be independently bypassed. Even if PLL usage is not required V_{DDPLL} and V_{SSPLL} must be connected properly.

9.2.2 XFC — PLL Loop Filter Pin

A passive external loop filter must be placed on the XFC pin. The filter is a second-order, low-pass filter to eliminate the VCO input ripple. The value of the external filter network and the reference frequency determines the speed of the corrections and the stability of the PLL. Refer to the device overview chapter for calculation of PLL loop filter (XFC) components. If PLL usage is not required the XFC pin must be tied to V_{DDPLL}.

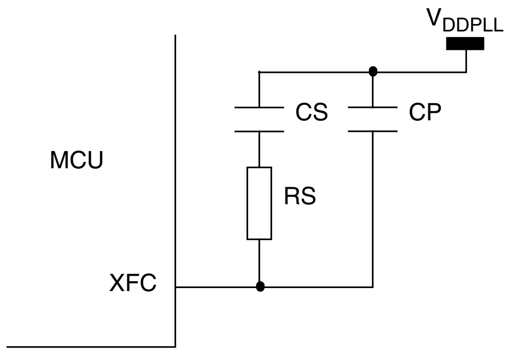


Figure 9-2. PLL Loop Filter Connections

9.2.3 $\overline{\text{RESET}}$ — Reset Pin

$\overline{\text{RESET}}$ is an active low bidirectional reset pin. As an input it initializes the MCU asynchronously to a known start-up state. As an open-drain output it indicates that an system reset (internal to MCU) has been triggered.

9.3 Memory Map and Register Definition

This section provides a detailed description of all registers accessible in the CRG.

9.3.1 Register Descriptions

This section describes in address order all the CRG registers and their individual bits.

Register Name		Bit 7	6	5	4	3	2	1	Bit 0
0x0000 SYNR	R	0	0	SYN5	SYN4	SYN3	SYN2	SYN1	SYN0

Figure 9-3. CRG Register Summary (continued)

9.3.1.1 CRG Synthesizer Register (SYNR)

The SYNR register controls the multiplication factor of the PLL. If the PLL is on, the count in the loop divider (SYNR) register effectively multiplies up the PLL clock (PLLCLK) from the reference frequency by 2 x (SYNR+1). PLLCLK will not be below the minimum VCO frequency (f_{SCM}).

$$PLLCLK = 2xOSCCLKx\frac{(SYNR+1)}{(REFDV+1)}$$

NOTE

If PLL is selected (PLLSEL=1), Bus Clock = PLLCLK / 2
Bus Clock must not exceed the maximum operating system frequency.

Module Base + 0x0000

	7	6	5	4	3	2	1	0
R	0	0	SYN5	SYNR	SYN3	SYN2	SYN1	SYN0
W								
Reset	0	0	0	0	0	0	0	0

= Unimplemented or Reserved

Figure 9-4. CRG Synthesizer Register (SYNR)

Read: anytime

Write: anytime except if PLLSEL = 1

NOTE

Write to this register initializes the lock detector bit and the track detector bit.

9.3.1.2 CRG Reference Divider Register (REFDV)

The REFDV register provides a finer granularity for the PLL multiplier steps. The count in the reference divider divides OSCCLK frequency by REFDV + 1.

Module Base + 0x0001

	7	6	5	4	3	2	1	0
R	0	0	0	0	REFDV3	REFDV2	REFDV1	REFDV0
W								
Reset	0	0	0	0	0	0	0	0

= Unimplemented or Reserved

Figure 9-5. CRG Reference Divider Register (REFDV)

Read: anytime

Write: anytime except when PLLSEL = 1

NOTE

Write to this register initializes the lock detector bit and the track detector bit.

9.3.1.3 Reserved Register (CTFLG)

This register is reserved for factory testing of the CRG module and is not available in normal modes.

Module Base + 0x0002

	7	6	5	4	3	2	1	0
R	0	0	0	0	0	0	0	0
W								
Reset	0	0	0	0	0	0	0	0

= Unimplemented or Reserved

Figure 9-6. CRG Reserved Register (CTFLG)

Read: always reads 0x0000 in normal modes

Write: unimplemented in normal modes

NOTE

Writing to this register when in special mode can alter the CRG functionality.

9.3.1.4 CRG Flags Register (CRGFLG)

This register provides CRG status bits and flags.

Module Base + 0x0003

	7	6	5	4	3	2	1	0
R	RTIF	PORF	LVRF	LOCKIF	LOCK	TRACK	SCMIF	SCM
W								
Reset	0	Note 1	Note 2	0	0	0	0	0

1. PORF is set to 1 when a power-on reset occurs. Unaffected by system reset.
2. LVRF is set to 1 when a low-voltage reset occurs. Unaffected by system reset.

= Unimplemented or Reserved

Figure 9-7. CRG Flag Register (CRGFLG)

Read: anytime

Write: refer to each bit for individual write conditions

Table 9-1. CRGFLG Field Descriptions

Field	Description
7 RTIF	**Real-Time Interrupt Flag** — RTIF is set to 1 at the end of the RTI period. This flag can only be cleared by writing a 1. Writing a 0 has no effect. If enabled (RTIE = 1), RTIF causes an interrupt request. 0 RTI time-out has not yet occurred. 1 RTI time-out has occurred.
6 PORF	**Power-on Reset Flag** — PORF is set to 1 when a power-on reset occurs. This flag can only be cleared by writing a 1. Writing a 0 has no effect. 0 Power-on reset has not occurred. 1 Power-on reset has occurred.
5 LVRF	**Low-Voltage Reset Flag** — If low voltage reset feature is not available (see the device overview chapter), LVRF always reads 0. LVRF is set to 1 when a low voltage reset occurs. This flag can only be cleared by writing a 1. Writing a 0 has no effect. 0 Low voltage reset has not occurred. 1 Low voltage reset has occurred.
4 LOCKIF	**PLL Lock Interrupt Flag** — LOCKIF is set to 1 when LOCK status bit changes. This flag can only be cleared by writing a 1. Writing a 0 has no effect.If enabled (LOCKIE = 1), LOCKIF causes an interrupt request. 0 No change in LOCK bit. 1 LOCK bit has changed.
3 LOCK	**Lock Status Bit** — LOCK reflects the current state of PLL lock condition. This bit is cleared in self-clock mode. Writes have no effect. 0 PLL VCO is not within the desired tolerance of the target frequency. 1 PLL VCO is within the desired tolerance of the target frequency.
2 TRACK	**Track Status Bit** — TRACK reflects the current state of PLL track condition. This bit is cleared in self-clock mode. Writes have no effect. 0 Acquisition mode status. 1 Tracking mode status.

Table 9-1. CRGFLG Field Descriptions (continued)

Field	Description
1 SCMIF	**Self-Clock Mode Interrupt Flag** — SCMIF is set to 1 when SCM status bit changes. This flag can only be cleared by writing a 1. Writing a 0 has no effect. If enabled (SCMIE=1), SCMIF causes an interrupt request. 0 No change in SCM bit. 1 SCM bit has changed.
0 SCM	**Self-Clock Mode Status Bit** — SCM reflects the current clocking mode. Writes have no effect. 0 MCU is operating normally with OSCCLK available. 1 MCU is operating in self-clock mode with OSCCLK in an unknown state. All clocks are derived from PLLCLK running at its minimum frequency f_{SCM}.

9.3.1.5 CRG Interrupt Enable Register (CRGINT)

This register enables CRG interrupt requests.

Module Base + 0x0004

	7	6	5	4	3	2	1	0
R	RTIE	0	0	LOCKIE	0	0	SCMIE	0
W								
Reset	0	0	0	0	0	0	0	0

= Unimplemented or Reserved

Figure 9-8. CRG Interrupt Enable Register (CRGINT)

Read: anytime

Write: anytime

Table 9-2. CRGINT Field Descriptions

Field	Description
7 RTIE	**Real-Time Interrupt Enable Bit** 0 Interrupt requests from RTI are disabled. 1 Interrupt will be requested whenever RTIF is set.
4 LOCKIE	**Lock Interrupt Enable Bit** 0 LOCK interrupt requests are disabled. 1 Interrupt will be requested whenever LOCKIF is set.
1 SCMIE	**Self-Clock Mode Interrupt Enable Bit** 0 SCM interrupt requests are disabled. 1 Interrupt will be requested whenever SCMIF is set.

9.3.1.6 CRG Clock Select Register (CLKSEL)

This register controls CRG clock selection. Refer to Figure 9-17 for details on the effect of each bit.

Module Base + 0x0005

	7	6	5	4	3	2	1	0
R W	PLLSEL	PSTP	SYSWAI	ROAWAI	PLLWAI	CWAI	RTIWAI	COPWAI
Reset	0	0	0	0	0	0	0	0

Figure 9-9. CRG Clock Select Register (CLKSEL)

Read: anytime

Write: refer to each bit for individual write conditions

Table 9-3. CLKSEL Field Descriptions

Field	Description
7 PLLSEL	**PLL Select Bit** — Write anytime. Writing a 1 when LOCK = 0 and AUTO = 1, or TRACK = 0 and AUTO = 0 has no effect. This prevents the selection of an unstable PLLCLK as SYSCLK. PLLSEL bit is cleared when the MCU enters self-clock mode, stop mode or wait mode with PLLWAI bit set. 0 System clocks are derived from OSCCLK (Bus Clock = OSCCLK / 2). 1 System clocks are derived from PLLCLK (Bus Clock = PLLCLK / 2).
6 PSTP	**Pseudo-Stop Bit** — Write: anytime — This bit controls the functionality of the oscillator during stop mode. 0 Oscillator is disabled in stop mode. 1 Oscillator continues to run in stop mode (pseudo-stop). The oscillator amplitude is reduced. Refer to oscillator block description for availability of a reduced oscillator amplitude. **Note:** Pseudo-stop allows for faster stop recovery and reduces the mechanical stress and aging of the resonator in case of frequent stop conditions at the expense of a slightly increased power consumption. **Note:** Lower oscillator amplitude exhibits lower power consumption but could have adverse effects during any electro-magnetic susceptibility (EMS) tests.
5 SYSWAI	**System Clocks Stop in Wait Mode Bit** — Write: anytime 0 In wait mode, the system clocks continue to run. 1 In wait mode, the system clocks stop. **Note:** RTI and COP are not affected by SYSWAI bit.
4 ROAWAI	**Reduced Oscillator Amplitude in Wait Mode Bit** — Write: anytime — Refer to oscillator block description chapter for availability of a reduced oscillator amplitude. If no such feature exists in the oscillator block then setting this bit to 1 will not have any effect on power consumption. 0 Normal oscillator amplitude in wait mode. 1 Reduced oscillator amplitude in wait mode. **Note:** Lower oscillator amplitude exhibits lower power consumption but could have adverse effects during any electro-magnetic susceptibility (EMS) tests.
3 PLLWAI	**PLL Stops in Wait Mode Bit** — Write: anytime — If PLLWAI is set, the CRG will clear the PLLSEL bit before entering wait mode. The PLLON bit remains set during wait mode but the PLL is powered down. Upon exiting wait mode, the PLLSEL bit has to be set manually if PLL clock is required. While the PLLWAI bit is set the AUTO bit is set to 1 in order to allow the PLL to automatically lock on the selected target frequency after exiting wait mode. 0 PLL keeps running in wait mode. 1 PLL stops in wait mode.

Table 9-3. CLKSEL Field Descriptions (continued)

Field	Description
2 CWAI	**Core Stops in Wait Mode Bit** — Write: anytime 0 Core clock keeps running in wait mode. 1 Core clock stops in wait mode.
1 RTIWAI	**RTI Stops in Wait Mode Bit** — Write: anytime 0 RTI keeps running in wait mode. 1 RTI stops and initializes the RTI dividers whenever the part goes into wait mode.
0 COPWAI	**COP Stops in Wait Mode Bit** — Normal modes: Write once —Special modes: Write anytime 0 COP keeps running in wait mode. 1 COP stops and initializes the COP dividers whenever the part goes into wait mode.

9.3.1.7 CRG PLL Control Register (PLLCTL)

This register controls the PLL functionality.

Module Base + 0x0006

	7	6	5	4	3	2	1	0
R	CME	PLLON	AUTO	ACQ	0	PRE	PCE	SCME
W								
Reset	1	1	1	1	0	0	0	1

= Unimplemented or Reserved

Figure 9-10. CRG PLL Control Register (PLLCTL)

Read: anytime

Write: refer to each bit for individual write conditions

Table 9-4. PLLCTL Field Descriptions

Field	Description
7 CME	**Clock Monitor Enable Bit** — CME enables the clock monitor. Write anytime except when SCM = 1. 0 Clock monitor is disabled. 1 Clock monitor is enabled. Slow or stopped clocks will cause a clock monitor reset sequence or self-clock mode. **Note:** Operating with CME = 0 will not detect any loss of clock. In case of poor clock quality this could cause unpredictable operation of the MCU. **Note:** In Stop Mode (PSTP = 0) the clock monitor is disabled independently of the CME bit setting and any loss of clock will not be detected.
6 PLLON	**Phase Lock Loop On Bit** — PLLON turns on the PLL circuitry. In self-clock mode, the PLL is turned on, but the PLLON bit reads the last latched value. Write anytime except when PLLSEL = 1. 0 PLL is turned off. 1 PLL is turned on. If AUTO bit is set, the PLL will lock automatically.

Table 9-4. PLLCTL Field Descriptions (continued)

Field	Description
5 AUTO	**Automatic Bandwidth Control Bit** — AUTO selects either the high bandwidth (acquisition) mode or the low bandwidth (tracking) mode depending on how close to the desired frequency the VCO is running. Write anytime except when PLLWAI=1, because PLLWAI sets the AUTO bit to 1. 0 Automatic mode control is disabled and the PLL is under software control, using ACQ bit. 1 Automatic mode control is enabled and ACQ bit has no effect.
4 ACQ	**Acquisition Bit** — Write anytime. If AUTO=1 this bit has no effect. 0 Low bandwidth filter is selected. 1 High bandwidth filter is selected.
2 PRE	**RTI Enable during Pseudo-Stop Bit** — PRE enables the RTI during pseudo-stop mode. Write anytime. 0 RTI stops running during pseudo-stop mode. 1 RTI continues running during pseudo-stop mode. **Note:** If the PRE bit is cleared the RTI dividers will go static while pseudo-stop mode is active. The RTI dividers will not initialize like in wait mode with RTIWAI bit set.
1 PCE	**COP Enable during Pseudo-Stop Bit** — PCE enables the COP during pseudo-stop mode. Write anytime. 0 COP stops running during pseudo-stop mode 1 COP continues running during pseudo-stop mode **Note:** If the PCE bit is cleared the COP dividers will go static while pseudo-stop mode is active. The COP dividers will *not* initialize like in wait mode with COPWAI bit set.
0 SCME	**Self-Clock Mode Enable Bit** — Normal modes: Write once —Special modes: Write anytime — SCME can not be cleared while operating in self-clock mode (SCM=1). 0 Detection of crystal clock failure causes clock monitor reset (see Section 9.5.1, “Clock Monitor Reset”). 1 Detection of crystal clock failure forces the MCU in self-clock mode (see Section 9.4.7.2, “Self-Clock Mode”).

9.3.1.8 CRG RTI Control Register (RTICTL)

This register selects the timeout period for the real-time interrupt.

Module Base + 0x0007

* Denotes the default value out of reset.This value should be used to disable the RTI to ensure future backwards compatibility.

9.3.1.9 CRG COP Control Register (COPCTL)

This register controls the COP (computer operating properly) watchdog.

Module Base + 0x0008

	7	6	5	4	3	2	1	0
R	WCOP	RSBCK	0	0	0	CR2	CR1	CR0
W								
Reset	0	0	0	0	0	0	0	0

= Unimplemented or Reserved

Figure 9-12. CRG COP Control Register (COPCTL)

Read: anytime

Write: WCOP, CR2, CR1, CR0: once in user mode, anytime in special mode

Write: RSBCK: once

Table 9-7. COPCTL Field Descriptions

Field	Description
7 WCOP	**Window COP Mode Bit** — When set, a write to the ARMCOP register must occur in the last 25% of the selected period. A write during the first 75% of the selected period will reset the part. As long as all writes occur during this window, 0x0055 can be written as often as desired. As soon as 0x00AA is written after the 0x0055, the time-out logic restarts and the user must wait until the next window before writing to ARMCOP. Table 9-8 shows the exact duration of this window for the seven available COP rates. 0 Normal COP operation 1 Window COP operation
6 RSBCK	COP and RTI Stop in Active BDM Mode Bit 0 Allows the COP and RTI to keep running in active BDM mode. 1 Stops the COP and RTI counters whenever the part is in active BDM mode.
2:0 CR[2:0]	**COP Watchdog Timer Rate Select** — These bits select the COP time-out rate (see Table 9-8). The COP time-out period is OSCCLK period divided by CR[2:0] value. Writing a nonzero value to CR[2:0] enables the COP counter and starts the time-out period. A COP counter time-out causes a system reset. This can be avoided by periodically (before time-out) reinitializing the COP counter via the ARMCOP register.

Table 9-8. COP Watchdog Rates[1]

CR2	CR1	CR0	OSCCLK Cycles to Time Out
0	0	0	COP disabled
0	0	1	2^{14}
0	1	0	2^{16}
0	1	1	2^{18}
1	0	0	2^{20}
1	0	1	2^{22}
1	1	0	2^{23}
1	1	1	2^{24}

1 OSCCLK cycles are referenced from the previous COP time-out reset (writing 0x0055/0x00AA to the ARMCOP register)

9.3.1.10 Reserved Register (FORBYP)

NOTE

This reserved register is designed for factory test purposes only, and is not intended for general user access. Writing to this register when in special modes can alter the CRG's functionality.

Module Base + 0x0009

	7	6	5	4	3	2	1	0
R	0	0	0	0	0	0	0	0
W								
Reset	0	0	0	0	0	0	0	0

= Unimplemented or Reserved

Figure 9-13. Reserved Register (FORBYP)

Read: always read 0x0000 except in special modes

Write: only in special modes

9.3.1.11 Reserved Register (CTCTL)

NOTE

This reserved register is designed for factory test purposes only, and is not intended for general user access. Writing to this register when in special test modes can alter the CRG's functionality.

Module Base + 0x000A

	7	6	5	4	3	2	1	0
R	0	0	0	0	0	0	0	0
W								
Reset	0	0	0	0	0	0	0	0

= Unimplemented or Reserved

Read: always read 0x0080 except in special modes

Write: only in special modes

9.3.1.12 CRG COP Timer Arm/Reset Register (ARMCOP)

This register is used to restart the COP time-out period.

Module Base + 0x000B

	7	6	5	4	3	2	1	0
R	0	0	0	0	0	0	0	0
W	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
Reset	0	0	0	0	0	0	0	0

Figure 9-15. ARMCOP Register Diagram

Read: always reads 0x0000

Write: anytime

When the COP is disabled (CR[2:0] = “000”) writing to this register has no effect.

When the COP is enabled by setting CR[2:0] nonzero, the following applies:

> Writing any value other than 0x0055 or 0x00AA causes a COP reset. To restart the COP time-out period you must write 0x0055 followed by a write of 0x00AA. Other instructions may be executed between these writes but the sequence (0x0055, 0x00AA) must be completed prior to COP end of time-out period to avoid a COP reset. Sequences of 0x0055 writes or sequences of 0x00AA writes are allowed. When the WCOP bit is set, 0x0055 and 0x00AA writes must be done in the last 25% of the selected time-out period; writing any value in the first 75% of the selected period will cause a COP reset.

9.4 Functional Description

This section gives detailed informations on the internal operation of the design.

9.4.1 Phase Locked Loop (PLL)

The PLL is used to run the MCU from a different time base than the incoming OSCCLK. For increased flexibility, OSCCLK can be divided in a range of 1 to 16 to generate the reference frequency. This offers a finer multiplication granularity. The PLL can multiply this reference clock by a multiple of 2, 4, 6,... 126,128 based on the SYNR register.

$$\mathrm{PLLCLK} = 2 \times \mathrm{OSCCLK} \times \frac{[\mathrm{SYNR} + 1]}{[\mathrm{REFDV} + 1]}$$

CAUTION

Although it is possible to set the two dividers to command a very high clock frequency, do not exceed the specified bus frequency limit for the MCU.
If (PLLSEL = 1), Bus Clock = PLLCLK / 2

The PLL is a frequency generator that operates in either acquisition mode or tracking mode, depending on the difference between the output frequency and the target frequency. The PLL can change between acquisition and tracking modes either automatically or manually.

The VCO has a minimum operating frequency, which corresponds to the self-clock mode frequency f_{SCM}.

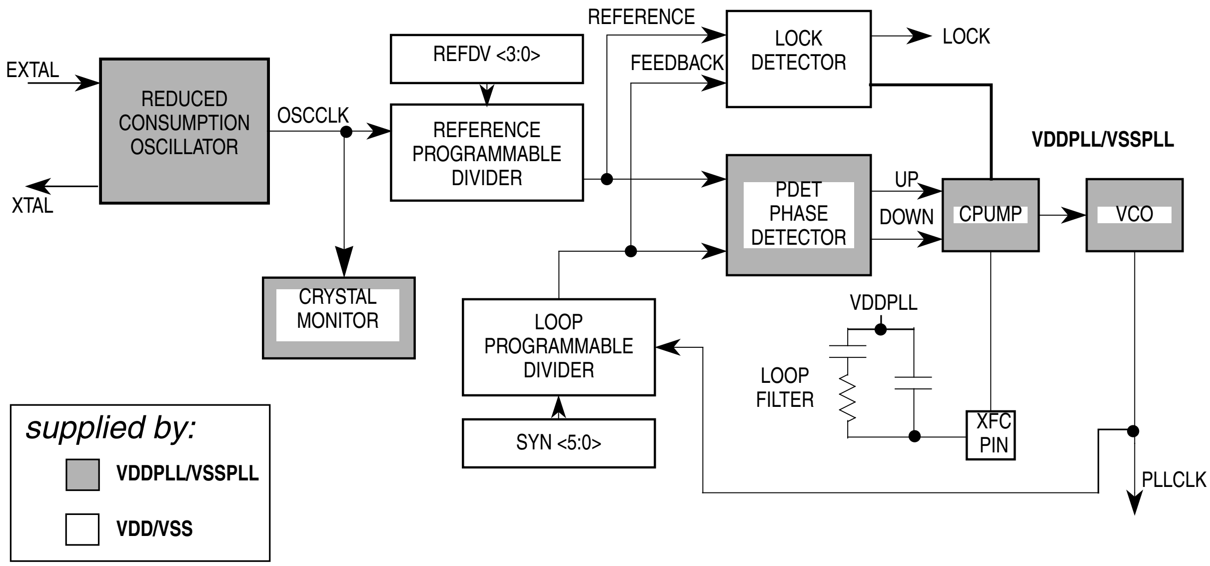

Figure 9-16. PLL Functional Diagram

9.4.1.1 PLL Operation

The oscillator output clock signal (OSCCLK) is fed through the reference programmable divider and is divided in a range of 1 to 16 (REFDV+1) to output the reference clock. The VCO output clock, (PLLCLK) is fed back through the programmable loop divider and is divided in a range of 2 to 128 in increments of [2 x (SYNR +1)] to output the feedback clock. See Figure 9-16.

The phase detector then compares the feedback clock, with the reference clock. Correction pulses are generated based on the phase difference between the two signals. The loop filter then slightly alters the DC voltage on the external filter capacitor connected to XFC pin, based on the width and direction of the correction pulse. The filter can make fast or slow corrections depending on its mode, as described in the next subsection. The values of the external filter network and the reference frequency determine the speed of the corrections and the stability of the PLL.

9.4.1.2 Acquisition and Tracking Modes

The lock detector compares the frequencies of the feedback clock, and the reference clock. Therefore, the speed of the lock detector is directly proportional to the final reference frequency. The circuit determines the mode of the PLL and the lock condition based on this comparison.

The PLL filter can be manually or automatically configured into one of two possible operating modes:

- Acquisition mode

  In acquisition mode, the filter can make large frequency corrections to the VCO. This mode is used at PLL start-up or when the PLL has suffered a severe noise hit and the VCO frequency is far off the desired frequency. When in acquisition mode, the TRACK status bit is cleared in the CRGFLG register.
- Tracking mode

  In tracking mode, the filter makes only small corrections to the frequency of the VCO. PLL jitter is much lower in tracking mode, but the response to noise is also slower. The PLL enters tracking mode when the VCO frequency is nearly correct and the TRACK bit is set in the CRGFLG register.

The PLL can change the bandwidth or operational mode of the loop filter manually or automatically.

In automatic bandwidth control mode (AUTO = 1), the lock detector automatically switches between acquisition and tracking modes. Automatic bandwidth control mode also is used to determine when the PLL clock (PLLCLK) is safe to use as the source for the system and core clocks. If PLL LOCK interrupt requests are enabled, the software can wait for an interrupt request and then check the LOCK bit. If CPU interrupts are disabled, software can poll the LOCK bit continuously (during PLL start-up, usually) or at periodic intervals. In either case, only when the LOCK bit is set, is the PLLCLK clock safe to use as the source for the system and core clocks. If the PLL is selected as the source for the system and core clocks and the LOCK bit is clear, the PLL has suffered a severe noise hit and the software must take appropriate action, depending on the application.

The following conditions apply when the PLL is in automatic bandwidth control mode (AUTO = 1):

- The TRACK bit is a read-only indicator of the mode of the filter.
- The TRACK bit is set when the VCO frequency is within a certain tolerance, Δ_{trk}, and is clear when the VCO frequency is out of a certain tolerance, Δ_{unt}.
- The LOCK bit is a read-only indicator of the locked state of the PLL.
- The LOCK bit is set when the VCO frequency is within a certain tolerance, Δ_{Lock}, and is cleared when the VCO frequency is out of a certain tolerance, Δ_{unl}.
- CPU interrupts can occur if enabled (LOCKIE = 1) when the lock condition changes, toggling the LOCK bit.

The PLL can also operate in manual mode (AUTO = 0). Manual mode is used by systems that do not require an indicator of the lock condition for proper operation. Such systems typically operate well below the maximum system frequency (f_{sys}) and require fast start-up. The following conditions apply when in manual mode:

- ACQ is a writable control bit that controls the mode of the filter. Before turning on the PLL in manual mode, the ACQ bit should be asserted to configure the filter in acquisition mode.
- After turning on the PLL by setting the PLLON bit software must wait a given time (t_{acq}) before entering tracking mode (ACQ = 0).
- After entering tracking mode software must wait a given time (t_{al}) before selecting the PLLCLK as the source for system and core clocks (PLLSEL = 1).

9.4.2 System Clocks Generator

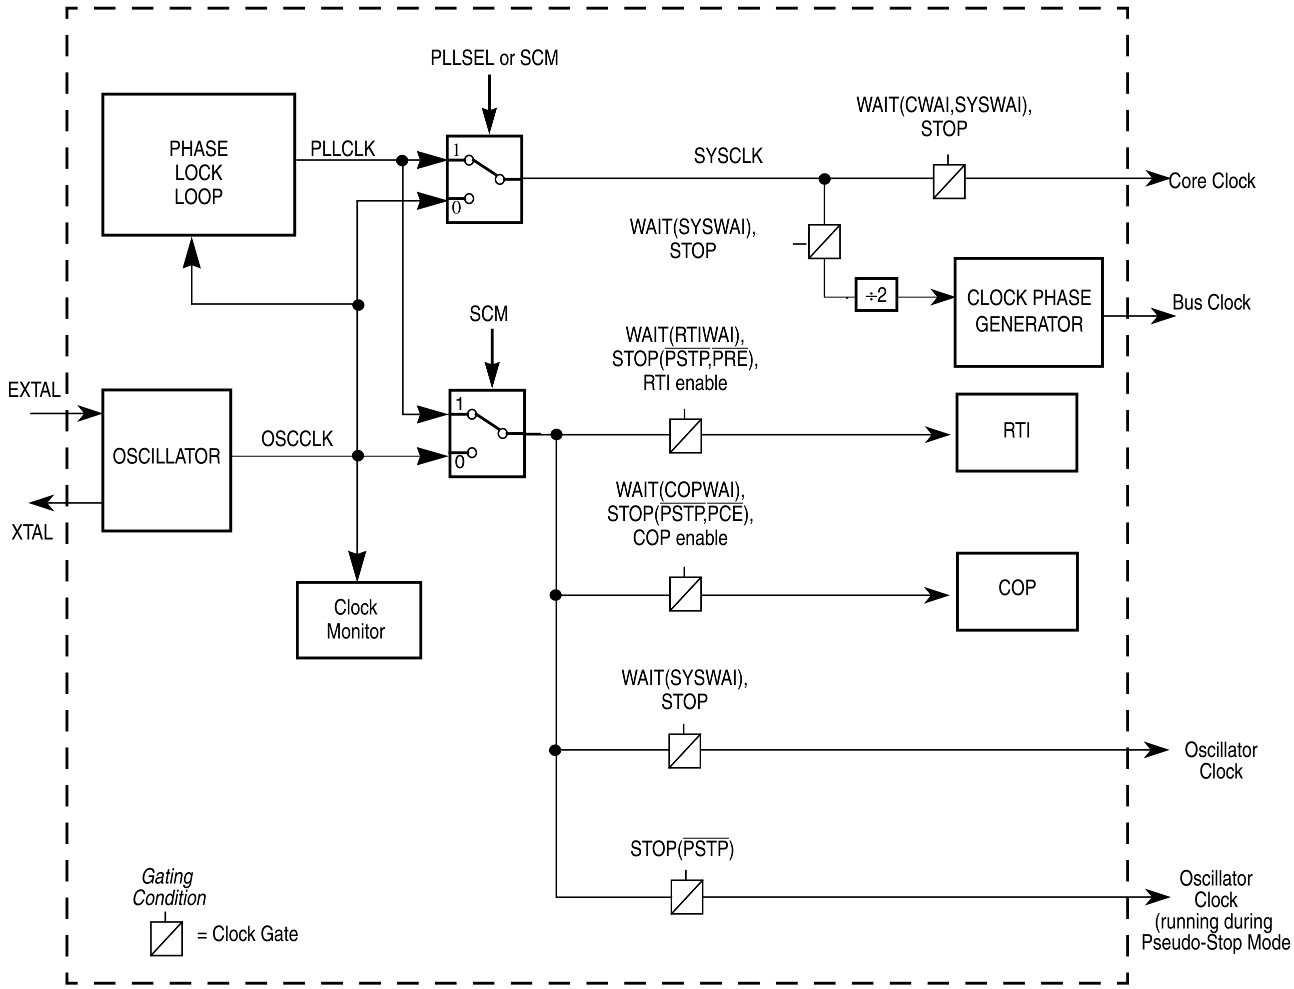

Figure 9-17. System Clocks Generator

The clock generator creates the clocks used in the MCU (see Figure 9-17). The gating condition placed on top of the individual clock gates indicates the dependencies of different modes (stop, wait) and the setting of the respective configuration bits.

The peripheral modules use the bus clock. Some peripheral modules also use the oscillator clock. The memory blocks use the bus clock. If the MCU enters self-clock mode (see Section 9.4.7.2, "Self-Clock Mode"), oscillator clock source is switched to PLLCLK running at its minimum frequency f_{SCM}. The bus clock is used to generate the clock visible at the ECLK pin. The core clock signal is the clock for the CPU. The core clock is twice the bus clock as shown in Figure 9-18. But note that a CPU cycle corresponds to one bus clock.

PLL clock mode is selected with PLLSEL bit in the CLKSEL register. When selected, the PLL output clock drives SYSCLK for the main system including the CPU and peripherals. The PLL cannot be turned off by clearing the PLLON bit, if the PLL clock is selected. When PLLSEL is changed, it takes a maximum of 4 OSCCLK plus 4 PLLCLK cycles to make the transition. During the transition, all clocks freeze and CPU activity ceases.

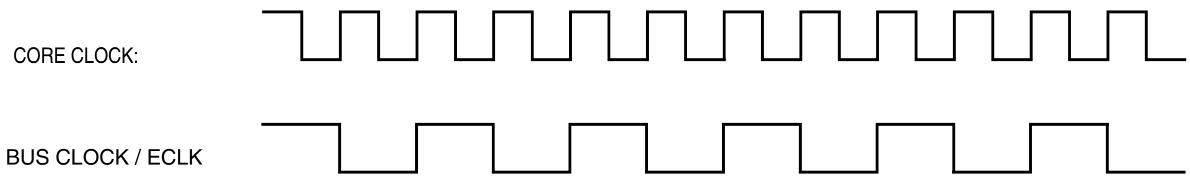

Figure 9-18. Core Clock and Bus Clock Relationship

9.4.3 Clock Monitor (CM)

If no OSCCLK edges are detected within a certain time, the clock monitor within the oscillator block generates a clock monitor fail event. The CRG then asserts self-clock mode or generates a system reset depending on the state of SCME bit. If the clock monitor is disabled or the presence of clocks is detected no failure is indicated by the oscillator block.The clock monitor function is enabled/disabled by the CME control bit.

9.4.4 Clock Quality Checker

The clock monitor performs a coarse check on the incoming clock signal. The clock quality checker provides a more accurate check in addition to the clock monitor.

A clock quality check is triggered by any of the following events:

- Power-on reset (POR)
- Low voltage reset (LVR)
- Wake-up from full stop mode (exit full stop)
- Clock monitor fail indication (CM fail)

A time window of 50000 VCO clock cycles[1] is called *check window*.

A number greater equal than 4096 rising OSCCLK edges within a *check window* is called *osc ok*. Note that *osc ok* immediately terminates the current *check window*. See Figure 9-19 as an example.

1. VCO clock cycles are generated by the PLL when running at minimum frequency f_{SCM}.

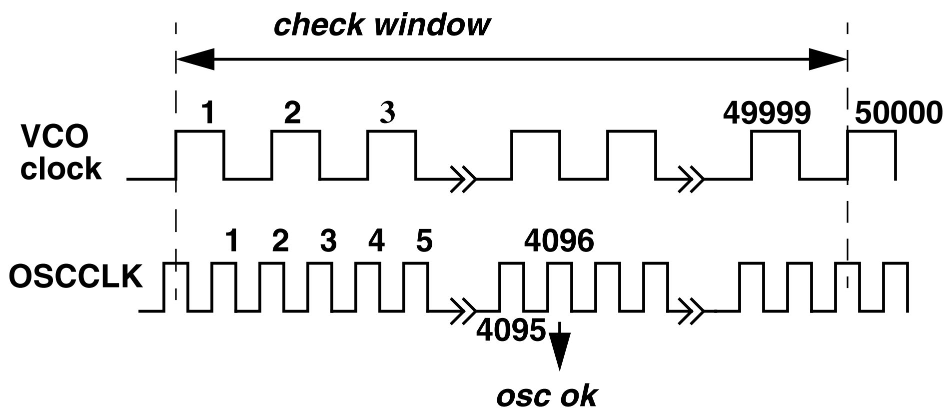

Figure 9-19. Check Window Example

The sequence for clock quality check is shown in Figure 9-20.

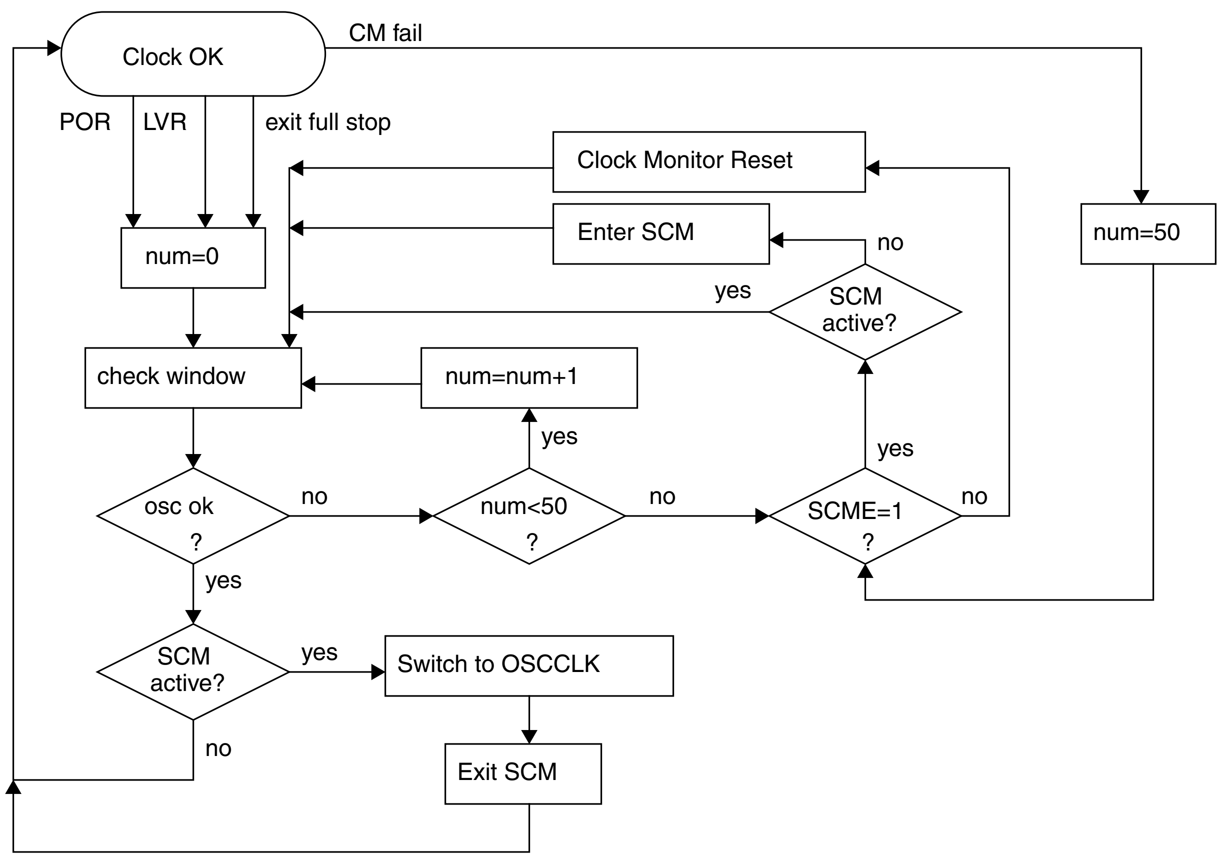

Figure 9-20. Sequence for Clock Quality Check

NOTE

Remember that in parallel to additional actions caused by self-clock mode or clock monitor reset[1] handling the clock quality checker **continues** to check the OSCCLK signal.

1. A Clock Monitor Reset will always set the SCME bit to logical'1'

NOTE

The clock quality checker enables the PLL and the voltage regulator (VREG) anytime a clock check has to be performed. An ongoing clock quality check could also cause a running PLL (f_{SCM}) and an active VREG during pseudo-stop mode or wait mode

9.4.5 Computer Operating Properly Watchdog (COP)

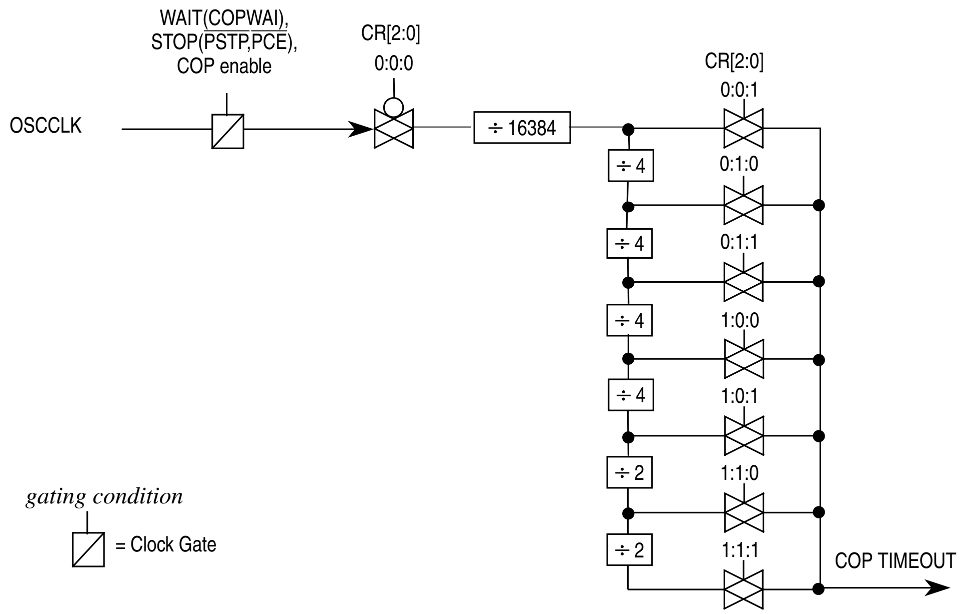

Figure 9-21. Clock Chain for COP

The COP (free running watchdog timer) enables the user to check that a program is running and sequencing properly. The COP is disabled out of reset. When the COP is being used, software is responsible for keeping the COP from timing out. If the COP times out it is an indication that the software is no longer being executed in the intended sequence; thus a system reset is initiated (see Section 9.5.2, "Computer Operating Properly Watchdog (COP) Reset)." The COP runs with a gated OSCCLK (see Section Figure 9-21., "Clock Chain for COP"). Three control bits in the COPCTL register allow selection of seven COP time-out periods.

When COP is enabled, the program must write 0x0055 and 0x00AA (in this order) to the ARMCOP register during the selected time-out period. As soon as this is done, the COP time-out period is restarted. If the program fails to do this and the COP times out, the part will reset. Also, if any value other than 0x0055 or 0x00AA is written, the part is immediately reset.

Windowed COP operation is enabled by setting WCOP in the COPCTL register. In this mode, writes to the ARMCOP register to clear the COP timer must occur in the last 25% of the selected time-out period. A premature write will immediately reset the part.

If PCE bit is set, the COP will continue to run in pseudo-stop mode.

9.4.6 Real-Time Interrupt (RTI)

The RTI can be used to generate a hardware interrupt at a fixed periodic rate. If enabled (by setting RTIE=1), this interrupt will occur at the rate selected by the RTICTL register. The RTI runs with a gated OSCCLK (see Section Figure 9-22., "Clock Chain for RTI"). At the end of the RTI time-out period the RTIF flag is set to 1 and a new RTI time-out period starts immediately.

A write to the RTICTL register restarts the RTI time-out period.

If the PRE bit is set, the RTI will continue to run in pseudo-stop mode.

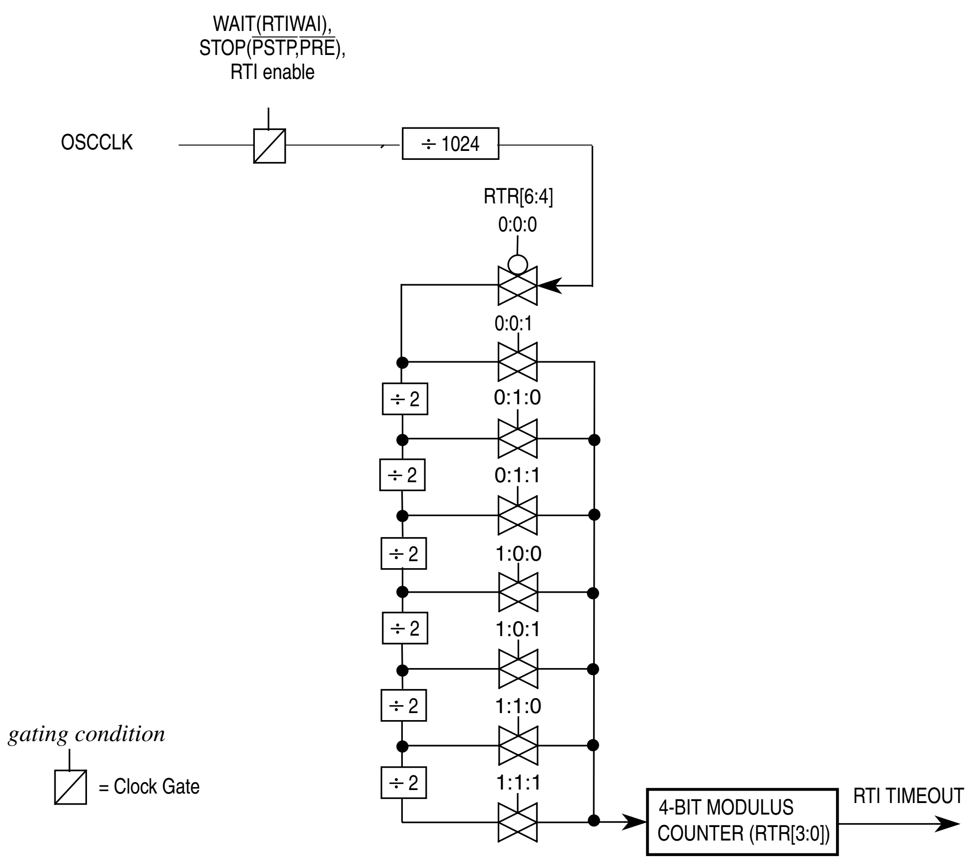

Figure 9-22. Clock Chain for RTI

9.4.7 Modes of Operation

9.4.7.1 Normal Mode

The CRG block behaves as described within this specification in all normal modes.

9.4.7.2 Self-Clock Mode

The VCO has a minimum operating frequency, f_{SCM}. If the external clock frequency is not available due to a failure or due to long crystal start-up time, the bus clock and the core clock are derived from the VCO running at minimum operating frequency; this mode of operation is called self-clock mode. This requires CME = 1 and SCME = 1. If the MCU was clocked by the PLL clock prior to entering self-clock mode, the PLLSEL bit will be cleared. If the external clock signal has stabilized again, the CRG will automatically select OSCCLK to be the system clock and return to normal mode. See Section 9.4.4, "Clock Quality Checker" for more information on entering and leaving self-clock mode.

NOTE

In order to detect a potential clock loss, the CME bit should be always enabled (CME=1).

If CME bit is disabled and the MCU is configured to run on PLL clock (PLLCLK), a loss of external clock (OSCCLK) will not be detected and will cause the system clock to drift towards the VCO's minimum frequency f_{SCM}. As soon as the external clock is available again the system clock ramps up to its PLL target frequency. If the MCU is running on external clock any loss of clock will cause the system to go static.

9.4.8 Low-Power Operation in Run Mode

The RTI can be stopped by setting the associated rate select bits to 0.

The COP can be stopped by setting the associated rate select bits to 0.

9.4.9 Low-Power Operation in Wait Mode

The WAI instruction puts the MCU in a low power consumption stand-by mode depending on setting of the individual bits in the CLKSEL register. All individual wait mode configuration bits can be superposed. This provides enhanced granularity in reducing the level of power consumption during wait mode. Table 9-9 lists the individual configuration bits and the parts of the MCU that are affected in wait mode.

Table 9-9. MCU Configuration During Wait Mode

	PLLWAI	CWAI	SYSWAI	RTIWAI	COPWAI	ROAWAI
PLL	stopped	—	—	—	—	—
Core	—	stopped	stopped	—	—	—
System	—	—	stopped	—	—	—
RTI	—	—	—	stopped	—	—
COP	—	—	—	—	stopped	—
Oscillator	—	—	—	—	—	reduced[1]

1 Refer to oscillator block description for availability of a reduced oscillator amplitude.

After executing the WAI instruction the core requests the CRG to switch MCU into wait mode. The CRG then checks whether the PLLWAI, CWAI and SYSWAI bits are asserted (see Figure 9-23). Depending on the configuration the CRG switches the system and core clocks to OSCCLK by clearing the PLLSEL bit, disables the PLL, disables the core clocks and finally disables the remaining system clocks. As soon as all clocks are switched off wait mode is active.

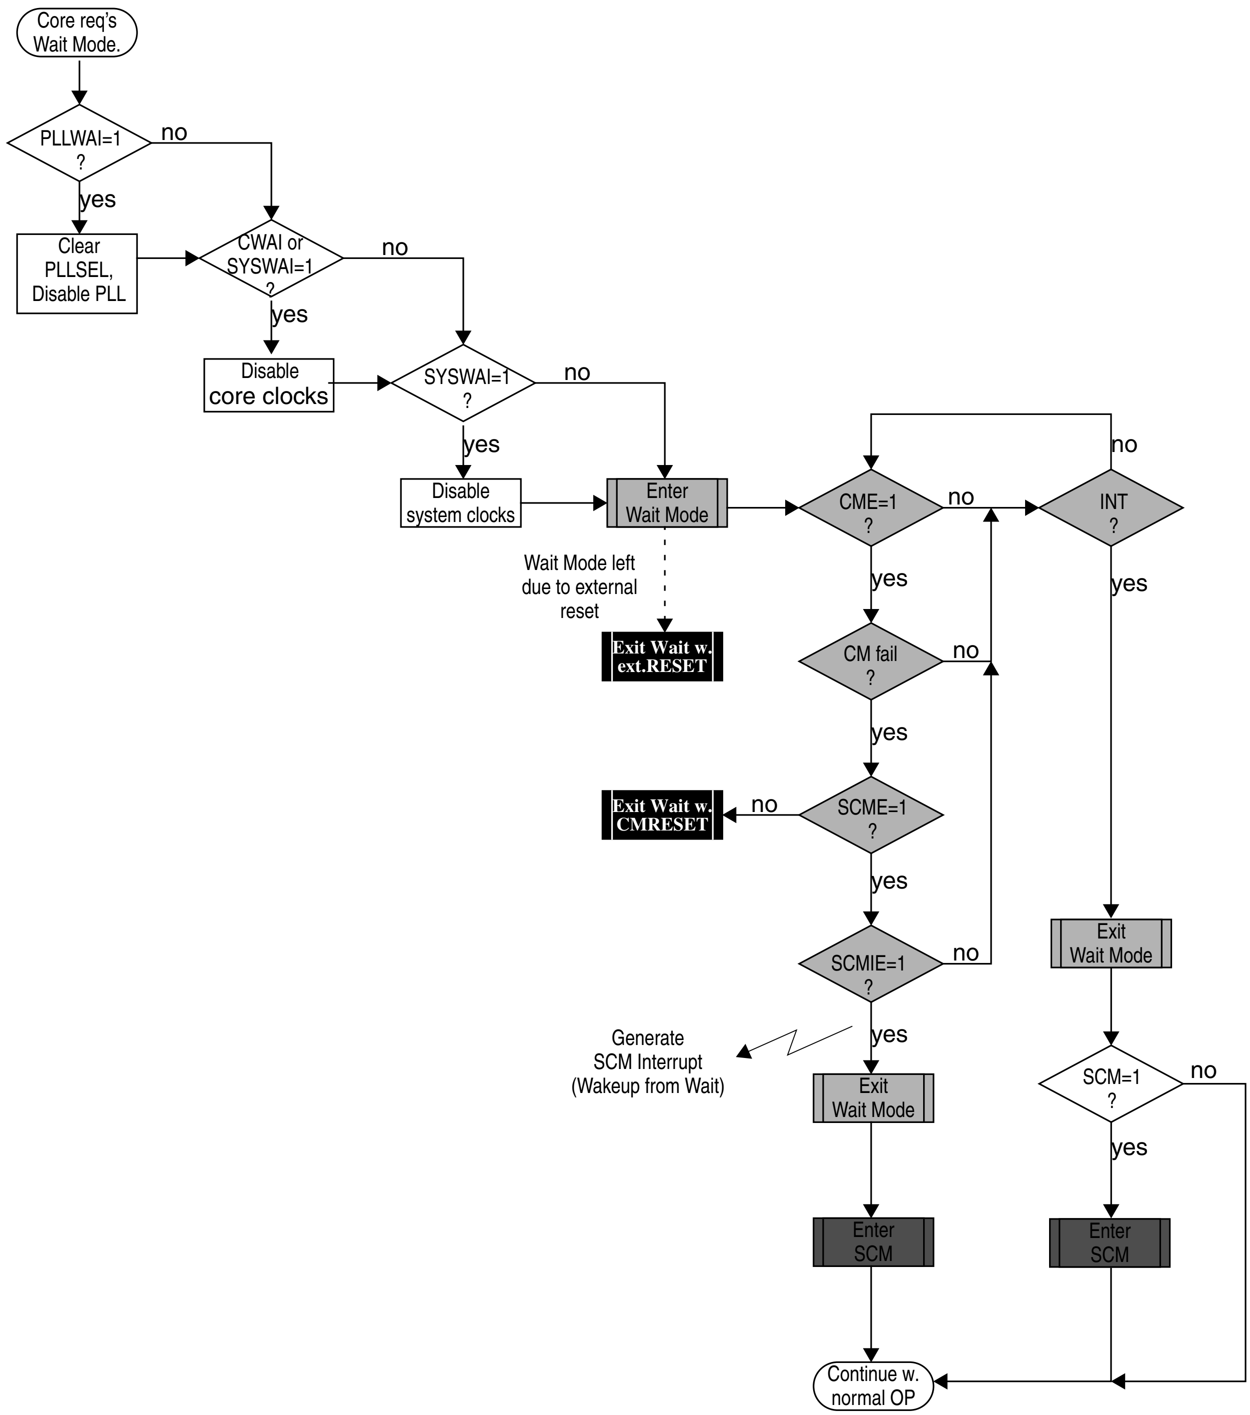

Figure 9-23. Wait Mode Entry/Exit Sequence

There are five different scenarios for the CRG to restart the MCU from wait mode:

- External reset
- Clock monitor reset
- COP reset
- Self-clock mode interrupt
- Real-time interrupt (RTI)

If the MCU gets an external reset during wait mode active, the CRG asynchronously restores all configuration bits in the register space to its default settings and starts the reset generator. After completing the reset sequence processing begins by fetching the normal reset vector. Wait mode is exited and the MCU is in run mode again.

If the clock monitor is enabled (CME=1) the MCU is able to leave wait mode when loss of oscillator/external clock is detected by a clock monitor fail. If the SCME bit is not asserted the CRG generates a clock monitor fail reset (CMRESET). The CRG's behavior for CMRESET is the same compared to external reset, but another reset vector is fetched after completion of the reset sequence. If the SCME bit is asserted the CRG generates a SCM interrupt if enabled (SCMIE=1). After generating the interrupt the CRG enters self-clock mode and starts the clock quality checker (see Section 9.4.4, "Clock Quality Checker"). Then the MCU continues with normal operation.If the SCM interrupt is blocked by SCMIE = 0, the SCMIF flag will be asserted and clock quality checks will be performed but the MCU will not wake-up from wait mode.

If any other interrupt source (e.g. RTI) triggers exit from wait mode the MCU immediately continues with normal operation. If the PLL has been powered-down during wait mode the PLLSEL bit is cleared and the MCU runs on OSCCLK after leaving wait mode. The software must manually set the PLLSEL bit again, in order to switch system and core clocks to the PLLCLK.

If wait mode is entered from self-clock mode, the CRG will continue to check the clock quality until clock check is successful. The PLL and voltage regulator (VREG) will remain enabled.

Table 9-10 summarizes the outcome of a clock loss while in wait mode.

Table 9-10. Outcome of Clock Loss in Wait Mode

CME	SCME	SCMIE	CRG Actions
0	X	X	Clock failure --> No action, clock loss not detected.
1	0	X	Clock failure --> CRG performs Clock Monitor Reset immediately
1	1	0	Clock failure --> Scenario 1: OSCCLK **recovers** prior to exiting Wait Mode. – MCU remains in Wait Mode, – VREG enabled, – PLL enabled, – SCM activated, – Start Clock Quality Check, – Set SCMIF interrupt flag. *Some time later OSCCLK recovers.* – CM no longer indicates a failure, – 4096 OSCCLK cycles later Clock Quality Check indicates clock o.k., – SCM deactivated, – PLL disabled depending on PLLWAI, – VREG remains enabled *(never gets disabled in Wait Mode).* – MCU remains in Wait Mode. S*ome time later either a wakeup interrupt occurs (no SCM interrupt)* – Exit Wait Mode using OSCCLK as system clock (SYSCLK), – Continue normal operation. *or an External Reset is applied.* – Exit Wait Mode using OSCCLK as system clock, – Start reset sequence. Scenario 2: OSCCLK **does not recover** prior to exiting Wait Mode. – MCU remains in Wait Mode, – VREG enabled, – PLL enabled, – SCM activated, – Start Clock Quality Check, – Set SCMIF interrupt flag, – Keep performing Clock Quality Checks (could continue infinitely) while in Wait Mode. S*ome time later either a wakeup interrupt occurs (no SCM interrupt)* – Exit Wait Mode in SCM using PLL clock (f_{SCM}) as system clock, – Continue to perform additional Clock Quality Checks until OSCCLK is o.k. again. or an External RESET is applied. – Exit Wait Mode in SCM using PLL clock (f_{SCM}) as system clock, – Start reset sequence, – Continue to perform additional Clock Quality Checks until OSCCLK is o.k.again.

Table 9-10. Outcome of Clock Loss in Wait Mode (continued)

CME	SCME	SCMIE	CRG Actions
1	1	1	Clock failure --> – VREG enabled, – PLL enabled, – SCM activated, – Start Clock Quality Check, – SCMIF set. SCMIF generates Self-Clock Mode wakeup interrupt. – Exit Wait Mode in SCM using PLL clock (f_{SCM}) as system clock, – Continue to perform a additional Clock Quality Checks until OSCCLK is o.k. again.

9.4.10 Low-Power Operation in Stop Mode

All clocks are stopped in STOP mode, dependent of the setting of the PCE, PRE and PSTP bit. The oscillator is disabled in STOP mode unless the PSTP bit is set. All counters and dividers remain frozen but do not initialize. If the PRE or PCE bits are set, the RTI or COP continues to run in pseudo-stop mode. In addition to disabling system and core clocks the CRG requests other functional units of the MCU (e.g. voltage-regulator) to enter their individual power-saving modes (if available). This is the main difference between pseudo-stop mode and wait mode.

After executing the STOP instruction the core requests the CRG to switch the MCU into stop mode. If the PLLSEL bit remains set when entering stop mode, the CRG will switch the system and core clocks to OSCCLK by clearing the PLLSEL bit. Then the CRG disables the PLL, disables the core clock and finally disables the remaining system clocks. As soon as all clocks are switched off, stop mode is active.

If pseudo-stop mode (PSTP = 1) is entered from self-clock mode the CRG will continue to check the clock quality until clock check is successful. The PLL and the voltage regulator (VREG) will remain enabled. If full stop mode (PSTP = 0) is entered from self-clock mode an ongoing clock quality check will be stopped. A complete timeout window check will be started when stop mode is exited again.

Wake-up from stop mode also depends on the setting of the PSTP bit.

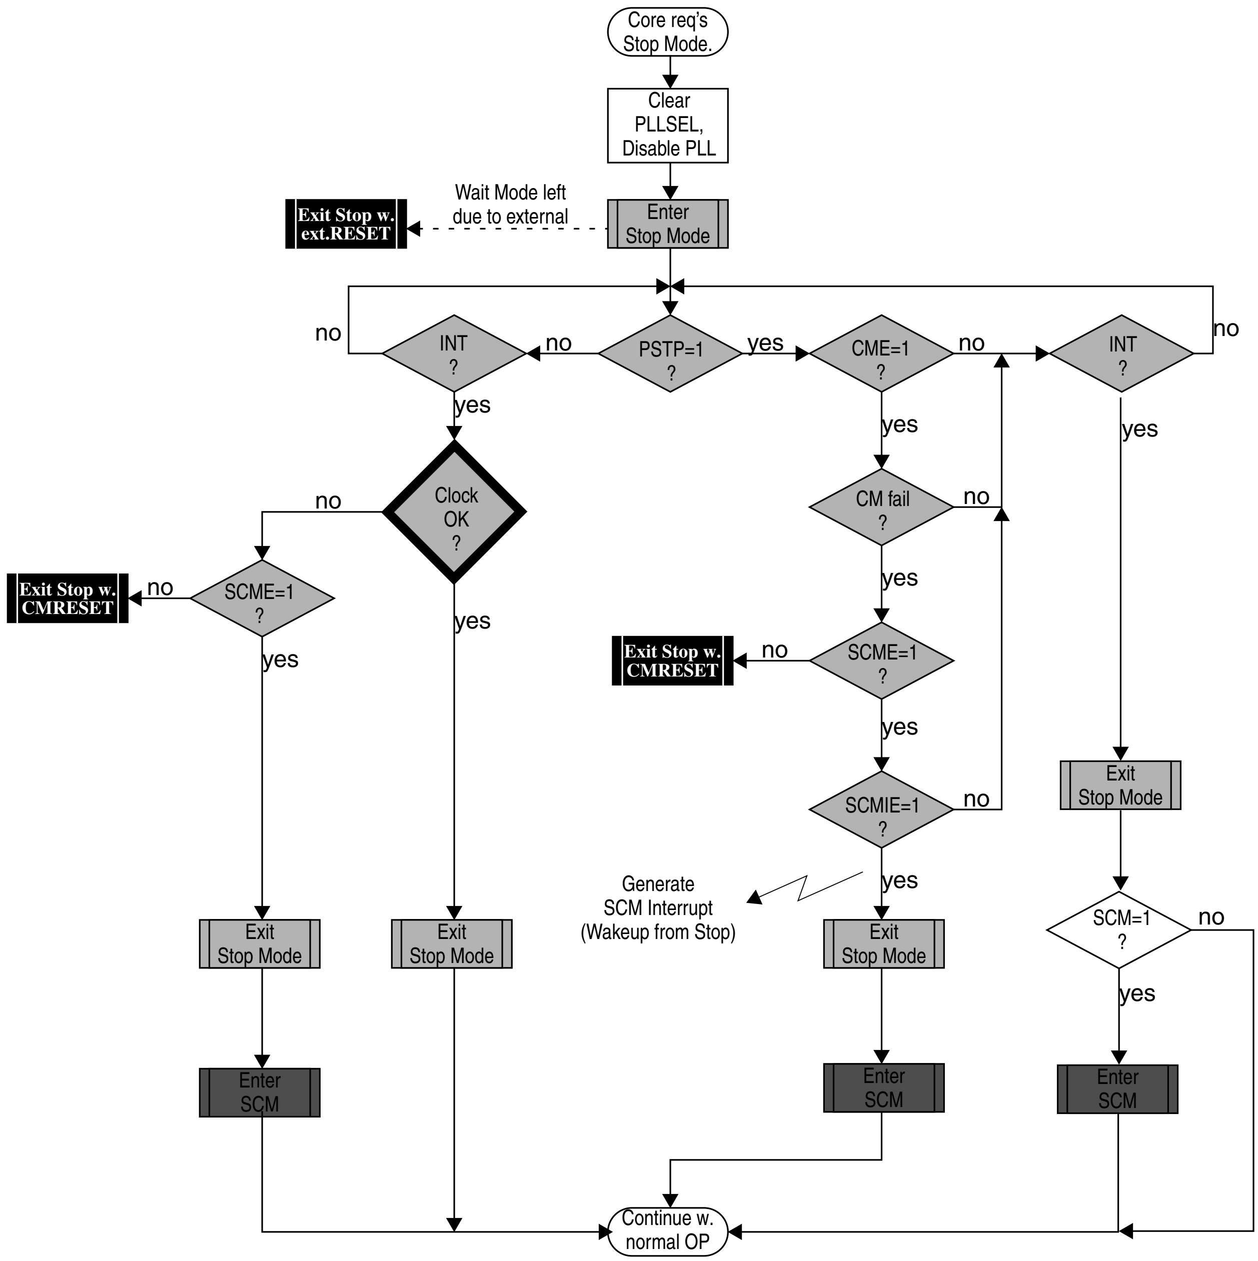

Figure 9-24. Stop Mode Entry/Exit Sequence

9.4.10.1 Wake-Up from Pseudo-Stop (PSTP=1)

Wake-up from pseudo-stop is the same as wake-up from wait mode. There are also three different scenarios for the CRG to restart the MCU from pseudo-stop mode:

- External reset
- Clock monitor fail
- Wake-up interrupt

If the MCU gets an external reset during pseudo-stop mode active, the CRG asynchronously restores all configuration bits in the register space to its default settings and starts the reset generator. After completing the reset sequence processing begins by fetching the normal reset vector. Pseudo-stop mode is exited and the MCU is in run mode again.

If the clock monitor is enabled (CME = 1) the MCU is able to leave pseudo-stop mode when loss of oscillator/external clock is detected by a clock monitor fail. If the SCME bit is not asserted the CRG generates a clock monitor fail reset (CMRESET). The CRG's behavior for CMRESET is the same compared to external reset, but another reset vector is fetched after completion of the reset sequence. If the SCME bit is asserted the CRG generates a SCM interrupt if enabled (SCMIE=1). After generating the interrupt the CRG enters self-clock mode and starts the clock quality checker (see Section 9.4.4, "Clock Quality Checker"). Then the MCU continues with normal operation. If the SCM interrupt is blocked by SCMIE = 0, the SCMIF flag will be asserted but the CRG will not wake-up from pseudo-stop mode.

If any other interrupt source (e.g. RTI) triggers exit from pseudo-stop mode the MCU immediately continues with normal operation. Because the PLL has been powered-down during stop mode the PLLSEL bit is cleared and the MCU runs on OSCCLK after leaving stop mode. The software must set the PLLSEL bit again, in order to switch system and core clocks to the PLLCLK.

Table 9-11 summarizes the outcome of a clock loss while in pseudo-stop mode.

Table 9-11. Outcome of Clock Loss in Pseudo-Stop Mode

CME	SCME	SCMIE	CRG Actions
0	X	X	Clock failure --> No action, clock loss not detected.
1	0	X	Clock failure --> CRG performs Clock Monitor Reset immediately
1	1	0	Clock Monitor failure --> Scenario 1: OSCCLK **recovers** prior to exiting Pseudo-Stop Mode. – MCU remains in Pseudo-Stop Mode, – VREG enabled, – PLL enabled, – SCM activated, – Start Clock Quality Check, – Set SCMIF interrupt flag. *Some time later OSCCLK recovers.* – CM no longer indicates a failure, – 4096 OSCCLK cycles later Clock Quality Check indicates clock o.k., – SCM deactivated, – PLL disabled, – VREG disabled. – MCU remains in Pseudo-Stop Mode. S*ome time later either a wakeup interrupt occurs (no SCM interrupt)* – Exit Pseudo-Stop Mode using OSCCLK as system clock (SYSCLK), – Continue normal operation. *or an External Reset is applied.* – Exit Pseudo-Stop Mode using OSCCLK as system clock, – Start reset sequence. Scenario 2: OSCCLK **does not recover** prior to exiting Pseudo-Stop Mode. – MCU remains in Pseudo-Stop Mode, – VREG enabled, – PLL enabled, – SCM activated, – Start Clock Quality Check, – Set SCMIF interrupt flag, – Keep performing Clock Quality Checks (could continue infinitely) while in Pseudo-Stop Mode. S*ome time later either a wakeup interrupt occurs (no SCM interrupt)* – Exit Pseudo-Stop Mode in SCM using PLL clock (f_{SCM}) as system clock – Continue to perform additional Clock Quality Checks until OSCCLK is o.k. again. or an External RESET is applied. – Exit Pseudo-Stop Mode in SCM using PLL clock (f_{SCM}) as system clock – Start reset sequence, – Continue to perform additional Clock Quality Checks until OSCCLK is o.k.again.

Table 9-11. Outcome of Clock Loss in Pseudo-Stop Mode (continued)

CME	SCME	SCMIE	CRG Actions
1	1	1	Clock failure --> – VREG enabled, – PLL enabled, – SCM activated, – Start Clock Quality Check, – SCMIF set. SCMIF generates Self-Clock Mode wakeup interrupt. – Exit Pseudo-Stop Mode in SCM using PLL clock (f_{SCM}) as system clock, – Continue to perform a additional Clock Quality Checks until OSCCLK is o.k. again.

9.4.10.2 Wake-up from Full Stop (PSTP=0)

The MCU requires an external interrupt or an external reset in order to wake-up from stop mode.

If the MCU gets an external reset during full stop mode active, the CRG asynchronously restores all configuration bits in the register space to its default settings and will perform a maximum of 50 clock *check_windows* (see Section 9.4.4, “Clock Quality Checker”). After completing the clock quality check the CRG starts the reset generator. After completing the reset sequence processing begins by fetching the normal reset vector. Full stop mode is exited and the MCU is in run mode again.

If the MCU is woken-up by an interrupt, the CRG will also perform a maximum of 50 clock *check_windows* (see Section 9.4.4, “Clock Quality Checker”). If the clock quality check is successful, the CRG will release all system and core clocks and will continue with normal operation. If all clock checks within the timeout-window are failing, the CRG will switch to self-clock mode or generate a clock monitor reset (CMRESET) depending on the setting of the SCME bit.

Because the PLL has been powered-down during stop mode the PLLSEL bit is cleared and the MCU runs on OSCCLK after leaving stop mode. The software must manually set the PLLSEL bit again, in order to switch system and core clocks to the PLLCLK.

NOTE

In full stop mode, the clock monitor is disabled and any loss of clock will not be detected.

9.5 Resets

This section describes how to reset the CRG and how the CRG itself controls the reset of the MCU. It explains all special reset requirements. Because the reset generator for the MCU is part of the CRG, this section also describes all automatic actions that occur during or as a result of individual reset conditions. The reset values of registers and signals are provided in Section 9.3, “Memory Map and Register

Definition." All reset sources are listed in Table 9-12. Refer to the device overview chapter for related vector addresses and priorities.

Table 9-12. Reset Summary

Reset Source	Local Enable
Power-on Reset	None
Low Voltage Reset	None
External Reset	None
Clock Monitor Reset	PLLCTL (CME=1, SCME=0)
COP Watchdog Reset	COPCTL (CR[2:0] nonzero)

The reset sequence is initiated by any of the following events:

- Low level is detected at the $\overline{\text{RESET}}$ pin (external reset).
- Power on is detected.
- Low voltage is detected.
- COP watchdog times out.
- Clock monitor failure is detected and self-clock mode was disabled (SCME = 0).

Upon detection of any reset event, an internal circuit drives the $\overline{\text{RESET}}$ pin low for 128 SYSCLK cycles (see Figure 9-25). Because entry into reset is asynchronous it does not require a running SYSCLK. However, the internal reset circuit of the CRG cannot sequence out of current reset condition without a running SYSCLK. The number of 128 SYSCLK cycles might be increased by n = 3 to 6 additional SYSCLK cycles depending on the internal synchronization latency. After 128+n SYSCLK cycles the $\overline{\text{RESET}}$ pin is released. The reset generator of the CRG waits for additional 64 SYSCLK cycles and then samples the RESET pin to determine the originating source. Table 9-13 shows which vector will be fetched.

Table 9-13. Reset Vector Selection

Sampled $\overline{\text{RESET}}$ Pin (64 Cycles After Release)	Clock Monitor Reset Pending	COP Reset Pending	Vector Fetch
1	0	0	POR / LVR / External Reset
1	1	X	Clock Monitor Reset
1	0	1	COP Reset
0	X	X	POR / LVR / External Reset with rise of $\overline{\text{RESET}}$ pin

NOTE

External circuitry connected to the $\overline{\text{RESET}}$ pin should not include a large capacitance that would interfere with the ability of this signal to rise to a valid logic 1 within 64 SYSCLK cycles after the low drive is released.

The internal reset of the MCU remains asserted while the reset generator completes the 192 SYSCLK long reset sequence. The reset generator circuitry always makes sure the internal reset is deasserted synchronously after completion of the 192 SYSCLK cycles. In case the RESET pin is externally driven low for more than these 192 SYSCLK cycles (external reset), the internal reset remains asserted too.

