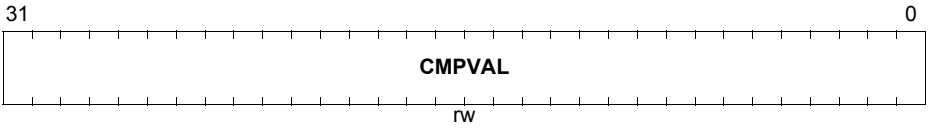
STM[55:32]	[23:0]	r	**Captured System Timer Bits [55:32]** The capture register STM_CAP always captures the STM bits [55:32] when one of the registers STM_TIM0 to STM_TIM5 is read. This capture operation is performed in order to enable software to operate with a coherent value of all the 56 STM bits at one time stamp.This bit field contains bits [55:32] of the 56-bit STM.
0	[31:24]	r	**Reserved** Read as 0.

Note: The bits in registers STM_CAP to STM_TIM0 are all read-only bits.

17.3.3 Compare Registers

The compare register CMPx holds up to 32-bits; its value is compared to the value of the STM.

STM_CMPx (x = 0-1)
STM Compare Register x **(30_H+x*4_H)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
CMPVAL	[31:0]	rw	**Compare Value of Compare Register x** This bit field holds up to 32 bits of the compare value (right-adjusted).

The STM Compare Match Control Register controls the parameters of the compare logic.

STM_CMCON
STM Compare Match Control Register

(38_H) **Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0			MSTART1					0			MSIZE1				
r			rw					r			rw				

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0			MSTART0					0			MSIZE0				
r			rw					r			rw				

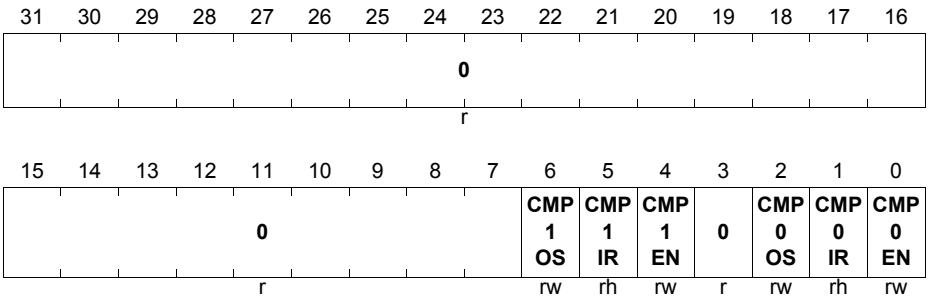
Field	Bits	Type	Description
MSIZE0	[4:0]	rw	**Compare Register Size for CMP0** This bit field determines the number of bits in register CMP0 (starting from bit 0) that are used for the compare operation with the System Timer. 00000_B CMP0[0] used for compare operation 00001_B CMP0[1:0] used for compare operation ... 11110_B CMP0[30:0] used for compare operation 11111_B CMP0[31:0] used for compare operation
MSTART0	[12:8]	rw	**Start Bit Location for CMP0** This bit field determines the lowest bit number of the 56-bit STM that is compared with the content of register CMP0 bit 0. The number of bits to be compared is defined by bit field MSIZE0. 00000_B STM[0] is the lowest bit number 00001_B STM[1] is the lowest bit number ... 10111_B STM[23] is the lowest bit number 11000_B STM[24] is the lowest bit number Bit combinations 11001_B to 11111_B are reserved and must not be used.

Field	Bits	Type	Description
MSIZE1	[20:16]	rw	**Compare Register Size for CMP1** This bit field determines the number of bits in register CMP1 (starting from bit 0) that are used for the compare operation with the System Timer. 00000_B CMP1[0] used for compare operation 00001_B CMP1[1:0] used for compare operation ... 11110_B CMP1[30:0] used for compare operation 11111_B CMP1[31:0] used for compare operation
MSTART1	[28:24]	rw	**Start Bit Location for CMP1** This bit field determines the lowest bit number of the 56-bit STM that is compared with the content of register CMP1 bit 0. The number of bits to be compared is defined by bit field MSIZE1. 00000_B STM[0] is the lowest bit number 00001_B STM[1] is the lowest bit number ... 10111_B STM[23] is the lowest bit number 11000_B STM[24] is the lowest bit number Bit combinations 11001_B to 11111_B are reserved and must not be used.
0	[7:5], [15:13], [23:21], [31:29]	r	**Reserved** Read as 0; should be written with 0.

17.3.4 Interrupt Registers

The two compare match interrupts of the STM are controlled by the STM Interrupt Control Register.

STM_ICR
STM Interrupt Control Register ($3C_H$) Reset Value: 0000 0000$_H$

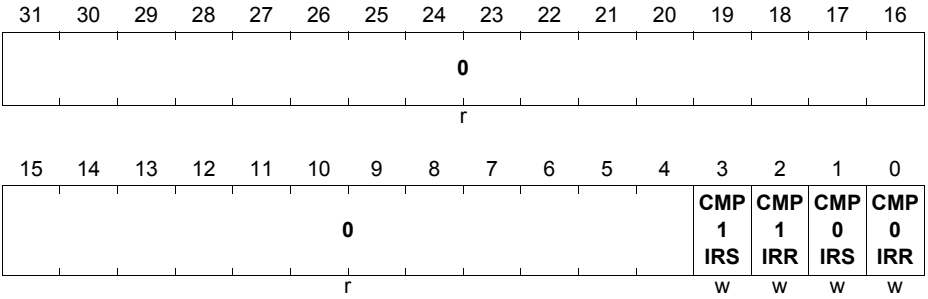


Field	Bits	Type	Description
CMP0EN	0	rw	**Compare Register CMP0 Interrupt Enable Control** This bit enables the compare match interrupt with compare register CMP0. 0_B Interrupt on compare match with CMP0 disabled 1_B Interrupt on compare match with CMP0 enabled
CMP0IR	1	rh	**Compare Register CMP0 Interrupt Request Flag** This bit indicates whether or not a compare match interrupt request of compare register CMP0 is pending. CMP0IR must be cleared by software. 0_B A compare match interrupt has not been detected since the bit has been cleared for the last time. 1_B A compare match interrupt has been detected. CMPIR0 must be cleared by software and can be set by software, too (see CMPISRR register). After a STM reset operation, CMP0IR is immediately set as a result of a compare match event with the reset values of the STM and the compare registers CMP0.

Field	Bits	Type	Description
CMP0OS	2	rw	**Compare Register CMP0 Interrupt Output Selection** This bit determines the interrupt output that is activated on a compare match event of compare register CMP0. 0_B Interrupt output STMIR0 selected 1_B Interrupt output STMIR1 selected
CMP1EN	4	rw	**Compare Register CMP1 Interrupt Enable Control** This bit enables the compare match interrupt with compare register CMP1. 0_B Interrupt on compare match with CMP1 disabled 1_B Interrupt on compare match with CMP1 enabled
CMP1IR	5	rh	**Compare Register CMP1 Interrupt Request Flag** This bit indicates whether or not a compare match interrupt request of compare register CMP1 is pending. CMP1IR must be cleared by software. 0_B A compare match interrupt has not been detected since the bit has been cleared for the last time. 1_B A compare match interrupt has been detected. CMPIR1 must be cleared by software and can be set by software, too (see CMPISRR register). After a STM reset, CMP1IR is immediately set as a result of a compare match event with the reset values of the STM and the compare register CMP1.
CMP1OS	6	rw	**Compare Register CMP1 Interrupt Output Selection** This bit determines the interrupt output that is activated on a compare match event of compare register CMP1. 0_B Interrupt output STMIR0 selected 1_B Interrupt output STMIR1 selected
0	3, [31:7]	r	**Reserved** Read as 0; should be written with 0.

The bits in the STM Interrupt Set/Reset Register make it possible to set or cleared the compare match interrupt request status flags of register ICR.

STM_ISRR
STM Interrupt Set/Reset Register (40_H) Reset Value: 0000 0000_H



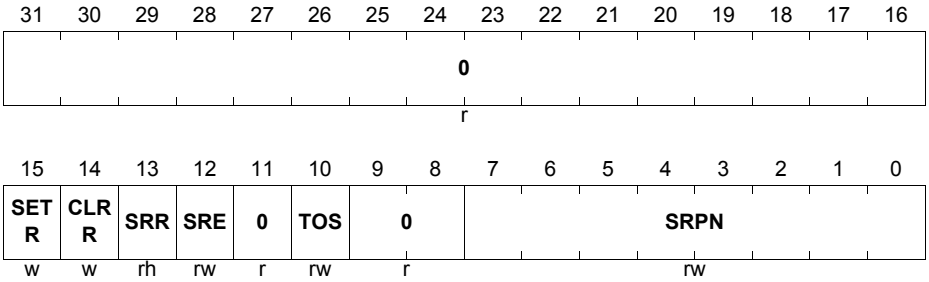
Field	Bits	Type	Description
CMP0IRR	0	w	**Reset Compare Register CMP0 Interrupt Flag** 0_B Bit ICR.CMP0IR is not changed. 1_B Bit ICR.CMP0IR is cleared.
CMP0IRS	1	w	**Set Compare Register CMP0 Interrupt Flag** 0_B Bit ICR.CMP0IR is not changed. 1_B Bit ICR.CMP0IR is set. The state of bit CMP0IRR is “don’t care” in this case.
CMP1IRR	2	w	**Reset Compare Register CMP1 Interrupt Flag** 0_B Bit ICR.CMP1IR is not changed. 1_B Bit ICR.CMP1IR is cleared.
CMP1IRS	3	w	**Set Compare Register CMP1 Interrupt Flag** 0_B Bit ICR.CMP1IR is not changed. 1_B Bit ICR.CMP1IR is set. The state of bit CMP1IRR is “don’t care” in this case.
0	[31:4]	r	**Reserved** Read as 0; should be written with 0.

Note: Reading register CMISRR always returns 0000 0000_H.

In the TC1798, the compare match interrupt output signals of the STM, STMIR0 and STMIR1 are controlled by the STM Service Request Control Registers STM_SRC0 and STM_SRC1.

STM_SRC0
STM Service Request Control Register 0
(FC_H) **Reset Value: 0000 0000$_H$**

STM_SRC1
STM Service Request Control Register 1
($F8_H$) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
SRPN	[7:0]	rw	**Service Request Priority Number**
TOS	10	rw	**Type of Service Control**
SRE	12	rw	**Service Request Enable**
SRR	13	rh	**Service Request Flag**
CLRR	14	w	**Request Clear Bit**
SETR	15	w	**Request Set Bit**
0	[9:8], 11, [31:16]	r	**Reserved** Read as 0; should be written with 0.

17.4 STM Module Implementation

This section defines implementation specific details of the STM in the TC1798.

17.4.1 On-chip Service Request Connections

The two compare match service request outputs STMIR0 and STMIR1 are connected in the TC1798 to on-chip devices as described in **Table 17-4**.

Table 17-4 System Timer On-Chip Interconnections

Service Request Signal	Connected to
STMIR0	DMA Channel 00 Request Input 8 DMA Channel 01 Request Input 8 DMA Channel 02 Request Input 8 DMA Channel 03 Request Input 8 DMA Channel 04 Request Input 8 DMA Channel 05 Request Input 8 DMA Channel 06 Request Input 8 DMA Channel 07 Request Input 8 DMA Channel 10 Request Input 8 DMA Channel 11 Request Input 8 DMA Channel 12 Request Input 8 DMA Channel 13 Request Input 8 DMA Channel 14 Request Input 8 DMA Channel 15 Request Input 8 DMA Channel 16 Request Input 8 DMA Channel 17 Request Input 8
STMIR1	ADC0_REQGT[4:0]_5 ADC1_REQGT[4:0]_5 ADC2_REQGT[4:0]_5

17.4.2 STM Address Map

Table 17-5 defines the complete address range of the STM with absolute addresses and the read/write access rights.

Table 17-5 Address Map of STM

18 Bus Monitor Unit (BMU)

This document describes the functionality of the Bus Monitor Unit (BMU). The BMU is primarily intended to be used in High Integrity Safety Applications. It provides the base hardware mechanisms to simplify the monitoring functions that safety applications need to implement. The core functionality of the BMU consists of logging the peripheral bus write activity. The logged information is stored in a local buffer managed as a cyclic buffer. In non-safety applications the BMU can be used as a PCP data memory extension. The BMU operates as a standard FPI bus slave peripheral and is fully controlled through a set of configuration and control registers. Additionally a dedicated slave interface enables burst accesses to the logged information.

This chapter is structured as follows:

- BMU Features (see **Section 18.2**)
- An operational overview of the BMU Module (see **Section 18.3**)
- Functional description of the BMU Module (see **Section 18.4**)
- Interfaces of the BMU Module (see **Section 18.5**)
- Description of the BMU Module registers (see **Section 18.6**)

18.2 BMU Features

The BMU implements the following features:

- Fully synchronous module running at the Peripheral Bus clock frequency
- Implements a standard interrupt service node connecting to the TriCore and PCP interrupt busses.
  - Every internal interrupt source can be identified by a dedicated status flag, cleared by software only. New interrupt events with an active status flag do not lead to a new interrupt.
- Logs write transactions to software selectable peripheral address space
  - Uses the System-on-chip Address decoders select lines to qualify target peripherals (no internal address space decoding)
  - The address phase from master accesses initiated by the Secure Hardware Extension module can optionally be logged. Data phase information is excluded because of secure keys exchange (the address map of the SHE is not visible to the BMU).
- Implements a Bus Transaction Fifo (BTF) that can be accessed via the FPI slave interface using BTR2, BTR4 or BTR8 FPI read bursts. The size of the BTF can be configured on a product basis. It must be a power of two in size.
  - The BTF entries are protected by Error Correction Codes (ECC) with single-bit error correction and double-bit error detection capability (SECDED) covering the data field.
  - The BTF is accessed as a cyclic buffer with automatic wrap around support. The BTF write and read pointers are controlled by Hardware.
- The BTF entries are made of the following FPI information:
  - FPI_A[27:2] address bits of the FPI transaction.
  - FPI_SVM FPI supervisor mode indication
  - FPI_TAG[3:0] FPI TAG, identifies the FPI bus master
  - FPI_STATUS Transaction completion status. This is not an FPI signal
  - FPI_D[31:0] FPI write data
- Fifo Handler that monitors the fullness of the BTF:
  - implements a configurable threshold register to early detect fullness threshold.
  - detects and prevents overruns and underruns (configurable).
- The BTF can be used as a standard memory mapped SRAM in non-safety applications. The SRAM can only be accessed using BTR2, BTR4 or BTR8 FPI bursts.

18.3 Operational overview

18.3.1 Microcontroller Monitoring Framework

The BMU is a component of the PRO-SIL™ Monitoring Framework that enables to simplify the overall software monitoring requirements a safety application must fulfil. Two practical use cases are presented that directly take benefit of the BMU:

- Break-After-Make flow
- Detection of illegal access to safety-related Configuration and Status Registers (CSFR)

Break-After-Make use case

In a single processing channel (a microcontroller without hardware redundancy at the application level) there are two common architectures dealing with the detection of failures at the execution level:

- two processors running in static lockstep or loosely coupled lockstep mode, executing the same safety code and comparing the results in a near cycle accurate fashion. Any discrepancy between the master CPU and the checker CPU caused by any soft or hardware fault is captured by an independent compare unit. The checker CPU does not produce any data to the peripherals nor to the storage elements (SRAMs). The lockstep flow is presented in **Figure 18-1 “Break-After-Make concept” on Page 18-5** (left side).
- a single processor runs sequentially two redundant tasks. The redundant tasks can be implemented with diversity. There is a control task (or control execution thread) that executes and commits its results to the peripherals. The results from the control task need to be saved in order to be checked at a later time. The monitor task (or monitor execution thread) is then scheduled and produces an alternate set of data. The results of both tasks/threads are gathered and compared by an hardware unit independent to the processor. The control flow is presented in **Figure 18-1 “Break-After-Make concept” on Page 18-5** (right side). This is the basic scheme used in the PRO-SIL™ safety concept. The combination of the BMU hardware and the BMU driver running on the PCP provide a generic mechanism that can be used by safety applications to monitor specific data flows to safety-relevant peripherals. The BMU software driver specification is not in the scope of this document.

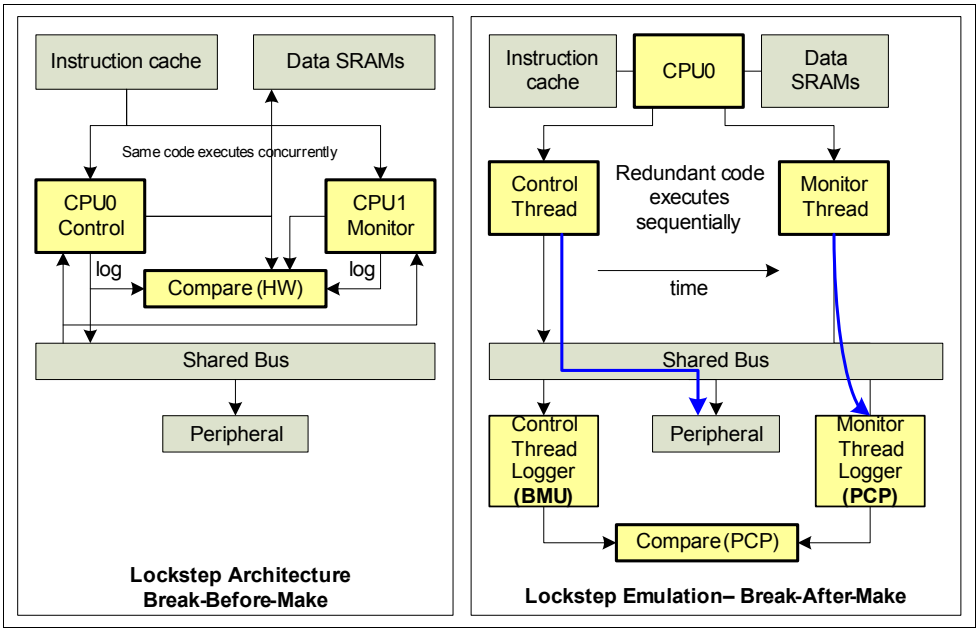

Figure 18-1 Break-After-Make concept

18.3.2 Bus Monitor Unit Overview

The BMU is a standard FPI slave module that implements a FPI slave interface and a Bus Peripheral Interface (BPI) compliant with the FPI bus architecture. The BMU is not FPI master capable. The BMU is fully synchronous with the FPI bus clock and runs with a 1:1 clock ratio. It does not implement a fractional divider

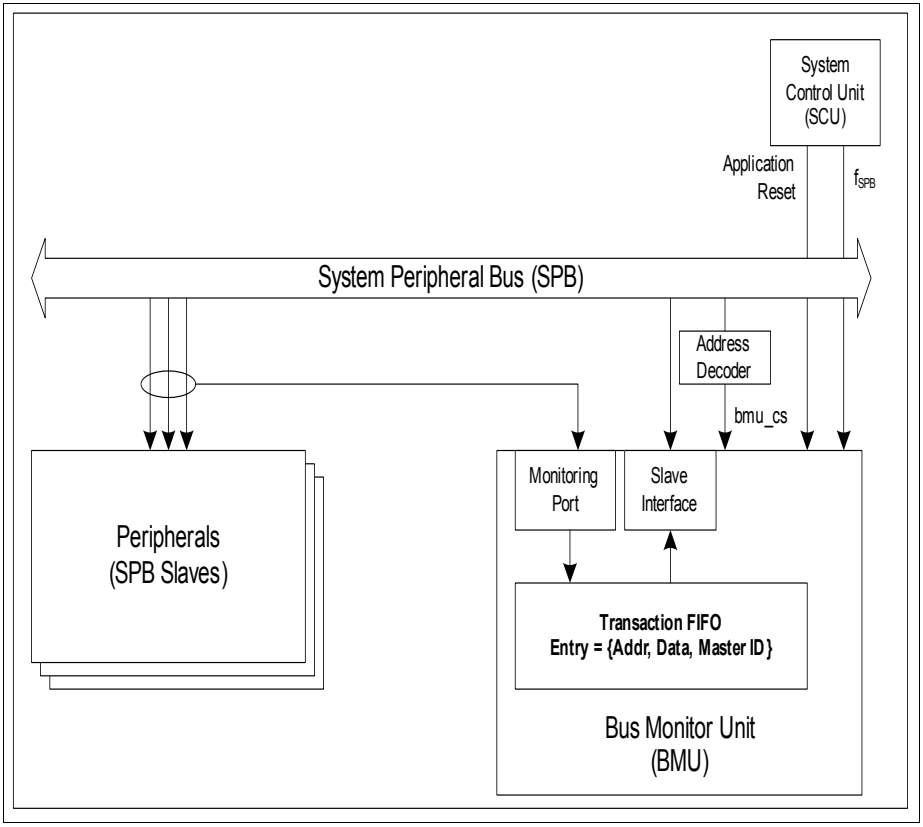

Figure 18-2 BMU overview

In addition to the standard FPI connectivity, the BMU also receives the individual peripheral select signals decoded by the address decoders. **The granularity of each select line is not a peripheral but a FPI region that may include several peripherals**. Each decoded region provides a FPI_ACK[1:0] signal that indicates the completion status of each individual data phase. The FPI_ACK[1:0] of the FPI regions listed in **Table 18-4 “Identification of FPI Regions” on Page 18-22** are required by the BMU to determine if write transactions have been normally terminated or not.

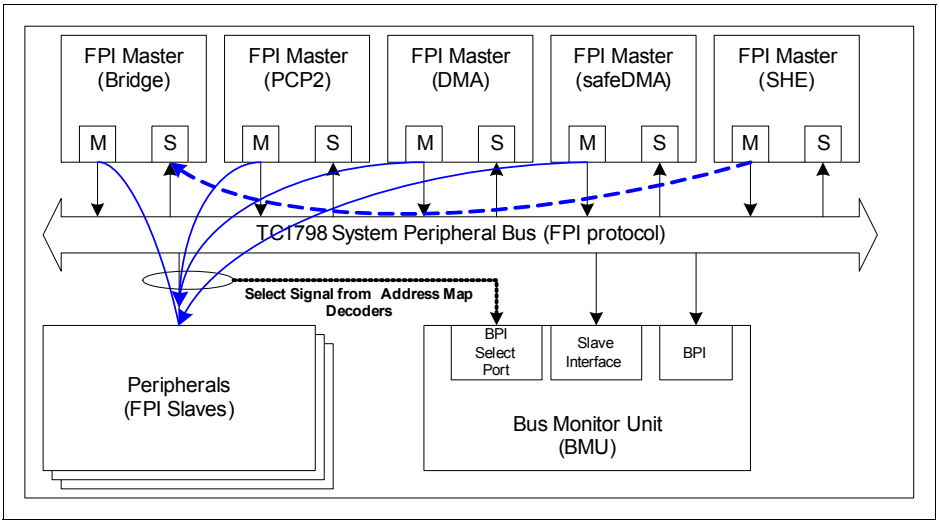

Figure 18-3 BMU operation in TC1798

In a typical microcontroller architecture, the write accesses to the peripherals can be directly controlled by the TriCore CPU or via DMA engines and possibly by the Peripheral Control Processor (PCP). In the TC1798 microcontroller four possible masters (see **Figure 18-3 "BMU operation in TC1798" on Page 18-7**) can control the write data accesses to the peripherals.

Logging SHE write transaction in the TC1798 microcontroller

The Secure Hardware Extension (SHE) module also implements a DMA capability but is not supposed to perform write accesses to peripherals in a Safety Application. Because the SHE module is used in security applications, logging of data written into the SHE is forbidden. For debug purposes it is possible to log the address of write accesses performed by the SHE module, the write data from the FPI bus is ignored and replaced by all zeros. The four upper bits of the address and the two lower bits of the address generated by the SHE module are not logged. The only way to identify that the logging information is related to a SHE write transaction is by using the master identifier information that is logged into the BMU (see **Figure 18-5 "Bus Transaction Information" on Page 18-12**).

18.4 BMU Functional Description

18.4.1 BMU Microarchitecture

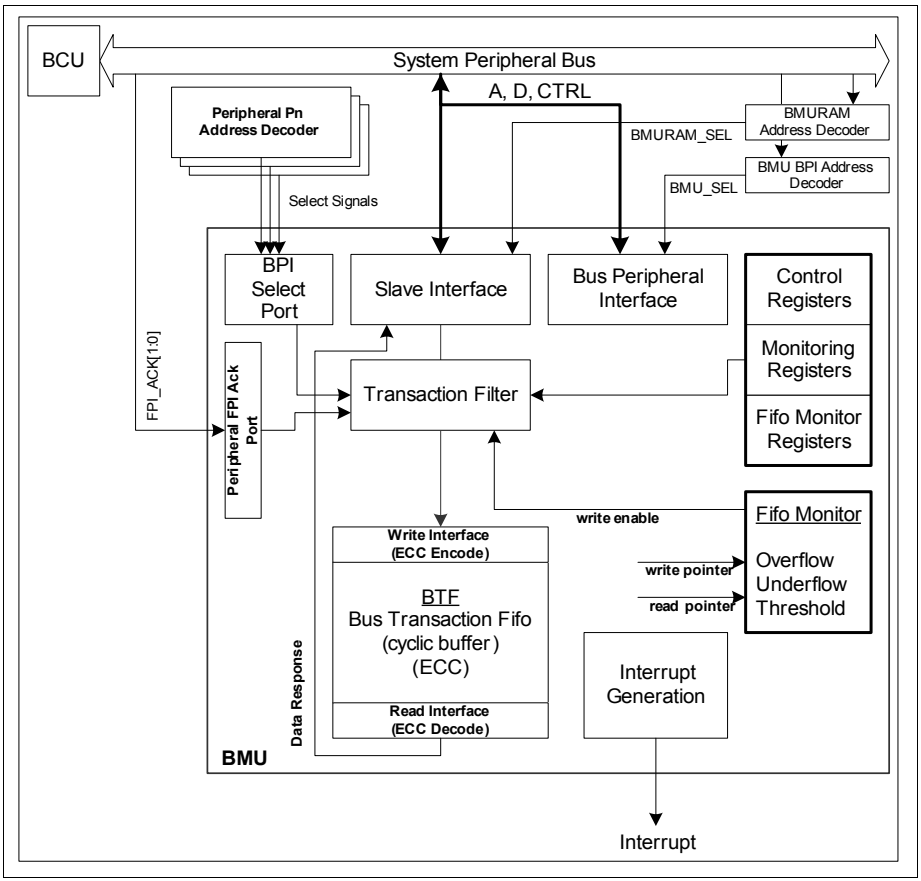

Figure 18-4 BMU Microarchitecture

The BMU is made of the following functions as represented in **Figure 18-4 "BMU Microarchitecture" on Page 18-8**:

- a FPI Bus Peripheral Interface (BPI) that allows software to control the features of the BMU and read status information.
- a cyclic buffer called the Bus Transaction Fifo (BTF) where the selected write transaction are stored.
- a Fifo Monitor that monitors the distance between the BTF write and read pointers. The Fifo Monitor is configured with a threshold register **FMTH** that enables the BMU to raise an interrupt if the threshold is reached.
- a FPI Slave Interface that provides the following functions:
  - filter write transactions taking place in the bus, and if all conditions are fulfilled write the information inside the BTF. The hardware is responsible for the write pointer wrap around conditions.
  - perform memory mapped read and write accesses to the BMU RAM. **This mode is the default one after power-on reset.** Refer to section **"Usage in non safety applications" on Page 18-20** for a description of this mode. The BMU RAM is intended to be use by the PCP processor.
  - perform FIFO-based accesses to the BTF to read the logged information. This mode should be enabled in the **CTL** register. In FIFO mode, the FPI_A[31:0] address information is not used to directly access an entry in the BTF. The internal read and write pointers are updated according to the size of the FPI bus burst transaction.
  - **Table 18-1 "FPI Access Modes to BMU FPI Slave Interface" on Page 18-10** provides the list of FPI transactions supported by the slave interface in the different modes.
- a Service Request Node that centralizes all internal interrupt sources and enables the BMU to directly send interrupt requests to the PCP or the TriCore CPUs.