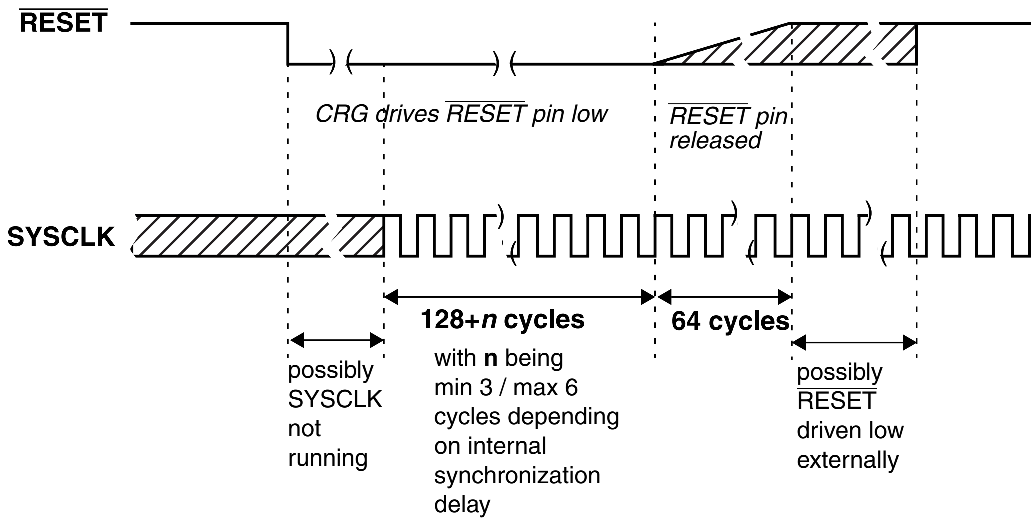

Figure 9-25. RESET Timing

9.5.1 Clock Monitor Reset

The CRG generates a clock monitor reset in case all of the following conditions are true:

- Clock monitor is enabled (CME=1)
- Loss of clock is detected
- Self-clock mode is disabled (SCME=0)

The reset event asynchronously forces the configuration registers to their default settings (see Section 9.3, "Memory Map and Register Definition"). In detail the CME and the SCME are reset to logical '1' (which doesn't change the state of the CME bit, because it has already been set). As a consequence, the CRG immediately enters self-clock mode and starts its internal reset sequence. In parallel the clock quality check starts. As soon as clock quality check indicates a valid oscillator clock the CRG switches to OSCCLK and leaves self-clock mode. Because the clock quality checker is running in parallel to the reset generator, the CRG may leave self-clock mode while completing the internal reset sequence. When the reset sequence is finished the CRG checks the internally latched state of the clock monitor fail circuit. If a clock monitor fail is indicated processing begins by fetching the clock monitor reset vector.

9.5.2 Computer Operating Properly Watchdog (COP) Reset

When COP is enabled, the CRG expects sequential write of 0x0055 and 0x00AA (in this order) to the ARMCOP register during the selected time-out period. As soon as this is done, the COP time-out period restarts. If the program fails to do this the CRG will generate a reset. Also, if any value other than 0x0055 or 0x00AA is written, the CRG immediately generates a reset. In case windowed COP operation is enabled writes (0x0055 or 0x00AA) to the ARMCOP register must occur in the last 25% of the selected time-out period. A premature write the CRG will immediately generate a reset.

As soon as the reset sequence is completed the reset generator checks the reset condition. If no clock monitor failure is indicated and the latched state of the COP timeout is true, processing begins by fetching the COP vector.

9.5.3 Power-On Reset, Low Voltage Reset

The on-chip voltage regulator detects when V_{DD} to the MCU has reached a certain level and asserts power-on reset or low voltage reset or both. As soon as a power-on reset or low voltage reset is triggered the CRG performs a quality check on the incoming clock signal. As soon as clock quality check indicates a valid oscillator clock signal the reset sequence starts using the oscillator clock. If after 50 check windows the clock quality check indicated a non-valid oscillator clock the reset sequence starts using self-clock mode.

Figure 9-26 and Figure 9-27 show the power-up sequence for cases when the $\overline{\text{RESET}}$ pin is tied to V_{DD} and when the $\overline{\text{RESET}}$ pin is held low.

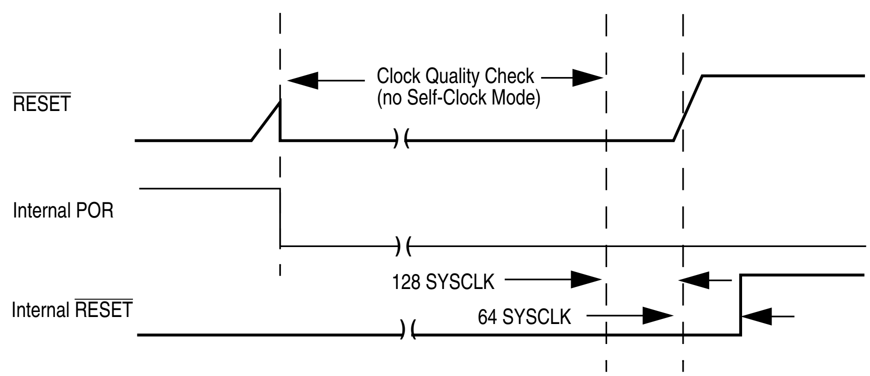

Figure 9-26. $\overline{\text{RESET}}$ Pin Tied to V_{DD} (by a Pull-Up Resistor)

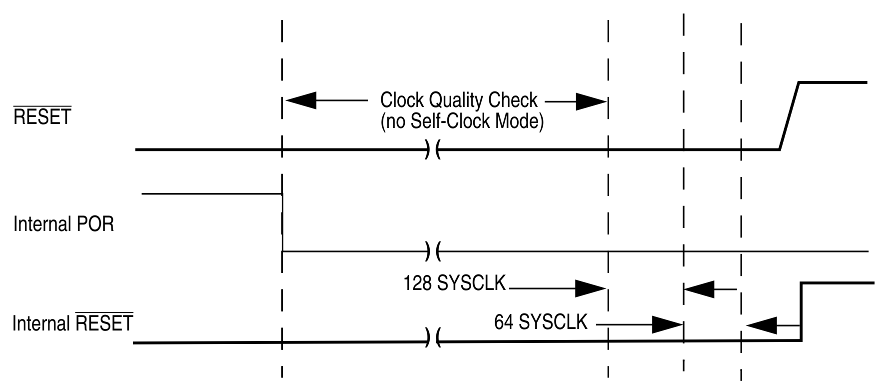

Figure 9-27. $\overline{\text{RESET}}$ Pin Held Low Externally

9.6 Interrupts

The interrupts/reset vectors requested by the CRG are listed in Table 9-14. Refer to the device overview chapter for related vector addresses and priorities.

Table 9-14. CRG Interrupt Vectors

Interrupt Source	CCR Mask	Local Enable
Real-time interrupt	I bit	CRGINT (RTIE)
LOCK interrupt	I bit	CRGINT (LOCKIE)
SCM interrupt	I bit	CRGINT (SCMIE)

9.6.1 Real-Time Interrupt

The CRG generates a real-time interrupt when the selected interrupt time period elapses. RTI interrupts are locally disabled by setting the RTIE bit to 0. The real-time interrupt flag (RTIF) is set to 1 when a timeout occurs, and is cleared to 0 by writing a 1 to the RTIF bit.

The RTI continues to run during pseudo-stop mode if the PRE bit is set to 1. This feature can be used for periodic wakeup from pseudo-stop if the RTI interrupt is enabled.

9.6.2 PLL Lock Interrupt

The CRG generates a PLL lock interrupt when the LOCK condition of the PLL has changed, either from a locked state to an unlocked state or vice versa. Lock interrupts are locally disabled by setting the LOCKIE bit to 0. The PLL Lock interrupt flag (LOCKIF) is set to1 when the LOCK condition has changed, and is cleared to 0 by writing a 1 to the LOCKIF bit.

9.6.3 Self-Clock Mode Interrupt

The CRG generates a self-clock mode interrupt when the SCM condition of the system has changed, either entered or exited self-clock mode. SCM conditions can only change if the self-clock mode enable bit (SCME) is set to 1. SCM conditions are caused by a failing clock quality check after power-on reset (POR) or low voltage reset (LVR) or recovery from full stop mode (PSTP = 0) or clock monitor failure. For details on the clock quality check refer to Section 9.4.4, "Clock Quality Checker." If the clock monitor is enabled (CME = 1) a loss of external clock will also cause a SCM condition (SCME = 1).

SCM interrupts are locally disabled by setting the SCMIE bit to 0. The SCM interrupt flag (SCMIF) is set to 1 when the SCM condition has changed, and is cleared to 0 by writing a 1 to the SCMIF bit.

Chapter 10
Enhanced Capture Timer (ECT16B8CV1) Block Description

10.1 Introduction

The HCS12 Enhanced Capture Timer module has the features of the HCS12 Standard Timer module enhanced by additional features in order to enlarge the field of applications, in particular for automotive ABS applications.

This design specification describes the standard timer as well as the additional features.

The basic timer consists of a 16-bit, software-programmable counter driven by a prescaler. This timer can be used for many purposes, including input waveform measurements while simultaneously generating an output waveform. Pulse widths can vary from microseconds to many seconds.

A full access for the counter registers or the input capture/output compare registers should take place in one clock cycle. Accessing high byte and low byte separately for all of these registers may not yield the same result as accessing them in one word.

10.1.1 Features

- 16-bit Buffer Register for four Input Capture (IC) channels.
- Four 8-bit Pulse Accumulators with 8-bit buffer registers associated with the four buffered IC channels. Configurable also as two 16-bit Pulse Accumulators.
- 16-bit Modulus Down-Counter with 4-bit Prescaler.
- Four user selectable Delay Counters for input noise immunity increase.

10.1.2 Modes of Operation

STOP: Timer and modulus counter are off since clocks are stopped.

FREEZE: Timer and modulus counter keep on running, unless TSFRZ in TSCR (0x0006) is set to one.

WAIT: Counters keep on running, unless TSWAI in TSCR (0x0006) is set to one.

NORMAL: Timer and modulus counter keep on running, unless TEN in TSCR (0x0006) respectively MCEN in MCCTL (0x0026) are cleared.

10.1.3 Block Diagram

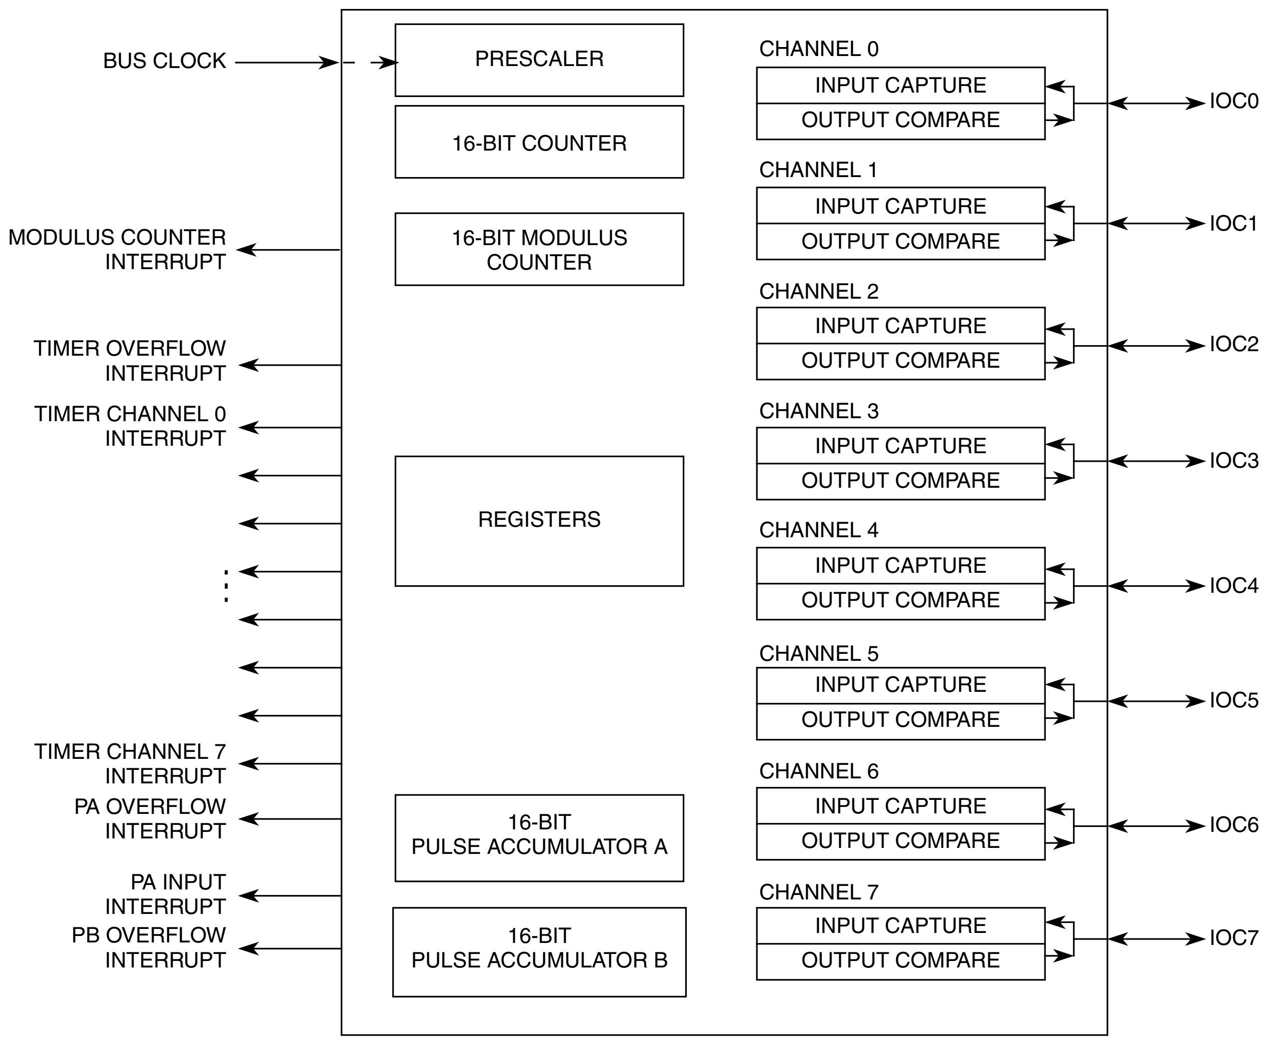

Figure 10-1. Timer Block Diagram

10.2 Signal Description

The ECT16B8C module has a total eight external pins.

10.2.1 IOC7 — Input Capture and Output Compare Channel 7

This pin serves as input capture or output compare for channel 7.

10.2.2 IOC6 — Input Capture and Output Compare Channel 6

This pin serves as input capture or output compare for channel 6.

10.2.3 IOC5 — Input Capture and Output Compare Channel 5

This pin serves as input capture or output compare for channel 7.

10.2.4 IOC4 — Input Capture and Output Compare Channel 4

This pin serves as input capture or output compare for channel 4.

10.2.5 IOC3 — Input Capture and Output Compare Channel 3

This pin serves as input capture or output compare for channel 3.

10.2.6 IOC2 — Input Capture and Output Compare Channel 2

This pin serves as input capture or output compare for channel 2.

10.2.7 IOC1 — Input Capture and Output Compare Channel 1

This pin serves as input capture or output compare for channel 1.

10.2.8 IOC0 — Input Capture and Output Compare Channel 0

This pin serves as input capture or output compare for channel 0.

NOTE

For the description of interrupts see Section 10.6, “Interrupts”.

10.3 Memory Map and Registers

This section provides a detailed description of all memory and registers.

10.3.1 Module Memory Map

A register summary for the ECT module is given below in Figure 10-2. The Address listed for each register is the address offset. The total address for each register is the sum of the base address for the ECT module and the address offset for each register.

Address	Name		Bit 7	6	5	4	3	2	1	Bit 0
0x0000	TIOS	R/W	IOS7	IOS6	IOS5	IOS4	IOS3	IOS2	IOS1	IOS0

10.3.2 Register Descriptions

This section consists of register descriptions in address order. Each description includes a standard register diagram with an associated figure number. Details of register bit and field function follow the register diagrams, in bit order.

10.3.2.1 Timer Input Capture/Output Compare Select Register (TIOS)

Module Base + 0x0000

	7	6	5	4	3	2	1	0
R W	IOS7	IOS6	IOS5	IOS4	IOS3	IOS2	IOS1	IOS0
Reset	0	0	0	0	0	0	0	0

Figure 10-3. Timer Input Capture/Output Compare Register (TIOS)

Read or write anytime.

Table 10-1. TIOS Field Descriptions

Field	Description
7–0 IOS[7:0]	**Input Capture or Output Compare Channel Configuration Bits** 0 The corresponding channel acts as an input capture 1 The corresponding channel acts as an output compare.

10.3.2.2 Timer Compare Force Register (CFORC)

Module Base + 0x0001

	7	6	5	4	3	2	1	0
R	0	0	0	0	0	0	0	0
W	FOC7	FOC6	FOC5	FOC4	FOC3	FOC2	FOC1	FOC0
Reset	0	0	0	0	0	0	0	0

Figure 10-4. Timer Compare Force Register (CFORC)

Read anytime but will always return 0x0000 (1 state is transient). Write anytime.

Table 10-2. CFORC Field Descriptions

Field	Description
7–0 FOC[7:0]	**Force Output Compare Action for Channel 7–0** — A write to this register with the corresponding data bit(s) set causes the action which is programmed for output compare “n” to occur immediately. The action taken is the same as if a successful comparison had just taken place with the TCn register except the interrupt flag does not get set. **Note:** A successful channel 7 output compare overrides any channel 6:0 compares.If forced output compare on any channel occurs at the same time as the successful output compare then forced output compare action will take precedence and interrupt flag won’t get set.

10.3.2.3 Output Compare 7 Mask Register (OC7M)

Module Base + 0x0002

	7	6	5	4	3	2	1	0
R W	OC7M7	OC7M6	OC7M5	OC7M4	OC7M3	OC7M2	OC7M1	OC7M0
Reset	0	0	0	0	0	0	0	0

Figure 10-5. Output Compare 7 Mask Register (OC7M)

Read or write anytime.

Setting the OC7Mn (n ranges from 0 to 6) bit of OC7M register configures the corresponding port to be an output port when the IOS7 bit and the corresponding IOSn (n ranges from 0 to 6) bit of TIOS register are set to be an output compare. Refer to the note on Section 10.4.1.4, “Channel Configurations” for more insight.

NOTE

A successful channel 7 output compare overrides any channel 6:0 compares. For each OC7M bit that is set, the output compare action reflects the corresponding OC7D bit.

10.3.2.4 Output Compare 7 Data Register (OC7D)

Module Base + 0x0003

	7	6	5	4	3	2	1	0
R W	OC7D7	OC7D6	OC7D5	OC7D4	OC7D3	OC7D2	OC7D1	OC7D0
Reset	0	0	0	0	0	0	0	0

Figure 10-6. Output Compare 7 Data Register (OC7D)

Read or write anytime.

A channel 7 output compare can cause bits in the output compare 7 data register to transfer to the timer port data register depending on the output compare 7 mask register.

10.3.2.5 Timer Count Register (TCNT)

Module Base + 0x0004–0x0005

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	tcnt 15	tcnt 14	tcnt 13	tcnt 12	tcnt 11	tcnt 10	tcnt 9	tcnt 8	tcnt 7	tcnt 6	tcnt 5	tcnt 4	tcnt 3	tcnt 2	tcnt 1	tcnt 0
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

= Unimplemented or Reserved

Figure 10-7. Timer Count Register (TCNT)

The 16-bit main timer is an up counter.

A full access for the counter register should take place in one clock cycle. A separate read (any mode)/ write (test mode) for high byte and low byte will give a different result than accessing them as a word.

Read anytime.

Write has no meaning or effect in the normal mode; only writable in special modes (test_mode = 1).

The period of the first count after a write to the TCNT registers may be a different size because the write is not synchronized with the prescaler clock.

10.3.2.6 Timer System Control Register 1 (TSCR1)

Module Base + 0x0006

	7	6	5	4	3	2	1	0
R	TEN	TSWAI	TSFRZ	TFFCA	0	0	0	0
W								
Reset	0	0	0	0	0	0	0	0

= Unimplemented or Reserved

Figure 10-8. Timer System Control Register 1 (TSCR1)

Read or write anytime.

Table 10-3. TSCR1 Field Descriptions

Field	Description
7 TEN	**Timer Enable** 0 Disables the main timer, including the counter. Can be used for reducing power consumption. 1 Allows the timer to function normally. **Note:** If for any reason the timer is not active, there is no ÷64 clock for the pulse accumulator since the ÷64 is generated by the timer prescaler.
6 TSWAI	**Timer Module Stops While in Wait** 0 Allows the timer module to continue running during wait. 1 Disables the timer module when the MCU is in the wait mode. Timer interrupts cannot be used to get the MCU out of wait. **Note:** TSWAI also affects pulse accumulators and modulus down counters.
5 TSFRZ	**Timer and Modulus Counter Stop While in Freeze Mode** 0 Allows the timer and modulus counter to continue running while in freeze mode. 1 Disables the timer and modulus counter whenever the MCU is in freeze mode. This is useful for emulation. **Note:** TSFRZ does not stop the pulse accumulator.
4 TFFCA	**Timer Fast Flag Clear All** 0 Allows the timer flag clearing to function normally. 1 For TFLG1(0x000E), a read from an input capture or a write to the output compare channel (0x0010–0x001F) causes the corresponding channel flag, CnF, to be cleared. For TFLG2 (0x000F), any access to the TCNT register (0x0004, 0x0005) clears the TOF flag. Any access to the PACN3 and PACN2 registers (0x0022, 0x0023) clears the PAOVF and PAIF flags in the PAFLG register (0x0021). Any access to the PACN1 and PACN0 registers (0x0024, 0x0025) clears the PBOVF flag in the PBFLG register (0x0031). This has the advantage of eliminating software overhead in a separate clear sequence. Extra care is required to avoid accidental flag clearing due to unintended accesses.

10.3.2.7 Timer Toggle On Overflow Register 1 (TTOV)

Module Base + 0x0007

	7	6	5	4	3	2	1	0
R W	TOV7	TOV6	TOV5	TOV4	TOV3	TOV2	TOV1	TOV0
Reset	0	0	0	0	0	0	0	0

Figure 10-9. Timer Toggle On Overflow Register 1 (TTOV)

Read or write anytime.

Table 10-4. TTOV Field Descriptions

Field	Description
7–0 TOV[7:0]	**Toggle On Overflow Bits** — TOVn toggles output compare pin on overflow. This feature only takes effect when in output compare mode. When set, it takes precedence over forced output compare but not channel 7 override events. 0 Toggle output compare pin on overflow feature disabled 1 Toggle output compare pin on overflow feature enabled

10.3.2.8 Timer Control Register 1/Timer Control Register 2 (TCTL1/TCTL2)

Module Base + 0x0008

	7	6	5	4	3	2	1	0
R/W	OM7	OL7	OM6	OL6	OM5	OL5	OM4	OL4
Reset	0	0	0	0	0	0	0	0

Module Base + 0x0009

	7	6	5	4	3	2	1	0
R/W	OM3	OL3	OM2	OL2	OM1	OL1	OM0	OL0
Reset	0	0	0	0	0	0	0	0

Figure 10-10. Timer Control Register 1/Timer Control Register 2 (TCTL1/TCTL2))

Read or write anytime.

Table 10-5. TCTL1/TCTL2 Field Descriptions

Field	Description
7–0 OM[7:0] OL[7:0]	**OMn — Output Mode** **OLn — Output Level** These eight pairs of control bits are encoded to specify the output action to be taken as a result of a successful OCn(n varies from 0 to 7) compare. When either OMn or OLn is one, the port associated with OCn becomes an output tied to OCn when the corresponding IOSn bit of TIOS register is set and TEN bit of TSCR1 register is set. Refer to the note on Section 10.4.1.4, "Channel Configurations" for more insight. See Table 10-6. **Note:** To enable output action by OMn and OLn bits on timer port, the corresponding bit in OC7M should be cleared. To operate the 16-bit pulse accumulators A and B (PACA and PACB) independently of input capture or output compare 7 and 0 respectively the user must set the corresponding bits IOSn = 1, OMn = 0 and OLn = 0. OC7M7 or OC7M0 in the OC7M register must also be cleared.

Table 10-6. Compare Result Output Action

OMn	OLn	Action
0	0	Timer disconnected from output pin logic
0	1	Toggle OCn output line
1	0	Clear OCn output line to zero
1	1	Set OCn output line to one

10.3.2.9 Timer Control Register 3/Timer Control Register 4 (TCTL3/TCTL4)

Module Base + 0x000A

	7	6	5	4	3	2	1	0
R W	EDG7B	EDG7A	EDG6B	EDG6A	EDG5B	EDG5A	EDG4B	EDG4A
Reset	0	0	0	0	0	0	0	0

Module Base + 0x000B

	7	6	5	4	3	2	1	0
R W	EDG3B	EDG3A	EDG2B	EDG2A	EDG1B	EDG1A	EDG0B	EDG0A
Reset	0	0	0	0	0	0	0	0

Figure 10-11. Timer Control Register 3/Timer Control Register 4 (TCTL3/TCTL4)

Read or write anytime.

Table 10-7. TCTL3/TCTL4 Field Descriptions

Field	Description
7–0 EDG[7:0]B EDG[7:0]A	**Input Capture Edge Control** — These eight pairs of control bits configure the input capture edge detector circuits. The four pairs of control bits of TCTL4 also configure the 8 bit pulse accumulators PAC0–PAC3. For 16-bit pulse accumulator PACB, EDGE0B, and EDGE0A, control bits of TCTL4 will decide the active edge. See Table 10-8.

Table 10-8. Edge Detector Circuit Configuration

EDGnB	EDGnA	Configuration
0	0	Capture disabled
0	1	Capture on rising edges only
1	0	Capture on falling edges only
1	1	Capture on any edge (rising or falling)

10.3.2.10 Timer Interrupt Enable Register (TIE)

Module Base + 0x000C

	7	6	5	4	3	2	1	0
R W	C7I	C6I	C5I	C4I	C3I	C2I	C1I	C0I
Reset	0	0	0	0	0	0	0	0

Figure 10-12. Timer Interrupt Enable Register (TIE)

Read or write anytime.

Table 10-9. TIE Field Descriptions

Field	Description
7–0 C[7:0]I	**Input Capture/Output Compare “n” Interrupt Enable** — The bits in TIE correspond bit-for-bit with the bits in the TFLG1 status register. If cleared, the corresponding flag is disabled from causing a hardware interrupt. If set, the corresponding flag is enabled to cause a interrupt.

10.3.2.11 Timer System Control Register 2 (TSCR2)

Module Base + 0x000D

	7	6	5	4	3	2	1	0
R	TOI	0	0	0	TCRE	PR2	PR1	PR0
W								
Reset	0	0	0	0	0	0	0	0

= Unimplemented or Reserved

Figure 10-13. Timer System Control Register 2 (TSCR2)

Read or write anytime.

Table 10-10. TSCR2 Field Descriptions

Field	Description
7 TOI	**Timer Overflow Interrupt Enable** 0 Interrupt inhibited 1 Hardware interrupt requested when TOF flag set
3 TCRE	**Timer Counter Reset Enable** — This bit allows the timer counter to be reset by a successful output compare 7 event. This mode of operation is similar to an up-counting modulus counter. 0 Counter reset inhibited and counter free runs 1 Counter reset by a successful output compare 7 **Note:** If TC7 = 0x0000 and TCRE = 1, TCNT will stay at 0x0000 continuously. If TC7 = 0xFFFF and TCRE = 1, TOF will never be set when TCNT is reset from 0xFFFF to 0x0000.
2–0 PR[2:0]	**Timer Prescaler Select** — These three bits specify the number of ÷2 stages that are to be inserted between the bus clock and the main timer counter. See Table 10-11. **Note:** The newly selected prescale factor will not take effect until the next synchronized edge where all prescale counter stages equal zero.

Table 10-11. Prescaler Selection

PR2	PR1	PR0	Prescale Factor
0	0	0	1
0	0	1	2
0	1	0	4
0	1	1	8
1	0	0	16
1	0	1	32
1	1	0	64
1	1	1	128

10.3.2.12 Main Timer Interrupt Flag 1 (TFLG1)

Module Base + 0x000E

	7	6	5	4	3	2	1	0
R/W	C7F	C6F	C5F	C4F	C3F	C2F	C1F	C0F
Reset	0	0	0	0	0	0	0	0

Figure 10-14. Main Timer Interrupt Flag 1 (TFLG1)

TFLG1 indicates when interrupt conditions have occurred. To clear a bit in the flag register, write a one to the bit. Use of the TFMOD bit in the ICSYS register (0x002B) in conjunction with the use of the ICOVW register (0x002A) allows a timer interrupt to be generated after capturing two values in the capture and holding registers instead of generating an interrupt for every capture.

Read anytime. Write used in the clearing mechanism (set bits cause corresponding bits to be cleared). Writing a zero will not affect current status of the bit.

When TFFCA bit in TSCR register is set, a read from an input capture or a write into an output compare channel (0x0010–0x001F) will cause the corresponding channel flag CnF to be cleared.

Table 10-12. TFLG1 Field Descriptions

Field	Description
7–0 C[7:0]F	**Input Capture/Output Compare Channel "n" Flag** — C0F can also be set by 16-bit Pulse Accumulator B (PACB). C3F–C0F can also be set by 8 - bit pulse accumulators PAC3–PAC0.

10.3.2.13 Main Timer Interrupt Flag 2 (TFLG2)

Module Base + 0x000F

	7	6	5	4	3	2	1	0
R	TOF	0	0	0	0	0	0	0
W								
Reset	0	0	0	0	0	0	0	0

= Unimplemented or Reserved

Figure 10-15. Main Timer Interrupt Flag 2 (TFLG2)

TFLG2 indicates when interrupt conditions have occurred. To clear a bit in the flag register, write the bit to one.

Read anytime. Write used in clearing mechanism (set bits cause corresponding bits to be cleared).

Any access to TCNT will clear TFLG2 register if the TFFCA bit in TSCR register is set.

Table 10-13. TFLG2 Field Descriptions

Field	Description
7 TOF	**Timer Overflow Flag** — Set when 16-bit free-running timer overflows from 0xFFFF to 0x0000. This bit is cleared automatically by a write to the TFLG2 register with bit 7 set. See also TCRE control bit explanation found in Section 10.3.2.11, "Timer System Control Register 2 (TSCR2)".

Figure 10-17. 16-Bit Pulse Accumulator Control Register (PACTL)

16-Bit Pulse Accumulator A (PACA) is formed by cascading the 8-bit pulse accumulators PAC3 and PAC2.

When PAEN is set, the PACA is enabled. The PACA shares the input pin with IC7.

Read: Anytime
Write: Anytime

Table 10-14. PACTL Field Descriptions

Field	Description
6 PAEN	**Pulse Accumulator A System Enable** — PAEN is independent from TEN. With timer disabled, the pulse accumulator can still function unless pulse accumulator is disabled. 0 16-Bit Pulse Accumulator A system disabled. 8-bit PAC3 and PAC2 can be enabled when their related enable bits in ICPAR (0x0028) are set. Pulse Accumulator Input Edge Flag (PAIF) function is disabled. 1 16-Bit Pulse Accumulator A system enabled. The two 8-bit pulse accumulators PAC3 and PAC2 are cascaded to form the PACA 16-bit pulse accumulator. When PACA in enabled, the PACN3 and PACN2 registers contents are respectively the high and low byte of the PACA. PA3EN and PA2EN control bits in ICPAR (0x0028) have no effect. Pulse Accumulator Input Edge Flag (PAIF) function is enabled.
5 PAMOD	**Pulse Accumulator Mode** — This bit is active only when the Pulse Accumulator A is enabled (PAEN = 1). 0 Event counter mode 1 Gated time accumulation mode

Table 10-14. PACTL Field Descriptions (continued)

Field	Description
4 PEDGE	**Pulse Accumulator Edge Control** — This bit is active only when the Pulse Accumulator A is enabled (PAEN = 1). See Table 10-15. For PAMOD bit = 0 (event counter mode). 0 Falling edges on PT7 pin cause the count to be incremented 1 Rising edges on PT7 pin cause the count to be incremented For PAMOD bit = 1 (gated time accumulation mode). 0 PT7 input pin high enables bus clock divided by 64 to Pulse Accumulator and the trailing falling edge on PT7 sets the PAIF flag. 1 PT7 input pin low enables bus clock divided by 64 to Pulse Accumulator and the trailing rising edge on PT7 sets the PAIF flag **Note:** If the timer is not active (TEN = 0 in TSCR), there is no divide-by-64 since the ÷64 clock is generated by the timer prescaler.
3–2 CLK[1:0]	**Clock Select Bits** — If the pulse accumulator is disabled (PAEN = 0), the prescaler clock from the timer is always used as an input clock to the timer counter. The change from one selected clock to the other happens immediately after these bits are written. Refer to Table 10-16 and for the description of PACLK please refer Figure 10-17.
1 PAOVI	**Pulse Accumulator A Overflow Interrupt Enable** 0 Interrupt inhibited 1nterrupt requested if PAOVF is set
0 PAI	**Pulse Accumulator Input Interrupt Enable** 0 Interrupt inhibited 1 Interrupt requested if PAIF is set

Table 10-15. Pin Action

PAMOD	PEDGE	Pin Action
0	0	Falling edge
0	1	Rising edge
1	0	Divide by 64 clock enabled with pin high level
1	1	Divide by 64 clock enabled with pin low level

Table 10-16. Clock Selection

CLK1	CLK0	Clock Source
0	0	Use timer prescaler clock as timer counter clock
0	1	Use PACLK as input to timer counter clock
1	0	Use PACLK/256 as timer counter clock frequency
1	1	Use PACLK/65536 as timer counter clock frequency

10.3.2.16 Pulse Accumulator A Flag Register (PAFLG)

Module Base + 0x0021

Figure 10-18. Pulse Accumulator A Flag Register (PAFLG)

Read or write anytime. When the TFFCA bit in the TSCR register is set, any access to the PACNT register will clear all the flags in the PAFLG register.

Table 10-17. PAFLG Field Descriptions

Field	Description
1 PAOVF	**Pulse Accumulator A Overflow Flag** — Set when the 16-bit pulse accumulator A overflows from 0xFFFF to 0x0000,or when 8-bit pulse accumulator 3 (PAC3) overflows from 0x00FF to 0x0000. When PACMX = 1, PAOVF bit can also be set if 8 - bit pulse accumulator 3 (PAC3) reaches 0x00FF followed by an active edge on PT3. This bit is cleared automatically by a write to the PAFLG register with bit 1 set.
0 PAIF	**Pulse Accumulator Input edge Flag** — Set when the selected edge is detected at the PT7 input pin. In event mode the event edge triggers PAIF and in gated time accumulation mode the trailing edge of the gate signal at the PT7 input pin triggers PAIF. This bit is cleared by a write to the PAFLG register with bit 0 set. Any access to the PACN3, PACN2 registers will clear all the flags in this register when TFFCA bit in register TSCR(0x0006) is set.

10.3.2.17 Pulse Accumulators Count Registers (PACN3/PACN2)

Module Base + 0x0022

	7	6	5	4	3	2	1	0
R W	PACNT7(15)	PACNT6(14)	PACNT5(13)	PACNT4(12)	PACNT3(11)	PACNT2(10)	PACNT1(9)	PACNT0(8)

Reset	0	0	0	0	0	0	0	0

Figure 10-20. Pulse Accumulators Count Register 2 (PACN2)

Read or write anytime.

The two 8-bit pulse accumulators PAC3 and PAC2 are cascaded to form the PACA 16-bit pulse accumulator. When PACA in enabled (PAEN = 1 in PACTL, 0x0020) the PACN3 and PACN2 registers contents are respectively the high and low byte of the PACA.

When PACN3 overflows from 0x00FF to 0x0000, the Interrupt flag PAOVF in PAFLG (0x0021) is set.

Full count register access should take place in one clock cycle. A separate read/write for high byte and low byte will give a different result than accessing them as a word.

NOTE

When clocking pulse and write to the registers occurs simultaneously, write takes priority and the register is not incremented.

10.3.2.18 Pulse Accumulators Count Registers (PACN1/PACN0)

Module Base + 0x0024

W				ICLAT	FLMC			
Reset	0	0	0	0	0	0	0	0

Figure 10-23. 16-Bit Modulus Down-Counter Control Register (MCCTL)

Read or write anytime.

Table 10-18. Field Descriptions

Field	Description
7 MCZI	**Modulus Counter Underflow Interrupt Enable** 0 Modulus counter interrupt is disabled. 1 Modulus counter interrupt is enabled.
6 MODMC	**Modulus Mode Enable** 0 The counter counts once from the value written to it and will stop at 0x0000. 1 Modulus mode is enabled. When the counter reaches 0x0000, the counter is loaded with the latest value written to the modulus count register. **Note:** For proper operation, the MCEN bit should be cleared before modifying the MODMC bit in order to reset the modulus counter to 0xFFFF.
5 RDMCL	**Read Modulus Down-Counter Load** 0 Reads of the modulus count register will return the present value of the count register. 1 Reads of the modulus count register will return the contents of the load register.
4 ICLAT	**Input Capture Force Latch Action** — When input capture latch mode is enabled (LATQ and BUFEN bit in ICSYS (0x002B) are set, a write one to this bit immediately forces the contents of the input capture registers TC0 to TC3 and their corresponding 8-bit pulse accumulators to be latched into the associated holding registers. The pulse accumulators will be automatically cleared when the latch action occurs. Writing zero to this bit has no effect. Read of this bit will return always zero.
3 FLMC	**Force Load Register into the Modulus Counter Count Register** — This bit is active only when the modulus down-counter is enabled (MCEN = 1). A write one into this bit loads the load register into the modulus counter count register. This also resets the modulus counter prescaler. Write zero to this bit has no effect. When MODMC = 0, counter starts counting and stops at 0x0000. Read of this bit will return always zero.
2 MCEN	**Modulus Down-Counter Enable** — When MCEN = 0, the counter is preset to 0xFFFF. This will prevent an early interrupt flag when the modulus down-counter is enabled. 0 Modulus counter disabled. 1 Modulus counter is enabled.
1–0 MCPR[1:0]	**Modulus Counter Prescaler Select** — These two bits specify the division rate of the modulus counter prescaler. The newly selected prescaler division rate will not be effective until a load of the load register into the modulus counter count register occurs. See Table 10-19.

Table 10-19. Modulus Counter Prescaler Select

MCPR1	MCPR0	Prescaler Division Rate
0	0	1
0	1	4
1	0	8
1	1	16

Read: Anytime
Write: Only for clearing bit 7

Table 10-20. MCFLG Field Descriptions

Field	Description
7 MCZF	**Modulus Counter Underflow Flag** — The flag is set when the modulus down-counter reaches 0x0000. A write one to this bit clears the flag. Write zero has no effect. Any access to the MCCNT register will clear the MCZF flag in this register when TFFCA bit in register TSCR(0x0006) is set.
3–0 POLF[3:0]	**First Input Capture Polarity Status** — This are read only bits. Write to these bits has no effect. Each status bit gives the polarity of the first edge which has caused an input capture to occur after capture latch has been read. Each POLFn corresponds to a timer PORTn input. 0 The first input capture has been caused by a falling edge. 1 The first input capture has been caused by a rising edge.

10.3.2.21 Input Control Pulse Accumulators Register (ICPAR)

W								
Reset	0	0	0	0	0	0	0	0

= Unimplemented or Reserved

Figure 10-26. Delay Counter Control Register (DLYCT)

Read or write anytime.

If enabled, after detection of a valid edge on input capture pin, the delay counter counts the pre-selected number of bus clock cycles, then it will generate a pulse on its output. The pulse is generated only if the level of input signal, after the preset delay, is the opposite of the level before the transition.This will avoid reaction to narrow input pulses.

After counting, the counter will be cleared automatically.

Delay between two active edges of the input signal period should be longer than the selected counter delay.

Table 10-22. DLYCT Field Descriptions

Field	Description
1–0 DLY[1:0]	**Delay Counter Select** — See Table 10-23.

Table 10-23. Delay Counter Select

DLY1	DLY0	Delay

Table 10-25. ICSYS Field Descriptions

Field	Description
7–4 SH37, SH26, SH15, SH04	**Share Input action of Input Capture Channels x and y** 0 Normal operation 1 The channel input ‘x’ causes the same action on the channel ‘y’. The port pin ‘x’ and the corresponding edge detector is used to be active on the channel ‘y’.

Table 10-25. ICSYS Field Descriptions (continued)

Field	Description
3 TFMOD	**Timer Flag-setting Mode** — Use of the TFMOD bit in the ICSYS register (0x002B) in conjunction with the use of the ICOVW register (0x002A) allows a timer interrupt to be generated after capturing two values in the capture and holding registers instead of generating an interrupt for every capture. By setting TFMOD in queue mode, when NOVW bit is set and the corresponding capture and holding registers are emptied, an input capture event will first update the related input capture register with the main timer contents. At the next event the TCn data is transferred to the TCnH register, The TCn is updated and the CnF interrupt flag is set. In all other input capture cases the interrupt flag is set by a valid external event on PTn. 0 The timer flags C3F–C0F in TFLG1 (0x000E) are set when a valid input capture transition on the corresponding port pin occurs. 1 If in queue mode (BUFEN = 1 and LATQ = 0), the timer flags C3F–C0F in TFLG1 (0x000E) are set only when a latch on the corresponding holding register occurs. If the queue mode is not engaged, the timer flags C3F–C0F are set the same way as for TFMOD = 0.
2 PACMX	**8-Bit Pulse Accumulators Maximum Count** 0 Normal operation. When the 8-bit pulse accumulator has reached the value 0x00FF, with the next active edge, it will be incremented to 0x0000. 1 When the 8-bit pulse accumulator has reached the value 0x00FF, it will not be incremented further. The value 0x00FF indicates a count of 255 or more.
1 BUFFEN	**IC Buffer Enable** 0 Input Capture and pulse accumulator holding registers are disabled. 1 Input Capture and pulse accumulator holding registers are enabled. The latching mode is defined by LATQ control bit. Write one into ICLAT bit in MCCTL (0x0026), when LATQ is set will produce latching of input capture and pulse accumulators registers into their holding registers.
0 LAT!	**Input Control Latch or Queue Mode Enable** — The BUFEN control bit should be set in order to enable the IC and pulse accumulators holding registers. Otherwise LATQ latching modes are disabled. Write one into ICLAT bit in MCCTL (0x0026), when LATQ and BUFEN are set will produce latching of input capture and pulse accumulators registers into their holding registers. 0 Queue Mode of Input Capture is enabled. The main timer value is memorized in the IC register by a valid input pin transition. With a new occurrence of a capture, the value of the IC register will be transferred to its holding register and the IC register memorizes the new timer value. 1 Latch Mode is enabled. Latching function occurs when modulus down-counter reaches zero or a zero is written into the count register MCCNT (seeSection 10.4.1.1.2, “Buffered IC Channels”). With a latching event the contents of IC registers and 8-bit pulse accumulators are transferred to their holding registers. 8-bit pulse accumulators are cleared.

Reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Figure 10-32. Modulus Down-Counter Count Register (MCCNT)

Read or write anytime.

A full access for the counter register should take place in one clock cycle. A separate read/write for high byte and low byte will give different result than accessing them as a word.

If the RDMCL bit in MCCTL register is cleared, reads of the MCCNT register will return the present value of the count register. If the RDMCL bit is set, reads of the MCCNT will return the contents of the load register.

If a 0x0000 is written into MCCNT and modulus counter while LATQ and BUFEN in ICSYS (0x002B) register are set, the input capture and pulse accumulator registers will be latched.

With a 0x0000 write to the MCCNT, the modulus counter will stay at zero and does not set the MCZF flag in MCFLG register.

If modulus mode is enabled (MODMC = 1), a write to this address will update the load register with the value written to it. The count register will not be updated with the new value until the next counter underflow.

The FLMC bit in MCCTL (0x0026) can be used to immediately update the count register with the new value if an immediate load is desired.

If modulus mode is not enabled (MODMC = 0), a write to this address will clear the prescaler and will immediately update the counter register with the value written to it and down-counts once to 0x0000.

10.4 Functional Description

This section provides a complete functional description of the ECT block, detailing the operation of the design from the end user perspective in a number of subsections.

Refer to the Timer Block Diagrams from Figure 10-37 to Figure 10-41 as necessary.

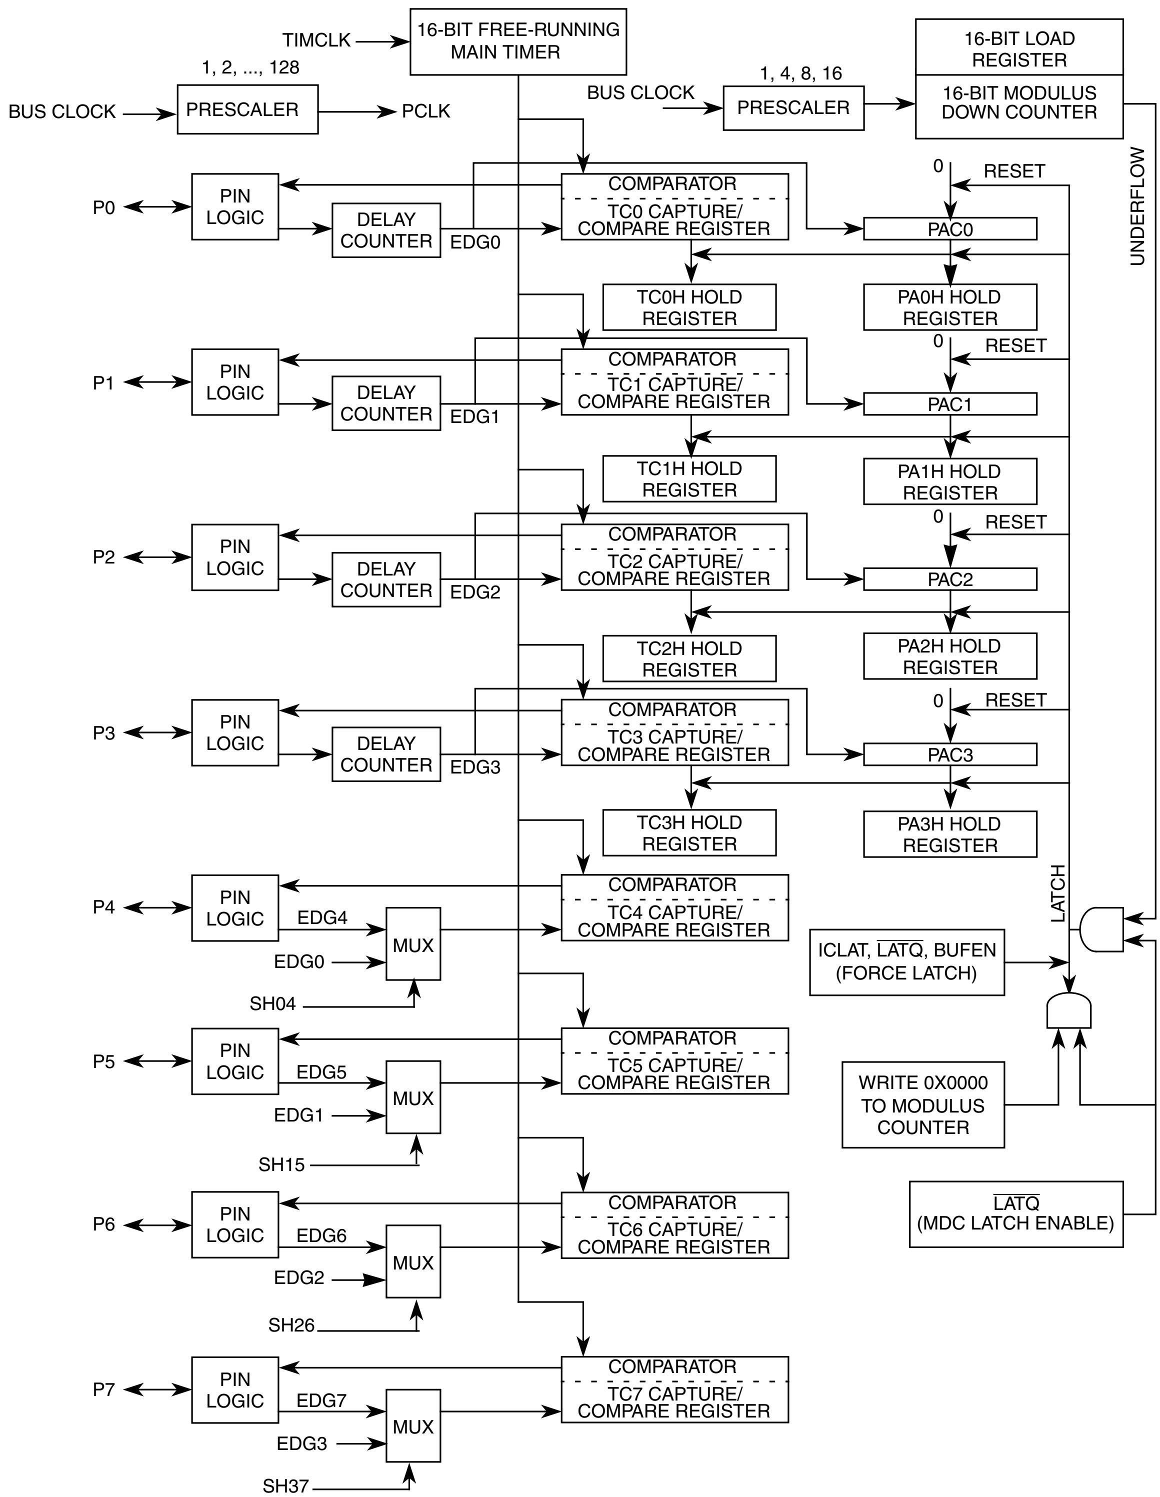

Figure 10-37. Detailed Timer Block Diagram in Latch Mode

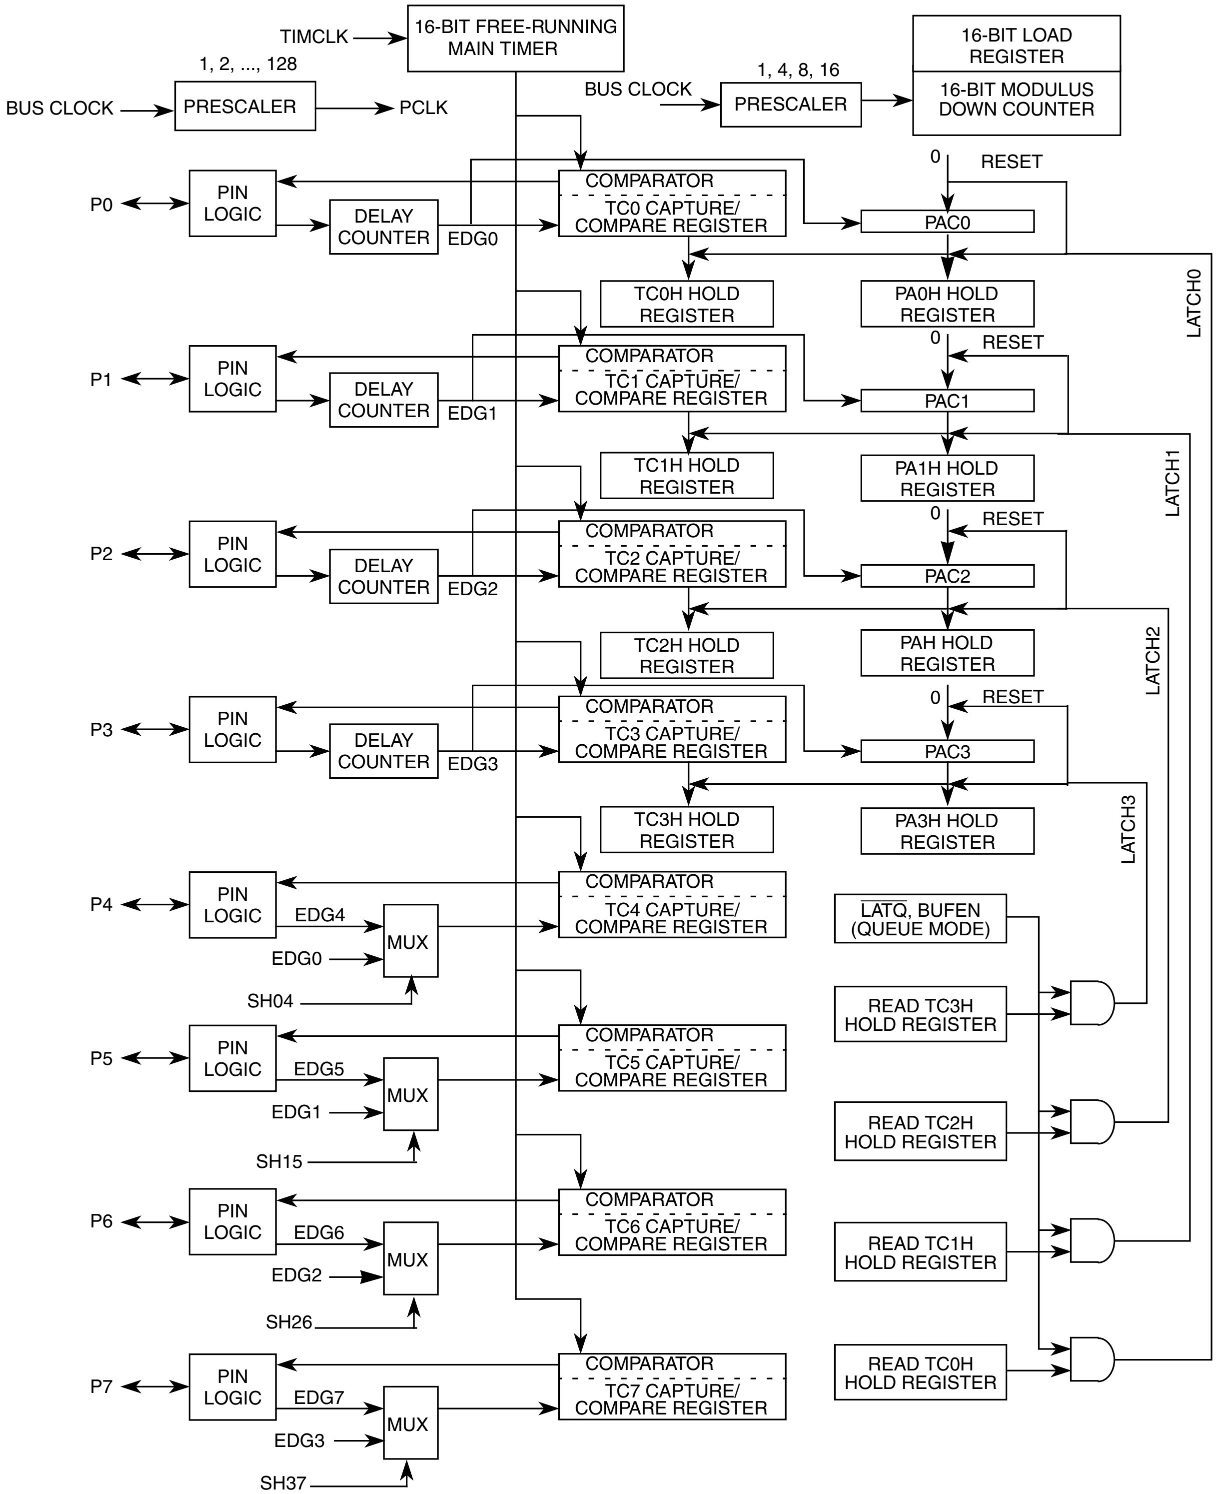

Figure 10-38. Detailed Timer Block Diagram in Queue Mode

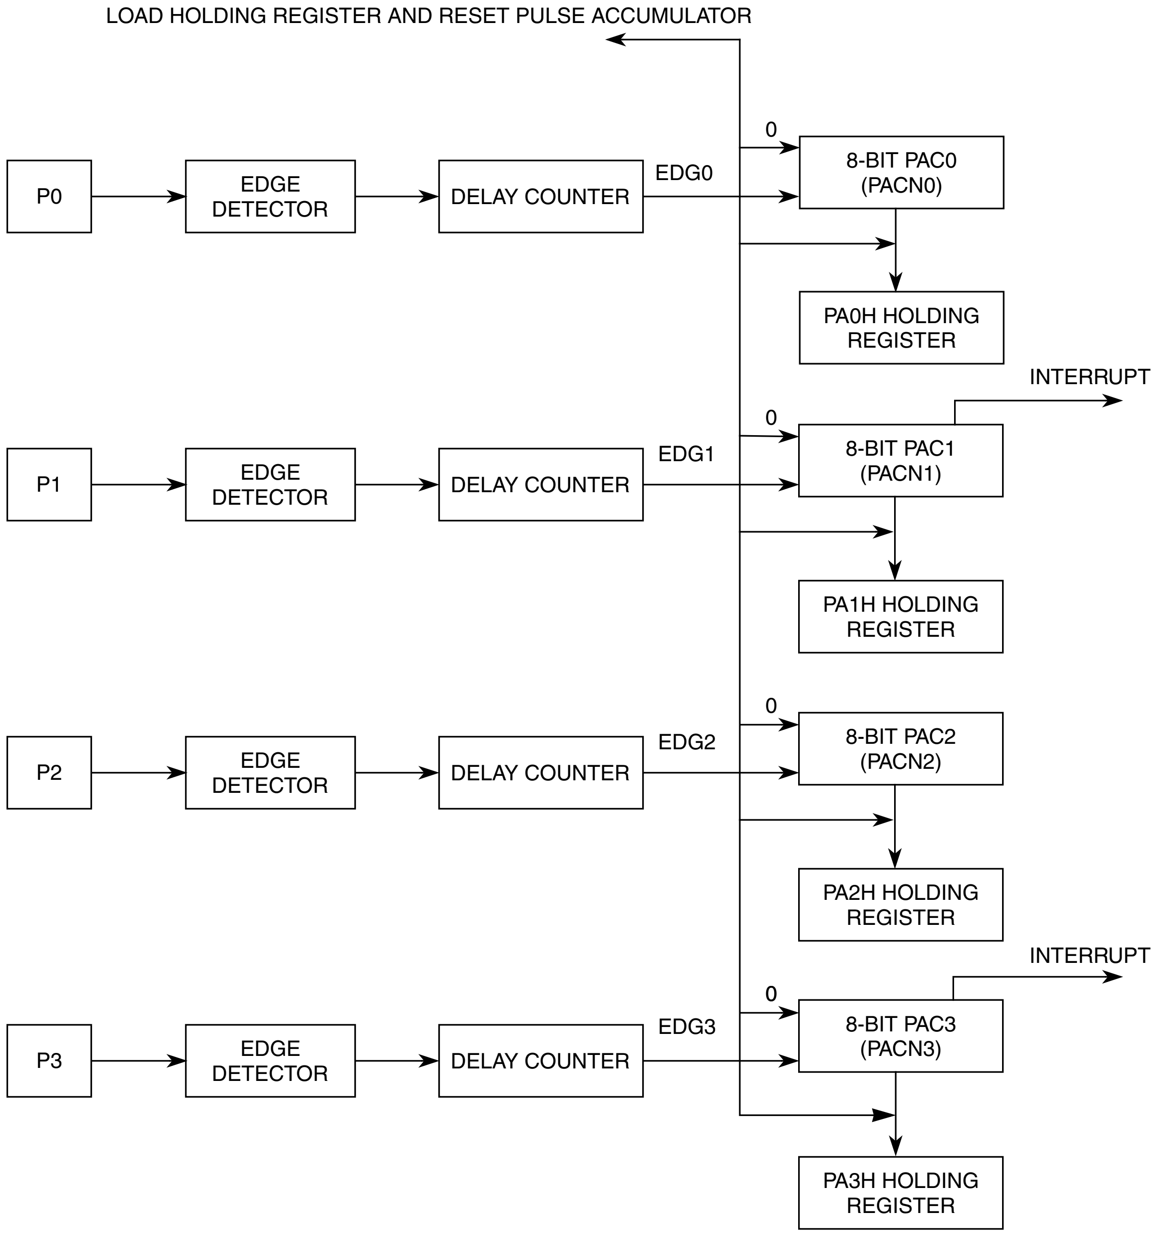

Figure 10-39. 8-Bit Pulse Accumulators Block Diagram

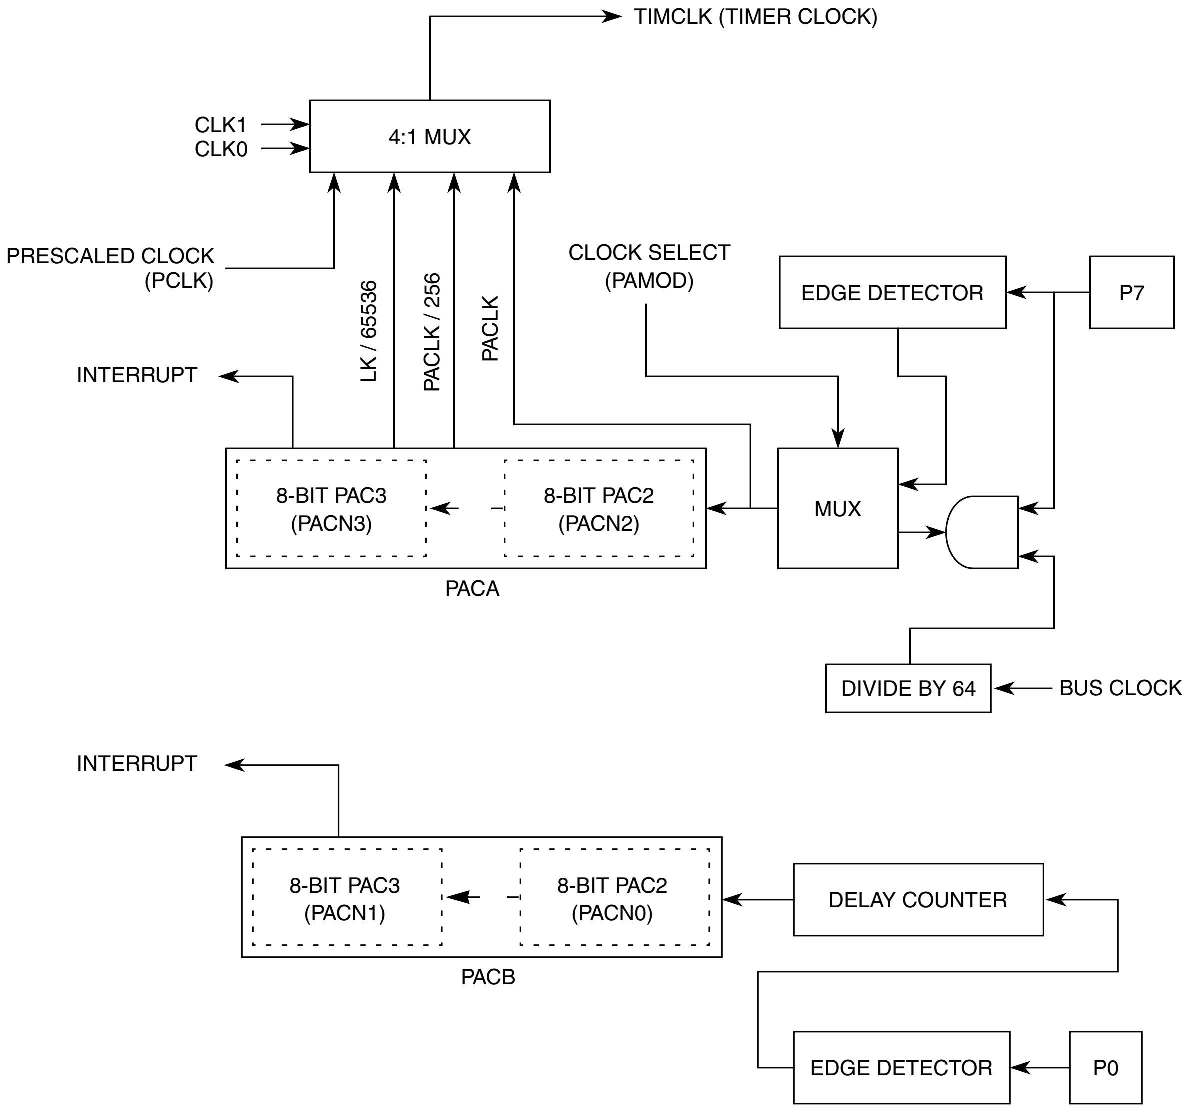

Figure 10-40. 16-Bit Pulse Accumulators Block Diagram

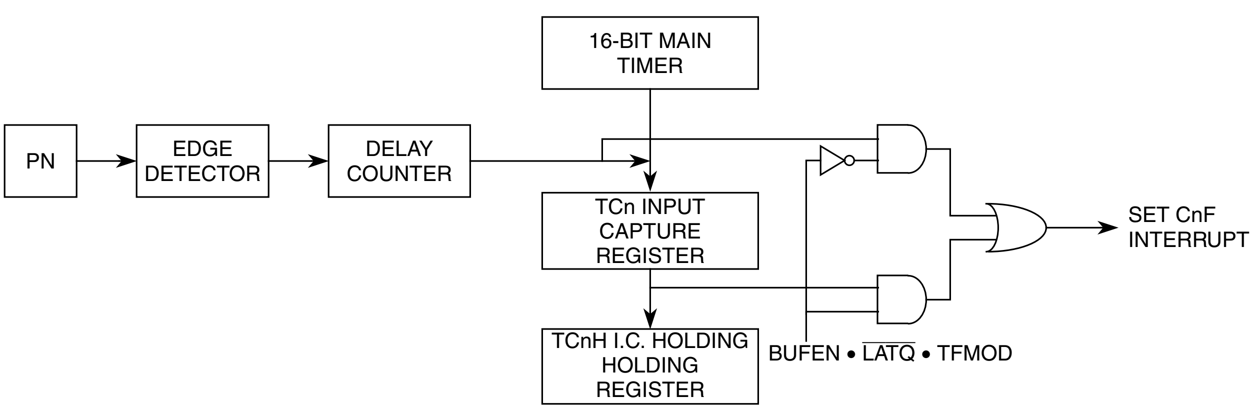

Figure 10-41. Block Diagram for Port 7 with Output Compare/Pulse Accumulator A

10.4.1 Enhanced Capture Timer Modes of Operation

The Enhanced Capture Timer has eight Input Capture, Output Compare (IC/OC) channels same as on the HC12 standard timer (timer channels TC0 to TC7). When channels are selected as input capture by selecting the IOSn bit in TIOS register, they are called Input Capture (IC) channels.

Four IC channels are the same as on the standard timer with one capture register each which memorizes the timer value captured by an action on the associated input pin.

Four other IC channels, in addition to the capture register, have also one buffer each called holding register. This permits to memorize two different timer values without generation of any interrupt.

Four 8-bit pulse accumulators are associated with the four buffered IC channels. Each pulse accumulator has a holding register to memorize their value by an action on its external input. Each pair of pulse accumulators can be used as a 16-bit pulse accumulator.

The 16-bit modulus down-counter can control the transfer of the IC registers contents and the pulse accumulators to the respective holding registers for a given period, every time the count reaches zero.

The modulus down-counter can also be used as a stand-alone time base with periodic interrupt capability.

10.4.1.1 IC Channels

The IC channels are composed of four standard IC registers and four buffered IC channels.

An **IC register** is **empty** when it has been read or latched into the holding register.

A **holding register** is **empty** when it has been read.

10.4.1.1.1 Non-Buffered IC Channels

The main timer value is memorized in the IC register by a valid input pin transition. If the corresponding NOVWx bit of the ICOVW register is cleared, with a new occurrence of a capture, the contents of IC register are overwritten by the new value.

If the corresponding NOVWx bit of the ICOVW register is set, the capture register cannot be written unless it is empty. This will prevent the captured value to be overwritten until it is read.

10.4.1.1.2 Buffered IC Channels

There are two modes of operations for the buffered IC channels.

1. IC Latch Mode:

    When enabled (LATQ = 1), the main timer value is memorized in the IC register by a valid input pin transition. See Figure 10-37.

    The value of the buffered IC register is latched to its holding register by the Modulus counter for a given period when the count reaches zero, by a write 0x0000 to the modulus counter or by a write to ICLAT in the MCCTL register.

    If the corresponding NOVWn bit of the ICOVW register is cleared, with a new occurrence of a capture, the contents of IC register are overwritten by the new value. In case of latching, the contents of its holding register are overwritten.

If the corresponding NOVWn bit of the ICOVW register is set, the capture register or its holding register cannot be written by an event unless they are empty (see Section 10.4.1.1, “IC Channels”). This will prevent the captured value to be overwritten until it is read or latched in the holding register.

2. IC queue mode:

   When enabled (LATQ = 0), the main timer value is memorized in the IC register by a valid input pin transition. See Figure 10-38.

   If the corresponding NOVWn bit of the ICOVW register is cleared, with a new occurrence of a capture, the value of the IC register will be transferred to its holding register and the IC register memorizes the new timer value.

   If the corresponding NOVWn bit of the ICOVW register is set, the capture register or its holding register cannot be written by an event unless they are empty (see Section 10.4.1.1, “IC Channels”).

   In queue mode, reads of holding register will latch the corresponding pulse accumulator value to its holding register.

10.4.1.1.3 Delayed IC Channels

There are four delay counters in this module associated with IC channels 0–3. The use of this feature is explained in the diagram (Figure 10-42) and notes below.

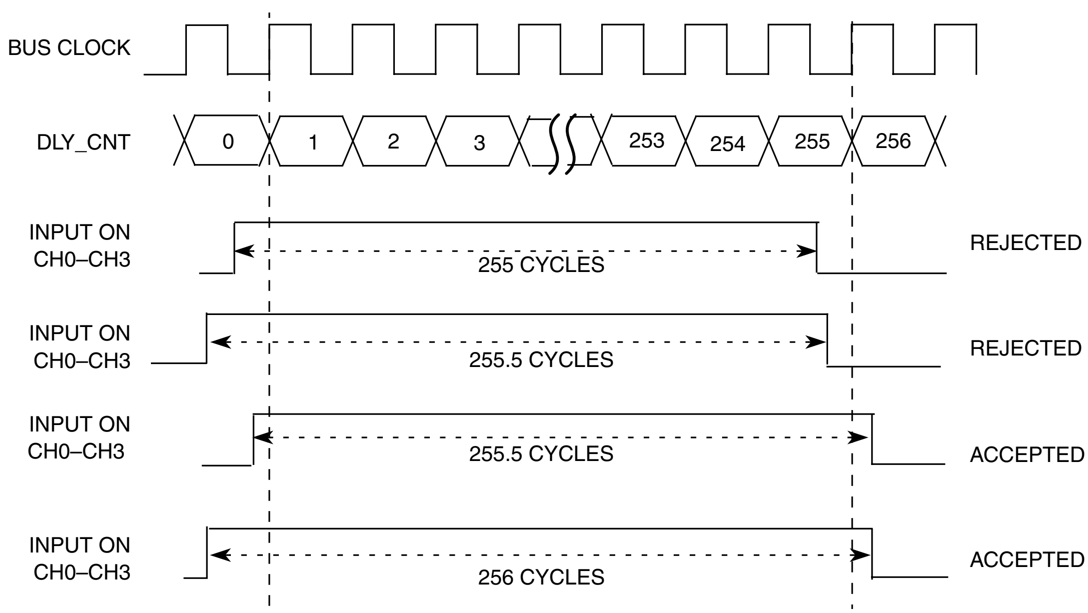

Figure 10-42. Channel Input Validity with Delay Counter Feature

In the diagram shown in Figure 10-42 a delay counter value of 256 bus cycles is considered.

1. Input pulses with a duration of (DLY_CNT – 1) cycles or shorter are rejected.
2. Input pulses with a duration between (DLY_CNT – 1) and DLY_CNT cycles may be rejected or accepted, depending on their relative alignment with the sample points.

3. Input pulses with a duration between (DLY_CNT – 1) and DLY_CNT cycles may be rejected or accepted, depending on their relative alignment with the sample points.
4. Input pulses with a duration of DLY_CNT or longer are accepted.

10.4.1.2 Pulse Accumulators

There are four 8-bit pulse accumulators with four 8-bit holding registers associated with the four IC buffered channels. A pulse accumulator counts the number of active edges at the input of its channel.

The user can prevent 8-bit pulse accumulators counting further than 0x00FF by PACMX control bit in ICSYS (0x002B). In this case a value of 0x00FF means that 255 counts or more have occurred.

Each pair of pulse accumulators can be used as a 16-bit pulse accumulator. See Figure 10-40. There are two modes of operation for the pulse accumulators.

10.4.1.2.1 Pulse Accumulator Latch Mode

The value of the pulse accumulator is transferred to its holding register when the modulus down-counter reaches zero, a write 0x0000 to the modulus counter or when the force latch control bit ICLAT is written.

At the same time the pulse accumulator is cleared.

10.4.1.2.2 Pulse Accumulator Queue Mode

When queue mode is enabled, reads of an input capture holding register will transfer the contents of the associated pulse accumulator to its holding register.

At the same time the pulse accumulator is cleared.

10.4.1.3 Modulus Down-Counter

The modulus down-counter can be used as a time base to generate a periodic interrupt. It can also be used to latch the values of the IC registers and the pulse accumulators to their holding registers.

The action of latching can be programmed to be periodic or only once.

10.4.1.4 Channel Configurations

Timer Channels can be configured as input capture channels or output compare channels. Following are the ways a port can be configured as an output for OC.

The pin associated with channel 7 becomes output-tied to OC7 when

- TEN = 1, IOS7 = 1, and either or both of OM7 and OL7 are set. or
- OC7M7 =1 and IOS7 = 1.

When masking, the timer does not have to be enabled so that the pin associated with OCn becomes an output tied to OCn.

The pins associated with channels 0-6 become output-tied to OCn (n = 0..6) when

- TEN = 1, IOSn = 1, and either or both of OMn and OLn are set or
- OC7Mn = 1, IOS7 = 1 and IOSn = 1

Once the pin is configured as OC, its initial state is zero and its status is changed (if needed) on consecutive clock cycles following the write which enabled the ECT to drive the pin. In other words after a pin starts to be driven by ECT OC logic, it is forced low for at least one clock cycle.

10.5 Reset

The reset state of each individual bit is listed within Section 10.3, “Memory Map and Registers” which details the registers and their bit-fields.

10.6 Interrupts

This section describes interrupts originated by the ECT16B8C block.The MCU must service the interrupt requests. Table 10-28 lists the interrupts generated by the ECT to communicate with the MCU.

The ECT only originates interrupt requests. The following is a description of how the module makes a request and how the MCU should acknowledge that request. The interrupt vector offset and interrupt number are chip dependent.

Table 10-28. ECT Interrupts

Interrupt Source	Description
Timer channel 7–0	Active high timer channel interrupts 7–0
Modulus counter underflow	Active high modulus counter interrupt
Pulse accumulator B overflow	Active high pulse accumulator B interrupt
Pulse accumulator A input	Active high pulse accumulator A input interrupt
Pulse accumulator A overflow	Pulse accumulator overflow interrupt
Timer overflow	Timer overflow interrupt

10.6.1 Channel [7:0] Interrupt

This active high output will be asserted by the module to request a timer channel 7 - 0 interrupt to be serviced by the system controller.

10.6.2 Modulus Counter Interrupt

This active high output will be asserted by the module to request a modulus counter underflow interrupt to be serviced by the system controller.

10.6.3 Pulse Accumulator B Overflow Interrupt)

This active high output will be asserted by the module to request a timer pulse accumulator B overflow interrupt to be serviced by the system controller.

10.6.4 Pulse Accumulator A Input Interrupt

This active high output will be asserted by the module to request a timer pulse accumulator A input interrupt to be serviced by the system controller.

10.6.5 Pulse Accumulator A Overflow Interrupt

This active high output will be asserted by the module to request a timer pulse accumulator A overflow interrupt to be serviced by the system controller.

10.6.6 Timer Overflow Interrupt

This active high output will be asserted by the module to request a timer overflow interrupt to be serviced by the system controller.

Chapter 11
Inter-Integrated Circuit (IICV2) Block Description

Version Number	Revision Date	Effective Date	Author	Description of Changes
0.1	8-Sep-99			Original draft. Distributed only within Freescale
2.06	18-Aug-20 02			Reformated for SRS3.0,and add examples for programing general use and some diagrams to make it more user friendly as suggested by Joachim
2.07	12-Mar-20 04			Changed to Freescale chapter format

11.1 Introduction

The inter-IC bus (IIC) is a two-wire, bidirectional serial bus that provides a simple, efficient method of data exchange between devices. Being a two-wire device, the IIC bus minimizes the need for large numbers of connections between devices, and eliminates the need for an address decoder.

This bus is suitable for applications requiring occasional communications over a short distance between a number of devices. It also provides flexibility, allowing additional devices to be connected to the bus for further expansion and system development.

The interface is designed to operate up to 100 kbps with maximum bus loading and timing. The device is capable of operating at higher baud rates, up to a maximum of clock/20, with reduced bus loading. The maximum communication length and the number of devices that can be connected are limited by a maximum bus capacitance of 400 pF.

11.1.1 Features

The IIC module has the following key features:

- Compatible with I2C bus standard
- Multi-master operation
- Software programmable for one of 256 different serial clock frequencies
- Software selectable acknowledge bit
- Interrupt driven byte-by-byte data transfer
- Arbitration lost interrupt with automatic mode switching from master to slave

- Calling address identification interrupt
- Start and stop signal generation/detection
- Repeated start signal generation
- Acknowledge bit generation/detection
- Bus busy detection

11.1.2 Modes of Operation

The IIC functions the same in normal, special, and emulation modes. It has two low power modes: wait and stop modes.

11.1.3 Block Diagram

The block diagram of the IIC module is shown in Figure 11-1.

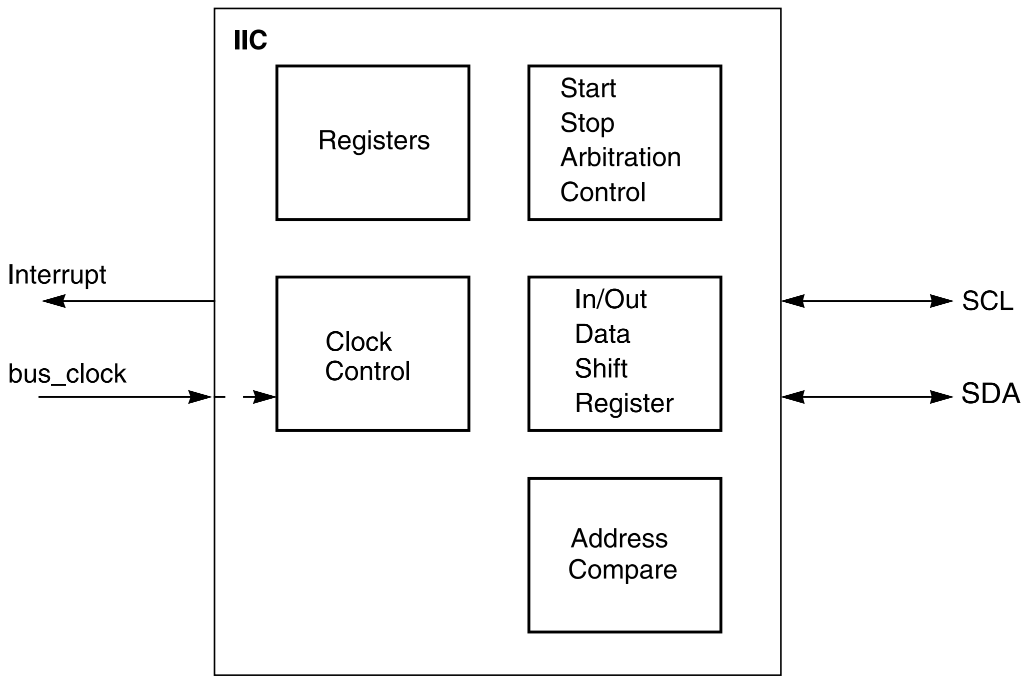

Figure 11-1. IIC Block Diagram

11.2 External Signal Description

The IICV2 module has two external pins.

11.2.1 IIC_SCL — Serial Clock Line Pin

This is the bidirectional serial clock line (SCL) of the module, compatible to the IIC bus specification.

11.2.2 IIC_SDA — Serial Data Line Pin

This is the bidirectional serial data line (SDA) of the module, compatible to the IIC bus specification.

11.3 Memory Map and Register Definition

This section provides a detailed description of all memory and registers for the IIC module.

11.3.1 Register Descriptions

This section consists of register descriptions in address order. Each description includes a standard register diagram with an associated figure number. Details of register bit and field function follow the register diagrams, in bit order.

Table 11-4. Multiplier Factor

IBC7-6	MUL
00	01
01	02
10	04
11	RESERVED

The number of clocks from the falling edge of SCL to the first tap (Tap[1]) is defined by the values shown in the scl2tap column of Table 11-3, all subsequent tap points are separated by 2^{IBC5-3} as shown in the tap2tap column in Table 11-3. The SCL Tap is used to generated the SCL period and the SDA Tap is used to determine the delay from the falling edge of SCL to SDA changing, the SDA hold time.

IBC7–6 defines the multiplier factor MUL. The values of MUL are shown in the Table 11-4.

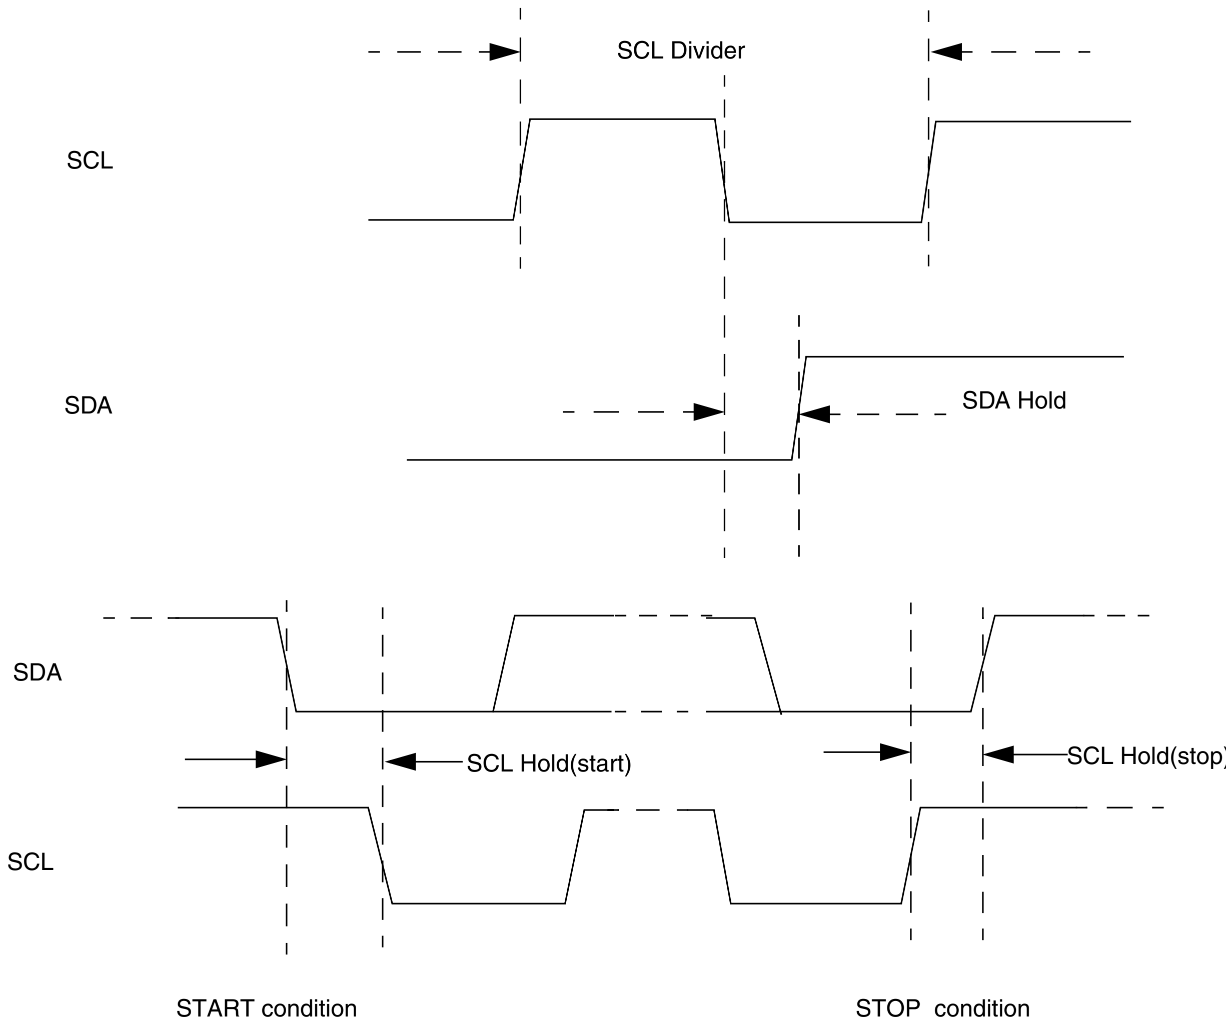

Figure 11-5. SCL Divider and SDA Hold

The equation used to generate the divider values from the IBFD bits is:

SCL Divider = MUL x {2 x (scl2tap + [(SCL_Tap -1) x tap2tap] + 2)}

The SDA hold delay is equal to the CPU clock period multiplied by the SDA Hold value shown in Table 11-5. The equation used to generate the SDA Hold value from the IBFD bits is:

SDA Hold = MUL x {scl2tap + [(SDA_Tap - 1) x tap2tap] + 3}

The equation for SCL Hold values to generate the start and stop conditions from the IBFD bits is:

SCL Hold(start) = MUL x [scl2start + (SCL_Tap - 1) x tap2tap]

SCL Hold(stop) = MUL x [scl2stop + (SCL_Tap - 1) x tap2tap]

Figure 11-6. IIC Bus Control Register (IBCR)

Read and write anytime

Table 11-6. IBCR Field Descriptions

Field	Description
7 IBEN	**I-Bus Enable** — This bit controls the software reset of the entire IIC bus module. 0 The module is reset and disabled. This is the power-on reset situation. When low the interface is held in reset but registers can be accessed 1 The IIC bus module is enabled.This bit must be set before any other IBCR bits have any effect If the IIC bus module is enabled in the middle of a byte transfer the interface behaves as follows: slave mode ignores the current transfer on the bus and starts operating whenever a subsequent start condition is detected. Master mode will not be aware that the bus is busy, hence if a start cycle is initiated then the current bus cycle may become corrupt. This would ultimately result in either the current bus master or the IIC bus module losing arbitration, after which bus operation would return to normal.
6 IBIE	**I-Bus Interrupt Enable** 0 Interrupts from the IIC bus module are disabled. Note that this does not clear any currently pending interrupt condition 1 Interrupts from the IIC bus module are enabled. An IIC bus interrupt occurs provided the IBIF bit in the status register is also set.
5 MS/SL	**Master/Slave Mode Select Bit** — Upon reset, this bit is cleared. When this bit is changed from 0 to 1, a START signal is generated on the bus, and the master mode is selected. When this bit is changed from 1 to 0, a STOP signal is generated and the operation mode changes from master to slave.A STOP signal should only be generated if the IBIF flag is set. MS/$\overline{\text{SL}}$ is cleared without generating a STOP signal when the master loses arbitration. 0 Slave Mode 1 Master Mode
4 Tx/Rx	**Transmit/Receive Mode Select Bit** — This bit selects the direction of master and slave transfers. When addressed as a slave this bit should be set by software according to the SRW bit in the status register. In master mode this bit should be set according to the type of transfer required. Therefore, for address cycles, this bit will always be high. 0 Receive 1 Transmit
3 TXAK	**Transmit Acknowledge Enable** — This bit specifies the value driven onto SDA during data acknowledge cycles for both master and slave receivers. The IIC module will always acknowledge address matches, provided it is enabled, regardless of the value of TXAK. Note that values written to this bit are only used when the IIC bus is a receiver, not a transmitter. 0 An acknowledge signal will be sent out to the bus at the 9th clock bit after receiving one byte data 1 No acknowledge signal response is sent (i.e., acknowledge bit = 1)
2 RSTA	**Repeat Start** — Writing a 1 to this bit will generate a repeated START condition on the bus, provided it is the current bus master. This bit will always be read as a low. Attempting a repeated start at the wrong time, if the bus is owned by another master, will result in loss of arbitration. 1 Generate repeat start cycle
1 RESERVED	**Reserved** — Bit 1 of the IBCR is reserved for future compatibility. This bit will always read 0.
0 IBSWAI	**I Bus Interface Stop in Wait Mode** 0 IIC bus module clock operates normally 1 Halt IIC bus module clock generation in wait mode

Wait mode is entered via execution of a CPU WAI instruction. In the event that the IBSWAI bit is set, all clocks internal to the IIC will be stopped and any transmission currently in progress will halt.If the CPU were woken up by a source other than the IIC module, then clocks would restart and the IIC would resume from where was during the previous transmission. It is not possible for the IIC to wake up the CPU when its internal clocks are stopped.

If it were the case that the IBSWAI bit was cleared when the WAI instruction was executed, the IIC internal clocks and interface would remain alive, continuing the operation which was currently underway. It is also possible to configure the IIC such that it will wake up the CPU via an interrupt at the conclusion of the current operation. See the discussion on the IBIF and IBIE bits in the IBSR and IBCR, respectively.

11.3.1.4 IIC Status Register (IBSR)

Offset Module Base + 0x0003

	7	6	5	4	3	2	1	0
R	TCF	IAAS	IBB	IBAL	0	SRW	IBIF	RXAK
W								
Reset	1	0	0	0	0	0	0	0

= Unimplemented or Reserved

Figure 11-7. IIC Bus Status Register (IBSR)

This status register is read-only with exception of bit 1 (IBIF) and bit 4 (IBAL), which are software clearable.

Table 11-7. IBSR Field Descriptions

Field	Description
7 TCF	**Data Transferring Bit** — While one byte of data is being transferred, this bit is cleared. It is set by the falling edge of the 9th clock of a byte transfer. Note that this bit is only valid during or immediately following a transfer to the IIC module or from the IIC module. 0 Transfer in progress 1 Transfer complete
6 IAAS	**Addressed as a Slave Bit** — When its own specific address (I-bus address register) is matched with the calling address, this bit is set.The CPU is interrupted provided the IBIE is set.Then the CPU needs to check the SRW bit and set its $Tx/\overline{Rx}$ mode accordingly.Writing to the I-bus control register clears this bit. 0 Not addressed 1 Addressed as a slave
5 IBB	Bus Busy Bit 0 This bit indicates the status of the bus. When a START signal is detected, the IBB is set. If a STOP signal is detected, IBB is cleared and the bus enters idle state. 1 Bus is busy
4 IBAL	**Arbitration Lost** — The arbitration lost bit (IBAL) is set by hardware when the arbitration procedure is lost. Arbitration is lost in the following circumstances: 1. SDA sampled low when the master drives a high during an address or data transmit cycle. 2. SDA sampled low when the master drives a high during the acknowledge bit of a data receive cycle. 3. A start cycle is attempted when the bus is busy. 4. A repeated start cycle is requested in slave mode. 5. A stop condition is detected when the master did not request it. This bit must be cleared by software, by writing a one to it. A write of 0 has no effect on this bit.
3 RESERVED	**Reserved** — Bit 3 of IBSR is reserved for future use. A read operation on this bit will return 0.

Table 11-7. IBSR Field Descriptions (continued)

Field	Description
2 SRW	**Slave Read/Write** — When IAAS is set this bit indicates the value of the R/W command bit of the calling address sent from the master This bit is only valid when the I-bus is in slave mode, a complete address transfer has occurred with an address match and no other transfers have been initiated. Checking this bit, the CPU can select slave transmit/receive mode according to the command of the master. 0 Slave receive, master writing to slave 1 Slave transmit, master reading from slave
1 IBIF	**I-Bus Interrupt** — The IBIF bit is set when one of the following conditions occurs: — Arbitration lost (IBAL bit set) — Byte transfer complete (TCF bit set) — Addressed as slave (IAAS bit set) It will cause a processor interrupt request if the IBIE bit is set. This bit must be cleared by software, writing a one to it. A write of 0 has no effect on this bit.
0 RXAK	**Received Acknowledge** — The value of SDA during the acknowledge bit of a bus cycle. If the received acknowledge bit (RXAK) is low, it indicates an acknowledge signal has been received after the completion of 8 bits data transmission on the bus. If RXAK is high, it means no acknowledge signal is detected at the 9th clock. 0 Acknowledge received 1 No acknowledge received

11.3.1.5 IIC Data I/O Register (IBDR)

Offset Module Base + 0x0004

	7	6	5	4	3	2	1	0
R W	D7	D6	D5	D4	D3	D2	D1	D0
Reset	0	0	0	0	0	0	0	0

Figure 11-8. IIC Bus Data I/O Register (IBDR)

In master transmit mode, when data is written to the IBDR a data transfer is initiated. The most significant bit is sent first. In master receive mode, reading this register initiates next byte data receiving. In slave mode, the same functions are available after an address match has occurred.Note that the Tx/Rx bit in the IBCR must correctly reflect the desired direction of transfer in master and slave modes for the transmission to begin. For instance, if the IIC is configured for master transmit but a master receive is desired, then reading the IBDR will not initiate the receive.

Reading the IBDR will return the last byte received while the IIC is configured in either master receive or slave receive modes. The IBDR does not reflect every byte that is transmitted on the IIC bus, nor can software verify that a byte has been written to the IBDR correctly by reading it back.

In master transmit mode, the first byte of data written to IBDR following assertion of MS/$\overline{\text{SL}}$ is used for the address transfer and should com.prise of the calling address (in position D7:D1) concatenated with the required R/$\overline{\text{W}}$ bit (in position D0).

11.4 Functional Description

This section provides a complete functional description of the IICV2.

11.4.1 I-Bus Protocol

The IIC bus system uses a serial data line (SDA) and a serial clock line (SCL) for data transfer. All devices connected to it must have open drain or open collector outputs. Logic AND function is exercised on both lines with external pull-up resistors. The value of these resistors is system dependent.

Normally, a standard communication is composed of four parts: START signal, slave address transmission, data transfer and STOP signal. They are described briefly in the following sections and illustrated in Figure 11-9.

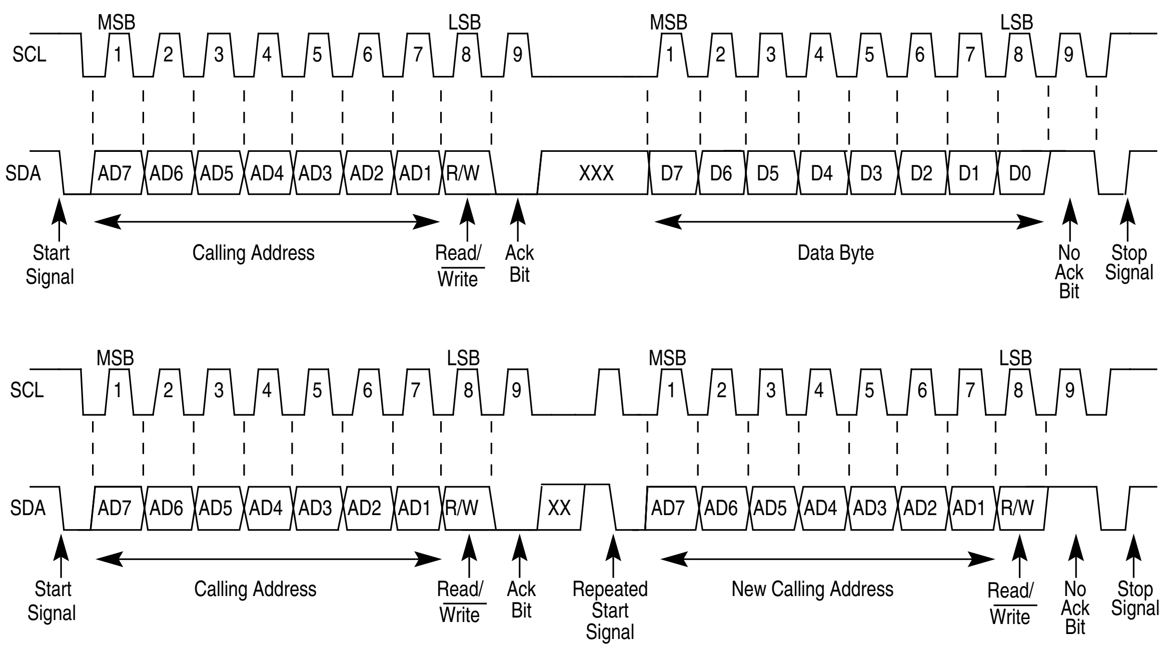

Figure 11-9. IIC-Bus Transmission Signals

11.4.1.1 START Signal

When the bus is free, i.e. no master device is engaging the bus (both SCL and SDA lines are at logical high), a master may initiate communication by sending a START signal.As shown in Figure 11-9, a START signal is defined as a high-to-low transition of SDA while SCL is high. This signal denotes the beginning of a new data transfer (each data transfer may contain several bytes of data) and brings all slaves out of their idle states.

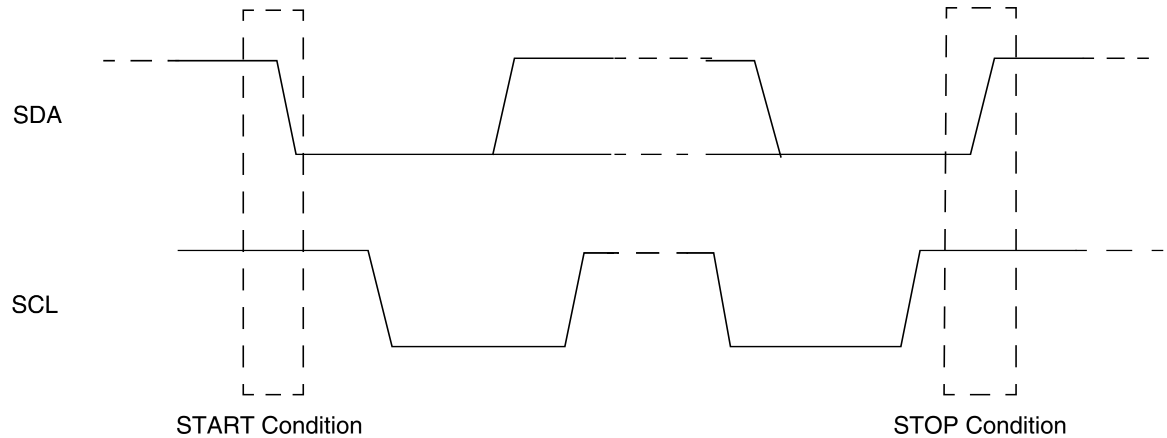

Figure 11-10. Start and Stop Conditions

11.4.1.2 Slave Address Transmission

The first byte of data transfer immediately after the START signal is the slave address transmitted by the master. This is a seven-bit calling address followed by a R/W bit. The R/W bit tells the slave the desired direction of data transfer.

1 = Read transfer, the slave transmits data to the master.
0 = Write transfer, the master transmits data to the slave.

Only the slave with a calling address that matches the one transmitted by the master will respond by sending back an acknowledge bit. This is done by pulling the SDA low at the 9th clock (see Figure 11-9).

No two slaves in the system may have the same address. If the IIC bus is master, it must not transmit an address that is equal to its own slave address. The IIC bus cannot be master and slave at the same time.However, if arbitration is lost during an address cycle the IIC bus will revert to slave mode and operate correctly even if it is being addressed by another master.

11.4.1.3 Data Transfer

As soon as successful slave addressing is achieved, the data transfer can proceed byte-by-byte in a direction specified by the R/W bit sent by the calling master

All transfers that come after an address cycle are referred to as data transfers, even if they carry sub-address information for the slave device.

Each data byte is 8 bits long. Data may be changed only while SCL is low and must be held stable while SCL is high as shown in Figure 11-9. There is one clock pulse on SCL for each data bit, the MSB being transferred first. Each data byte has to be followed by an acknowledge bit, which is signalled from the receiving device by pulling the SDA low at the ninth clock. So one complete data byte transfer needs nine clock pulses.

If the slave receiver does not acknowledge the master, the SDA line must be left high by the slave. The master can then generate a stop signal to abort the data transfer or a start signal (repeated start) to commence a new calling.

If the master receiver does not acknowledge the slave transmitter after a byte transmission, it means 'end of data' to the slave, so the slave releases the SDA line for the master to generate STOP or START signal.

11.4.1.4 STOP Signal

The master can terminate the communication by generating a STOP signal to free the bus. However, the master may generate a START signal followed by a calling command without generating a STOP signal first. This is called repeated START. A STOP signal is defined as a low-to-high transition of SDA while SCL at logical 1 (see Figure 11-9).

The master can generate a STOP even if the slave has generated an acknowledge at which point the slave must release the bus.

11.4.1.5 Repeated START Signal

As shown in Figure 11-9, a repeated START signal is a START signal generated without first generating a STOP signal to terminate the communication. This is used by the master to communicate with another slave or with the same slave in different mode (transmit/receive mode) without releasing the bus.

11.4.1.6 Arbitration Procedure

The Inter-IC bus is a true multi-master bus that allows more than one master to be connected on it. If two or more masters try to control the bus at the same time, a clock synchronization procedure determines the bus clock, for which the low period is equal to the longest clock low period and the high is equal to the shortest one among the masters. The relative priority of the contending masters is determined by a data arbitration procedure, a bus master loses arbitration if it transmits logic 1 while another master transmits logic 0. The losing masters immediately switch over to slave receive mode and stop driving SDA output. In this case the transition from master to slave mode does not generate a STOP condition. Meanwhile, a status bit is set by hardware to indicate loss of arbitration.

11.4.1.7 Clock Synchronization

Because wire-AND logic is performed on SCL line, a high-to-low transition on SCL line affects all the devices connected on the bus. The devices start counting their low period and as soon as a device's clock has gone low, it holds the SCL line low until the clock high state is reached.However, the change of low to high in this device clock may not change the state of the SCL line if another device clock is within its low period. Therefore, synchronized clock SCL is held low by the device with the longest low period. Devices with shorter low periods enter a high wait state during this time (see Figure 11-10). When all devices concerned have counted off their low period, the synchronized clock SCL line is released and pulled high. There is then no difference between the device clocks and the state of the SCL line and all the devices start counting their high periods.The first device to complete its high period pulls the SCL line low again.

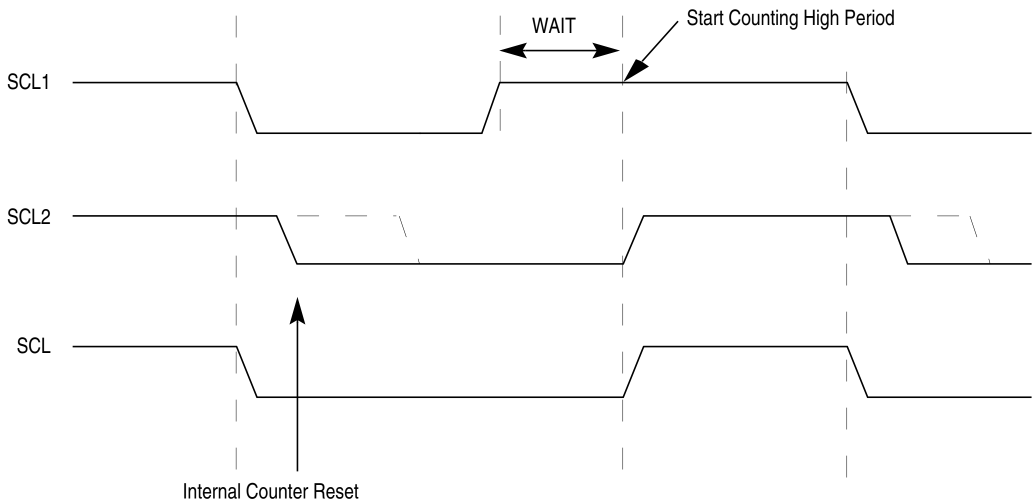

Figure 11-11. IIC-Bus Clock Synchronization

11.4.1.8 Handshaking

The clock synchronization mechanism can be used as a handshake in data transfer. Slave devices may hold the SCL low after completion of one byte transfer (9 bits). In such case, it halts the bus clock and forces the master clock into wait states until the slave releases the SCL line.

11.4.1.9 Clock Stretching

The clock synchronization mechanism can be used by slaves to slow down the bit rate of a transfer. After the master has driven SCL low the slave can drive SCL low for the required period and then release it.If the slave SCL low period is greater than the master SCL low period then the resulting SCL bus signal low period is stretched.

11.4.2 Operation in Run Mode

This is the basic mode of operation.

11.4.3 Operation in Wait Mode

IIC operation in wait mode can be configured. Depending on the state of internal bits, the IIC can operate normally when the CPU is in wait mode or the IIC clock generation can be turned off and the IIC module enters a power conservation state during wait mode. In the later case, any transmission or reception in progress stops at wait mode entry.

11.4.4 Operation in Stop Mode

The IIC is inactive in stop mode for reduced power consumption. The STOP instruction does not affect IIC register states.

11.5 Resets

The reset state of each individual bit is listed in Section 11.3, "Memory Map and Register Definition," which details the registers and their bit-fields.

11.6 Interrupts

IICV2 uses only one interrupt vector.

Table 11-8. Interrupt Summary

Interrupt	Offset	Vector	Priority	Source	Description
IIC Interrupt	—	—	—	IBAL, TCF, IAAS bits in IBSR register	When either of IBAL, TCF or IAAS bits is set may cause an interrupt based on arbitration lost, transfer complete or address detect conditions

Internally there are three types of interrupts in IIC. The interrupt service routine can determine the interrupt type by reading the status register.

IIC Interrupt can be generated on

1. Arbitration lost condition (IBAL bit set)
2. Byte transfer condition (TCF bit set)
3. Address detect condition (IAAS bit set)

The IIC interrupt is enabled by the IBIE bit in the IIC control register. It must be cleared by writing 0 to the IBF bit in the interrupt service routine.

11.7 Initialization/Application Information

11.7.1 IIC Programming Examples

11.7.1.1 Initialization Sequence

Reset will put the IIC bus control register to its default status. Before the interface can be used to transfer serial data, an initialization procedure must be carried out, as follows:

1. Update the frequency divider register (IBFD) and select the required division ratio to obtain SCL frequency from system clock.
2. Update the IIC bus address register (IBAD) to define its slave address.
3. Set the IBEN bit of the IIC bus control register (IBCR) to enable the IIC interface system.
4. Modify the bits of the IIC bus control register (IBCR) to select master/slave mode, transmit/receive mode and interrupt enable or not.

11.7.1.2 Generation of START

After completion of the initialization procedure, serial data can be transmitted by selecting the 'master transmitter' mode. If the device is connected to a multi-master bus system, the state of the IIC bus busy bit (IBB) must be tested to check whether the serial bus is free.

If the bus is free (IBB=0), the start condition and the first byte (the slave address) can be sent. The data written to the data register comprises the slave calling address and the LSB set to indicate the direction of transfer required from the slave.

The bus free time (i.e., the time between a STOP condition and the following START condition) is built into the hardware that generates the START cycle. Depending on the relative frequencies of the system clock and the SCL period it may be necessary to wait until the IIC is busy after writing the calling address to the IBDR before proceeding with the following instructions. This is illustrated in the following example.

An example of a program which generates the START signal and transmits the first byte of data (slave address) is shown below:

```
CHFLAG     BRSET   IBSR,#$20,*      ;WAIT FOR IBB FLAG TO CLEAR
TXSTART    BSET    IBCR,#$30        ;SET TRANSMIT AND MASTER MODE;i.e. GENERATE START CONDITION
           MOVB    CALLING,IBDR     ;TRANSMIT THE CALLING ADDRESS, D0=R/W
IBFREE     BRCLR   IBSR,#$20,*      ;WAIT FOR IBB FLAG TO SET
```

11.7.1.3 Post-Transfer Software Response

Transmission or reception of a byte will set the data transferring bit (TCF) to 1, which indicates one byte communication is finished. The IIC bus interrupt bit (IBIF) is set also; an interrupt will be generated if the interrupt function is enabled during initialization by setting the IBIE bit. Software must clear the IBIF bit in the interrupt routine first. The TCF bit will be cleared by reading from the IIC bus data I/O register (IBDR) in receive mode or writing to IBDR in transmit mode.

Software may service the IIC I/O in the main program by monitoring the IBIF bit if the interrupt function is disabled. Note that polling should monitor the IBIF bit rather than the TCF bit because their operation is different when arbitration is lost.

Note that when an interrupt occurs at the end of the address cycle the master will always be in transmit mode, i.e. the address is transmitted. If master receive mode is required, indicated by R/W bit in IBDR, then the Tx/Rx bit should be toggled at this stage.

During slave mode address cycles (IAAS=1), the SRW bit in the status register is read to determine the direction of the subsequent transfer and the Tx/Rx bit is programmed accordingly. For slave mode data cycles (IAAS=0) the SRW bit is not valid, the Tx/Rx bit in the control register should be read to determine the direction of the current transfer.

The following is an example of a software response by a 'master transmitter' in the interrupt routine.

```
ISR        BCLR    IBSR,#$02            ;CLEAR THE IBIF FLAG
           BRCLR   IBCR,#$20,SLAVE      ;BRANCH IF IN SLAVE MODE
           BRCLR   IBCR,#$10,RECEIVE    ;BRANCH IF IN RECEIVE MODE
           BRSET   IBSR,#$01,END        ;IF NO ACK, END OF TRANSMISSION
TRANSMIT   MOVB    DATABUF,IBDR         ;TRANSMIT NEXT BYTE OF DATA
```

11.7.1.4 Generation of STOP

A data transfer ends with a STOP signal generated by the 'master' device. A master transmitter can simply generate a STOP signal after all the data has been transmitted. The following is an example showing how a stop condition is generated by a master transmitter.

```
MASTX    TST     TXCNT           ;GET VALUE FROM THE TRANSMITING COUNTER
         BEQ     END             ;END IF NO MORE DATA
         BRSET   IBSR,#$01,END   ;END IF NO ACK
         MOVB    DATABUF,IBDR    ;TRANSMIT NEXT BYTE OF DATA
         DEC     TXCNT           ;DECREASE THE TXCNT
         BRA     EMASTX          ;EXIT
END      BCLR    IBCR,#$20       ;GENERATE A STOP CONDITION
EMASTX   RTI                     ;RETURN FROM INTERRUPT
```

If a master receiver wants to terminate a data transfer, it must inform the slave transmitter by not acknowledging the last byte of data which can be done by setting the transmit acknowledge bit (TXAK) before reading the 2nd last byte of data. Before reading the last byte of data, a STOP signal must be generated first. The following is an example showing how a STOP signal is generated by a master receiver.

```
MASR     DEC     RXCNT           ;DECREASE THE RXCNT
         BEQ     ENMASR          ;LAST BYTE TO BE READ
         MOVB    RXCNT,D1        ;CHECK SECOND LAST BYTE
         DEC     D1              ;TO BE READ
         BNE     NXMAR           ;NOT LAST OR SECOND LAST
LAMAR    BSET    IBCR,#$08       ;SECOND LAST, DISABLE ACK
                                 ;TRANSMITTING
         BRA     NXMAR
ENMASR   BCLR    IBCR,#$20       ;LAST ONE, GENERATE ‘STOP’ SIGNAL
NXMAR    MOVB    IBDR,RXBUF      ;READ DATA AND STORE
         RTI
```

11.7.1.5 Generation of Repeated START

At the end of data transfer, if the master continues to want to communicate on the bus, it can generate another START signal followed by another slave address without first generating a STOP signal. A program example is as shown.

```
RESTART  BSET    IBCR,#$04       ;ANOTHER START (RESTART)
         MOVB    CALLING,IBDR    ;TRANSMIT THE CALLING ADDRESS;D0=R/W
```

11.7.1.6 Slave Mode

In the slave interrupt service routine, the module addressed as slave bit (IAAS) should be tested to check if a calling of its own address has just been received. If IAAS is set, software should set the transmit/receive mode select bit (Tx/Rx bit of IBCR) according to the R/W command bit (SRW). Writing to the IBCR clears the IAAS automatically. Note that the only time IAAS is read as set is from the interrupt at the end of the address cycle where an address match occurred, interrupts resulting from subsequent data transfers will have IAAS cleared. A data transfer may now be initiated by writing information to IBDR, for slave transmits, or dummy reading from IBDR, in slave receive mode. The slave will drive SCL low in-between byte transfers, SCL is released when the IBDR is accessed in the required mode.

In slave transmitter routine, the received acknowledge bit (RXAK) must be tested before transmitting the next byte of data. Setting RXAK means an 'end of data' signal from the master receiver, after which it must be switched from transmitter mode to receiver mode by software. A dummy read then releases the SCL line so that the master can generate a STOP signal.

11.7.1.7 Arbitration Lost

If several masters try to engage the bus simultaneously, only one master wins and the others lose arbitration. The devices which lost arbitration are immediately switched to slave receive mode by the hardware. Their data output to the SDA line is stopped, but SCL continues to be generated until the end of the byte during which arbitration was lost. An interrupt occurs at the falling edge of the ninth clock of this transfer with IBAL=1 and MS/SL=0. If one master attempts to start transmission while the bus is being engaged by another master, the hardware will inhibit the transmission; switch the MS/SL bit from 1 to 0 without generating STOP condition; generate an interrupt to CPU and set the IBAL to indicate that the attempt to engage the bus is failed. When considering these cases, the slave service routine should test the IBAL first and the software should clear the IBAL bit if it is set.

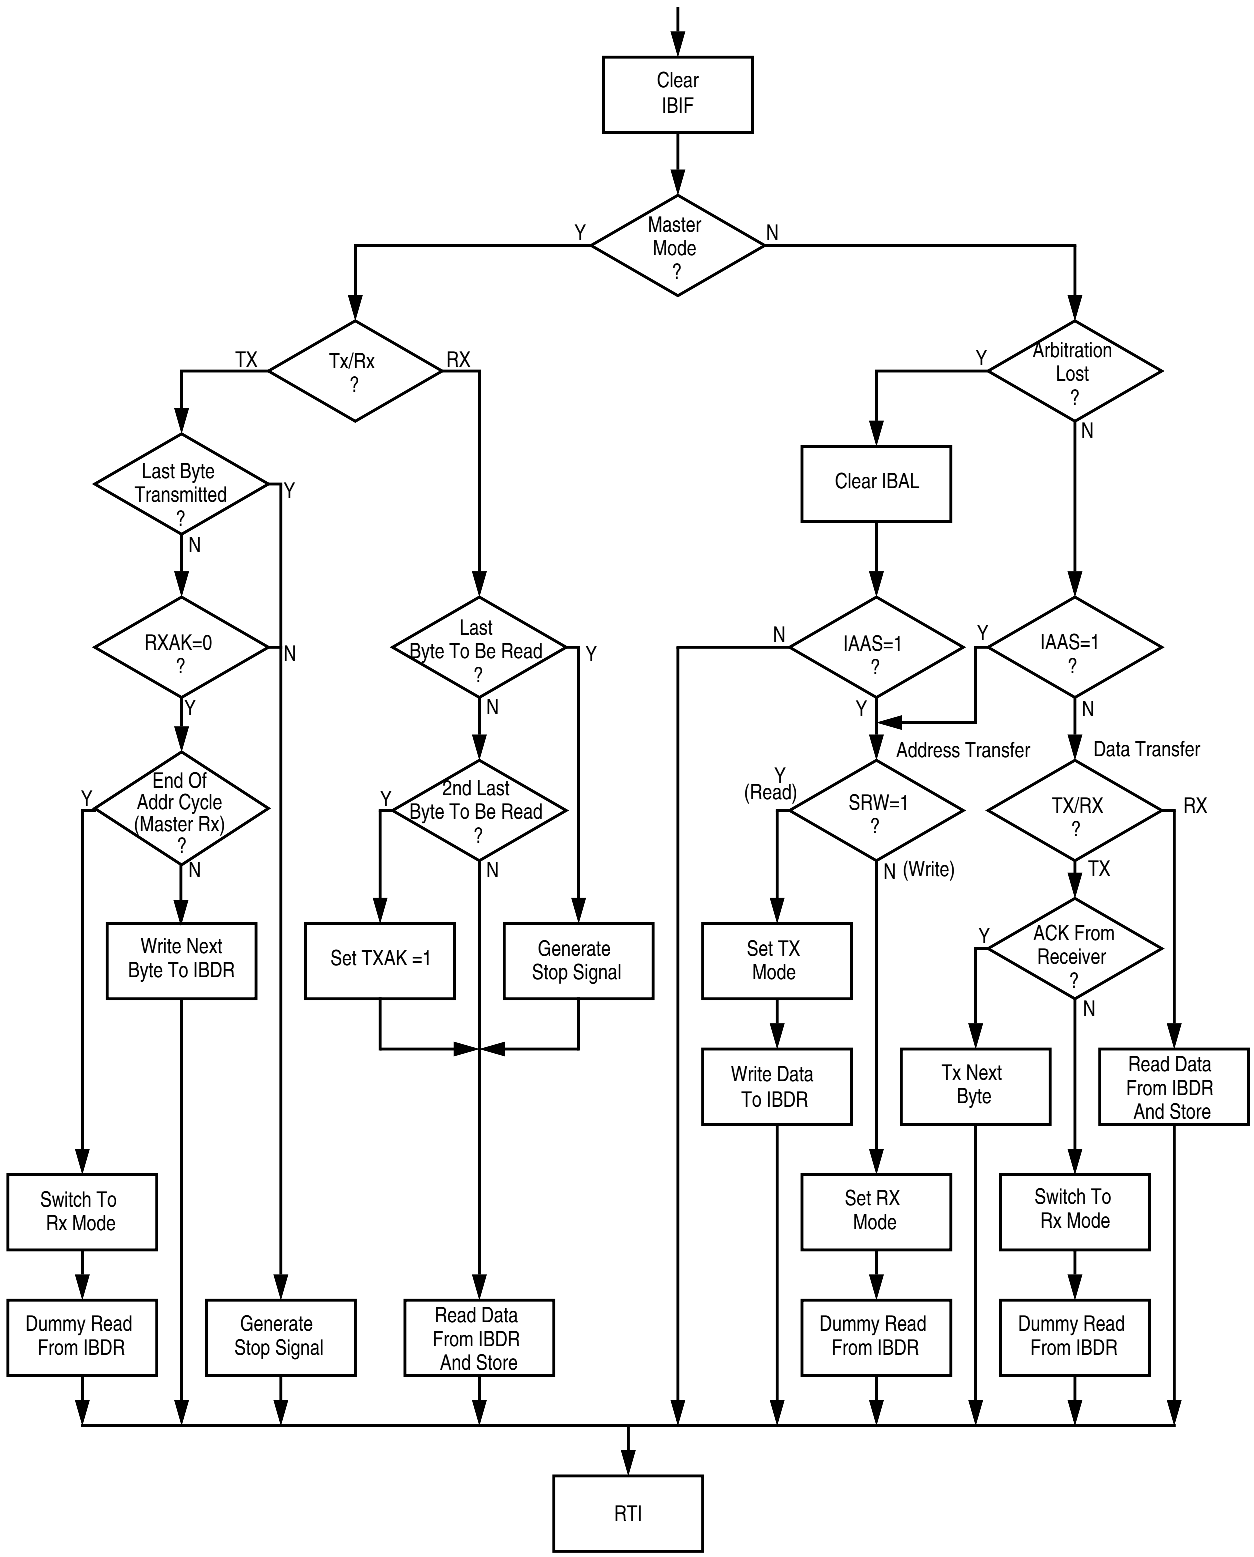

Figure 11-12. Flow-Chart of Typical IIC Interrupt Routine

Chapter 12
Freescale's Scalable Controller Area Network (MSCANV2)

12.1 Introduction

Freescale's scalable controller area network (MSCANV2) definition is based on the MSCAN12 definition, which is the specific implementation of the MSCAN concept targeted for the M68HC12 microcontroller family.

The module is a communication controller implementing the CAN 2.0A/B protocol as defined in the Bosch specification dated September 1991. For users to fully understand the MSCAN specification, it is recommended that the Bosch specification be read first to familiarize the reader with the terms and concepts contained within this document.

Though not exclusively intended for automotive applications, CAN protocol is designed to meet the specific requirements of a vehicle serial data bus: real-time processing, reliable operation in the EMI environment of a vehicle, cost-effectiveness, and required bandwidth.

MSCAN uses an advanced buffer arrangement resulting in predictable real-time behavior and simplified application software.

12.1.1 Glossary

ACK: Acknowledge of CAN message

CAN: Controller Area Network

CRC: Cyclic Redundancy Code

EOF: End of Frame

FIFO: First-In-First-Out Memory

IFS: Inter-Frame Sequence

SOF: Start of Frame

CPU bus: CPU related read/write data bus

CAN bus: CAN protocol related serial bus

oscillator clock: Direct clock from external oscillator

bus clock: CPU bus realated clock

CAN clock: CAN protocol related clock

12.1.2 Block Diagram

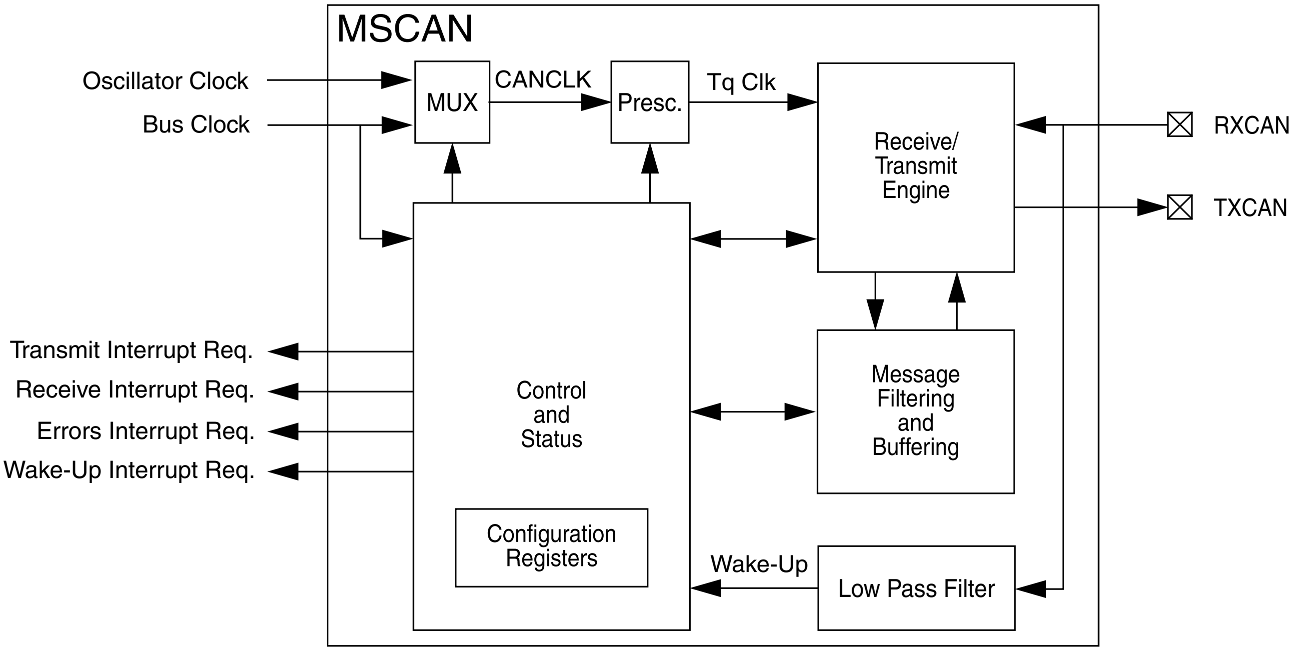

Figure 12-1. MSCAN Block Diagram

12.1.3 Features

The basic features of the MSCAN are as follows:

- Implementation of the CAN protocol — Version 2.0A/B
  - Standard and extended data frames
  - Zero to eight bytes data length
  - Programmable bit rate up to 1 Mbps[1]
  - Support for remote frames
- Five receive buffers with FIFO storage scheme
- Three transmit buffers with internal prioritization using a "local priority" concept
- Flexible maskable identifier filter supports two full-size (32-bit) extended identifier filters, or four 16-bit filters, or eight 8-bit filters
- Programmable wakeup functionality with integrated low-pass filter
- Programmable loopback mode supports self-test operation
- Programmable listen-only mode for monitoring of CAN bus
- Separate signalling and interrupt capabilities for all CAN receiver and transmitter error states (warning, error passive, bus-off)
- Programmable MSCAN clock source either bus clock or oscillator clock
- Internal timer for time-stamping of received and transmitted messages
- Three low-power modes: sleep, power down, and MSCAN enable

1. Depending on the actual bit timing and the clock jitter of the PLL.

- Global initialization of configuration registers

12.1.4 Modes of Operation

The following modes of operation are specific to the MSCAN. See Section 12.4, "Functional Description," for details.

- Listen-Only Mode
- MSCAN Sleep Mode
- MSCAN Initialization Mode
- MSCAN Power Down Mode

12.2 External Signal Description

The MSCAN uses two external pins:

12.2.1 RXCAN — CAN Receiver Input Pin

RXCAN is the MSCAN receiver input pin.

12.2.2 TXCAN — CAN Transmitter Output Pin

TXCAN is the MSCAN transmitter output pin. The TXCAN output pin represents the logic level on the CAN bus:

0 = Dominant state
1 = Recessive state

12.2.3 CAN System

A typical CAN system with MSCAN is shown in Figure 12-2. Each CAN station is connected physically to the CAN bus lines through a transceiver device. The transceiver is capable of driving the large current needed for the CAN bus and has current protection against defective CAN or defective stations.

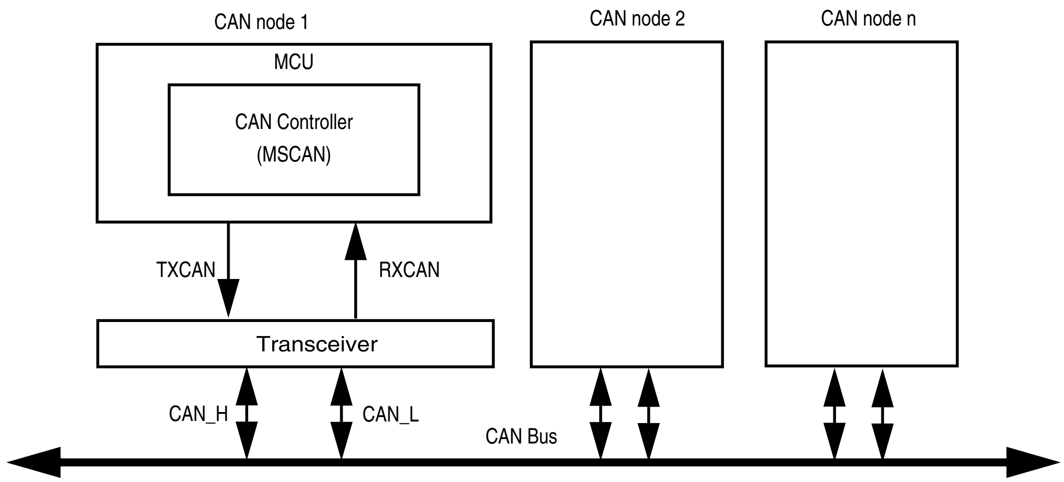

Figure 12-2. CAN System

12.3 Memory Map and Register Definition

This section provides a detailed description of all registers accessible in the MSCAN.

12.3.1 Module Memory Map

Figure 12-3 gives an overview on all registers and their individual bits in the MSCAN memory map. The *register address* results from the addition of *base address* and *address offset*. The *base address* is determined at the MCU level and can be found in the MCU memory map description. The *address offset* is defined at the module level.

The MSCAN occupies 64 bytes in the memory space. The base address of the MSCAN module is determined at the MCU level when the MCU is defined. The register decode map is fixed and begins at the first address of the module address offset.

The detailed register descriptions follow in the order they appear in the register map.

Register Name		Bit 7	6	5	4	3	2	1	Bit 0

Figure 12-3. MSCAN Register Summary (continued)

12.3.2 Register Descriptions

This section describes in detail all the registers and register bits in the MSCAN module. Each description includes a standard register diagram with an associated figure number. Details of register bit and field function follow the register diagrams, in bit order. All bits of all registers in this module are completely synchronous to internal clocks during a register read.

12.3.2.1 MSCAN Control Register 0 (CANCTL0)

The CANCTL0 register provides various control bits of the MSCAN module as described below.

Module Base + 0x0000

	7	6	5	4	3	2	1	0
R	RXFRM	RXACT	CSWAI	SYNCH	TIME	WUPE	SLPRQ	INITRQ
W		(shaded)		(shaded)				
Reset:	0	0	0	0	0	0	0	1

(shaded) = Unimplemented

Figure 12-4. MSCAN Control Register 0 (CANCTL0)

NOTE

The CANCTL0 register, except WUPE, INITRQ, and SLPRQ, is held in the reset state when the initialization mode is active (INITRQ = 1 and INITAK = 1). This register is writable again as soon as the initialization mode is exited (INITRQ = 0 and INITAK = 0).

Read: Anytime

Write: Anytime when out of initialization mode; exceptions are read-only RXACT and SYNCH, RXFRM (which is set by the module only), and INITRQ (which is also writable in initialization mode).

Table 12-1. CANCTL0 Register Field Descriptions

Field	Description
7 RXFRM[1]	**Received Frame Flag** — This bit is read and clear only. It is set when a receiver has received a valid message correctly, independently of the filter configuration. After it is set, it remains set until cleared by software or reset. Clearing is done by writing a 1. Writing a 0 is ignored. This bit is not valid in loopback mode. 0 No valid message was received since last clearing this flag 1 A valid message was received since last clearing of this flag
6 RXACT	**Receiver Active Status** — This read-only flag indicates the MSCAN is receiving a message. The flag is controlled by the receiver front end. This bit is not valid in loopback mode. 0 MSCAN is transmitting or idle[2] 1 MSCAN is receiving a message (including when arbitration is lost)[2]
5 CSWAI[3]	**CAN Stops in Wait Mode** — Enabling this bit allows for lower power consumption in wait mode by disabling all the clocks at the CPU bus interface to the MSCAN module. 0 The module is not affected during wait mode 1 The module ceases to be clocked during wait mode
4 SYNCH	**Synchronized Status** — This read-only flag indicates whether the MSCAN is synchronized to the CAN bus and able to participate in the communication process. It is set and cleared by the MSCAN. 0 MSCAN is not synchronized to the CAN bus 1 MSCAN is synchronized to the CAN bus
3 TIME	**Timer Enable** — This bit activates an internal 16-bit wide free running timer which is clocked by the bit clock rate. If the timer is enabled, a 16-bit time stamp will be assigned to each transmitted/received message within the active TX/RX buffer. Right after the EOF of a valid message on the CAN bus, the time stamp is written to the highest bytes (0x000E, 0x000F) in the appropriate buffer (see Section 12.3.3, "Programmer's Model of Message Storage"). The internal timer is reset (all bits set to 0) when disabled. This bit is held low in initialization mode. 0 Disable internal MSCAN timer 1 Enable internal MSCAN timer
2 WUPE[4]	**Wake-Up Enable** — This configuration bit allows the MSCAN to restart from sleep mode when traffic on CAN is detected (see Section 12.4.5.4, "MSCAN Sleep Mode"). 0 Wake-up disabled — The MSCAN ignores traffic on CAN 1 Wake-up enabled — The MSCAN is able to restart

Table 12-1. CANCTL0 Register Field Descriptions (continued)

Field	Description
1 SLPRQ[5]	**Sleep Mode Request** — This bit requests the MSCAN to enter sleep mode, which is an internal power saving mode (see Section 12.4.5.4, "MSCAN Sleep Mode"). The sleep mode request is serviced when the CAN bus is idle, i.e., the module is not receiving a message and all transmit buffers are empty. The module indicates entry to sleep mode by setting SLPAK = 1 (see Section 12.3.2.2, "MSCAN Control Register 1 (CANCTL1)"). SLPRQ cannot be set while the WUPIF flag is set (see Section 12.3.2.5, "MSCAN Receiver Flag Register (CANRFLG)"). Sleep mode will be active until SLPRQ is cleared by the CPU or, depending on the setting of WUPE, the MSCAN detects activity on the CAN bus and clears SLPRQ itself. 0 Running — The MSCAN functions normally 1 Sleep mode request — The MSCAN enters sleep mode when CAN bus idle
0 INITRQ[6,7]	**Initialization Mode Request** — When this bit is set by the CPU, the MSCAN skips to initialization mode (see Section 12.4.5.5, "MSCAN Initialization Mode"). Any ongoing transmission or reception is aborted and synchronization to the CAN bus is lost. The module indicates entry to initialization mode by setting INITAK = 1 (Section 12.3.2.2, "MSCAN Control Register 1 (CANCTL1)"). The following registers enter their hard reset state and restore their default values: CANCTL0[8], CANRFLG[9], CANRIER[10], CANTFLG, CANTIER, CANTARQ, CANTAAK, and CANTBSEL. The registers CANCTL1, CANBTR0, CANBTR1, CANIDAC, CANIDAR0-7, and CANIDMR0-7 can only be written by the CPU when the MSCAN is in initialization mode (INITRQ = 1 and INITAK = 1). The values of the error counters are not affected by initialization mode. When this bit is cleared by the CPU, the MSCAN restarts and then tries to synchronize to the CAN bus. If the MSCAN is not in bus-off state, it synchronizes after 11 consecutive recessive bits on the CAN bus; if the MSCAN is in bus-off state, it continues to wait for 128 occurrences of 11 consecutive recessive bits. Writing to other bits in CANCTL0, CANRFLG, CANRIER, CANTFLG, or CANTIER must be done only after initialization mode is exited, which is INITRQ = 0 and INITAK = 0. 0 Normal operation 1 MSCAN in initialization mode

1 The MSCAN must be in normal mode for this bit to become set.

2 See the Bosch CAN 2.0A/B specification for a detailed definition of transmitter and receiver states.

3 In order to protect from accidentally violating the CAN protocol, the TXCAN pin is immediately forced to a recessive state when the CPU enters wait (CSWAI = 1) or stop mode (see Section 12.4.5.2, "Operation in Wait Mode" and Section 12.4.5.3, "Operation in Stop Mode").

4 The CPU has to make sure that the WUPE register and the WUPIE wake-up interrupt enable register (see Section 12.3.2.6, "MSCAN Receiver Interrupt Enable Register (CANRIER)) is enabled, if the recovery mechanism from stop or wait is required.

5 The CPU cannot clear SLPRQ before the MSCAN has entered sleep mode (SLPRQ = 1 and SLPAK = 1).

6 The CPU cannot clear INITRQ before the MSCAN has entered initialization mode (INITRQ = 1 and INITAK = 1).

7 In order to protect from accidentally violating the CAN protocol, the TXCAN pin is immediately forced to a recessive state when the initialization mode is requested by the CPU. Thus, the recommended procedure is to bring the MSCAN into sleep mode (SLPRQ = 1 and SLPAK = 1) before requesting initialization mode.

8 Not including WUPE, INITRQ, and SLPRQ.

9 TSTAT1 and TSTAT0 are not affected by initialization mode.

10 RSTAT1 and RSTAT0 are not affected by initialization mode.

12.3.2.2 MSCAN Control Register 1 (CANCTL1)

The CANCTL1 register provides various control bits and handshake status information of the MSCAN module as described below.

Module Base + 0x0001

	7	6	5	4	3	2	1	0
R	CANE	CLKSRC	LOOPB	LISTEN		WUPM	SLPAK	INITAK
W								
Reset:	0	0	0	1	0	0	0	1

= Unimplemented

Figure 12-5. MSCAN Control Register 1 (CANCTL1)

Read: Anytime

Write: Anytime when INITRQ = 1 and INITAK = 1, except CANE which is write once in normal and anytime in special system operation modes when the MSCAN is in initialization mode (INITRQ = 1 and INITAK = 1).

Table 12-2. CANCTL1 Register Field Descriptions

Field	Description
7 CANE	**MSCAN Enable** 0 MSCAN module is disabled 1 MSCAN module is enabled
6 CLKSRC	**MSCAN Clock Source** — This bit defines the clock source for the MSCAN module (only for systems with a clock generation module; Section 12.4.3.2, "Clock System," and Section Figure 12-42., "MSCAN Clocking Scheme,"). 0 MSCAN clock source is the oscillator clock 1 MSCAN clock source is the bus clock
5 LOOPB	**Loopback Self Test Mode** — When this bit is set, the MSCAN performs an internal loopback which can be used for self test operation. The bit stream output of the transmitter is fed back to the receiver internally. The RXCAN input pin is ignored and the TXCAN output goes to the recessive state (logic 1). The MSCAN behaves as it does normally when transmitting and treats its own transmitted message as a message received from a remote node. In this state, the MSCAN ignores the bit sent during the ACK slot in the CAN frame acknowledge field to ensure proper reception of its own message. Both transmit and receive interrupts are generated. 0 Loopback self test disabled 1 Loopback self test enabled
4 LISTEN	**Listen Only Mode** — This bit configures the MSCAN as a CAN bus monitor. When LISTEN is set, all valid CAN messages with matching ID are received, but no acknowledgement or error frames are sent out (see Section 12.4.4.4, "Listen-Only Mode"). In addition, the error counters are frozen. Listen only mode supports applications which require "hot plugging" or throughput analysis. The MSCAN is unable to transmit any messages when listen only mode is active. 0 Normal operation 1 Listen only mode activated
2 WUPM	**Wake-Up Mode** — If WUPE in CANCTL0 is enabled, this bit defines whether the integrated low-pass filter is applied to protect the MSCAN from spurious wake-up (see Section 12.4.5.4, "MSCAN Sleep Mode"). 0 MSCAN wakes up on any dominant level on the CAN bus 1 MSCAN wakes up only in case of a dominant pulse on the CAN bus that has a length of T_{wup}

Table 12-2. CANCTL1 Register Field Descriptions (continued)

Field	Description
1 SLPAK	**Sleep Mode Acknowledge** — This flag indicates whether the MSCAN module has entered sleep mode (see Section 12.4.5.4, "MSCAN Sleep Mode"). It is used as a handshake flag for the SLPRQ sleep mode request. Sleep mode is active when SLPRQ = 1 and SLPAK = 1. Depending on the setting of WUPE, the MSCAN will clear the flag if it detects activity on the CAN bus while in sleep mode. 0 Running — The MSCAN operates normally 1 Sleep mode active — The MSCAN has entered sleep mode
0 INITAK	**Initialization Mode Acknowledge** — This flag indicates whether the MSCAN module is in initialization mode (see Section 12.4.5.5, "MSCAN Initialization Mode"). It is used as a handshake flag for the INITRQ initialization mode request. Initialization mode is active when INITRQ = 1 and INITAK = 1. The registers CANCTL1, CANBTR0, CANBTR1, CANIDAC, CANIDAR0–CANIDAR7, and CANIDMR0–CANIDMR7 can be written only by the CPU when the MSCAN is in initialization mode. 0 Running — The MSCAN operates normally 1 Initialization mode active — The MSCAN has entered initialization mode

12.3.2.3 MSCAN Bus Timing Register 0 (CANBTR0)

The CANBTR0 register configures various CAN bus timing parameters of the MSCAN module.

Module Base + 0x0002

	7	6	5	4	3	2	1	0
R W	SJW1	SJW0	BRP5	BRP4	BRP3	BRP2	BRP1	BRP0
Reset:	0	0	0	0	0	0	0	0

Figure 12-6. MSCAN Bus Timing Register 0 (CANBTR0)

Read: Anytime

Write: Anytime in initialization mode (INITRQ = 1 and INITAK = 1)

Table 12-3. CANBTR0 Register Field Descriptions

Field	Description
7:6 SJW[1:0]	**Synchronization Jump Width** — The synchronization jump width defines the maximum number of time quanta (Tq) clock cycles a bit can be shortened or lengthened to achieve resynchronization to data transitions on the CAN bus (see Table 12-4).
5:0 BRP[5:0]	**Baud Rate Prescaler** — These bits determine the time quanta (Tq) clock which is used to build up the bit timing (see Table 12-5).

Table 12-4. Synchronization Jump Width

SJW1	SJW0	Synchronization Jump Width
0	0	1 Tq clock cycle
0	1	2 Tq clock cycles
1	0	3 Tq clock cycles
1	1	4 Tq clock cycles

Table 12-5. Baud Rate Prescaler

BRP5	BRP4	BRP3	BRP2	BRP1	BRP0	Prescaler value (P)
0	0	0	0	0	0	1
0	0	0	0	0	1	2
0	0	0	0	1	0	3
0	0	0	0	1	1	4
:	:	:	:	:	:	:
1	1	1	1	1	1	64

12.3.2.4 MSCAN Bus Timing Register 1 (CANBTR1)

The CANBTR1 register configures various CAN bus timing parameters of the MSCAN module.

Module Base + 0x0003

	7	6	5	4	3	2	1	0
R W	SAMP	TSEG22	TSEG21	TSEG20	TSEG13	TSEG12	TSEG11	TSEG10
Reset:	0	0	0	0	0	0	0	0

Figure 12-7. MSCAN Bus Timing Register 1 (CANBTR1)

Read: Anytime
Write: Anytime in initialization mode (INITRQ = 1 and INITAK = 1)

Table 12-6. CANBTR1 Register Field Descriptions

Field	Description
7 SAMP	**Sampling** — This bit determines the number of CAN bus samples taken per bit time. 0 One sample per bit. 1 Three samples per bit[1]. If SAMP = 0, the resulting bit value is equal to the value of the single bit positioned at the sample point. If SAMP = 1, the resulting bit value is determined by using majority rule on the three total samples. For higher bit rates, it is recommended that only one sample is taken per bit time (SAMP = 0).
6:4 TSEG2[2:0]	**Time Segment 2** — Time segments within the bit time fix the number of clock cycles per bit time and the location of the sample point (see Figure 12-43). Time segment 2 (TSEG2) values are programmable as shown in Table 12-7.
3:0 TSEG1[3:0]	**Time Segment 1** — Time segments within the bit time fix the number of clock cycles per bit time and the location of the sample point (see Figure 12-43). Time segment 1 (TSEG1) values are programmable as shown in Table 12-8.