Table 18-1 FPI Access Modes to BMU FPI Slave Interface

FPI Transaction FPI_OPC[3:0]		Transaction Logging in FIFO Mode	Transaction Support in FIFO Mode	Transaction Support in SRAM Mode
SDTB (8-bit single transfer)	Read	Not Applicable	No (Bus Error)	No (Bus Error)
	Write	**Yes**	No (Bus Error)	No (Bus Error)
SDTH (16-bit single transfer)	Read	Not Applicable	No (Bus Error)	No (Bus Error)
	Write	**Yes**	No (Bus Error)	No (Bus Error)
SDTW (32-bit single transfer)	Read	Not Applicable	No (Bus Error)	No (Bus Error)
	Write	**Yes**	No (Bus Error)	No (Bus Error)
BTR2 (2 transfers of 32-bit)	Read	Not Applicable	**Yes**	**Yes**
	Write	**Yes**	No (Bus Error)	**Yes**
BTR4 (4 transfers of 32-bit)	Read	Not Applicable	**Yes**	**Yes**
	Write	**Yes**	No (Bus Error)	**Yes**
BTR8 (8 transfers of 32-bit)	Read	Not Applicable	**Yes**	**Yes**
	Write	**Yes**	No (Bus Error)	**Yes**

*Note: Single transfer transactions (SDTB, SDTH,SDTW) part of a **Read-Modify-Write** are logged as well.*

Note: During any SDTB, SDTH single transfer transactions the whole 32-bit data bus is written. As the FPI opcode and the lower two bits of the FPI address are not logged, it is not possible to know which bytes were valid during the write. This is a limitation that should be considered by the data monitoring applications using the BMU.

18.4.2 Handling of FPI corner cases

There are specific situations that lead to exceptions with respect to the correct termination of a FPI write transaction, like: master aborts, slave retries, time-out,... The flag FPI_STATUS indicates if the write data phase has been normally completed (FPI_STATUS = 1) or not (FPI_STATUS = 0). In the case of an error there is no additional information that defines the nature of the error.

A Data Phase is completed when the target BPI interface issues a FPI_RDY=1; the signal FPI_ACK[1:0] provides additional information about the status of the completion. The BPI can insert wait states in the FPI bus by delaying the assertion of FPI_RDY. The following situations lead to the detection of an error condition indicating that a write data phase has been either aborted by the master or not accepted by the slave:

- The FPI Master FPI_ABORT_N is asserted during the data phase wait states or coincides with the FPI_RDY assertion by the BPI. If this happens during a burst all subsequent data phases are aborted.
- The BPI issues FPI_RDY=1 together with FPI_ACK=2'b11 (ERR).
- The BPI issues FPI_RDY=1 together with FPI_ACK=2'b10 (RTY).
- In the occurrence of a timeout, FPI_TOUT is issued by the Bus Control Unit during one clock cycle and the selected slave must terminate the data transfer with an error condition (FPI_RDY=1 with FPI_ACK=2'b11) in the following cycle. Therefore the FPI_TOUT does not need to be handled by BMU.

Please refer to the FPI specification version V4.2, 2003-11 chapter 6: FPI Bus Termination conditions for a detailed overview.

18.4.3 Bus Transaction Table

The **Figure 18-5 “Bus Transaction Information” on Page 18-12** defines how each phase of a FPI transaction is written into the BTF. The set of information bits related to a write data is written as a 64-bit value into the BTF. A BTF word or entry is made of:

- the write data itself, referred as the BTF[DataPhase] field and
- the BTF[Control] field

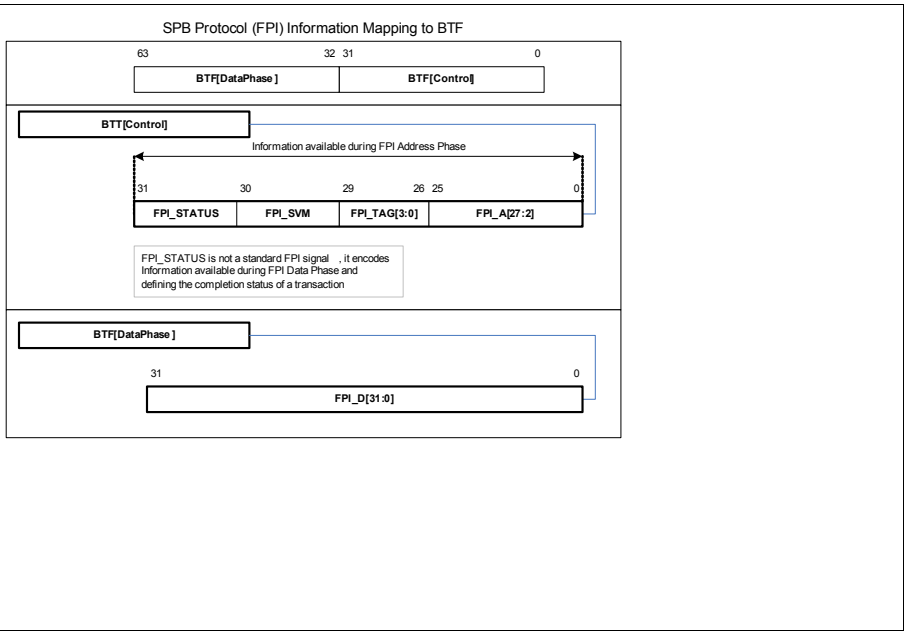

Figure 18-5 Bus Transaction Information

The logging of burst transactions follows the same rules as for single write transactions: the FPI master provides for each data phase the corresponding address information. Examples with single write and burst are given in **Figure 18-6 “Logging information for FPI burst transactions” on Page 18-13**. The address information shown is directly the information present in the FPI bus.

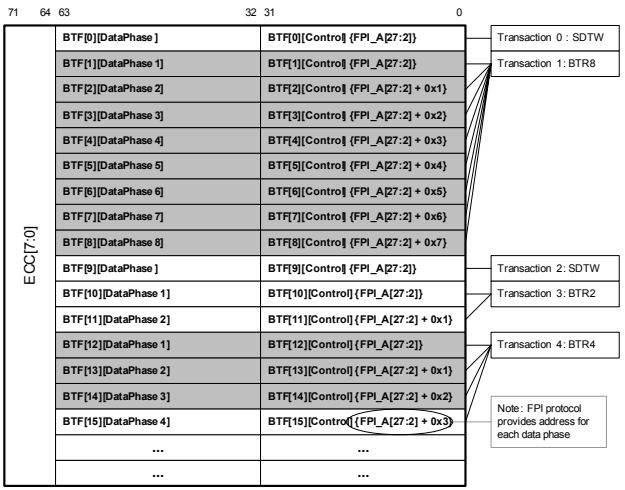

Figure 18-6 Logging information for FPI burst transactions

18.4.4 Write Operation and Fifo Structure

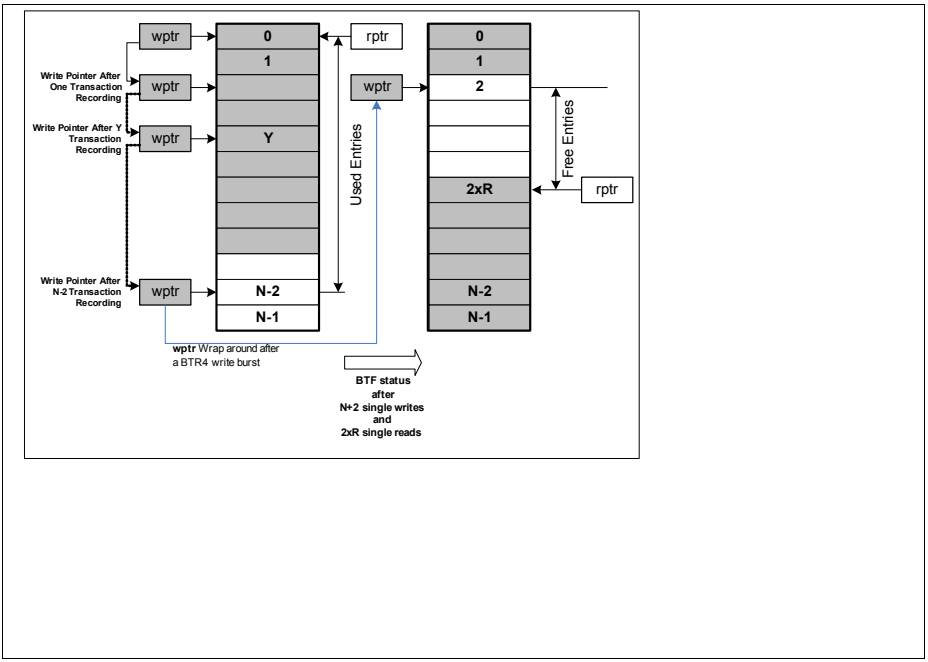

Figure 18-7 BTF Cyclic Buffer Write Pointer Management

The write pointer is controlled by the BMU internal logic. If N is the number of words in the BTF (corresponding a maximum of N single write FPI transactions), when the write pointer reaches the word at position N-1 and a new single write FPI transaction is logged, the new position of the write pointer is 0. If in the meantime no read pointer update took place, the BTF is declared full.

18.4.5 Read Operation and Fifo Structure

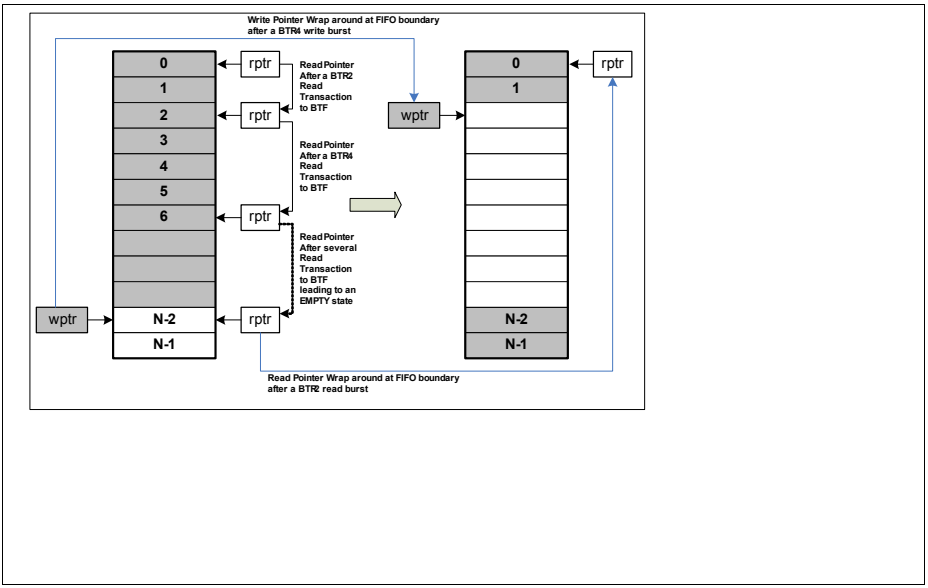

Figure 18-8 BTF Cyclic Buffer Read Pointer Management

The read pointer (**rptr** in Figure 18-7) is also only controlled by hardware. **Depending on the FPI transaction size given by the FPI_OPC[3:0] opcode the read pointer is incremented accordingly**. A BTR2 read burst will increment the read pointer by 2 and so on. The FPI_A[31:0] address information is not used to directly access an entry in the BTF. The FPI_A[31:0] shall point to the base address of the BTF SRAM, otherwise a Bus Error will be returned with the first read data terminating the FPI burst.

Having the read pointer controlled by hardware enables to free the fifo space in a faster way, increasing the logging performance.

18.4.6 Fullness Monitoring

The **Figure 18-9 "BTF Fullness Monitoring" on Page 18-16** shows how the fullness is calculated in order to check if the fullness threshold defined by the register **FMTH** is reached or not. The BufferSize is a constant value defining the number of 64-bit words of the internal SRAM building the Bus Transaction Fifo.

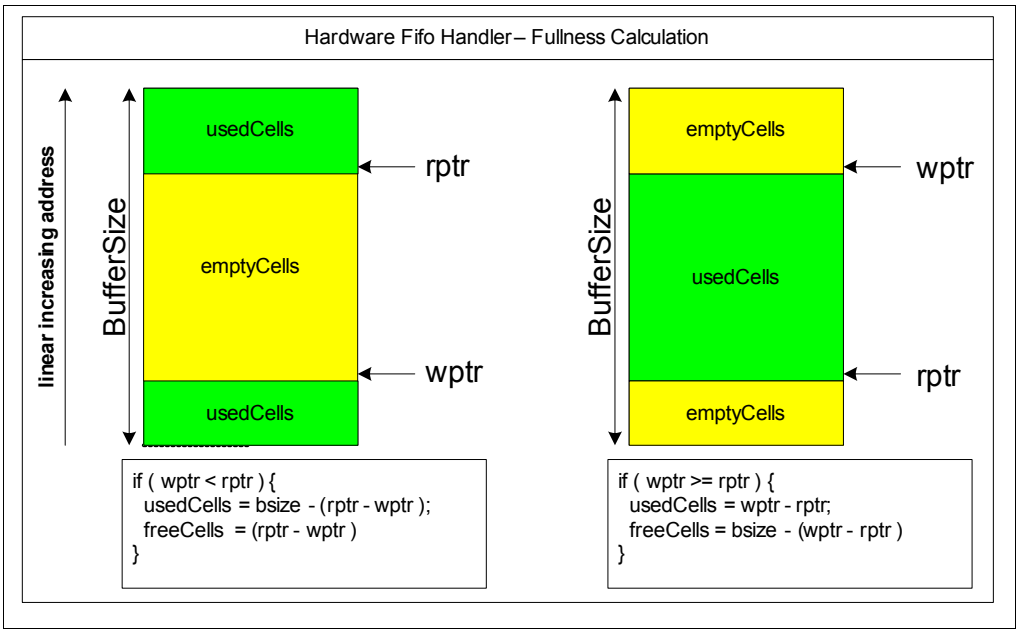

Figure 18-9 BTF Fullness Monitoring

The fullness information is computed dynamically based on the contents of the read and write pointers and the corresponding events (write pulse/read pulse indicators). For convenience the fullness information (see **Figure 18-9 "BTF Fullness Monitoring" on Page 18-16**) is made visible to software via the **FULLNESS** registers. If a write event takes place and the next position of the write pointer is identical to the read pointer and if no read event takes place the BTF is declared **FULL**. If a read event only takes place and the value of the read pointer equals the value of the write pointer the BTF is declared **EMPTY**.

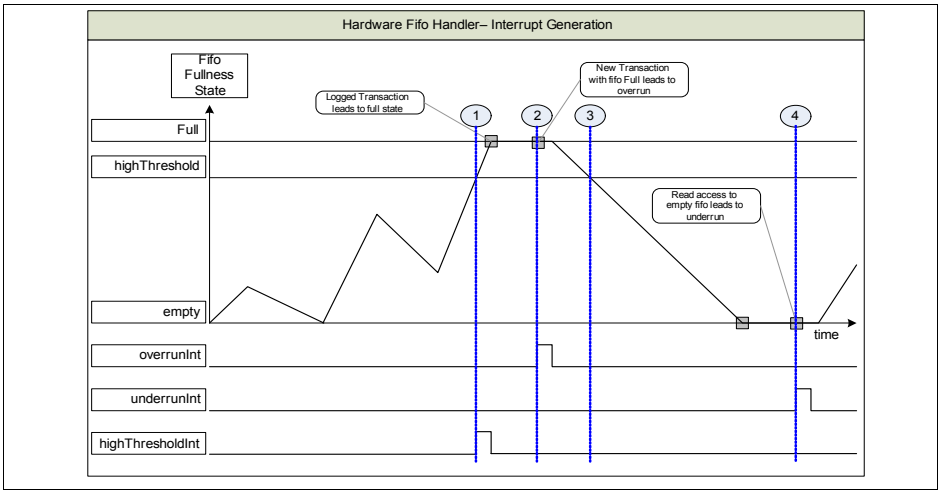

Figure 18-10 BTF Fullness Monitoring - Threshold Interrupts

Figure 18-10 "BTF Fullness Monitoring - Threshold Interrupts" on Page 18-17 shows the fullness conditions that can be reported by the Fifo Monitor:

- [1] The fullness reaches or crosses the High Threshold level as configured in the register **FMTH**. If the corresponding bit is set in the **FMCTL** register an interrupt is triggered to the Interrupt Service Request Node and the corresponding flag is set in the **FMSTS** register. The flag is set regardless of the interrupt generation mode.
- [2] The BTF is full. A new write access is detected leading to an overrun condition. The interrupt reporting is similar to the one described for the case [1]. The write pointer is not incremented and the FPI transaction information is not logged. If the overrun situation occurs during a burst transaction, only the data phases that can do not lead to the overrun condition are logged.
- [3] Reaching again the High Threshold value while the fullness is decreasing does not trigger an interrupt.
- [4] The fifo (BTF) is empty, a read takes place leading to an underrun condition. The interrupt reporting is similar to the one described for the case [1]. The read pointer is not incremented. If the underrun condition occurs during a read burst, a data phase error acknowledge will be issued by the BMU. The software handling the BMU should take care to avoid such conditions. However errors taking place in the system caused by soft errors (single event upsets for instance), may lead to such condition.

18.4.7 Error Correction Code (ECC)

The BMU SRAM is protected by information redundancy based on Error Correction Codes with a Hamming Distance of 4. The ECC information redundancy applies to the data bits of each BMU SRAM word. **CTL**

Limitations with ECC accesses

When the ECC mapping is enabled the memory access limitations described in **"Usage in non safety applications" on Page 18-20** apply as well. Therefore the ECC information can only be accessed using FPI BTR2 bursts as described in **Figure 18-11 "ECC information mapping into FPI BTR2 transactions" on Page 18-18**. The burst base address is 8-byte aligned (FPI_A[2:0] = 3'b000).

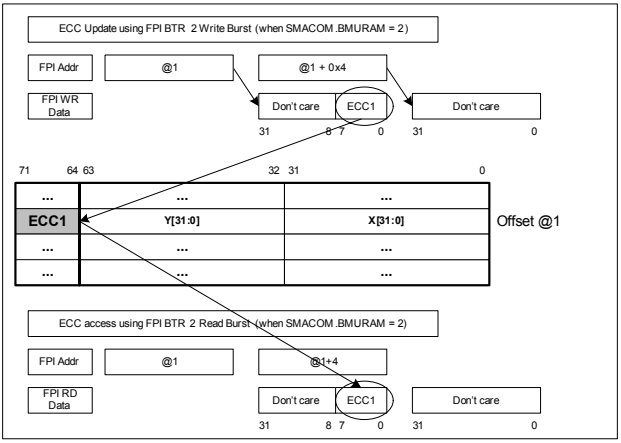

Figure 18-11 ECC information mapping into FPI BTR2 transactions

Memory Integrity Error Control

A pair of architecturally visible registers (MIECON, MIECON2) are included to allow software to control the memory integrity error detection / correction mechanisms. The existence of the MIECON and MIECON2 registers is architecturally defined. However, the fields within these registers are implementation specific. The behavior of MIECON2

is configured according to the “secwen_i” input to the BMU. “secwen_i” is connected to a Product Configuration bit from the SCU, and is locked after execution of Startup Software (SSW). With “secwen_i” not asserted, and the MIECON2 bits previously set by SSW, single-bit correction of memory integrity errors is transparent to software and may not be disabled or detected.

When “secwen_i” is asserted, MIECON2 may only be written in supervisor mode and is ENDINIT protected. MIECON2 reads return the register contents. When “secwen_i” is not asserted accesses to MIECON2 will generate an FPI error acknowledge.

The DED_EN and SEC_EN bits (located **MIECON** and **MIECON2** respectively) and the appropriate SMACON field settings interact to perform the following general function:

Table 18-2 Memory integrity error modes

SEC_EN	DED_EN	SMACON	Description
X	X	01_B or 10_B	**Array Mapping** All single and double-bit memory integrity errors ignored.
0	0	00_B or 11_B	**No Memory Integrity Handling** All single and double-bit memory integrity errors ignored.
0	1	00_B or 11_B	**Error Detection Mode** Single and double-bit errors treated as un-correctable errors. In this mode the BMU_ECC_ERROR_O is asserted every time a single or double bit error is detected.
1	0	00_B or 11_B	**SEC Only Mode** Single-bit errors corrected by ECC, double-bit errors ignored. BMU_ECC_ERROR_O is never asserted in this mode
1	1	00_B or 11_B	**SECDED Mode** Single-bit errors corrected by ECC, double-bit errors treated as un-correctable errors. BMU_ECC_ERROR_O is asserted every time a double bit error is detected.

18.4.8 Usage in non safety applications

When the BMU is not used in a safety application the BTF fifo can be accessed as a standard linear memory through the BMU slave interface using BTR2, BTR4 or BTR8 FPI transactions. This mode of operation is controlled by the **CTL**.MODE field. Single word or sub word (8/16-bit) accesses are not allowed; such requests will result in a Bus Error. **The start address of the FPI burst transactions is aligned with the size of the burst.**

Table 18-3 SRAM address map

Module	Base address	End address	Note
Bus Monitoring Unit	$F032\ 4000_H$	$F032\ 5FFF_H$	BMURAM

Figure 18-12 "Mapping between FPI Burst transaction and SRAM contents" on Page 18-20 shows how the FPI bus 32-bit data phases are mapped into the 64-bit word of the BMU SRAM. An example with read and write bursts is given.

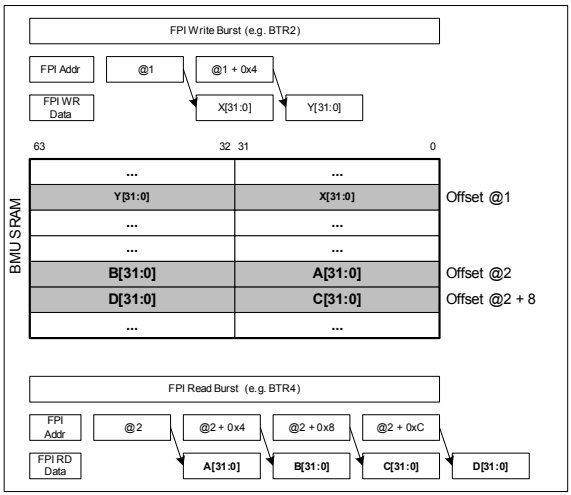

Figure 18-12 Mapping between FPI Burst transaction and SRAM contents

18.4.9 BMU interrupts

Interrupt generation rules

- Each interrupt source has a dedicated status bit that indicates if an interrupt has been issued or not.
- A status flag shall be cleared by software by writing a 1 to the corresponding bit position.
- If a status flag is set and a new hardware condition leading to an interrupt occurs, no new interrupt is generated. **If a software access to clear the interrupt status bit takes place and in the same cycle the hardware wants to set the bit, the hardware condition wins the arbitration**.

18.4.10 Peripheral Monitoring Selection

The **Table 18-4** shows the list of peripherals present in the TC1798 device together with an identifier. The FPI bus infrastructure provides address decoders that are configured to generate chip select signals. The chip select signals are connected to the standard BPI modules or to the FPI Slave Interfaces or directly to custom FPI interfaces (some FPI peripherals have neither a BPI nor a FPI slave interface). Each select line identifies a FPI region that corresponds to the FPI regions defined in the **PSET0** and **PSET1** registers. Behind a decoded FPI region there may be multiple peripherals. This situation is reflected in **Table 18-4**. Peripherals that belong to the DMA subsystem (FPI extension) will all use the DMA identifier. Only the FPI write transactions enabled by **PSET0** and **PSET1** will be stored in the BMU.

18.5 Interfaces of the BMU Module

This section only describes the signals that do not belong to the system-on-chip standard interfaces (Interrupt Bus, FPI Bus).

Table 18-5 Generic BMU Digital Connections[1)]

Signal	from/to Module	I/O to BMU	Reset Value
EINIT	SCU (System Control Unit)	I	
FPI_CLK_EN	SCU (System Control Unit)	I	
OCDS_P_SUSPEND	On Chip Debug	I	
SLEEP_N	SCU (System Control Unit)	I	
SECWEN	SCU (System Control Unit) Connects to SCU PRDCFG2.SENAV Single Error Correction Availability Control	I	
BMU_ECC_ERROR	SCU (System Control Unit) un-correctable ECC error detected output	O	0
BMU_SPB_SEL[63:0]	System Peripheral Bus (SPB) Address Decoders	I	
BMU_SPB_ACK[1:0]	Global FPI_ACK[1:0] generated by the FPI bus	I	

1) The postfix indicating the direction of the signal is not part of the signal name specification as it depends on the naming conventions used by the development flow. The I/O column indicated the direction of the signal. When the signal is specific to the BMU module it gets “BMU_” as prefix.

Notes

- FPI_CLK_EN is the FPI clock signal.
- OCDS_P_SUSPEND: the suspend feature is not supported by BMU. The OCDS_P_SUSPEND signal is not used.
- SLEEP_N is used to control the sleep mode. The sleep mode function is not supported by BMU, the SLEEP_N signal is not used.
- The FPI_ACK[1:0] signals from the FPI bus are ored together and sent to all masters (only the granted master interprets the FPI_ACK[1:0] contents). The BMU will see the global FPI_ACK[1:0] signal and not directly the individual FPI_ACK corresponding to a FPI region.
- The width of the BMU_SPB_SEL signal is set to 64 bits to make it independent from the peripheral configuration. The non-used upper bits of BMU_SPB_SEL must be set to the logic value LOW. The order of the select lines is given by **Table 18-4 “Identification of FPI Regions” on Page 18-22**.

- The BMU_ECC_ERROR is an active HIGH signal that delivers a pulse of one FPI clock cycle duration. See **Table 18-2 “Memory integrity error modes” on Page 18-19** for the un-correctable modes.
- In TC1798 microcontroller there are 47 BMU_SPB_SEL signals connected to the BMU.

18.6 BMU Module Registers

Figure 18-13 shows the BMU module register map.

Table 18-6 shows the BMU Address Space

Table 18-7 lists all registers implemented in the BMU.

BMU Address Map Overview

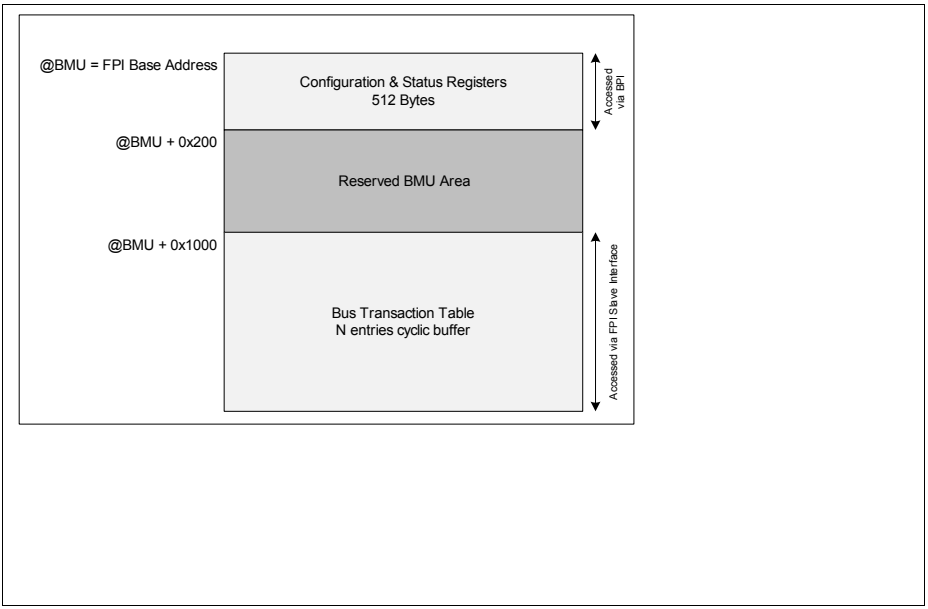

Figure 18-13 BMU Register Map

In TC1798 device the Bus Transaction Table is made of 1024 entries, where each entry is made of 64-bits. **Table 18-6** shows the base address of the addressable SRAM space when the access mode defined by the **CTL**.MODE configuration register is set to 0.