[1] In this case, PHASE_SEG1 must be at least 2 time quanta (Tq).

Table 12-7. Time Segment 2 Values

TSEG22	TSEG21	TSEG20	Time Segment 2
0	0	0	1 Tq clock cycle[1]
0	0	1	2 Tq clock cycles
:	:	:	:
1	1	0	7 Tq clock cycles
1	1	1	8 Tq clock cycles

[1] This setting is not valid. Please refer to Table 12-34 for valid settings.

Table 12-8. Time Segment 1 Values

TSEG13	TSEG12	TSEG11	TSEG10	Time segment 1
0	0	0	0	1 Tq clock cycle[1]
0	0	0	1	2 Tq clock cycles[1]
0	0	1	0	3 Tq clock cycles[1]
0	0	1	1	4 Tq clock cycles
:	:	:	:	:
1	1	1	0	15 Tq clock cycles
1	1	1	1	16 Tq clock cycles

[1] This setting is not valid. Please refer to Table 12-34 for valid settings.

The bit time is determined by the oscillator frequency, the baud rate prescaler, and the number of time quanta (Tq) clock cycles per bit (as shown in Table 12-7 and Table 12-8).

Eqn. 12-1

$$\text{Bit Time} = \frac{(\text{Prescaler value})}{f_{CANCLK}} \bullet (1 + \text{TimeSegment1} + \text{TimeSegment2})$$

12.3.2.5 MSCAN Receiver Flag Register (CANRFLG)

A flag can be cleared only by software (writing a 1 to the corresponding bit position) when the condition which caused the setting is no longer valid. Every flag has an associated interrupt enable bit in the CANRIER register.

Figure 12-8. MSCAN Receiver Flag Register (CANRFLG)

NOTE

The CANRFLG register is held in the reset state[1] when the initialization mode is active (INITRQ = 1 and INITAK = 1). This register is writable again as soon as the initialization mode is exited (INITRQ = 0 and INITAK = 0).

Read: Anytime
Write: Anytime when out of initialization mode, except RSTAT[1:0] and TSTAT[1:0] flags which are read-only; write of 1 clears flag; write of 0 is ignored.

1. The RSTAT[1:0], TSTAT[1:0] bits are not affected by initialization mode.

Table 12-9. CANRFLG Register Field Descriptions

Field	Description
7 WUPIF	**Wake-Up Interrupt Flag** — If the MSCAN detects CAN bus activity while in sleep mode (see Section 12.4.5.4, "MSCAN Sleep Mode,") and WUPE = 1 in CANTCTL0 (see Section 12.3.2.1, "MSCAN Control Register 0 (CANCTL0)"), the module will set WUPIF. If not masked, a wake-up interrupt is pending while this flag is set. 0 No wake-up activity observed while in sleep mode 1 MSCAN detected activity on the CAN bus and requested wake-up
6 CSCIF	**CAN Status Change Interrupt Flag** — This flag is set when the MSCAN changes its current CAN bus status due to the actual value of the transmit error counter (TEC) and the receive error counter (REC). An additional 4-bit (RSTAT[1:0], TSTAT[1:0]) status register, which is split into separate sections for TEC/REC, informs the system on the actual CAN bus status (see Section 12.3.2.6, "MSCAN Receiver Interrupt Enable Register (CANRIER)"). If not masked, an error interrupt is pending while this flag is set. CSCIF provides a blocking interrupt. That guarantees that the receiver/transmitter status bits (RSTAT/TSTAT) are only updated when no CAN status change interrupt is pending. If the TECs/RECs change their current value after the CSCIF is asserted, which would cause an additional state change in the RSTAT/TSTAT bits, these bits keep their status until the current CSCIF interrupt is cleared again. 0 No change in CAN bus status occurred since last interrupt 1 MSCAN changed current CAN bus status
5:4 RSTAT[1:0]	**Receiver Status Bits** — The values of the error counters control the actual CAN bus status of the MSCAN. As soon as the status change interrupt flag (CSCIF) is set, these bits indicate the appropriate receiver related CAN bus status of the MSCAN. The coding for the bits RSTAT1, RSTAT0 is: 00 RxOK: $0 \leq$ receive error counter ≤ 96 01 RxWRN: $96 <$ receive error counter ≤ 127 10 RxERR: $127 <$ receive error counter 11 Bus-off[1]: transmit error counter > 255
3:2 TSTAT[1:0]	**Transmitter Status Bits** — The values of the error counters control the actual CAN bus status of the MSCAN. As soon as the status change interrupt flag (CSCIF) is set, these bits indicate the appropriate transmitter related CAN bus status of the MSCAN. The coding for the bits TSTAT1, TSTAT0 is: 00 TxOK: $0 \leq$ transmit error counter ≤ 96 01 TxWRN: $96 <$ transmit error counter ≤ 127 10 TxERR: $127 <$ transmit error counter ≤ 255 11 Bus-Off: transmit error counter > 255
1 OVRIF	**Overrun Interrupt Flag** — This flag is set when a data overrun condition occurs. If not masked, an error interrupt is pending while this flag is set. 0 No data overrun condition 1 A data overrun detected
0 RXF[2]	**Receive Buffer Full Flag** — RXF is set by the MSCAN when a new message is shifted in the receiver FIFO. This flag indicates whether the shifted buffer is loaded with a correctly received message (matching identifier, matching cyclic redundancy code (CRC) and no other errors detected). After the CPU has read that message from the RxFG buffer in the receiver FIFO, the RXF flag must be cleared to release the buffer. A set RXF flag prohibits the shifting of the next FIFO entry into the foreground buffer (RxFG). If not masked, a receive interrupt is pending while this flag is set. 0 No new message available within the RxFG 1 The receiver FIFO is not empty. A new message is available in the RxFG

[1] Redundant Information for the most critical CAN bus status which is "bus-off". This only occurs if the Tx error counter exceeds a number of 255 errors. Bus-off affects the receiver state. As soon as the transmitter leaves its bus-off state the receiver state skips to RxOK too. Refer also to TSTAT[1:0] coding in this register.

[2] To ensure data integrity, do not read the receive buffer registers while the RXF flag is cleared. For MCUs with dual CPUs, reading the receive buffer registers while the RXF flag is cleared may result in a CPU fault condition.

12.3.2.6 MSCAN Receiver Interrupt Enable Register (CANRIER)

This register contains the interrupt enable bits for the interrupt flags described in the CANRFLG register.

Module Base + 0x0005

	7	6	5	4	3	2	1	0
R W	WUPIE	CSCIE	RSTATE1	RSTATE0	TSTATE1	TSTATE0	OVRIE	RXFIE
Reset:	0	0	0	0	0	0	0	0

Figure 12-9. MSCAN Receiver Interrupt Enable Register (CANRIER)

NOTE

The CANRIER register is held in the reset state when the initialization mode is active (INITRQ=1 and INITAK=1). This register is writable when not in initialization mode (INITRQ=0 and INITAK=0).

The RSTATE[1:0], TSTATE[1:0] bits are not affected by initialization mode.

Read: Anytime
Write: Anytime when not in initialization mode

Table 12-10. CANRIER Register Field Descriptions

Field	Description
7 WUPIE[1]	**Wake-Up Interrupt Enable** 0 No interrupt request is generated from this event. 1 A wake-up event causes a Wake-Up interrupt request.
6 CSCIE	**CAN Status Change Interrupt Enable** 0 No interrupt request is generated from this event. 1 A CAN Status Change event causes an error interrupt request.
5:4 RSTATE[1:0]	**Receiver Status Change Enable** — These RSTAT enable bits control the sensitivity level in which receiver state changes are causing CSCIF interrupts. Independent of the chosen sensitivity level the RSTAT flags continue to indicate the actual receiver state and are only updated if no CSCIF interrupt is pending. 00 Do not generate any CSCIF interrupt caused by receiver state changes. 01 Generate CSCIF interrupt only if the receiver enters or leaves "bus-off" state. Discard other receiver state changes for generating CSCIF interrupt. 10 Generate CSCIF interrupt only if the receiver enters or leaves "RxErr" or "bus-off"[2] state. Discard other receiver state changes for generating CSCIF interrupt. 11 Generate CSCIF interrupt on all state changes.
3:2 TSTATE[1:0]	**Transmitter Status Change Enable** — These TSTAT enable bits control the sensitivity level in which transmitter state changes are causing CSCIF interrupts. Independent of the chosen sensitivity level, the TSTAT flags continue to indicate the actual transmitter state and are only updated if no CSCIF interrupt is pending. 00 Do not generate any CSCIF interrupt caused by transmitter state changes. 01 Generate CSCIF interrupt only if the transmitter enters or leaves "bus-off" state. Discard other transmitter state changes for generating CSCIF interrupt. 10 Generate CSCIF interrupt only if the transmitter enters or leaves "TxErr" or "bus-off" state. Discard other transmitter state changes for generating CSCIF interrupt. 11 Generate CSCIF interrupt on all state changes.

Table 12-10. CANRIER Register Field Descriptions (continued)

Field	Description
1 OVRIE	**Overrun Interrupt Enable** 0 No interrupt request is generated from this event. 1 An overrun event causes an error interrupt request.
0 RXFIE	**Receiver Full Interrupt Enable** 0 No interrupt request is generated from this event. 1 A receive buffer full (successful message reception) event causes a receiver interrupt request.

[1] WUPIE and WUPE (see Section 12.3.2.1, "MSCAN Control Register 0 (CANCTL0)") must both be enabled if the recovery mechanism from stop or wait is required.

[2] Bus-off state is defined by the CAN standard (see Bosch CAN 2.0A/B protocol specification: for only transmitters. Because the only possible state change for the transmitter from bus-off to TxOK also forces the receiver to skip its current state to RxOK, the coding of the RXSTAT[1:0] flags define an additional bus-off state for the receiver (see Section 12.3.2.5, "MSCAN Receiver Flag Register (CANRFLG)").

12.3.2.7 MSCAN Transmitter Flag Register (CANTFLG)

The transmit buffer empty flags each have an associated interrupt enable bit in the CANTIER register.

Module Base + 0x0006

	7	6	5	4	3	2	1	0
R	0	0	0	0	0	TXE2	TXE1	TXE0
W								
Reset:	0	0	0	0	0	1	1	1

= Unimplemented

Figure 12-10. MSCAN Transmitter Flag Register (CANTFLG)

NOTE

The CANTFLG register is held in the reset state when the initialization mode is active (INITRQ = 1 and INITAK = 1). This register is writable when not in initialization mode (INITRQ = 0 and INITAK = 0).

Read: Anytime
Write: Anytime for TXEx flags when not in initialization mode; write of 1 clears flag, write of 0 is ignored

Table 12-11. CANTFLG Register Field Descriptions

Field	Description
2:0 TXE[2:0]	**Transmitter Buffer Empty** — This flag indicates that the associated transmit message buffer is empty, and thus not scheduled for transmission. The CPU must clear the flag after a message is set up in the transmit buffer and is due for transmission. The MSCAN sets the flag after the message is sent successfully. The flag is also set by the MSCAN when the transmission request is successfully aborted due to a pending abort request (see Section 12.3.2.9, "MSCAN Transmitter Message Abort Request Register (CANTARQ)"). If not masked, a transmit interrupt is pending while this flag is set. Clearing a TXEx flag also clears the corresponding ABTAKx (see Section 12.3.2.10, "MSCAN Transmitter Message Abort Acknowledge Register (CANTAAK)"). When a TXEx flag is set, the corresponding ABTRQx bit is cleared (see Section 12.3.2.9, "MSCAN Transmitter Message Abort Request Register (CANTARQ)"). When listen-mode is active (see Section 12.3.2.2, "MSCAN Control Register 1 (CANCTL1)") the TXEx flags cannot be cleared and no transmission is started. Read and write accesses to the transmit buffer will be blocked, if the corresponding TXEx bit is cleared (TXEx = 0) and the buffer is scheduled for transmission. 0 The associated message buffer is full (loaded with a message due for transmission) 1 The associated message buffer is empty (not scheduled)

12.3.2.8 MSCAN Transmitter Interrupt Enable Register (CANTIER)

This register contains the interrupt enable bits for the transmit buffer empty interrupt flags.

Module Base + 0x0007

	7	6	5	4	3	2	1	0
R	0	0	0	0	0	TXEIE2	TXEIE1	TXEIE0
W								
Reset:	0	0	0	0	0	0	0	0

= Unimplemented

Figure 12-11. MSCAN Transmitter Interrupt Enable Register (CANTIER)

NOTE

The CANTIER register is held in the reset state when the initialization mode is active (INITRQ = 1 and INITAK = 1). This register is writable when not in initialization mode (INITRQ = 0 and INITAK = 0).

Read: Anytime
Write: Anytime when not in initialization mode

Table 12-12. CANTIER Register Field Descriptions

Field	Description
2:0 TXEIE[2:0]	**Transmitter Empty Interrupt Enable** 0 No interrupt request is generated from this event. 1 A transmitter empty (transmit buffer available for transmission) event causes a transmitter empty interrupt request.

12.3.2.9 MSCAN Transmitter Message Abort Request Register (CANTARQ)

The CANTARQ register allows abort request of queued messages as described below.

Module Base + 0x0008

	7	6	5	4	3	2	1	0
R	0	0	0	0	0	ABTRQ2	ABTRQ1	ABTRQ0
W								
Reset:	0	0	0	0	0	0	0	0

= Unimplemented

Figure 12-12. MSCAN Transmitter Message Abort Request Register (CANTARQ)

NOTE

The CANTARQ register is held in the reset state when the initialization mode is active (INITRQ = 1 and INITAK = 1). This register is writable when not in initialization mode (INITRQ = 0 and INITAK = 0).

Read: Anytime
Write: Anytime when not in initialization mode

Table 12-13. CANTARQ Register Field Descriptions

Field	Description
2:0 ABTRQ[2:0]	**Abort Request** — The CPU sets the ABTRQx bit to request that a scheduled message buffer (TXEx = 0) be aborted. The MSCAN grants the request if the message has not already started transmission, or if the transmission is not successful (lost arbitration or error). When a message is aborted, the associated TXE (see Section 12.3.2.7, "MSCAN Transmitter Flag Register (CANTFLG)") and abort acknowledge flags (ABTAK, see Section 12.3.2.10, "MSCAN Transmitter Message Abort Acknowledge Register (CANTAAK)") are set and a transmit interrupt occurs if enabled. The CPU cannot reset ABTRQx. ABTRQx is reset whenever the associated TXE flag is set. 0 No abort request 1 Abort request pending

12.3.2.10 MSCAN Transmitter Message Abort Acknowledge Register (CANTAAK)

The CANTAAK register indicates the successful abort of a queued message, if requested by the appropriate bits in the CANTARQ register.

Module Base + 0x0009

	7	6	5	4	3	2	1	0
R	0	0	0	0	0	ABTAK2	ABTAK1	ABTAK0
W								
Reset:	0	0	0	0	0	0	0	0

= Unimplemented

Figure 12-13. MSCAN Transmitter Message Abort Acknowledge Register (CANTAAK)

NOTE

The CANTAAK register is held in the reset state when the initialization mode is active (INITRQ = 1 and INITAK = 1).

Read: Anytime
Write: Unimplemented for ABTAKx flags

Table 12-14. CANTAAK Register Field Descriptions

Field	Description
2:0 ABTAK[2:0]	**Abort Acknowledge** — This flag acknowledges that a message was aborted due to a pending abort request from the CPU. After a particular message buffer is flagged empty, this flag can be used by the application software to identify whether the message was aborted successfully or was sent anyway. The ABTAKx flag is cleared whenever the corresponding TXE flag is cleared. 0 The message was not aborted. 1 The message was aborted.

12.3.2.11 MSCAN Transmit Buffer Selection Register (CANTBSEL)

The CANTBSEL register allows the selection of the actual transmit message buffer, which then will be accessible in the CANTXFG register space.

Module Base + 0x000A

	7	6	5	4	3	2	1	0
R	0	0	0	0	0	TX2	TX1	TX0
W								
Reset:	0	0	0	0	0	0	0	0

= Unimplemented

Figure 12-14. MSCAN Transmit Buffer Selection Register (CANTBSEL)

NOTE

The CANTBSEL register is held in the reset state when the initialization mode is active (INITRQ = 1 and INITAK=1). This register is writable when not in initialization mode (INITRQ = 0 and INITAK = 0).

Read: Find the lowest ordered bit set to 1, all other bits will be read as 0
Write: Anytime when not in initialization mode

Table 12-15. CANTBSEL Register Field Descriptions

Field	Description
2:0 TX[2:0]	**Transmit Buffer Select** — The lowest numbered bit places the respective transmit buffer in the CANTXFG register space (e.g., TX1 = 1 and TX0 = 1 selects transmit buffer TX0; TX1 = 1 and TX0 = 0 selects transmit buffer TX1). Read and write accesses to the selected transmit buffer will be blocked, if the corresponding TXEx bit is cleared and the buffer is scheduled for transmission (see Section 12.3.2.7, "MSCAN Transmitter Flag Register (CANTFLG)"). 0 The associated message buffer is deselected 1 The associated message buffer is selected, if lowest numbered bit

The following gives a short programming example of the usage of the CANTBSEL register:

To get the next available transmit buffer, application software must read the CANTFLG register and write this value back into the CANTBSEL register. In this example Tx buffers TX1 and TX2 are available. The value read from CANTFLG is therefore 0b0000_0110. When writing this value back to CANTBSEL, the Tx buffer TX1 is selected in the CANTXFG because the lowest numbered bit set to 1 is at bit position 1. Reading back this value out of CANTBSEL results in 0b0000_0010, because only the lowest numbered bit position set to 1 is presented. This mechanism eases the application software the selection of the next available Tx buffer.

- LDD CANTFLG; value read is 0b0000_0110
- STD CANTBSEL; value written is 0b0000_0110
- LDD CANTBSEL; value read is 0b0000_0010

If all transmit message buffers are deselected, no accesses are allowed to the CANTXFG registers.

12.3.2.12 MSCAN Identifier Acceptance Control Register (CANIDAC)

The CANIDAC register is used for identifier acceptance control as described below.

Module Base + 0x000B

	7	6	5	4	3	2	1	0
R	0	0	IDAM1	IDAM0	0	IDHIT2	IDHIT1	IDHIT0
W								
Reset:	0	0	0	0	0	0	0	0

= Unimplemented

Figure 12-15. MSCAN Identifier Acceptance Control Register (CANIDAC)

Read: Anytime
Write: Anytime in initialization mode (INITRQ = 1 and INITAK = 1), except bits IDHITx, which are read-only

Table 12-16. CANIDAC Register Field Descriptions

Field	Description
5:4 IDAM[1:0]	**Identifier Acceptance Mode** — The CPU sets these flags to define the identifier acceptance filter organization (see Section 12.4.3, "Identifier Acceptance Filter"). Table 12-17 summarizes the different settings. In filter closed mode, no message is accepted such that the foreground buffer is never reloaded.
2:0 IDHIT[2:0]	Identifier Acceptance Hit Indicator — The MSCAN sets these flags to indicate an identifier acceptance hit (see Section 12.4.3, "Identifier Acceptance Filter"). Table 12-18 summarizes the different settings.

Table 12-17. Identifier Acceptance Mode Settings

IDAM1	IDAM0	Identifier Acceptance Mode
0	0	Two 32-bit acceptance filters
0	1	Four 16-bit acceptance filters
1	0	Eight 8-bit acceptance filters
1	1	Filter closed

Table 12-18. Identifier Acceptance Hit Indication

IDHIT2	IDHIT1	IDHIT0	Identifier Acceptance Hit
0	0	0	Filter 0 hit
0	0	1	Filter 1 hit
0	1	0	Filter 2 hit
0	1	1	Filter 3 hit
1	0	0	Filter 4 hit
1	0	1	Filter 5 hit
1	1	0	Filter 6 hit
1	1	1	Filter 7 hit

The IDHITx indicators are always related to the message in the foreground buffer (RxFG). When a message gets shifted into the foreground buffer of the receiver FIFO the indicators are updated as well.

12.3.2.13 MSCAN Reserved Registers

These registers are reserved for factory testing of the MSCAN module and is not available in normal system operation modes.

Module Base + 0x000C, 0x000D

	7	6	5	4	3	2	1	0
R	0	0	0	0	0	0	0	0
W								
Reset:	0	0	0	0	0	0	0	0

= Unimplemented

Figure 12-16. MSCAN Reserved Registers

Read: Always read 0x0000 in normal system operation modes
Write: Unimplemented in normal system operation modes

NOTE

Writing to this register when in special modes can alter the MSCAN functionality.

12.3.2.14 MSCAN Receive Error Counter (CANRXERR)

This register reflects the status of the MSCAN receive error counter.

Module Base + 0x000E

	7	6	5	4	3	2	1	0
R	RXERR7	RXERR6	RXERR5	RXERR4	RXERR3	RXERR2	RXERR1	RXERR0
W								
Reset:	0	0	0	0	0	0	0	0

= Unimplemented

Figure 12-17. MSCAN Receive Error Counter (CANRXERR)

Read: Only when in sleep mode (SLPRQ = 1 and SLPAK = 1) or initialization mode (INITRQ = 1 and INITAK = 1)

Write: Unimplemented

NOTE

Reading this register when in any other mode other than sleep or initialization mode may return an incorrect value. For MCUs with dual CPUs, this may result in a CPU fault condition.

Writing to this register when in special modes can alter the MSCAN functionality.

12.3.2.15 MSCAN Transmit Error Counter (CANTXERR)

This register reflects the status of the MSCAN transmit error counter.

Module Base + 0x000F

	7	6	5	4	3	2	1	0
R	TXERR7	TXERR6	TXERR5	TXERR4	TXERR3	TXERR2	TXERR1	TXERR0

Figure 12-18. MSCAN Transmit Error Counter (CANTXERR)

Read: Only when in sleep mode (SLPRQ = 1 and SLPAK = 1) or initialization mode (INITRQ = 1 and INITAK = 1)

Write: Unimplemented

NOTE

Reading this register when in any other mode other than sleep or initialization mode, may return an incorrect value. For MCUs with dual CPUs, this may result in a CPU fault condition.

Writing to this register when in special modes can alter the MSCAN functionality.

12.3.2.16 MSCAN Identifier Acceptance Registers (CANIDAR0-7)

On reception, each message is written into the background receive buffer. The CPU is only signalled to read the message if it passes the criteria in the identifier acceptance and identifier mask registers (accepted); otherwise, the message is overwritten by the next message (dropped).

The acceptance registers of the MSCAN are applied on the IDR0–IDR3 registers (see Section 12.3.3.1, "Identifier Registers (IDR0–IDR3)") of incoming messages in a bit by bit manner (see Section 12.4.3, "Identifier Acceptance Filter").

For extended identifiers, all four acceptance and mask registers are applied. For standard identifiers, only the first two (CANIDAR0/1, CANIDMR0/1) are applied.

Module Base + 0x0010 (CANIDAR0)

Table 12-22. CANIDMR4–CANIDMR7 Register Field Descriptions

Field	Description
7:0 AM[7:0]	**Acceptance Mask Bits** — If a particular bit in this register is cleared, this indicates that the corresponding bit in the identifier acceptance register must be the same as its identifier bit before a match is detected. The message is accepted if all such bits match. If a bit is set, it indicates that the state of the corresponding bit in the identifier acceptance register does not affect whether or not the message is accepted. 0 Match corresponding acceptance code register and identifier bits 1 Ignore corresponding acceptance code register bit

12.3.3 Programmer's Model of Message Storage

The following section details the organization of the receive and transmit message buffers and the associated control registers.

To simplify the programmer interface, the receive and transmit message buffers have the same outline. Each message buffer allocates 16 bytes in the memory map containing a 13 byte data structure.

An additional transmit buffer priority register (TBPR) is defined for the transmit buffers. Within the last two bytes of this memory map, the MSCAN stores a special 16-bit time stamp, which is sampled from an internal timer after successful transmission or reception of a message. This feature is only available for transmit and receiver buffers, if the TIME bit is set (see Section 12.3.2.1, "MSCAN Control Register 0 (CANCTL0)").

The time stamp register is written by the MSCAN. The CPU can only read these registers.

Table 12-23. Message Buffer Organization

Offset Address	Register	Access
0x00X0	Identifier Register 0	
0x00X1	Identifier Register 1	
0x00X2	Identifier Register 2	
0x00X3	Identifier Register 3

0x00XD	Transmit Buffer Priority Register[1]	
0x00XE	Time Stamp Register (High Byte)[2]	
0x00XF	Time Stamp Register (Low Byte)[3]	

[1] Not applicable for receive buffers
[2] Read-only for CPU
[3] Read-only for CPU

Figure 12-23 shows the common 13-byte data structure of receive and transmit buffers for extended identifiers. The mapping of standard identifiers into the IDR registers is shown in Figure 12-24.

All bits of the receive and transmit buffers are 'x' out of reset because of RAM-based implementation[1]. All reserved or unused bits of the receive and transmit buffers always read 'x'.

1. Exception: The transmit priority registers are 0 out of reset.

Table 12-31. DLR Register Field Descriptions

Field	Description
3:0 DLC[3:0]	**Data Length Code Bits** — The data length code contains the number of bytes (data byte count) of the respective message. During the transmission of a remote frame, the data length code is transmitted as programmed while the number of transmitted data bytes is always 0. The data byte count ranges from 0 to 8 for a data frame. Table 12-32 shows the effect of setting the DLC bits.

Table 12-32. Data Length Codes

Data Length Code				Data Byte Count
DLC3	DLC2	DLC1	DLC0	
0	0	0	0	0
0	0	0	1	1
0	0	1	0	2
0	0	1	1	3
0	1	0	0	4
0	1	0	1	5
0	1	1	0	6
0	1	1	1	7
1	0	0	0	8

12.3.3.4 Transmit Buffer Priority Register (TBPR)

This register defines the local priority of the associated message buffer. The local priority is used for the internal prioritization process of the MSCAN and is defined to be highest for the smallest binary number. The MSCAN implements the following internal prioritization mechanisms:

- All transmission buffers with a cleared TXEx flag participate in the prioritization immediately before the SOF (start of frame) is sent.
- The transmission buffer with the lowest local priority field wins the prioritization.

In cases of more than one buffer having the same lowest priority, the message buffer with the lower index number wins.

Module Base + 0xXXXD

	7	6	5	4	3	2	1	0
R/W	PRIO7	PRIO6	PRIO5	PRIO4	PRIO3	PRIO2	PRIO1	PRIO0
Reset:	0	0	0	0	0	0	0	0

Read: Anytime when TXEx flag is set (see Section 12.3.2.7, "MSCAN Transmitter Flag Register (CANTFLG)") and the corresponding transmit buffer is selected in CANTBSEL (see Section 12.3.2.11, "MSCAN Transmit Buffer Selection Register (CANTBSEL)").

Write: Anytime when TXEx flag is set (see Section 12.3.2.7, "MSCAN Transmitter Flag Register (CANTFLG)") and the corresponding transmit buffer is selected in CANTBSEL (see Section 12.3.2.11, "MSCAN Transmit Buffer Selection Register (CANTBSEL)").

12.3.3.5 Time Stamp Register (TSRH–TSRL)

If the TIME bit is enabled, the MSCAN will write a time stamp to the respective registers in the active transmit or receive buffer right after the EOF of a valid message on the CAN bus (see Section 12.3.2.1, "MSCAN Control Register 0 (CANCTL0)"). In case of a transmission, the CPU can only read the time stamp after the respective transmit buffer has been flagged empty.

The timer value, which is used for stamping, is taken from a free running internal CAN bit clock. A timer overrun is not indicated by the MSCAN. The timer is reset (all bits set to 0) during initialization mode. The CPU can only read the time stamp registers.

Write: Unimplemented

12.4 Functional Description

12.4.1 General

This section provides a complete functional description of the MSCAN. It describes each of the features and modes listed in the introduction.

12.4.2 Message Storage

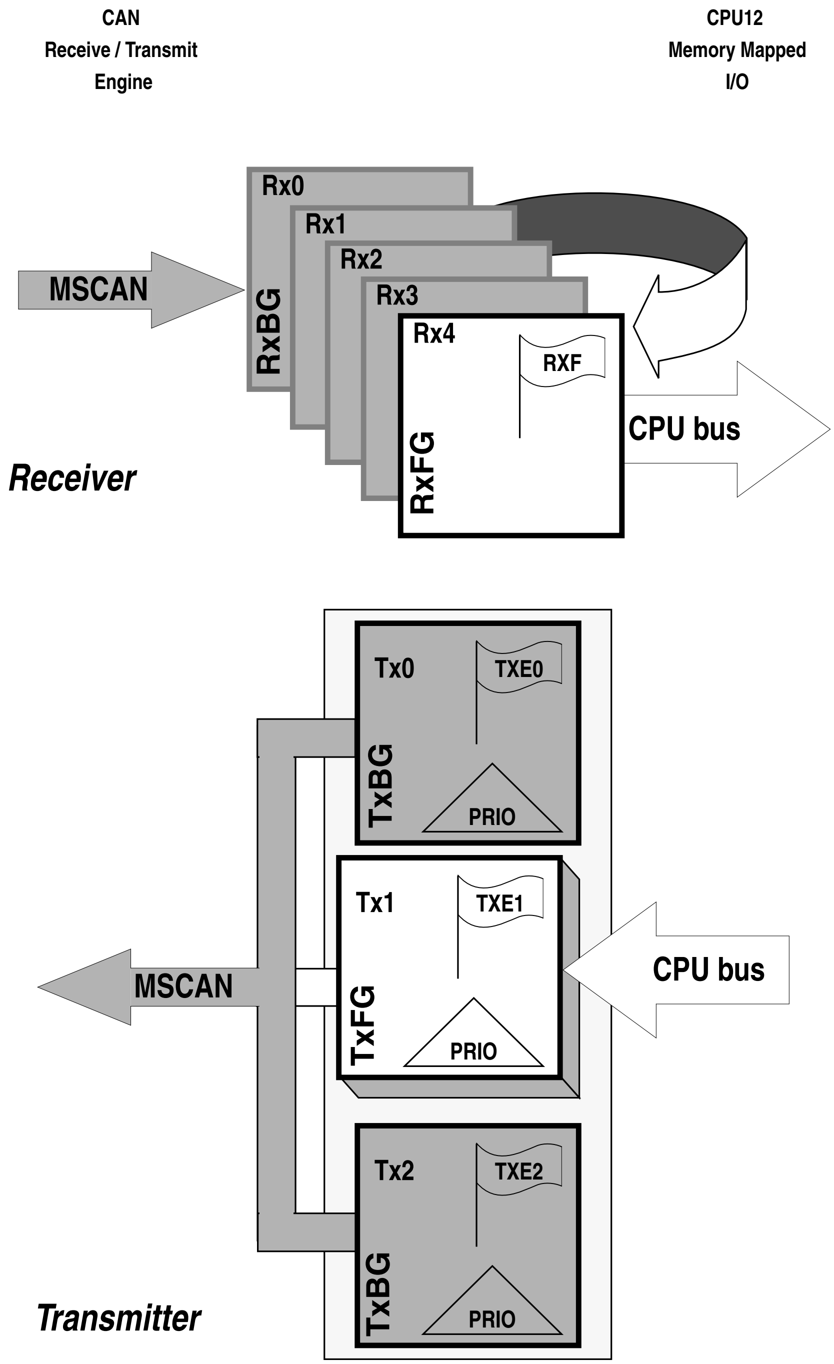

Figure 12-38. User Model for Message Buffer Organization

MSCAN facilitates a sophisticated message storage system which addresses the requirements of a broad range of network applications.

12.4.2.1 Message Transmit Background

Modern application layer software is built upon two fundamental assumptions:

- Any CAN node is able to send out a stream of scheduled messages without releasing the CAN bus between the two messages. Such nodes arbitrate for the CAN bus immediately after sending the previous message and only release the CAN bus in case of lost arbitration.
- The internal message queue within any CAN node is organized such that the highest priority message is sent out first, if more than one message is ready to be sent.

The behavior described in the bullets above cannot be achieved with a single transmit buffer. That buffer must be reloaded immediately after the previous message is sent. This loading process lasts a finite amount of time and must be completed within the inter-frame sequence (IFS) to be able to send an uninterrupted stream of messages. Even if this is feasible for limited CAN bus speeds, it requires that the CPU reacts with short latencies to the transmit interrupt.

A double buffer scheme de-couples the reloading of the transmit buffer from the actual message sending and, therefore, reduces the reactiveness requirements of the CPU. Problems can arise if the sending of a message is finished while the CPU re-loads the second buffer. No buffer would then be ready for transmission, and the CAN bus would be released.

At least three transmit buffers are required to meet the first of the above requirements under all circumstances. The MSCAN has three transmit buffers.

The second requirement calls for some sort of internal prioritization which the MSCAN implements with the "local priority" concept described in Section 12.4.2.2, "Transmit Structures."

12.4.2.2 Transmit Structures

The MSCAN triple transmit buffer scheme optimizes real-time performance by allowing multiple messages to be set up in advance. The three buffers are arranged as shown in Figure 12-38.

All three buffers have a 13-byte data structure similar to the outline of the receive buffers (see Section 12.3.3, "Programmer's Model of Message Storage"). An additional Section 12.3.3.4, "Transmit Buffer Priority Register (TBPR) contains an 8-bit local priority field (PRIO) (see Section 12.3.3.4, "Transmit Buffer Priority Register (TBPR)"). The remaining two bytes are used for time stamping of a message, if required (see Section 12.3.3.5, "Time Stamp Register (TSRH–TSRL)").

To transmit a message, the CPU must identify an available transmit buffer, which is indicated by a set transmitter buffer empty (TXEx) flag (see Section 12.3.2.7, "MSCAN Transmitter Flag Register (CANTFLG)"). If a transmit buffer is available, the CPU must set a pointer to this buffer by writing to the CANTBSEL register (see Section 12.3.2.11, "MSCAN Transmit Buffer Selection Register (CANTBSEL)"). This makes the respective buffer accessible within the CANTXFG address space (see Section 12.3.3, "Programmer's Model of Message Storage"). The algorithmic feature associated with the CANTBSEL register simplifies the transmit buffer selection. In addition, this scheme makes the handler software simpler because only one address area is applicable for the transmit process, and the required address space is minimized.

The CPU then stores the identifier, the control bits, and the data content into one of the transmit buffers. Finally, the buffer is flagged as ready for transmission by clearing the associated TXE flag.

The MSCAN then schedules the message for transmission and signals the successful transmission of the buffer by setting the associated TXE flag. A transmit interrupt (see Section 12.4.7.2, "Transmit Interrupt") is generated[1] when TXEx is set and can be used to drive the application software to re-load the buffer.

If more than one buffer is scheduled for transmission when the CAN bus becomes available for arbitration, the MSCAN uses the local priority setting of the three buffers to determine the prioritization. For this purpose, every transmit buffer has an 8-bit local priority field (PRIO). The application software programs this field when the message is set up. The local priority reflects the priority of this particular message relative to the set of messages being transmitted from this node. The lowest binary value of the PRIO field is defined to be the highest priority. The internal scheduling process takes place whenever the MSCAN arbitrates for the CAN bus. This is also the case after the occurrence of a transmission error.

When a high priority message is scheduled by the application software, it may become necessary to abort a lower priority message in one of the three transmit buffers. Because messages that are already in transmission cannot be aborted, the user must request the abort by setting the corresponding abort request bit (ABTRQ) (see Section 12.3.2.9, "MSCAN Transmitter Message Abort Request Register (CANTARQ)".) The MSCAN then grants the request, if possible, by:

1. Setting the corresponding abort acknowledge flag (ABTAK) in the CANTAAK register.
2. Setting the associated TXE flag to release the buffer.
3. Generating a transmit interrupt. The transmit interrupt handler software can determine from the setting of the ABTAK flag whether the message was aborted (ABTAK = 1) or sent (ABTAK = 0).

12.4.2.3 Receive Structures

The received messages are stored in a five stage input FIFO. The five message buffers are alternately mapped into a single memory area (see Figure 12-38). The background receive buffer (RxBG) is exclusively associated with the MSCAN, but the foreground receive buffer (RxFG) is addressable by the CPU (see Figure 12-38). This scheme simplifies the handler software because only one address area is applicable for the receive process.

All receive buffers have a size of 15 bytes to store the CAN control bits, the identifier (standard or extended), the data contents, and a time stamp, if enabled (see Section 12.3.3, "Programmer's Model of Message Storage").

The receiver full flag (RXF) (see Section 12.3.2.5, "MSCAN Receiver Flag Register (CANRFLG)") signals the status of the foreground receive buffer. When the buffer contains a correctly received message with a matching identifier, this flag is set.

On reception, each message is checked to see whether it passes the filter (see Section 12.4.3, "Identifier Acceptance Filter") and simultaneously is written into the active RxBG. After successful reception of a valid message, the MSCAN shifts the content of RxBG into the receiver FIFO[2], sets the RXF flag, and generates a receive interrupt (see Section 12.4.7.3, "Receive Interrupt") to the CPU[3]. The user's receive handler must read the received message from the RxFG and then reset the RXF flag to acknowledge the interrupt and to release the foreground buffer. A new message, which can follow immediately after the IFS

1. The transmit interrupt occurs only if not masked. A polling scheme can be applied on TXEx also.
2. Only if the RXF flag is not set.
3. The receive interrupt occurs only if not masked. A polling scheme can be applied on RXF also.

field of the CAN frame, is received into the next available RxBG. If the MSCAN receives an invalid message in its RxBG (wrong identifier, transmission errors, etc.) the actual contents of the buffer will be over-written by the next message. The buffer will then not be shifted into the FIFO.

When the MSCAN module is transmitting, the MSCAN receives its own transmitted messages into the background receive buffer, RxBG, but does not shift it into the receiver FIFO, generate a receive interrupt, or acknowledge its own messages on the CAN bus. The exception to this rule is in loopback mode (see Section 12.3.2.2, "MSCAN Control Register 1 (CANCTL1)") where the MSCAN treats its own messages exactly like all other incoming messages. The MSCAN receives its own transmitted messages in the event that it loses arbitration. If arbitration is lost, the MSCAN must be prepared to become a receiver.

An overrun condition occurs when all receive message buffers in the FIFO are filled with correctly received messages with accepted identifiers and another message is correctly received from the CAN bus with an accepted identifier. The latter message is discarded and an error interrupt with overrun indication is generated if enabled (see Section 12.4.7.5, "Error Interrupt"). The MSCAN remains able to transmit messages while the receiver FIFO being filled, but all incoming messages are discarded. As soon as a receive buffer in the FIFO is available again, new valid messages will be accepted.

12.4.3 Identifier Acceptance Filter

The MSCAN identifier acceptance registers (see Section 12.3.2.12, "MSCAN Identifier Acceptance Control Register (CANIDAC)") define the acceptable patterns of the standard or extended identifier (ID[10:0] or ID[28:0]). Any of these bits can be marked 'don't care' in the MSCAN identifier mask registers (see Section 12.3.2.17, "MSCAN Identifier Mask Registers (CANIDMR0–CANIDMR7)").

A filter hit is indicated to the application software by a set receive buffer full flag (RXF = 1) and three bits in the CANIDAC register (see Section 12.3.2.12, "MSCAN Identifier Acceptance Control Register (CANIDAC)"). These identifier hit flags (IDHIT[2:0]) clearly identify the filter section that caused the acceptance. They simplify the application software's task to identify the cause of the receiver interrupt. If more than one hit occurs (two or more filters match), the lower hit has priority.

A very flexible programmable generic identifier acceptance filter has been introduced to reduce the CPU interrupt loading. The filter is programmable to operate in four different modes (see Bosch CAN 2.0A/B protocol specification):

- Two identifier acceptance filters, each to be applied to:
  - The full 29 bits of the extended identifier and to the following bits of the CAN 2.0B frame:
    - Remote transmission request (RTR)
    - Identifier extension (IDE)
    - Substitute remote request (SRR)
  - The 11 bits of the standard identifier plus the RTR and IDE bits of the CAN 2.0A/B messages[1]. This mode implements two filters for a full length CAN 2.0B compliant extended identifier. Figure 12-39 shows how the first 32-bit filter bank (CANIDAR0–CANIDAR3, CANIDMR0–CANIDMR3) produces a filter 0 hit. Similarly, the second filter bank (CANIDAR4–CANIDAR7, CANIDMR4–CANIDMR7) produces a filter 1 hit.

1.Although this mode can be used for standard identifiers, it is recommended to use the four or eight identifier acceptance filters for standard identifiers

- Four identifier acceptance filters, each to be applied to
  - a) the 14 most significant bits of the extended identifier plus the SRR and IDE bits of CAN 2.0B messages or
  - b) the 11 bits of the standard identifier, the RTR and IDE bits of CAN 2.0A/B messages. Figure 12-40 shows how the first 32-bit filter bank (CANIDAR0–CANIDA3, CANIDMR0–3CANIDMR) produces filter 0 and 1 hits. Similarly, the second filter bank (CANIDAR4–CANIDAR7, CANIDMR4–CANIDMR7) produces filter 2 and 3 hits.
- Eight identifier acceptance filters, each to be applied to the first 8 bits of the identifier. This mode implements eight independent filters for the first 8 bits of a CAN 2.0A/B compliant standard identifier or a CAN 2.0B compliant extended identifier. Figure 12-41 shows how the first 32-bit filter bank (CANIDAR0–CANIDAR3, CANIDMR0–CANIDMR3) produces filter 0 to 3 hits. Similarly, the second filter bank (CANIDAR4–CANIDAR7, CANIDMR4–CANIDMR7) produces filter 4 to 7 hits.
- Closed filter. No CAN message is copied into the foreground buffer RxFG, and the RXF flag is never set.

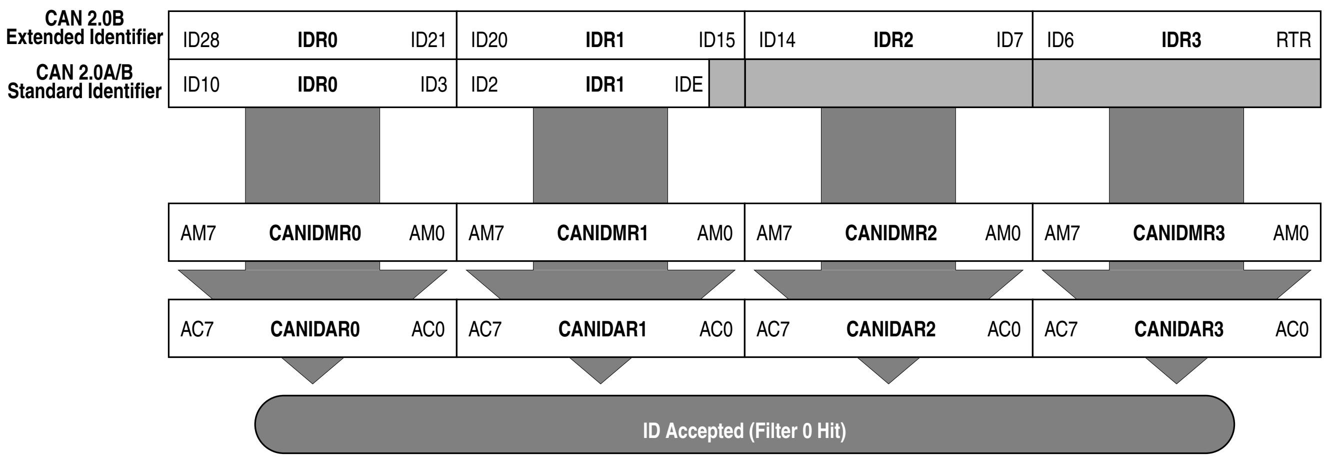

Figure 12-39. 32-bit Maskable Identifier Acceptance Filter

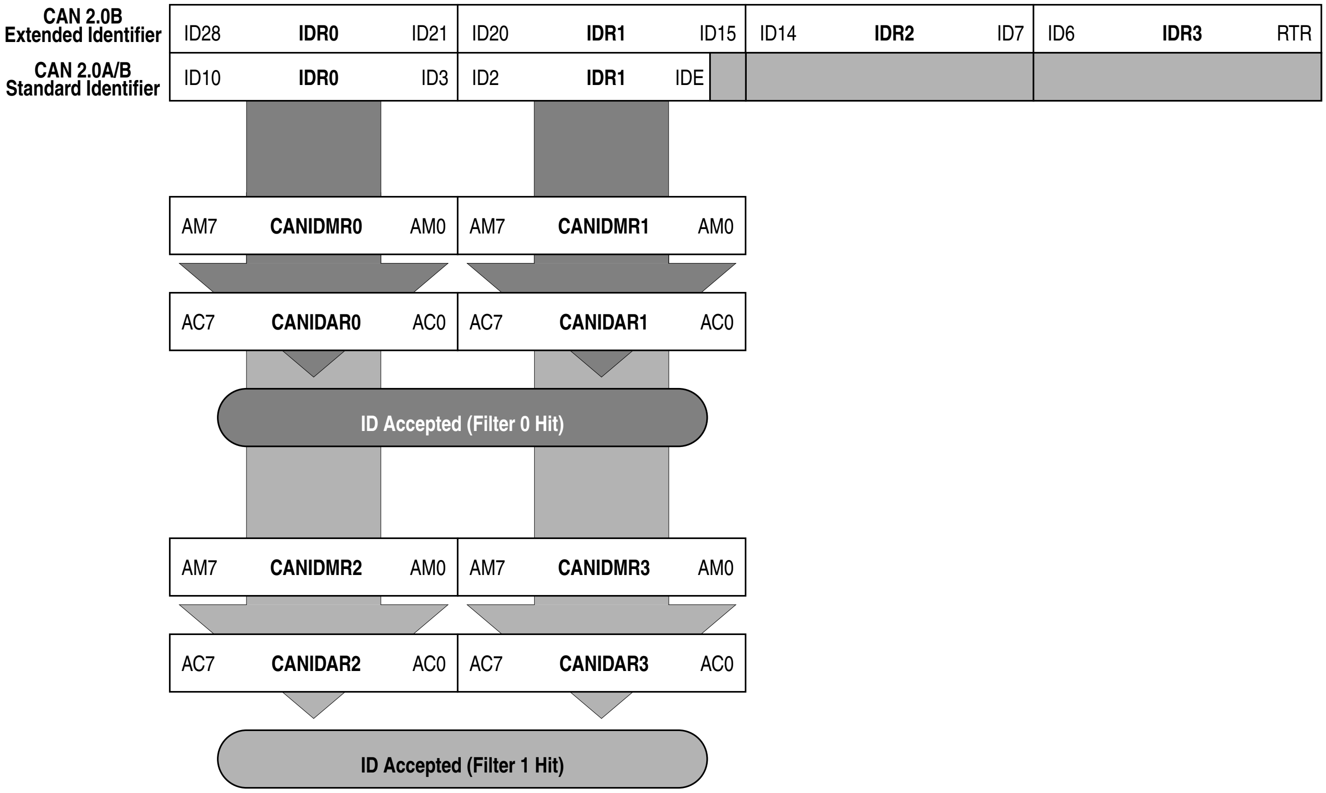

Figure 12-40. 16-bit Maskable Identifier Acceptance Filters

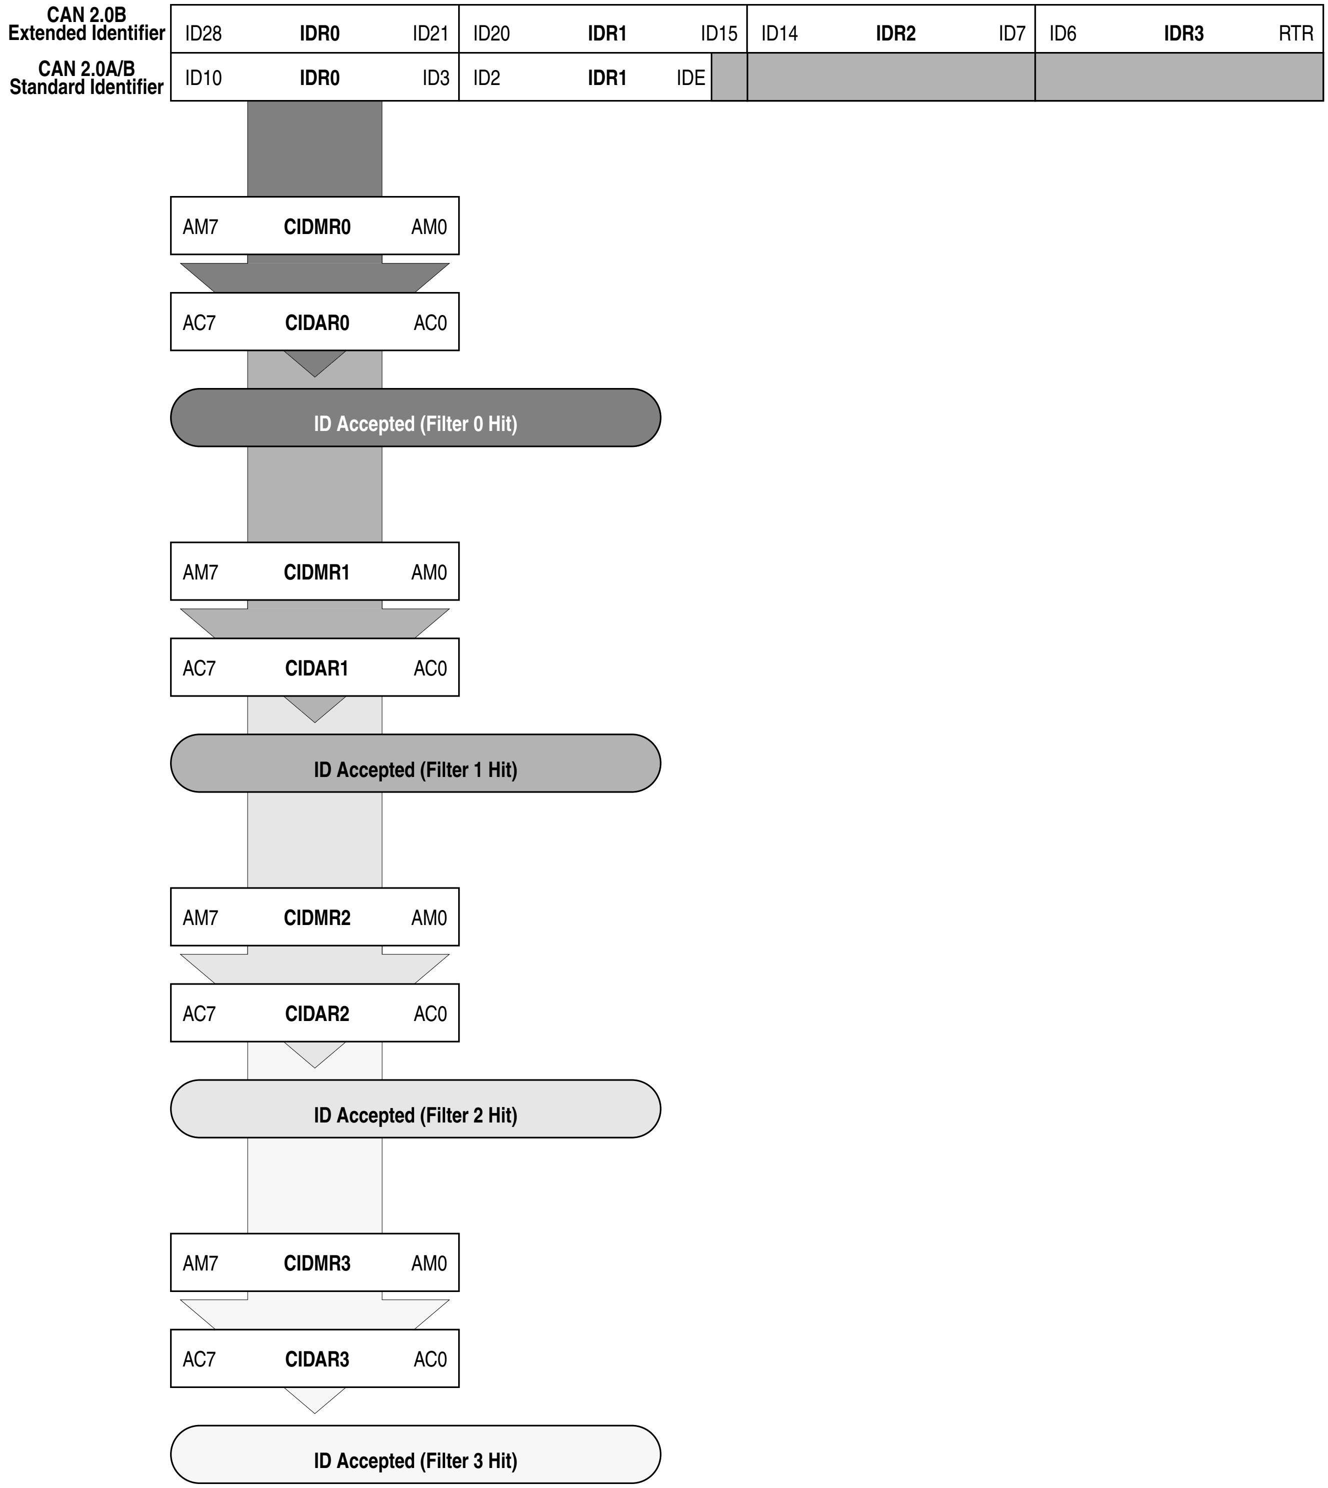

Figure 12-41. 8-bit Maskable Identifier Acceptance Filters

12.4.3.1 Protocol Violation Protection

The MSCAN protects the user from accidentally violating the CAN protocol through programming errors. The protection logic implements the following features:

- The receive and transmit error counters cannot be written or otherwise manipulated.
- All registers which control the configuration of the MSCAN cannot be modified while the MSCAN is on-line. The MSCAN has to be in Initialization Mode. The corresponding INITRQ/INITAK handshake bits in the CANCTL0/CANCTL1 registers (see Section 12.3.2.1, "MSCAN Control Register 0 (CANCTL0)") serve as a lock to protect the following registers:
  - — MSCAN control 1 register (CANCTL1)
  - — MSCAN bus timing registers 0 and 1 (CANBTR0, CANBTR1)
  - — MSCAN identifier acceptance control register (CANIDAC)
  - — MSCAN identifier acceptance registers (CANIDAR0–CANIDAR7)
  - — MSCAN identifier mask registers (CANIDMR0–CANIDMR7)
- The TXCAN pin is immediately forced to a recessive state when the MSCAN goes into the power down mode or initialization mode (see Section 12.4.5.6, "MSCAN Power Down Mode," and Section 12.4.5.5, "MSCAN Initialization Mode").
- The MSCAN enable bit (CANE) is writable only once in normal system operation modes, which provides further protection against inadvertently disabling the MSCAN.

12.4.3.2 Clock System

Figure 12-42 shows the structure of the MSCAN clock generation circuitry.

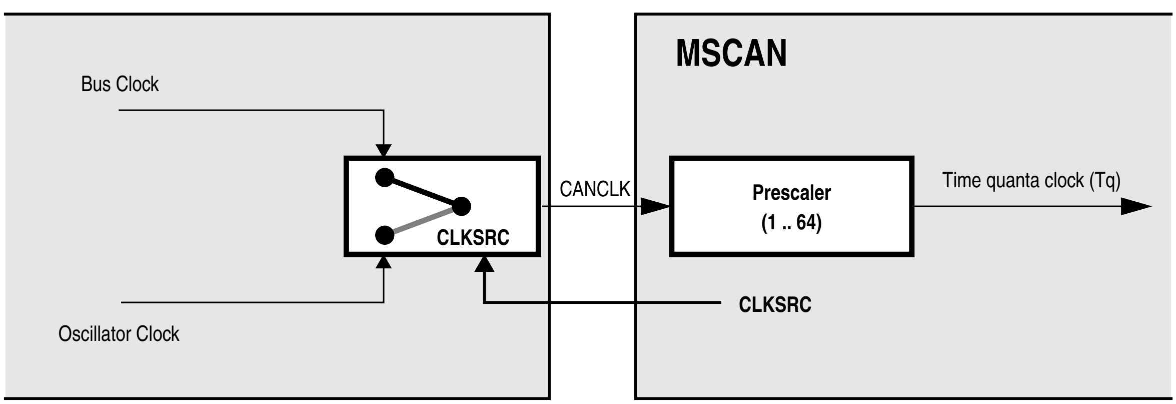

Figure 12-42. MSCAN Clocking Scheme

The clock source bit (CLKSRC) in the CANCTL1 register (12.3.2.2/12-350) defines whether the internal CANCLK is connected to the output of a crystal oscillator (oscillator clock) or to the bus clock.

The clock source has to be chosen such that the tight oscillator tolerance requirements (up to 0.4%) of the CAN protocol are met. Additionally, for high CAN bus rates (1 Mbps), a 45% to 55% duty cycle of the clock is required.

If the bus clock is generated from a PLL, it is recommended to select the oscillator clock rather than the bus clock due to jitter considerations, especially at the faster CAN bus rates.

For microcontrollers without a clock and reset generator (CRG), CANCLK is driven from the crystal oscillator (oscillator clock).

A programmable prescaler generates the time quanta (Tq) clock from CANCLK. A time quantum is the atomic unit of time handled by the MSCAN.

Eqn. 12-2

$$Tq = \frac{f_{CANCLK}}{(\text{Prescaler value})}$$

A bit time is subdivided into three segments as described in the Bosch CAN specification. (see Figure 12-43):

- SYNC_SEG: This segment has a fixed length of one time quantum. Signal edges are expected to happen within this section.
- Time Segment 1: This segment includes the PROP_SEG and the PHASE_SEG1 of the CAN standard. It can be programmed by setting the parameter TSEG1 to consist of 4 to 16 time quanta.
- Time Segment 2: This segment represents the PHASE_SEG2 of the CAN standard. It can be programmed by setting the TSEG2 parameter to be 2 to 8 time quanta long.

Eqn. 12-3

$$\text{Bit Rate} = \frac{f_{Tq}}{(\text{number of Time Quanta})}$$

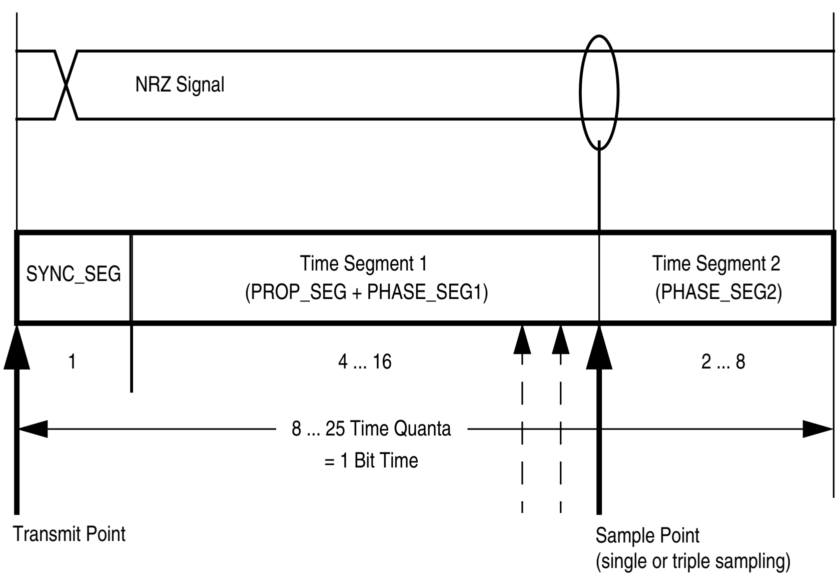

Figure 12-43. Segments within the Bit Time

Table 12-33. Time Segment Syntax

Syntax	Description
SYNC_SEG	System expects transitions to occur on the CAN bus during this period.
Transmit Point	A node in transmit mode transfers a new value to the CAN bus at this point.
Sample Point	A node in receive mode samples the CAN bus at this point. If the three samples per bit option is selected, then this point marks the position of the third sample.

The synchronization jump width (see the Bosch CAN specification for details) can be programmed in a range of 1 to 4 time quanta by setting the SJW parameter.

The SYNC_SEG, TSEG1, TSEG2, and SJW parameters are set by programming the MSCAN bus timing registers (CANBTR0, CANBTR1) (see Section 12.3.2.3, "MSCAN Bus Timing Register 0 (CANBTR0)" and Section 12.3.2.4, "MSCAN Bus Timing Register 1 (CANBTR1)").

Table 12-34 gives an overview of the CAN compliant segment settings and the related parameter values.

NOTE

It is the user's responsibility to ensure the bit time settings are in compliance with the CAN standard.

Table 12-34. CAN Standard Compliant Bit Time Segment Settings

Time Segment 1	TSEG1	Time Segment 2	TSEG2	Synchronization Jump Width	SJW
5 .. 10	4 .. 9	2	1	1 .. 2	0 .. 1
4 .. 11	3 .. 10	3	2	1 .. 3	0 .. 2
5 .. 12	4 .. 11	4	3	1 .. 4	0 .. 3
6 .. 13	5 .. 12	5	4	1 .. 4	0 .. 3
7 .. 14	6 .. 13	6	5	1 .. 4	0 .. 3
8 .. 15	7 .. 14	7	6	1 .. 4	0 .. 3
9 .. 16	8 .. 15	8	7	1 .. 4	0 .. 3

12.4.4 Modes of Operation

12.4.4.1 Normal Modes

The MSCAN module behaves as described within this specification in all normal system operation modes.

12.4.4.2 Special Modes

The MSCAN module behaves as described within this specification in all special system operation modes.

12.4.4.3 Emulation Modes

In all emulation modes, the MSCAN module behaves just like normal system operation modes as described within this specification.

12.4.4.4 Listen-Only Mode

In an optional CAN bus monitoring mode (listen-only), the CAN node is able to receive valid data frames and valid remote frames, but it sends only "recessive" bits on the CAN bus. In addition, it cannot start a transmision. If the MAC sub-layer is required to send a "dominant" bit (ACK bit, overload flag, or active error flag), the bit is rerouted internally so that the MAC sub-layer monitors this "dominant" bit, although the CAN bus may remain in recessive state externally.

12.4.4.5 Security Modes

The MSCAN module has no security features.

12.4.5 Low-Power Options

If the MSCAN is disabled (CANE = 0), the MSCAN clocks are stopped for power saving.

If the MSCAN is enabled (CANE = 1), the MSCAN has two additional modes with reduced power consumption, compared to normal mode: sleep and power down mode. In sleep mode, power consumption is reduced by stopping all clocks except those to access the registers from the CPU side. In power down mode, all clocks are stopped and no power is consumed.

Table 12-35 summarizes the combinations of MSCAN and CPU modes. A particular combination of modes is entered by the given settings on the CSWAI and SLPRQ/SLPAK bits.

For all modes, an MSCAN wake-up interrupt can occur only if the MSCAN is in sleep mode (SLPRQ = 1 and SLPAK = 1), wake-up functionality is enabled (WUPE = 1), and the wake-up interrupt is enabled (WUPIE = 1).

Table 12-35. CPU vs. MSCAN Operating Modes

CPU Mode	MSCAN Mode			
	Normal	Reduced Power Consumption		
		Sleep	Power Down	Disabled (CANE=0)
RUN	CSWAI = X[1] SLPRQ = 0 SLPAK = 0	CSWAI = X SLPRQ = 1 SLPAK = 1		CSWAI = X SLPRQ = X SLPAK = X
WAIT	CSWAI = 0 SLPRQ = 0 SLPAK = 0	CSWAI = 0 SLPRQ = 1 SLPAK = 1	CSWAI = 1 SLPRQ = X SLPAK = X	CSWAI = X SLPRQ = X SLPAK = X
STOP			CSWAI = X SLPRQ = X SLPAK = X	CSWAI = X SLPRQ = X SLPAK = X

[1] 'X' means don't care.

12.4.5.1 Operation in Run Mode

As shown in Table 12-35, only MSCAN sleep mode is available as low power option when the CPU is in run mode.

12.4.5.2 Operation in Wait Mode

The WAI instruction puts the MCU in a low power consumption stand-by mode. If the CSWAI bit is set, additional power can be saved in power down mode because the CPU clocks are stopped. After leaving this power down mode, the MSCAN restarts its internal controllers and enters normal mode again.

While the CPU is in wait mode, the MSCAN can be operated in normal mode and generate interrupts (registers can be accessed via background debug mode). The MSCAN can also operate in any of the low-power modes depending on the values of the SLPRQ/SLPAK and CSWAI bits as seen in Table 12-35.

12.4.5.3 Operation in Stop Mode

The STOP instruction puts the MCU in a low power consumption stand-by mode. In stop mode, the MSCAN is set in power down mode regardless of the value of the SLPRQ/SLPAK and CSWAI bits Table 12-35.

12.4.5.4 MSCAN Sleep Mode

The CPU can request the MSCAN to enter this low power mode by asserting the SLPRQ bit in the CANCTL0 register. The time when the MSCAN enters sleep mode depends on a fixed synchronization delay and its current activity:

- If there are one or more message buffers scheduled for transmission (TXEx = 0), the MSCAN will continue to transmit until all transmit message buffers are empty (TXEx = 1, transmitted successfully or aborted) and then goes into sleep mode.
- If the MSCAN is receiving, it continues to receive and goes into sleep mode as soon as the CAN bus next becomes idle.
- If the MSCAN is neither transmitting nor receiving, it immediately goes into sleep mode.

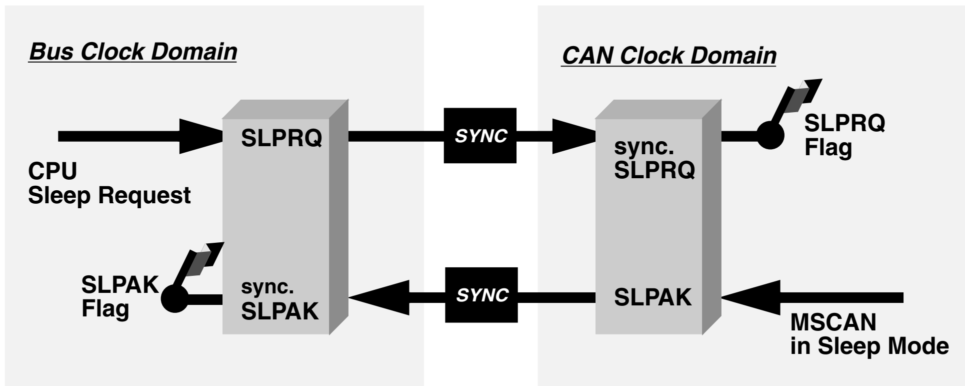

Figure 12-44. Sleep Request / Acknowledge Cycle

NOTE

The application software must avoid setting up a transmission (by clearing one or more TXEx flag(s)) and immediately request sleep mode (by setting SLPRQ). Whether the MSCAN starts transmitting or goes into sleep mode directly depends on the exact sequence of operations.

If sleep mode is active, the SLPRQ and SLPAK bits are set (Figure 12-44). The application software must use SLPAK as a handshake indication for the request (SLPRQ) to go into sleep mode.

When in sleep mode (SLPRQ = 1 and SLPAK = 1), the MSCAN stops its internal clocks. However, clocks that allow register accesses from the CPU side continue to run.

If the MSCAN is in bus-off state, it stops counting the 128 occurrences of 11 consecutive recessive bits due to the stopped clocks. The TXCAN pin remains in a recessive state. If RXF = 1, the message can be read and RXF can be cleared. Shifting a new message into the foreground buffer of the receiver FIFO (RxFG) does not take place while in sleep mode.

It is possible to access the transmit buffers and to clear the associated TXE flags. No message abort takes place while in sleep mode.

If the WUPE bit in CANCLT0 is not asserted, the MSCAN will mask any activity it detects on CAN. The RXCAN pin is therefore held internally in a recessive state. This locks the MSCAN in sleep mode (Figure 12-45). WUPE must be set before entering sleep mode to take effect.

The MSCAN is able to leave sleep mode (wake up) only when:

- CAN bus activity occurs and WUPE = 1
  or
- the CPU clears the SLPRQ bit

NOTE

The CPU cannot clear the SLPRQ bit before sleep mode (SLPRQ = 1 and SLPAK = 1) is active.

After wake-up, the MSCAN waits for 11 consecutive recessive bits to synchronize to the CAN bus. As a consequence, if the MSCAN is woken-up by a CAN frame, this frame is not received.

The receive message buffers (RxFG and RxBG) contain messages if they were received before sleep mode was entered. All pending actions will be executed upon wake-up; copying of RxBG into RxFG, message aborts and message transmissions. If the MSCAN remains in bus-off state after sleep mode was exited, it continues counting the 128 occurrences of 11 consecutive recessive bits.

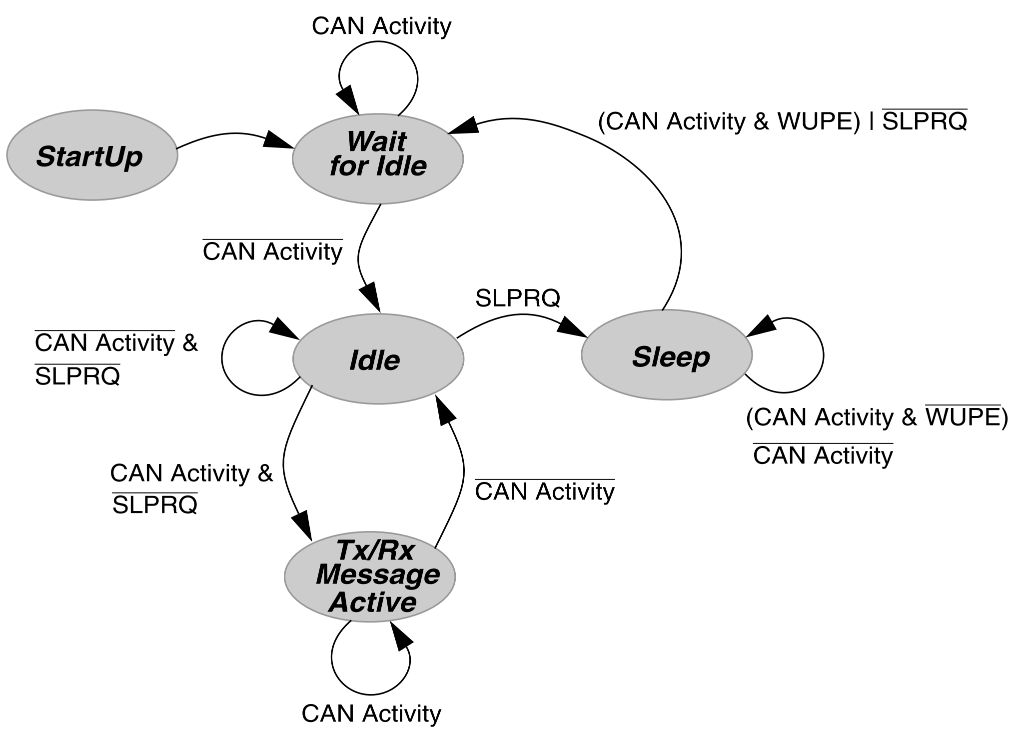

Figure 12-45. Simplified State Transitions for Entering/Leaving Sleep Mode

12.4.5.5 MSCAN Initialization Mode

In initialization mode, any on-going transmission or reception is immediately aborted and synchronization to the CAN bus is lost, potentially causing CAN protocol violations. To protect the CAN bus system from fatal consequences of violations, the MSCAN immediately drives the TXCAN pin into a recessive state.