Access Mode Rules

The **Table 18-7 “Registers Overview” on Page 18-28** uses the standard access mode conventions.

- **E** indicates that an access is only possible if the **end of initialization** signal from the System Control Unit is active. In this case Supervisor Mode (SV) is also mandatory.
- When U, SV are both listed it means that a read or write access can be done either in user mode (U) or supervisor mode (V).

- BE stands for Bus Error, NSC stands for No Special Condition

*Note: Configuration registers that determine the behavior of the BMU are protected by the end of init protection mechanism. They are intended to be only configured once during the initial system startup phase. In safety-related applications the configuration is controlled by the Safety Driver. Registers that need to be updated by the application (run-time interaction) are only protected by supervisor mode: applies to **FMSTS**.*

Register access constraints

The registers that control the operation of the BMU are assumed to be static, they are configured by the safety driver according to the requirements of the safety application(s) during the initial microcontroller configuration. Exceptions will be documented in each register sub-chapter. As indication the list of registers that are assumed to be static are:

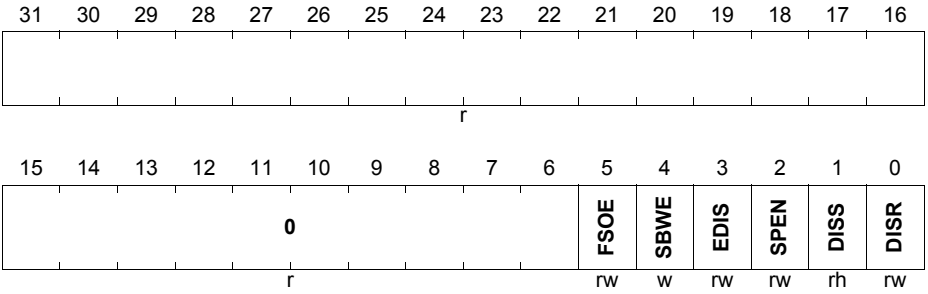
- **PSET0**, **PSET1**, **TID**[1)], **FMCTL**, **FMTH**
- **CTL** is only allowed to be change if SIST mode is used during run-time for ECC checks. The necessity to do ECC checks during run-time will depend on the safety monitoring concept.

1) Currently **TID** is a read-only register, this may change in future enhancements of the BMU.

18.6.1 System Registers description

BMU Module Clock Control Register.

CLC
Control Clock Register **(00_H)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
DISR	0	rw	**Module Disable Bit Request** Used for enable/disable control of the module 0_B Module disable is not requested 1_B Module disable is requested
DISS	1	rh	**Module Disable Bit Status** Bit indicates the current status of the module 0_B Module is enabled 1_B Module is disabled
0	[31:2]	r	**Reserved** Read as 0; write has no effect.

Note: The BMU does not implement a fractional divider.

Note: Sleep and Suspend modes are not supported by BMU, therefore the bit fields controlling those features are not present in the CLC register.

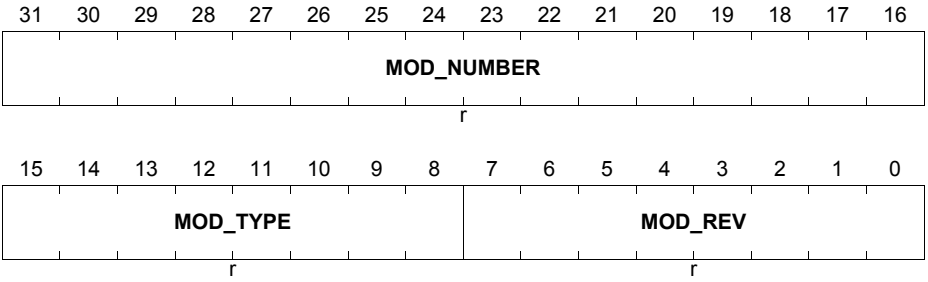
Note: The BMU can be disabled. When the disable state is requested all pending transactions running on the FPI slave interface must be completed before the disabled state is entered. The CLC Register Module Disable Bit Status BMU_CLC.DISS indicates whether the module is currently disabled (DISS == 1). Any attempt to write any of the BPI writable registers with the exception of the CLC Register will generate a bus error. A read operation of BPI registers is allowed and does not generate a bus error. As long as the BMU is disabled no logging is possible (including the write access to the BMU_CLC register to enable again the

BMU). Logging is possible after software writes 0 to DISR and the DISS field value indicates the enabled state.

BMU Module Identification Register.

ID

Module Identification Register **(08_H)** **Reset Value: $0089\ C001_H$**

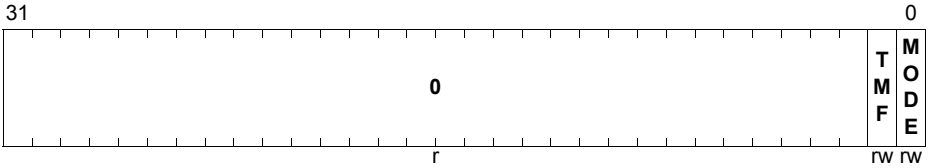


Field	Bits	Type	Description
MOD_REV	[7:0]	r	**Module Revision Number** This bit field defines the module revision number. The value of a module revision starts with 01_H (first revision).
MOD_TYPE	[15:8]	r	**Module Type** The bit field is set to $C0_H$ which defines the module as a 32-bit module.
MOD_NUMBER	[31:16]	r	**Module Number Value** This bit field defines a module identification number. The value for the BMU module is 0089_H.

18.6.2 BMU Control/Status Registers

CTL
Transaction Filtering Control

(20_H) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
MODE	0	rw	**Access Mode** 0_B The BTF is accessed in linear mode as a standard memory mapped SRAM 1_B The BTF is used in FIFO Mode enabling to log the write transaction to the regions selected in **PSET0** and **PSET1** registers.
TMF	1	rw	**Transaction Master Filtering** In FIFO mode, this field enables an additional logging mechanism controlled by the master identifier of a FPI write transaction. 0_B Logging controlled by the transaction master identifier disabled. 1_B Logging controlled by the transaction master identifier Enabled.
0	[31:2]	r	reserved bit fields. A write has no effect. Returns 0s on read.

CTL defines the access mode to the internal SRAM and enables to control additional logging mechanisms based on the initiator of the transaction. The operation mode is statically defined for the whole run-time, changes of operating mode are to be avoided.

In the event the BMU is configured in FIFO mode (CTL.MODE = 1) then the CTL register should be polled to confirm the FIFO mode is set before any write transaction on the FPI bus is logged.

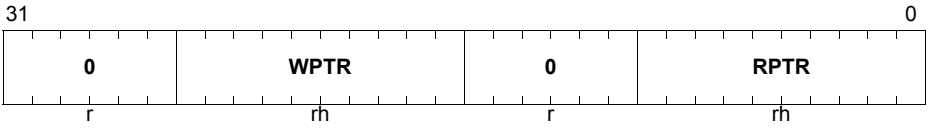
However when the BMU is configured in FIFO mode, it may be necessary to switch to SRAM mode if run time diagnostics of the ECC logic is required. It must be ensured at system level that during the time the diagnostics will be performed, the safety application

will not be able to use the logging capability of the BMU. If the BMU is intended to be used in SRAM mode only, it is not allowed to switch during run-time to FIFO mode.

In the FPI bus protocol the initiator (also called the master) is uniquely identified by the FPI Transaction Identifier made of 4-bits. When the MODE field and TMF field are both set to 1, the BMU monitors the master identifier of every FPI write transaction. When the master identifier matches with the value(s) present in the **TID** register, the address information of every address phase of the transaction is logged into the BMU FIFO. The logging based on the master identifier monitoring has precedence over the logging based on the FPI region monitoring.

PTR
Pointer Information for Bus Transaction Fifo

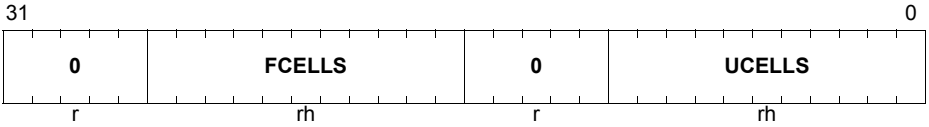
(24_H) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
RPTR	[9:0]	rh	**Read Pointer for a 1024 entry SRAM** Indicates the current position of the read pointer. A write to this field has no hardware effect. For debug purposes only.
WPTR	[25:16]	rh	**Write Pointer for a 1024 entry SRAM** Indicates the current position of the write pointer. A write to this field has no hardware effect. For debug purposes only.
0	[15:10], [31:26]	r	**reserved bit fields. A write has no effect. Returns 0s on read.**

PTR is to be used for debug or verification purposes.

FULLNESS
Fullness Information for Bus Transaction Fifo (28_H) **Reset Value: $0400\ 0000_H$**



Field	Bits	Type	Description
UCELLS	[10:0]	rh	**Number of valid (used) entries in the BTF** Fullness of the BTF as a number of words. UCELLS value ranges from 0 to N, where N is the number of fifo entries. UCELLS = N represents a full fifo. For TC1798 microcontroller, N = 1024. Writing to this field has no effect.
FCELLS	[26:16]	rh	**Number of free entries in the BTF** Writing to this field has no effect. FCELLS value ranges from 0 to N, where N is the number of fifo entries. FCELLS = N represents an empty fifo. For TC1798 microcontroller, N = 1024. Writing to this field has no effect.
0	[31:27], [15:11]	r	reserved bit fields. A write has no effect. Returns 0s on read.

The **UCELLS** and **FCELLS** information can be used to schedule the number of consecutive burst reads that can be made to read the available information from the BTF.

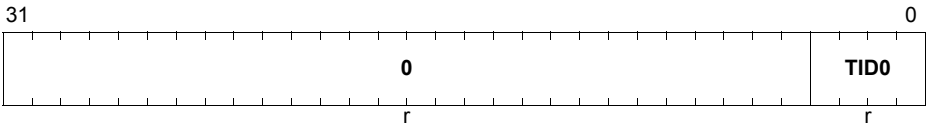
FPI_SEL50	18	rw	**Select Bit for FPI Region 50** 0_B Region Disabled 1_B Region Enabled
FPI_SEL51	19	rw	**Select Bit for FPI Region 51** 0_B Region Disabled 1_B Region Enabled

Field	Bits	Type	Description
FPI_SEL52	20	rw	**Select Bit for FPI Region 52** 0_B Region Disabled 1_B Region Enabled
FPI_SEL53	21	rw	**Select Bit for FPI Region 53** 0_B Region Disabled 1_B Region Enabled
FPI_SEL54	22	rw	**Select Bit for FPI Region 54** 0_B Region Disabled 1_B Region Enabled
FPI_SEL55	23	rw	**Select Bit for FPI Region 55** 0_B Region Disabled 1_B Region Enabled
FPI_SEL56	24	rw	**Select Bit for FPI Region 56** 0_B Region Disabled 1_B Region Enabled
FPI_SEL57	25	rw	**Select Bit for FPI Region 57** 0_B Region Disabled 1_B Region Enabled
FPI_SEL58	26	rw	**Select Bit for FPI Region 58** 0_B Region Disabled 1_B Region Enabled
FPI_SEL59	27	rw	**Select Bit for FPI Region 59** 0_B Region Disabled 1_B Region Enabled
FPI_SEL60	28	rw	**Select Bit for FPI Region 60** 0_B Region Disabled 1_B Region Enabled
FPI_SEL61	29	rw	**Select Bit for FPI Region 61** 0_B Region Disabled 1_B Region Enabled
FPI_SEL62	30	rw	**Select Bit for FPI Region 62** 0_B Region Disabled 1_B Region Enabled
FPI_SEL63	31	rw	**Select Bit for FPI Region 63** 0_B Region Disabled 1_B Region Enabled

PSET0 and **PSET1** are used to control which FPI region is to be monitored by the BMU.

TID
FPI Transaction ID Set 0 Configuration

(38_H) **Reset Value: 0000 000D$_H$**



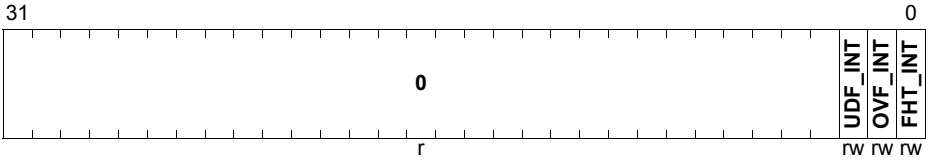
Field	Bits	Type	Description
TID0	[3:0]	r	**Transaction Identifier 0** This field is statically encoded with the 4'b1101 value that corresponds to the SHE FPI master identifier in the TC1798 device.
0	[31:4]	r	reserved bit fields. A write has no effect. Returns 0s on read.

The Transaction Identifier **TID** enables to perform monitoring actions based on the master identifier provided by the FPI master. This mode can be further extended (in future versions of the BMU) to do broader checks based on the TID: for instance in a multi-processor system, the TID can uniquely identity the CPU core that initiated the transaction. The current implementation only allows to do a static detection of write accesses initiated by the SHE module when present in the product.

18.6.4 BMU: Fifo Monitoring Registers

FMCTL
Fifo Monitor control register

(40_H) **Reset Value: 0000 0000$_H$**

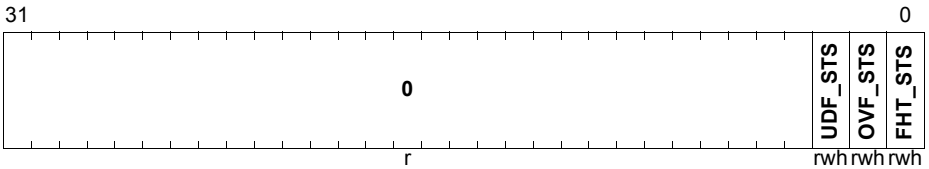


Field	Bits	Type	Description
FHT_INT	0	rw	**Interrupt Enable for Fifo High Threshold** 0_B interrupt generation disabled 1_B interrupt generation enabled
OVF_INT	1	rw	**Interrupt Enable for Overflow Detection** 0_B interrupt generation disabled 1_B interrupt generation enabled
UDF_INT	2	rw	**Interrupt Enable for Underflow Detection** 0_B interrupt generation disabled 1_B interrupt generation enabled
0	[31:3]	r	reserved bit fields. A write has no effect. Returns 0s on read.

FMCTL controls the interrupt generation related to the Fifo Fullness Monitoring.

FMSTS
Fifo Monitor Status Register

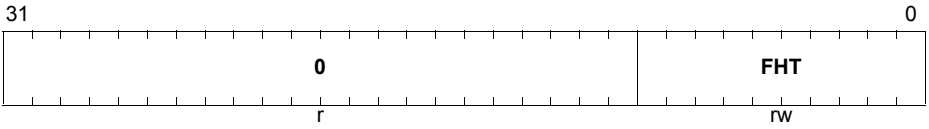
(44_H) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
FHT_STS	0	rwh	**Status Flag for Fifo High Threshold interrupt** 0_B No interrupt pending 1_B Event related to High Threshold monitoring has been detected. The event leads to an interrupt if FMCTL.FHT_INT = 1.
OVF_STS	1	rwh	**Status Flag for Overrun interrupt** 0_B No interrupt pending 1_B Event related to overflow monitoring has been detected. The event leads to an interrupt if FMCTL.OVF_INT = 1.
UDF_STS	2	rwh	**Status Flag for Underflow interrupt** 0_B No interrupt pending 1_B Event related to underflow monitoring has been detected. The event leads to an interrupt if FMCTL.UDF_INT = 1.
0	[31:3]	r	reserved bit fields. A write has no effect. Returns 0s on read.

FMSTS is used to log the status of the interrupt source(s). The bits are set to 1 by hardware. To clear a status bit the software must write a 0 at the bit position corresponding to be bit to be cleared (writing a 1 per software has no effect on the status bits). If software writes a 0 to a status bit that is already cleared and in the same cycle the hardware wants to set the bit, the hardware has priority over the software.

FMTH
Fifo Monitor: Fullness Threshold Register
(48_H) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
FHT	[9:0]	rw	**Fifo High Threshold** This field defines a number of used entries defining a threshold. When set to 0 the threshold monitoring is disabled.
0	[31:10]	r	reserved bit fields. A write has no effect. Returns 0s on read.

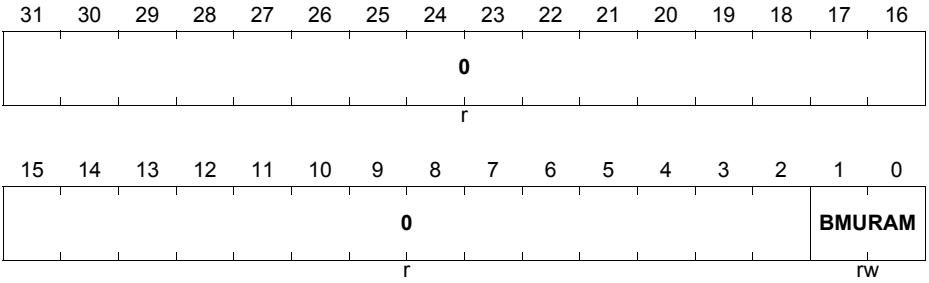
FMTH defines a boundary for the number of used words in the Bus Transaction Fifo that will be monitored during run-time. When the number of words configured in the **FHT** field is reached (or crossed) and if the **FMCTL**.**FHT_INT** field is set, an interrupt is triggered. This FHT field must be initialized by SW to the expected threshold before enabling the interrupt generation.

18.6.5 BMU: SIST Mode Access Control Register

*Note: Please see **"Error Correction Code (ECC)" on Page 18-18** for more information regarding the use of this register.*

This register is ENDINIT protected.

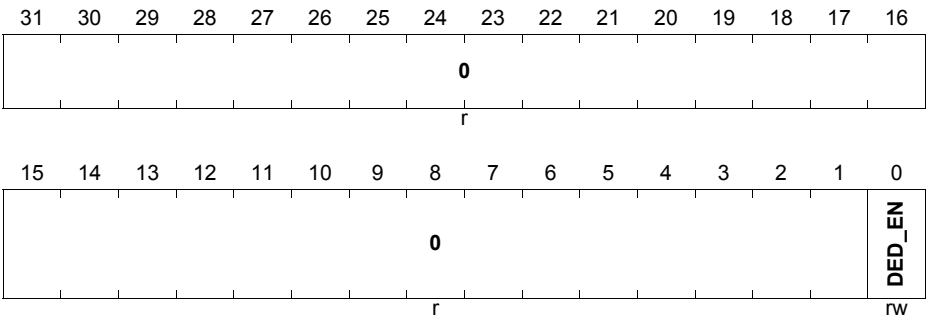
SMACON
SIST Mode Access Control Register (50$_H$) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
BMURAM	[1:0]	rw	**SIST mode access control** 00_B Normal Operation, No Mapping 01_B Data Array Mapping, no error detection/correction 10_B Check Array Mapping, no error detection/correction 11_B Data Array Mapping, error detection/correction enabled
0	[31:2]	r	**reserved** returns '0' if read; should be written with '0'.

MIECON

Memory Integrity Error Control Register(54_H) **Reset Value: 0000 0000$_H$**

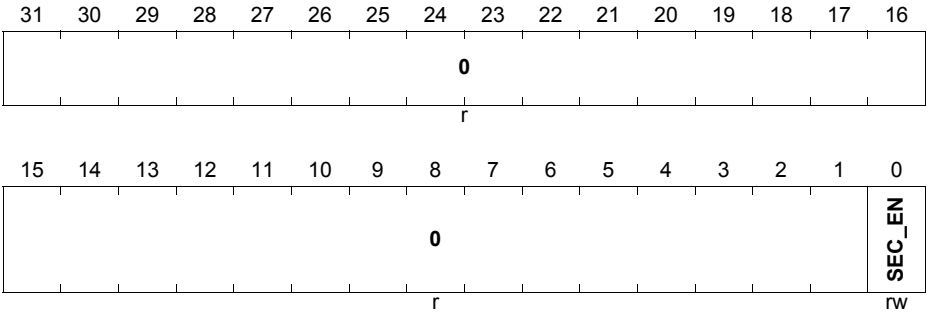


Field	Bits	Type	Description
DED_EN	0	rw	**Double error detection enable** 0_B Double bit error detection for BMURAM disabled 1_B Double bit error detection for BMURAM enabled
0	[31:1]	r	**reserved** returns ‘0’ if read; should be written with ‘0’.

Please see **“Error Correction Code (ECC)” on Page 18-18** for more information regarding the use of this register.

MIECON2

Memory Integrity Error Control 2 Register(58_H) **Reset Value: 0000 0000$_H$**



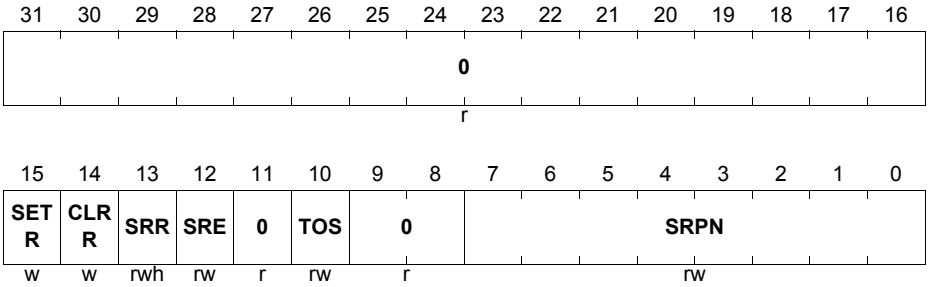
Field	Bits	Type	Description
SEC_EN	0	rw	**Single error correction enable** 0_B Single bit error correction for BMURAM disabled 1_B Single bit error correction for BMURAM enabled
0	[31:1]	r	**reserved** returns ‘0’ if read; should be written with ‘0’.

Please see **“Error Correction Code (ECC)” on Page 18-18** for more information regarding the use of this register.

*Note: This register is ENDINIT protected, in addition the register cannot be accessed unless the “secwen_i” input is asserted. When “secwen_i” is not asserted accesses to **MIECON2** will generate an FPI error acknowledge.*

18.6.6 Interrupt System Registers

SRC
Service Request Control Register (FC_H) Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
SRPN	[7:0]	rw	**Service Request Priority Number** 00_H Service request is never serviced 01_H Service request is on lowest priority ... FF_H Service request is on highest priority
TOS	10	rw	**Type of Service Control** 0_B CPU service is initiated 1_B PCP service is initiated
SRE	12	rw	**Service Request Enable** 0_B Service request is disabled 1_B Service request is enabled
SRR	13	rwh	**Service Request Flag** 0_B No service request is pending 1_B A service request is pending[1)]
CLRR	14	w	**Request Clear Bit** CLRR is required to clear SRR. 0_B No action 1_B Clear SRR; bit value is not stored; read always returns 0; no action if SETR is set also.

Field	Bits	Type	Description
SETR	15	w	**Request Set Bit** SETR is required to set SRR. 0_B No action 1_B Set SRR; bit value is not stored; read always returns 0; no action if CLRR is set also.
0	[9:8], 11, [31:16]	r	**Reserved** Read as 0; should be written with 0.

1) The bit field SRR is automatically cleared by hardware at the end of an interrupt arbitration round if the node was the winner, therefore this information is not suitable for interrupt plausibility checks.

19 On-Chip Debug Support (OCDS)

This chapter gives an overview about the debug features of the TC1798 device. This chapter does not describe the TC1798 debug functionality and capabilities in detail. For detailed information about the On-Chip Debug Support (OCDS) functionality as required by tool suppliers please contact local Infineon representatives.

19.1 Overview

TC1798 supports OCDS Level 1 and 3.

OCDS Level 1

The OCDS Level 1 is mainly assigned for system software debugging purposes which have a demand for low-cost standard debugger hardware.

The OCDS Level 1 is based on a Debug Interface that is used by the external debug hardware to communicate with the system. The on-chip Cerberus module controls the interactions between the Debug Interface and the on-chip modules and allows in particular to access the whole address space of the device. The memory mapped on-chip debug resources make it possible to trigger on instruction and data addresses as well as to control user program execution (run/stop, breakpoint, single-step).

OCDS Level 3

The OCDS Level 3 is based on a Multi Core Debug Solution (MCDS) using an Emulation Device. This device has the following features required for high-end emulation purposes:

- Emulation Device is available in the same package variants as TC1798
- Higher current consumption due to trace and overlay RAM is the only difference
- TriCore program trace
- TriCore data trace (no register file trace)
- PCP ownership trace
- PCP program trace
- PCP data write to PRAM trace (no register file trace)
- Full visibility of internal peripheral bus (SPB)
- Full visibility of up to two arbitrary SRI bus slaves
- Time aligned parallel trace of all sources
- Breakpoints and watchpoints based on common event generation logic
- Magnitude comparators working on instruction pointers and memory addresses: A <= IP <= B
- Masked magnitude comparators working on the data busses: DATA = “xxxx55xx”
- Sequential event logic: Counters driven by events and equipped with limit comparators are used as event sources again for breakpoint or trace qualification
- Optimized compression of buffered trace data
- Code and data fetch from Emulation Memory

- Highly sophisticated complex qualification- and trigger mechanism
- Pre- and post event trace buffering (“digital oscilloscope”)
- Performance counters
- Continuous trace logging and trace data acquisition up to the bandwidth of the used host interface
- Central time stamp unit to correlate traces from different cores or other sources
- Central mechanism to start and stop all cores simultaneously or selectively
- Halt the system when trace memory is full

The Emulation Device includes the product chip part extended with additional emulation hardware. For detailed information about the Emulation Device functionality (e.g. as required by tool suppliers), please contact local Infineon representatives.

Figure 19-1 shows a block diagram of the TC1798 OCDS system.