NOTE

The user is responsible for ensuring that the MSCAN is not active when initialization mode is entered. The recommended procedure is to bring the MSCAN into sleep mode (SLPRQ = 1 and SLPAK = 1) before setting the INITRQ bit in the CANCTL0 register. Otherwise, the abort of an on-going message can cause an error condition and can impact other CAN bus devices.

In initialization mode, the MSCAN is stopped. However, interface registers remain accessible. This mode is used to reset the CANCTL0, CANRFLG, CANRIER, CANTFLG, CANTIER, CANTARQ, CANTAAK, and CANTBSEL registers to their default values. In addition, the MSCAN enables the configuration of the CANBTR0, CANBTR1 bit timing registers; CANIDAC; and the CANIDAR, CANIDMR message filters. See Section 12.3.2.1, "MSCAN Control Register 0 (CANCTL0)," for a detailed description of the initialization mode.

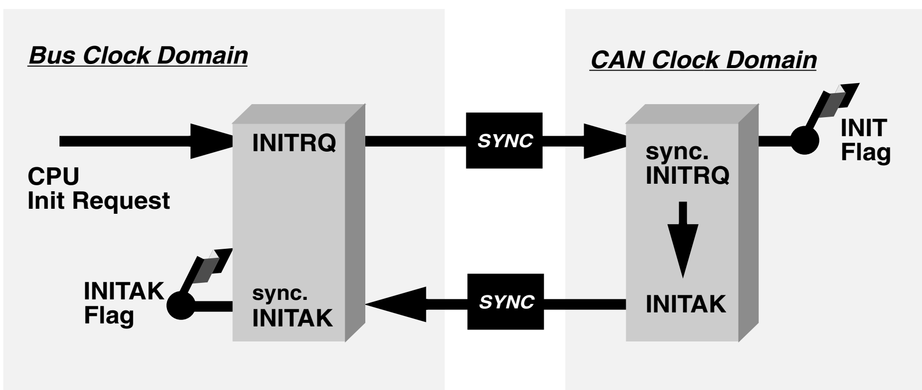

Figure 12-46. Initialization Request/Acknowledge Cycle

Due to independent clock domains within the MSCAN, INITRQ must be synchronized to all domains by using a special handshake mechanism. This handshake causes additional synchronization delay (see Section Figure 12-46., "Initialization Request/Acknowledge Cycle").

If there is no message transfer ongoing on the CAN bus, the minimum delay will be two additional bus clocks and three additional CAN clocks. When all parts of the MSCAN are in initialization mode, the INITAK flag is set. The application software must use INITAK as a handshake indication for the request (INITRQ) to go into initialization mode.

NOTE

The CPU cannot clear INITRQ before initialization mode (INITRQ = 1 and INITAK = 1) is active.

12.4.5.6 MSCAN Power Down Mode

The MSCAN is in power down mode (Table 12-35) when

- CPU is in stop mode

  or
- CPU is in wait mode and the CSWAI bit is set

When entering the power down mode, the MSCAN immediately stops all ongoing transmissions and receptions, potentially causing CAN protocol violations. To protect the CAN bus system from fatal consequences of violations to the above rule, the MSCAN immediately drives the TXCAN pin into a recessive state.

NOTE

The user is responsible for ensuring that the MSCAN is not active when power down mode is entered. The recommended procedure is to bring the MSCAN into Sleep mode before the STOP or WAI instruction (if CSWAI is set) is executed. Otherwise, the abort of an ongoing message can cause an error condition and impact other CAN bus devices.

In power down mode, all clocks are stopped and no registers can be accessed. If the MSCAN was not in sleep mode before power down mode became active, the module performs an internal recovery cycle after powering up. This causes some fixed delay before the module enters normal mode again.

12.4.5.7 Programmable Wake-Up Function

The MSCAN can be programmed to wake up the MSCAN as soon as CAN bus activity is detected (see control bit WUPE in Section 12.3.2.1, "MSCAN Control Register 0 (CANCTL0)"). The sensitivity to existing CAN bus action can be modified by applying a low-pass filter function to the RXCAN input line while in sleep mode (see control bit WUPM in Section 12.3.2.2, "MSCAN Control Register 1 (CANCTL1)").

This feature can be used to protect the MSCAN from wake-up due to short glitches on the CAN bus lines. Such glitches can result from—for example—electromagnetic interference within noisy environments.

12.4.6 Reset Initialization

The reset state of each individual bit is listed in Section 12.3.2, "Register Descriptions," which details all the registers and their bit-fields.

12.4.7 Interrupts

This section describes all interrupts originated by the MSCAN. It documents the enable bits and generated flags. Each interrupt is listed and described separately.

12.4.7.1 Description of Interrupt Operation

The MSCAN supports four interrupt vectors (see Table 12-36), any of which can be individually masked (for details see sections from Section 12.3.2.6, "MSCAN Receiver Interrupt Enable Register (CANRIER)," to Section 12.3.2.8, "MSCAN Transmitter Interrupt Enable Register (CANTIER)").

NOTE

The dedicated interrupt vector addresses are defined in the Resets and Interrupts chapter.

Table 12-36. Interrupt Vectors

Interrupt Source	CCR Mask	Local Enable
Wake-Up Interrupt (WUPIF)	I bit	CANRIER (WUPIE)
Error Interrupts Interrupt (CSCIF, OVRIF)	I bit	CANRIER (CSCIE, OVRIE)
Receive Interrupt (RXF)	I bit	CANRIER (RXFIE)
Transmit Interrupts (TXE[2:0])	I bit	CANTIER (TXEIE[2:0])

12.4.7.2 Transmit Interrupt

At least one of the three transmit buffers is empty (not scheduled) and can be loaded to schedule a message for transmission. The TXEx flag of the empty message buffer is set.

12.4.7.3 Receive Interrupt

A message is successfully received and shifted into the foreground buffer (RxFG) of the receiver FIFO. This interrupt is generated immediately after receiving the EOF symbol. The RXF flag is set. If there are multiple messages in the receiver FIFO, the RXF flag is set as soon as the next message is shifted to the foreground buffer.

12.4.7.4 Wake-Up Interrupt

A wake-up interrupt is generated if activity on the CAN bus occurs during MSCN internal sleep mode. WUPE (see Section 12.3.2.1, "MSCAN Control Register 0 (CANCTL0)") must be enabled.

12.4.7.5 Error Interrupt

An error interrupt is generated if an overrun of the receiver FIFO, error, warning, or bus-off condition occurs. Section 12.3.2.5, "MSCAN Receiver Flag Register (CANRFLG) indicates one of the following conditions:

- **Overrun** — An overrun condition of the receiver FIFO as described in Section 12.4.2.3, "Receive Structures," occurred.
- **CAN Status Change** — The actual value of the transmit and receive error counters control the CAN bus state of the MSCAN. As soon as the error counters skip into a critical range (Tx/Rx-warning, Tx/Rx-error, bus-off) the MSCAN flags an error condition. The status change, which caused the error condition, is indicated by the TSTAT and RSTAT flags (see

Section 12.3.2.5, "MSCAN Receiver Flag Register (CANRFLG)" and Section 12.3.2.6, "MSCAN Receiver Interrupt Enable Register (CANRIER)").

12.4.7.6 Interrupt Acknowledge

Interrupts are directly associated with one or more status flags in either the Section 12.3.2.5, "MSCAN Receiver Flag Register (CANRFLG)" or the Section 12.3.2.7, "MSCAN Transmitter Flag Register (CANTFLG)." Interrupts are pending as long as one of the corresponding flags is set. The flags in CANRFLG and CANTFLG must be reset within the interrupt handler to handshake the interrupt. The flags are reset by writing a 1 to the corresponding bit position. A flag cannot be cleared if the respective condition prevails.

NOTE

It must be guaranteed that the CPU clears only the bit causing the current interrupt. For this reason, bit manipulation instructions (BSET) must not be used to clear interrupt flags. These instructions may cause accidental clearing of interrupt flags which are set after entering the current interrupt service routine.

12.4.7.7 Recovery from Stop or Wait

The MSCAN can recover from stop or wait via the wake-up interrupt. This interrupt can only occur if the MSCAN was in sleep mode (SLPRQ = 1 and SLPAK = 1) before entering power down mode, the wake-up option is enabled (WUPE = 1), and the wake-up interrupt is enabled (WUPIE = 1).

12.5 Initialization/Application Information

12.5.1 MSCAN initialization

The procedure to initially start up the MSCAN module out of reset is as follows:

1. Assert CANE
2. Write to the configuration registers in initialization mode
3. Clear INITRQ to leave initialization mode and enter normal mode

If the configuration of registers which are writable in initialization mode needs to be changed only when the MSCAN module is in normal mode:

1. Bring the module into sleep mode by setting SLPRQ and awaiting SLPAK to assert after the CAN bus becomes idle.
2. Enter initialization mode: assert INITRQ and await INITAK
3. Write to the configuration registers in initialization mode
4. Clear INITRQ to leave initialization mode and continue in normal mode

Chapter 13
Oscillator (OSCV2) Block Description

13.1 Introduction

The OSC module provides two alternative oscillator concepts:

- A low noise and low power Colpitts oscillator with amplitude limitation control (ALC)
- A robust full swing Pierce oscillator with the possibility to feed in an external square wave

13.1.1 Features

The Colpitts OSC option provides the following features:

- Amplitude limitation control (ALC) loop:
  - Low power consumption and low current induced RF emission
  - Sinusoidal waveform with low RF emission
  - Low crystal stress (an external damping resistor is not required)
  - Normal and low amplitude mode for further reduction of power and emission
- An external biasing resistor is not required

The Pierce OSC option provides the following features:

- Wider high frequency operation range
- No DC voltage applied across the crystal
- Full rail-to-rail (2.5 V nominal) swing oscillation with low EM susceptibility
- Fast start up

Common features:

- Clock monitor (CM)
- Operation from the V_{DDPLL} 2.5 V (nominal) supply rail

13.1.2 Modes of Operation

Two modes of operation exist:

- Amplitude limitation controlled Colpitts oscillator mode suitable for power and emission critical applications
- Full swing Pierce oscillator mode that can also be used to feed in an externally generated square wave suitable for high frequency operation and harsh environments

13.2 External Signal Description

This section lists and describes the signals that connect off chip.

13.2.1 V_{DDPLL} and V_{SSPLL} — PLL Operating Voltage, PLL Ground

These pins provide the operating voltage (V_{DDPLL}) and ground (V_{SSPLL}) for the OSC circuitry. This allows the supply voltage to the OSC to be independently bypassed.

13.2.2 EXTAL and XTAL — Clock/Crystal Source Pins

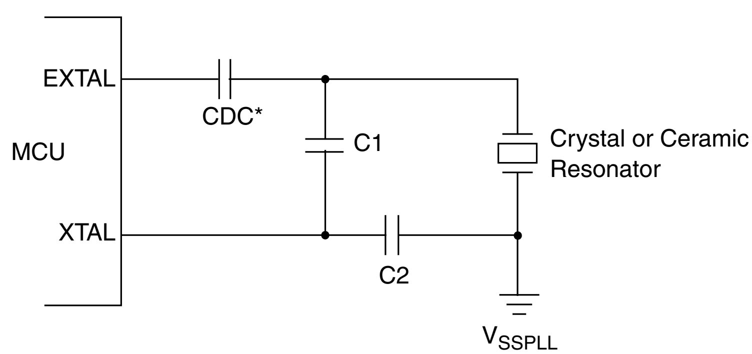
These pins provide the interface for either a crystal or a CMOS compatible clock to control the internal clock generator circuitry. EXTAL is the external clock input or the input to the crystal oscillator amplifier. XTAL is the output of the crystal oscillator amplifier. All the MCU internal system clocks are derived from the EXTAL input frequency. In full stop mode (PSTP = 0) the EXTAL pin is pulled down by an internal resistor of typical 200 kΩ.

NOTE

Freescale Semiconductor recommends an evaluation of the application board and chosen resonator or crystal by the resonator or crystal supplier.

The Crystal circuit is changed from standard.

The Colpitts circuit is not suited for overtone resonators and crystals.



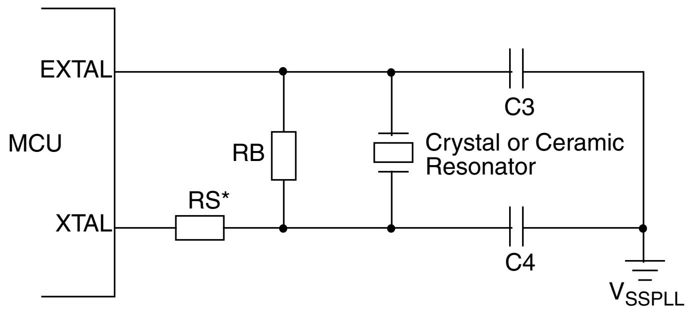
* Due to the nature of a translated ground Colpitts oscillator a DC voltage bias is applied to the crystal.

Please contact the crystal manufacturer for crystal DC bias conditions and recommended capacitor value CDC.

Figure 13-1. Colpitts Oscillator Connections (XCLKS = 0)

NOTE

The Pierce circuit is not suited for overtone resonators and crystals without a careful component selection.



* Rs can be zero (shorted) when used with higher frequency crystals.
Refer to manufacturer's data.

Figure 13-2. Pierce Oscillator Connections (XCLKS = 1)

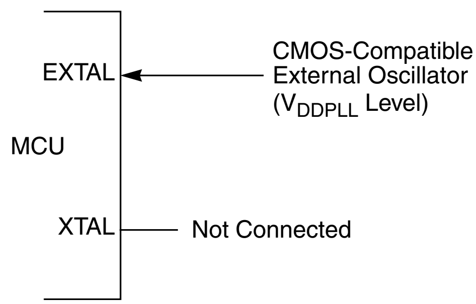


Figure 13-3. External Clock Connections (XCLKS = 1)

13.2.3 XCLKS — Colpitts/Pierce Oscillator Selection Signal

The XCLKS is an input signal which controls whether a crystal in combination with the internal Colpitts (low power) oscillator is used or whether the Pierce oscillator/external clock circuitry is used. The XCLKS signal is sampled during reset with the rising edge of $\overline{\text{RESET}}$. Table 13-1 lists the state coding of the sampled XCLKS signal. Refer to the device overview chapter for polarity of the XCLKS pin.

Table 13-1. Clock Selection Based on XCLKS

XCLKS	Description
0	Colpitts oscillator selected
1	Pierce oscillator/external clock selected

13.3 Memory Map and Register Definition

The CRG contains the registers and associated bits for controlling and monitoring the OSC module.

13.4 Functional Description

The OSC block has two external pins, EXTAL and XTAL. The oscillator input pin, EXTAL, is intended to be connected to either a crystal or an external clock source. The selection of Colpitts oscillator or Pierce oscillator/external clock depends on the XCLKS signal which is sampled during reset. The XTAL pin is an output signal that provides crystal circuit feedback.

A buffered EXTAL signal, OSCCLK, becomes the internal reference clock. To improve noise immunity, the oscillator is powered by the V_{DDPLL} and V_{SSPLL} power supply pins.

The Pierce oscillator can be used for higher frequencies compared to the low power Colpitts oscillator.

13.4.1 Amplitude Limitation Control (ALC)

The Colpitts oscillator is equipped with a feedback system which does not waste current by generating harmonics. Its configuration is “Colpitts oscillator with translated ground.” The transconductor used is driven by a current source under the control of a peak detector which will measure the amplitude of the AC signal appearing on EXTAL node in order to implement an amplitude limitation control (ALC) loop. The ALC loop is in charge of reducing the quiescent current in the transconductor as a result of an increase in the oscillation amplitude. The oscillation amplitude can be limited to two values. The normal amplitude which is intended for non power saving modes and a small amplitude which is intended for low power operation modes. Please refer to the CRG block description chapter for the control and assignment of the amplitude value to operation modes.

13.4.2 Clock Monitor (CM)

The clock monitor circuit is based on an internal resistor-capacitor (RC) time delay so that it can operate without any MCU clocks. If no OSCCLK edges are detected within this RC time delay, the clock monitor indicates a failure which asserts self clock mode or generates a system reset depending on the state of SCME bit. If the clock monitor is disabled or the presence of clocks is detected no failure is indicated.The clock monitor function is enabled/disabled by the CME control bit, described in the CRG block description chapter.

13.5 Interrupts

OSC contains a clock monitor, which can trigger an interrupt or reset. The control bits and status bits for the clock monitor are described in the CRG block description chapter.

Chapter 14
Pulse-Width Modulator (PWM8B8CV1)

14.1 Introduction

The PWM definition is based on the HC12 PWM definitions. It contains the basic features from the HC11 with some of the enhancements incorporated on the HC12: center aligned output mode and four available clock sources.The PWM module has eight channels with independent control of left and center aligned outputs on each channel.

Each of the eight channels has a programmable period and duty cycle as well as a dedicated counter. A flexible clock select scheme allows a total of four different clock sources to be used with the counters. Each of the modulators can create independent continuous waveforms with software-selectable duty rates from 0% to 100%. The PWM outputs can be programmed as left aligned outputs or center aligned outputs.

14.1.1 Features

The PWM block includes these distinctive features:

- Eight independent PWM channels with programmable period and duty cycle
- Dedicated counter for each PWM channel
- Programmable PWM enable/disable for each channel
- Software selection of PWM duty pulse polarity for each channel
- Period and duty cycle are double buffered. Change takes effect when the end of the effective period is reached (PWM counter reaches zero) or when the channel is disabled.
- Programmable center or left aligned outputs on individual channels
- Eight 8-bit channel or four 16-bit channel PWM resolution
- Four clock sources (A, B, SA, and SB) provide for a wide range of frequencies
- Programmable clock select logic
- Emergency shutdown

14.1.2 Modes of Operation

There is a software programmable option for low power consumption in wait mode that disables the input clock to the prescaler.

In freeze mode there is a software programmable option to disable the input clock to the prescaler. This is useful for emulation.

14.1.3 Block Diagram

Figure 14-1 shows the block diagram for the 8-bit 8-channel PWM block.

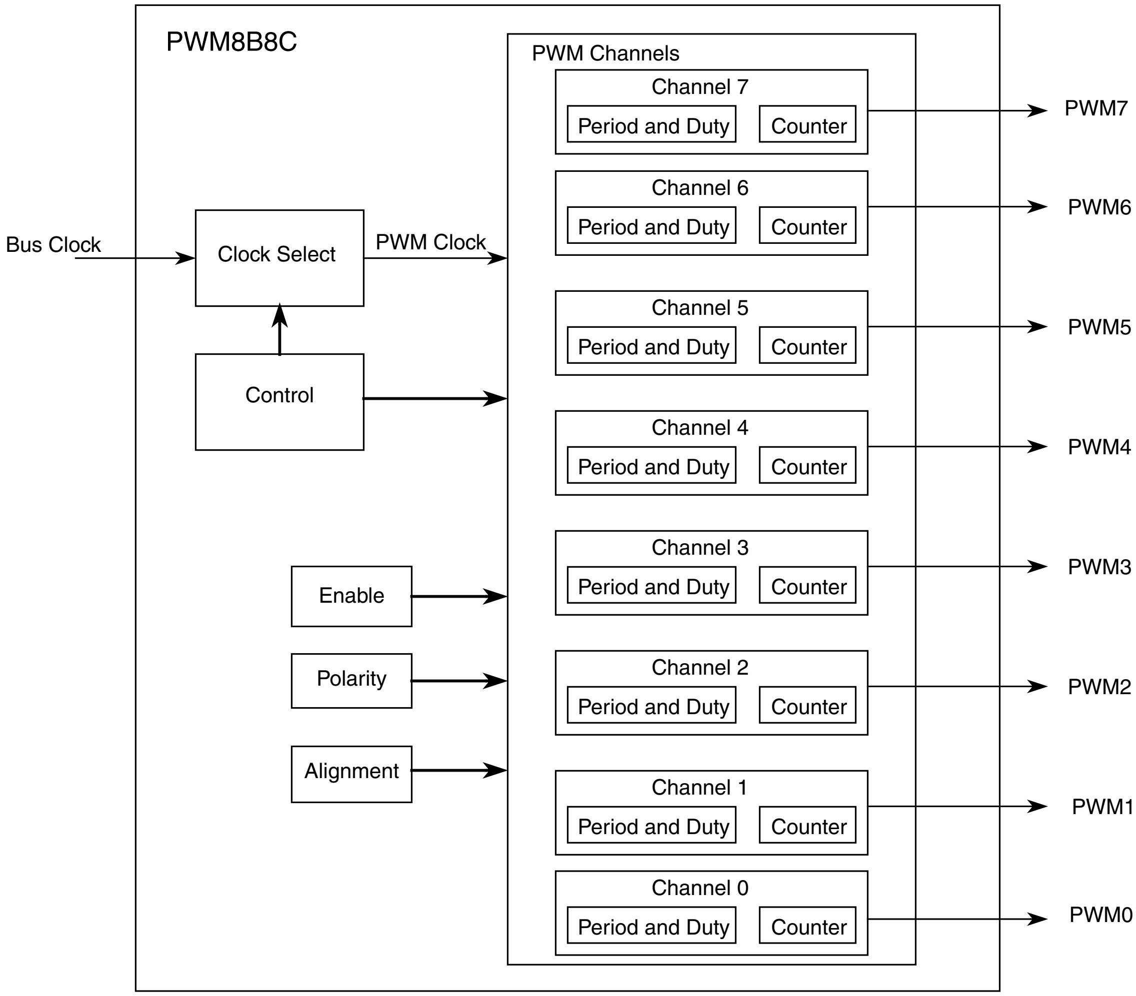

Figure 14-1. PWM Block Diagram

14.2 External Signal Description

The PWM module has a total of 8 external pins.

14.2.1 PWM7 — PWM Channel 7

This pin serves as waveform output of PWM channel 7 and as an input for the emergency shutdown feature.

14.2.2 PWM6 — PWM Channel 6

This pin serves as waveform output of PWM channel 6.

14.2.3 PWM5 — PWM Channel 5

This pin serves as waveform output of PWM channel 5.

14.2.4 PWM4 — PWM Channel 4

This pin serves as waveform output of PWM channel 4.

14.2.5 PWM3 — PWM Channel 3

This pin serves as waveform output of PWM channel 3.

14.2.6 PWM3 — PWM Channel 2

This pin serves as waveform output of PWM channel 2.

14.2.7 PWM3 — PWM Channel 1

This pin serves as waveform output of PWM channel 1.

14.2.8 PWM3 — PWM Channel 0

This pin serves as waveform output of PWM channel 0.

14.3 Memory Map and Register Definition

This section describes in detail all the registers and register bits in the PWM module.

The special-purpose registers and register bit functions that are not normally available to device end users, such as factory test control registers and reserved registers, are clearly identified by means of shading the appropriate portions of address maps and register diagrams. Notes explaining the reasons for restricting access to the registers and functions are also explained in the individual register descriptions.

14.3.1 Module Memory Map

This section describes the content of the registers in the PWM module. The base address of the PWM module is determined at the MCU level when the MCU is defined. The register decode map is fixed and begins at the first address of the module address offset. The figure below shows the registers associated with the PWM and their relative offset from the base address. The register detail description follows the order they appear in the register map.

Reserved bits within a register will always read as 0 and the write will be unimplemented. Unimplemented functions are indicated by shading the bit. .

NOTE

Register Address = Base Address + Address Offset, where the Base Address is defined at the MCU level and the Address Offset is defined at the module level.

14.3.2 Register Descriptions

This section describes in detail all the registers and register bits in the PWM module.

Register Name		Bit 7	6	5	4	3	2	1	Bit 0
0x0000 PWME	R/W	PWME7	PWME6	PWME5	PWME4	PWME3	PWME2	PWME1	PWME0
0x0001 PWMPOL	R/W	PPOL7	PPOL6	PPOL5	PPOL4	PPOL3	PPOL2	PPOL1	PPOL0

Figure 14-2. PWM Register Summary (Sheet 3 of 3)

1 Intended for factory test purposes only.

14.3.2.1 PWM Enable Register (PWME)

Each PWM channel has an enable bit (PWMEx) to start its waveform output. When any of the PWMEx bits are set (PWMEx = 1), the associated PWM output is enabled immediately. However, the actual PWM waveform is not available on the associated PWM output until its clock source begins its next cycle due to the synchronization of PWMEx and the clock source.

NOTE

The first PWM cycle after enabling the channel can be irregular.

An exception to this is when channels are concatenated. Once concatenated mode is enabled (CONxx bits set in PWMCTL register), enabling/disabling the corresponding 16-bit PWM channel is controlled by the low order PWMEx bit.In this case, the high order bytes PWMEx bits have no effect and their corresponding PWM output lines are disabled.

While in run mode, if all eight PWM channels are disabled (PWME7–0 = 0), the prescaler counter shuts off for power savings.

Module Base + 0x0000

Table 14-1. PWME Field Descriptions

Field	Description
7 PWME7	**Pulse Width Channel 7 Enable** 0 Pulse width channel 7 is disabled. 1 Pulse width channel 7 is enabled. The pulse modulated signal becomes available at PWM output bit 7 when its clock source begins its next cycle.
6 PWME6	**Pulse Width Channel 6 Enable** 0 Pulse width channel 6 is disabled. 1 Pulse width channel 6 is enabled. The pulse modulated signal becomes available at PWM output bit6 when its clock source begins its next cycle. If CON67=1, then bit has no effect and PWM output line 6 is disabled.
5 PWME5	**Pulse Width Channel 5 Enable** 0 Pulse width channel 5 is disabled. 1 Pulse width channel 5 is enabled. The pulse modulated signal becomes available at PWM output bit 5 when its clock source begins its next cycle.
4 PWME4	**Pulse Width Channel 4 Enable** 0 Pulse width channel 4 is disabled. 1 Pulse width channel 4 is enabled. The pulse modulated signal becomes available at PWM, output bit 4 when its clock source begins its next cycle. If CON45 = 1, then bit has no effect and PWM output bit4 is disabled.
3 PWME3	**Pulse Width Channel 3 Enable** 0 Pulse width channel 3 is disabled. 1 Pulse width channel 3 is enabled. The pulse modulated signal becomes available at PWM, output bit 3 when its clock source begins its next cycle.
2 PWME2	**Pulse Width Channel 2 Enable** 0 Pulse width channel 2 is disabled. 1 Pulse width channel 2 is enabled. The pulse modulated signal becomes available at PWM, output bit 2 when its clock source begins its next cycle. If CON23 = 1, then bit has no effect and PWM output bit2 is disabled.

Table 14-1. PWME Field Descriptions (continued)

Field	Description
1 PWME1	**Pulse Width Channel 1 Enable** 0 Pulse width channel 1 is disabled. 1 Pulse width channel 1 is enabled. The pulse modulated signal becomes available at PWM, output bit 1 when its clock source begins its next cycle.
0 PWME0	**Pulse Width Channel 0 Enable** 0 Pulse width channel 0 is disabled. 1 Pulse width channel 0 is enabled. The pulse modulated signal becomes available at PWM, output bit 0 when its clock source begins its next cycle. If CON01 = 1, then bit has no effect and PWM output line0 is disabled.

14.3.2.2 PWM Polarity Register (PWMPOL)

The starting polarity of each PWM channel waveform is determined by the associated PPOLx bit in the PWMPOL register. If the polarity bit is one, the PWM channel output is high at the beginning of the cycle and then goes low when the duty count is reached. Conversely, if the polarity bit is zero, the output starts low and then goes high when the duty count is reached.

Module Base + 0x0001

	7	6	5	4	3	2	1	0
R W	PPOL7	PPOL6	PPOL5	PPOL4	PPOL3	PPOL2	PPOL1	PPOL0

1	1	0	Bus clock / 64
1	1	1	Bus clock / 128

14.3.2.5 PWM Center Align Enable Register (PWMCAE)

The PWMCAE register contains eight control bits for the selection of center aligned outputs or left aligned outputs for each PWM channel. If the CAEx bit is set to a one, the corresponding PWM output will be center aligned. If the CAEx bit is cleared, the corresponding PWM output will be left aligned. See Section 14.4.2.5, “Left Aligned Outputs” and Section 14.4.2.6, “Center Aligned Outputs” for a more detailed description of the PWM output modes.

Module Base + 0x0004

	7	6	5	4	3	2	1	0

= Unimplemented or Reserved

Figure 14-8. PWM Control Register (PWMCTL)

Read: Anytime

Write: Anytime

There are three control bits for concatenation, each of which is used to concatenate a pair of PWM channels into one 16-bit channel. When channels 6 and 7are concatenated, channel 6 registers become the high order bytes of the double byte channel. When channels 4 and 5 are concatenated, channel 4 registers become the high order bytes of the double byte channel. When channels 2 and 3 are concatenated, channel

2 registers become the high order bytes of the double byte channel. When channels 0 and 1 are concatenated, channel 0 registers become the high order bytes of the double byte channel.

See Section 14.4.2.7, “PWM 16-Bit Functions” for a more detailed description of the concatenation PWM Function.

NOTE

Change these bits only when both corresponding channels are disabled.

Table 14-8. PWMCTL Field Descriptions

Field	Description
7 CON67	**Concatenate Channels 6 and 7** 0 Channels 6 and 7 are separate 8-bit PWMs. 1 Channels 6 and 7 are concatenated to create one 16-bit PWM channel. Channel 6 becomes the high order byte and channel 7 becomes the low order byte. Channel 7 output pin is used as the output for this 16-bit PWM (bit 7 of port PWMP). Channel 7 clock select control-bit determines the clock source, channel 7 polarity bit determines the polarity, channel 7 enable bit enables the output and channel 7 center aligned enable bit determines the output mode.
6 CON45	**Concatenate Channels 4 and 5** 0 Channels 4 and 5 are separate 8-bit PWMs. 1 Channels 4 and 5 are concatenated to create one 16-bit PWM channel. Channel 4 becomes the high order byte and channel 5 becomes the low order byte. Channel 5 output pin is used as the output for this 16-bit PWM (bit 5 of port PWMP). Channel 5 clock select control-bit determines the clock source, channel 5 polarity bit determines the polarity, channel 5 enable bit enables the output and channel 5 center aligned enable bit determines the output mode.
5 CON23	**Concatenate Channels 2 and 3** 0 Channels 2 and 3 are separate 8-bit PWMs. 1 Channels 2 and 3 are concatenated to create one 16-bit PWM channel. Channel 2 becomes the high order byte and channel 3 becomes the low order byte. Channel 3 output pin is used as the output for this 16-bit PWM (bit 3 of port PWMP). Channel 3 clock select control-bit determines the clock source, channel 3 polarity bit determines the polarity, channel 3 enable bit enables the output and channel 3 center aligned enable bit determines the output mode.
4 CON01	**Concatenate Channels 0 and 1** 0 Channels 0 and 1 are separate 8-bit PWMs. 1 Channels 0 and 1 are concatenated to create one 16-bit PWM channel. Channel 0 becomes the high order byte and channel 1 becomes the low order byte. Channel 1 output pin is used as the output for this 16-bit PWM (bit 1 of port PWMP). Channel 1 clock select control-bit determines the clock source, channel 1 polarity bit determines the polarity, channel 1 enable bit enables the output and channel 1 center aligned enable bit determines the output mode.
3 PSWAI	**PWM Stops in Wait Mode —** Enabling this bit allows for lower power consumption in wait mode by disabling the input clock to the prescaler. 0 Allow the clock to the prescaler to continue while in wait mode. 1 Stop the input clock to the prescaler whenever the MCU is in wait mode.
2 PFREZ	**PWM Counters Stop in Freeze Mode** — In freeze mode, there is an option to disable the input clock to the prescaler by setting the PFRZ bit in the PWMCTL register. If this bit is set, whenever the MCU is in freeze mode, the input clock to the prescaler is disabled. This feature is useful during emulation as it allows the PWM function to be suspended. In this way, the counters of the PWM can be stopped while in freeze mode so that once normal program flow is continued, the counters are re-enabled to simulate real-time operations. Since the registers can still be accessed in this mode, to re-enable the prescaler clock, either disable the PFRZ bit or exit freeze mode. 0 Allow PWM to continue while in freeze mode. 1 Disable PWM input clock to the prescaler whenever the part is in freeze mode. This is useful for emulation.

14.3.2.7 Reserved Register (PWMTST)

This register is reserved for factory testing of the PWM module and is not available in normal modes.

Module Base + 0x0006

	7	6	5	4	3	2	1	0
R	0	0	0	0	0	0	0	0
W								
Reset	0	0	0	0	0	0	0	0

Write: Unimplemented in normal modes

NOTE

Writing to this register when in special modes can alter the PWM functionality.

14.3.2.9 PWM Scale A Register (PWMSCLA)

PWMSCLA is the programmable scale value used in scaling clock A to generate clock SA. Clock SA is generated by taking clock A, dividing it by the value in the PWMSCLA register and dividing that by two.

Clock SA = Clock A / (2 * PWMSCLA)

NOTE

When PWMSCLA = $00, PWMSCLA value is considered a full scale value of 256. Clock A is thus divided by 512.

Any value written to this register will cause the scale counter to load the new scale value (PWMSCLA).

Module Base + 0x0008

	7	6	5	4	3	2	1	0
R W	Bit 7	6	5	4	3	2	1	Bit 0
Reset	0	0	0	0	0	0	0	0

Read: Anytime

Write: Anytime (causes the scale counter to load the PWMSCLA value)

14.3.2.10 PWM Scale B Register (PWMSCLB)

PWMSCLB is the programmable scale value used in scaling clock B to generate clock SB. Clock SB is generated by taking clock B, dividing it by the value in the PWMSCLB register and dividing that by two.

Clock SB = Clock B / (2 * PWMSCLB)

NOTE

When PWMSCLB = $00, PWMSCLB value is considered a full scale value of 256. Clock B is thus divided by 512.

Any value written to this register will cause the scale counter to load the new scale value (PWMSCLB).

Module Base + 0x0009

Write: Anytime (causes the scale counter to load the PWMSCLB value).

14.3.2.11 Reserved Registers (PWMSCNTx)

The registers PWMSCNTA and PWMSCNTB are reserved for factory testing of the PWM module and are not available in normal modes.

Module Base + 0x000A, 0x000B

	7	6	5	4	3	2	1	0
R	0	0	0	0	0	0	0	0
W								
Reset	0	0	0	0	0	0	0	0

= Unimplemented or Reserved

Figure 14-13. Reserved Registers (PWMSCNTx)

Read: Always read $00 in normal modes

Write: Unimplemented in normal modes

NOTE

Writing to these registers when in special modes can alter the PWM functionality.

14.3.2.12 PWM Channel Counter Registers (PWMCNTx)

Each channel has a dedicated 8-bit up/down counter which runs at the rate of the selected clock source. The counter can be read at any time without affecting the count or the operation of the PWM channel. In left aligned output mode, the counter counts from 0 to the value in the period register - 1. In center aligned output mode, the counter counts from 0 up to the value in the period register and then back down to 0.

Any value written to the counter causes the counter to reset to $00, the counter direction to be set to up, the immediate load of both duty and period registers with values from the buffers, and the output to change according to the polarity bit. The counter is also cleared at the end of the effective period (see Section 14.4.2.5, "Left Aligned Outputs" and Section 14.4.2.6, "Center Aligned Outputs" for more details). When the channel is disabled (PWMEx = 0), the PWMCNTx register does not count. When a channel becomes enabled (PWMEx = 1), the associated PWM counter starts at the count in the PWMCNTx register. For more detailed information on the operation of the counters, see Section 14.4.2.4, "PWM Timer Counters".

In concatenated mode, writes to the 16-bit counter by using a 16-bit access or writes to either the low or high order byte of the counter will reset the 16-bit counter. Reads of the 16-bit counter must be made by 16-bit access to maintain data coherency.

NOTE

Writing to the counter while the channel is enabled can cause an irregular PWM cycle to occur.

Module Base + 0x000C = PWMCNT0, 0x000D = PWMCNT1, 0x000E = PWMCNT2, 0x000F = PWMCNT3
Module Base + 0x0010 = PWMCNT4, 0x0011 = PWMCNT5, 0x0012 = PWMCNT6, 0x0013 = PWMCNT7

Figure 14-14. PWM Channel Counter Registers (PWMCNTx)

Read: Anytime

Write: Anytime (any value written causes PWM counter to be reset to $00).

14.3.2.13 PWM Channel Period Registers (PWMPERx)

There is a dedicated period register for each channel. The value in this register determines the period of the associated PWM channel.

The period registers for each channel are double buffered so that if they change while the channel is enabled, the change will NOT take effect until one of the following occurs:

- The effective period ends
- The counter is written (counter resets to $00)
- The channel is disabled

In this way, the output of the PWM will always be either the old waveform or the new waveform, not some variation in between. If the channel is not enabled, then writes to the period register will go directly to the latches as well as the buffer.

NOTE

Reads of this register return the most recent value written. Reads do not necessarily return the value of the currently active period due to the double buffering scheme.

See Section 14.4.2.3, "PWM Period and Duty" for more information.

To calculate the output period, take the selected clock source period for the channel of interest (A, B, SA, or SB) and multiply it by the value in the period register for that channel:

- Left aligned output (CAEx = 0)
- PWMx Period = Channel Clock Period * PWMPERx Center Aligned Output (CAEx = 1)

  PWMx Period = Channel Clock Period * (2 * PWMPERx)

For boundary case programming values, please refer to Section 14.4.2.8, "PWM Boundary Cases".

Module Base + 0x0014 = PWMPER0, 0x0015 = PWMPER1, 0x0016 = PWMPER2, 0x0017 = PWMPER3
Module Base + 0x0018 = PWMPER4, 0x0019 = PWMPER5, 0x001A = PWMPER6, 0x001B = PWMPER7

Write: Anytime

14.3.2.14 PWM Channel Duty Registers (PWMDTYx)

There is a dedicated duty register for each channel. The value in this register determines the duty of the associated PWM channel. The duty value is compared to the counter and if it is equal to the counter value a match occurs and the output changes state.

The duty registers for each channel are double buffered so that if they change while the channel is enabled, the change will NOT take effect until one of the following occurs:

- The effective period ends
- The counter is written (counter resets to $00)
- The channel is disabled

In this way, the output of the PWM will always be either the old duty waveform or the new duty waveform, not some variation in between. If the channel is not enabled, then writes to the duty register will go directly to the latches as well as the buffer.

NOTE

Reads of this register return the most recent value written. Reads do not necessarily return the value of the currently active duty due to the double buffering scheme.

See Section 14.4.2.3, “PWM Period and Duty” for more information.

NOTE

Depending on the polarity bit, the duty registers will contain the count of either the high time or the low time. If the polarity bit is one, the output starts high and then goes low when the duty count is reached, so the duty registers contain a count of the high time. If the polarity bit is zero, the output starts low and then goes high when the duty count is reached, so the duty registers contain a count of the low time.

To calculate the output duty cycle (high time as a% of period) for a particular channel:

- Polarity = 0 (PPOL x =0)

  Duty Cycle = [(PWMPERx-PWMDTYx)/PWMPERx] * 100%
- Polarity = 1 (PPOLx = 1)

  Duty Cycle = [PWMDTYx / PWMPERx] * 100%

For boundary case programming values, please refer to Section 14.4.2.8, “PWM Boundary Cases”.

14.3.2.15 PWM Shutdown Register (PWMSDN)

The PWMSDN register provides for the shutdown functionality of the PWM module in the emergency cases. For proper operation, channel 7 must be driven to the active level for a minimum of two bus clocks.

Module Base + 0x0024

= Unimplemented or Reserved

Figure 14-17. PWM Shutdown Register (PWMSDN)

Read: Anytime

Write: Anytime

Table 14-9. PWMSDN Field Descriptions

Field	Description
7 PWMIF	**PWM Interrupt Flag** — Any change from passive to asserted (active) state or from active to passive state will be flagged by setting the PWMIF flag = 1. The flag is cleared by writing a logic 1 to it. Writing a 0 has no effect. 0 No change on PWM7IN input. 1 Change on PWM7IN input
6 PWMIE	**PWM Interrupt Enable** — If interrupt is enabled an interrupt to the CPU is asserted. 0 PWM interrupt is disabled. 1 PWM interrupt is enabled.
5 PWMRSTRT	**PWM Restart** — The PWM can only be restarted if the PWM channel input 7 is de-asserted. After writing a logic 1 to the PWMRSTRT bit (trigger event) the PWM channels start running after the corresponding counter passes next “counter == 0” phase. Also, if the PWM7ENA bit is reset to 0, the PWM do not start before the counter passes $00. The bit is always read as “0”.
4 PWMLVL	**PWM Shutdown Output Level** If active level as defined by the PWM7IN input, gets asserted all enabled PWM channels are immediately driven to the level defined by PWMLVL. 0 PWM outputs are forced to 0 1 Outputs are forced to 1.
2 PWM7IN	**PWM Channel 7 Input Status** — This reflects the current status of the PWM7 pin.
1 PWM7INL	**PWM Shutdown Active Input Level for Channel 7** — If the emergency shutdown feature is enabled (PWM7ENA = 1), this bit determines the active level of the PWM7channel. 0 Active level is low 1 Active level is high
0 PWM7ENA	**PWM Emergency Shutdown Enable** — If this bit is logic 1, the pin associated with channel 7 is forced to input and the emergency shutdown feature is enabled. All the other bits in this register are meaningful only if PWM7ENA = 1. 0 PWM emergency feature disabled. 1 PWM emergency feature is enabled.

14.4 Functional Description

14.4.1 PWM Clock Select

There are four available clocks: clock A, clock B, clock SA (scaled A), and clock SB (scaled B). These four clocks are based on the bus clock.

Clock A and B can be software selected to be 1, 1/2, 1/4, 1/8,..., 1/64, 1/128 times the bus clock. Clock SA uses clock A as an input and divides it further with a reloadable counter. Similarly, clock SB uses clock B as an input and divides it further with a reloadable counter. The rates available for clock SA are software selectable to be clock A divided by 2, 4, 6, 8,..., or 512 in increments of divide by 2. Similar rates are available for clock SB. Each PWM channel has the capability of selecting one of two clocks, either the pre-scaled clock (clock A or B) or the scaled clock (clock SA or SB).

The block diagram in Figure 14-18 shows the four different clocks and how the scaled clocks are created.

14.4.1.1 Prescale

The input clock to the PWM prescaler is the bus clock. It can be disabled whenever the part is in freeze mode by setting the PFRZ bit in the PWMCTL register. If this bit is set, whenever the MCU is in freeze mode (freeze mode signal active) the input clock to the prescaler is disabled. This is useful for emulation in order to freeze the PWM. The input clock can also be disabled when all eight PWM channels are disabled (PWME7-0 = 0). This is useful for reducing power by disabling the prescale counter.

Clock A and clock B are scaled values of the input clock. The value is software selectable for both clock A and clock B and has options of 1, 1/2, 1/4, 1/8, 1/16, 1/32, 1/64, or 1/128 times the bus clock. The value selected for clock A is determined by the PCKA2, PCKA1, PCKA0 bits in the PWMPRCLK register. The value selected for clock B is determined by the PCKB2, PCKB1, PCKB0 bits also in the PWMPRCLK register.

14.4.1.2 Clock Scale

The scaled A clock uses clock A as an input and divides it further with a user programmable value and then divides this by 2. The scaled B clock uses clock B as an input and divides it further with a user programmable value and then divides this by 2. The rates available for clock SA are software selectable to be clock A divided by 2, 4, 6, 8,..., or 512 in increments of divide by 2. Similar rates are available for clock SB.

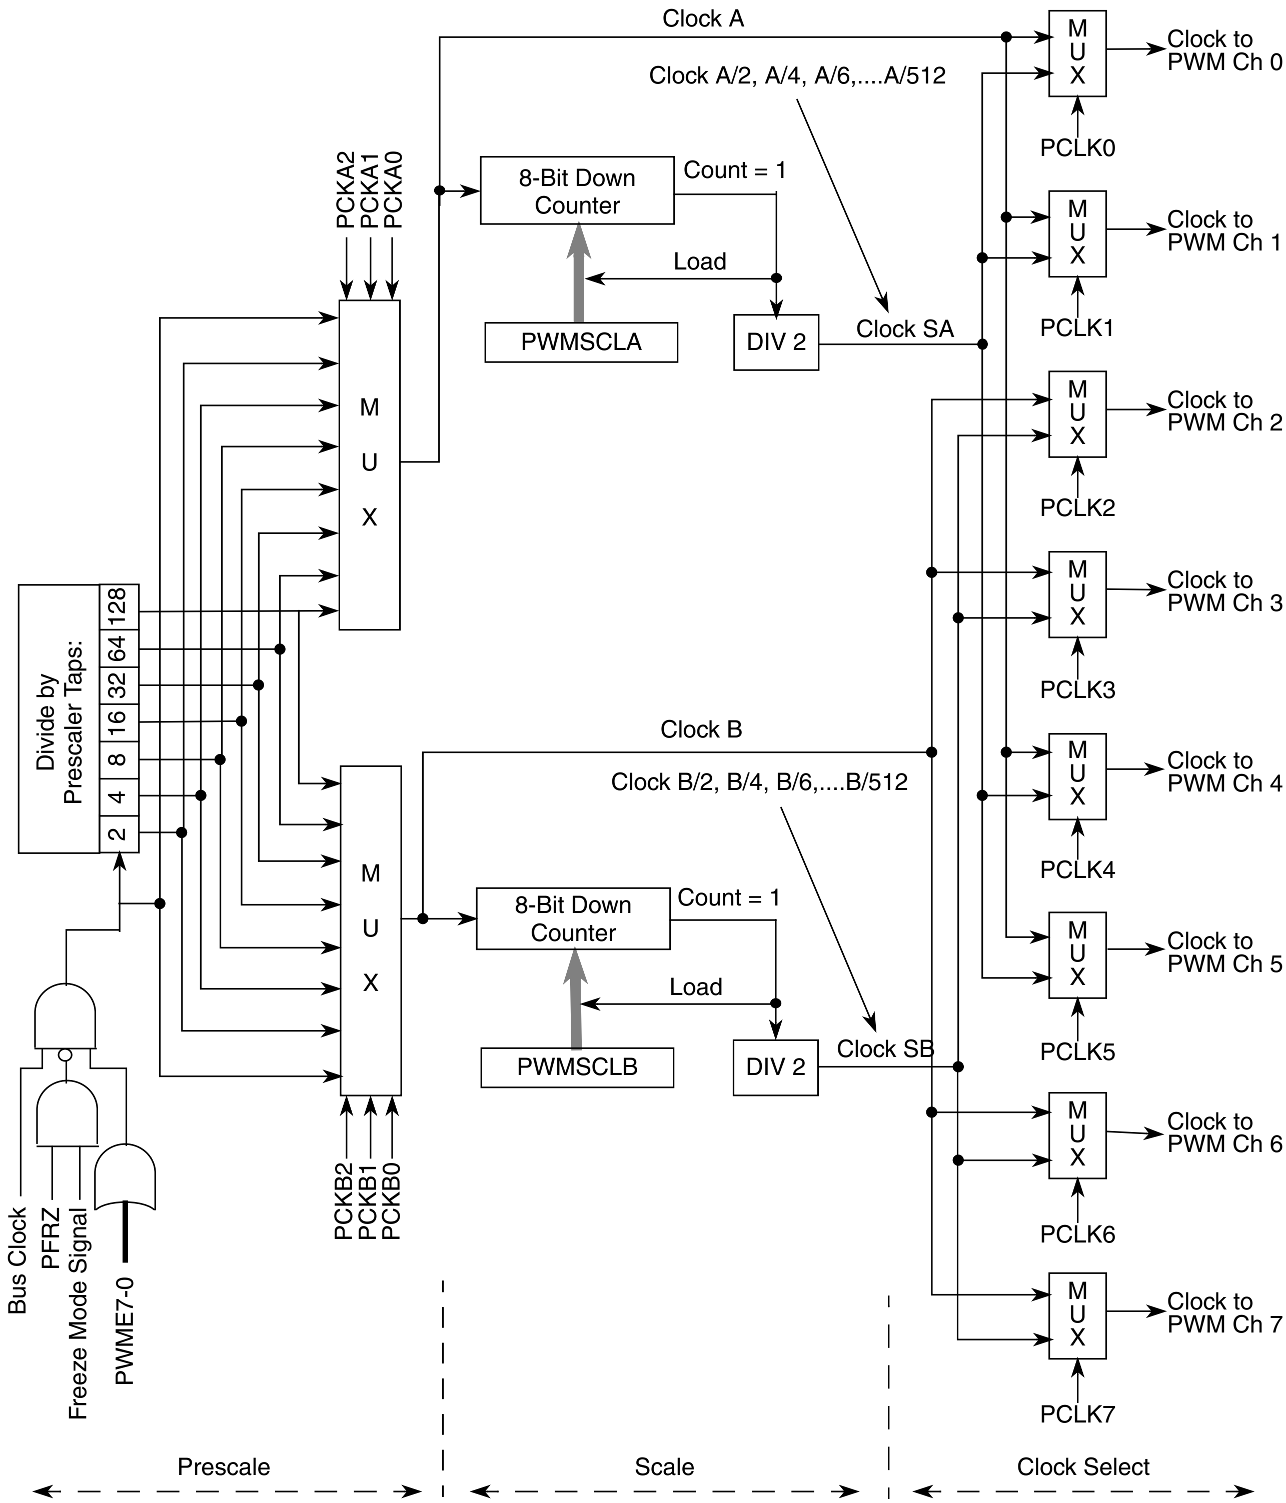

Figure 14-18. PWM Clock Select Block Diagram

Clock A is used as an input to an 8-bit down counter. This down counter loads a user programmable scale value from the scale register (PWMSCLA). When the down counter reaches one, a pulse is output and the 8-bit counter is re-loaded. The output signal from this circuit is further divided by two. This gives a greater range with only a slight reduction in granularity. Clock SA equals clock A divided by two times the value in the PWMSCLA register.

NOTE

Clock SA = Clock A / (2 * PWMSCLA)

When PWMSCLA = $00, PWMSCLA value is considered a full scale value of 256. Clock A is thus divided by 512.

Similarly, clock B is used as an input to an 8-bit down counter followed by a divide by two producing clock SB. Thus, clock SB equals clock B divided by two times the value in the PWMSCLB register.

NOTE

Clock SB = Clock B / (2 * PWMSCLB)

When PWMSCLB = $00, PWMSCLB value is considered a full scale value of 256. Clock B is thus divided by 512.

As an example, consider the case in which the user writes $FF into the PWMSCLA register. Clock A for this case will be E divided by 4. A pulse will occur at a rate of once every 255x4 E cycles. Passing this through the divide by two circuit produces a clock signal at an E divided by 2040 rate. Similarly, a value of $01 in the PWMSCLA register when clock A is E divided by 4 will produce a clock at an E divided by 8 rate.

Writing to PWMSCLA or PWMSCLB causes the associated 8-bit down counter to be re-loaded. Otherwise, when changing rates the counter would have to count down to $01 before counting at the proper rate. Forcing the associated counter to re-load the scale register value every time PWMSCLA or PWMSCLB is written prevents this.

NOTE

Writing to the scale registers while channels are operating can cause irregularities in the PWM outputs.

14.4.1.3 Clock Select

Each PWM channel has the capability of selecting one of two clocks. For channels 0, 1, 4, and 5 the clock choices are clock A or clock SA. For channels 2, 3, 6, and 7 the choices are clock B or clock SB. The clock selection is done with the PCLKx control bits in the PWMCLK register.

NOTE

Changing clock control bits while channels are operating can cause irregularities in the PWM outputs.

14.4.2 PWM Channel Timers

The main part of the PWM module are the actual timers. Each of the timer channels has a counter, a period register and a duty register (each are 8-bit). The waveform output period is controlled by a match between the period register and the value in the counter. The duty is controlled by a match between the duty register and the counter value and causes the state of the output to change during the period. The starting polarity of the output is also selectable on a per channel basis. Shown below in Figure 14-19 is the block diagram for the PWM timer.

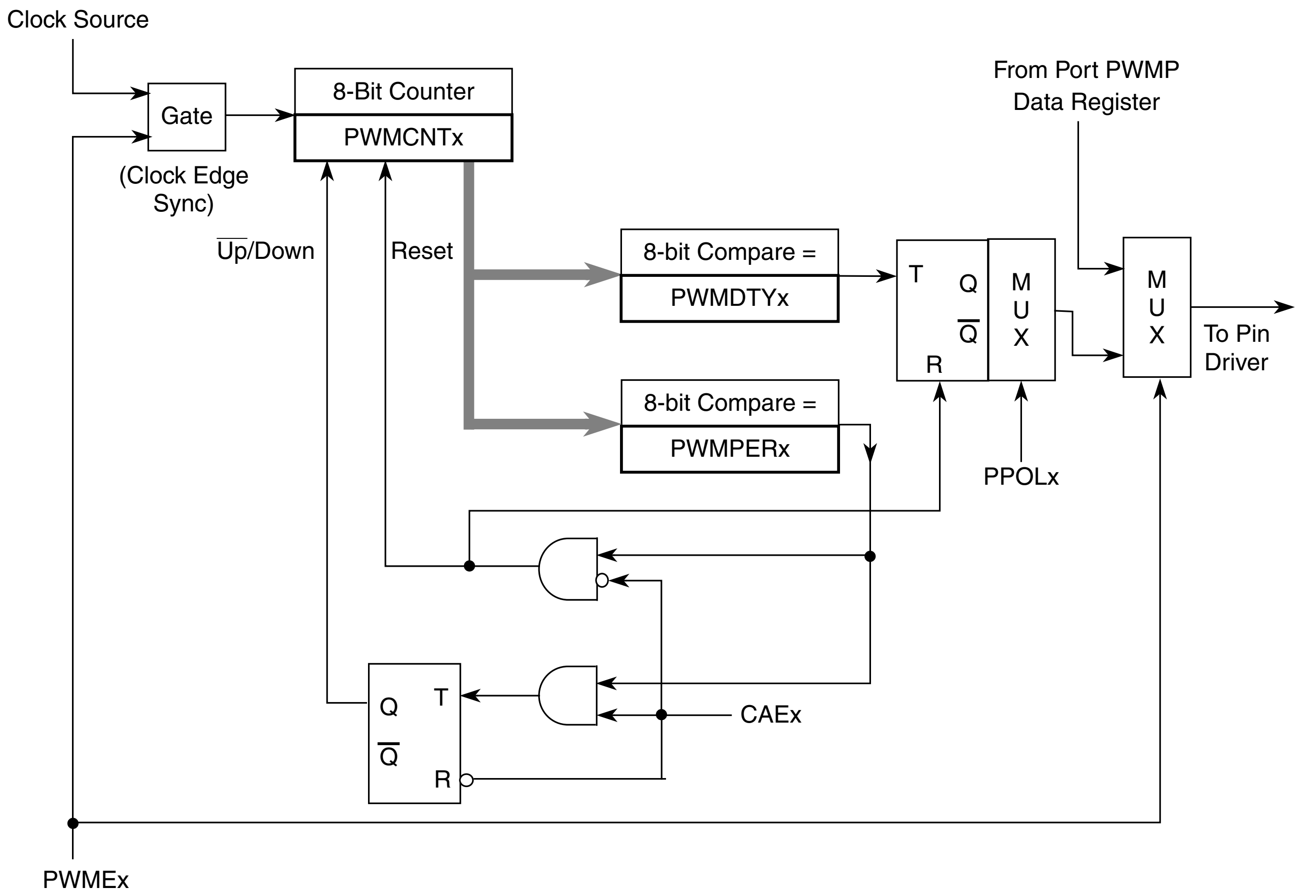

Figure 14-19. PWM Timer Channel Block Diagram

14.4.2.1 PWM Enable

Each PWM channel has an enable bit (PWMEx) to start its waveform output. When any of the PWMEx bits are set (PWMEx = 1), the associated PWM output signal is enabled immediately. However, the actual PWM waveform is not available on the associated PWM output until its clock source begins its next cycle due to the synchronization of PWMEx and the clock source. An exception to this is when channels are concatenated. Refer to Section 14.4.2.7, "PWM 16-Bit Functions" for more detail.

NOTE

The first PWM cycle after enabling the channel can be irregular.

On the front end of the PWM timer, the clock is enabled to the PWM circuit by the PWMEx bit being high. There is an edge-synchronizing circuit to guarantee that the clock will only be enabled or disabled at an edge. When the channel is disabled (PWMEx = 0), the counter for the channel does not count.

14.4.2.2 PWM Polarity

Each channel has a polarity bit to allow starting a waveform cycle with a high or low signal. This is shown on the block diagram as a mux select of either the Q output or the $\overline{Q}$ output of the PWM output flip flop. When one of the bits in the PWMPOL register is set, the associated PWM channel output is high at the beginning of the waveform, then goes low when the duty count is reached. Conversely, if the polarity bit is zero, the output starts low and then goes high when the duty count is reached.

14.4.2.3 PWM Period and Duty

Dedicated period and duty registers exist for each channel and are double buffered so that if they change while the channel is enabled, the change will NOT take effect until one of the following occurs:

- The effective period ends
- The counter is written (counter resets to $00)
- The channel is disabled

In this way, the output of the PWM will always be either the old waveform or the new waveform, not some variation in between. If the channel is not enabled, then writes to the period and duty registers will go directly to the latches as well as the buffer.

A change in duty or period can be forced into effect “immediately” by writing the new value to the duty and/or period registers and then writing to the counter. This forces the counter to reset and the new duty and/or period values to be latched. In addition, since the counter is readable, it is possible to know where the count is with respect to the duty value and software can be used to make adjustments

NOTE

When forcing a new period or duty into effect immediately, an irregular PWM cycle can occur.

Depending on the polarity bit, the duty registers will contain the count of either the high time or the low time.

14.4.2.4 PWM Timer Counters

Each channel has a dedicated 8-bit up/down counter which runs at the rate of the selected clock source (see Section 14.4.1, “PWM Clock Select” for the available clock sources and rates). The counter compares to two registers, a duty register and a period register as shown in Figure 14-19. When the PWM counter matches the duty register, the output flip-flop changes state, causing the PWM waveform to also change state. A match between the PWM counter and the period register behaves differently depending on what output mode is selected as shown in Figure 14-19 and described in Section 14.4.2.5, “Left Aligned Outputs” and Section 14.4.2.6, “Center Aligned Outputs”.

Each channel counter can be read at anytime without affecting the count or the operation of the PWM channel.

Any value written to the counter causes the counter to reset to $00, the counter direction to be set to up, the immediate load of both duty and period registers with values from the buffers, and the output to change according to the polarity bit. When the channel is disabled (PWMEx = 0), the counter stops. When a channel becomes enabled (PWMEx = 1), the associated PWM counter continues from the count in the PWMCNTx register. This allows the waveform to continue where it left off when the channel is re-enabled. When the channel is disabled, writing “0” to the period register will cause the counter to reset on the next selected clock.

NOTE

If the user wants to start a new “clean” PWM waveform without any “history” from the old waveform, the user must write to channel counter (PWMCNTx) prior to enabling the PWM channel (PWMEx = 1).

Generally, writes to the counter are done prior to enabling a channel in order to start from a known state. However, writing a counter can also be done while the PWM channel is enabled (counting). The effect is similar to writing the counter when the channel is disabled, except that the new period is started immediately with the output set according to the polarity bit.

NOTE

Writing to the counter while the channel is enabled can cause an irregular PWM cycle to occur.

The counter is cleared at the end of the effective period (see Section 14.4.2.5, “Left Aligned Outputs” and Section 14.4.2.6, “Center Aligned Outputs” for more details).

Table 14-10. PWM Timer Counter Conditions

Counter Clears ($00)	Counter Counts	Counter Stops
When PWMCNTx register written to any value	When PWM channel is enabled (PWMEx = 1). Counts from last value in PWMCNTx.	When PWM channel is disabled (PWMEx = 0)
Effective period ends		

14.4.2.5 Left Aligned Outputs

The PWM timer provides the choice of two types of outputs, left aligned or center aligned. They are selected with the CAEx bits in the PWMCAE register. If the CAEx bit is cleared (CAEx = 0), the corresponding PWM output will be left aligned.

In left aligned output mode, the 8-bit counter is configured as an up counter only. It compares to two registers, a duty register and a period register as shown in the block diagram in Figure 14-19. When the PWM counter matches the duty register the output flip-flop changes state causing the PWM waveform to also change state. A match between the PWM counter and the period register resets the counter and the output flip-flop, as shown in Figure 14-19, as well as performing a load from the double buffer period and duty register to the associated registers, as described in Section 14.4.2.3, “PWM Period and Duty”. The counter counts from 0 to the value in the period register – 1.

NOTE

Changing the PWM output mode from left aligned to center aligned output (or vice versa) while channels are operating can cause irregularities in the PWM output. It is recommended to program the output mode before enabling the PWM channel.

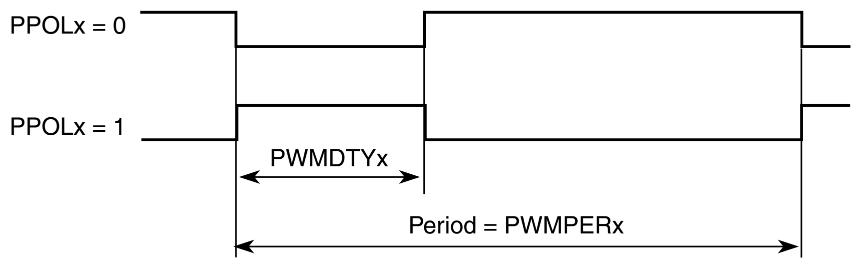

Figure 14-20. PWM Left Aligned Output Waveform

To calculate the output frequency in left aligned output mode for a particular channel, take the selected clock source frequency for the channel (A, B, SA, or SB) and divide it by the value in the period register for that channel.

- PWMx Frequency = Clock (A, B, SA, or SB) / PWMPERx
- PWMx Duty Cycle (high time as a% of period):
  - — Polarity = 0 (PPOLx = 0)
- Duty Cycle = [(PWMPERx-PWMDTYx)/PWMPERx] * 100%
  - — Polarity = 1 (PPOLx = 1)

Duty Cycle = [PWMDTYx / PWMPERx] * 100%

As an example of a left aligned output, consider the following case:

Clock Source = E, where E = 10 MHz (100 ns period)

PPOLx = 0

PWMPERx = 4

PWMDTYx = 1

PWMx Frequency = 10 MHz/4 = 2.5 MHz

PWMx Period = 400 ns

PWMx Duty Cycle = 3/4 *100% = 75%

The output waveform generated is shown in Figure 14-21.

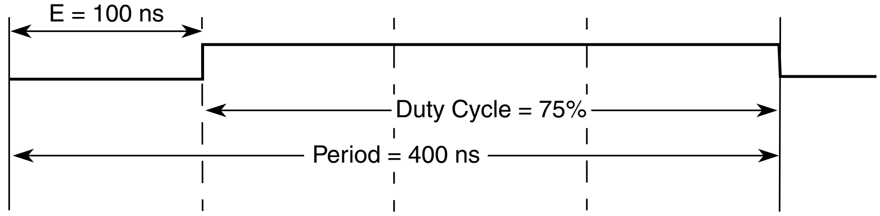

Figure 14-21. PWM Left Aligned Output Example Waveform

14.4.2.6 Center Aligned Outputs

For center aligned output mode selection, set the CAEx bit (CAEx = 1) in the PWMCAE register and the corresponding PWM output will be center aligned.

The 8-bit counter operates as an up/down counter in this mode and is set to up whenever the counter is equal to $00. The counter compares to two registers, a duty register and a period register as shown in the block diagram in Figure 14-19. When the PWM counter matches the duty register, the output flip-flop changes state, causing the PWM waveform to also change state. A match between the PWM counter and the period register changes the counter direction from an up-count to a down-count. When the PWM counter decrements and matches the duty register again, the output flip-flop changes state causing the PWM output to also change state. When the PWM counter decrements and reaches zero, the counter direction changes from a down-count back to an up-count and a load from the double buffer period and duty registers to the associated registers is performed, as described in Section 14.4.2.3, “PWM Period and Duty”. The counter counts from 0 up to the value in the period register and then back down to 0. Thus the effective period is PWMPERx*2.

NOTE

Changing the PWM output mode from left aligned to center aligned output (or vice versa) while channels are operating can cause irregularities in the PWM output. It is recommended to program the output mode before enabling the PWM channel.

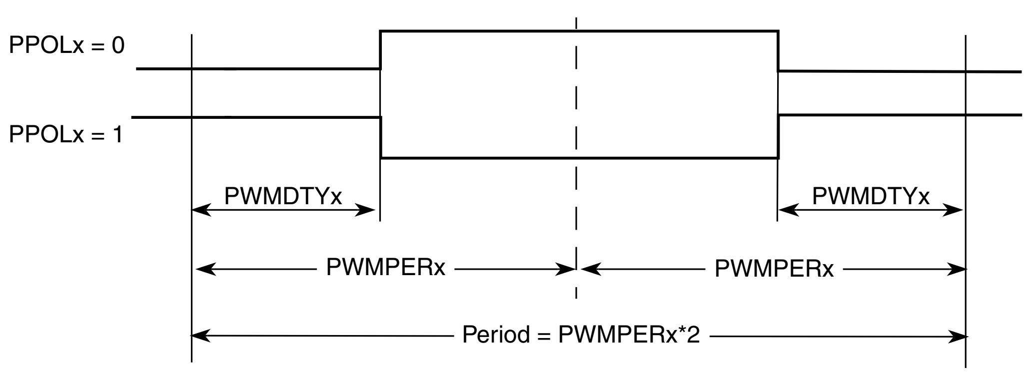

Figure 14-22. PWM Center Aligned Output Waveform

To calculate the output frequency in center aligned output mode for a particular channel, take the selected clock source frequency for the channel (A, B, SA, or SB) and divide it by twice the value in the period register for that channel.

- PWMx Frequency = Clock (A, B, SA, or SB) / (2*PWMPERx)
- PWMx Duty Cycle (high time as a% of period):
  - Polarity = 0 (PPOLx = 0)

    Duty Cycle = [(PWMPERx-PWMDTYx)/PWMPERx] * 100%
  - Polarity = 1 (PPOLx = 1)

    Duty Cycle = [PWMDTYx / PWMPERx] * 100%

As an example of a center aligned output, consider the following case:

Clock Source = E, where E = 10 MHz (100 ns period)

PPOLx = 0

PWMPERx = 4

PWMDTYx = 1

PWMx Frequency = 10 MHz/8 = 1.25 MHz

PWMx Period = 800 ns

PWMx Duty Cycle = 3/4 *100% = 75%

Shown in Figure 14-23 is the output waveform generated.

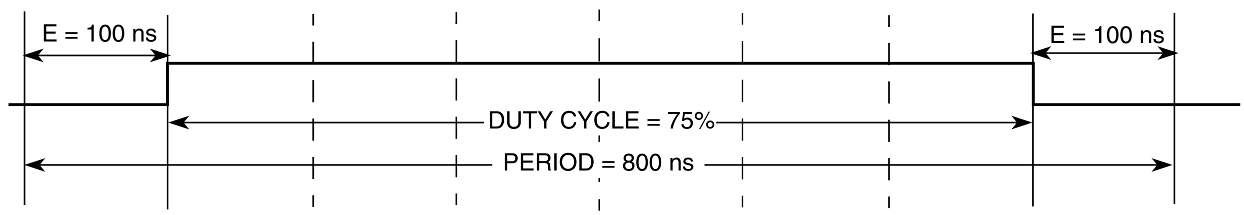

Figure 14-23. PWM Center Aligned Output Example Waveform

14.4.2.7 PWM 16-Bit Functions

The PWM timer also has the option of generating 8-channels of 8-bits or 4-channels of 16-bits for greater PWM resolution. This 16-bit channel option is achieved through the concatenation of two 8-bit channels.

The PWMCTL register contains four control bits, each of which is used to concatenate a pair of PWM channels into one 16-bit channel. Channels 6 and 7 are concatenated with the CON67 bit, channels 4 and 5 are concatenated with the CON45 bit, channels 2 and 3 are concatenated with the CON23 bit, and channels 0 and 1 are concatenated with the CON01 bit.

NOTE

Change these bits only when both corresponding channels are disabled.

When channels 6 and 7 are concatenated, channel 6 registers become the high order bytes of the double byte channel, as shown in Figure 14-24. Similarly, when channels 4 and 5 are concatenated, channel 4 registers become the high order bytes of the double byte channel. When channels 2 and 3 are concatenated, channel 2 registers become the high order bytes of the double byte channel. When channels 0 and 1 are concatenated, channel 0 registers become the high order bytes of the double byte channel.

When using the 16-bit concatenated mode, the clock source is determined by the low order 8-bit channel clock select control bits. That is channel 7 when channels 6 and 7 are concatenated, channel 5 when channels 4 and 5 are concatenated, channel 3 when channels 2 and 3 are concatenated, and channel 1 when channels 0 and 1 are concatenated. The resulting PWM is output to the pins of the corresponding low order 8-bit channel as also shown in Figure 14-24. The polarity of the resulting PWM output is controlled by the PPOLx bit of the corresponding low order 8-bit channel as well.

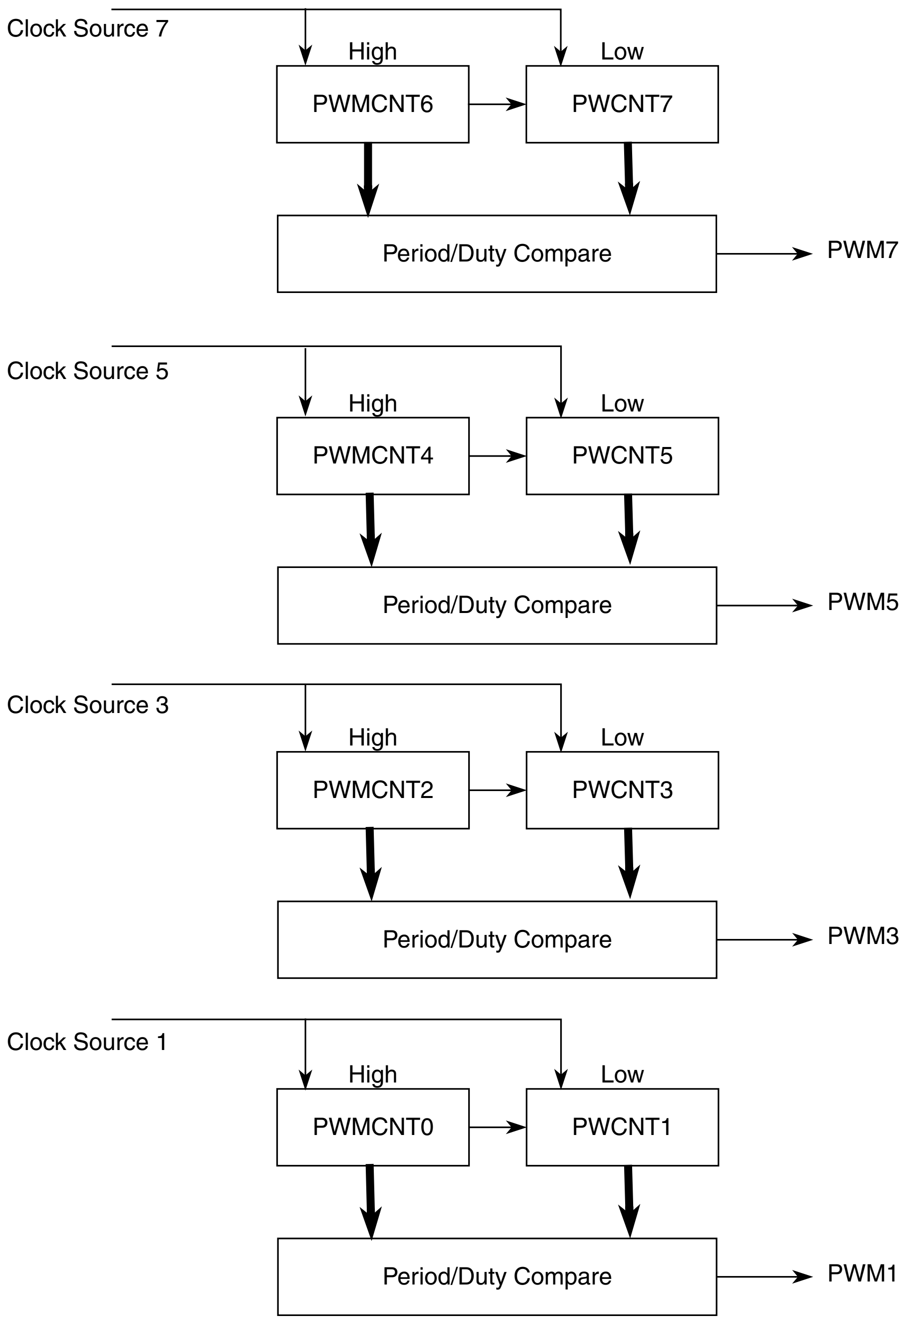

Figure 14-24. PWM 16-Bit Mode

Once concatenated mode is enabled (CONxx bits set in PWMCTL register), enabling/disabling the corresponding 16-bit PWM channel is controlled by the low order PWMEx bit. In this case, the high order bytes PWMEx bits have no effect and their corresponding PWM output is disabled.