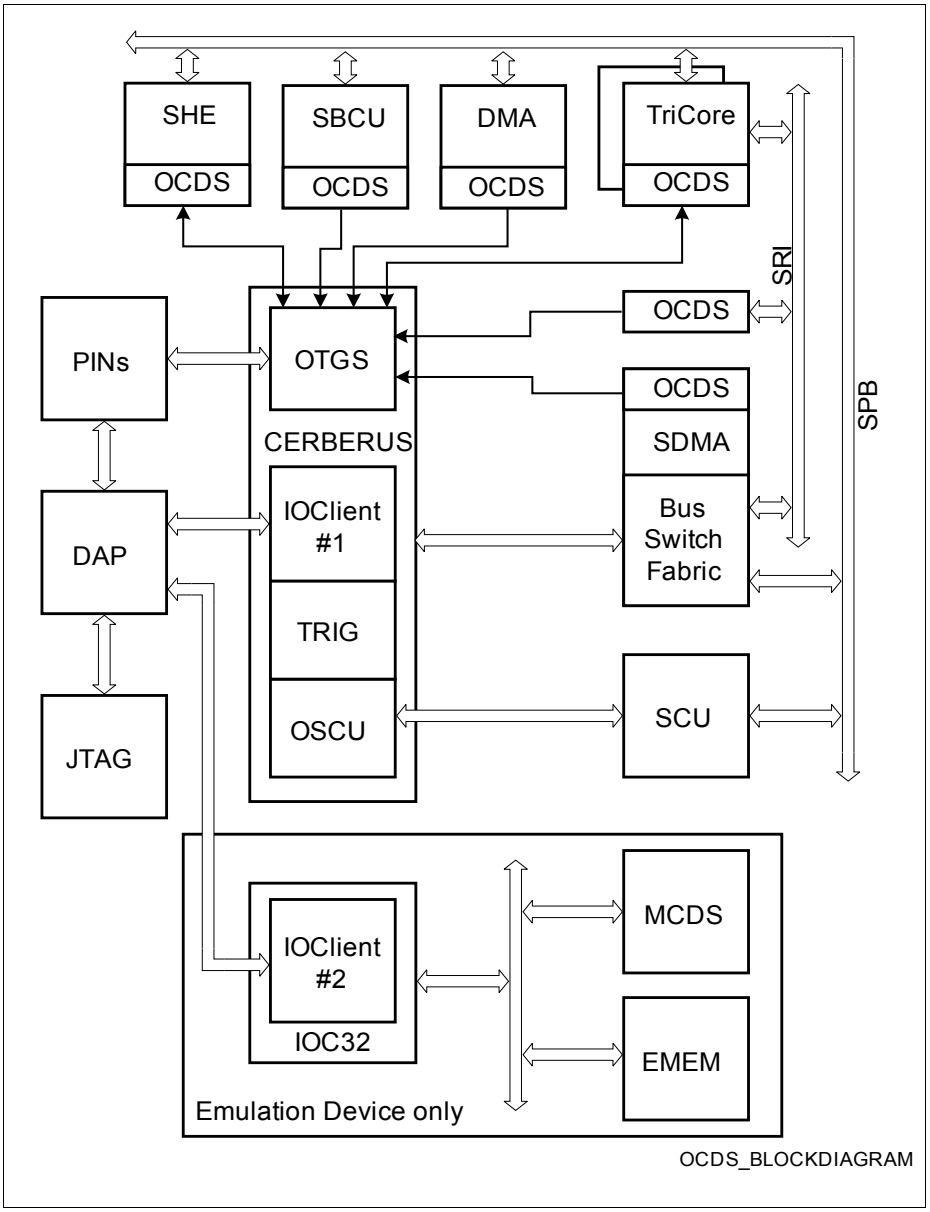


Figure 19-1 OCDS System Block Diagram

Components

The OCDS of the TC1798 consists of the following building blocks:

- OCDS System Control Unit (OSCU)
- TriCore OCDS
- PCP OCDS
- DMA OCDS
- SBCU OCDS
- SRI OCDS
- Multi Core Break Switch (MCBS)
- Break Pin Control
- IOClient
- Device Access Port (DAP)
- JTAG Interface
- Overlay Control

Summary of OCDS Features

- OCDS System Control Unit (OSCU)
  - Controls OCDS enabling
  - Automatic Power Saving
  - Reset control of debug resources
  - Halt After Reset
  - Hot attach of a debugger to a running system
  - Key mechanism allows control the device access in a secure way.
  - State-aware watchdog timer suspension during debugging
  - Control of SoC specific OCDS features
  - Interrupt service request node for debug purposes
- TriCore OCDS features
  - Hardware event generation
  - Break by DEBUG instruction or Break signal from break switch
  - Suspend by Suspend bus or Break signal from break switch
  - Full hardware supported single step
  - Concurrent access to memory and SFRs via Cerberus
- PCP OCDS features
  - Break by DEBUG instruction or Break signal from break switch
  - Concurrent access to memory and SFRs via Cerberus
- DMA/SDMA OCDS features
  - Soft-suspend Mode of DMA channels
  - Break signal generation
  - Trace signal generation
- SBCU OCDS features
  - Event generation on specified transactions

- SRI OCDS features
  - Error recording and service request on bus error
- Multi-Core Break Switch (Cerberus MCBS)
  - TriCore, PCP, DMA/SDMA, break pins and SBCU available as break sources
  - TriCore and PCP available as break targets; other parts can be suspended in addition
  - Synchronous stop and restart of the system
  - Break to Suspend converter

19.2 OCDS Level 1

The basic principle of the TriCore OCDS Level 1 is that all relevant user and debug resources are memory mapped. These resources include on-chip memories, CPU core registers and registers of the peripheral units.

A typical OCDS Level 1 debugging configuration is shown in **Figure 19-2**. It comprises two parts:

- The tool software
- The tool access hardware interface adapter

This configuration makes it possible to realize a cost effective debugging environment that permits comprehensive real-time debugging tasks to be performed.

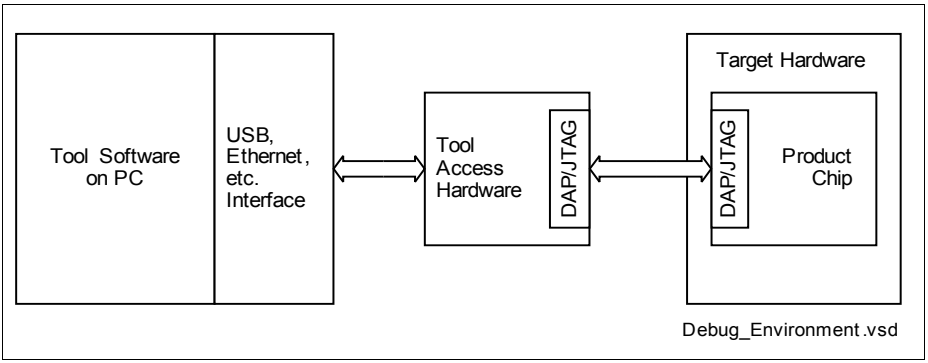

Figure 19-2 Typical OCDS Level 1 Hardware Connections

19.2.1 TriCore CPU OCDS Level 1

This section describes the basic features of the TriCore OCDS Level 1 hardware. For more details please refer to the “TriCore Core Architecture V1.6” manual.

Features

- Single-step support by hardware
- Up to 8 programmable hardware breakpoints. Each one can be defined as a combination of program counter and data address:
  - Breaks on program counter (PC) value
    Two precise PC values or one PC range
    Break before make (BBM) possible
  - Breaks on data address
    Two precise data addresses or one data address range
    No break before make possible (due to pipelined architecture)
  - Combinations of the above break conditions
- Suspend features
  - Core Suspend-Out to suspend bus
  - Configurable Core Suspend-In
- Real-time features
  - Read and write of memory/registers independent of CPU, with minimum intrusion (stealing bus cycles by Cerberus)
  - High-priority requests can still be serviced when the core is in emulation mode - by interrupting the monitor program

19.2.1.1 Basic Concept

The TriCore CPU in the TC1798 provides OCDS with the following two basic parts:

- Debug Event Trigger Generation
- Debug Event Trigger Processing

The first part controls the generation of debug events and the second part controls what actions are taken when a debug event is generated.

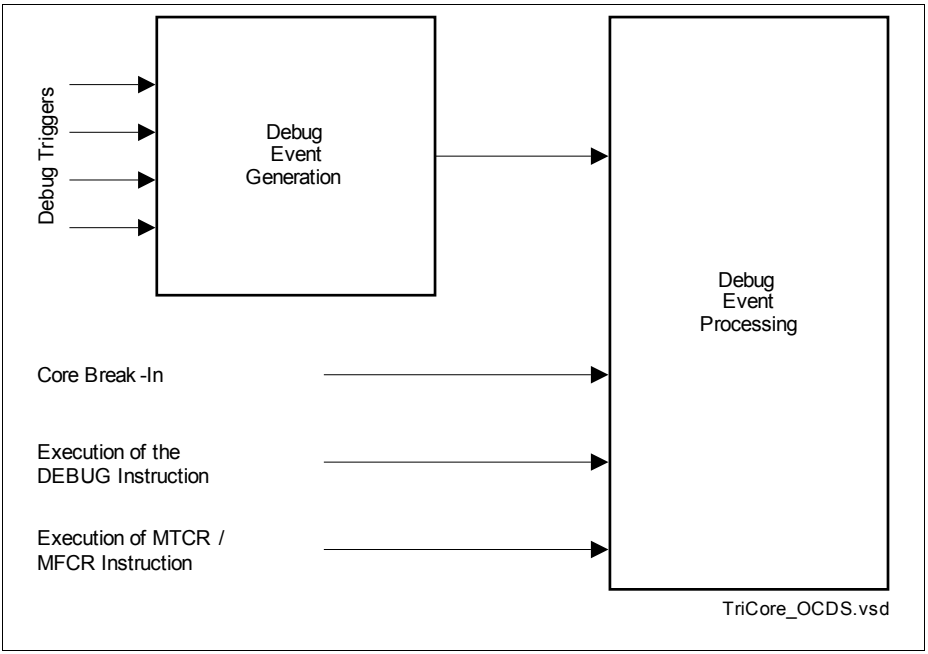

Figure 19-3 Basic TriCore Debug Concept

19.2.1.2 Debug Event Generation

If debug mode is enabled, debug events can be generated by:

- Debug event generation from debug triggers
- Activation of the external Core Break-In signal to the core
- Execution of a DEBUG instruction
- Execution of an MTCR/MFCR instruction

Debug Event Generation from Debug Triggers

The debug event generation unit is responsible for generating debug events when a programmable set of debug triggers is active. TC1.6 has 8 address comparator registers dedicated for debug. Pairs can be used for range triggers.

These debug triggers provide the inputs to a programmable block of combinational logic that outputs debug events. The aim is to be able to specify the breakpoints that use fairly simple criteria purely in the on-chip debug event generation unit, and to rely on help from the external debug system or debug monitor to implement more complex breakpoints.

Activation of the External Core Break-in signal

When activating the TC1798 device pin $\overline{\text{BRKIN}}$ = 0 and if MCBS and port control is configured to forward this event to the Core Break-In signal, a break event is induced as specified in an External Break Input Event Specifier Register EXEVT (**Figure 19-4**).

Execution of a DEBUG Instruction

The TriCore architecture supports a mechanism through which software can explicitly generate a debug event. This can be used, for instance, by a debugger to patch code held in RAM in order to implement breakpoints. A special DEBUG instruction is defined which is a user mode instruction, and its operation depends on whether the debug mode is enabled. 16-bit and 32-bit forms of the DEBUG instruction are provided.

If debug mode is enabled, the DEBUG instruction causes a debug event to be raised and the action defined in the Software Break Event Specifier Register SWEVT is taken. If the debug mode is not enabled, then the DEBUG instruction is treated as a NOP instruction.

Execution of an MTCR/MFCR Instruction

In order to protect the emulator resource, a debug event is raised whenever an MTCR or MFCR instruction is used to read or modify a user core SFR, but an event is not raised when the user reads or modifies one of the dedicated core debug registers: DBSR, CREVT, SWEVT, EXEVT, TR0EVT, TR1EVT, DMS, DCX or DBGTCR.

The action that is performed when an MTCR or MFCR instruction is executed on user core SFRs defined by the content of the Emulator Resource Protection Event Specifier Register CREVT.

19.2.1.3 Debug Actions

Four types of debug actions are available:

- Assert Core Break-out signal and $\overline{\text{BRKOUT}}$ (**Figure 19-4**) via MCBS unit and port control
- Halt the CPU core
- Cause a breakpoint trap
- Generate an interrupt request

These debug actions are selected by programming the corresponding Event Specifier registers. Their contents determine which action shall be taken when the corresponding debug event occurs. In parallel the Core Suspend-Out signal can be activated.

19.2.1.4 TriCore OCDS Registers

Please refer to “TriCore Core Architecture V1.6” manual.

19.2.2 PCP OCDS Level 1

PCP has no hardware means of generating trigger events.

To set breakpoints, the debugger is expected to patch the code in the PCP code memory (CMEM) with DEBUG instructions. If a DEBUG instruction is executed, the running channel program is terminated, either with Debug Exit or with Error Exit.

The PCP has a suspend input, a break input and a break output. The Break Switch can send an external break request to the PCP, with the same consequence as above (Debug Exit or Error Exit).

19.2.3 SBCU OCDS Level 1

The BCU of the SPB bus in the TC1798 offers very powerful means for trigger generation. The BCU contains comparators for

- the arbitration phase (look for specific bus master)
- the address phase (look for specific address or range)
- the data phase (look for read, write, supervisor mode, etc.)

The results can be combined to generate a break request signal, which is sent to the Break Switch.

The OCDS registers of SBCU are described in chapter “On-Chip System Buses and Bus Bridges” starting from section “System Bus Control Unit Registers”.

19.2.4 DMA/SDMA OCDS Level 1

The DMA/SDMA controller in the TC1798 provides the following debugging capabilities:

- Hard suspend mode of the DMA/SDMA controller (for test purposes only)
- Soft suspend mode of DMA/SDMA channels
- Break signal generation

In suspend modes, the operations of DMA/SDMA channels or the complete module are stopped. Under certain conditions, a break signal is also generated for the on-chip debug support logic.

More details on the OCDS Level 1 debug capabilities of the DMA/SDMA controller are provided in section “On-Chip Debug Capabilities” of the DMA/SDMA chapter.

19.3 Debug Interface (Cerberus)

The Cerberus module is the on-chip unit that controls all OCDS main debug functions. Generally, the Cerberus may not be used by any application software, since this could disturb the emulation tool behavior.

The Cerberus module is built up by three parts (see also **Figure 19-1**):

- OCDS System Control Unit - OSCU
- IOClient
- Multi Core Break Switch - MCBS

A tool can be connected to the device in two ways:

- A two line DAP interface via the DAP module receives the debugger commands, converts them and outputs them to the IOClient interface.
- Standard JTAG interface is connected via the JTAG controller with the IOClient interface

Two additional pins are available to handle an external break condition. The external debug hardware can access the Cerberus registers and arbitrary memory locations across the System Peripheral Bus.

Features

- OCDS Level 1 control via
  - 5-pin standard JTAG interface
  - 2-pin DAP interface
- Generation of external break condition via $\overline{\text{BRKIN}}$/$\overline{\text{BRKOUT}}$ pins possible
- Full access to the complete SPB Bus address space via DAP/JTAG
- No user resources (hardware/software) are required
- No or minimum run-time impact (Cerberus bus priority can be controlled)
- Generic memory read/write functionality
- Write word, half-word and byte
- Block read and write
- Full support for communication between an on-chip monitor program and the external debugger
- Pending reads/writes can be optionally triggered by the OCDS module (memory tracing)
- Download of programs and data via DAP/JTAG
- Control of the OCDS blocks
- Data acquisition

19.3.1 RW Mode

As the name implies, the RW mode is used by a DAP/JTAG host to read or write arbitrary memory locations via the DAP/JTAG interface. The RW mode needs the SPB Bus master interface of the Cerberus to actively request data reads or data writes.

Data Types Supported

- WORD (32-bit): The default data type; used for single word transfers and block transfers.
- HWORD (16-bit): For reading 16-bit registers without getting a bus error, a dedicated IOClient instruction is provided.
- BYTE (8-bit): If the DAP/JTAG host wants to read a byte, it has to read the associated word or half-word. Then the host has to extract the part needed itself.

19.3.2 Communication Mode

In Communication Mode, the Cerberus has no access to the internal buses and communication is established between the external DAP/JTAG host and a software monitor (embedded into the application program) via the Cerberus registers. The communication mode is the default mode after reset.

In Communication Mode, the external DAP/JTAG host is master of all transactions. The host requests the monitor to write or read a value to/from the Cerberus register COMDATA. The difference to RW Mode is that the read or write request is not actively executed by Cerberus. The request just sets bits in the CPU accessible IOSR register to signal the monitor that the debugger wants to send or receive a value. The software monitor has to poll the IOSR register for that.

19.3.3 Triggered Transfers

Triggered transfers can be used to read from or write to a certain memory location when an OCDS trigger becomes active.

The main application for Triggered Transfers is to trace a certain memory location. This can be done, when the OCDS of the CPU activates its break out signal, if this memory location is written by the user program. This event is used as a transfer trigger through the configuration of the MCBS. Cerberus is configured to read the location on this trigger.

19.3.4 Multi Core Break Switch

In TC1798, there are several sources and targets for break signals. For instance the OCDS run control of one processor can break the other processor unit. The Multi Core Break Switch (MCBS) is a part of the Cerberus and allows to propagate break requests from sources to targets in a generic and flexible way. **Figure 19-4** shows the break signal interfaces of the MCBS.

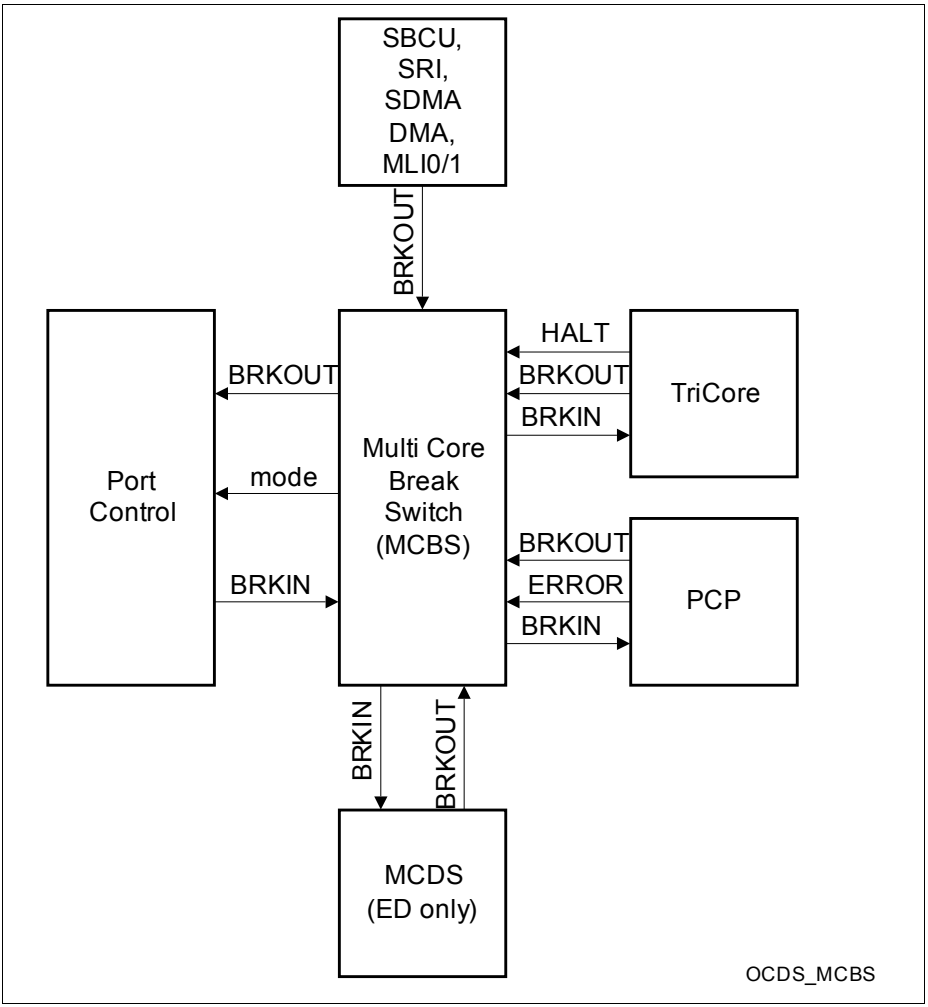

Figure 19-4 Break Switch Interfaces

The MCBS unit supports the following features:

- Break-in sources: TriCore, PCP, DMA, SBCU, MLI0, MLI1
- Up to two device pins configurable as BRKIN/BRKOUT pins
- Two independent break buses
- Suspend generation supports delayed suspend
- Break-to-suspend converter

- Create interrupt request with a break coming from a source
- Synchronous restart of the system

19.4 JTAG Interface

The JTAG interface is a standardized unit that is typically used for boundary scan and internal device tests. Because both of these applications are not active during normal device operation in a system, the JTAG port can be used during normal device operation as an ideal interface for debugging tasks.

19.5 Device Access Port (DAP)

The cost inferred by each non-functional pin is a strong argument to reduce the tool access port to as few pins as possible. The standardized Device Access Port (DAP) of Infineon's latest micro controllers offers a convenient method to get the required functionality at the least possible cost. With DAP only two pins (DAP0 for the clock, DAP1 for the bidirectional data) are needed to communicate with the tool.

DAP uses a straightforward half-duplex protocol, i.e. the DAP1 pin is used for data transfer from tool to device and from device to tool at different periods of time while the clock is provided by the tool to the DAP0 input.

19.5.1 DAP Telegram Format

All information transport between tool and device is done in telegrams. Mandatory 6 bit CRC check sums assure secure transport even in noisy environments. Splitting command and reply into separate units transported sequentially allows half-duplex transmission over a single bidirectional line. The physical interface medium can be chosen independently as long as the serial bit stream can be transported.

19.5.2 DAP Telegram Catalog

This chapter lists the telegrams implemented by the TC1798. Other telegrams are silently ignored, resulting in a time-out condition on the tool side.

Three groups of telegrams can be distinguished:

Control Telegrams

These four telegrams are needed to establish and maintain the connection from tool to device as such. No data is transported.

- sync - request synchronization pattern
- turn_off - shut down DAP
- poll - get the current service request
- set_maxwait - adjust the parameter for time out

JTAG Telegrams

The telegrams of this group are simple wrappers around the standard JTAG commands, adding the relaxed timing and increased transmission speed and quality of DAP.

- jtag_mode - switch DAP to BYPASS mode
- jtag_reset - reset the TAP controller
- jtag_setIR - write the TAP's INSTRUCTION register
- jtag_swapIR - write and read the TAP's INSTRUCTION register
- jtag_setDR - write the current JTAG data register
- jtag_swapDR - write and read the current JTAG data register
- jtag_moreDR - write and read part of a long JTAG data register

Client Telegrams

The last group allows direct access to IOClients like Cerberus of the device, completely hiding the asynchronous timing between tool clock and system clock of the device.

The following five telegrams belong to this group:

- client_set - define the current IOClient
- client_get - ask for the index of the current IOClient
- client_reset - reset the current IOClient
- client_write - write to the current IOClient
- client_read - read from the current IOClient

19.6 Cerberus and JTAG Registers

This section summarizes all Cerberus and JTAG registers for reference purposes. Details on these registers are contained in OCDS documents that are available for tool suppliers on request (please contact local Infineon representatives). All CERBERUS registers are prefixed “CBS_” in the register map of a device.

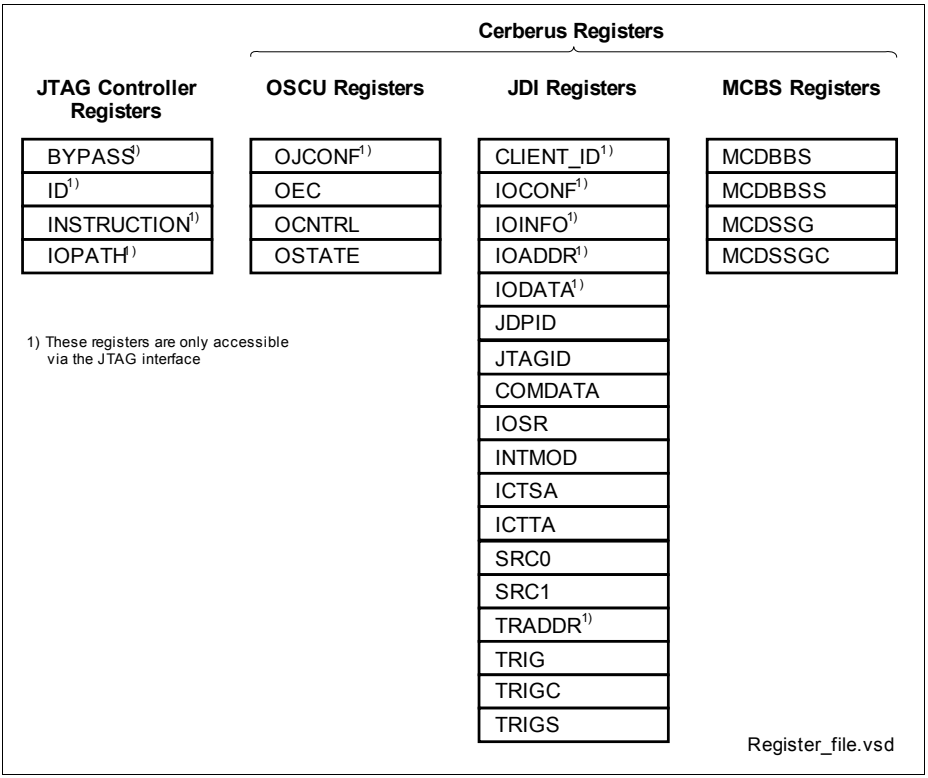

Figure 19-5 JTAG/Cerberus Register Overview

Table 19-1 JTAG/Cerberus Register Overview

Register Short Name	Register Long Name	Address
JTAG Controller Registers		
BYPASS	JTAG Bypass Register (1-bit)	1)
ID	JTAG Device Identification Register (32-bit)	1)
INSTRUCTION	JTAG Instruction Register (8-bit)	1)
IOPATH	IO Client Selection Register (2-bit)	1)
Cerberus Registers		
OJCONF	OSCU Configuration by JTAG Register	1)

Table 19-1 JTAG/Cerberus Register Overview (cont'd)

Register Short Name	Register Long Name	Address
OEC	OCDS Enable Control Register	F000 0478$_H$
OCNTRL	OSCU Configuration and Control Register	F000 047C$_H$
OSTATE	OSCU Status Register	F000 0480$_H$
CLIENT_ID	JTAG Client Identification Register (32-bit)	1)
IOCONF	Configuration Register (12-bit)	1)
IOINFO	State Information for Error Analysis Register (16-bit)	1)
IOADDR	Address for Data Access Register (32-bit)	1)
IODATA	RW Mode Data Register (32-bit)	1)
JDPID	Cerberus Module Identification Register	F000 0408$_H$
JTAGID	JTAG Device Identification Register	F000 0464$_H$

MCDSSGC	Suspend Signal Generation Configuration Register	F000 0494$_H$
SRC0	Service Request Control Register 0	F000 04FC$_H$
SRC1	Service Request Control Register 1	F000 04F8$_H$
TRADDR	Triggered Transfer Destination Address	1)
TRIG	Trigger to Host	F000 04A8$_H$
TRIGC	Clear Trigger to Host	F000 04A4$_H$
TRIGS	Set Trigger to Host	F000 04A0$_H$

1) These registers are only accessible via the JTAG interface.

20 Asynchronous/Synchronous Serial Interface (ASC)

This chapter describes the two ASC Asynchronous/Synchronous Serial Interfaces, ASC0 and ASC1, of the TC1798. It contains the following sections:

- Functional description of the ASC kernel, valid for ASC0 and ASC1 (see **Page 20-1**)
- ASC kernel register description, describes all ASC kernel specific registers (see **Page 20-19**)
- TC1798 implementation-specific details and registers of the ASC0/ASC1 modules (see **Page 20-30**).

*Note: The ASC kernel register names described in **Section 20.2** are referenced in the TC1798 User´s Manual by the module name prefix "ASC0_" for the ASC0 interface and by "ASC1_" for the ASC1 interface.*

20.1 ASC Kernel Description

Figure 20-1 shows a global view of the ASC interface.

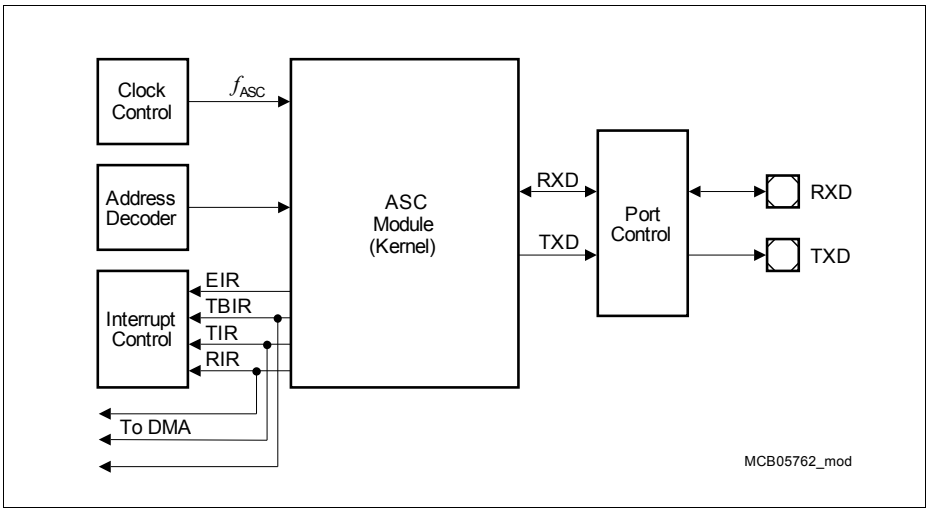

Figure 20-1 General Block Diagram of the ASC Interface

The ASC module communicates with the external world via two I/O lines. The RXD line is the receive data input signal (and also output signal in Synchronous Mode), and TXD is the transmit output signal.

Clock control, address decoding, and interrupt service request control are managed outside the ASC module kernel.

20.1.1 Overview

The ASC provides serial communication between the TC1798 and other microcontrollers, microprocessors, or external peripherals.

The ASC supports full-duplex asynchronous communication and half-duplex synchronous communication. In Synchronous Mode, data is transmitted or received synchronous to a shift clock that is generated by the ASC internally. In Asynchronous Mode, 8-bit or 9-bit data transfer, parity generation, and the number of stop bits can be selected. Parity, framing, and overrun error detection are provided to increase the reliability of data transfers. Transmission and reception of data is double-buffered. For multiprocessor communication, a mechanism is included to distinguish address bytes from data bytes. Testing is supported by a loop-back option. A 13-bit baud rate generator provides the ASC with a separate serial clock signal, which can be accurately adjusted by a prescaler implemented as fractional divider.

Features

- Full-duplex asynchronous operating modes
  - 8-bit or 9-bit data frames, LSB first
  - Parity-bit generation/checking
  - One or two stop bits
  - Baud rate from 6.875 Mbit/s to 1.64 bit/s (@ 110 MHz module clock)
  - Multiprocessor mode for automatic address/data byte detection
  - Loop-back capability
- Half-duplex 8-bit synchronous operating mode
  - Baud rate from 13.75 Mbit/s to 1119 bit/s (@ 110 MHz module clock)
- Double-buffered transmitter/receiver
- Interrupt generation
  - On a transmit buffer empty condition
  - On a transmit last bit of a frame condition
  - On a receive buffer full condition
  - On an error condition (frame, parity, overrun error)
- Implementation features
  - Connections to DMA Controller
  - Connections of receiver input to GPTA (LTC) for baud rate detection and LIN break signal measuring

20.1.2 General Operation

The ASC supports full-duplex asynchronous communication up to Mbit/s and half-duplex synchronous communication up to Mbit/s (@ MHz module clock). In Synchronous Mode, data is transmitted or received synchronous to a shift clock generated by the microcontroller. In Asynchronous Mode, 8-bit or 9-bit data transfer, parity generation, and the number of stop bits can be selected. Parity, framing, and overrun error detection are provided to increase the reliability of data transfers. Transmission and reception of data are double-buffered. For multiprocessor communication, a mechanism is included to distinguish address bytes from data bytes. Testing is supported by a loop-back option. A 13-bit baud rate generator provides the ASC with a separate serial clock signal, which can be accurately adjusted by a prescaler implemented as fractional divider.

A transmission is started by writing to the Transmit Buffer Register, TBUF. Only the number of data bits determined by the selected operating mode will actually be transmitted; that is, bits written to positions 9 through 15 of register TBUF are always insignificant. Data transmission is double-buffered, so a new character may be written to TBUF before the transmission of the previous character is complete. This allows a back-to-back transmission of characters to take place without gaps.

Data reception is enabled by the receiver enable bit CON.REN. After a reception has been completed, the received data and, if provided by the selected operating mode, the received parity bit can be read from the (read-only) receive buffer register RBUF. Unused bits in the upper half of RBUF that are not required in the selected operating mode will be read as zeros.

Data reception is double-buffered, so that reception of a second character may already begin before the previously received character has been read out of the receive buffer register. In all modes, receive buffer overrun error detection can be selected through bit CON.OEN. When enabled, the overrun error status flag CON.OE and the error interrupt request line EIR will be activated when the receive buffer register has not been read by the time reception of a second character is complete. In this case, the previously received character in the receive buffer is overwritten.

The loop-back option (selected by bit CON.LB) allows the data currently being transmitted to be received simultaneously in the receive buffer. This may be used to test serial communication routines at an early stage without having to provide an external network. In loop-back mode, the alternate input/output function of port pins is not required.

20.1.3 Asynchronous Operation

Asynchronous Mode supports full-duplex communication, in which both transmitter and receiver use the same data frame format and have the same baud rate. Data is transmitted on pin TXD and received on pin RXD. **Figure 20-2** shows the block diagram of the ASC when operating in Asynchronous Mode.

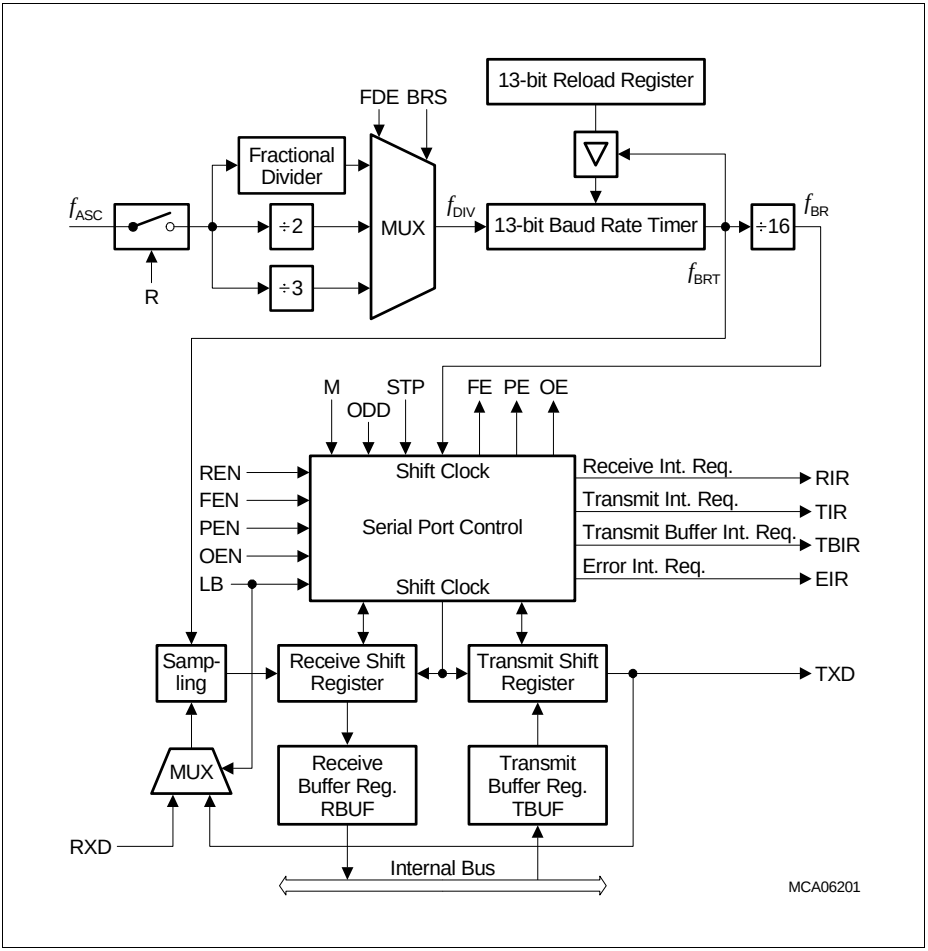

Figure 20-2 Asynchronous Mode of the ASC

20.1.3.1 Asynchronous Data Frames

Asynchronous data frames can consist of 8-bit or 9-bit data frames.

8-bit Data Frames

The 8-bit data frames consist of either eight data bits D7 … D0 (CON.M = 001_B), or of seven data bits D6 … D0 plus an automatically generated parity bit (CON.M = 011_B). Parity may be odd or even, depending on bit CON.ODD. An even parity bit will be set if the modulo-2 sum of the seven data bits is 1. An odd parity bit will be cleared in this case. Parity checking is enabled via bit CON.PEN (always OFF in 8-bit data mode). The parity error flag CON.PE will be set, along with the error interrupt request flag, if a wrong parity bit is received. The received parity bit itself will be stored in RBUF too.

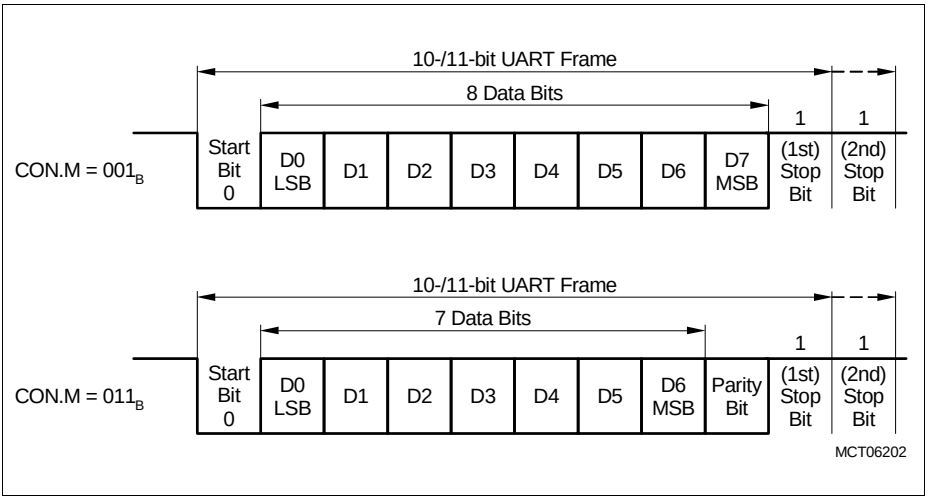

Figure 20-3 Asynchronous 8-bit Frames

9-bit Data Frames

The 9-bit data frames consist of nine data bits D8 … D0 (CON.M = 100_B), or of eight data bits D7 … D0 plus an automatically generated parity bit (CON.M = 111_B) or of eight data bits D7 … D0 plus wake-up bit (CON.M = 101_B). Parity may be odd or even, depending on bit CON.ODD. An even parity bit will be set if the modulo-2-sum of the eight data bits is 1. An odd parity bit will be cleared in this case. Parity checking is enabled via bit CON.PEN (always OFF in 9-bit data and wake-up mode). The parity error flag CON.PE will be set along with the error interrupt request flag if a wrong parity bit is received. The received parity bit itself will be stored in RBUF too.

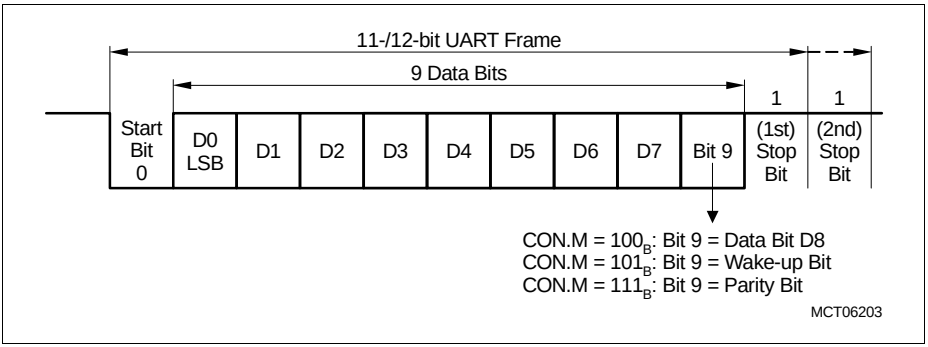

Figure 20-4 Asynchronous 9-bit Frames

In Wake-up Mode (CON.M = 101_B), received frames are transferred to the receive buffer register only if the 9th bit (the wake-up bit) of the frame is 1. If this bit is 0, no receive interrupt request will be activated and no data will be transferred.

This feature can be used to control communication in multi-processor systems, for example:
When the master processor aims to transmit a block of data to one of several slaves, it first sends out an address ‘byte’ (in this case, a ‘byte’ consists of nine bits) that identifies the target slave. An address ‘byte’ differs from a data ‘byte’ in that the additional 9th bit is a 1 for an address ‘byte’ but is a 0 for a data ‘byte’, so, no slave will be interrupted by a data ‘byte’. An address ‘byte’ will interrupt all slaves (operating in 8-bit data + wake-up bit mode), so each slave can examine the eight LSBs of the received character (the address). The addressed slave will switch to 9-bit data mode (for example, by clearing bit CON.M[0]), which enables it to also receive the data bytes that will be coming (having the wake-up bit cleared). The slaves that were not being addressed remain in 8-bit data + wake-up bit mode, ignoring the following data ‘bytes’.

20.1.3.2 Asynchronous Transmission

Asynchronous transmission begins when the next overflow of the divide-by-16 baud rate timer (transition of the baud rate clock f_{BR}) occurs, if bit CON.R is set and data has been loaded into TBUF. The transmitted data frame consists of three elements:

1. The start bit
2. The data field (8 or 9 bits, LSB first, including a parity bit, if selected)
3. The delimiter (1 or 2 stop bits)

Data transmission is double-buffered. When the transmitter is idle, the transmit data loaded into TBUF is immediately moved to the transmit shift register; thus, freeing TBUF for the next transmit data to be loaded. This is indicated by the transmit buffer interrupt request line TBIR being activated. TBUF may then be loaded with the next transmit data while transmission of the previous one continues.

The Transmit Interrupt Request line TIR will be activated before the last bit of a frame is transmitted, that is, before the first or the second stop bit is shifted out of the transmit shift register.

Note: A dedicated GPIO device pin which is connected to the module output pin TXD must be configured by software as alternate data output for asynchronous transmission.

20.1.3.3 Asynchronous Reception

Asynchronous reception is initiated by a falling edge (1-to-0 transition) on pin RXD, on the condition that bits CON.R and CON.REN are set. The receive data input pin RXD is sampled at sixteen times the rate of the selected baud rate. A majority decision of the 7^{th}, 8^{th} and 9^{th} sample determines the effective sampled bit value. This avoids erroneous results that may be caused by noise.

If the detected value is not a 0 when the start bit is sampled, the receive circuit is reset and waits for the next 1-to-0 transition at pin RXD. If the start bit proves valid, the receive circuit continues sampling and shifts the incoming data frame into the receive shift register.

When the last stop bit has been received, the contents of the receive shift register are transferred to the Receive Data Buffer Register RBUF. Simultaneously, the receive interrupt request line RIR is activated after the 9^{th} sample in the last stop bit time-slot (as programmed), regardless whether valid stop bits have been received or not. The receive circuit then waits for the next start bit (1-to-0 transition) at the receive data input line.

Note: A dedicated GPIO pin that is connected to the module input pin RXD must be configured by software as input for asynchronous reception.

Asynchronous reception is stopped by clearing bit CON.REN. A currently received frame is completed including generation of the receive interrupt request and an error interrupt request, if appropriate. Start bits that follow this frame will not be recognized.

Note: In wake-up mode, received frames are transferred to the receive buffer register only if the 9th bit (the wake-up bit) is 1. If this bit is 0, no receive interrupt request will be activated and no data will be transferred.

20.1.3.4 RXD/TXD Data Path Selection in Asynchronous Modes

The data paths for the serial input and output data in Asynchronous Modes are affected by control bit CON.LB (loop-back) as shown in **Figure 20-5**.

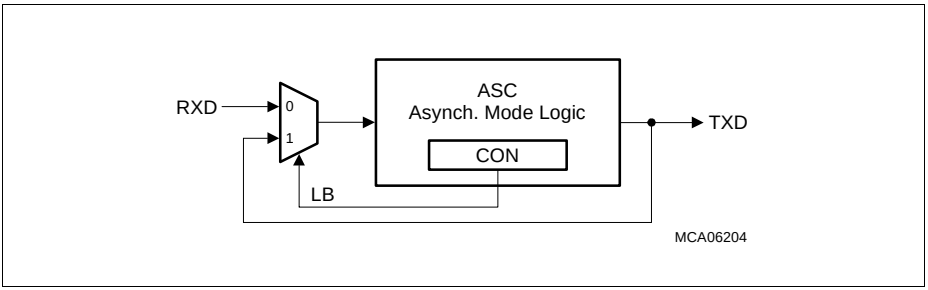

Figure 20-5 RXD/TXD Data Path Selection in Asynchronous Modes

20.1.4 Synchronous Operation

Synchronous Mode supports half-duplex communication, usable for simple I/O expansion via shift registers. Data is transmitted and received via pin RXD while pin TXD outputs the shift clock. These signals are typically connected as alternate functions with GPIO port pins. Synchronous Mode is selected with CON.M = 000_B.

Eight data bits are transmitted or received synchronous to a shift clock generated by the internal baud rate generator. The shift clock is active only as long as data bits are transmitted or received.

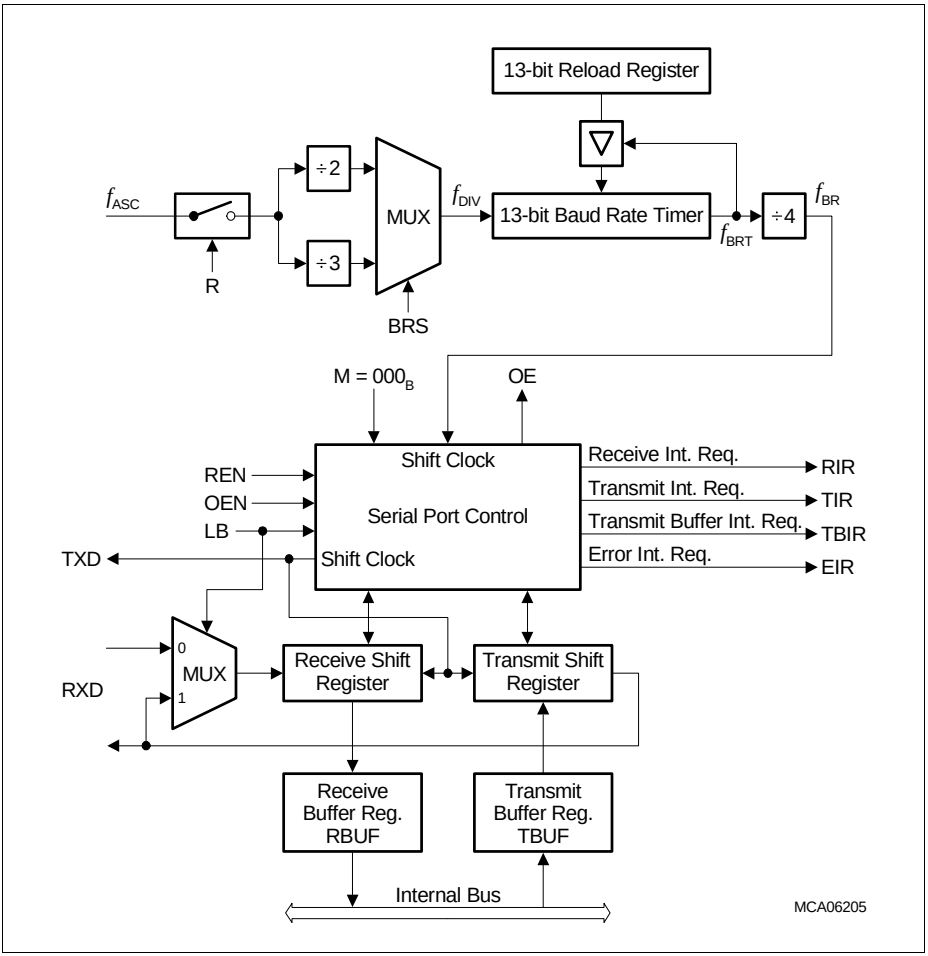

Figure 20-6 Synchronous Mode of Serial Channel ASC

20.1.4.1 Synchronous Transmission

Synchronous transmission begins within four state times after data has been loaded into TBUF, provided that CON.R is set and CON.REN = 0 (half-duplex, no reception), with one exception: in Loop-back Mode (bit CON.LB set), CON.REN must be set for reception of the transmitted byte. Data transmission is double-buffered. When the transmitter is idle, the transmit data loaded into TBUF is immediately moved to the transmit shift register, thus freeing TBUF for the next data to be sent. This is indicated by the transmit buffer interrupt request line TBIR being activated. TBUF may now be loaded with the next data, while transmission of the previous one continues. The data bits are transmitted synchronously with the shift clock. After the bit time for the 8th data bit, both TXD and RXD will be set to high level, the transmit interrupt request line TIR is activated, and serial data transmission stops.

Note: The dedicated GPIO device pins that are connected to TXD and RXD must be configured by software as alternate data outputs in order to provide the shift clock and the output data during synchronous transmission.

20.1.4.2 Synchronous Reception

Synchronous reception is initiated by setting bit CON.REN = 1. If bit CON.R = 1, the data applied at RXD is clocked into the receive shift register synchronously to the clock which is output at TXD. After the 8th bit has been shifted in, the contents of the receive shift register are transferred to the receive data buffer RBUF, the receive interrupt request line RIR is activated, the receiver enable bit CON.REN is reset, and serial data reception stops.

Synchronous reception is stopped by clearing bit CON.REN. Any byte that is currently being received is completed, including the generation of the receive interrupt request and an error interrupt request, if appropriate. Writing to the transmit buffer register while a reception is in progress has no effect on reception and will not start a transmission.

If a previously received byte has not been read out of the receive buffer register by the time the reception of the next byte is complete, both the error interrupt request line EIR and the overrun error status flag CON.OE will be activated/set, provided that the overrun check has been enabled by bit CON.OEN.

Note: The dedicated GPIO device pin that is connected to TXD must be configured by software as alternate data output in order to provide the shift clock. The dedicated GPIO device pin that is connected to RXD must be configured by software as input during synchronous reception.

20.1.4.3 Synchronous Timing

Figure 20-7 shows timing diagrams of the ASC Synchronous Mode data reception and data transmission. In idle state, the shift clock is at high level. With the beginning of a synchronous transmission of a data byte, the data is shifted out at RXD with the falling edge of the shift clock. If a data byte is received through RXD, data is latched with the rising edge of the shift clock.

One shift clock cycle (f_{BR}) delay is inserted between two consecutive receive or transmit data bytes.

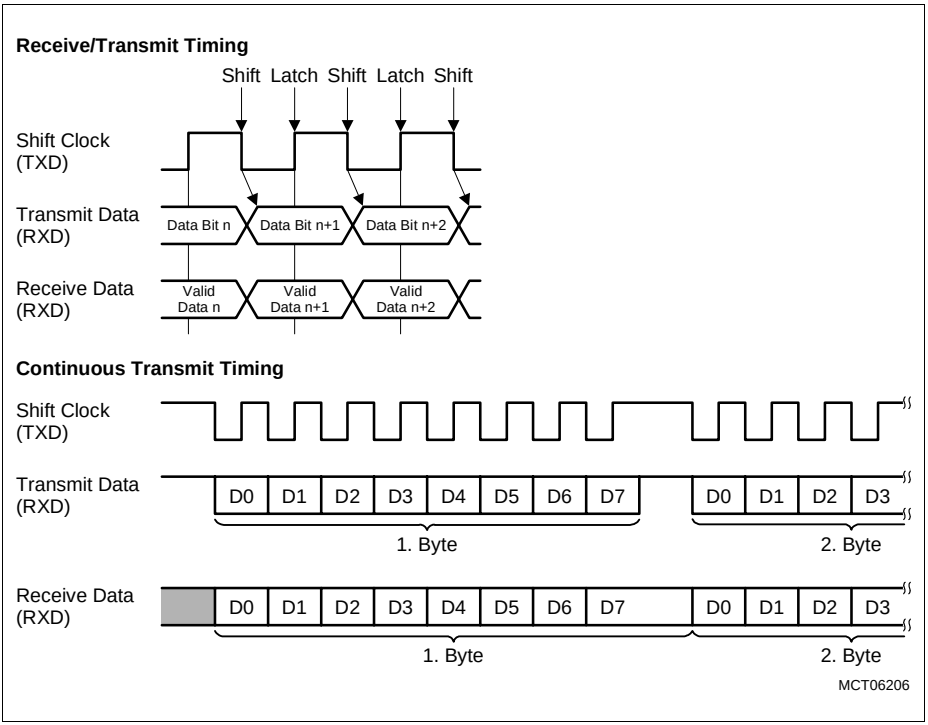

Figure 20-7 ASC Synchronous Mode Waveforms

20.1.5 Baud Rate Generation

The ASC has its own dedicated 13-bit baud rate generator with 13-bit reload capability, allowing baud rate generation independent of other timers.

The baud rate generator is clocked with a clock (f_{DIV}) which is derived via a prescaler from the ASC module clock f_{ASC}. The baud rate timer is counting downwards and can be started or stopped through the baud rate generator run bit CON.R. Each underflow of the timer generates one clock pulse to the serial channel. The timer is reloaded with the value stored in its 13-bit reload register at each underflow. The resulting clock f_{BRT} is again divided by a factor for the baud rate clock (÷ 16 in asynchronous operating modes and ÷ 4 in synchronous operating mode). The prescaler is selected by the bits CON.BRS and CON.FDE. In the asynchronous operating modes, a fractional divider prescaler unit is available (in addition to the two fixed dividers) that allows selection of prescaler divider ratios of n/512 with n = 0-511. Therefore, the baud rate of ASC is determined by the module clock, the content of register FDV, the reload value in register BG, and the operating mode (asynchronous or synchronous).

Register BG is the dual-function baud rate generator/reload register. Reading BG returns the contents of the timer in bit field BR_VALUE (bits 31:13 return zero), while writing to BG always updates the reload register (bits 31:13 are insignificant).

An auto-reload of the timer with the contents of the reload register is performed each time BG is written to. However, if CON.R = 0 at the time the write operation to BG is performed, the timer will not be reloaded until the first instruction cycle after CON.R = 1. For a clean baud rate initialization, BG should only be written if CON.R = 0. If BG is written with CON.R = 1, an unpredictable behavior of the ASC may occur during running transmit or receive operations.

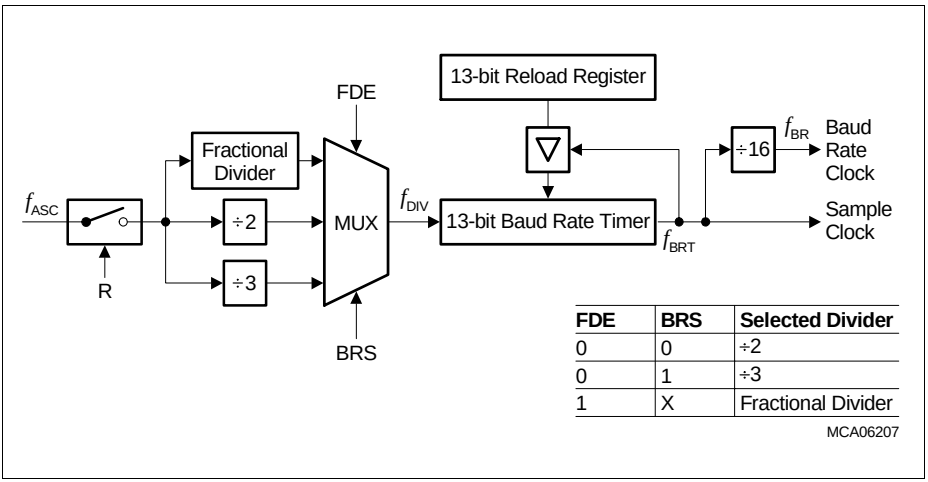
20.1.5.1 Baud Rates in Asynchronous Mode

For asynchronous operation, the baud rate generator provides a clock f_{BRT} with sixteen times the rate of the established baud rate. Every received bit is sampled on the 7th, 8th and 9th cycle of this clock. The clock divider circuitry, which generates the input clock f_{DIV} for the 13-bit baud rate timer, is extended by a fractional divider circuitry that allows the adjustment of more accurate baud rates and the extension of the baud rate range.