In concatenated mode, writes to the 16-bit counter by using a 16-bit access or writes to either the low or high order byte of the counter will reset the 16-bit counter. Reads of the 16-bit counter must be made by 16-bit access to maintain data coherency.

Either left aligned or center aligned output mode can be used in concatenated mode and is controlled by the low order CAEx bit. The high order CAEx bit has no effect.

Table 14-11 is used to summarize which channels are used to set the various control bits when in 16-bit mode.

Table 14-11. 16-bit Concatenation Mode Summary

CONxx	PWMEx	PPOLx	PCLKx	CAEx	PWMx Output
CON67	PWME7	PPOL7	PCLK7	CAE7	PWM7
CON45	PWME5	PPOL5	PCLK5	CAE5	PWM5
CON23	PWME3	PPOL3	PCLK3	CAE3	PWM3
CON01	PWME1	PPOL1	PCLK1	CAE1	PWM1

14.4.2.8 PWM Boundary Cases

Table 14-12 summarizes the boundary conditions for the PWM regardless of the output mode (left aligned or center aligned) and 8-bit (normal) or 16-bit (concatenation).

Table 14-12. PWM Boundary Cases

PWMDTYx	PWMPERx	PPOLx	PWMx Output
$00 (indicates no duty)	>$00	1	Always low
$00 (indicates no duty)	>$00	0	Always high
XX	$00[1] (indicates no period)	1	Always high
XX	$00[1] (indicates no period)	0	Always low
>= PWMPERx	XX	1	Always high
>= PWMPERx	XX	0	Always low

1 Counter = $00 and does not count.

14.5 Resets

The reset state of each individual bit is listed within the Section 14.3.2, “Register Descriptions” which details the registers and their bit-fields. All special functions or modes which are initialized during or just following reset are described within this section.

- The 8-bit up/down counter is configured as an up counter out of reset.
- All the channels are disabled and all the counters do not count.

14.6 Interrupts

The PWM module has only one interrupt which is generated at the time of emergency shutdown, if the corresponding enable bit (PWMIE) is set. This bit is the enable for the interrupt. The interrupt flag PWMIF is set whenever the input level of the PWM7 channel changes while PWM7ENA = 1 or when PWMENA is being asserted while the level at PWM7 is active.

In stop mode or wait mode (with the PSWAI bit set), the emergency shutdown feature will drive the PWM outputs to their shutdown output levels but the PWMIF flag will not be set.

A description of the registers involved and affected due to this interrupt is explained in Section 14.3.2.15, "PWM Shutdown Register (PWMSDN)".

The PWM block only generates the interrupt and does not service it. The interrupt signal name is PWM interrupt signal.

Chapter 15
Read-Only Memory 64K x 16 (ROM64KX16V1) Block Description

15.1 Introduction

This document describes the ROM64KX16 module which controls a 128 K byte mask-programmed read-only memory array for use with 0.25 micron HCS12 devices.

15.1.1 Glossary

The following terms and abbreviations are used in the document.

Table 15-1. Terminology

Term	Meaning
ROM	Read-Only Memory

15.1.2 Features

The ROM64KX16 includes the following features:

- Control read access to 128 K bytes of mask-programmed ROM memory comprised of one 64Kx16 byte block
- Security with user backdoor key entry

15.1.3 Modes of Operation

The modes of operation for ROM64KX16 are listed below.

- Run

  The ROM64KX16 interface provides one cycle read access to the ROM hard block.
- Standby

  Whenever the on-chip ROM is not being accessed, the ROM64KX16 module holds the ROM hard block in standby.

15.1.4 Block Diagram

Figure 15-1 is a high level block diagram of the ROM64KX16 interface control block.

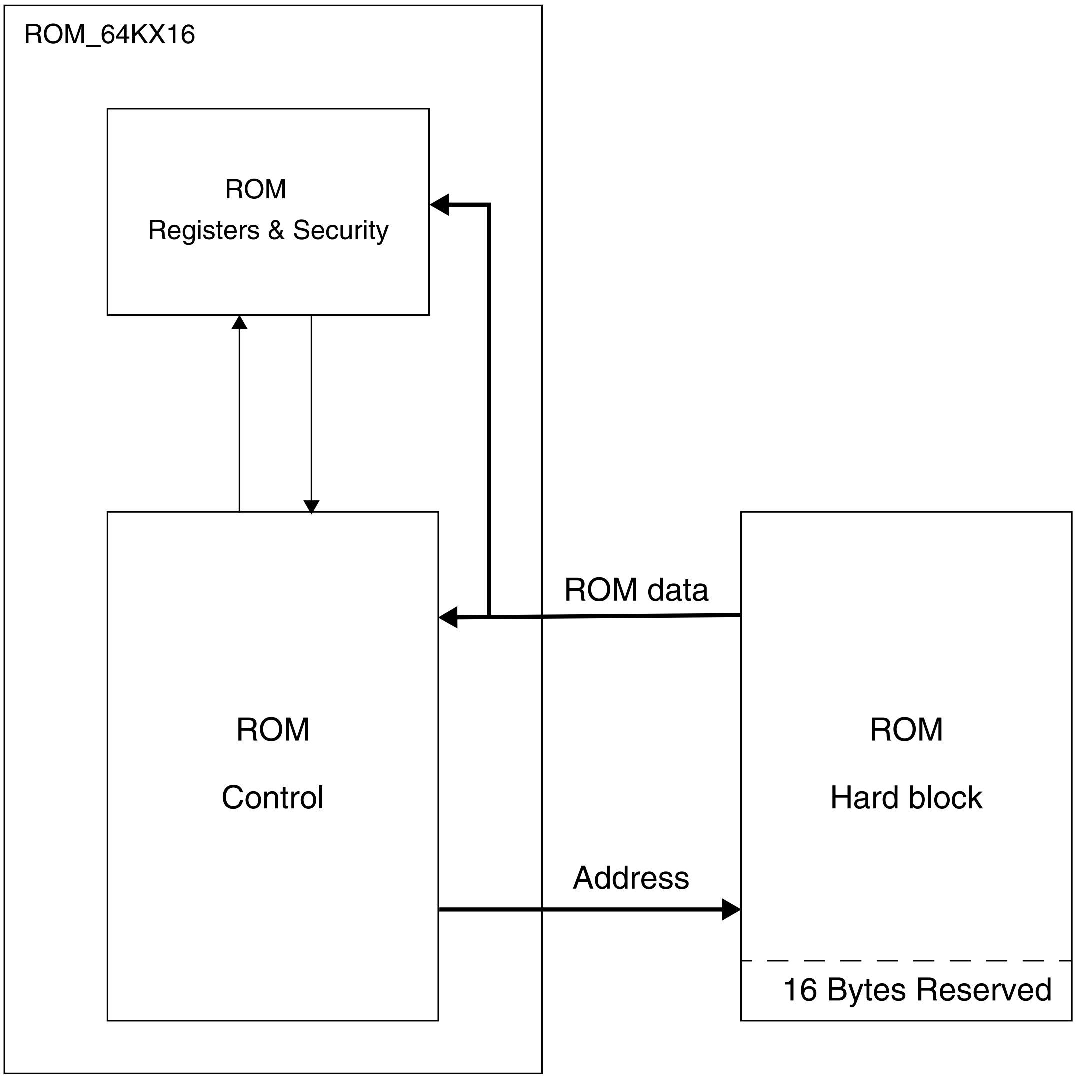

Figure 15-1. ROM64KX16 Block Diagram

15.2 External Signal Description

No external signal connections exist for the ROM64KX16 module.

15.3 Memory Map and Registers

This section provides a detailed description of all memory and registers.

15.3.1 Module Memory Map

The ROM64KX16 module occupies a 16 byte memory space within the on-chip memory map (address offsets $0000 – $000F). A summary of the ROM control registers is given in Figure 15-2 while their accessibility is detailed in section Section 15.3.2, “Register Descriptions”.

Table 15-2. ROPT Field Descriptions

Field	Description
7–6 KEYEN[1:0]	**Key Enable Bits** — Backdoor Key Mechanism Enable. The KEYEN[1:0] bits control backdoor key access to the ROM module as shown in Table 15-3. If the backdoor key mechanism is enabled, user firmware can write a 4-words value that matches the non-volatile backdoor key (NVBACKKEY+0x0000 through NVBACKKEY+0x0007 in that order), to temporarily disengage security until the next reset. The backdoor key mechanism is accessible only from user (secured) firmware. BDM commands cannot be used to write key comparison values that would unlock the backdoor key. If disabled, no backdoor key access allowed. **Note:** Please note that backdoor keywords $0000 and $FFFF are invalid and will effectively disable backdoor key access when used. **Note:** On Mask-ROM devices the backdoor key is also used to protect access to internal product analysis features. No product analysis will be possible on a secured ROM if backdoor key access is disabled or keywords are invalid.
5–2 NV[5:2]	**Non-Volatile Flag Bits** — These 4 bits are available to the user as non-volatile flags.
1–0 SEC[1:0]	**Security State Code** — This 2-bit field determines the security state of the MCU. The security state is coded as shown in Table 15-4.

Table 15-3. ROM Backdoor Key Enable States

KEYEN[1:0]	Status of Backdoor Key Access
00	Disabled
01	Disabled[1]
10	Enabled
11	Disabled

Write: Anytime

Table 15-5. RCNFG Field Descriptions

Field	Description
5 KEYACC	**Key Access Bit** — Enable writing of security access (backdoor) key. This bit enables writing of the backdoor comparison key for disabling security. This bit cannot be set unless the KEYEN[1:0] bits in the ROPT register are set to “10”. While this bit is set, normal accesses to the ROM array are blocked, returned data is undefined. 0 Backdoor key access enabled 1 Backdoor key access disabled

15.3.2.3 ROM Device SC Number Registers (RDSC0–RDSC2)

Module Base + 0x000C

Read: Anytime

Write: Never

Table 15-6. RDSC0–RDSC2 Field Descriptions

Field	Description
7–0 DSCn[7:0]	**Device SC Number n** — Device SC Number byte n (n=<0,1,2>).

15.3.3 Non-volatile Registers

A range of addresses in the ROM array is reserved for the option bits and backdoor key. Additionally, some locations are reserved for the ROM Device SC number and for the 32 bit CRC value which is used by the ROM BIST engine to verify the ROM array content during production test.

Address	Name	Bit 7	6	5	4	3	2	1	Bit 0
0xFF00 - 0xFF07	NVBACKKEY	8-Byte Comparison Key							
0xFF08	NVCRC0	CRC value Byte 0							
0xFF09	NVCRC1	CRC value Byte 1							
0xFF0A	NVCRC2	CRC value Byte 2							
0xFF0B	NVCRC3	CRC value Byte 3							
0xFF0C	NVSC0	Device SC number Byte 0							
0xFF0D	NVSC1	Device SC number Byte 1							
0xFF0E	NVSC2	Device SC number Byte 2							
0xFF0F	NVOPT	KEYEN1	KEYEN0	NV5	NV4	NV3	NV2	SEC1	SEC0

NOTE

Both the CRC bytes and the Device SC number bytes are reserved for Freescale use. Any data present in these locations will be overwritten with Freescale assigned values when a ROM code is submitted.

NOTE

Please note that backdoor keywords $0000 or $FFFF are invalid and will effectively disable backdoor key access when used.

NOTE

On Mask-ROM devices the backdoor key is also used to protect access to internal product analysis features. No product analysis will be possible on a secured ROM if backdoor key access is disabled or keywords are invalid.

15.4 Functional Description

15.4.1 ROM Security

The ROM64KX16 module provides the necessary security information to the rest of the device. After each reset, the ROM64KX16 module determines the security state of the microcontroller as defined in Section 15.3.2.1, “ROM Options Register (ROPT)”.

If the NVM Options byte at 0xFF0F in the NVM Options Field is in secure state, any reset will cause the microcontroller to return to the secure operating mode

15.4.1.1 Security and Backdoor Key Access definition

Security is engaged or disengaged based on the state of two non-volatile register bits (SEC[1:0]) in the ROPT register. During reset, the contents of the non-volatile location NVOPT are copied from ROM into the working ROPT register in high-page register space.

A user engages security by defining the security bits in the NVOPT location to select security enabled. This data is included along with the ROM program and data file which is delivered when ordering a ROM device. The SEC[1:0] = “10” state disengages security while the other three combinations engage security.

In a similar manner the user can choose to allow or disallow a security unlocking mechanism through an 8-byte backdoor security key. There is no way to disable security unless the non-volatile KEYEN[1:0] bits in NVOPT/ROPT are set to “10”.

NOTE

On Mask-ROM devices the backdoor key is also used to protect access to internal product analysis features. No product analysis will be possible on a secured ROM if backdoor key access is disabled or keywords are invalid.

15.4.1.2 Unsecuring the MCU using the Backdoor Key Access

Provided that the key access is permitted, security can be disabled by the backdoor access sequence described below:

1. Write 1 to KEYACC in the RCNFG register. This causes the ROM control logic to block read accesses to the ROM array and to interpret writes to the backdoor comparison key locations (NVBACKKEY+0x0000 through NVBACKKEY+0x0007) as values to be compared against the key rather than as writes to ROM locations.
2. Write the correct four 16-bit key values to addresses NVBACKKEY+0x0000 through NVBACKKEY+0x0007 locations. These writes must be done in order starting with the value for NVBACKKEY+0x0000 and ending with NVBACKKEY+0x0007. User software normally would get the key codes from outside the MCU system through a communication interface such as a serial I/O.
3. Write 0 to KEYACC in the RCNFG register. If the 8-byte key that was just written matches the key stored in the backdoor comparison key locations, SEC[1:0] in the ROPT register are automatically changed to “10” and security will be disengaged until the next system reset.

The security key can be written only from a secure memory, so it cannot be entered through background commands without the cooperation of a secure user program.

15.5 Initialization Information

15.5.1 Resets

The contents of the ROM array are unaffected by reset.

15.5.2 Interrupts

No interrupt is generated by the ROM module.

Chapter 16
Serial Communications Interface (SCIV2) Block Description

16.1 Introduction

This block guide provide an overview of serial communication interface (SCI) module. The SCI allows asynchronous serial communications with peripheral devices and other CPUs.

16.1.1 Glossary

IRQ — Interrupt Request

LSB — Least Significant Bit

MSB — Most Significant Bit

NRZ — Non-Return-to-Zero

RZI — Return-to-Zero-Inverted

RXD — Receive Pin

SCI — Serial Communication Interface

TXD — Transmit Pin

16.1.2 Features

The SCI includes these distinctive features:

- Full-duplex operation
- Standard mark/space non-return-to-zero (NRZ) format
- 13-bit baud rate selection
- Programmable 8-bit or 9-bit data format
- Separately enabled transmitter and receiver
- Programmable transmitter output parity
- Two receiver wake up methods:
  - Idle line wake-up
  - Address mark wake-up
- Interrupt-driven operation with eight flags:
  - Transmitter empty

— Transmission complete
— Receiver full
— Idle receiver input
— Receiver overrun
— Noise error
— Framing error
— Parity error

- Receiver framing error detection
- Hardware parity checking
- 1/16 bit-time noise detection

16.1.3 Modes of Operation

The SCI operation is the same independent of device resource mapping and bus interface mode. Different power modes are available to facilitate power saving.

16.1.3.1 Run Mode

Normal mode of operation.

16.1.3.2 Wait Mode

SCI operation in wait mode depends on the state of the SCISWAI bit in the SCI control register 1 (SCICR1).

- If SCISWAI is clear, the SCI operates normally when the CPU is in wait mode.
- If SCISWAI is set, SCI clock generation ceases and the SCI module enters a power-conservation state when the CPU is in wait mode. Setting SCISWAI does not affect the state of the receiver enable bit, RE, or the transmitter enable bit, TE.
- If SCISWAI is set, any transmission or reception in progress stops at wait mode entry. The transmission or reception resumes when either an internal or external interrupt brings the CPU out of wait mode. Exiting wait mode by reset aborts any transmission or reception in progress and resets the SCI.

16.1.3.3 Stop Mode

The SCI is inactive during stop mode for reduced power consumption. The STOP instruction does not affect the SCI register states, but the SCI module clock will be disabled. The SCI operation resumes from where it left off after an external interrupt brings the CPU out of stop mode. Exiting stop mode by reset aborts any transmission or reception in progress and resets the SCI.

16.1.4 Block Diagram

Figure 16-1 is a high level block diagram of the SCI module, showing the interaction of various functional blocks.

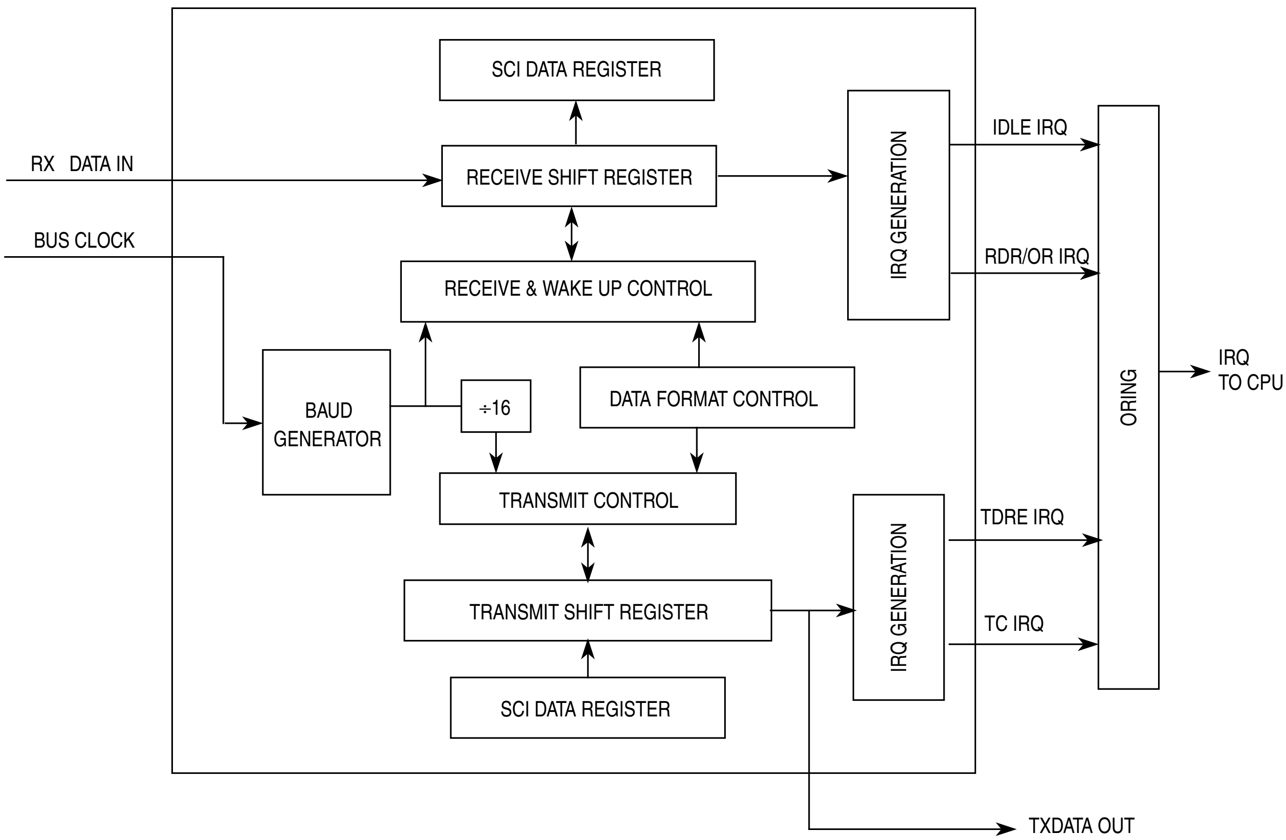

Figure 16-1. SCI Block Diagram

16.2 External Signal Description

The SCI module has a total of two external pins:

16.2.1 TXD-SCI Transmit Pin

This pin serves as transmit data output of SCI.

16.2.2 RXD-SCI Receive Pin

This pin serves as receive data input of the SCI.

16.3 Memory Map and Registers

This section provides a detailed description of all memory and registers.

16.3.1 Module Memory Map

The memory map for the SCI module is given below in Figure 16-2. The Address listed for each register is the address offset. The total address for each register is the sum of the base address for the SCI module and the address offset for each register.

Address	Name		Bit 7	6	5	4	3	2	1	Bit 0

Figure 16-2. SCI Register Summary

16.3.2 Register Descriptions

This section consists of register descriptions in address order. Each description includes a standard register diagram with an associated figure number. Writes to a reserved register location do not have any effect and reads of these locations return a zero. Details of register bit and field function follow the register diagrams, in bit order.

16.3.2.1 SCI Baud Rate Registers (SCIBDH and SCHBDL)

Module Base + 0x_0000

Reset	0	0	0	0	0	1	0	0

= Unimplemented or Reserved

Figure 16-3. SCI Baud Rate Registers (SCIBDH and SCIBDL)

The SCI Baud Rate Register is used by the counter to determine the baud rate of the SCI. The formula for calculating the baud rate is:

SCI baud rate = SCI module clock / (16 x BR)

where:

BR is the content of the SCI baud rate registers, bits SBR12 through SBR0. The baud rate registers can contain a value from 1 to 8191.

Read: Anytime. If only SCIBDH is written to, a read will not return the correct data until SCIBDL is written to as well, following a write to SCIBDH.

Write: Anytime

Table 16-1. SCIBDH AND SCIBDL Field Descriptions

Field	Description
4–0 7–0 SBR[12:0]	**SCI Baud Rate Bits** — The baud rate for the SCI is determined by these 13 bits. **Note:** The baud rate generator is disabled until the TE bit or the RE bit is set for the first time after reset. The baud rate generator is disabled when BR = 0. Writing to SCIBDH has no effect without writing to SCIBDL, since writing to SCIBDH puts the data in a temporary location until SCIBDL is written to.

16.3.2.2 SCI Control Register 1 (SCICR1)

Module Base + 0x_0002

	7	6	5	4	3	2	1	0

Reset	0	0	0	0	0	0	0	0

Figure 16-4. SCI Control Register 1 (SCICR1)

Read: Anytime

Write: Anytime

Table 16-2. SCICR1 Field Descriptions

Field	Description
7 LOOPS	**Loop Select Bit** — LOOPS enables loop operation. In loop operation, the RXD pin is disconnected from the SCI and the transmitter output is internally connected to the receiver input. Both the transmitter and the receiver must be enabled to use the loop function.See Table 16-3. 0 Normal operation enabled 1 Loop operation enabled **Note:** The receiver input is determined by the RSRC bit.
6 SCISWAI	**SCI Stop in Wait Mode Bit** — SCISWAI disables the SCI in wait mode. 0 SCI enabled in wait mode 1 SCI disabled in wait mode
5 RSRC	**Receiver Source Bit** — When LOOPS = 1, the RSRC bit determines the source for the receiver shift register input. 0 Receiver input internally connected to transmitter output 1 Receiver input connected externally to transmitter
4 M	**Data Format Mode Bit** — MODE determines whether data characters are eight or nine bits long. 0 One start bit, eight data bits, one stop bit 1 One start bit, nine data bits, one stop bit
3 WAKE	**Wakeup Condition Bit** — WAKE determines which condition wakes up the SCI: a logic 1 (address mark) in the most significant bit position of a received data character or an idle condition on the RXD. 0 Idle line wakeup 1 Address mark wakeup
2 ILT	**Idle Line Type Bit** — ILT determines when the receiver starts counting logic 1s as idle character bits. The counting begins either after the start bit or after the stop bit. If the count begins after the start bit, then a string of logic 1s preceding the stop bit may cause false recognition of an idle character. Beginning the count after the stop bit avoids false idle character recognition, but requires properly synchronized transmissions. 0 Idle character bit count begins after start bit 1 Idle character bit count begins after stop bit
1 PE	**Parity Enable Bit** — PE enables the parity function. When enabled, the parity function inserts a parity bit in the most significant bit position. 0 Parity function disabled 1 Parity function enabled
0 PT	**Parity Type Bit** — PT determines whether the SCI generates and checks for even parity or odd parity. With even parity, an even number of 1s clears the parity bit and an odd number of 1s sets the parity bit. With odd parity, an odd number of 1s clears the parity bit and an even number of 1s sets the parity bit. 0 Even parity 1 Odd parity

Table 16-3. Loop Functions

LOOPS	RSRC	Function
0	x	Normal operation
1	0	Loop mode with Rx input internally connected to Tx output
1	1	Single-wire mode with Rx input connected to TXD

16.3.2.3 SCI Control Register 2 (SCICR2)

Write: Anytime

Table 16-4. SCICR2 Field Descriptions

Field	Description
7 TIE	**Transmitter Interrupt Enable Bit** — TIE enables the transmit data register empty flag, TDRE, to generate interrupt requests. 0 TDRE interrupt requests disabled 1 TDRE interrupt requests enabled
6 TCIE	**Transmission Complete Interrupt Enable Bit** — TCIE enables the transmission complete flag, TC, to generate interrupt requests. 0 TC interrupt requests disabled 1 TC interrupt requests enabled
5 RIE	**Receiver Full Interrupt Enable Bit** — RIE enables the receive data register full flag, RDRF, or the overrun flag, OR, to generate interrupt requests. 0 RDRF and OR interrupt requests disabled 1 RDRF and OR interrupt requests enabled
4 ILIE	**Idle Line Interrupt Enable Bit** — ILIE enables the idle line flag, IDLE, to generate interrupt requests. 0 IDLE interrupt requests disabled 1 IDLE interrupt requests enabled
3 TE	**Transmitter Enable Bit** — TE enables the SCI transmitter and configures the TXD pin as being controlled by the SCI. The TE bit can be used to queue an idle preamble. 0 Transmitter disabled 1 Transmitter enabled
2 RE	**Receiver Enable Bit** — RE enables the SCI receiver. 0 Receiver disabled 1 Receiver enabled

Table 16-4. SCICR2 Field Descriptions (continued)

Field	Description
1 RWU	**Receiver Wakeup Bit** — Standby state 0 Normal operation. 1 RWU enables the wakeup function and inhibits further receiver interrupt requests. Normally, hardware wakes the receiver by automatically clearing RWU.
0 SBK	**Send Break Bit** — Toggling SBK sends one break character (10 or 11 logic 0s, respectively 13 or 14 logics 0s if BRK13 is set). Toggling implies clearing the SBK bit before the break character has finished transmitting. As long as SBK is set, the transmitter continues to send complete break characters (10 or 11 bits, respectively 13 or 14 bits). 0 No break characters 1 Transmit break characters

16.3.2.4 SCI Status Register 1 (SCISR1)

The SCISR1 and SCISR2 registers provides inputs to the MCU for generation of SCI interrupts. Also, these registers can be polled by the MCU to check the status of these bits. The flag-clearing procedures require that the status register be read followed by a read or write to the SCI Data Register.It is permissible to execute other instructions between the two steps as long as it does not compromise the handling of I/O, but the order of operations is important for flag clearing.

Module Base + 0x_0004

	7	6	5	4	3	2	1	0
R	TDRE	TC	RDRF	IDLE	OR	NF	FE	PF
W								
Reset	0	0	0	0	0	0	0	0

= Unimplemented or Reserved

Figure 16-6. SCI Status Register 1 (SCISR1)

Read: Anytime

Write: Has no meaning or effect

Table 16-5. SCISR1 Field Descriptions

Field	Description
7 TDRE	**Transmit Data Register Empty Flag** — TDRE is set when the transmit shift register receives a byte from the SCI data register. When TDRE is 1, the transmit data register (SCIDRH/L) is empty and can receive a new value to transmit.Clear TDRE by reading SCI status register 1 (SCISR1), with TDRE set and then writing to SCI data register low (SCIDRL). 0 No byte transferred to transmit shift register 1 Byte transferred to transmit shift register; transmit data register empty
6 TC	**Transmit Complete Flag** — TC is set low when there is a transmission in progress or when a preamble or break character is loaded. TC is set high when the TDRE flag is set and no data, preamble, or break character is being transmitted.When TC is set, the TXD out signal becomes idle (logic 1). Clear TC by reading SCI status register 1 (SCISR1) with TC set and then writing to SCI data register low (SCIDRL). TC is cleared automatically when data, preamble, or break is queued and ready to be sent. TC is cleared in the event of a simultaneous set and clear of the TC flag (transmission not complete). 0 Transmission in progress 1 No transmission in progress

Table 16-5. SCISR1 Field Descriptions (continued)

Field	Description
5 RDRF	**Receive Data Register Full Flag** — RDRF is set when the data in the receive shift register transfers to the SCI data register. Clear RDRF by reading SCI status register 1 (SCISR1) with RDRF set and then reading SCI data register low (SCIDRL). 0 Data not available in SCI data register 1 Received data available in SCI data register
4 IDLE	**Idle Line Flag** — IDLE is set when 10 consecutive logic 1s (if M=0) or 11 consecutive logic 1s (if M=1) appear on the receiver input. Once the IDLE flag is cleared, a valid frame must again set the RDRF flag before an idle condition can set the IDLE flag.Clear IDLE by reading SCI status register 1 (SCISR1) with IDLE set and then reading SCI data register low (SCIDRL). 0 Receiver input is either active now or has never become active since the IDLE flag was last cleared 1 Receiver input has become idle **Note:** When the receiver wakeup bit (RWU) is set, an idle line condition does not set the IDLE flag.
3 OR	**Overrun Flag** — OR is set when software fails to read the SCI data register before the receive shift register receives the next frame. The OR bit is set immediately after the stop bit has been completely received for the second frame. The data in the shift register is lost, but the data already in the SCI data registers is not affected. Clear OR by reading SCI status register 1 (SCISR1) with OR set and then reading SCI data register low (SCIDRL). 0 No overrun 1 Overrun **Note:** OR flag may read back as set when RDRF flag is clear. This may happen if the following sequence of events occurs: 1. After the first frame is received, read status register SCISR1 (returns RDRF set and OR flag clear); 2. Receive second frame without reading the first frame in the data register (the second frame is not received and OR flag is set); 3. Read data register SCIDRL (returns first frame and clears RDRF flag in the status register); 4. Read status register SCISR1 (returns RDRF clear and OR set). Event 3 may be at exactly the same time as event 2 or any time after. When this happens, a dummy SCIDRL read following event 4 will be required to clear the OR flag if further frames are to be received.
2 NF	**Noise Flag** — NF is set when the SCI detects noise on the receiver input. NF bit is set during the same cycle as the RDRF flag but does not get set in the case of an overrun. Clear NF by reading SCI status register 1(SCISR1), and then reading SCI data register low (SCIDRL). 0 No noise 1 Noise
1 FE	**Framing Error Flag** — FE is set when a logic 0 is accepted as the stop bit. FE bit is set during the same cycle as the RDRF flag but does not get set in the case of an overrun. FE inhibits further data reception until it is cleared. Clear FE by reading SCI status register 1 (SCISR1) with FE set and then reading the SCI data register low (SCIDRL). 0 No framing error 1 Framing error
0 PF	**Parity Error Flag** — PF is set when the parity enable bit (PE) is set and the parity of the received data does not match the parity type bit (PT). PF bit is set during the same cycle as the RDRF flag but does not get set in the case of an overrun. Clear PF by reading SCI status register 1 (SCISR1), and then reading SCI data register low (SCIDRL). 0 No parity error 1 Parity error

Figure 16-8. SCI Data Registers (SCIDRH and SCIDRL)

Read: Anytime; reading accesses SCI receive data register

Write: Anytime; writing accesses SCI transmit data register; writing to R8 has no effect

Table 16-7. SCIDRH AND SCIDRL Field Descriptions

Field	Description
7 R8	**Received Bit 8** — R8 is the ninth data bit received when the SCI is configured for 9-bit data format (M = 1).
6 T8	**Transmit Bit 8** — T8 is the ninth data bit transmitted when the SCI is configured for 9-bit data format (M = 1).
7–0 R[7:0] T[7:0]	**Received Bits** — Received bits seven through zero for 9-bit or 8-bit data formats **Transmit Bits** — Transmit bits seven through zero for 9-bit or 8-bit formats

NOTE

If the value of T8 is the same as in the previous transmission, T8 does not have to be rewritten.The same value is transmitted until T8 is rewritten

In 8-bit data format, only SCI data register low (SCIDRL) needs to be accessed.

When transmitting in 9-bit data format and using 8-bit write instructions, write first to SCI data register high (SCIDRH), then SCIDRL.

16.4 Functional Description

This section provides a complete functional description of the SCI block, detailing the operation of the design from the end user perspective in a number of subsections.

Figure 16-9 shows the structure of the SCI module. The SCI allows full duplex, asynchronous, NRZ serial communication between the CPU and remote devices, including other CPUs. The SCI transmitter and receiver operate independently, although they use the same baud rate generator. The CPU monitors the status of the SCI, writes the data to be transmitted, and processes received data.

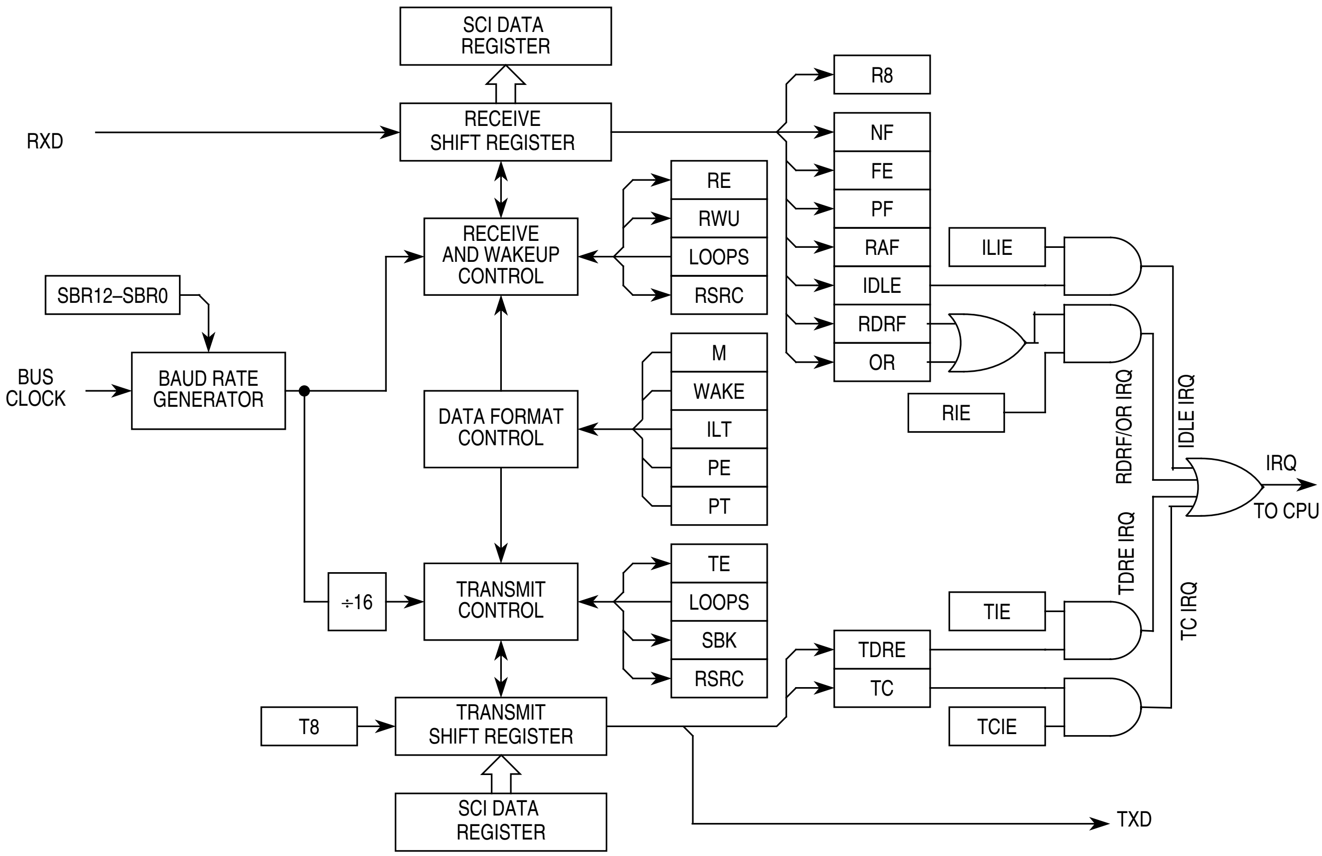

Figure 16-9. SCI Block Diagram

16.4.1 Data Format

The SCI uses the standard NRZ mark/space data format illustrated in Figure 16-10 below.

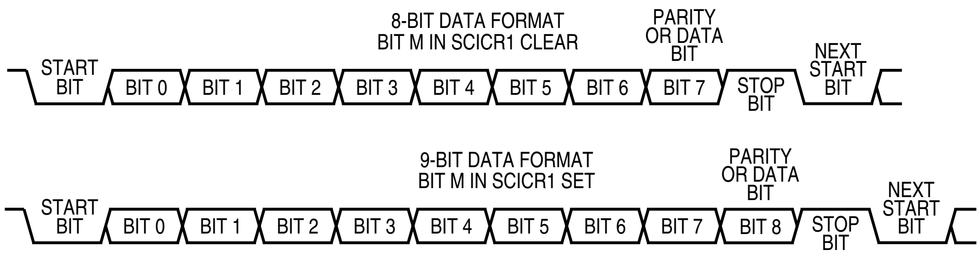

Figure 16-10. SCI Data Formats

Each data character is contained in a frame that includes a start bit, eight or nine data bits, and a stop bit. Clearing the M bit in SCI control register 1 configures the SCI for 8-bit data characters.A frame with eight data bits has a total of 10 bits. Setting the M bit configures the SCI for nine-bit data characters. A frame with nine data bits has a total of 11 bits

Table 16-8. Example of 8-Bit Data Formats

Start Bit	Data Bits	Address Bits	Parity Bits	Stop Bit
1	8	0	0	1
1	7	0	1	1
1	7	1[1]	0	1

[1] The address bit identifies the frame as an address character. See Section 16.4.4.6, “Receiver Wakeup”.

When the SCI is configured for 9-bit data characters, the ninth data bit is the T8 bit in SCI data register high (SCIDRH). It remains unchanged after transmission and can be used repeatedly without rewriting it. A frame with nine data bits has a total of 11 bits.

Table 16-9. Example of 9-Bit Data Formats

Start Bit	Data Bits	Address Bits	Parity Bits	Stop Bit
1	9	0	0	1
1	8	0	1	1
1	8	1[1]	0	1

[1] The address bit identifies the frame as an address character. See Section 16.4.4.6, “Receiver Wakeup”.

16.4.2 Baud Rate Generation

A 13-bit modulus counter in the baud rate generator derives the baud rate for both the receiver and the transmitter. The value from 0 to 8191 written to the SBR12–SBR0 bits determines the module clock divisor. The SBR bits are in the SCI baud rate registers (SCIBDH and SCIBDL). The baud rate clock is synchronized with the bus clock and drives the receiver. The baud rate clock divided by 16 drives the transmitter. The receiver has an acquisition rate of 16 samples per bit time.

Baud rate generation is subject to one source of error:

Integer division of the module clock may not give the exact target frequency.

Table 16-10 lists some examples of achieving target baud rates with a module clock frequency of 25 MHz

SCI baud rate = SCI module clock / (16 * SCIBR[12:0])

Table 16-10. Baud Rates (Example: Module Clock = 25 MHz)

Bits SBR[12-0]	Receiver Clock (Hz)	Transmitter Clock (Hz)	Target Baud Rate	Error (%)
41	609,756.1	38,109.8	38,400	.76
81	308,642.0	19,290.1	19,200	.47
163	153,374.2	9585.9	9600	.16
326	76,687.1	4792.9	4800	.15
651	38,402.5	2400.2	2400	.01
1302	19,201.2	1200.1	1200	.01
2604	9600.6	600.0	600	.00
5208	4800.0	300.0	300	.00

16.4.3 Transmitter

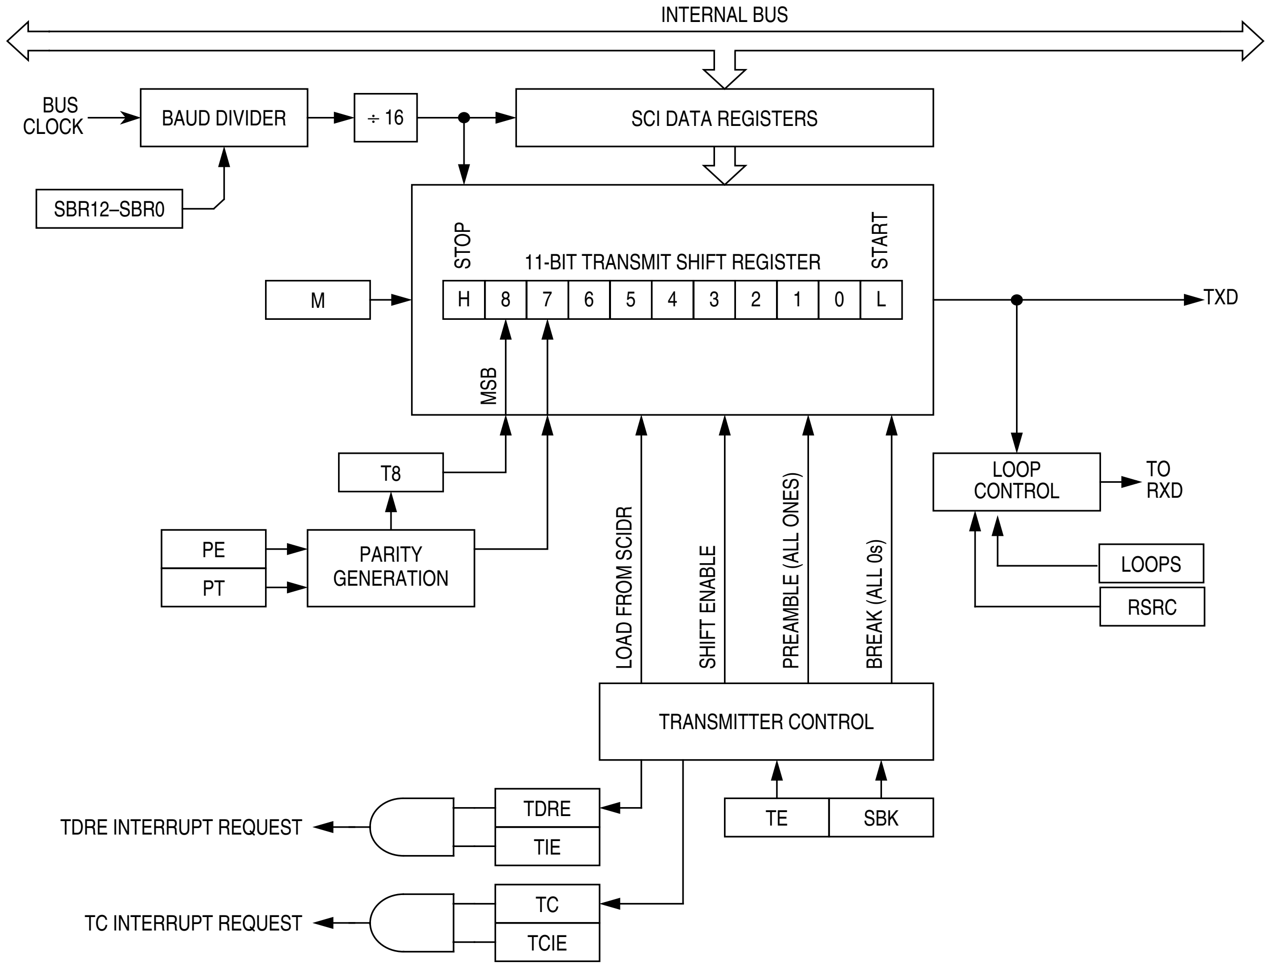

Figure 16-11. Transmitter Block Diagram

16.4.3.1 Transmitter Character Length

The SCI transmitter can accommodate either 8-bit or 9-bit data characters. The state of the M bit in SCI control register 1 (SCICR1) determines the length of data characters. When transmitting 9-bit data, bit T8 in SCI data register high (SCIDRH) is the ninth bit (bit 8).

16.4.3.2 Character Transmission

To transmit data, the MCU writes the data bits to the SCI data registers (SCIDRH/SCIDRL), which in turn are transferred to the transmitter shift register. The transmit shift register then shifts a frame out through the **Tx output** signal, after it has prefaced them with a start bit and appended them with a stop bit. The SCI data registers (SCIDRH and SCIDRL) are the write-only buffers between the internal data bus and the transmit shift register.

The SCI also sets a flag, the transmit data register empty flag (TDRE), every time it transfers data from the buffer (SCIDRH/L) to the transmitter shift register.The transmit driver routine may respond to this flag by writing another byte to the Transmitter buffer (SCIDRH/SCIDRL), while the shift register is still shifting out the first byte.

To initiate an SCI transmission:

1. Configure the SCI:
   a) Select a baud rate. Write this value to the SCI baud registers (SCIBDH/L) to begin the baud rate generator. Remember that the baud rate generator is disabled when the baud rate is zero. Writing to the SCIBDH has no effect without also writing to SCIBDL.
   b) Write to SCICR1 to configure word length, parity, and other configuration bits (LOOPS,RSRC,M,WAKE,ILT,PE,PT).
   c) Enable the transmitter, interrupts, receive, and wake up as required, by writing to the SCICR2 register bits (TIE,TCIE,RIE,ILIE,TE,RE,RWU,SBK). A preamble or idle character will now be shifted out of the transmitter shift register.
2. Transmit Procedure for Each Byte:
   a. Poll the TDRE flag by reading the SCISR1 or responding to the TDRE interrupt. Keep in mind that the TDRE bit resets to one.
   d) If the TDRE flag is set, write the data to be transmitted to SCIDRH/L, where the ninth bit is written to the T8 bit in SCIDRH if the SCI is in 9-bit data format. A new transmission will not result until the TDRE flag has been cleared.
3. Repeat step 2 for each subsequent transmission.

NOTE

The TDRE flag is set when the shift register is loaded with the next data to be transmitted from SCIDRH/L, which happens, generally speaking, a little over half-way through the stop bit of the previous frame. Specifically, this transfer occurs 9/16ths of a bit time AFTER the start of the stop bit of the previous frame.

Writing the TE bit from 0 to a 1 automatically loads the transmit shift register with a preamble of 10 logic 1s (if M = 0) or 11 logic 1s (if M = 1). After the preamble shifts out, control logic transfers the data from the SCI data register into the transmit shift register. A logic 0 start bit automatically goes into the least significant bit position of the transmit shift register. A logic 1 stop bit goes into the most significant bit position.

Hardware supports odd or even parity. When parity is enabled, the most significant bit (msb) of the data character is the parity bit.

The transmit data register empty flag, TDRE, in SCI status register 1 (SCISR1) becomes set when the SCI data register transfers a byte to the transmit shift register. The TDRE flag indicates that the SCI data register can accept new data from the internal data bus. If the transmit interrupt enable bit, TIE, in SCI control register 2 (SCICR2) is also set, the TDRE flag generates a transmitter interrupt request.

When the transmit shift register is not transmitting a frame, the **Tx output** signal goes to the idle condition, logic 1. If at any time software clears the TE bit in SCI control register 2 (SCICR2), the transmitter enable signal goes low and the transmit signal goes idle.

If software clears TE while a transmission is in progress (TC = 0), the frame in the transmit shift register continues to shift out. To avoid accidentally cutting off the last frame in a message, always wait for TDRE to go high after the last frame before clearing TE.

To separate messages with preambles with minimum idle line time, use this sequence between messages:

1. Write the last byte of the first message to SCIDRH/L.
2. Wait for the TDRE flag to go high, indicating the transfer of the last frame to the transmit shift register.
3. Queue a preamble by clearing and then setting the TE bit.
4. Write the first byte of the second message to SCIDRH/L.

16.4.3.3 Break Characters

Writing a logic 1 to the send break bit, SBK, in SCI control register 2 (SCICR2) loads the transmit shift register with a break character. A break character contains all logic 0s and has no start, stop, or parity bit. Break character length depends on the M bit in SCI control register 1 (SCICR1). As long as SBK is at logic 1, transmitter logic continuously loads break characters into the transmit shift register. After software clears the SBK bit, the shift register finishes transmitting the last break character and then transmits at least one logic 1. The automatic logic 1 at the end of a break character guarantees the recognition of the start bit of the next frame.

The SCI recognizes a break character when a start bit is followed by eight or nine logic 0 data bits and a logic 0 where the stop bit should be. Receiving a break character has these effects on SCI registers:

- Sets the framing error flag, FE
- Sets the receive data register full flag, RDRF
- Clears the SCI data registers (SCIDRH/L)
- May set the overrun flag, OR, noise flag, NF, parity error flag, PE, or the receiver active flag, RAF (see Section 16.3.2.4, “SCI Status Register 1 (SCISR1)” and Section 16.3.2.5, “SCI Status Register 2 (SCISR2)”

16.4.3.4 Idle Characters

An idle character contains all logic 1s and has no start, stop, or parity bit. Idle character length depends on the M bit in SCI control register 1 (SCICR1). The preamble is a synchronizing idle character that begins the first transmission initiated after writing the TE bit from 0 to 1.

If the TE bit is cleared during a transmission, the **Tx output** signal becomes idle after completion of the transmission in progress. Clearing and then setting the TE bit during a transmission queues an idle character to be sent after the frame currently being transmitted.

NOTE

When queueing an idle character, return the TE bit to logic 1 before the stop bit of the current frame shifts out through the **Tx output** signal. Setting TE after the stop bit appears on **Tx output signal** causes data previously written to the SCI data register to be lost. Toggle the TE bit for a queued idle character while the TDRE flag is set and immediately before writing the next byte to the SCI data register.

NOTE

If the TE bit is clear and the transmission is complete, the SCI is not the master of the TXD pin

16.4.4 Receiver

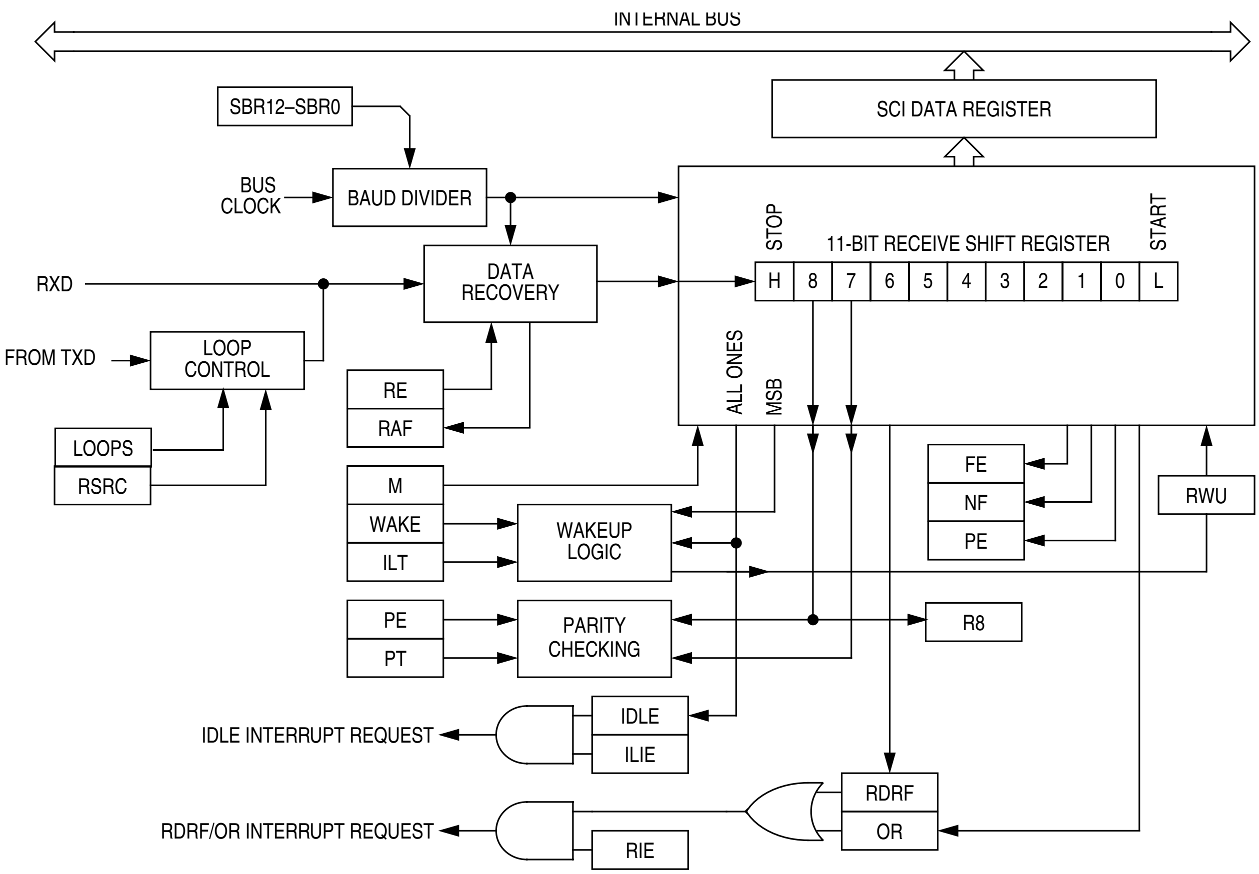

Figure 16-12. SCI Receiver Block Diagram

16.4.4.1 Receiver Character Length

The SCI receiver can accommodate either 8-bit or 9-bit data characters. The state of the M bit in SCI control register 1 (SCICR1) determines the length of data characters. When receiving 9-bit data, bit R8 in SCI data register high (SCIDRH) is the ninth bit (bit 8).

16.4.4.2 Character Reception

During an SCI reception, the receive shift register shifts a frame in from the **Rx input** signal. The SCI data register is the read-only buffer between the internal data bus and the receive shift register.

After a complete frame shifts into the receive shift register, the data portion of the frame transfers to the SCI data register. The receive data register full flag, RDRF, in SCI status register 1 (SCISR1) becomes set, indicating that the received byte can be read. If the receive interrupt enable bit, RIE, in SCI control register 2 (SCICR2) is also set, the RDRF flag generates an RDRF interrupt request.

16.4.4.3 Data Sampling

The receiver samples the **Rx input** signal at the RT clock rate. The RT clock is an internal signal with a frequency 16 times the baud rate. To adjust for baud rate mismatch, the RT clock (see Figure 16-13) is re-synchronized:

- After every start bit
- After the receiver detects a data bit change from logic 1 to logic 0 (after the majority of data bit samples at RT8, RT9, and RT10 returns a valid logic 1 and the majority of the next RT8, RT9, and RT10 samples returns a valid logic 0)

To locate the start bit, data recovery logic does an asynchronous search for a logic 0 preceded by three logic 1s.When the falling edge of a possible start bit occurs, the RT clock begins to count to 16.

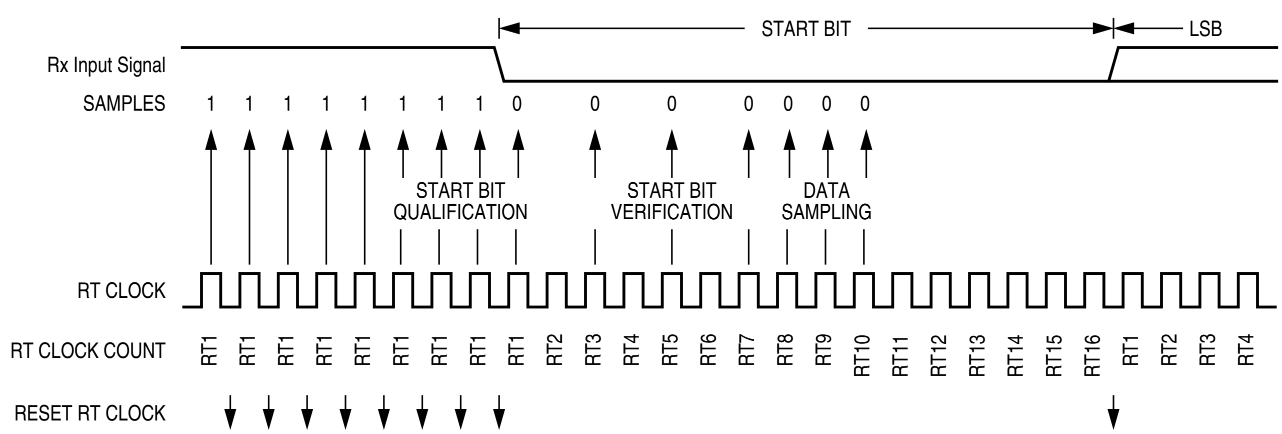

Figure 16-13. Receiver Data Sampling

To verify the start bit and to detect noise, data recovery logic takes samples at RT3, RT5, and RT7. Table 16-11 summarizes the results of the start bit verification samples.

Table 16-11. Start Bit Verification

RT3, RT5, and RT7 Samples	Start Bit Verification	Noise Flag
000	Yes	0
001	Yes	1
010	Yes	1
011	No	0

Table 16-11. Start Bit Verification

RT3, RT5, and RT7 Samples	Start Bit Verification	Noise Flag
100	Yes	1
101	No	0
110	No	0
111	No	0

If start bit verification is not successful, the RT clock is reset and a new search for a start bit begins.

To determine the value of a data bit and to detect noise, recovery logic takes samples at RT8, RT9, and RT10. Table 16-12 summarizes the results of the data bit samples.

Table 16-12. Data Bit Recovery

RT8, RT9, and RT10 Samples	Data Bit Determination	Noise Flag
000	0	0
001	0	1
010	0	1
011	1	1
100	0	1
101	1	1
110	1	1
111	1	0

NOTE

The RT8, RT9, and RT10 samples do not affect start bit verification. If any or all of the RT8, RT9, and RT10 start bit samples are logic 1s following a successful start bit verification, the noise flag (NF) is set and the receiver assumes that the bit is a start bit (logic 0).

To verify a stop bit and to detect noise, recovery logic takes samples at RT8, RT9, and RT10. Table 16-13 summarizes the results of the stop bit samples.

Table 16-13. Stop Bit Recovery

RT8, RT9, and RT10 Samples	Framing Error Flag	Noise Flag
000	1	0
001	1	1
010	1	1
011	0	1
100	1	1
101	0	1
110	0	1
111	0	0

In Figure 16-14 the verification samples RT3 and RT5 determine that the first low detected was noise and not the beginning of a start bit. The RT clock is reset and the start bit search begins again. The noise flag is not set because the noise occurred before the start bit was found.

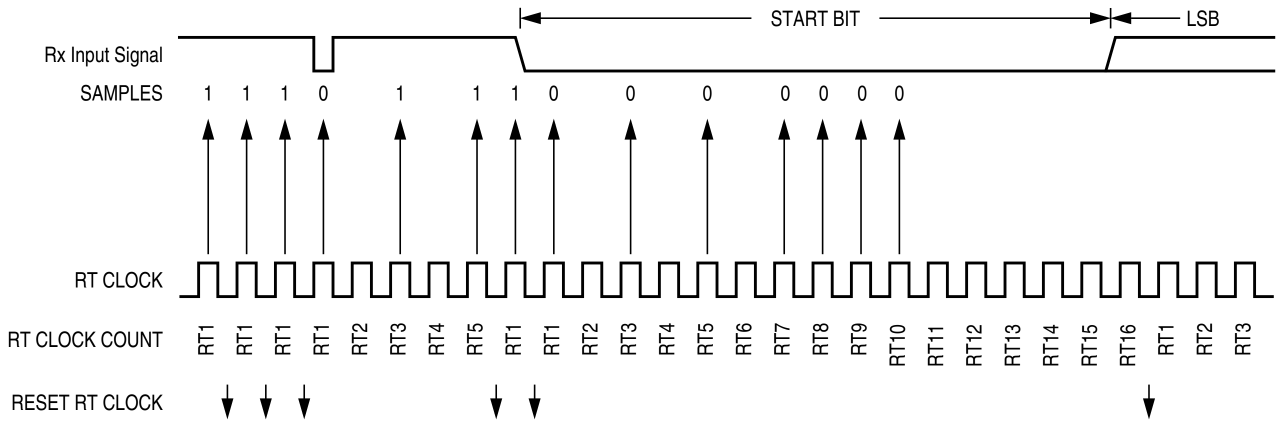

Figure 16-14. Start Bit Search Example 1

In Figure 16-15, verification sample at RT3 is high. The RT3 sample sets the noise flag. Although the perceived bit time is misaligned, the data samples RT8, RT9, and RT10 are within the bit time and data recovery is successful.

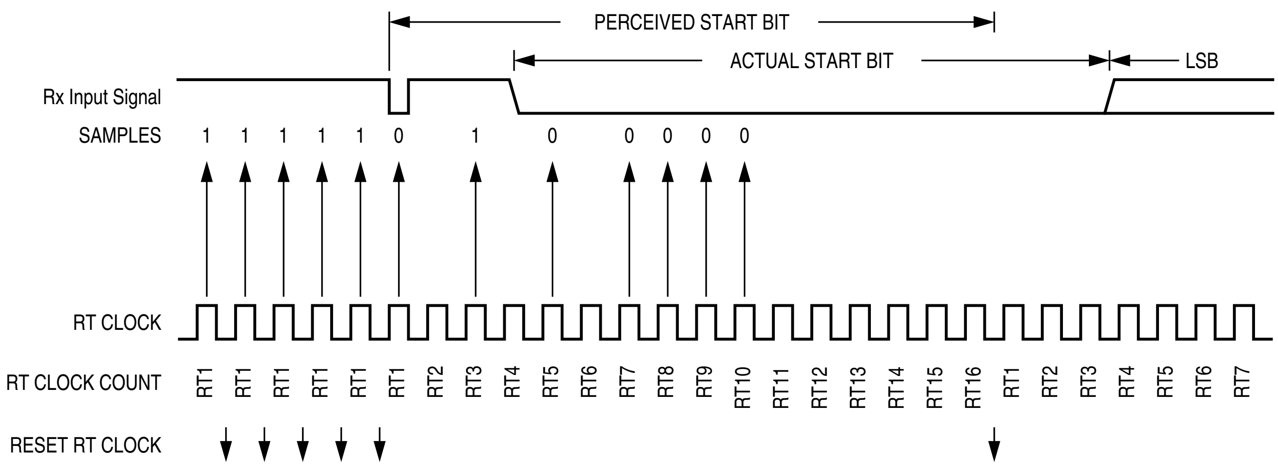

Figure 16-15. Start Bit Search Example 2

In Figure 16-16, a large burst of noise is perceived as the beginning of a start bit, although the test sample at RT5 is high. The RT5 sample sets the noise flag. Although this is a worst-case misalignment of perceived bit time, the data samples RT8, RT9, and RT10 are within the bit time and data recovery is successful.

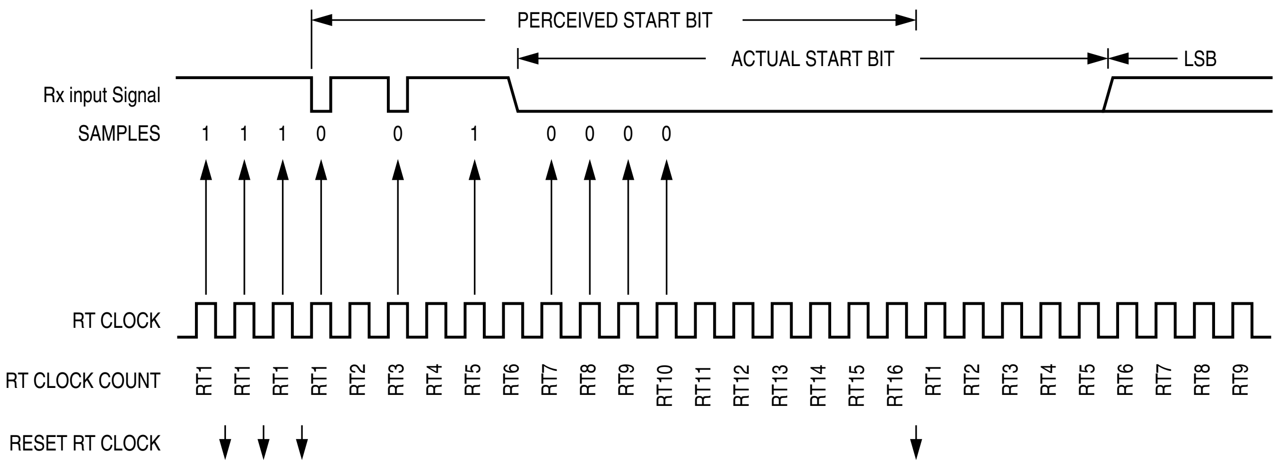

Figure 16-16. Start Bit Search Example 3

Figure 16-17 shows the effect of noise early in the start bit time. Although this noise does not affect proper synchronization with the start bit time, it does set the noise flag.

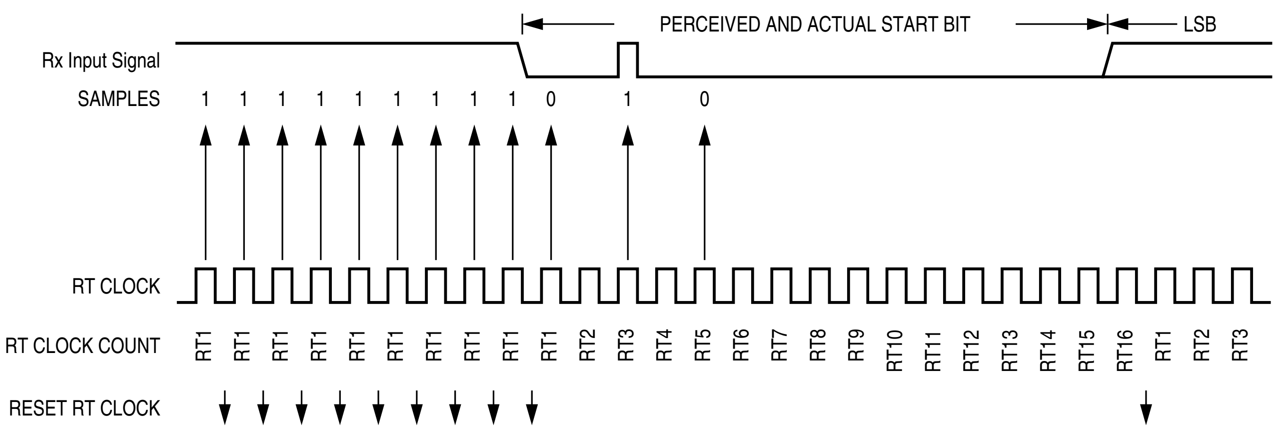

Figure 16-17. Start Bit Search Example 4

Figure 16-18 shows a burst of noise near the beginning of the start bit that resets the RT clock. The sample after the reset is low but is not preceded by three high samples that would qualify as a falling edge. Depending on the timing of the start bit search and on the data, the frame may be missed entirely or it may set the framing error flag.

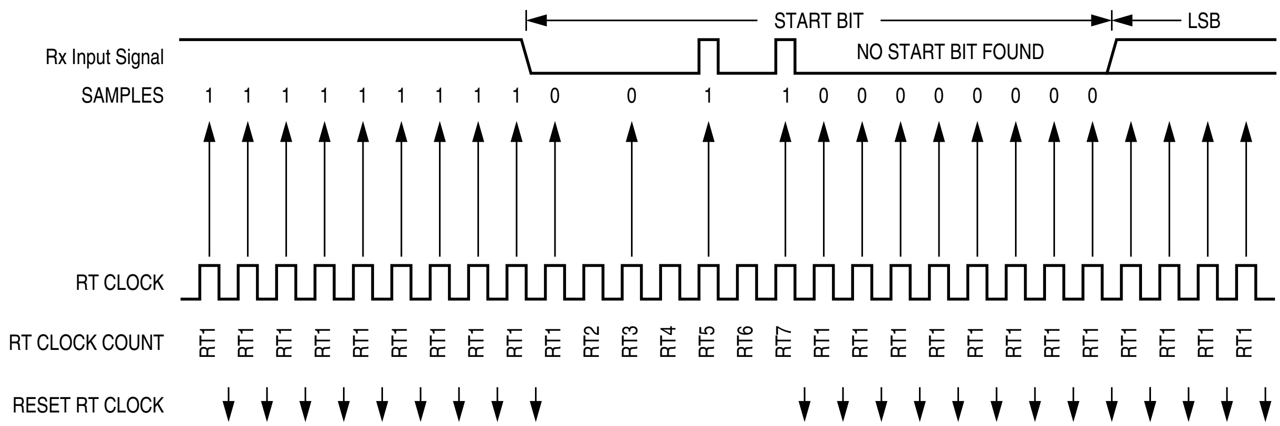

Figure 16-18. Start Bit Search Example 5

In Figure 16-19, a noise burst makes the majority of data samples RT8, RT9, and RT10 high. This sets the noise flag but does not reset the RT clock. In start bits only, the RT8, RT9, and RT10 data samples are ignored.