The baud rate of the baud rate generator depends on the settings of the following bits and register values:

- Input clock f_{ASC}
- Selection of the baud rate timer input clock f_{DIV} by bits CON.FDE and CON.BRS
- If bit CON.FDE = 1 (fractional divider): value of register FDV
- Value of the 13-bit reload register BG

The output clock of the baud rate timer with the reload register is the sample clock in the asynchronous operating modes of the ASC. For baud rate calculations, this baud rate clock f_{BR} is derived from the sample clock f_{BRT} by a division of sixteen.



FDE	BRS	Selected Divider
0	0	÷2
0	1	÷3
1	X	Fractional Divider

Figure 20-8 ASC Baud Rate Generator Circuitry in Asynchronous Modes

Using the Fixed Input Clock Divider

The baud rate for asynchronous operation of the serial channel ASC when using the fixed input clock divider ratios (CON.FDE = 0) and the required BG reload value for a given baud rate can be determined by the following formulas:

Table 20-1 Asynchronous Baud Rate Formulas using the Fixed Input Clock Dividers

FDE	BRS	BG	Formula
0	0	0 … 8191	$\text{Baud rate} = \frac{f_{ASC}}{32 \times (BG + 1)}$ $BG = \frac{f_{ASC}}{32 \times \text{Baud rate}} - 1$
	1		$\text{Baud rate} = \frac{f_{ASC}}{48 \times (BG + 1)}$ $BG = \frac{f_{ASC}}{48 \times \text{Baud rate}} - 1$

BG represents the content of the reload register bit field BG.BR_VALUE, taken as an unsigned 13-bit integer.

The maximum baud rate that can be achieved for the asynchronous operating modes when using the two fixed clock dividers and a module clock of 110 MHz is 3.4375 Mbit/s. **Table 20-2** lists various commonly used baud rates together with the required reload values and the deviation errors compared to the intended baud rate.

Table 20-2 Typical Asynchronous Baud Rates using Fixed Input Clock Dividers

Baud Rate	CON.BRS = 0, f_{ASC} = 110 MHz		CON.BRS = 1, f_{ASC} = 110 MHz	
	Deviation Error	Reload Value	Deviation Error	Reload Value
3.4375 Mbit/s	–	0000_H	–	–
19.2 kbit/s	+0.02% / -0.6%	$00B2_H$ / $00B3_H$	+0.3% / -0.6%	0076_H / 0077_H
9600 bit/s	+0.02% / -0.3%	0165_H / 0166_H	+0.3% / -0.1%	$00ED_H$ / $00EE_H$
4800 bit/s	+0.02% / -0.1%	$02CB_H$ / $02CC_H$	+0.1% / -0.1%	$01DC_H$ / $01DD_H$

Note: CON.FDE must be 0 to achieve the baud rates in the table above. The deviation errors given in the table are rounded. Using a baud rate crystal will provide correct baud rates without deviation errors.

Using the Fractional Divider

When the fractional divider is selected, the input clock f_{DIV} for the baud rate timer is derived from the module clock f_{ASC} by a programmable fractional divider. If CON.FDE = 1, the fractional divider is activated. It divides f_{ASC} by a fraction of n/512 for any value of n from 0 to 511. If n = 0, the divider ratio is 1, which means that $f_{DIV} = f_{ASC}$. In general, the fractional divider allows the baud rate to be programmed with much better accuracy than with the two fixed prescaler divider stages.

Note: In fractional divider mode, the clock f_{DIV} can have a maximum period jitter of one f_{ASC} clock period.

Table 20-3 Asynchronous Baud Rate Formulas using the Fractional Input Clock Divider

FDE	BRS	BG	FDV	Formula
1	–	0 … 8191	1 … 511	$\text{Baud rate} = \frac{FDV}{512} \times \frac{f_{ASC}}{16 \times (BG + 1)}$
			0	$\text{Baud rate} = \frac{f_{ASC}}{16 \times (BG + 1)}$

BG represents the content of the reload register bit field BG.BR_VALUE, taken as an unsigned 13-bit integer. FDV represents the contents of the fractional divider register bit field FDV.FD_VALUE, taken as an unsigned 9-bit integer.

Table 20-4 Typical Asynchronous Baud Rates using the Fractional Input Clock Divider

f_{ASC}	Desired Baud Rate	BG	FDV	Resulting Baud Rate	Deviation
110 MHz	115.2 kbit/s	$003A_H$	$1FA_H$	115.160 kbit/s	-0.04%
	57.6 kbit/s	0075_H	$1FA_H$	57.579 kbit/s	-0.04%

20.1.5.2 Baud Rates in Synchronous Mode

For synchronous operation, the baud rate generator provides a clock f_{BRT} that runs with four times the established baud rate (see **Figure 20-9**).

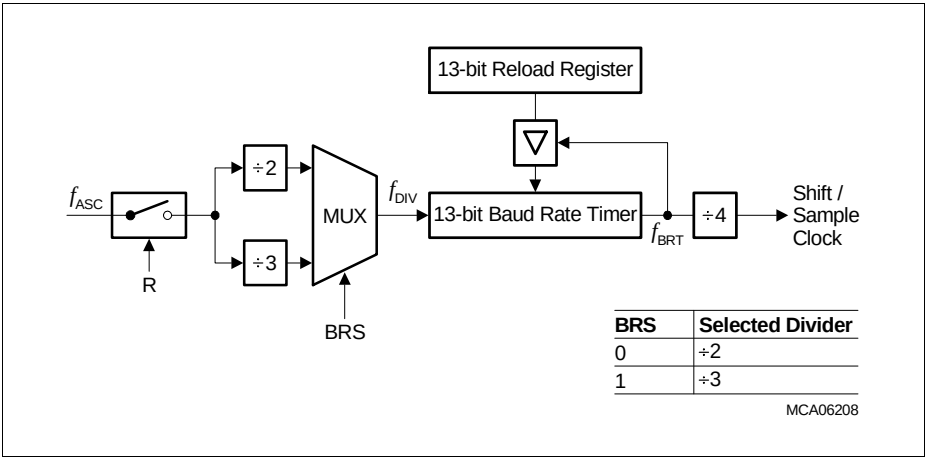


Figure 20-9 ASC Baud Rate Generator Circuitry in Synchronous Mode

The baud rate for synchronous operation of the serial channel ASC can be determined by the formulas as shown in **Table 20-5**.

Table 20-5 Synchronous Baud Rate Formulas

BRS	BG	Formula
0	0 … 8191	$\text{Baud rate} = \frac{f_{ASC}}{8 \times (BG + 1)}$ $\quad BG = \frac{f_{ASC}}{8 \times \text{Baud rate}} - 1$
1		$\text{Baud rate} = \frac{f_{ASC}}{12 \times (BG + 1)}$ $\quad BG = \frac{f_{ASC}}{12 \times \text{Baud rate}} - 1$

BG represents the content of the reload register bit field BG.BR_VALUE, taken as an unsigned 13-bit integer.

The maximum baud rate that can be achieved in Synchronous Mode when using a module clock of MHz is Mbit/s.

20.1.6 Hardware Error Detection Capabilities

To improve the reliability of serial data exchange, the serial channel ASC provides an error interrupt request flag that indicates the presence of an error and three (selectable) error status flags in register CON that indicate which error has been detected during reception. Upon completion of a reception, the error interrupt request line EIR will be activated simultaneously with the receive interrupt request line RIR, if one or more of the following conditions are met:

- If the framing error detection enable bit CON.FEN is set and any of the expected stop bits is not high, the framing error flag CON.FE is set, indicating that the error interrupt request is due to a framing error (asynchronous operating modes only).
- If the parity error detection enable bit CON.PEN is set in the modes where a parity bit is received and the parity check on the received data bits proves false, the parity error flag CON.PE is set, indicating that the error interrupt request is due to a parity error (asynchronous operating modes only).
- If the overrun error detection enable bit CON.OEN is set and the last character received was not read out of the receive buffer by software or DMA transfer at the time the reception of a new frame is complete, the overrun error flag CON.OE is set indicating that the error interrupt request is due to an overrun error (Asynchronous and Synchronous Modes).

20.1.7 Interrupts

Four interrupt sources are provided for serial channel ASC. Line TIR indicates a transmit interrupt, TBIR indicates a transmit buffer interrupt, RIR indicates a receive interrupt, and EIR indicates an error interrupt of the serial channel. The interrupt output lines TBIR, TIR, RIR, and EIR are activated (active state) for two periods of the module clock f_{ASC}.

The cause of an error interrupt request EIR (framing, parity, overrun error) can be identified by the error status flags CON.FE, CON.PE, and CON.OE.

Note: By contrast to the error interrupt request line EIR, the error status flags CON.FE/CON.PE/CON.OE are not reset automatically but must be cleared by software.

For normal operation (that is, other than error interrupt), the ASC provides three interrupt requests to control data exchange via this serial channel:

- TBIR is activated when data is moved from TBUF to the transmit shift register.
- TIR is activated before the last bit of an asynchronous frame is transmitted, or after the last bit of a synchronous frame has been transmitted.
- RIR is activated when the received frame is moved to RBUF.

While the task of the receive interrupt handler is quite clear, the transmitter is serviced by two interrupt handlers. This provides advantages for the servicing software.

For single transfers, it is sufficient to use the transmitter interrupt (TIR), which indicates that the previously loaded data has been transmitted, except for the last bit of an asynchronous frame.

For multiple back-to-back transfers, it is necessary to load the following piece of data at least before the last bit of the previous frame has been transmitted. In Asynchronous Mode, this leaves just one bit-time for the handler to respond to the transmitter interrupt request; in Synchronous Mode, it is entirely impossible.

Using the Transmit Buffer Interrupt (TBIR) to reload transmit data provides the time necessary to transmit a complete frame for the service routine, as TBUF may be reloaded while the previous data is still being transmitted.

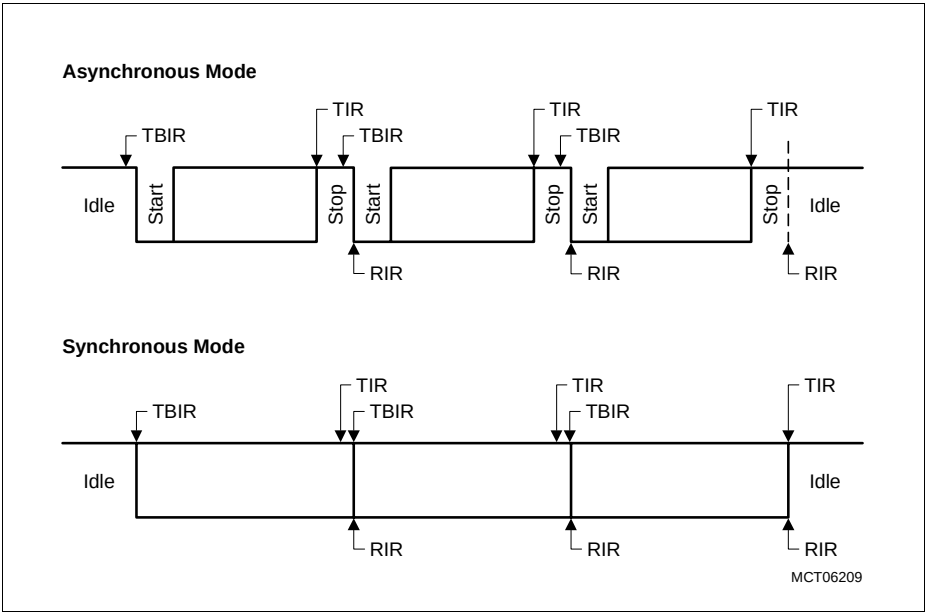

Figure 20-10 ASC Interrupt Generation

As shown in **Figure 20-10**, TBIR is an early trigger for the reload routine, while TIR indicates the completed transmission. Software using handshake should, therefore, rely on TIR at the end of a data block to ensure that all data has been transmitted.

20.2 ASC Kernel Registers

This section describes the kernel registers of the ASC module. All ASC kernel register names described in this section will be referenced in other parts of the TC1798 User´s Manual by the module name prefix “ASC0_” for the ASC0 interface and “ASC1_” for the ASC1 interface.

All registers in the ASC address spaces are reset with the application reset.

ASC Kernel Register Overview

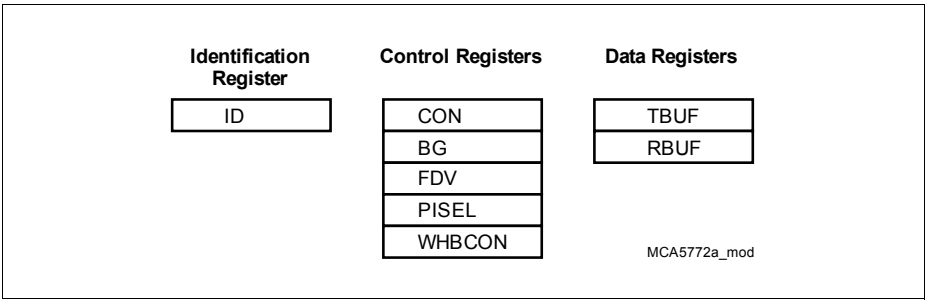

Figure 20-11 ASC Kernel Registers

The complete and detailed address map of the of the ASC module and its registers is described in **Table 20-10** on **Page 20-42**.

Table 20-6 Registers Address Space

Module	Base Address	End Address	Note
ASC0	F000 0A00$_H$	F000 0AFF$_H$	–
ASC1	F000 0B00$_H$	F000 0BFF$_H$	–

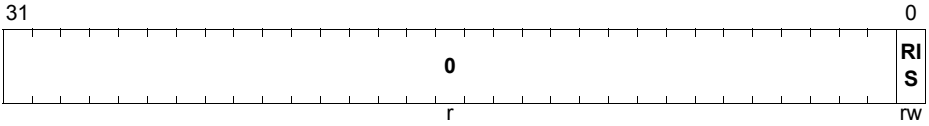
20.2.1 Control Registers

The ASC module kernel provides two receive input lines, RXD_I0 and RXD_I1. Bit RIS in the Peripheral Input Select Register PISEL determines which of theses two input lines is taken for RXD receive input purposes.

PISEL
Peripheral Input Select Register (04_H) Reset Value: 0000 0000$_H$

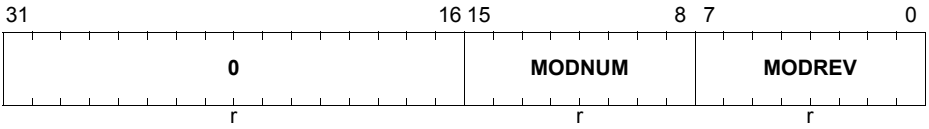


Field	Bits	Type	Description
RIS	0	rw	**Receive Input Select** 0_B ASC receiver input RXD_I0 selected 1_B ASC receiver input RXD_I1 selected
0	[31:1]	r	**Reserved** Read as 0; should be written with 0.

Note: Implementation specific details (RIS functionality) see "Peripheral Input Select Register" on Page 20-35.

The ASC Module Identification Register ID contains read-only information about the module version.

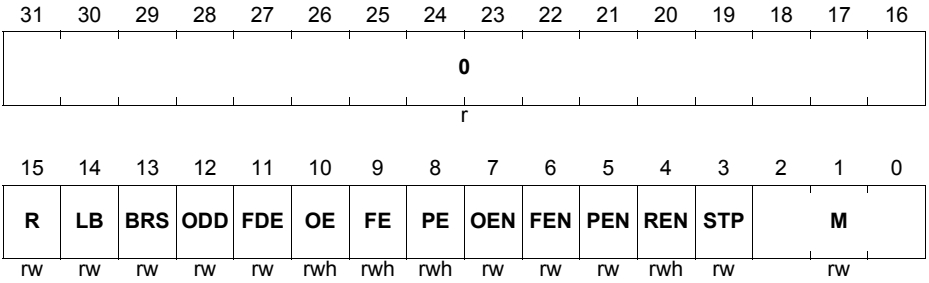
ID
Module Identification Register **(08_H)** **Reset Value: 0000 44XX$_H$**



Field	Bits	Type	Description
MODREV	[7:0]	r	**Module Revision Number** This bit field defines the module revision number. The value of a module revision starts with 01_H (first revision).
MODNUM	[15:8]	r	**Module Number Value** This bit field defines the module identification number for the ASC: 44_H
0	[31:16]	r	**Reserved** Read as 0.

The serial operating modes of the ASC module are controlled by its Control Register CON. This register contains control bits for mode and error check selection, and status flags for error identification.

CON
Control Register **(10_H)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
M	[2:0]	rw	**Mode Selection** 000_B 8-bit data Synchronous Mode 001_B 8-bit data Asynchronous Mode 010_B Reserved. Do not use this combination. 011_B 7-bit data + parity Asynchronous Mode 100_B 9-bit data Asynchronous Mode 101_B 8-bit data + wake up bit Asynchronous Mode 110_B Reserved. Do not use this combination. 111_B 8-bit data + parity Asynchronous Mode
STP	3	rw	**Number of Stop Bit Selection** 0_B One stop bit 1_B Two stop bits
REN	4	rwh	**Receiver Enable Control** 0_B Receiver disabled 1_B Receiver enabled Bit is reset by hardware after reception of a byte in Synchronous Mode.
PEN	5	rw	**Parity Check Enable (asynchronous mode only)** 0_B Ignore parity 1_B Check parity

Field	Bits	Type	Description
FEN	6	rw	**Framing Check Enable (asynchronous mode only)** 0_B Ignore framing errors 1_B Check framing errors
OEN	7	rw	**Overrun Check Enable** 0_B Ignore overrun errors 1_B Check overrun errors
PE	8	rwh	**Parity Error Flag** Set by hardware on a parity error (PEN = 1). Must be reset by software.
FE	9	rwh	**Framing Error Flag** Set by hardware on a framing error (FEN = 1). Must be reset by software.
OE	10	rwh	**Overrun Error Flag** Set by hardware on an overrun error (OEN = 1). Must be reset by software.
FDE	11	rw	**Fractional Divider Enable** 0_B Fractional divider disabled 1_B Fractional divider is enabled and used as prescaler for baud rate timer (bit BRS is don't care)
ODD	12	rw	**Parity Selection** 0_B Even parity selected (parity bit = 1 on odd number of 1s in data, parity bit = 0 on even number of 1s in data) 1_B Odd parity selected (parity bit = 1 on even number of 1s in data, parity bit = 0 on odd number of 1s in data)
BRS	13	rw	**Baud Rate Selection** 0_B Baud rate timer prescaler divide-by-2 selected 1_B Baud rate timer prescaler divide-by-3 selected BRS is don't care if FDE = 1 (fractional divider enabled)
LB	14	rw	**Loop-back Mode Enable** 0_B Loop-Back mode disabled 1_B Loop-Back mode enabled

Field	Bits	Type	Description
R	15	rw	**Baud Rate Generator Run Control** 0_B Baud rate generator disabled (ASC inactive) 1_B Baud rate generator enabled Register BG should only be written if R = 0.
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

Serial data transmission or reception is possible only when the run bit CON.R is set to 1. Otherwise, the serial interface is idle. To avoid unpredictable behavior of the serial interface, do not program the mode control field CON.M to one of the reserved combinations.

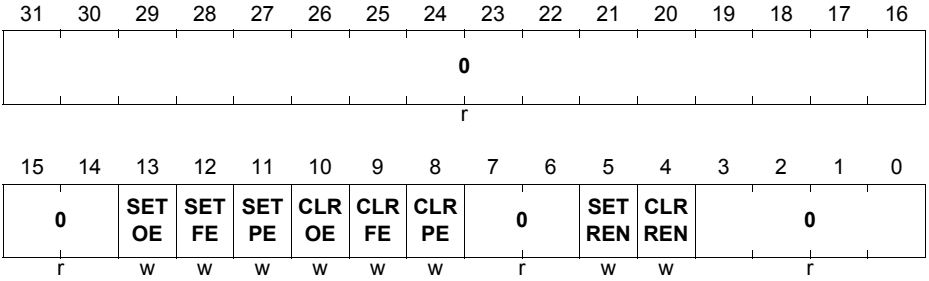
Critical “rwh” Bits

Register CON contains three error flags: PE, FE, and OE. If the software modifies only one of these error flags, it uses typically a Read-Modify-Write (RMW) instruction. When one of the other error flags that is not intended to be modified by the RMW instruction is changed by hardware after the read access but before the write back access of the RMW instruction, it is overwritten with the old bit value, and the hardware change of the bit gets lost. This problem does not affect the bits that are intended to be modified by the RMW instruction. It only affects bits that were not intended to be changed with the RMW instruction.

The three error flags in register CON and the REN bit can be additionally set or reset by software via register WHBCON. This capability avoids the problem with the CON register RMW instruction access to the error flags. WHBCON is a write-only register. Reading WHBCON always returns 0000 0000_H.

WHBCON

Write Hardware Bits Control Register (50_H) **Reset Value: $0000\ 0000_H$**



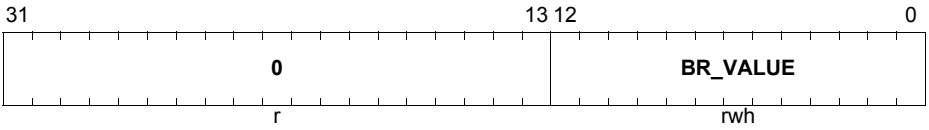
Field	Bits	Type	Description
CLRREN	4	w	**Clear Receiver Enable Bit** 0_B No effect 1_B Bit CON.REN is cleared. Bit is always read as 0.
SETREN	5	w	**Set Receiver Enable Bit** 0_B No effect 1_B Bit CON.REN is set. Bit is always read as 0.
CLRPE	8	w	**Clear Parity Error Flag** 0_B No effect 1_B Bit CON.PE is cleared. Bit is always read as 0.
CLRFE	9	w	**Clear Framing Error Flag** 0_B No effect 1_B Bit CON.FE is cleared. Bit is always read as 0.
CLROE	10	w	**Clear Overrun Error Flag** 0_B No effect 1_B Bit CON.OE is cleared. Bit is always read as 0.
SETPE	11	w	**Set Parity Error Flag** 0_B No effect 1_B Bit CON.PE is set. Bit is always read as 0.

Field	Bits	Type	Description
SETFE	12	w	**Set Framing Error Flag** 0_B No effect 1_B Bit CON.FE is set. Bit is always read as 0.
SETOE	13	w	**Set Overrun Error Flag** 0_B No effect 1_B Bit CON.OE is set. Bit is always read as 0.
0	[3:0], [7:6], [31:14]	r	**Reserved** Read as 0; should be written with 0.

Note: When the set and clear bits for an error flag are set at the same time during a WHBCON write operation (e.g SETPE = CLRPE = 1), the error flag in CON is not affected.

The Baud Rate Timer Reload Register BG of the ASC module contains the 13-bit reload value for the baud rate timer in Asynchronous and Synchronous Modes.

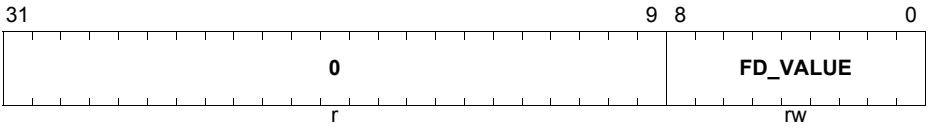
BG
Baud Rate Timer/Reload Register (14_H) Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
BR_VALUE	[12:0]	rwh	**Baud Rate Timer/Reload Register Value** Reading BR_VALUE returns the 13-bit content of the baud rate timer. Writing BR_VALUE loads the baud rate timer reload register. BG should only be written if CON.R = 0.
0	[31:13]	r	**Reserved** Read as 0; should be written with 0.

The Fractional Divider Register FDV of the ASC module contains the 9-bit divider value for the fractional divider (asynchronous mode only).

FDV
Fractional Divider Register (18_H) Reset Value: 0000 0000$_H$

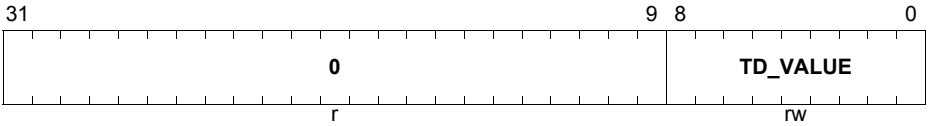


Field	Bits	Type	Description
FD_VALUE	[8:0]	rw	**Fractional Divider Register Value** FD_VALUE contains the 9-bit value n of the fractional divider which determines the fractional divider ratio n/512 (n = 0-511). With n = 0, the fractional divider is switched off (divider ratio = 1).
0	[31:9]	r	**Reserved** Read as 0; should be written with 0.

20.2.2 Data Registers

The Transmit Buffer Register TBUF of the ASC module contains the transmit data value in Asynchronous And Synchronous Modes.

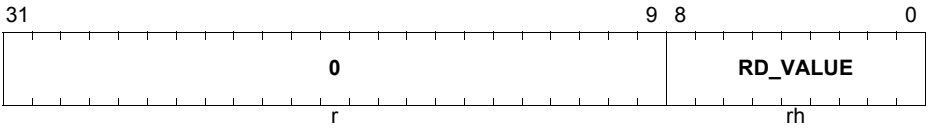
TBUF
Transmit Buffer Register **(20_H)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
TD_VALUE	[8:0]	rw	**Transmit Data Register Value** TBUF contains the data to be transmitted in the asynchronous and synchronous operating modes of the ASC. Data transmission is double-buffered; therefore, a new value can be written to TBUF before the transmission of the previous value is complete.
0	[31:9]	r	**Reserved** Read as 0; should be written with 0.

The receive buffer register RBUF of the ASC module contains the receive data value in Asynchronous and Synchronous Modes.

RBUF
Receive Buffer Register **(24_H)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
RD_VALUE	[8:0]	rh	**Receive Data Register Value** RBUF contains the received data bits and, depending on the selected mode, the parity bit in the asynchronous and synchronous operating modes of the ASC. In Asynchronous Mode, with CON.M = 011_B (7-bit data + parity), the received parity bit is written into RBUF.7. In Asynchronous Mode, with CON.M = 111_B (8-bit data + parity), the received parity bit is written into RBUF.8.
0	[31:9]	r	**Reserved** Read as 0.

20.3 ASC0/ASC1 Module Implementation

This section describes ASC0/ASC1 module interfaces with the clock control, port connections, interrupt control, and address decoding.

20.3.1 Interfaces of the ASC Modules

The serial I/O lines of both modules are connected either to Port 5 or Port 6. Each of the ASC modules is further supplied with interrupt control, address decoding, and port control logic. Two DMA requests can be generated by each ASC module. Both ASC modules are supplied by one common clock control unit.