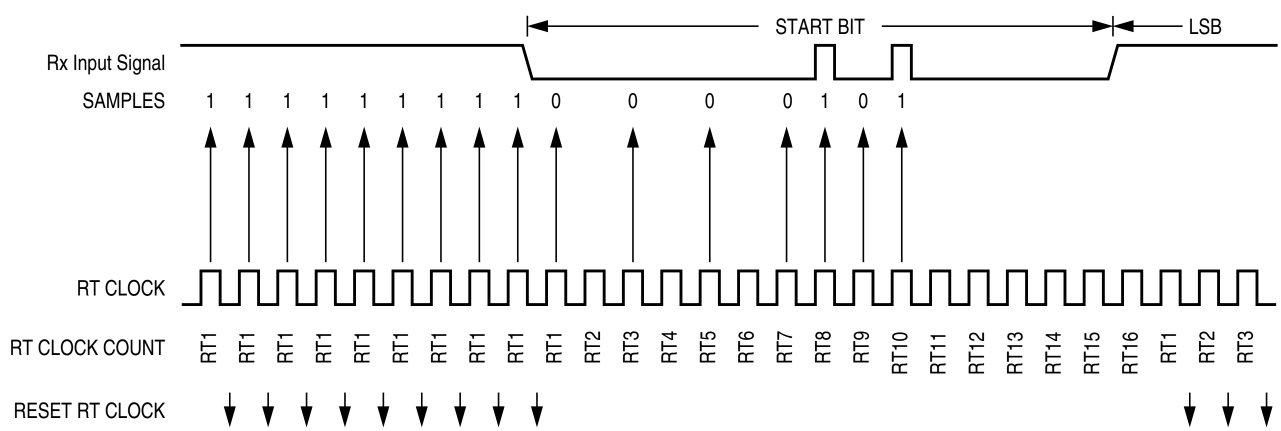

Figure 16-19. Start Bit Search Example 6

16.4.4.4 Framing Errors

If the data recovery logic does not detect a logic 1 where the stop bit should be in an incoming frame, it sets the framing error flag, FE, in SCI status register 1 (SCISR1). A break character also sets the FE flag because a break character has no stop bit. The FE flag is set at the same time that the RDRF flag is set.

16.4.4.5 Baud Rate Tolerance

A transmitting device may be operating at a baud rate below or above the receiver baud rate. Accumulated bit time misalignment can cause one of the three stop bit data samples (RT8, RT9, and RT10) to fall outside the actual stop bit.A noise error will occur if the RT8, RT9, and RT10 samples are not all the same logical values. A framing error will occur if the receiver clock is misaligned in such a way that the majority of the RT8, RT9, and RT10 stop bit samples are a logic zero.

As the receiver samples an incoming frame, it re-synchronizes the RT clock on any valid falling edge within the frame. Re synchronization within frames will correct a misalignment between transmitter bit times and receiver bit times.

16.4.4.5.1 Slow Data Tolerance

Figure 16-20 shows how much a slow received frame can be misaligned without causing a noise error or a framing error. The slow stop bit begins at RT8 instead of RT1 but arrives in time for the stop bit data samples at RT8, RT9, and RT10.

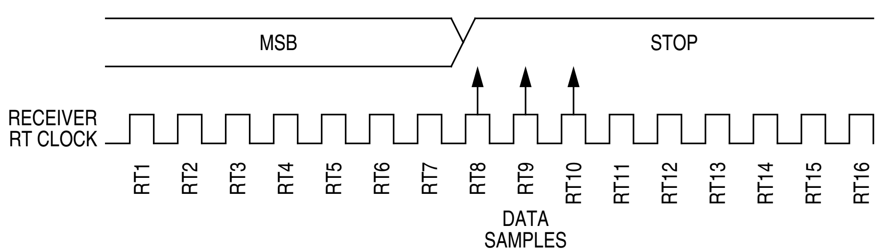

Figure 16-20. Slow Data

Let’s take RTr as receiver RT clock and RTt as transmitter RT clock.

For an 8-bit data character, it takes the receiver 9 bit times x 16 RTr cycles +7 RTr cycles =151 RTr cycles to start data sampling of the stop bit.

With the misaligned character shown in Figure 16-20, the receiver counts 151 RTr cycles at the point when the count of the transmitting device is 9 bit times x 16 RTt cycles = 144 RTt cycles.

The maximum percent difference between the receiver count and the transmitter count of a slow 8-bit data character with no errors is:

$$((151 – 144) / 151) \times 100 = 4.63\%$$

For a 9-bit data character, it takes the receiver 10 bit times x 16 RTr cycles + 7 RTr cycles = 167 RTr cycles to start data sampling of the stop bit.

With the misaligned character shown in Figure 16-20, the receiver counts 167 RTr cycles at the point when the count of the transmitting device is 10 bit times x 16 RTt cycles = 160 RTt cycles.

The maximum percent difference between the receiver count and the transmitter count of a slow 9-bit character with no errors is:

((167 – 160) / 167) X 100 = 4.19%

16.4.4.5.2 Fast Data Tolerance

Figure 16-21 shows how much a fast received frame can be misaligned. The fast stop bit ends at RT10 instead of RT16 but is still sampled at RT8, RT9, and RT10.

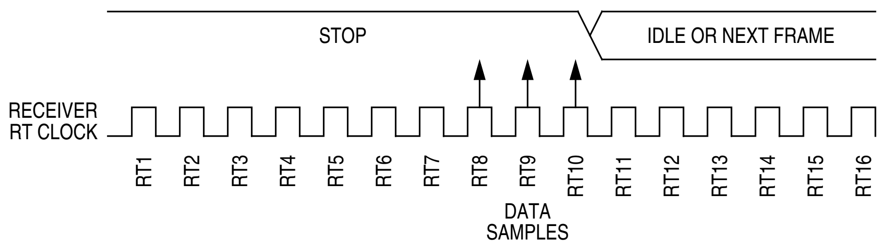

Figure 16-21. Fast Data

For an 8-bit data character, it takes the receiver 9 bit times x 16 RTr cycles + 10 RTr cycles = 154 RTr cycles to finish data sampling of the stop bit.

With the misaligned character shown in Figure 16-21, the receiver counts 154 RTr cycles at the point when the count of the transmitting device is 10 bit times x 16 RTt cycles = 160 RTt cycles.

The maximum percent difference between the receiver count and the transmitter count of a fast 8-bit character with no errors is:

((160 – 154) / 160) x 100 = 3.75%

For a 9-bit data character, it takes the receiver 10 bit times x 16 RTr cycles + 10 RTr cycles = 170 RTr cycles to finish data sampling of the stop bit.

With the misaligned character shown in Figure 16-21, the receiver counts 170 RTr cycles at the point when the count of the transmitting device is 11 bit times x 16 RTt cycles = 176 RTt cycles.

The maximum percent difference between the receiver count and the transmitter count of a fast 9-bit character with no errors is:

((176 – 170) / 176) x 100 = 3.40%

16.4.4.6 Receiver Wakeup

To enable the SCI to ignore transmissions intended only for other receivers in multiple-receiver systems, the receiver can be put into a standby state. Setting the receiver wakeup bit, RWU, in SCI control register 2 (SCICR2) puts the receiver into standby state during which receiver interrupts are disabled.The SCI will still load the receive data into the SCIDRH/L registers, but it will not set the RDRF flag.

The transmitting device can address messages to selected receivers by including addressing information in the initial frame or frames of each message.

The WAKE bit in SCI control register 1 (SCICR1) determines how the SCI is brought out of the standby state to process an incoming message. The WAKE bit enables either idle line wakeup or address mark wakeup.

16.4.4.6.1 Idle Input Line Wakeup (WAKE = 0)

In this wakeup method, an idle condition on the **Rx Input** signal clears the RWU bit and wakes up the SCI. The initial frame or frames of every message contain addressing information. All receivers evaluate the addressing information, and receivers for which the message is addressed process the frames that follow. Any receiver for which a message is not addressed can set its RWU bit and return to the standby state. The RWU bit remains set and the receiver remains on standby until another idle character appears on the **Rx Input** signal.

Idle line wakeup requires that messages be separated by at least one idle character and that no message contains idle characters.

The idle character that wakes a receiver does not set the receiver idle bit, IDLE, or the receive data register full flag, RDRF.

The idle line type bit, ILT, determines whether the receiver begins counting logic 1s as idle character bits after the start bit or after the stop bit. ILT is in SCI control register 1 (SCICR1).

16.4.4.6.2 Address Mark Wakeup (WAKE = 1)

In this wakeup method, a logic 1 in the most significant bit (msb) position of a frame clears the RWU bit and wakes up the SCI. The logic 1 in the msb position marks a frame as an address frame that contains addressing information. All receivers evaluate the addressing information, and the receivers for which the message is addressed process the frames that follow.Any receiver for which a message is not addressed can set its RWU bit and return to the standby state. The RWU bit remains set and the receiver remains on standby until another address frame appears on the **Rx Input** signal.

The logic 1 msb of an address frame clears the receiver's RWU bit before the stop bit is received and sets the RDRF flag.

Address mark wakeup allows messages to contain idle characters but requires that the msb be reserved for use in address frames.{sci_wake}

NOTE

With the WAKE bit clear, setting the RWU bit after the **Rx Input** signal has been idle can cause the receiver to wake up immediately.

16.4.5 Single-Wire Operation

Normally, the SCI uses two pins for transmitting and receiving. In single-wire operation, the RXD pin is disconnected from the SCI. The SCI uses the TXD pin for both receiving and transmitting.

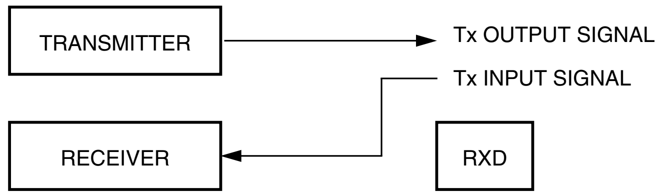

Figure 16-22. Single-Wire Operation (LOOPS = 1, RSRC = 1)

Enable single-wire operation by setting the LOOPS bit and the receiver source bit, RSRC, in SCI control register 1 (SCICR1). Setting the LOOPS bit disables the path from the **Rx Input** signal to the receiver. Setting the RSRC bit connects the receiver input to the output of the TXD pin driver. Both the transmitter and receiver must be enabled (TE = 1 and RE = 1).The TXDIR bit (SCISR2[1]) determines whether the TXD pin is going to be used as an input (TXDIR = 0) or an output (TXDIR = 1) in this mode of operation.

16.4.6 Loop Operation

In loop operation the transmitter output goes to the receiver input. The **Rx Input** signal is disconnected from the SCI

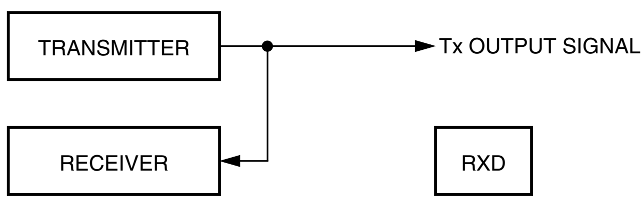

Figure 16-23. Loop Operation (LOOPS = 1, RSRC = 0)

Enable loop operation by setting the LOOPS bit and clearing the RSRC bit in SCI control register 1 (SCICR1). Setting the LOOPS bit disables the path from the **Rx Input** signal to the receiver. Clearing the RSRC bit connects the transmitter output to the receiver input. Both the transmitter and receiver must be enabled (TE = 1 and RE = 1).

16.5 Initialization Information

16.5.1 Reset Initialization

The reset state of each individual bit is listed in Section 16.3, “Memory Map and Registers” which details the registers and their bit fields. All special functions or modes which are initialized during or just following reset are described within this section.

16.5.2 Interrupt Operation

16.5.2.1 System Level Interrupt Sources

There are five interrupt sources that can generate an SCI interrupt in to the CPU. They are listed in Table 16-14.

Table 16-14. SCI Interrupt Source

Interrupt Source	Flag	Local Enable
Transmitter	TDRE	TIE
Transmitter	TC	TCIE
Receiver	RDRF	RIE
	OR	
Receiver	IDLE	ILIE

16.5.2.2 Interrupt Descriptions

The SCI only originates interrupt requests. The following is a description of how the SCI makes a request and how the MCU should acknowledge that request. The interrupt vector offset and interrupt number are chip dependent. The SCI only has a single interrupt line (**SCI Interrupt Signal**, active high operation) and all the following interrupts, when generated, are ORed together and issued through that port.

16.5.2.2.1 TDRE Description

The TDRE interrupt is set high by the SCI when the transmit shift register receives a byte from the SCI data register. A TDRE interrupt indicates that the transmit data register (SCIDRH/L) is empty and that a new byte can be written to the SCIDRH/L for transmission.Clear TDRE by reading SCI status register 1 with TDRE set and then writing to SCI data register low (SCIDRL).

16.5.2.2.2 TC Description

The TC interrupt is set by the SCI when a transmission has been completed.A TC interrupt indicates that there is no transmission in progress. TC is set high when the TDRE flag is set and no data, preamble, or break character is being transmitted. When TC is set, the TXD pin becomes idle (logic 1). Clear TC by reading SCI status register 1 (SCISR1) with TC set and then writing to SCI data register low (SCIDRL).TC is cleared automatically when data, preamble, or break is queued and ready to be sent.

16.5.2.2.3 RDRF Description

The RDRF interrupt is set when the data in the receive shift register transfers to the SCI data register. A RDRF interrupt indicates that the received data has been transferred to the SCI data register and that the byte can now be read by the MCU. The RDRF interrupt is cleared by reading the SCI status register one (SCISR1) and then reading SCI data register low (SCIDRL).

16.5.2.2.4 OR Description

The OR interrupt is set when software fails to read the SCI data register before the receive shift register receives the next frame. The newly acquired data in the shift register will be lost in this case, but the data already in the SCI data registers is not affected. The OR interrupt is cleared by reading the SCI status register one (SCISR1) and then reading SCI data register low (SCIDRL).

16.5.2.3 IDLE Description

The IDLE interrupt is set when 10 consecutive logic 1s (if M = 0) or 11 consecutive logic 1s (if M = 1) appear on the receiver input. Once the IDLE is cleared, a valid frame must again set the RDRF flag before an idle condition can set the IDLE flag. Clear IDLE by reading SCI status register 1 (SCISR1) with IDLE set and then reading SCI data register low (SCIDRL).

16.5.3 Recovery from Wait Mode

The SCI interrupt request can be used to bring the CPU out of wait mode.

Chapter 17
Serial Peripheral Interface (SPIV3) Block Description

17.1 Introduction

The SPI module allows a duplex, synchronous, serial communication between the MCU and peripheral devices. Software can poll the SPI status flags or the SPI operation can be interrupt driven.

17.1.1 Features

The SPI includes these distinctive features:

- Master mode and slave mode
- Bidirectional mode
- Slave select output
- Mode fault error flag with CPU interrupt capability
- Double-buffered data register
- Serial clock with programmable polarity and phase
- Control of SPI operation during wait mode

17.1.2 Modes of Operation

The SPI functions in three modes, run, wait, and stop.

- Run Mode
  This is the basic mode of operation.
- Wait Mode
  SPI operation in wait mode is a configurable low power mode, controlled by the SPISWAI bit located in the SPICR2 register. In wait mode, if the SPISWAI bit is clear, the SPI operates like in Run Mode. If the SPISWAI bit is set, the SPI goes into a power conservative state, with the SPI clock generation turned off. If the SPI is configured as a master, any transmission in progress stops, but is resumed after CPU goes into Run Mode. If the SPI is configured as a slave, reception and transmission of a byte continues, so that the slave stays synchronized to the master.
- Stop Mode
  The SPI is inactive in stop mode for reduced power consumption. If the SPI is configured as a master, any transmission in progress stops, but is resumed after CPU goes into run mode. If the SPI is configured as a slave, reception and transmission of a byte continues, so that the slave stays synchronized to the master.

This is a high level description only, detailed descriptions of operating modes are contained in Section 17.4, "Functional Description."

17.1.3 Block Diagram

Figure 17-1 gives an overview on the SPI architecture. The main parts of the SPI are status, control, and data registers, shifter logic, baud rate generator, master/slave control logic, and port control logic.

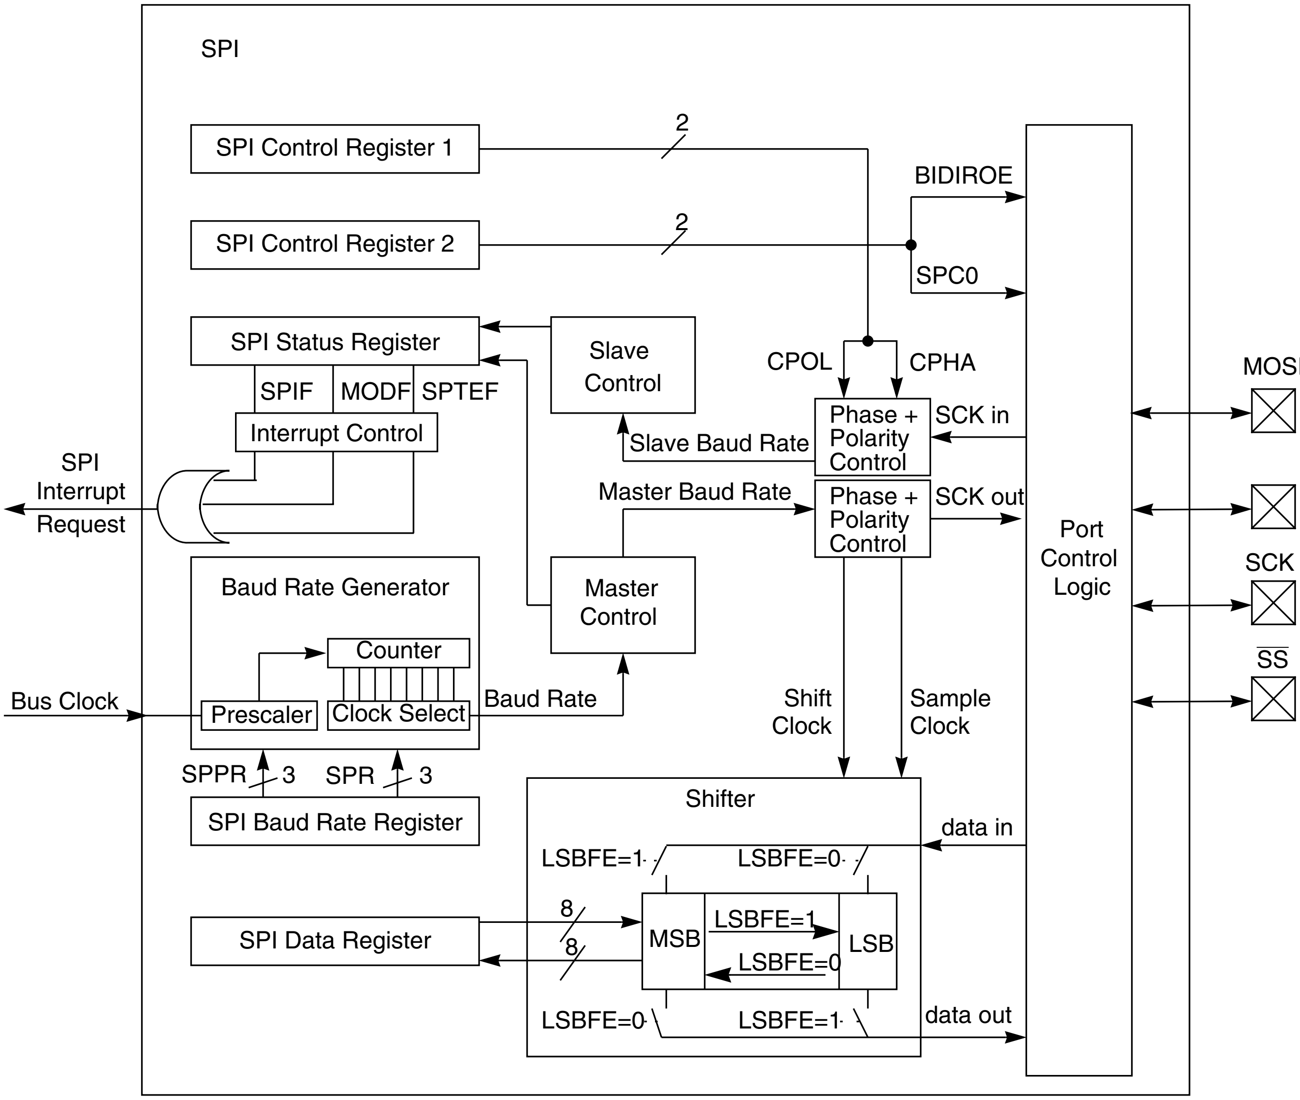

Figure 17-1. SPI Block Diagram

17.2 External Signal Description

This section lists the name and description of all ports including inputs and outputs that do, or may, connect off chip. The SPI module has a total of four external pins.

17.2.1 MOSI — Master Out/Slave In Pin

This pin is used to transmit data out of the SPI module when it is configured as a master and receive data when it is configured as slave.

17.2.2 MISO — Master In/Slave Out Pin

This pin is used to transmit data out of the SPI module when it is configured as a slave and receive data when it is configured as master.

17.2.3 $\overline{\text{SS}}$ — Slave Select Pin

This pin is used to output the select signal from the SPI module to another peripheral with which a data transfer is to take place when its configured as a master and its used as an input to receive the slave select signal when the SPI is configured as slave.

17.2.4 SCK — Serial Clock Pin

This pin is used to output the clock with respect to which the SPI transfers data or receive clock in case of slave.

17.3 Memory Map and Register Definition

This section provides a detailed description of address space and registers used by the SPI.

17.3.1 Register Descriptions

This section consists of register descriptions in address order. Each description includes a standard register diagram with an associated figure number. Details of register bit and field function follow the register diagrams, in bit order.

Read: anytime

Write: anytime

Table 17-1. SPICR1 Field Descriptions

Field	Description
7 SPIE	**SPI Interrupt Enable Bit** — This bit enables SPI interrupt requests, if SPIF or MODF status flag is set. 0 SPI interrupts disabled. 1 SPI interrupts enabled.
6 SPE	**SPI System Enable Bit** — This bit enables the SPI system and dedicates the SPI port pins to SPI system functions. If SPE is cleared, SPI is disabled and forced into idle state, status bits in SPISR register are reset. 0 SPI disabled (lower power consumption). 1 SPI enabled, port pins are dedicated to SPI functions.
5 SPTIE	**SPI Transmit Interrupt Enable** — This bit enables SPI interrupt requests, if SPTEF flag is set. 0 SPTEF interrupt disabled. 1 SPTEF interrupt enabled.
4 MSTR	**SPI Master/Slave Mode Select Bit** — This bit selects, if the SPI operates in master or slave mode. Switching the SPI from master to slave or vice versa forces the SPI system into idle state. 0 SPI is in slave mode 1 SPI is in master mode
3 CPOL	**SPI Clock Polarity Bit** — This bit selects an inverted or non-inverted SPI clock. To transmit data between SPI modules, the SPI modules must have identical CPOL values. In master mode, a change of this bit will abort a transmission in progress and force the SPI system into idle state. 0 Active-high clocks selected. In idle state SCK is low. 1 Active-low clocks selected. In idle state SCK is high.
2 CPHA	**SPI Clock Phase Bit** — This bit is used to select the SPI clock format. In master mode, a change of this bit will abort a transmission in progress and force the SPI system into idle state. 0 Sampling of data occurs at odd edges (1,3,5,...,15) of the SCK clock 1 Sampling of data occurs at even edges (2,4,6,...,16) of the SCK clock
1 SSOE	**Slave Select Output Enable** — The $\overline{SS}$ output feature is enabled only in master mode, if MODFEN is set, by asserting the SSOE as shown in Table 17-2. In master mode, a change of this bit will abort a transmission in progress and force the SPI system into idle state.
0 LSBFE	**LSB-First Enable** — This bit does not affect the position of the MSB and LSB in the data register. Reads and writes of the data register always have the MSB in bit 7. In master mode, a change of this bit will abort a transmission in progress and force the SPI system into idle state. 0 Data is transferred most significant bit first. 1 Data is transferred least significant bit first.

Table 17-2. $\overline{SS}$ Input / Output Selection

MODFEN	SSOE	Master Mode	Slave Mode
0	0	$\overline{SS}$ not used by SPI	$\overline{SS}$ input
0	1	$\overline{SS}$ not used by SPI	$\overline{SS}$ input
1	0	$\overline{SS}$ input with MODF feature	$\overline{SS}$ input
1	1	$\overline{SS}$ is slave select output	$\overline{SS}$ input

Field	Description
4 MODFEN	**Mode Fault Enable Bit** — This bit allows the MODF failure being detected. If the SPI is in master mode and MODFEN is cleared, then the $\overline{SS}$ port pin is not used by the SPI. In slave mode, the $\overline{SS}$ is available only as an input regardless of the value of MODFEN. For an overview on the impact of the MODFEN bit on the $\overline{SS}$ port pin configuration refer to Table 17-2. In master mode, a change of this bit will abort a transmission in progress and force the SPI system into idle state. 0 $\overline{SS}$ port pin is not used by the SPI 1 $\overline{SS}$ port pin with MODF feature
3 BIDIROE	**Output Enable in the Bidirectional Mode of Operation** — This bit controls the MOSI and MISO output buffer of the SPI, when in bidirectional mode of operation (SPC0 is set). In master mode this bit controls the output buffer of the MOSI port, in slave mode it controls the output buffer of the MISO port. In master mode, with SPC0 set, a change of this bit will abort a transmission in progress and force the SPI into idle state. 0 Output buffer disabled 1 Output buffer enabled
1 SPISWAI	**SPI Stop in Wait Mode Bit** — This bit is used for power conservation while in wait mode. 0 SPI clock operates normally in wait mode 1 Stop SPI clock generation when in wait mode
0 SPC0	**Serial Pin Control Bit 0** — This bit enables bidirectional pin configurations as shown in Table 17-4. In master mode, a change of this bit will abort a transmission in progress and force the SPI system into idle state

Table 17-5. SPIBR Field Descriptions

Field	Description
6:4 SPPR[2:0]	**SPI Baud Rate Preselection Bits** — These bits specify the SPI baud rates as shown in Table 17-6. In master mode, a change of these bits will abort a transmission in progress and force the SPI system into idle state.
2:0 SPR[2:0}	**SPI Baud Rate Selection Bits** — These bits specify the SPI baud rates as shown in Table 17-6. In master mode, a change of these bits will abort a transmission in progress and force the SPI system into idle state.

The baud rate divisor equation is as follows:

$$\mathrm{BaudRateDivisor} = (\mathrm{SPPR} + 1) \bullet 2^{(\mathrm{SPR} + 1)}$$

The baud rate can be calculated with the following equation:

$$\mathrm{Baud\ Rate} = \mathrm{BusClock} / \mathrm{BaudRateDivisor}$$

Table 17-6. Example SPI Baud Rate Selection (25 MHz Bus Clock)

Write: has no effect

Table 17-7. SPISR Field Descriptions

Field	Description
7 SPIF	**SPIF Interrupt Flag** — This bit is set after a received data byte has been transferred into the SPI Data Register. This bit is cleared by reading the SPISR register (with SPIF set) followed by a read access to the SPI Data Register. 0 Transfer not yet complete 1 New data copied to SPIDR
5 SPTEF	**SPI Transmit Empty Interrupt Flag** — If set, this bit indicates that the transmit data register is empty. To clear this bit and place data into the transmit data register, SPISR has to be read with SPTEF = 1, followed by a write to SPIDR. Any write to the SPI Data Register without reading SPTEF = 1, is effectively ignored. 0 SPI Data register not empty 1 SPI Data register empty
4 MODF	**Mode Fault Flag** — This bit is set if the $\overline{SS}$ input becomes low while the SPI is configured as a master and mode fault detection is enabled, MODFEN bit of SPICR2 register is set. Refer to MODFEN bit description in Section 17.3.1.2, “SPI Control Register 2 (SPICR2).” The flag is cleared automatically by a read of the SPI Status Register (with MODF set) followed by a write to the SPI Control Register 1. 0 Mode fault has not occurred. 1 Mode fault has occurred.

Figure 17-7. SPI Data Register (SPIDR)

Read: anytime; normally read only after SPIF is set

Write: anytime

The SPI Data Register is both the input and output register for SPI data. A write to this register allows a data byte to be queued and transmitted. For a SPI configured as a master, a queued data byte is transmitted immediately after the previous transmission has completed. The SPI Transmitter Empty Flag SPTEF in the SPISR register indicates when the SPI Data Register is ready to accept new data.

Reading the data can occur anytime from after the SPIF is set to before the end of the next transfer. If the SPIF is not serviced by the end of the successive transfers, those data bytes are lost and the data within the SPIDR retains the first byte until SPIF is serviced.

17.4 Functional Description

The SPI module allows a duplex, synchronous, serial communication between the MCU and peripheral devices. Software can poll the SPI status flags or SPI operation can be interrupt driven.

The SPI system is enabled by setting the SPI enable (SPE) bit in SPI Control Register 1. While SPE bit is set, the four associated SPI port pins are dedicated to the SPI function as:

- Slave select ($\overline{SS}$)
- Serial clock (SCK)
- Master out/slave in (MOSI)
- Master in/slave out (MISO)

The main element of the SPI system is the SPI Data Register. The 8-bit data register in the master and the 8-bit data register in the slave are linked by the MOSI and MISO pins to form a distributed 16-bit register. When a data transfer operation is performed, this 16-bit register is serially shifted eight bit positions by the S-clock from the master, so data is exchanged between the master and the slave. Data written to the master SPI Data Register becomes the output data for the slave, and data read from the master SPI Data Register after a transfer operation is the input data from the slave.

A read of SPISR with SPTEF = 1 followed by a write to SPIDR puts data into the transmit data register. When a transfer is complete, received data is moved into the receive data register. Data may be read from this double-buffered system any time before the next transfer has completed. This 8-bit data register acts as the SPI receive data register for reads and as the SPI transmit data register for writes. A single SPI register address is used for reading data from the read data buffer and for writing data to the transmit data register.

The clock phase control bit (CPHA) and a clock polarity control bit (CPOL) in the SPI Control Register 1 (SPICR1) select one of four possible clock formats to be used by the SPI system. The CPOL bit simply selects a non-inverted or inverted clock. The CPHA bit is used to accommodate two fundamentally different protocols by sampling data on odd numbered SCK edges or on even numbered SCK edges (see Section 17.4.3, “Transmission Formats”).

The SPI can be configured to operate as a master or as a slave. When the MSTR bit in SPI Control Register1 is set, master mode is selected, when the MSTR bit is clear, slave mode is selected.

17.4.1 Master Mode

The SPI operates in master mode when the MSTR bit is set. Only a master SPI module can initiate transmissions. A transmission begins by writing to the master SPI Data Register. If the shift register is empty, the byte immediately transfers to the shift register. The byte begins shifting out on the MOSI pin under the control of the serial clock.

- S-clock

  The SPR2, SPR1, and SPR0 baud rate selection bits in conjunction with the SPPR2, SPPR1, and SPPR0 baud rate preselection bits in the SPI Baud Rate register control the baud rate generator and determine the speed of the transmission. The SCK pin is the SPI clock output. Through the SCK pin, the baud rate generator of the master controls the shift register of the slave peripheral.

- MOSI and MISO Pins

  In master mode, the function of the serial data output pin (MOSI) and the serial data input pin (MISO) is determined by the SPC0 and BIDIROE control bits.

- $\overline{SS}$ Pin

  If MODFEN and SSOE bit are set, the $\overline{SS}$ pin is configured as slave select output. The $\overline{SS}$ output becomes low during each transmission and is high when the SPI is in idle state.

  If MODFEN is set and SSOE is cleared, the $\overline{SS}$ pin is configured as input for detecting mode fault error. If the $\overline{SS}$ input becomes low this indicates a mode fault error where another master tries to drive the MOSI and SCK lines. In this case, the SPI immediately switches to slave mode, by clearing the MSTR bit and also disables the slave output buffer MISO (or SISO in bidirectional mode). So the result is that all outputs are disabled and SCK, MOSI and MISO are inputs. If a transmission is in progress when the mode fault occurs, the transmission is aborted and the SPI is forced into idle state.

This mode fault error also sets the mode fault (MODF) flag in the SPI Status Register (SPISR). If the SPI interrupt enable bit (SPIE) is set when the MODF flag gets set, then an SPI interrupt sequence is also requested.

When a write to the SPI Data Register in the master occurs, there is a half SCK-cycle delay. After the delay, SCK is started within the master. The rest of the transfer operation differs slightly, depending on the clock format specified by the SPI clock phase bit, CPHA, in SPI Control Register 1 (see Section 17.4.3, “Transmission Formats”).

NOTE

A change of the bits CPOL, CPHA, SSOE, LSBFE, MODFEN, SPC0, BIDIROE with SPC0 set, SPPR2–SPPR0 and SPR2–SPR0 in master mode will abort a transmission in progress and force the SPI into idle state. The remote slave cannot detect this, therefore the master has to ensure that the remote slave is set back to idle state.

17.4.2 Slave Mode

The SPI operates in slave mode when the MSTR bit in SPI Control Register1 is clear.

- SCK Clock

  In slave mode, SCK is the SPI clock input from the master.

- MISO and MOSI Pins

  In slave mode, the function of the serial data output pin (MISO) and serial data input pin (MOSI) is determined by the SPC0 bit and BIDIROE bit in SPI Control Register 2.

- $\overline{SS}$ Pin

  The $\overline{SS}$ pin is the slave select input. Before a data transmission occurs, the $\overline{SS}$ pin of the slave SPI must be low. $\overline{SS}$ must remain low until the transmission is complete. If $\overline{SS}$ goes high, the SPI is forced into idle state.

  The $\overline{SS}$ input also controls the serial data output pin, if $\overline{SS}$ is high (not selected), the serial data output pin is high impedance, and, if $\overline{SS}$ is low the first bit in the SPI Data Register is driven out of the serial data output pin. Also, if the slave is not selected ($\overline{SS}$ is high), then the SCK input is ignored and no internal shifting of the SPI shift register takes place.

Although the SPI is capable of duplex operation, some SPI peripherals are capable of only receiving SPI data in a slave mode. For these simpler devices, there is no serial data out pin.

NOTE

When peripherals with duplex capability are used, take care not to simultaneously enable two receivers whose serial outputs drive the same system slave's serial data output line.

As long as no more than one slave device drives the system slave's serial data output line, it is possible for several slaves to receive the same transmission from a master, although the master would not receive return information from all of the receiving slaves.

If the CPHA bit in SPI Control Register 1 is clear, odd numbered edges on the SCK input cause the data at the serial data input pin to be latched. Even numbered edges cause the value previously latched from the serial data input pin to shift into the LSB or MSB of the SPI shift register, depending on the LSBFE bit.

If the CPHA bit is set, even numbered edges on the SCK input cause the data at the serial data input pin to be latched. Odd numbered edges cause the value previously latched from the serial data input pin to shift into the LSB or MSB of the SPI shift register, depending on the LSBFE bit.

When CPHA is set, the first edge is used to get the first data bit onto the serial data output pin. When CPHA is clear and the $\overline{SS}$ input is low (slave selected), the first bit of the SPI data is driven out of the serial data output pin. After the eighth shift, the transfer is considered complete and the received data is transferred into the SPI Data Register. To indicate transfer is complete, the SPIF flag in the SPI Status Register is set.

NOTE

A change of the bits CPOL, CPHA, SSOE, LSBFE, MODFEN, SPC0 and BIDIROE with SPC0 set in slave mode will corrupt a transmission in progress and has to be avoided.

17.4.3 Transmission Formats

During an SPI transmission, data is transmitted (shifted out serially) and received (shifted in serially) simultaneously. The serial clock (SCK) synchronizes shifting and sampling of the information on the two serial data lines. A slave select line allows selection of an individual slave SPI device, slave devices that are not selected do not interfere with SPI bus activities. Optionally, on a master SPI device, the slave select line can be used to indicate multiple-master bus contention.

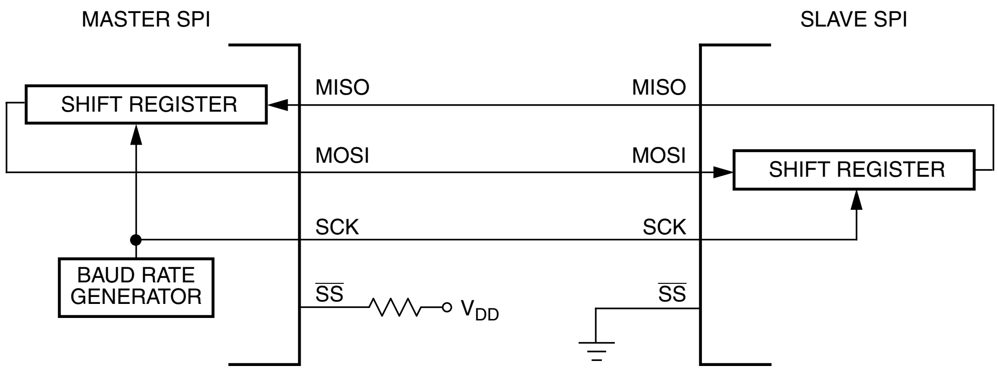

Figure 17-8. Master/Slave Transfer Block Diagram

17.4.3.1 Clock Phase and Polarity Controls

Using two bits in the SPI Control Register1, software selects one of four combinations of serial clock phase and polarity.

The CPOL clock polarity control bit specifies an active high or low clock and has no significant effect on the transmission format.

The CPHA clock phase control bit selects one of two fundamentally different transmission formats.

Clock phase and polarity should be identical for the master SPI device and the communicating slave device. In some cases, the phase and polarity are changed between transmissions to allow a master device to communicate with peripheral slaves having different requirements.

17.4.3.2 CPHA = 0 Transfer Format

The first edge on the SCK line is used to clock the first data bit of the slave into the master and the first data bit of the master into the slave. In some peripherals, the first bit of the slave's data is available at the slave's data out pin as soon as the slave is selected. In this format, the first SCK edge is issued a half cycle after $\overline{SS}$ has become low.

A half SCK cycle later, the second edge appears on the SCK line. When this second edge occurs, the value previously latched from the serial data input pin is shifted into the LSB or MSB of the shift register, depending on LSBFE bit.

After this second edge, the next bit of the SPI master data is transmitted out of the serial data output pin of the master to the serial input pin on the slave. This process continues for a total of 16 edges on the SCK line, with data being latched on odd numbered edges and shifted on even numbered edges.

Data reception is double buffered. Data is shifted serially into the SPI shift register during the transfer and is transferred to the parallel SPI Data Register after the last bit is shifted in.

After the 16th (last) SCK edge:

- Data that was previously in the master SPI Data Register should now be in the slave data register and the data that was in the slave data register should be in the master.
- The SPIF flag in the SPI Status Register is set indicating that the transfer is complete.

Figure 17-9 is a timing diagram of an SPI transfer where CPHA = 0. SCK waveforms are shown for CPOL = 0 and CPOL = 1. The diagram may be interpreted as a master or slave timing diagram because the SCK, MISO, and MOSI pins are connected directly between the master and the slave. The MISO signal is the output from the slave and the MOSI signal is the output from the master. The $\overline{SS}$ pin of the master must be either high or reconfigured as a general-purpose output not affecting the SPI.

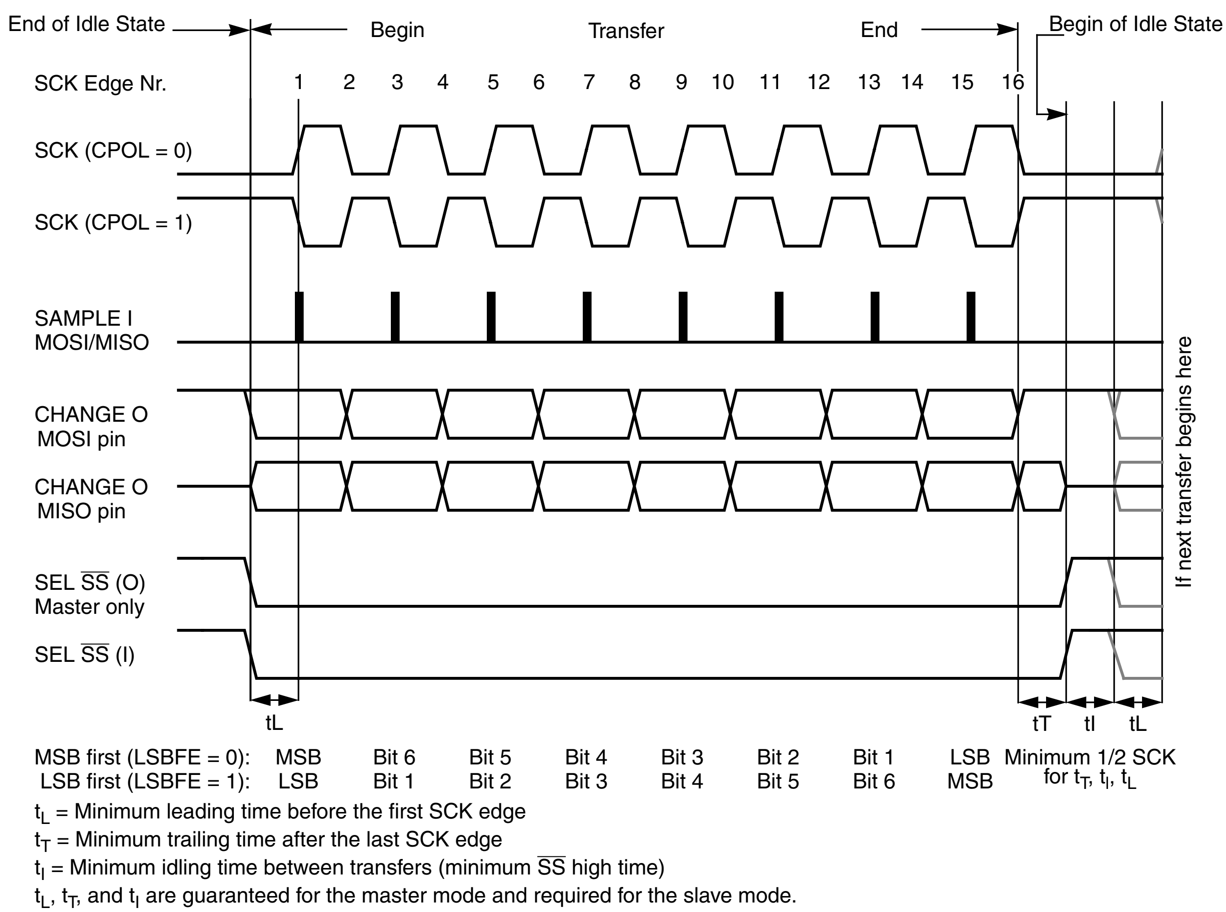

Figure 17-9. SPI Clock Format 0 (CPHA = 0)

In slave mode, if the $\overline{SS}$ line is not deasserted between the successive transmissions then the content of the SPI Data Register is not transmitted, instead the last received byte is transmitted. If the $\overline{SS}$ line is deasserted for at least minimum idle time (half SCK cycle) between successive transmissions then the content of the SPI Data Register is transmitted.

In master mode, with slave select output enabled the $\overline{SS}$ line is always deasserted and reasserted between successive transfers for at least minimum idle time.

17.4.3.3 CPHA = 1 Transfer Format

Some peripherals require the first SCK edge before the first data bit becomes available at the data out pin, the second edge clocks data into the system. In this format, the first SCK edge is issued by setting the CPHA bit at the beginning of the 8-cycle transfer operation.

The first edge of SCK occurs immediately after the half SCK clock cycle synchronization delay. This first edge commands the slave to transfer its first data bit to the serial data input pin of the master.

A half SCK cycle later, the second edge appears on the SCK pin. This is the latching edge for both the master and slave.

When the third edge occurs, the value previously latched from the serial data input pin is shifted into the LSB or MSB of the SPI shift register, depending on LSBFE bit. After this edge, the next bit of the master data is coupled out of the serial data output pin of the master to the serial input pin on the slave.

This process continues for a total of 16 edges on the SCK line with data being latched on even numbered edges and shifting taking place on odd numbered edges.

Data reception is double buffered, data is serially shifted into the SPI shift register during the transfer and is transferred to the parallel SPI Data Register after the last bit is shifted in.

After the 16th SCK edge:

- Data that was previously in the SPI Data Register of the master is now in the data register of the slave, and data that was in the data register of the slave is in the master.
- The SPIF flag bit in SPISR is set indicating that the transfer is complete.

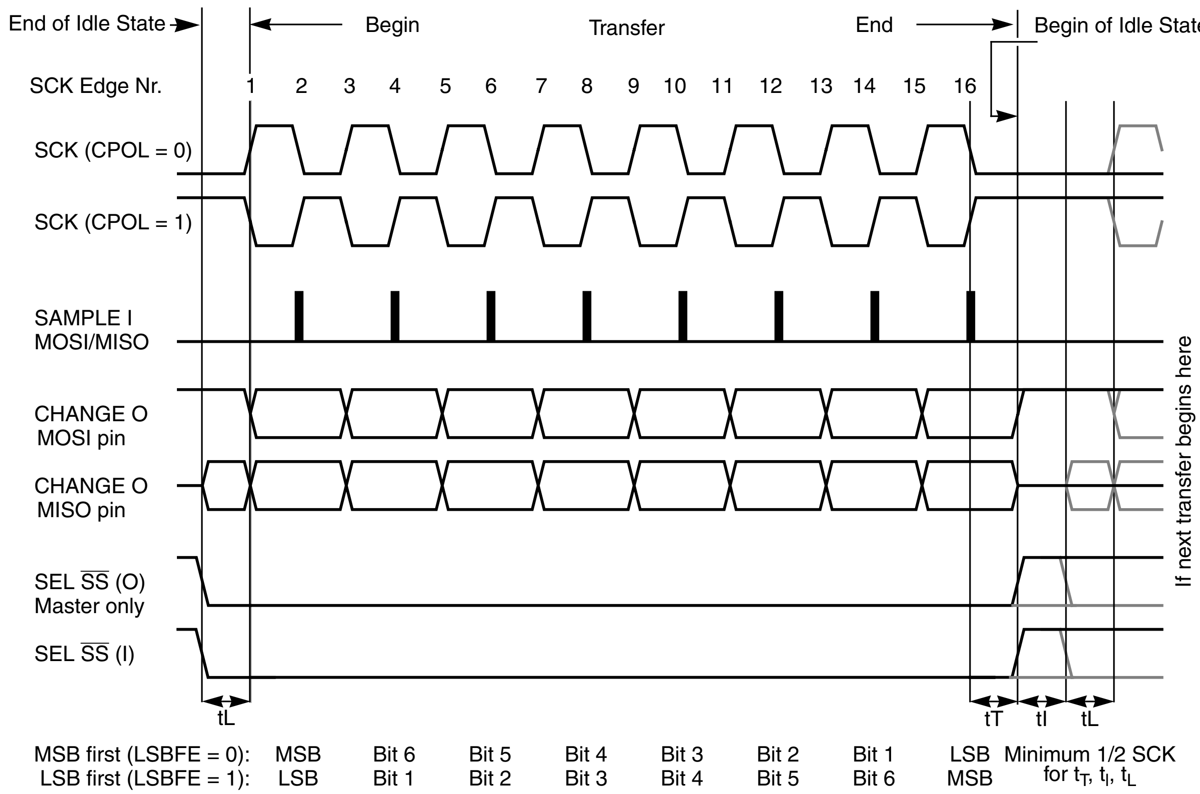
Figure 17-10 shows two clocking variations for CPHA = 1. The diagram may be interpreted as a master or slave timing diagram because the SCK, MISO, and MOSI pins are connected directly between the master and the slave. The MISO signal is the output from the slave, and the MOSI signal is the output from the master. The $\overline{SS}$ line is the slave select input to the slave. The $\overline{SS}$ pin of the master must be either high or reconfigured as a general-purpose output not affecting the SPI.

The $\overline{SS}$ line can remain active low between successive transfers (can be tied low at all times). This format is sometimes preferred in systems having a single fixed master and a single slave that drive the MISO data line.

- Back-to-back transfers in master mode

In master mode, if a transmission has completed and a new data byte is available in the SPI Data Register, this byte is send out immediately without a trailing and minimum idle time.

The SPI interrupt request flag (SPIF) is common to both the master and slave modes. SPIF gets set one half SCK cycle after the last SCK edge.



t_L = Minimum leading time before the first SCK edge, not required for back to back transfers
t_T = Minimum trailing time after the last SCK edge
t_I = Minimum idling time between transfers (minimum $\overline{SS}$ high time), not required for back to back transfers

Figure 17-10. SPI Clock Format 1 (CPHA = 1)

17.4.4 SPI Baud Rate Generation

Baud rate generation consists of a series of divider stages. Six bits in the SPI Baud Rate register (SPPR2, SPPR1, SPPR0, SPR2, SPR1, and SPR0) determine the divisor to the SPI module clock which results in the SPI baud rate.

The SPI clock rate is determined by the product of the value in the baud rate preselection bits (SPPR2–SPPR0) and the value in the baud rate selection bits (SPR2–SPR0). The module clock divisor equation is shown in Figure 17-11

When all bits are clear (the default condition), the SPI module clock is divided by 2. When the selection bits (SPR2–SPR0) are 001 and the preselection bits (SPPR2–SPPR0) are 000, the module clock divisor becomes 4. When the selection bits are 010, the module clock divisor becomes 8 etc.

When the preselection bits are 001, the divisor determined by the selection bits is multiplied by 2. When the preselection bits are 010, the divisor is multiplied by 3, etc. See Table 17-6 for baud rate calculations for all bit conditions, based on a 25-MHz bus clock. The two sets of selects allows the clock to be divided by a non-power of two to achieve other baud rates such as divide by 6, divide by 10, etc.

The baud rate generator is activated only when the SPI is in the master mode and a serial transfer is taking place. In the other cases, the divider is disabled to decrease I_{DD} current.

$$\text{BaudRateDivisor} = (\text{SPPR} + 1) \bullet 2^{(\text{SPR} + 1)}$$

Figure 17-11. Baud Rate Divisor Equation

17.4.5 Special Features

17.4.5.1 $\overline{\text{SS}}$ Output

The $\overline{\text{SS}}$ output feature automatically drives the $\overline{\text{SS}}$ pin low during transmission to select external devices and drives it high during idle to deselect external devices. When $\overline{\text{SS}}$ output is selected, the $\overline{\text{SS}}$ output pin is connected to the $\overline{\text{SS}}$ input pin of the external device.

The $\overline{\text{SS}}$ output is available only in master mode during normal SPI operation by asserting SSOE and MODFEN bit as shown in Table 17-2.

The mode fault feature is disabled while $\overline{\text{SS}}$ output is enabled.

NOTE

Care must be taken when using the $\overline{\text{SS}}$ output feature in a multimaster system because the mode fault feature is not available for detecting system errors between masters.

17.4.5.2 Bidirectional Mode (MOSI or MISO)

The bidirectional mode is selected when the SPC0 bit is set in SPI Control Register 2 (see Table 17-8). In this mode, the SPI uses only one serial data pin for the interface with external device(s). The MSTR bit decides which pin to use. The MOSI pin becomes the serial data I/O (MOMI) pin for the master mode, and the MISO pin becomes serial data I/O (SISO) pin for the slave mode. The MISO pin in master mode and MOSI pin in slave mode are not used by the SPI.

Table 17-8. Normal Mode and Bidirectional Mode

When SPE = 1	Master Mode MSTR = 1	Slave Mode MSTR = 0
Normal Mode SPC0 = 0		Bidirectional Mode SPC0 = 1		
The direction of each serial I/O pin depends on the BIDIROE bit. If the pin is configured as an output, serial data from the shift register is driven out on the pin. The same pin is also the serial input to the shift register.

The SCK is output for the master mode and input for the slave mode.

The $\overline{SS}$ is the input or output for the master mode, and it is always the input for the slave mode.

The bidirectional mode does not affect SCK and $\overline{SS}$ functions.

NOTE

In bidirectional master mode, with mode fault enabled, both data pins MISO and MOSI can be occupied by the SPI, though MOSI is normally used for transmissions in bidirectional mode and MISO is not used by the SPI. If a mode fault occurs, the SPI is automatically switched to slave mode, in this case MISO becomes occupied by the SPI and MOSI is not used. This has to be considered, if the MISO pin is used for other purpose.

17.4.6 Error Conditions

The SPI has one error condition:

- Mode fault error

17.4.6.1 Mode Fault Error

If the $\overline{SS}$ input becomes low while the SPI is configured as a master, it indicates a system error where more than one master may be trying to drive the MOSI and SCK lines simultaneously. This condition is not permitted in normal operation, the MODF bit in the SPI Status Register is set automatically provided the MODFEN bit is set.

In the special case where the SPI is in master mode and MODFEN bit is cleared, the $\overline{SS}$ pin is not used by the SPI. In this special case, the mode fault error function is inhibited and MODF remains cleared. In case the SPI system is configured as a slave, the $\overline{SS}$ pin is a dedicated input pin. Mode fault error doesn’t occur in slave mode.

If a mode fault error occurs the SPI is switched to slave mode, with the exception that the slave output buffer is disabled. So SCK, MISO and MOSI pins are forced to be high impedance inputs to avoid any possibility of conflict with another output driver. A transmission in progress is aborted and the SPI is forced into idle state.

If the mode fault error occurs in the bidirectional mode for a SPI system configured in master mode, output enable of the MOMI (MOSI in bidirectional mode) is cleared if it was set. No mode fault error occurs in the bidirectional mode for SPI system configured in slave mode.

The mode fault flag is cleared automatically by a read of the SPI Status Register (with MODF set) followed by a write to SPI Control Register 1. If the mode fault flag is cleared, the SPI becomes a normal master or slave again.

17.4.7 Operation in Run Mode

In run mode with the SPI system enable (SPE) bit in the SPI control register clear, the SPI system is in a low-power, disabled state. SPI registers remain accessible, but clocks to the core of this module are disabled.

17.4.8 Operation in Wait Mode

SPI operation in wait mode depends upon the state of the SPISWAI bit in SPI Control Register 2.

- If SPISWAI is clear, the SPI operates normally when the CPU is in wait mode
- If SPISWAI is set, SPI clock generation ceases and the SPI module enters a power conservation state when the CPU is in wait mode.
  - If SPISWAI is set and the SPI is configured for master, any transmission and reception in progress stops at wait mode entry. The transmission and reception resumes when the SPI exits wait mode.
  - If SPISWAI is set and the SPI is configured as a slave, any transmission and reception in progress continues if the SCK continues to be driven from the master. This keeps the slave synchronized to the master and the SCK.

    If the master transmits several bytes while the slave is in wait mode, the slave will continue to send out bytes consistent with the operation mode at the start of wait mode (i.e. If the slave is currently sending its SPIDR to the master, it will continue to send the same byte. Else if the slave is currently sending the last received byte from the master, it will continue to send each previous master byte).

NOTE

Care must be taken when expecting data from a master while the slave is in wait or stop mode. Even though the shift register will continue to operate, the rest of the SPI is shut down (i.e. a SPIF interrupt will **not** be generated until exiting stop or wait mode). Also, the byte from the shift register will not be copied into the SPIDR register until after the slave SPI has exited wait or stop mode. A SPIF flag and SPIDR copy is only generated if wait mode is entered or exited during a tranmission. If the slave enters wait mode in idle mode and exits wait mode in idle mode, neither a SPIF nor a SPIDR copy will occur.

17.4.9 Operation in Stop Mode

Stop mode is dependent on the system. The SPI enters stop mode when the module clock is disabled (held high or low). If the SPI is in master mode and exchanging data when the CPU enters stop mode, the transmission is frozen until the CPU exits stop mode. After stop, data to and from the external SPI is exchanged correctly. In slave mode, the SPI will stay synchronized with the master.

The stop mode is not dependent on the SPISWAI bit.

17.5 Reset

The reset values of registers and signals are described in the Memory Map and Registers section (see Section 17.3, "Memory Map and Register Definition") which details the registers and their bit-fields.

- If a data transmission occurs in slave mode after reset without a write to SPIDR, it will transmit garbage, or the byte last received from the master before the reset.
- Reading from the SPIDR after reset will always read a byte of zeros.

17.6 Interrupts

The SPI only originates interrupt requests when SPI is enabled (SPE bit in SPICR1 set). The following is a description of how the SPI makes a request and how the MCU should acknowledge that request. The interrupt vector offset and interrupt priority are chip dependent.

The interrupt flags MODF, SPIF and SPTEF are logically ORed to generate an interrupt request.

17.6.1 MODF

MODF occurs when the master detects an error on the $\overline{SS}$ pin. The master SPI must be configured for the MODF feature (see Table 17-2). After MODF is set, the current transfer is aborted and the following bit is changed:

- MSTR = 0, The master bit in SPICR1 resets.

The MODF interrupt is reflected in the status register MODF flag. Clearing the flag will also clear the interrupt. This interrupt will stay active while the MODF flag is set. MODF has an automatic clearing process which is described in Section 17.3.1.4, "SPI Status Register (SPISR)."

17.6.2 SPIF

SPIF occurs when new data has been received and copied to the SPI Data Register. After SPIF is set, it does not clear until it is serviced. SPIF has an automatic clearing process which is described in Section 17.3.1.4, "SPI Status Register (SPISR)." In the event that the SPIF is not serviced before the end of the next transfer (i.e. SPIF remains active throughout another transfer), the latter transfers will be ignored and no new data will be copied into the SPIDR.

17.6.3 SPTEF

SPTEF occurs when the SPI Data Register is ready to accept new data. After SPTEF is set, it does not clear until it is serviced. SPTEF has an automatic clearing process which is described in Section 17.3.1.4, "SPI Status Register (SPISR)."

Chapter 18
Dual Output Voltage Regulator (VREG3V3V2) Block Description

18.1 Introduction

The VREG3V3 is a dual output voltage regulator providing two separate 2.5 V (typical) supplies differing in the amount of current that can be sourced. The regulator input voltage range is from 3.3 V up to 5 V (typical).

18.1.1 Features

The block VREG3V3 includes these distinctive features:

- Two parallel, linear voltage regulators
  - Bandgap reference
- Low-voltage detect (LVD) with low-voltage interrupt (LVI)
- Power-on reset (POR)
- Low-voltage reset (LVR)

18.1.2 Modes of Operation

There are three modes VREG3V3 can operate in:

- Full-performance mode (FPM) (MCU is not in stop mode)

  The regulator is active, providing the nominal supply voltage of 2.5 V with full current sourcing capability at both outputs. Features LVD (low-voltage detect), LVR (low-voltage reset), and POR (power-on reset) are available.
- Reduced-power mode (RPM) (MCU is in stop mode)

  The purpose is to reduce power consumption of the device. The output voltage may degrade to a lower value than in full-performance mode, additionally the current sourcing capability is substantially reduced. Only the POR is available in this mode, LVD and LVR are disabled.
- Shutdown mode

  Controlled by V_{REGEN} (see device overview chapter for connectivity of V_{REGEN}).

  This mode is characterized by minimum power consumption. The regulator outputs are in a high impedance state, only the POR feature is available, LVD and LVR are disabled.

  This mode must be used to disable the chip internal regulator VREG3V3, i.e., to bypass the VREG3V3 to use external supplies.

18.1.3 Block Diagram

Figure 18-1 shows the function principle of VREG3V3 by means of a block diagram. The regulator core REG consists of two parallel sub-blocks, REG1 and REG2, providing two independent output voltages.

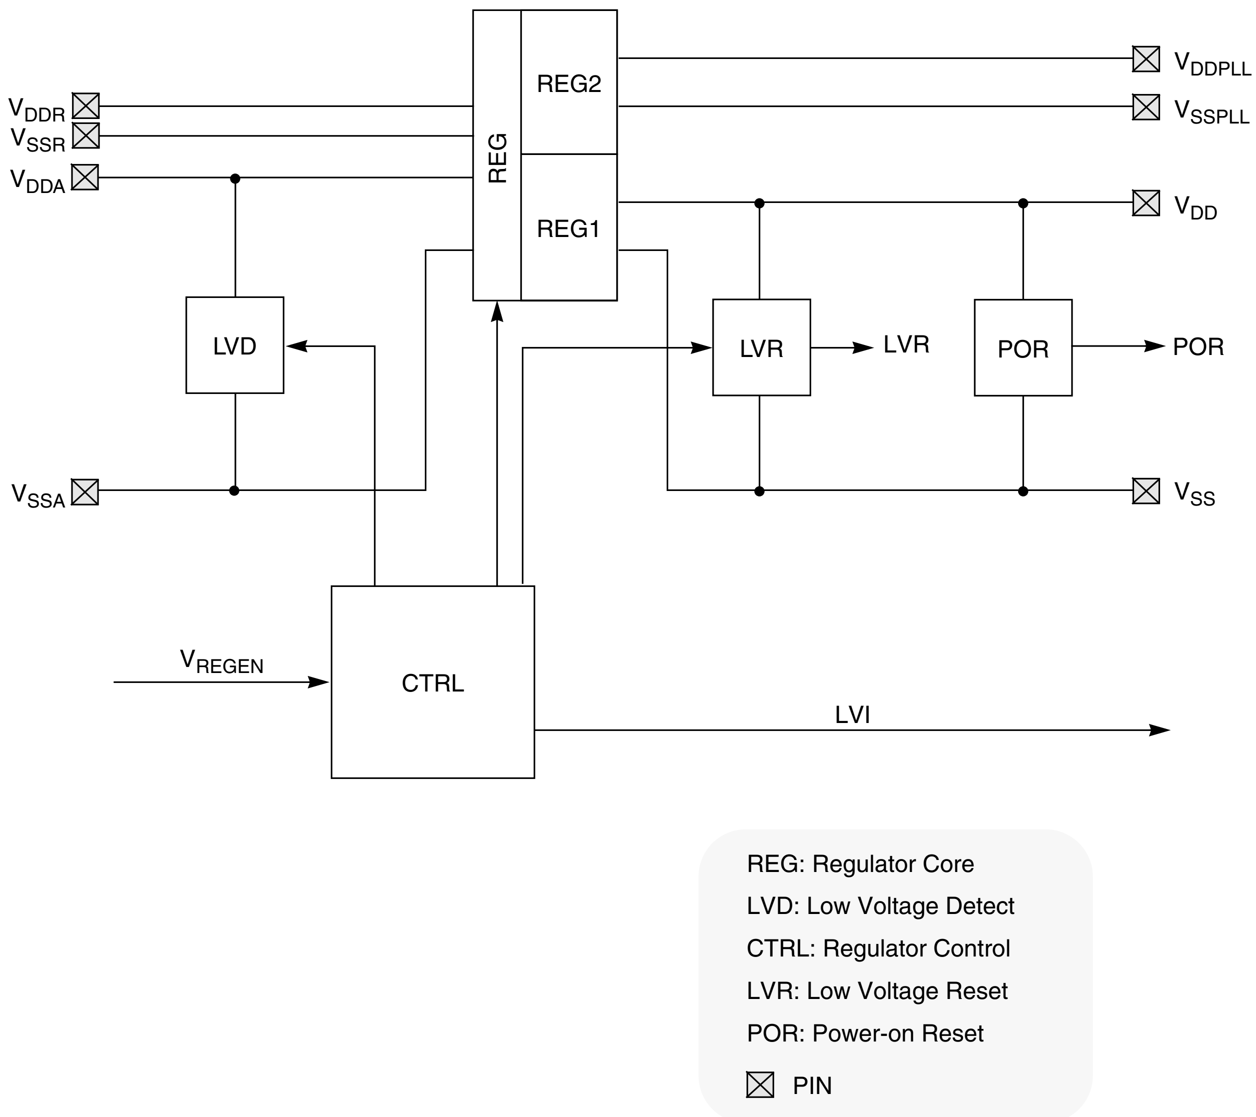

Figure 18-1. VREG3V3 Block Diagram

18.2 External Signal Description

Due to the nature of VREG3V3 being a voltage regulator providing the chip internal power supply voltages most signals are power supply signals connected to pads.

Table 18-1 shows all signals of VREG3V3 associated with pins.

Table 18-1. VREG3V3 — Signal Properties

Name	Port	Function	Reset State	Pull Up
V_{DDR}	—	VREG3V3 power input (positive supply)	—	—
V_{SSR}	—	VREG3V3 power input (ground)	—	—
V_{DDA}	—	VREG3V3 quiet input (positive supply)	—	—
V_{SSA}	—	VREG3V3 quiet input (ground)	—	—
V_{DD}	—	VREG3V3 primary output (positive supply)	—	—
V_{SS}	—	VREG3V3 primary output (ground)	—	—
V_{DDPLL}	—	VREG3V3 secondary output (positive supply)	—	—
V_{SSPLL}	—	VREG3V3 secondary output (ground)	—	—
V_{REGEN} (optional)	—	VREG3V3 (Optional) Regulator Enable	—	—

NOTE

Check device overview chapter for connectivity of the signals.

18.2.1 V_{DDR}, V_{SSR} — Regulator Power Input

Signal V_{DDR} is the power input of VREG3V3. All currents sourced into the regulator loads flow through this pin. A chip external decoupling capacitor (100 nF...220 nF, X7R ceramic) between V_{DDR} and V_{SSR} can smoothen ripple on V_{DDR}.

For entering shutdown mode, pin V_{DDR} should also be tied to ground on devices without a V_{REGEN} pin.

18.2.2 V_{DDA}, V_{SSA} — Regulator Reference Supply

Signals V_{DDA}/V_{SSA} which are supposed to be relatively quiet are used to supply the analog parts of the regulator. Internal precision reference circuits are supplied from these signals. A chip external decoupling capacitor (100 nF...220 nF, X7R ceramic) between V_{DDA} and V_{SSA} can further improve the quality of this supply.

18.2.3 V_{DD}, V_{SS} — Regulator Output1 (Core Logic)

Signals V_{DD}/V_{SS} are the primary outputs of VREG3V3 that provide the power supply for the core logic. These signals are connected to device pins to allow external decoupling capacitors (100 nF...220 nF, X7R ceramic).

In shutdown mode an external supply at V_{DD}/V_{SS} can replace the voltage regulator.

18.2.4 V_{DDPLL}, V_{SSPLL} — Regulator Output2 (PLL)

Signals V_{DDPLL}/V_{SSPLL} are the secondary outputs of VREG3V3 that provide the power supply for the PLL and oscillator. These signals are connected to device pins to allow external decoupling capacitors (100 nF...220 nF, X7R ceramic).

In shutdown mode an external supply at V_{DDPLL}/V_{SSPLL} can replace the voltage regulator.

18.2.5 V_{REGEN} — Optional Regulator Enable

This optional signal is used to shutdown VREG3V3. In that case V_{DD}/V_{SS} and V_{DDPLL}/V_{SSPLL} must be provided externally. shutdown mode is entered with V_{REGEN} being low. If V_{REGEN} is high, the VREG3V3 is either in full-performance mode or in reduced-power mode.

For the connectivity of V_{REGEN} see device overview chapter.

NOTE

Switching from FPM or RPM to shutdown of VREG3V3 and vice versa is not supported while the MCU is powered.

18.3 Memory Map and Register Definition

This subsection provides a detailed description of all registers accessible in VREG3V3.

18.3.1 Register Descriptions

The following paragraphs describe, in address order, all the VREG3V3 registers and their individual bits.

18.3.1.1 VREG3V3 — Control Register (VREGCTRL)

The VREGCTRL register allows to separately enable features of VREG3V3.

Module Base + 0x000

	7	6	5	4	3	2	1	0
R	0	0	0	0	0	LVDS	LVIE	LVIF
W								
Reset	0	0	0	0	0	0	0	0

= Unimplemented or Reserved

Figure 18-2. VREG3V3 — Control Register (VREGCTRL)

Table 18-2. MCCTL1 Field Descriptions

Field	Description
2 LVDS	**Low-Voltage Detect Status Bit** — This read-only status bit reflects the input voltage. Writes have no effect. 0 Input voltage V_{DDA} is above level V_{LVID} or RPM or shutdown mode. 1 Input voltage V_{DDA} is below level V_{LVIA} and FPM.
1 LVIE	**Low-Voltage Interrupt Enable Bit** 0 Interrupt request is disabled. 1 Interrupt will be requested whenever LVIF is set.
0 LVIF	**Low-Voltage Interrupt Flag** — LVIF is set to 1 when LVDS status bit changes. This flag can only be cleared by writing a 1. Writing a 0 has no effect. If enabled (LVIE = 1), LVIF causes an interrupt request. 0 No change in LVDS bit. 1 LVDS bit has changed.

NOTE

On entering the reduced-power mode the LVIF is not cleared by the VREG3V3.

18.4 Functional Description

Block VREG3V3 is a voltage regulator as depicted in Figure 18-1. The regulator functional elements are the regulator core (REG), a low-voltage detect module (LVD), a power-on reset module (POR) and a low-voltage reset module (LVR). There is also the regulator control block (CTRL) which represents the interface to the digital core logic but also manages the operating modes of VREG3V3.

18.4.1 REG — Regulator Core

VREG3V3, respectively its regulator core has two parallel, independent regulation loops (REG1 and REG2) that differ only in the amount of current that can be sourced to the connected loads. Therefore, only REG1 providing the supply at V_{DD}/V_{SS} is explained. The principle is also valid for REG2.

The regulator is a linear series regulator with a bandgap reference in its full-performance mode and a voltage clamp in reduced-power mode. All load currents flow from input V_{DDR} to V_{SS} or V_{SSPLL}, the reference circuits are connected to V_{DDA} and V_{SSA}.

18.4.2 Full-Performance Mode

In full-performance mode, a fraction of the output voltage (V_{DD}) and the bandgap reference voltage are fed to an operational amplifier. The amplified input voltage difference controls the gate of an output driver which basically is a large NMOS transistor connected to the output.

18.4.3 Reduced-Power Mode

In reduced-power mode, the driver gate is connected to a buffered fraction of the input voltage (V_{DDR}). The operational amplifier and the bandgap are disabled to reduce power consumption.

18.4.4 LVD — Low-Voltage Detect

sub-block LVD is responsible for generating the low-voltage interrupt (LVI). LVD monitors the input voltage (V_{DDA}–V_{SSA}) and continuously updates the status flag LVDS. Interrupt flag LVIF is set whenever status flag LVDS changes its value. The LVD is available in FPM and is inactive in reduced-power mode and shutdown mode.

18.4.5 POR — Power-On Reset

This functional block monitors output V_{DD}. If V_{DD} is below V_{PORD}, signal POR is high, if it exceeds V_{PORD}, the signal goes low. The transition to low forces the CPU in the power-on sequence.

Due to its role during chip power-up this module must be active in all operating modes of VREG3V3.

18.4.6 LVR — Low-Voltage Reset

Block LVR monitors the primary output voltage V_{DD}. If it drops below the assertion level (V_{LVRA}) signal LVR asserts and when rising above the deassertion level (V_{LVRD}) signal LVR negates again. The LVR function is available only in full-performance mode.

18.4.7 CTRL — Regulator Control

This part contains the register block of VREG3V3 and further digital functionality needed to control the operating modes. CTRL also represents the interface to the digital core logic.

18.5 Resets

This subsection describes how VREG3V3 controls the reset of the MCU.The reset values of registers and signals are provided in Section 18.3, “Memory Map and Register Definition”. Possible reset sources are listed in Table 18-3.

Table 18-3. VREG3V3 — Reset Sources

Reset Source	Local Enable
Power-on reset	Always active
Low-voltage reset	Available only in full-performance mode

18.5.1 Power-On Reset

During chip power-up the digital core may not work if its supply voltage V_{DD} is below the POR deassertion level (V_{PORD}). Therefore, signal POR which forces the other blocks of the device into reset is kept high until V_{DD} exceeds V_{PORD}. Then POR becomes low and the reset generator of the device continues the start-up sequence. The power-on reset is active in all operation modes of VREG3V3.

18.5.2 Low-Voltage Reset

For details on low-voltage reset see Section 18.4.6, “LVR — Low-Voltage Reset”.

18.6 Interrupts

This subsection describes all interrupts originated by VREG3V3.

The interrupt vectors requested by VREG3V3 are listed in Table 18-4. Vector addresses and interrupt priorities are defined at MCU level.