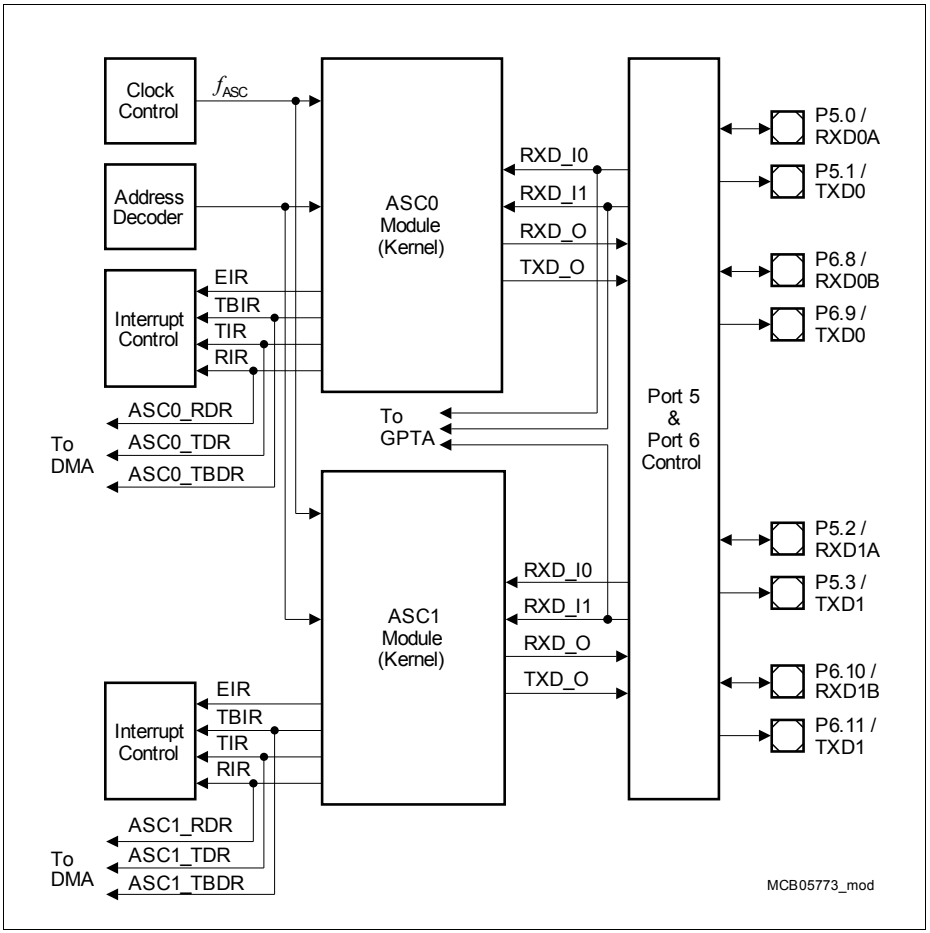


Figure 20-12 ASC0/ASC1 Module Implementation and Interconnections

Some of the receive inputs of the ASC0 and ASC1 are connected via a multiplexer to an LTC input of the GPTA module. Details are described in the SCU and the GPTA chapters.

20.3.2 ASC0/ASC1 Module Related External Registers

Figure 20-13 summarizes the module-related external registers which are required for ASC0/ASC1 programming (see also **Figure 20-11** for the module kernel-specific registers).

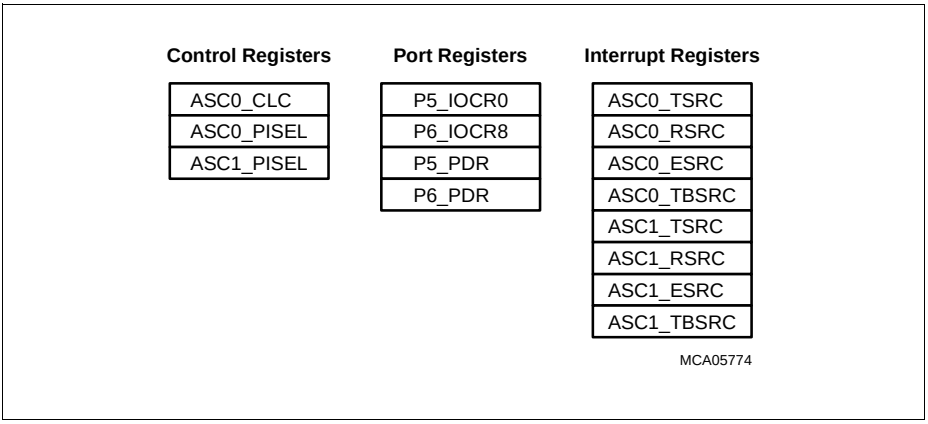

Figure 20-13 ASC0/ASC1 Implementation-specific Special Function Registers

20.3.2.1 Clock Control Register

The Clock Control Register ASC0_CLC allows the programmer to adapt the functionality and power consumption of the ASC modules to the requirements of the application. The description below shows the clock control register functionality which is implemented for the ASC modules. Because ASC0 and ASC1 share one common clock control interface, ASC0_CLC controls the f_{ASC} module clock signal, sleep mode, suspend mode and fast shut-off mode for both modules.

ASC0_CLC
ASC0 Clock Control Register **(00_H)** **Reset Value: 0000 0003$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RMC								0		FSOE	SBWE	EDIS	SPEN	DISS	DISR
rw								r		rw	w	rw	rw	r	rw

Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module.
DISS	1	r	**Module Disable Status Bit** Bit indicates the current status of the module.
SPEN	2	rw	**Module Suspend Enable for OCDS** Used to enable the suspend mode.
EDIS	3	rw	**Sleep Mode Enable Control** Used to control module's sleep mode.
SBWE	4	w	**Module Suspend Bit Write Enable for OCDS** Determines whether SPEN and FSOE are write-protected.
FSOE	5	rw	**Fast Switch Off Enable** Used to switch off fast clock in Suspend Mode.
RMC	[15:8]	rw	**8-bit Clock Divider Value in RUN Mode**
0	[7:6], [31:16]	r	**Reserved** Read as 0; should be written with 0.

Note: After a hardware reset operation, the two ASC modules are disabled.

Note: The number of module clock cycles (wait states) which are required for a "destructive read" access (means: flags/bits are set/reset by one read access) to ASC module register depends on the selected CLC clock frequency, which is selected via bit field RMC in the CLC register. Therefore, increasing ASC0_CLC.RMC may result in a longer FPI Bus read cycle access time.

20.3.2.2 Peripheral Input Select Register

The ASC0/ASC1 modules include a peripheral input select registers that are used to switch the RXD input lines of the ASC0/ASC1 module kernels between different pairs of pins of Port 5 and Port 6 as shown in **Figure 20-14**. Register ASC0_PISEL controls the RXD input selection for ASC0, and ASC1_PISEL controls the RXD input selection for ASC1.

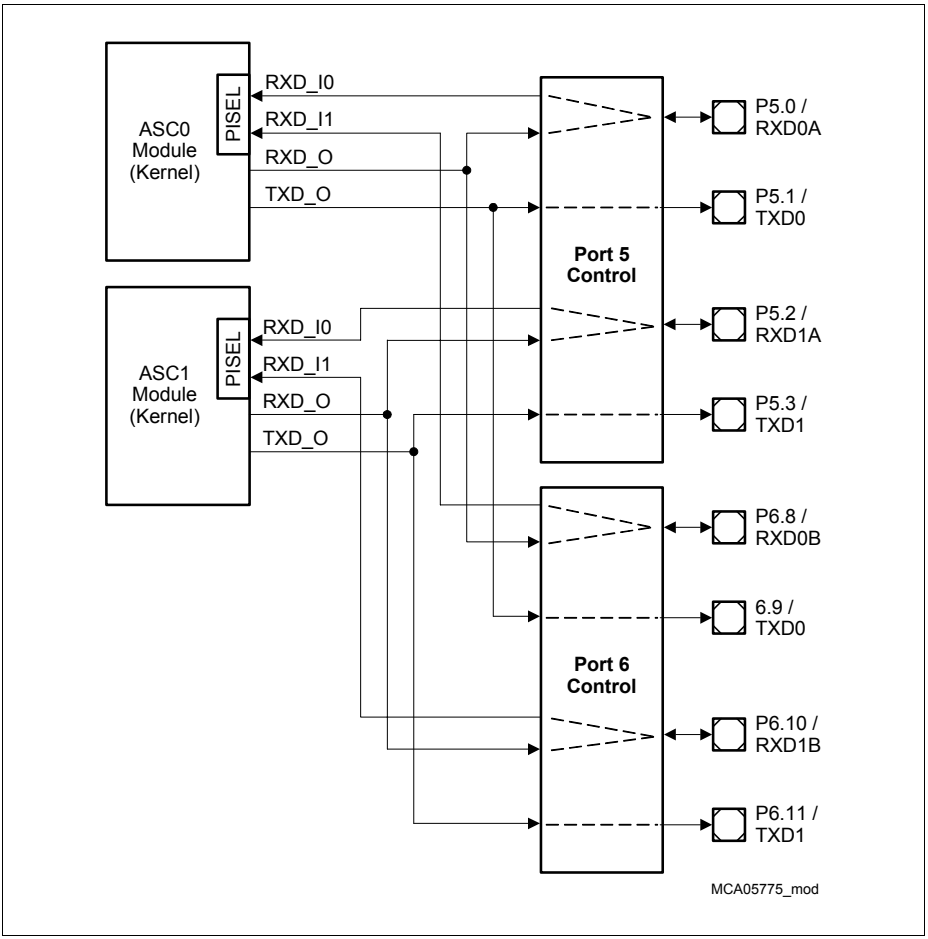

Figure 20-14 RXD Input Line Selection of the ASC Modules

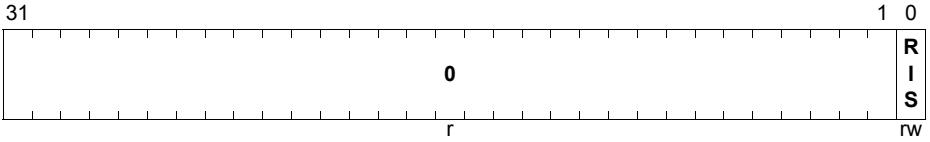
ASC0_PISEL
ASC0 Peripheral Input Select Register

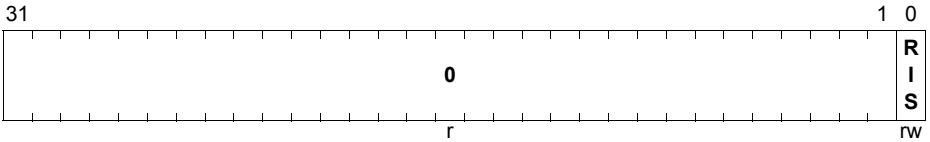
(04_H) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
RIS	0	rw	**Receive Input Select** 0_B ASC0 receiver input RXD0A (P5.0) selected 1_B ASC0 receiver input RXD0B (P6.8) selected
0	[31:1]	0	**Reserved** Read as 0; should be written with 0.

ASC1_PISEL
ASC1 Peripheral Input Select Register

(04_H) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
RIS	0	rw	**Receive Input Select** 0_B ASC1 receiver input RXD1A (P5.2) selected 1_B ASC1 receiver input RXD1B (P6.10) selected
0	[31:1]	0	**Reserved** Read as 0; should be written with 0.

20.3.2.3 Port Control Registers

As shown in **Figure 20-14**, the I/O lines of the ASC modules are connected to Class A2 port pins of Port 3. Additionally to the PISEL register programming, the required ASC port lines must be programmed by software for the desired ASC input/output functionality. Two selections must be executed:

- Input/output function selection
  (controlled by the port input/output control registers IOCR)
- Pad driver characteristics selection for the outputs
  (controlled by the port pad driver mode register PDR)

Input/Output Function Selection

The port input/output control registers contain the 4-bit wide bit fields that select the digital output and input driver characteristics such as pull-up/down devices, port direction (input/output), open-drain, and alternate output selections individually for each pin. The I/O lines for the ASC modules are controlled by the port input/output control registers P5_IOCR0 and P6_IOCR8.

Table 20-8 shows how bits and bit fields must be programmed for the required I/O functionality of the ASC I/O lines. This table also shows the values of the peripheral input select registers.

Table 20-8 ASC0/ASC1 I/O Control Selection and Setup

Module	Related ASC Interrupt	DMA Request Line	Description	I/O
ASC0	P5.0/RXD0A	ASC0_PISEL.RIS = 0	P5_IOCR0.PC0 = $0XXX_B$	Input
		–	P5_IOCR0.PC0 = $1X01_B$	Output[1)]
	P6.8/RXD0B	ASC0_PISEL.RIS = 1	P6_IOCR8.PC8 = $0XXX_B$	Input
		–	P6_IOCR8.PC8 = $1X10_B$	Output[1)]
	P5.1/TXD0	–	P5_IOCR0.PC1 = $1X01_B$	Output
	P6.9/TXD0		P6_IOCR8.PC9 = $1X10_B$	Output
ASC1	P5.2/RXD1A	ASC1_PISEL.RIS = 0	P5_IOCR0.PC2 = $0XXX_B$	Input
		–	P5_IOCR0.PC2 = $1X01_B$	Output[1)]
	P6.10/RXD1B	ASC1_PISEL.RIS = 1	P6_IOCR8.PC10 = $0XXX_B$	Input
		–	P6_IOCR8.PC10 = $1X10_B$	Output[1)]
	P5.3/TXD1	–	P5_IOCR0.PC3 = $1X01_B$	Output
	P6.11/TXD1		P6_IOCR8.PC11 = $1X10_B$	Output

1) Applicable in Synchronous Mode only.

*Note: In synchronous operating mode of the ASC, the type of the selected RXD port pin (input or output) is **not** automatically controlled by the ASC but must be defined by a user program by writing the appropriate bit field in the IOCR registers.*

20.3.2.4 Interrupt Control Registers

The eight interrupts of the ASC0 and ASC1 modules are controlled by the following service request control registers:

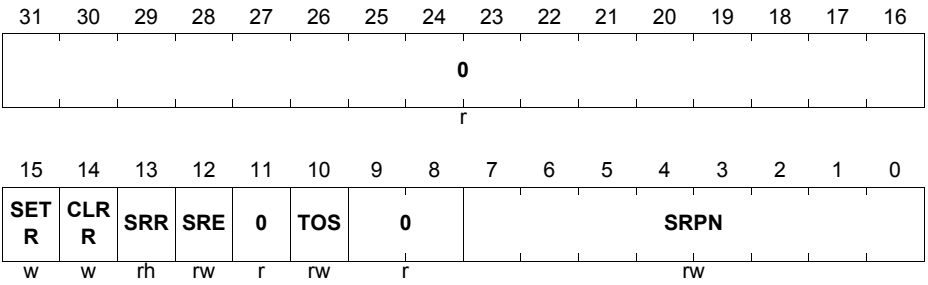
- ASC0_TSRC, ASC1_TSRC: control the transmit interrupts
- ASC0_RSRC, ASC1_RSRC: control the receive interrupts
- ASC0_ESRC, ASC1_ESRC: control the error interrupts
- ASC0_TBSRC, ASC1_TBSRC: control the transmit buffer empty interrupts

TSRC
Transmit Interrupt Service Request Control Register
($F0_H$) **Reset Value: 0000 0000$_H$**

RSRC
Receive Interrupt Service Request Control Register
($F4_H$) **Reset Value: 0000 0000$_H$**

ESRC
Error Interrupt Service Request Control Register
($F8_H$) **Reset Value: 0000 0000$_H$**

TBSRC
Transmit Buffer Interrupt Service Request Control Register
(FC_H) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
SRPN	[7:0]	rw	**Service Request Priority Number**
TOS	10	rw	**Type of Service Control**
SRE	12	rw	**Service Request Enable**
SRR	13	rh	**Service Request Flag**
CLRR	14	w	**Request Clear Bit**
SETR	15	w	**Request Set Bit**

Field	Bits	Type	Description
0	[9:8], 11, [31:16]	r	**Reserved** Read as 0; should be written with 0.

20.3.3 DMA Requests

The DMA request output lines of the ASC0/ASC1 modules become active whenever the related ASC interrupt line becomes activated. The DMA request lines are connected to the DMA controller as shown in **Table 20-9**.

Table 20-9 DMA Request Lines of ASC0/ASC1

Module	Related ASC Interrupt	DMA Request Line	Description
ASC0	RIR	ASC0_RDR	DMA Channel 00 Request Input 5
			DMA Channel 10 Request Input 5
			DMA Channel 06 Request Input 5
			DMA Channel 16 Request Input 5

20.3.5 Application Hint Regarding the ATM Feature

If the ASC0 is operated under certain conditions, the communication can be affected by the ATM functionality overlaid to the RXD0B pin.

The conditions are:

- ASC communication is using the pin where CAN RXDCAN0 is mapped to as well
- ASC protocol uses only one stop bit
- Start bit follows immediately after stop bit of previous data byte
- Block transfer with more than 100 bytes
- Data is 0xAA for all bytes
- ASC baud rate is higher than XTAL1 frequency / 14
  (for example, 1.42 Mbaud for a 20 MHz crystal)

There are two options to prevent the effect:

- Add a wait cycle between start and stop bit after 100 or less transferred bytes.
- Disable (temporarily) the ATM feature from within the SCU module
- Use 0x55, 0xAA55 or 0x55AA instead of 0xAA as fill or test data pattern

21 Synchronous Serial Interface (SSC)

This chapter describes the four SSC Synchronous Serial Interfaces SSC0, SSC1, SSC2 and SSC3 of the TC1798. It contains the following sections:

- Functional description of the SSC kernel, valid for SSC0, SSC1, SSC2 and SSC3 (see **Page 21-1**).
- SSC kernel register description, describes all SSC kernel specific registers (see **Page 21-27**).
- TC1798 implementation-specific details and registers of the SSC0/SSC1/SSC2 modules (port connections and control, interrupt control, address decoding, clock control, see **Page 21-43**).

*Note: The SSC kernel register names described in **Section 21.2** are referenced in the TC1798 User´s Manual by the module name prefix "SSC0_" for the SSC0 interface, by "SSC1_" for the SSC1 interface, and by "SSC2_" for the SSC2 interface.*

21.1 SSC Kernel Description

Figure 21-1 shows a global view of the SSC interface.

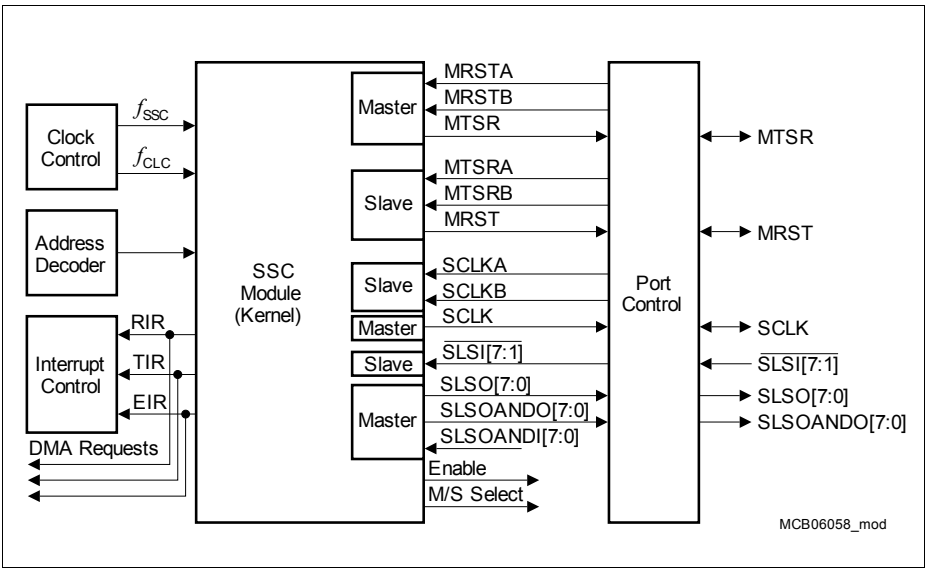

Figure 21-1 General Block Diagram of the SSC Interface

21.1.1 Overview

The SSC supports full-duplex and half-duplex serial synchronous communication up to 55.0 Mbit/s (@ 110.0 MHz module clock, Master Mode). The serial clock signal can be generated by the SSC itself (Master Mode) or can be received from an external master (Slave Mode). Data width, shift direction, clock polarity and phase are programmable. This allows communication with SPI-compatible devices. Transmission and reception of data is double-buffered. A shift clock generator provides the SSC with a separate serial clock signal. Seven slave select inputs are available for Slave Mode operation. Eight programmable slave select outputs (chip selects) are supported in Master Mode.

Features:

- Master and Slave Mode operation
  - Full-duplex or half-duplex operation
  - Automatic pad control possible
- Flexible data format
  - Programmable number of data bits: 2 to 16 data bits (with parity: 1 to 15 data bits)
  - Programmable shift direction: LSB or MSB shift first
  - Programmable clock polarity: Idle low or idle high state for the shift clock
  - Programmable clock/data phase: Data shift with leading or trailing edge of the shift clock
- Baud rate generation
  - Master Mode: 33.25 Mbit/s to 507.4 bit/s (@ 66.5 MHz module clock)
  - Master Mode: 55.0 Mbit/s to 839.3 bit/s (@ 110 MHz module clock)
  - Slave Mode: 16.625 Mbit/s to 507.4 bit/s (@ 66.5 MHz module clock)
  - Slave Mode: 27.5 Mbit/s to 839.3 bit/s (@ 110 MHz module clock)
- Interrupt generation
  - On a transmitter empty condition
  - On a receiver full condition
  - On an error condition (receive, phase, baud rate, transmit error, parity error)
- Queued SSC Mode supports control and data handling by the DMA controller
- Flexible SSC pin configuration
- Hardware supported parity mode
  - Individually selectable for transmit and receive frames
  - Even/odd parity selection
- Seven slave select inputs $\overline{\text{SLSI}}$[7:1] in Slave Mode
- Eight programmable slave select outputs SLSO[7:0] in Master Mode
  - Automatic SLSO generation with programmable timing
  - Programmable active level and enable control
  - Combinable with SLSO output signals from other SSC modules

21.1.2 General Operation

The SSC supports full-duplex and half-duplex synchronous communication up to 55.0 Mbit/s (@ 110.0 MHz module clock). The serial clock signal can be generated by the SSC itself (Master Mode) or be received from an external master (Slave Mode). Data width, shift direction, clock polarity and phase are programmable. This allows communication with SPI-compatible devices. Transmission and reception of data are double-buffered. A shift clock generator provides the SSC with a separate serial clock signal.

Configuration of the high-speed synchronous serial interface is very flexible, so it can work with other synchronous serial interfaces, can serve master/slave or multi-master interconnections, or can operate compatibly with the popular SPI interface. It can be used to communicate with shift registers (I/O expansion), peripherals (e.g. EEPROMs etc.), or other controllers (networking). The SSC supports half-duplex and full-duplex communication. Data is transmitted or received on pins MTSR (Master Transmit/Slave Receive) and MRST (Master Receive/Slave Transmit). The clock signal is output or input via pin SCLK (Serial Clock). These three pins are typically used for alternate output functions of port pins. If they are implemented as dedicated bi-directional pins, they can be directly controlled by the SSC. In Slave Mode, the SSC can be selected from a master via dedicated slave select input lines (SLSI). In Master Mode, automatic generation of slave select output lines (SLSO) is supported. In Master Mode, control and data handling of transfers can be also be controlled independently by the DMA controller (Queued SSC Mode).

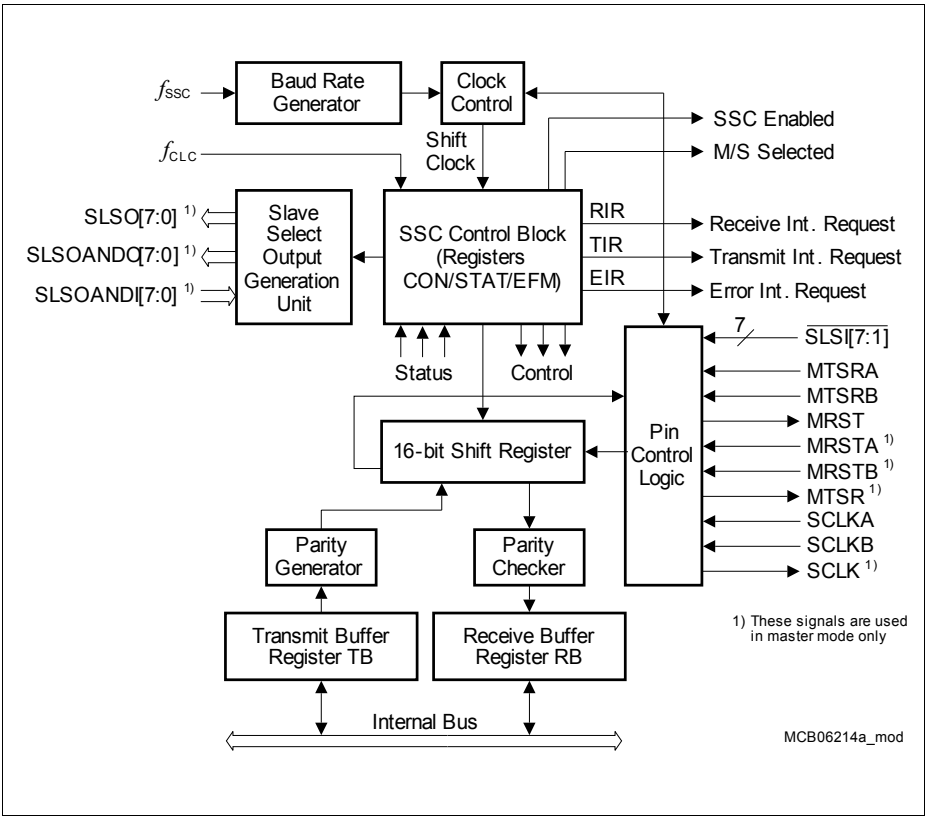

Figure 21-2 Synchronous Serial Channel SSC Block Diagram

21.1.2.1 Operating Mode Selection

The operating mode of the serial channel SSC is controlled by its Control Register, CON. Status information is contained in its Status Register, STAT.

The shift register of the SSC is connected to both the transmit pin and the receive pin via the pin control logic (see block diagram in **Figure 21-2**). Transmission and reception of serial data are synchronized and take place at the same time, that is, the same number of transmitted bits is also received. Transmit data is written into the Transmit Buffer TB. It is moved to the shift register as soon as this is empty, including the generated parity bit for the transmit data if transmit parity mode is enabled (CON.PARTEN = 1). An SSC master (CON.MS = 1) immediately begins transmitting, while an SSC slave (CON.MS = 0) will wait for an active shift clock. When the transfer starts, the busy flag STAT.BSY is set, and the transmit interrupt request line (TIR) will be activated to indicate that the Transmit Buffer Register (TB) may be reloaded. When the number of bits as programmed in CON.BM have been received, the data bits of the shift register are moved to the Receive Buffer Register (RB) right-aligned, the receive parity bit (if enabled by CON.PARREN = 1) is loaded into STAT.PARRVAL, and the receive interrupt request line (RIR) will be activated. If no further transfer is to take place (TB is empty), STAT.BSY will be cleared at the same time. Software should not modify STAT.BSY, as this flag is hardware-controlled.

Note: Only one SSC can be master at a given time.

The following features of the serial data bit transfer can be programmed:

- The data width can be selected from 2 to 16 data bits (with parity: 1 to 15 data bits)
- A transfer may start with the LSB or the MSB of the data bits
- The shift clock may be idle low or idle high
- The data bits may be shifted with the leading or trailing edge of the clock signal
- The baud rate (shift clock) can be set from 839.3 bit/s up to 55.0Mbit/s (@ 110 MHz module clock)
- The shift clock can be generated (master) or received (slave)

These features allow the SSC to be adapted to a wide range of applications that require serial data transfer.

The Data Width Selection supports the transfer of frames of any data length from 2-bit “characters” up to 16-bit “characters”. If parity is enabled, the maximum number of data bits of a frame is 15-bit.

Starting the serial data bit transfer with the LSB (CON.HB = 0) allows communication with devices such as an SSC device in Synchronous Mode, or 8051-like serial interfaces. If parity mode is enabled, the parity bit preceeds the serial data bit transfer (see **Page 21-12**).

Starting with the MSB (CON.HB = 1) allows operation compatible with the SPI interface. If parity mode is enabled, the parity bit follows the serial data bit transfer (see **Page 21-12**).

Regardless of the selected data width and whether the MSB or the LSB is transmitted first, the transfer data is always right-aligned in registers TB and RB, with the LSB of the transfer data in bit 0 of these registers. The data bits are rearranged for transfer by the internal shift register logic. The unselected bits of TB are ignored, and the unselected bits of RB will not be valid and should be ignored by the receiver service routine.