Table 18-4. VREG3V3 — Interrupt Vectors

Interrupt Source	Local Enable
Low Voltage Interrupt (LVI)	LVIE = 1; Available only in full-performance mode

18.6.1 LVI — Low-Voltage Interrupt

In FPM VREG3V3 monitors the input voltage V_{DDA}. Whenever V_{DDA} drops below level V_{LVIA} the status bit LVDS is set to 1. Vice versa, LVDS is reset to 0 when V_{DDA} rises above level V_{LVID}. An interrupt, indicated by flag LVIF = 1, is triggered by any change of the status bit LVDS if interrupt enable bit LVIE = 1.

NOTE

On entering the reduced-power mode, the LVIF is not cleared by the VREG3V3.

Appendix A
Electrical Characteristics

A.1 General

NOTE

The electrical characteristics given in this section are preliminary and should be used as a guide only. Values cannot be guaranteed by Freescale and are subject to change without notice.

This supplement contains the most accurate electrical information for the MC3S12RG128 microcontroller available at the time of publication. The information should be considered **PRELIMINARY** and is subject to change.

This introduction is intended to give an overview on several common topics like power supply, current injection etc.

A.1.1 Parameter Classification

The electrical parameters shown in this supplement are guaranteed by various methods. To give the customer a better understanding the following classification is used and the parameters are tagged accordingly in the tables where appropriate.

NOTE

This classification is shown in the column labeled “C” in the parameter tables where appropriate.

P: Those parameters are guaranteed during production testing on each individual device.

C: Those parameters are achieved by the design characterization by measuring a statistically relevant sample size across process variations.

T: Those parameters are achieved by design characterization on a small sample size from typical devices under typical conditions unless otherwise noted. All values shown in the typical column are within this category.

D: Those parameters are derived mainly from simulations.

A.1.2 Power Supply

The MC3S12RG128 utilizes several pins to supply power to the I/O ports, A/D converter, oscillator, PLL and internal logic.

The V_{DDA}, V_{SSA} pair supplies the A/D converter and the internal voltage regulator.

The V_{DDX}, V_{SSX}, V_{DDR} and V_{SSR} pairs supply the I/O pins, V_{DDR} also supplies the internal voltage regulator.

V_{DD1}, V_{SS1}, V_{DD2} and V_{SS2} are the supply pins for the internal logic, V_{DDPLL}, V_{SSPLL} supply the oscillator and the PLL.

V_{SS1} and V_{SS2} are internally connected by metal.

V_{DDA}, V_{DDX}, V_{DDR} as well as V_{SSA}, V_{SSX}, V_{SSR} are connected by anti-parallel diodes for ESD protection.

NOTE

In the following context V_{DD35} is used for either V_{DDA}, V_{DDR} and V_{DDX}; V_{SS35} is used for either V_{SSA}, V_{SSR} and V_{SSX} unless otherwise noted.

I_{DD35} denotes the sum of the currents flowing into the V_{DDA}, V_{DDX} and V_{DDR} pins.

V_{DD} is used for V_{DD1}, V_{DD2} and V_{DDPLL}, V_{SS} is used for V_{SS1}, V_{SS2} and V_{SSPLL}.

I_{DD} is used for the sum of the currents flowing into V_{DD1} and V_{DD2}.

A.1.3 Pins

There are four groups of functional pins.

A.1.3.1 I/O pins

Those I/O pins have a nominal level in the range of 3.15V to 5.5V. This class of pins is comprised of all port I/O pins, the analog inputs, BKGD and the $\overline{\text{RESET}}$ pins.The internal structure of all those pins is identical, however some of the functionality may be disabled. E.g. for the analog inputs the output drivers, pull-up and pull-down resistors are disabled permanently.

A.1.3.2 Analog Reference

This group is made up by the V_{RH} and V_{RL} pins.

A.1.3.3 Oscillator

The pins XFC, EXTAL, XTAL dedicated to the oscillator have a nominal 2.5V level. They are supplied by V_{DDPLL}.

A.1.3.4 TEST

This pin is used for production testing only. It must be tied to V_{SS}.

A.1.3.5 VREGEN

This pin is used to enable the on chip voltage regulator.

A.1.4 Current Injection

Power supply must maintain regulation within operating V_{DD35} or V_{DD} range during instantaneous and operating maximum current conditions. If positive injection current ($V_{in} > V_{DD35}$) is greater than I_{DD35}, the injection current may flow out of V_{DD35} and could result in external power supply going out of regulation. Ensure external V_{DD35} load will shunt current greater than maximum injection current. This will be the greatest risk when the MCU is not consuming power; e.g. if no system clock is present, or if clock rate is very low which would reduce overall power consumption.

A.1.5 Absolute Maximum Ratings

Absolute maximum ratings are stress ratings only. A functional operation under or outside those maxima is not guaranteed. Stress beyond those limits may affect the reliability or cause permanent damage of the device.

This device contains circuitry protecting against damage due to high static voltage or electrical fields; however, it is advised that normal precautions be taken to avoid application of any voltages higher than maximum-rated voltages to this high-impedance circuit. Reliability of operation is enhanced if unused inputs are tied to an appropriate logic voltage level (e.g., either V_{SS35} or V_{DD35}).

Table A-1. Absolute Maximum Ratings[1]

Num	Rating	Symbol	Min	Max	Unit
1	I/O, Regulator and Analog Supply Voltage	V_{DD35}	–0.3	6.5	V
2	Internal Logic Supply Voltage [2]	V_{DD}	–0.3	3.0	V
3	PLL Supply Voltage [2]	V_{DDPLL}	–0.3	3.0	V
4	Voltage difference VDDX to VDDR and VDDA	Δ_{VDDX}	–0.3	0.3	V
5	Voltage difference VSSX to VSSR and VSSA	Δ_{VSSX}	–0.3	0.3	V
6	Digital I/O Input Voltage	V_{IN}	–0.3	6.5	V
7	Analog Reference	V_{RH}, V_{RL}	–0.3	6.5	V
8	XFC, EXTAL, XTAL inputs	V_{ILV}	–0.3	3.0	V
9	TEST input (for test purposes only, tie to V_{SS})	V_{TEST}	–0.3	6.5	V
10	Instantaneous Maximum Current Single pin limit for all digital I/O pins [3]	I_D	–25	25	mA
11	Instantaneous Maximum Current Single pin limit for XFC, EXTAL, XTAL[4]	I_{DL}	–25	25	mA
15	Storage Temperature Range	T_{stg}	–65	155	°C

[1] Beyond absolute maximum ratings device might be damaged.

[2] The device contains an internal voltage regulator to generate the logic and PLL supply out of the I/O supply. The absolute maximum ratings apply when the device is powered from an external source.

[3] All digital I/O pins are internally clamped to V_{SSX} and V_{DDX}, V_{SSR} and V_{DDR} or V_{SSA} and V_{DDA}.

[4] Those pins are internally clamped to V_{SSPLL} and V_{DDPLL}.

A.1.6 ESD Protection and Latch-up Immunity

All ESD testing is in conformity with CDF-AEC-Q100 Stress test qualification for Automotive Grade Integrated Circuits. During the device qualification ESD stresses were performed for the Human Body Model (HBM), the Machine Model (MM) and the Charge Device Model.

A device will be defined as a failure if after exposure to ESD pulses the device no longer meets the device specification. Complete DC parametric and functional testing is performed per the applicable device specification at room temperature followed by hot temperature, unless specified otherwise in the device specification.

Table A-2. ESD and Latch-up Test Conditions

Model	Description	Symbol	Value	Unit
Human Body	Series Resistance	R1	1500	Ohm
	Storage Capacitance	C	100	pF
	Number of Pulse per pin positive negative	–	– 3 3	
Machine	Series Resistance	R1	0	Ohm
	Storage Capacitance	C	200	pF
	Number of Pulse per pin positive negative	–	– 3 3	
Latch-up	Minimum input voltage limit		–2.5	V
	Maximum input voltage limit		7.5	V

Table A-3. ESD and Latch-Up Protection Characteristics

Num	C	Rating	Symbol	Min	Max	Unit
1	T	Human Body Model (HBM)	V_{HBM}	2000	–	V
2	T	Machine Model (MM)	V_{MM}	200	–	V
3	T	Charge Device Model (CDM)	V_{CDM}	500	–	V
4	T	Latch-up Current at T_A = 125°C positive negative	I_{LAT}	 +100 –100	–	mA
5	T	Latch-up Current at T_A = 27°C positive negative	I_{LAT}	 +200 –200	–	mA

A.1.7 Operating Conditions

This chapter describes the operating conditions of the device. Unless otherwise noted those conditions apply to all the following data.

NOTE

Please refer to the temperature rating of the device (C, V, M) with regards to the ambient temperature T_A and the junction temperature T_J. For power dissipation calculations refer to Section A.1.8, "Power Dissipation and Thermal Characteristics".

Table A-4. Operating Conditions

Rating	Symbol	Min	Typ	Max	Unit
I/O, Regulator and Analog Supply Voltage	V_{DD35}	2.97	5	5.5	V
Internal Logic Supply Voltage [1]	V_{DD}	2.35	2.5	2.75	V
PLL Supply Voltage [1]	V_{DDPLL}	2.35	2.5	2.75	V
Voltage Difference VDDX to VDDR and VDDA	Δ_{VDDX}	–0.1	0	0.1	V
Voltage Difference VSSX to VSSR and VSSA	Δ_{VSSX}	–0.1	0	0.1	V
Oscillator	f_{osc}	0.5	–	16	MHz
Bus Frequency	f_{bus}	0.25[2]	–	33[3]	MHz

Operating Junction Temperature Range	T_J	–40	–	120	°C
Operating Ambient Temperature Range [4]	T_A	–40	27	105	°C
MC3S12RG128**M**					
Operating Junction Temperature Range	T_J	–40	–	140	°C
Operating Ambient Temperature Range [4]	T_A	–40	27	125	°C

1 The device contains an internal voltage regulator to generate the logic and PLL supply out of the I/O supply. This applies when this regulator is disabled and the device is powered from an external source.

2 Some blocks e.g. ATD (conversion) require higher bus frequencies for proper operation.

3 single-chip modes only; for expanded modes the max. bus frequency is 25 MHz

4 Please refer to Section A.1.8, "Power Dissipation and Thermal Characteristics" for more details about the relation between ambient temperature T_A and device junction temperature T_J.

A.1.8 Power Dissipation and Thermal Characteristics

Power dissipation and thermal characteristics are closely related. The user must assure that the maximum operating junction temperature is not exceeded. The average chip-junction temperature (T_J) in °C can be obtained from:

$$T_J = T_A + (P_D \bullet \Theta_{JA})$$

T_J = Junction Temperature, [°C]

T_A = Ambient Temperature, [°C]

P_D = Total Chip Power Dissipation, [W]

Θ_{JA} = Package Thermal Resistance, [°C/W]

The total power dissipation can be calculated from:

$$P_D = P_{INT} + P_{IO}$$

P_{INT} = Chip Internal Power Dissipation, [W]

Two cases with internal voltage regulator enabled and disabled must be considered:

1. Internal voltage regulator disabled

$$P_{INT} = I_{DD} \cdot V_{DD} + I_{DDPLL} \cdot V_{DDPLL} + I_{DDA} \cdot V_{DDA}$$

$$P_{IO} = \sum_i R_{DSON} \cdot I_{IO_i}^2$$

P_{IO} is the sum of all output currents on I/O ports associated with V_{DDX} and V_{DDR}.
For R_{DSON} is valid:

$$R_{DSON} = \frac{V_{OL}}{I_{OL}};\text{for outputs driven low}$$

respectively

$$R_{DSON} = \frac{V_{DD5} - V_{OH}}{I_{OH}};\text{for outputs driven high}$$

2. Internal voltage regulator enabled

$$P_{INT} = I_{DDR} \cdot V_{DDR} + I_{DDA} \cdot V_{DDA}$$

I_{DDR} is the current shown in Table A-8 and not the overall current flowing into V_{DDR}, which additionally contains the current flowing into the external loads with output high.

$$P_{IO} = \sum_i R_{DSON} \cdot I_{IO_i}^2$$

P_{IO} is the sum of all output currents on I/O ports associated with V_{DDX} and V_{DDR}.

Table A-5. Thermal Package Characteristics[1]

Num	C	Rating	Symbol	Min	Typ	Max	Unit
1	T	Thermal Resistance LQFP112, single sided PCB[2]	θ_{JA}	–	–	54	$^oC/W$
2	T	Thermal Resistance LQFP112, double sided PCB with 2 internal planes[3]	θ_{JA}	–	–	41	$^oC/W$
3	T	Junction to Board LQFP112	θ_{JB}	–	–	31	$^oC/W$
4	T	Junction to Case LQFP112	θ_{JC}	–	–	11	$^oC/W$
5	T	Junction to Package Top LQFP112	Ψ_{JT}	–	–	2	$^oC/W$
6	T	Thermal Resistance QFP 80, single sided PCB	θ_{JA}	–	–	51	$^oC/W$
7	T	Thermal Resistance QFP 80, double sided PCB with 2 internal planes	θ_{JA}	–	–	41	$^oC/W$
8	T	Junction to Board QFP80	θ_{JB}	–	–	27	$^oC/W$
9	T	Junction to Case QFP80	θ_{JC}	–	–	14	$^oC/W$
10	T	Junction to Package Top QFP80	Ψ_{JT}	–	–	3	$^oC/W$

1 The values for thermal resistance are achieved by package simulations

2 PC Board according to EIA/JEDEC Standard 51-3

3 PC Board according to EIA/JEDEC Standard 51-7

A.1.9 I/O Characteristics

This section describes the characteristics of all I/O pins except EXTAL, XTAL, XFC, TEST and supply pins. All parameters are not always applicable, e.g. not all pins feature pull up/down resistances.

Table A-6. 3.3V I/O Characteristics

Num	C	Rating	Symbol	Min	Typ	Max	Unit
Conditions are VDDX=3.3V +/-10% Temperature from -40C to 140C, unless otherwise noted. I/O Characteristics for all I/O pins except EXTAL, XTAL,XFC,TEST and supply pins.							
1	P	Input High Voltage	V_{IH}	0.65*V_{DD35}	–	–	V
	T	Input High Voltage	V_{IH}	–	–	V_{DD35} + 0.3	V
2	P	Input Low Voltage	V_{IL}	–	–	0.35*V_{DD35}	V
	T	Input Low Voltage	V_{IL}	V_{SS35} – 0.3	–	–	V
3	C	Input Hysteresis	V_{HYS}	–	250	–	mV
4	C	Input Leakage Current (pins in high impedance input mode)[1] V_{in} = V_{DD35} or V_{SS35}	I_{in}	–1	–	1	µA
5	C	Output High Voltage (pins in output mode) Partial Drive I_{OH} = –0.75mA	V_{OH}	V_{DD35} – 0.4	–	–	V
6	P	Output High Voltage (pins in output mode) Full Drive I_{OH} = –4.0mA	V_{OH}	V_{DD35} – 0.4	–	–	V
7	C	Output Low Voltage (pins in output mode) Partial Drive I_{OL} = +0.9mA	V_{OL}	–	–	0.4	V
8	P	Output Low Voltage (pins in output mode) Full Drive I_{OL} = +4.75mA	V_{OL}	–	–	0.4	V
9	P	Internal Pull Up Device Current, tested at V_{IL} max	I_{PUL}	–	–	–60	µA
10	C	Internal Pull Up Device Current,tested at V_{IH} min	I_{PUH}	–6	–	–	µA
11	P	Internal Pull Down Device Current, tested at V_{IH} min	I_{PDH}	–	–	60	µA
12	C	Internal Pull Down Device Current, tested at V_{IL} max	I_{PDL}	6	–	–	µA
13	D	Input Capacitance	C_{in}	–	6	–	pF
14	T	Injection current[2] Single Pin limit Total Device Limit. Sum of all injected currents	 I_{ICS} I_{ICP}	 –2.5 –25	–	 2.5 25	mA
15	P	Port H, J, P Interrupt Input Pulse filtered[3]	t_{PULSE}	–	–	3	µs
16	P	Port H, J, P Interrupt Input Pulse passed[3]	t_{PULSE}	10	–	–	µs

[1] Maximum leakage current occurs at maximum operating temperature. Current decreases by approximately one-half for each 8˚C to 12˚C in the temperature range from 50˚C to 125˚C.

[2] Refer to Section A.1.4, "Current Injection", for more details

[3] Parameter only applies in STOP or Pseudo STOP mode.

Table A-7. 5V I/O Characteristics

Conditions are 4.5< V_{DD35} <5.5V Temperature from -40C to 140C, unless otherwise noted
I/O Characteristics for all I/O pins except EXTAL, XTAL, XFC, TEST and supply pins.

Num	C	Rating	Symbol	Min	Typ	Max	Unit
1	P	Input High Voltage	V_{IH}	0.65*V_{DD35}	–	–	V
	T	Input High Voltage	V_{IH}	–	–	V_{DD35} + 0.3	V
2	P	Input Low Voltage	V_{IL}	–	–	0.35*V_{DD35}	V
	T	Input Low Voltage	V_{IL}	V_{SS35} – 0.3	–	–	V
3	C	Input Hysteresis	V_{HYS}	–	250	–	mV
4	P	Input Leakage Current (pins in high impedance input mode)[1] measured at V_{in} = 5.5V and V_{in} = 0V	I_{in}	–1	–	1	µA
5	C	Output High Voltage (pins in output mode) Partial Drive I_{OH} = –2mA	V_{OH}	V_{DD35} – 0.8	–	–	V
6	P	Output High Voltage (pins in output mode) Full Drive I_{OH} = –10mA	V_{OH}	V_{DD35} – 0.8	–	–	V
7	C	Output Low Voltage (pins in output mode) Partial Drive I_{OL} = +2mA	V_{OL}	–	–	0.8	V
8	P	Output Low Voltage (pins in output mode) Full Drive I_{OL} = +10mA	V_{OL}	–	–	0.8	V
9	P	Internal Pull Up Device Current, tested at V_{IL} max	I_{PUL}	–	–	–130	µA
10	C	Internal Pull Up Device Current, tested at V_{IH} min	I_{PUH}	–10	–	–	µA
11	P	Internal Pull Down Device Current, tested at V_{IH} min	I_{PDH}	–	–	130	µA
12	C	Internal Pull Down Device Current, tested at V_{IL} max	I_{PDL}	10	–	–	µA
13	D	Input Capacitance	C_{in}	–	6	–	pF
14	T	Injection current[2] Single Pin limit Total Device Limit. Sum of all injected currents	 I_{ICS} I_{ICP}	 –2.5 –25	–	 2.5 25	mA
15	P	Port H, J, P Interrupt Input Pulse filtered[3]	t_{PULSE}	–	–	3	µs
16	P	Port H, J, P Interrupt Input Pulse passed[3]	t_{PULSE}	10	–	–	µs

[1] Maximum leakage current occurs at maximum operating temperature. Current decreases by approximately one-half for each 8˚C to 12˚C in the temperature range from 50˚C to 125˚C.
[2] Refer to Section A.1.4, “Current Injection”, for more details
[3] Parameter only applies in STOP or Pseudo STOP mode.

A.1.10 Supply Currents

This section describes the current consumption characteristics of the device as well as the conditions for the measurements.

A.1.10.1 Measurement Conditions

All measurements are without output loads. Unless otherwise noted the currents are measured in single chip mode, internal voltage regulator enabled and at 33MHz bus frequency using a 4MHz oscillator in Colpitts mode. Production testing is performed using a square wave signal at the EXTAL input.

A.1.10.2 Additional Remarks

In expanded modes the currents flowing in the system are highly dependent on the load at the address, data and control signals as well as on the duty cycle of those signals. No generally applicable numbers can be given. A very good estimate is to take the single chip currents and add the currents due to the external loads.

Table A-8. Supply Current Characteristics at 33 MHz Bus Frequency

Conditions are shown in Table A-4 unless otherwise noted							
Num	**C**	**Rating**	**Symbol**	**Min**	**Typ**	**Max**	**Unit**
1		Run supply currents (33 MHz)	I_{DD35}				mA
	P	Single Chip, Internal regulator enabled				70	
2		Wait Supply current	I_{DDW}				mA
	P	All modules enabled, PLL on (33 MHz)				35	
	P	only RTI enabled [1]				7	
3		Pseudo Stop Current (RTI and COP disabled) [1, 2]	I_{DDPS}				µA
	C	-40°C			90		
	P	25°C			100	140	
	C	70°C			250		
	C	85°C			300		
	P	"C" Temp Option 100°C			350	1200	
	C	105°C			400		
	P	"V" Temp Option 120°C			650	2200	
	C	125°C			750		
	P	"M" Temp Option 140°C			1000	4000	
4		Pseudo Stop Current (RTI and COP enabled) [1, 2]	I_{DDPS}				µA
	C	-40°C			120		
	C	25°C			140		
	C	70°C			275		
	C	85°C			325		
	C	105°C			450		
	C	125°C			800		
	C	140°C			1200		
5		Stop Current [2]	I_{DDS}				µA
	C	-40°C			20		
	P	25°C			35	100	
	C	70°C			150		
	C	85°C			250		
	P	"C" Temp Option 100°C			300	1000	
	C	105°C			350		
	P	"V" Temp Option 120°C			600	2000	
	C	125°C			700		
	P	"M" Temp Option 140°C			900	3800	

[1] PLL off

[2] At those low power dissipation levels $T_J = T_A$ can be assumed

A.2 ATD Characteristics

This section describes the characteristics of the analog to digital converter.

The ATD is specified and tested for both the 3.3V and 5V range. For ranges between 3.3V and 5V the ATD accuracy is generally the same as in the 3.3V range but is not tested in this range in production test.

A.2.1 ATD Operating Characteristics In 5V Range

The Table A-9 shows conditions under which the ATD operates.

The following constraints exist to obtain full-scale, full range results:
$V_{SSA} \leq V_{RL} \leq V_{IN} \leq V_{RH} \leq V_{DDA}$. This constraint exists since the sample buffer amplifier can not drive beyond the power supply levels that it ties to. If the input level goes outside of this range it will effectively be clipped.

Table A-9. ATD Operating Characteristics

Conditions are shown in Table A-4 unless otherwise noted. Supply Voltage 5V-10% <= V_{DDA} <=5V+10%							
Num	**C**	**Rating**	**Symbol**	**Min**	**Typ**	**Max**	**Unit**
1	D	Reference Potential Low High	 V_{RL} V_{RH}	 V_{SSA} $V_{DDA}/2$		 $V_{DDA}/2$ V_{DDA}	 V V
2	C	Differential Reference Voltage[1]	V_{RH}-V_{RL}	4.50	5.00	5.50	V
3	D	ATD Clock Frequency	f_{ATDCLK}	0.5		2.0	MHz
4	D	ATD 10-Bit Conversion Period Clock Cycles[2] Conv, Time at 2.0MHz ATD Clock f_{ATDCLK}	 N_{CONV10} T_{CONV10}	 14 7		 28 14	 Cycles µs
5	D	ATD 8-Bit Conversion Period Clock Cycles Conv, Time at 2.0MHz ATD Clock f_{ATDCLK}	 N_{CONV10} T_{CONV10}	 12 6		 26 13	 Cycles µs
6	D	Recovery Time (V_{DDA}=5.0 Volts)	t_{REC}			20	µs
7	P	Reference Supply current	I_{REF}			0.375[3]	mA

[1] Full accuracy is not guaranteed when differential voltage is less than 4.75V

[2] The minimum time assumes a final sample period of 2 ATD clocks cycles while the maximum time assumes a final sample period of 16 ATD clocks.

[3] This applies per ATD module, i.e. for 2 ATD modules this number is doubled.

A.2.2 ATD Operating Characteristics In 3.3V Range

The Table A-10 shows conditions under which the ATD operates.

The following constraints exist to obtain full-scale, full range results:
$V_{SSA} \leq V_{RL} \leq V_{IN} \leq V_{RH} \leq V_{DDA}$. This constraint exists since the sample buffer amplifier can not drive beyond the power supply levels that it ties to. If the input level goes outside of this range it will effectively be clipped

Table A-10. ATD Operating Characteristics

Conditions are shown in Table A-4 unless otherwise noted; Supply Voltage 3.3V-10% <= V_{DDA} <= 3.3V+10%							
Num	**C**	**Rating**	**Symbol**	**Min**	**Typ**	**Max**	**Unit**
1	D	Reference Potential Low High	 V_{RL} V_{RH}	 V_{SSA} $V_{DDA}/2$		 $V_{DDA}/2$ V_{DDA}	 V V
2	C	Differential Reference Voltage	V_{RH}-V_{RL}	3.0	3.3	3.6	V
3	D	ATD Clock Frequency	f_{ATDCLK}	0.5		2.0	MHz
4	D	ATD 10-Bit Conversion Period Clock Cycles[1] Conv, Time at 2.0MHz ATD Clock f_{ATDCLK}	 N_{CONV10} T_{CONV10}	 14 7		 28 14	 Cycles µs
5	D	ATD 8-Bit Conversion Period Clock Cycles[1] Conv, Time at 2.0MHz ATD Clock f_{ATDCLK}	 N_{CONV8} T_{CONV8}	 12 6		 26 13	 Cycles µs
6	D	Recovery Time (V_{DDA}=3.3 Volts)	t_{REC}			20	µs
7	P	Reference Supply current	I_{REF}			0.250[2]	mA

1 The minimum time assumes a final sample period of 2 ATD clocks cycles while the maximum time assumes a final sample period of 16 ATD clocks.

2 This applies per ATD module, i.e. for 2 ATD modules this number is doubled.

A.2.3 Factors influencing accuracy

Three factors - source resistance, source capacitance and current injection - have an influence on the accuracy of the ATD.

A.2.3.1 Source Resistance:

Due to the input pin leakage current as specified in Table A-7 in conjunction with the source resistance there will be a voltage drop from the signal source to the ATD input. The maximum source resistance R_S specifies results in an error of less than 1/2 LSB (2.5mV) at the maximum leakage current. If device or operating conditions are less than worst case or leakage-induced error is acceptable, larger values of source resistance is allowable.

A.2.3.2 Source capacitance

When sampling an additional internal capacitor is switched to the input. This can cause a voltage drop due to charge sharing with the external and the pin capacitance. For a maximum sampling error of the input voltage ≤ 1LSB, then the external filter capacitor, $C_f \geq 1024 * (C_{INS}- C_{INN})$.

A.2.3.3 Current injection

There are two cases to consider.

1. A current is injected into the channel being converted. The channel being stressed has conversion values of $3FF ($FF in 8-bit mode) for analog inputs greater than VRH and $000 for values less than VRL unless the current is higher than specified as disruptive conditions.
2. Current is injected into pins in the neighborhood of the channel being converted. A portion of this current is picked up by the channel (coupling ratio K), This additional current impacts the accuracy of the conversion depending on the source resistance.
   The additional input voltage error on the converted channel can be calculated as $V_{ERR} = K * R_S * I_{INJ}$, with I_{INJ} being the sum of the currents injected into the two pins adjacent to the converted channel.

Table A-11. ATD Electrical Characteristics

Conditions are shown in Table A-4 unless otherwise noted							
Num	**C**	**Rating**	**Symbol**	**Min**	**Typ**	**Max**	**Unit**
1	C	Max input Source Resistance	R_S	–	–	1	KΩ
2	T	Total Input Capacitance Non Sampling Sampling	 C_{INN} C_{INS}			 10 22	pF
3	C	Disruptive Analog Input Current	I_{NA}	–2.5		2.5	mA
4	C	Coupling Ratio positive current injection	K_p			10^{-4}	A/A
5	C	Coupling Ratio negative current injection	K_n			10^{-2}	A/A

A.2.4 ATD accuracy (5V Range)

Table A-12 specifies the ATD conversion performance excluding any errors due to current injection, input capacitance and source resistance.

Table A-12. 5V ATD Conversion Performance

Conditions are shown in Table A-4 unless otherwise noted $V_{REF} = V_{RH} - V_{RL} = 5.12V$. Resulting to one 8 bit count = 20mV and one 10 bit count = 5mV $f_{ATDCLK} = 2.0MHz$							
Num	**C**	**Rating**	**Symbol**	**Min**	**Typ**	**Max**	**Unit**
1	P	10-Bit Resolution	LSB	–	5	–	mV
2	P	10-Bit Differential Nonlinearity	DNL	–1	–	+1	Counts
3	P	10-Bit Integral Nonlinearity	INL	–2.5	±1.5	+2.5	Counts
4	P	10-Bit Absolute Error[1]	AE	–3	±2	3	Counts
5	P	8-Bit Resolution	LSB	–	20	–	mV
6	P	8-Bit Differential Nonlinearity	DNL	–0.5	–	0.5	Counts
7	P	8-Bit Integral Nonlinearity	INL	–1.0	±0.5	1.0	Counts
8	P	8-Bit Absolute Error[1]	AE	–1.5	±1.0	1.5	Counts

[1] These values include quantization error which is inherently 1/2 count for any A/D converter.

A.2.5 ATD accuracy (3.3V Range)

Table A-13 specifies the ATD conversion performance excluding any errors due to current injection, input capacitance and source resistance.

Table A-13. 3.3V ATD Conversion Performance

Num	C	Rating	Symbol	Min	Typ	Max	Unit
Conditions are shown in Table A-4 unless otherwise noted $V_{REF} = V_{RH} - V_{RL}$ = 3.328V. Resulting to one 8 bit count = 13mV and one 10 bit count = 3.25mV f_{ATDCLK} = 2.0MHz							
1	P	10-Bit Resolution	LSB	–	3.25	–	mV
2	P	10-Bit Differential Nonlinearity	DNL	–1.5	–	+1.5	Counts
3	P	10-Bit Integral Nonlinearity	INL	–3.5	±1.5	+3.5	Counts
4	P	10-Bit Absolute Error[1]	AE	–5	±2.5	+5	Counts
5	P	8-Bit Resolution	LSB	–	13	–	mV
6	P	8-Bit Differential Nonlinearity	DNL	–0.5	–	0.5	Counts
7	P	8-Bit Integral Nonlinearity	INL	–1.5	±1.0	1.5	Counts
8	P	8-Bit Absolute Error[1]	AE	–2.0	±1.5	2.0	Counts

[1] These values include the quantization error which is inherently 1/2 count for any A/D converter.

For the following definitions see also Figure A-1.

Differential Non-Linearity (DNL) is defined as the difference between two adjacent switching steps.

$$DNL(i) = \frac{V_i - V_{i-1}}{1LSB} - 1$$

The Integral Non-Linearity (INL) is defined as the sum of all DNLs:

$$INL(n) = \sum_{i=1}^{n} DNL(i) = \frac{V_n - V_0}{1LSB} - n$$

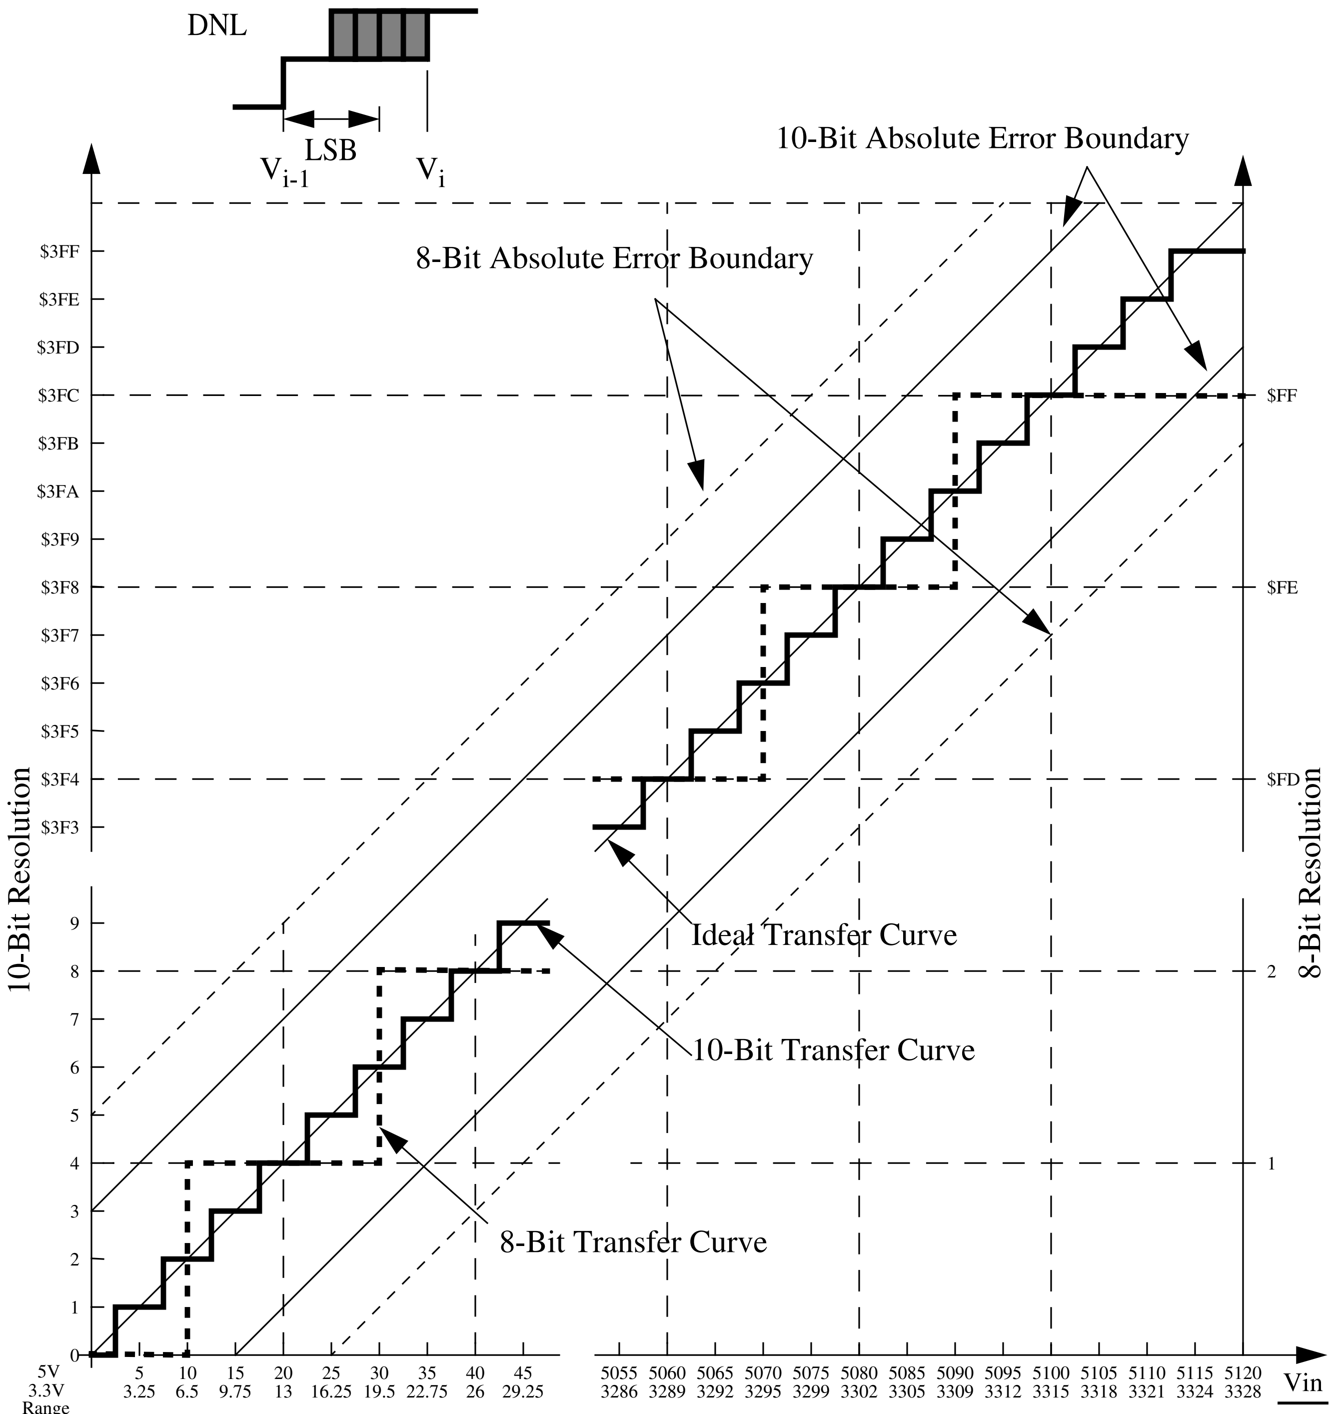

Figure A-1. ATD Accuracy Definitions

NOTE

Figure A-1 shows only definitions, for specification values refer to Table A-12 and Table A-13.

A.3 Voltage Regulator Operating Conditions

Table A-14. Voltage Regulator Electrical Parameters

Num	C	Characteristic	Symbol	Min	Typical	Max	Unit
1	P	Input Voltages	$V_{VDDR, A}$	2.97	—	5.5	V
2	P	Output Voltage Core Full Performance Mode	V_{DD}	 2.35	 2.54	 2.75	 V
3	P	Output Voltage PLL Full Performance Mode	V_{DDPLL}	 2.35	 2.54	 2.75	 V
4	P	Low Voltage Interrupt[1] Assert Level Deassert Level	 V_{LVIA} V_{LVID}	 4.00 4.15	 4.37 4.52	 4.66 4.77	 V V
5	P	Low Voltage Reset[2] Assert Level	 V_{LVRA}	 2.25	 2.35	 —	 V
6	C	Power-on Reset[3] Assert Level Deassert Level	 V_{PORA} V_{PORD}	 0.97 —	 — —	 — 2.05	 V V

1 Monitors V_{DDA}, active only in Full Performance Mode. Indicates I/O & ADC performance degradation due to low supply voltage.
2 Monitors V_{DD}, active only in Full Performance Mode. MCU is monitored by the POR in Reduced Power Mode
3 Monitors V_{DD}. Active in all modes.

NOTE

The electrical characteristics given in this section are preliminary and should be used as a guide only. Values in this section cannot be guaranteed by Freescale and are subject to change without notice.

A.4 Chip Power-up and LVI/LVR graphical explanation

Voltage regulator sub modules LVI (low voltage interrupt), POR (power-on reset) and LVR (low voltage reset) handle chip power-up or drops of the supply voltage. Their function is described in the VREG3V3 block guide.

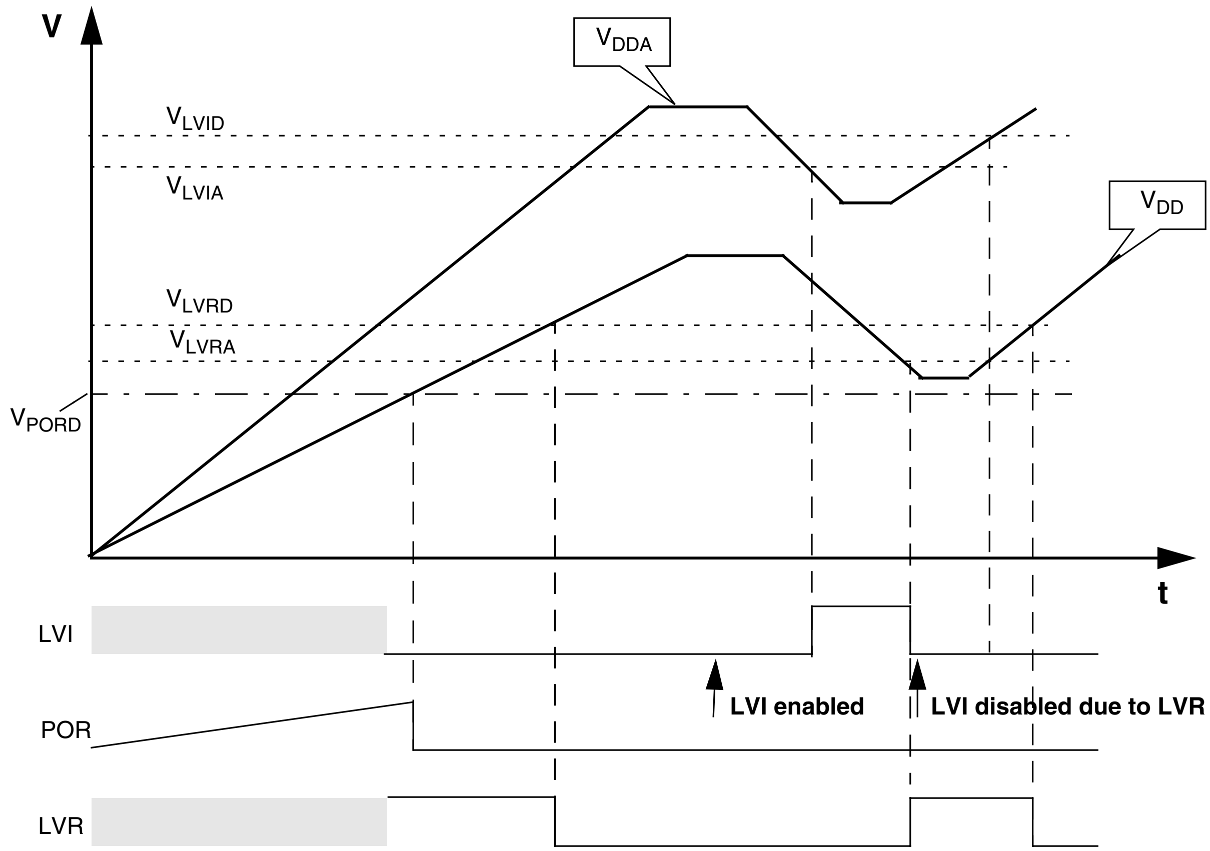

Figure A-2. Voltage Regulator - Chip Power-up and Voltage Drops (not scaled)

A.5 Output Loads

A.5.1 Resistive Loads

The on-chip voltage regulator is intended to supply the internal logic and oscillator circuits allows no external DC loads.

A.5.2 Capacitive Loads

The capacitive loads are specified in Table A-15. Ceramic capacitors with X7R dielectricum are required.

Table A-15. Voltage Regulator - Capacitive Loads

Num	Characteristic	Symbol	Min	Typical	Max	Unit
1	V_{DD} external capacitive load	C_{DDext}	400	440	12000	nF
2	V_{DDPLL} external capacitive load	$C_{DDPLLext}$	90	220	5000	nF

A.6 Reset, Oscillator and PLL

This section summarizes the electrical characteristics of the various startup scenarios for Oscillator and Phase-Locked-Loop (PLL).

A.6.1 Startup

Table A-16 summarizes several startup characteristics explained in this section. Detailed description of the startup behavior can be found in the Clock and Reset Generator (CRG) Block User Guide.

Table A-16. Startup Characteristics

Conditions are shown in Table A-4 unless otherwise noted							
Num	C	Rating	Symbol	Min	Typ	Max	Unit
1	D	Reset input pulse width, minimum input time	PW_{RSTL}	2			t_{osc}
2	D	Startup from Reset	n_{RST}	192		196	n_{osc}
3	D	Interrupt pulse width, $\overline{IRQ}$ edge-sensitive mode	PW_{IRQ}	20			ns
4	D	Wait recovery startup time	t_{WRS}			14	t_{cyc}

A.6.1.1 POR

Both the deassert level V_{PORD} and the assert level V_{PORA} (Table A-14) are derived from the V_{DD} supply. They are also valid if the device is powered externally. After releasing the POR reset the oscillator and the clock quality check are started. If after a time t_{CQOUT} no valid oscillation is detected, the MCU will start using the internal self clock. The fastest startup time possible is given by n_{uposc}.

A.6.1.2 SRAM Data Retention

Provided an appropriate external reset signal is applied to the MCU, preventing the CPU from executing code if V_{DD35} is out of specification limits, the SRAM contents integrity is guaranteed if after the reset the PORF bit in the CRG Flags Register has not been set.

A.6.1.3 External Reset

When external reset is asserted for a time greater than PW_{RSTL} the CRG module generates an internal reset, and the CPU starts fetching the reset vector without doing a clock quality check, if there was an oscillation before reset.

A.6.1.4 Stop Recovery

Out of STOP the controller can be woken up by an external interrupt. A clock quality check as after POR is performed before releasing the clocks to the system.

A.6.1.5 Pseudo Stop and Wait Recovery

The recovery from Pseudo STOP and Wait are essentially the same since the oscillator was not stopped in both modes. The controller can be woken up by internal or external interrupts. After t_{wrs} the CPU starts fetching the interrupt vector.

A.6.2 Oscillator

The device features an internal Colpitts and Pierce oscillator. The selection of Colpitts oscillator or Pierce oscillator/external clock depends on the XCLKS signal which is sampled during reset.By asserting the $\overline{XCLKS}$ input during reset this oscillator can be bypassed allowing the input of a square wave. Before asserting the oscillator to the internal system clocks the quality of the oscillation is checked for each start from either power-on, STOP or oscillator fail. t_{CQOUT} specifies the maximum time before switching to the internal self clock mode after POR or STOP if a proper oscillation is not detected. The quality check also determines the minimum oscillator start-up time t_{UPOSC}. The device also features a clock monitor. A Clock Monitor Failure is asserted if the frequency of the incoming clock signal is below the Assert Frequency f_{CMFA}.

Table A-17. Oscillator Characteristics

Conditions are shown in Table A-4 unless otherwise noted							
Num	**C**	**Rating**	**Symbol**	**Min**	**Typ**	**Max**	**Unit**
1a	C	Crystal oscillator range (Colpitts)	f_{OSC}	0.5		16	MHz
1b	C	Crystal oscillator range (Pierce) [1]	f_{OSC}	0.5		40	MHz
2	P	Startup Current	i_{OSC}	100			μA
3	C	Oscillator start-up time (Colpitts)	t_{UPOSC}		8[2]	100[3]	ms
4	D	Clock Quality check time-out	t_{CQOUT}	0.45		2.5	s
5	P	Clock Monitor Failure Assert Frequency	f_{CMFA}	50	100	200	KHz
6	P	External square wave input frequency [4]	f_{EXT}	0.5		66	MHz
7	D	External square wave pulse width low	t_{EXTL}	7.2			ns
8	D	External square wave pulse width high	t_{EXTH}	7.2			ns
9	D	External square wave rise time	t_{EXTR}			1	ns
10	D	External square wave fall time	t_{EXTF}			1	ns
11	D	Input Capacitance (EXTAL, XTAL pins)	C_{IN}		7		pF
12	C	DC Operating Bias in Colpitts Configuration on EXTAL Pin	V_{DCBIAS}		1.1		V

1 Depending on the crystal a damping series resistor might be necessary
2 f_{osc} = 4MHz, C = 22pF.
3 Maximum value is for extreme cases using high Q, low frequency crystals

4 $\overline{XCLKS}$ =0 during reset

A.6.3 Phase Locked Loop

The oscillator provides the reference clock for the PLL. The PLL´s Voltage Controlled Oscillator (VCO) is also the system clock source in self clock mode.

A.6.3.1 XFC Component Selection

This section describes the selection of the XFC components to achieve good filter characteristics.

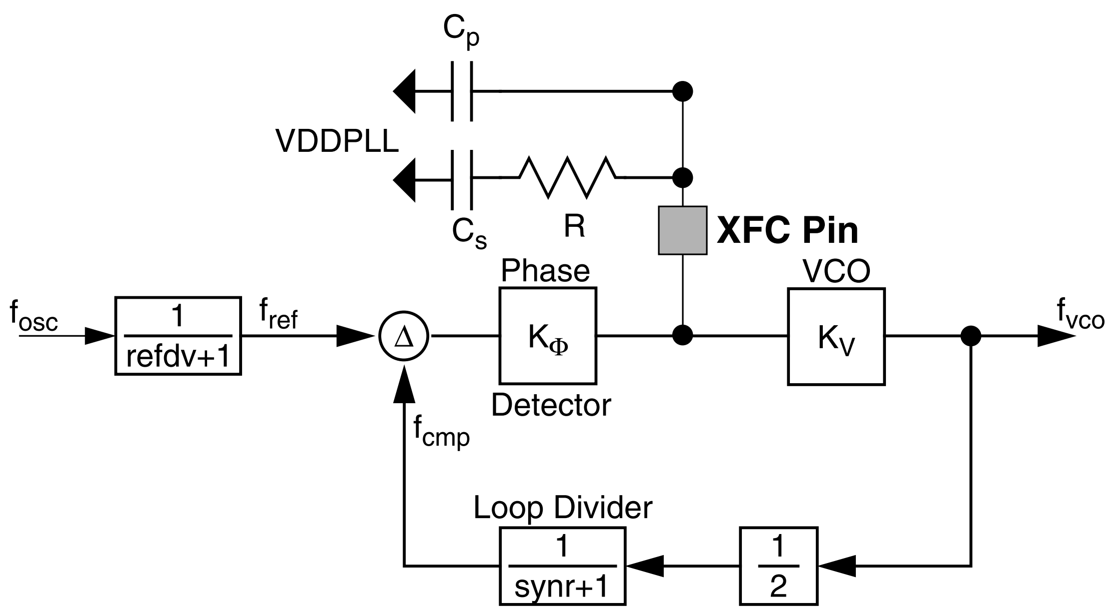

Figure A-3. Basic PLL functional diagram

The following procedure can be used to calculate the resistance and capacitance values using typical values for K_1, f_1 and i_{ch} from Table A-18.

The grey boxes show the calculation for f_{VCO} = 50MHz and f_{ref} = 1MHz. E.g., these frequencies are used for f_{OSC} = 4MHz and a 25MHz bus clock.

The VCO Gain at the desired VCO frequency is approximated by:

$$K_V = K_1 \cdot e^{\frac{(f_1 - f_{vco})}{K_1 \cdot 1V}} = -100 \cdot e^{\frac{(60-50)}{-100}} = -90.48\text{MHz/V}$$

The phase detector relationship is given by:

$$K_\Phi = -|i_{ch}| \cdot K_V \qquad = 316.7\text{Hz}/\Omega$$

i_{ch} is the current in tracking mode.

The loop bandwidth f_C should be chosen to fulfill the Gardner's stability criteria by at least a factor of 10, typical values are 50. $\zeta = 0.9$ ensures a good transient response.

$$f_C < \frac{2 \cdot \zeta \cdot f_{ref}}{\pi \cdot \left(\zeta + \sqrt{1 + \zeta^2}\right)} \frac{1}{10} \rightarrow f_C < \frac{f_{ref}}{4 \cdot 10};(\zeta = 0.9)$$

$f_C < 25kHz$

And finally the frequency relationship is defined as

$$n = \frac{f_{VCO}}{f_{ref}} = 2 \cdot (synr + 1) \quad = 50$$

With the above values the resistance can be calculated. The example is shown for a loop bandwidth f_C=10KHz:

$$R = \frac{2 \cdot \pi \cdot n \cdot f_C}{K_\Phi} \quad = 2*\pi*50*10kHz/(316.7Hz/\Omega)=9.9k\Omega =\sim 10k\Omega$$

The capacitance C_s can now be calculated as:

$$C_s = \frac{2 \cdot \zeta^2}{\pi \cdot f_C \cdot R} \approx \frac{0.516}{f_C \cdot R};(\zeta = 0.9) \quad = 5.19nF =\sim 4.7nF$$

The capacitance C_p should be chosen in the range of:

$$C_s/20 \le C_p \le C_s/10 \quad C_p = 470pF$$

A.6.3.2 Jitter Information

The basic functionality of the PLL is shown in Figure A-3. With each transition of the clock f_{cmp}, the deviation from the reference clock f_{ref} is measured and input voltage to the VCO is adjusted accordingly.The adjustment is done continuously with no abrupt changes in the clock output frequency. Noise, voltage, temperature and other factors cause slight variations in the control loop resulting in a clock jitter. This jitter affects the real minimum and maximum clock periods as illustrated in Figure A-4.

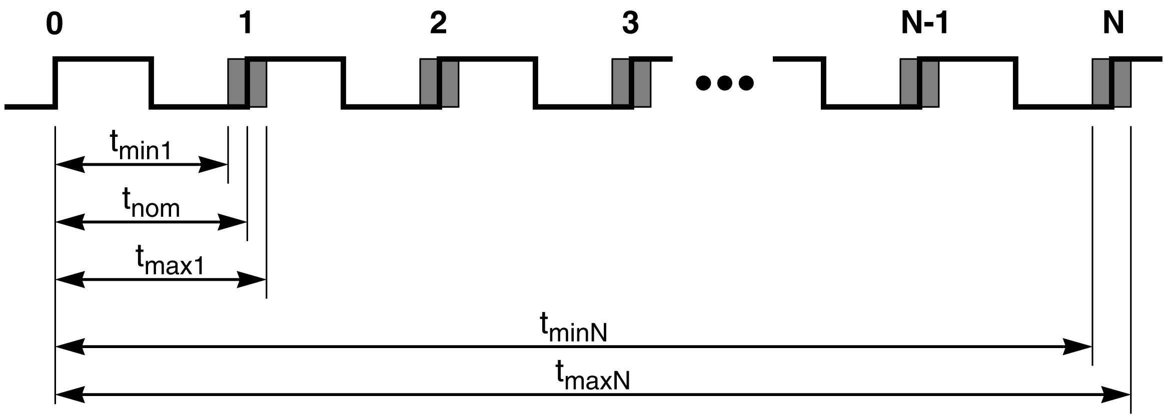

Figure A-4. Jitter Definitions

The relative deviation of t_{nom} is at its maximum for one clock period, and decreases towards zero for larger number of clock periods (N).

Defining the jitter as:

$$J(N) = \max\left(\left|1 - \frac{t_{max}(N)}{N \cdot t_{nom}}\right|, \left|1 - \frac{t_{min}(N)}{N \cdot t_{nom}}\right|\right)$$

For N < 100, the following equation is a good fit for the maximum jitter:

$$J(N) = \frac{j_1}{\sqrt{N}} + j_2$$

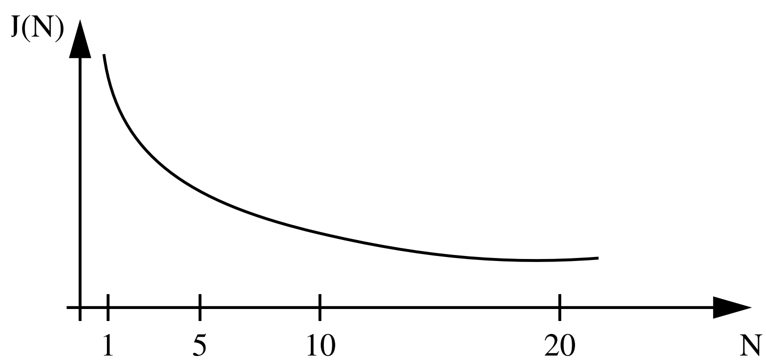

Figure A-5. Maximum bus clock jitter approximation

This is very important to notice with respect to timers, serial modules where a pre-scaler will eliminate the effect of the jitter to a large extent.

Table A-18. PLL Characteristics

Conditions are shown in Table A-4 unless otherwise noted							
Num	C	Rating	Symbol	Min	Typ	Max	Unit
1	P	Self Clock Mode frequency	f_{SCM}	1		5.5	MHz
2	D	VCO locking range	f_{VCO}	8		66	MHz
3	D	Lock Detector transition from Acquisition to Tracking mode	$\|\Delta_{trk}\|$	3		4	%[1]
4	D	Lock Detection	$\|\Delta_{Lock}\|$	0		1.5	%[1]
5	D	Un-Lock Detection	$\|\Delta_{unl}\|$	0.5		2.5	%[1]
6	D	Lock Detector transition from Tracking to Acquisition mode	$\|\Delta_{unt}\|$	6		8	%[1]
7	C	PLLON Total Stabilization delay (Auto Mode) [2]	t_{stab}		0.5		ms
8	D	PLLON Acquisition mode stabilization delay [2]	t_{acq}		0.3		ms
9	D	PLLON Tracking mode stabilization delay [2]	t_{al}		0.2		ms
10	D	Fitting parameter VCO loop gain	K_1		–100		MHz/V
11	D	Fitting parameter VCO loop frequency	f_1		60		MHz
12	D	Charge pump current acquisition mode	$\| i_{ch} \|$		38.5		µA
13	D	Charge pump current tracking mode	$\| i_{ch} \|$		3.5		µA
14	C	Jitter fit parameter 1[2] (f_{BUS} = 25MHz)	j_1			1.1	%
15	C	Jitter fit parameter 1[3] (f_{BUS} = 33MHz)	j_1			1.5	%
16	C	Jitter fit parameter 2[2] (f_{BUS} = 25MHz)	j_2			0.13	%

[1] % deviation from target frequency

[2] f_{OSC} = 4MHz, f_{BUS} = 25MHz equivalent f_{VCO} = 50MHz: REFDV = 0x03, SYNR = 0x18, C_s = 4.7nF, C_p = 470pF, R_s = 10kΩ.

[3] f_{OSC} = 4MHz, f_{BUS} = 33MHz equivalent f_{VCO} = 66MHz: REFDV = 0x03, SYNR = 0x20, C_s = 22nF, C_p = 2.2nF, R_s = 4.7kΩ

A.7 MSCAN

Table A-19. MSCAN Wake-up Pulse Characteristics

Conditions are shown in Table A-4 unless otherwise noted							
Num	C	Rating	Symbol	Min	Typ	Max	Unit
1	P	MSCAN Wake-up dominant pulse filtered	t_{WUP}			1	µs
2	P	MSCAN Wake-up dominant pulse pass	t_{WUP}	5			µs

A.8 SPI

This section provides electrical parametrics and ratings for the SPI.

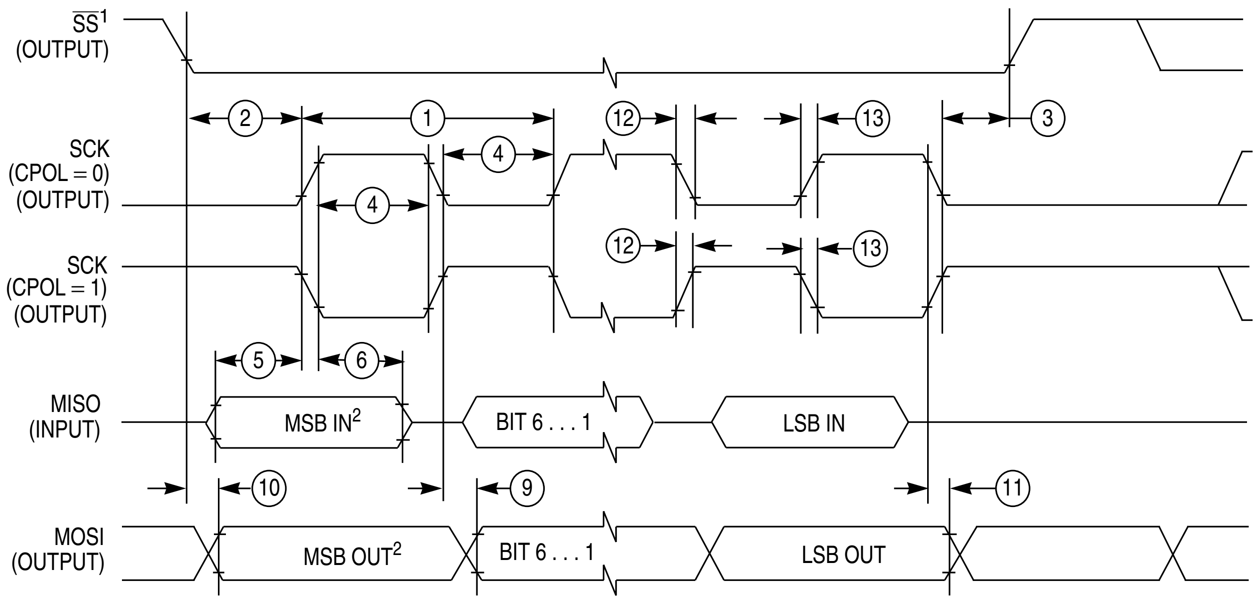
In Table A-20 the measurement conditions are listed.

Table A-20. Measurement Conditions

Description	Value	Unit
Drive mode	full drive mode	—
Load capacitance C_{LOAD}, on all outputs	50	pF
Thresholds for delay measurement points	(20% / 80%) V_{DDX}	V

A.8.1 Master Mode

In Figure A-6 the timing diagram for master mode with transmission format CPHA=0 is depicted.

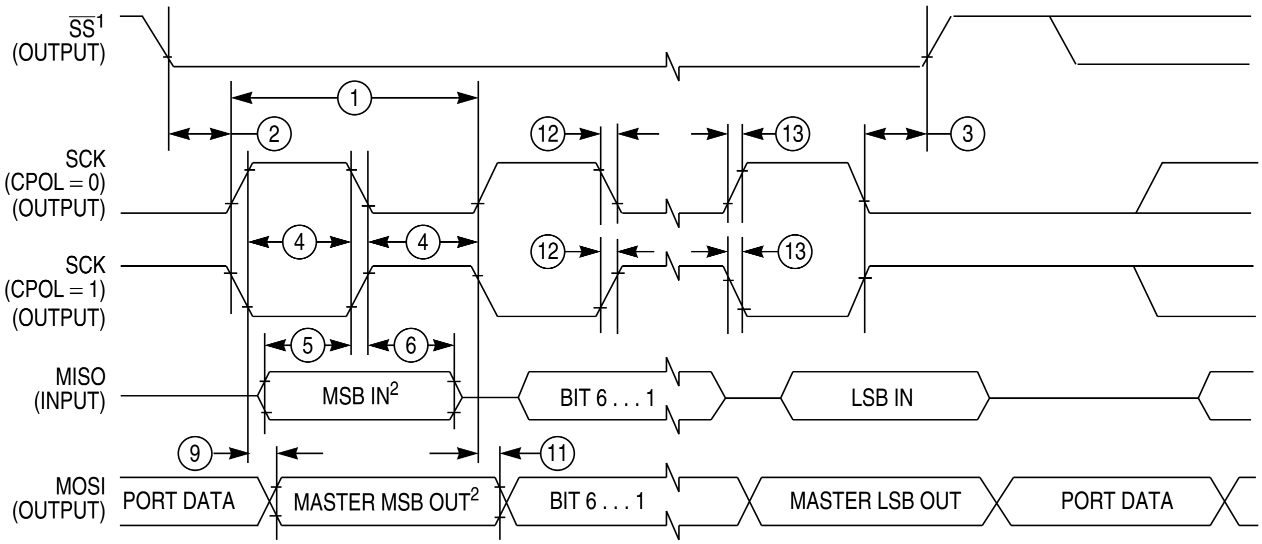


1.if configured as an output.

2. LSBF = 0. For LSBF = 1, bit order is LSB, bit 1, ..., bit 6, MSB.

Figure A-6. SPI Master Timing (CPHA=0)

In Figure A-7 the timing diagram for master mode with transmission format CPHA=1 is depicted.



1.If configured as output

2. LSBF = 0. For LSBF = 1, bit order is LSB, bit 1, ..., bit 6, MSB.

Figure A-7. SPI Master Timing (CPHA=1)

In Table A-21 the timing characteristics for master mode are listed.

Table A-21. SPI Master Mode Timing Characteristics

Num	Characteristic	Symbol	Min	Typ	Max	Unit
1	SCK Frequency	f_{sck}	1/2048	—	1/2	f_{bus}
1	SCK Period	t_{sck}	2	—	2048	t_{bus}
2	Enable Lead Time	t_{lead}	—	1/2	—	t_{sck}
3	Enable Lag Time	t_{lag}	—	1/2	—	t_{sck}
4	Clock (SCK) High or Low Time	t_{wsck}	—	1/2	—	t_{sck}
5	Data Setup Time (Inputs)	t_{su}	8	—	—	ns
6	Data Hold Time (Inputs)	t_{hi}	8	—	—	ns
9	Data Valid after SCK Edge	t_{vsck}	—	—	30	ns
10	Data Valid after $\overline{SS}$ fall (CPHA=0)	t_{vss}	—	—	15	ns

12	Rise and Fall Time Inputs	t_{rfi}	—	—	8	ns
13	Rise and Fall Time Outputs	t_{rfo}	—	—	8	ns

[1] t_{bus} added due to internal synchronization delay

A.9 External Bus Timing

A timing diagram of the external multiplexed-bus is illustrated in Figure A-10 with the actual timing values shown on Table A-23 in 5V range. All major bus signals are included in the diagram. While both a data write and data read cycle are shown, only one or the other would occur on a particular bus cycle.

A.9.1 General Muxed Bus Timing

The expanded bus timings are highly dependent on the load conditions. The timing parameters shown assume a balanced load across all outputs.

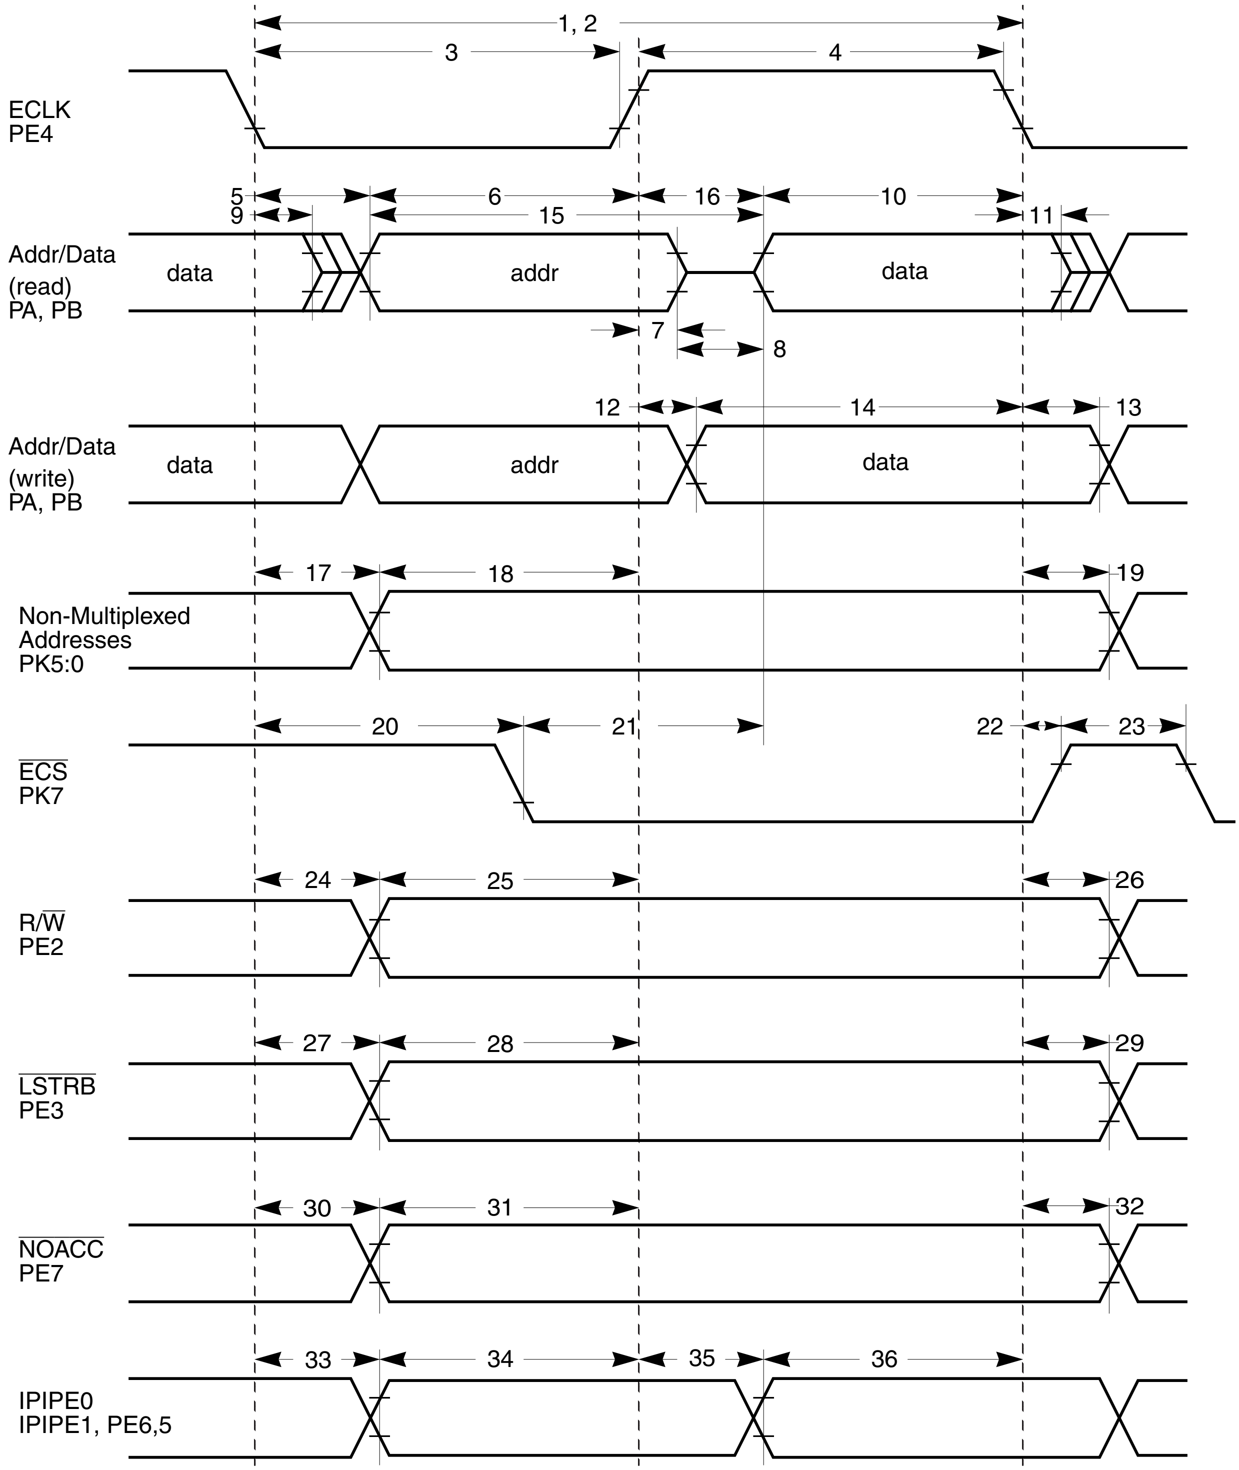

Figure A-10. General External Bus Timing

Table A-23. Expanded Bus Timing Characteristics In 5V Range

Conditions are shown in Table A-4 unless otherwise noted, C_{LOAD} = 50pF.
Supply Voltage 5V-10% <= V_{DDX} <=5V+10%

Num	C	Rating	Symbol	Min	Typ	Max	Unit
1	P	Frequency of operation (E-clock)	f_o	0		25.0	MHz

R2 / R_B		Pierce mode only	
R3 / R_S			
Q1	Quartz		

The PCB must be carefully laid out to ensure proper operation of the voltage regulator as well as of the MCU itself. The following rules must be observed:

- Every supply pair must be decoupled by a ceramic capacitor connected as near as possible to the corresponding pins (C1 – C6).
- Central point of the ground star should be the VSSR pin.
- Use low ohmic low inductance connections between VSS1, VSS2 and VSSR.
- VSSPLL must be directly connected to VSSR.
- Keep traces of VSSPLL, EXTAL and XTAL as short as possible and occupied board area for C7, C8, C11 and Q1 as small as possible.
- Do not place other signals or supplies underneath area occupied by C7, C8, C10 and Q1 and the connection area to the MCU.
- Central power input should be fed in at the VDDA/VSSA pins.