The Clock Control allows the adaptation of transmit and receive behavior of the SSC to a variety of serial interfaces. A specific clock edge (rising or falling) is used to shift out transmit data, while the other clock edge is used to latch in receive data. Bit CON.PH selects the leading edge or the trailing edge for each function. Bit CON.PO selects the level of the clock line in the idle state. For an idle-high clock, the leading edge is a falling one, a 1-to-0 transition (see **Figure 21-3**).

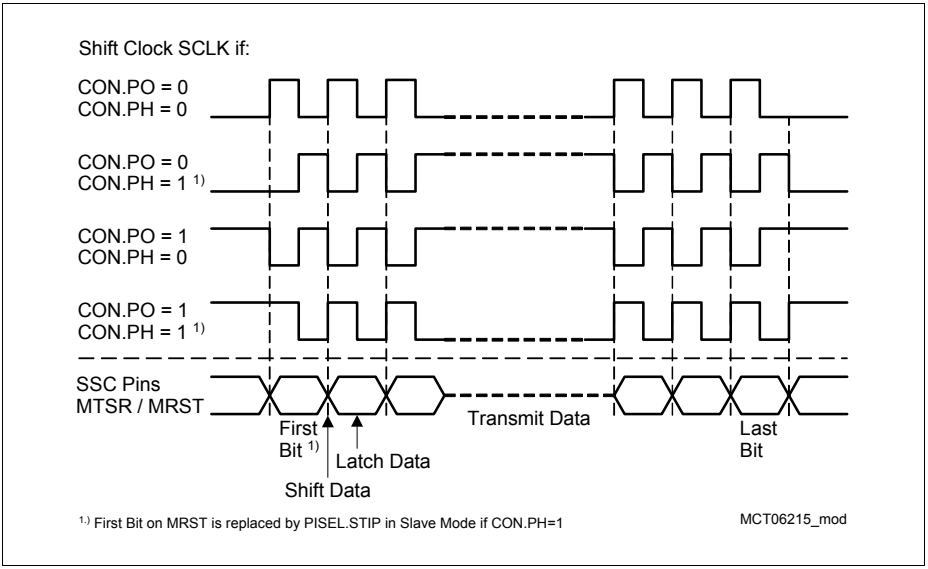

Figure 21-3 Serial Clock SCLK Phase and Polarity Options

21.1.2.2 Full-Duplex Operation

The description in this section assumes that the SSC is used with software controlled bi-directional GPIO port lines that have open-drain capability (see also **Section 21.1.2.6**).

The various devices are connected through three lines. The definition of these lines is always determined by the master. The line connected to the master's data output pin MTSR is the transmit line, the receive line is connected to its data input line MRST, and the clock line is connected to pin SCLK. Only the device selected for master operation generates and outputs the serial clock on pin SCLK. All slaves receive this clock, so their

pin SCLK must be switched to input mode. The output of the master's shift register is connected to the external transmit line, which in turn is connected to the slaves' shift register input. The output of the slaves' shift register is connected to the external receive line in order to enable the master to receive the data shifted out of the slave. The external connections are hard-wired, with the function and direction of these pins determined by the master or slave operation of the individual device.

*Note: The shift direction shown in **Figure 21-4** applies to both MSB-first and LSB-first operation.*

When initializing the devices in this configuration, one device must be selected for master operation while all other devices must be programmed for slave operation. Initialization includes the operating mode of the device's SSC and also the function of the respective port lines.

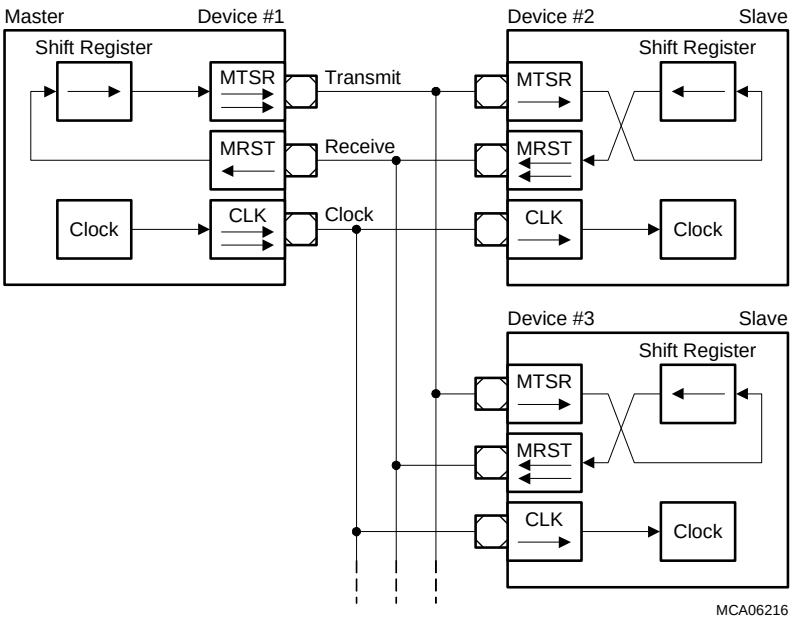

Figure 21-4 SSC Full-Duplex Configuration

The data output pins MRST of all slave devices are connected onto one receive line in this configuration. During a transfer, each slave shifts out data from its shift register. There are two ways to avoid collisions on the receive line due to different slave data:

- **Only one slave drives the line** and enables the driver of its MRST pin. All the other slaves must program their MRST pins to input. Therefore, only one slave can put its data onto the master's receive line. Only reception of data from the master is possible. The master selects the slave device from which it expects data either by separate select lines, or by sending a special command to this slave. The selected slave then switches its MRST line to output until it gets a de-selection signal or command.
- **The slaves use open drain output on MRST.** This forms a wired-AND connection. The receive line needs an external pull-up in this case. Corruption of the data on the receive line sent by the selected slave is avoided when all slaves not selected for transmission to the master send only 1s. Since this high level is not actively driven onto the line, but is only held through the pull-up device, the selected slave can pull this line actively to a low level when transmitting a zero bit. The master selects the slave device from which it expects data either by separate select lines, or by sending a special command to this slave.

After performing all necessary initializations of the SSC, the serial interfaces can be enabled. For a master device, the alternate clock line will now go to its programmed polarity. The alternate data line will go to either 0 or 1, until the first transfer starts. After a transfer, the alternate data line will always remain at the logic level of the last transmitted data bit.

When the serial interfaces are enabled, the master device can initiate the first data transfer by writing the transmit data into register TB. This value is copied into the shift register (assumed to be empty at this time), and the selected first bit of the transmit data will be placed onto the MTSR line on the next clock from the shift clock generator (transmission only starts, if CON.EN = 1). Depending on the selected clock phase, a clock pulse is generated on the SCLK line. With the opposite clock edge, the master simultaneously latches and shifts in the data detected at its input line MRST. This "exchanges" the transmit data with the receive data. Because the clock line is connected to all slaves, their shift registers will be shifted synchronously with the master's shift register, shifting out the data contained in the registers, and shifting in the data detected at the input line. After the pre-programmed number of clock pulses (via the data width selection), the data transmitted by the master is contained in all slaves' shift registers, while the master's shift register holds the data of the selected slave. In the master and all slaves, the content of the shift register is copied into the Receive Buffer (RB) and the receive interrupt line (RIR) is activated.

A slave device will immediately output the selected first bit (MSB or LSB of the transfer data) at pin MRST when the contents of the transmit buffer are copied into the slave's shift register. Bit STAT.BSY is not set until the first clock edge at SCLK appears. The slave device will not wait for the next clock from the shift clock generator – as the master does – because the first clock edge generated by the master may be already used to clock in the first data bit, depending on the selected clock phase. So the slave's first data bit must already be valid at this time.

*Note: On the SSC, a transmission **and** a reception always take place at the same time, regardless whether valid data has been transmitted or received.*

21.1.2.3 Half-Duplex Operation

The description in this section assumes that the SSC is used with software controlled bi-directional GPIO port lines that provide open-drain capability (see also **Section 21.1.2.6**).

In a half-duplex configuration, only one data line is necessary for both receiving **and** transmitting data. The data exchange line is connected to both pins MTSR and MRST of each device, and the clock line is connected to the SCLK pin.

The master device controls the data transfer by generating the shift clock, while the slave devices receive it. Due to the fact that all transmit and receive pins are connected to the one data exchange line, serial data may be moved between arbitrary stations.

As in full-duplex mode, there are two ways to avoid collisions on the data exchange line:

- Only the transmitting device may enable its transmit pin driver
- The non-transmitting devices use open-drain output and send only 1s

Because the data inputs and outputs are connected together, a transmitting device will clock in its own data at the input pin (MRST for a master device, MTSR for a slave). In this way, any corruption is detected on the common data exchange line when the received data is not equal to the transmitted data.

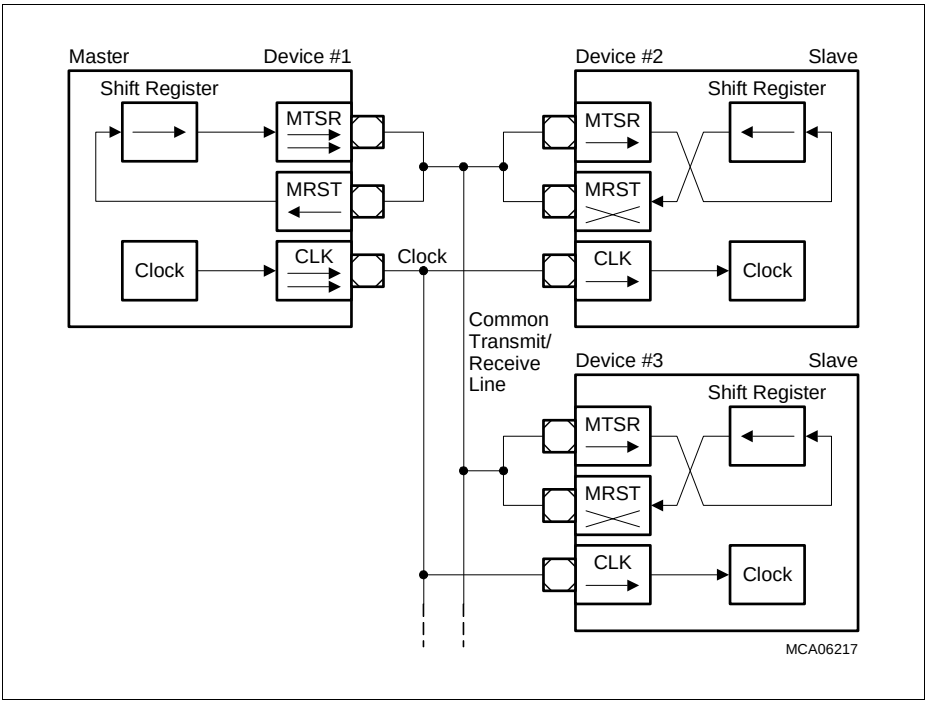

Figure 21-5 SSC Half-Duplex Configuration

21.1.2.4 Continuous Transfers

When the transmit interrupt request flag is set, it indicates that the Transmit Buffer (TB) is empty and is ready to be loaded with the next transmit data. If the TB has been reloaded by the time the current transmission is finished, the data is immediately transferred to the shift register and the next transmission can start without any additional delay (according to the selected SLSO timings). On the data line, there is no gap between the two successive frames if no delays are selected. For example, two byte transfers would look the same as one word transfer. This feature can be used to interface with devices that can operate with (or require more than) 16 data bits per transfer. It is just a matter for software how long a total data frame length can be. This option can also be used, e.g., to interface to byte-wide and word-wide devices on the same serial bus.

Note: This option can only happen in multiples of the selected basic data width, because it would require disabling/enabling of the SSC to reprogram the basic data width on-the-fly.

Note: In Master Mode, the Transmit Buffer register TB is loaded with new data for the following transmission just at the end of the current transmission and a leading delay > 0 is selected (SSOTC.LEAD not equal 00_B), a slightly enlarged leading delay (< one SCLK shift clock period) is generated for the following transmission.

21.1.2.5 Parity Mode

The SSC allows to add a parity bit to a serial frame. The parity mode can be enabled individually for frame transmission (CON.PARTEN) and frame reception (CON.PARREN). The type of parity (even/odd parity) can be selected, valid for transmit and receive parity.

If transmit parity is enabled (CON.PARTEN = 1), the shift register is loaded for a frame transmission by the content of the Transmit Buffer TB, the parity bit becomes calculated and stored in STAT.PARTVAL. Depending on bit CON.HB, the parity bit preceeds or follows the transmitted data bits.

If receive parity is enabled (CON.PARREN = 1) and the last bit of a frame has been received, the received data of the frame is stored in RB and the received parity bit is stored in STAT.PARRVAL. The received and calculated parity bits are now compared. If this comparison fails, a parity error is detected and the error status flag STAT.PARE is set. If enabled by bit CON.PAREEN, a parity error activates the error interrupt request line EIR.

Figure 21-6 shows how a parity bit is added to the transmitted data bits of a frame. The number of the transmitted bits of a complete frame remains constant without or with parity, assuming that COM.BM is not changed. Therefore, the number of transmitted data bits is reduced by one bit when parity mode is enabled.

If the heading control bit CON.HB = 0 (LSB first), the parity bit preceeds the data bits in parity mode and is transmitted as the first bit of a frame. If the heading control bit CON.HB = 1 (MSB first), the parity bit follows the data bits in parity mode and is transmitted as the last bit of a frame.

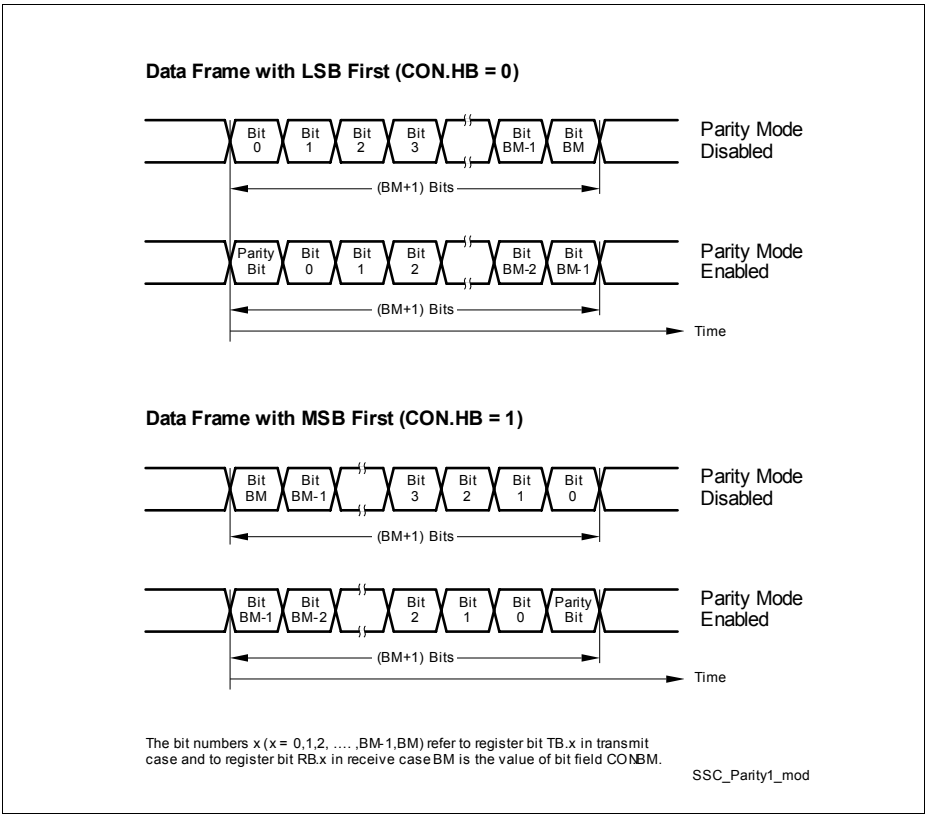

Figure 21-6 Data Frames without/with Parity

21.1.2.6 Port Control

The SSC uses three lines to communicate with the external world. Pin SCLK serves as the clock line, while pins MRST (Master Receive/Slave Transmit) and MTSR (Master Transmit/Slave Receive) serve as the serial data input/output lines. As shown in **Figure 21-1** these three lines (SCLK as input, Master Receive, Slave Receive) have two inputs each at the SSC Module kernel. Three bits in register PISEL determine which of the two kernel inputs (A or B) are connected. This feature allows for each of the three SSC communication lines to be connected to two inputs coming from different port pins.

Operation of the SSC I/O lines depends on the selected operating mode (master or slave). The direction of the port lines depends on the operating mode. The SSC will automatically use the correct kernel output or kernel input line of the ports when

switching modes. Port pins assigned as SSC I/O lines can be controlled either by hardware or by software.

When the SSC I/O lines are connected to dedicated pins, hardware I/O control should typically be used. In this case, two output signals reflect the state of the CON.EN and CON.MS bits directly (the M/S select line is inverted to the CON.MS bit definition).

When the SSC I/O lines are connected with bi-directional lines of general purpose I/O ports, software I/O control should be typically used. In this case port registers must be programmed for alternate output and input selection. When switching between master and slave mode port registers must be reprogrammed.

Using the open-drain output feature of port lines helps to avoid bus contention problems and reduces the need for hard-wired hand-shaking or slave select lines. In open-drain output mode, it is not always necessary to switch the direction of a port pin. Note that in hardware-controlled I/O mode, the availability of open-drain outputs depends on the type of the dedicated output pins that are used. The SSC module itself does not provide any control capability for open-drain control.

Note: For details of SSC port connections and configuration, see ***Page 21-53****.*

21.1.2.7 Baud Rate Generation

The serial channel SSC has its own dedicated 16-bit baud rate generator with 16-bit reload capability, allowing baud rate generation independent of timers. In addition to **Figure 21-2**, **Figure 21-7** shows the baud rate generator of the SSC in more detail.

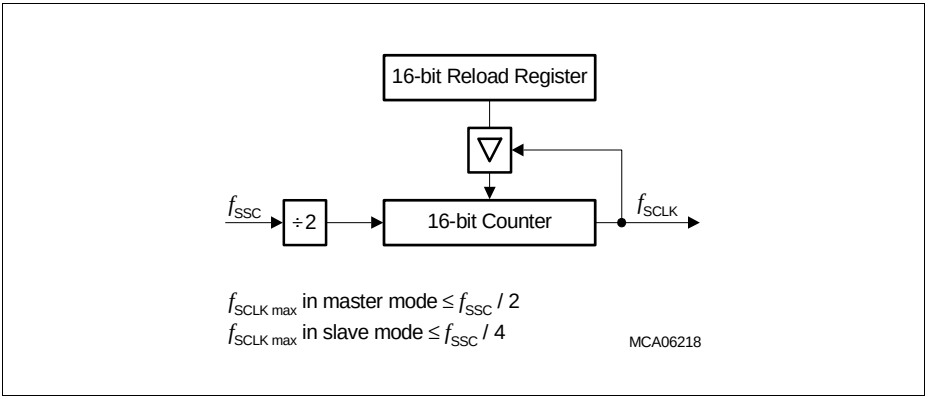

Figure 21-7 SSC Baud Rate Generator

The baud rate generator is clocked with f_{SSC}. The timer counts downwards. Register BR is the dual-function Baud Rate Generator/Reload register. Reading BR while the SSC is enabled returns the contents of the timer. Reading BR while the SSC is disabled returns the programmed reload value. In this mode, the desired reload value can be written to BR.

Note: Never write to BR while the SSC is enabled.

The formulas below calculate either the resulting baud rate for a given reload value, or the required reload value for a given baud rate:

$$\text{Baud rate}_{SSC} = \frac{f_{SSC}}{2 \times (\text{BR\_VALUE} + 1)} \qquad \text{BR\_VALUE} = \frac{f_{SSC}}{2 \times \text{Baud rate}_{SSC}} - 1 \qquad (21.1)$$

BR_VALUE represents the content of the reload register, taken as an unsigned 16-bit integer, while Baud rate_{SSC} is equal to f_{SCLK} as shown in **Figure 21-7**.

The maximum baud rate that can be achieved with f_{SSC} = 110 MHz is 55.0 Mbit/s in Master Mode (with BR_VALUE = 0000_H) and 275.0 Mbit/s in Slave Mode (with BR_VALUE = 0001_H).

Table 21-1 lists some possible baud rates together with the required reload values and the resulting bit times, assuming a module clock f_{SSC} of 110 MHz.

Table 21-1 Typical Asynchronous Baud Rates using Fixed Input Clock Dividers

Reload Value	Baud Rate (= f_{SCLK})	Deviation
0000_H	55 Mbit/s (only in Master Mode)	0.0%
0001_H	27.5 Mbit/s	0.0%
0003_H	13.75 Mbit/s	0.0%
0036_H	1 Mbit/s	0.0%
$006D_H$	500 kbit/s	0.0%
0225_H	100 kbit/s	0.0%
$157B_H$	10 kbit/s	0.0%
$D6D7_H$	1 kbit/s	0.0%
$FFFF_H$	839.3 bit/s	0.0%

In the TC1798, the module clock f_{SSC} is generated outside the SSC module kernel. Therefore, for baud rate calculations the dependencies of f_{SSC} from f_{FPI} must be taken into account. on describes these dependencies in detail.

21.1.2.8 Slave Select Input Operation

For systems with multiple slaves, the SSC module provides seven $\overline{SLSI}$ slave select input lines, that permit enabling or disabling of the SCLK, MTSR, and MRST signals in Slave Mode. Slave Mode is selected by CON.MS = 0. The $\overline{SLSI}$ input logic shown in **Figure 21-8** is controlled by register PISEL and CON.

Note: In the following description, only one of the seven $\overline{SLSI}$ input lines is mentioned. The remaining six $\overline{SLSI}$ input lines are connected to the other six inputs of the input multiplexer, which is controlled by PISEL.SLSIS.

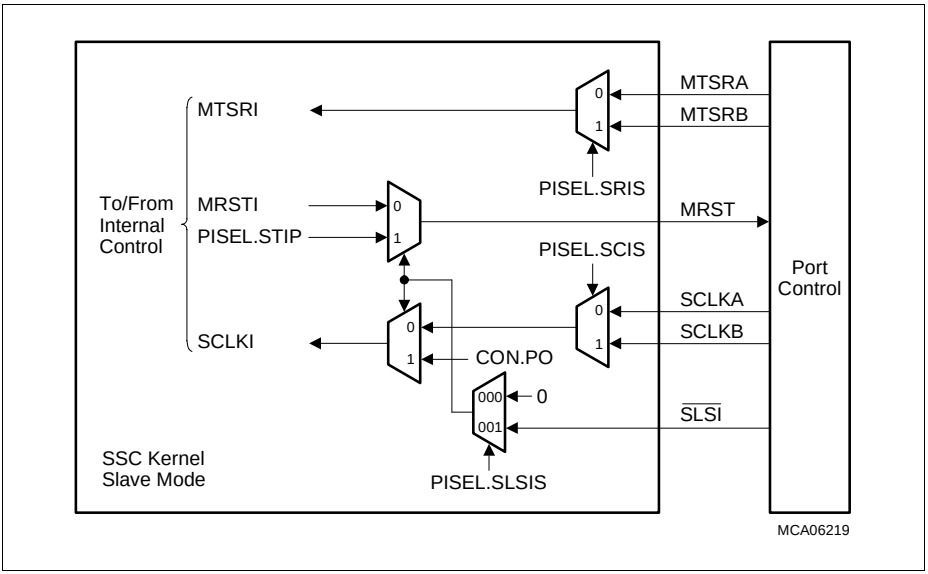

Figure 21-8 Slave Select Input Logic

With PISEL.SLSIS = 000_B and Slave Mode selected, the $\overline{SLSI}$ input line does not control the SSC I/O lines. The slave receive input signal MTSRA or MTSRB (selected by PISEL.SRIS) and the slave clock input signal SCLKA or SCLKB (selected by PISEL.SCIS) are passed further as MTRSI and SCLKI to the internal SSC control logic. The slave transmit signal MRSTI from the internal SSC control logic MRSTI is passed directly to MRST.

With PISEL.SLSIS = 001_B, input signal $\overline{SLSI}$ controls the operation of the SSC I/O lines as a slave select signal as follows:

- $\overline{SLSI}$ = 1: SSC slave is not selected.
  - The slave receive input signals, MTSRA or MTSRB are connected to MTSRI, depending on PISEL.SRIS (Slave Mode receive input select).

  - MRST is driven with the logic level of bit PISEL.STIP (slave transmit idle state).
  - SCLKI is driven with the logic level of CON.PO (clock polarity control).
- $\overline{SLSI}$ = 0: SSC is selected as slave.
  - The slave receive input signals MTSRA or MTSRB are connected to MTSRI, depending on PISEL.SRIS (Slave Mode receive input select).
  - MRST is directly driven with the slave transmit output signal MRSTI.
  - The slave clock input signals SCLKA or SCLKB are connected to SCLKI, depending on PISEL.SCIS (Slave Mode clock input select).

21.1.2.9 Slave Select Output Generation Unit

In Master Mode, the slave select output generation unit of the SSC automatically generates up to eight slave select output lines SLSO[7:0] for serial transmit operations. The slave select output generation unit further makes it possible to adjust the chip select timing parameters. The active/inactive state of a slave select output as well as the enable/disable state can be controlled individually for each slave select output (see **Figure 21-10**). The basic slave select output timing is shown in **Figure 21-9**, assuming a low active level of the SLSOn lines.

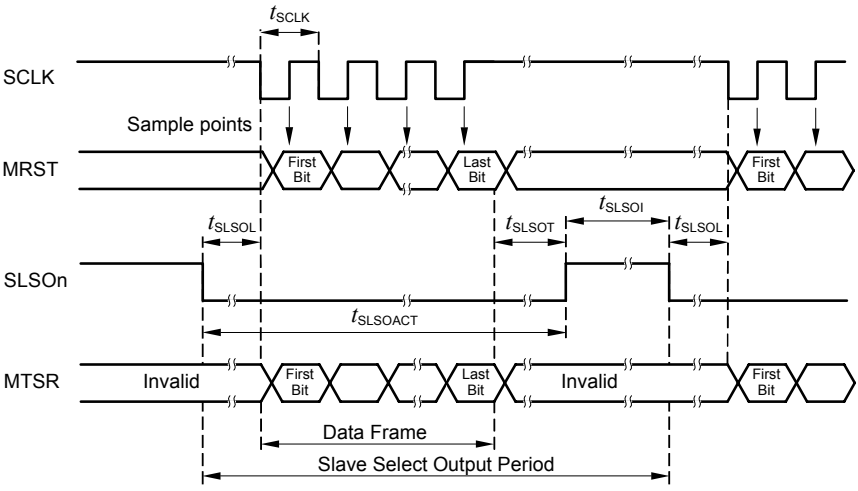

Figure 21-9 SSC Slave Select Output Timing

A slave select output period always starts after a write operation to register TB. With a TB write operation, all timing parameters stored in register SSOTC (LEAD, TRAIL,

INACT, and SLSO7MOD) and register SSOC (AOLn and OENn) are latched and remain valid for the consecutive transmission. Following that, SLSOn becomes active (low) for a number of SCLK cycles (leading delay cycles) before the first bit of the serial data stream occurs at MTSR. After the transmission of the data frame, SLSOn remains active (low) for a number of SCLK cycles (trailing delay cycles) before it becomes inactive again. This inactive state of SLSOn is valid at least for a number of SCLK cycles (inactive delay cycles) before a new chip select period can be started.

Note: When operating in Master Mode with CON.PH = 1 and sampling data from a slave device that becomes enabled by an SLSOn output, a leading delay of at least one leading delay clock cycle should be selected. The reason is that with CON.PH = 1, the first SCLK edge already latches the first data bit at MRST.

The three parameters of a chip select period are controlled by bit fields in the Slave Select Output Timing Control Register SSOTC. Each of these bit fields can contain a value from 0 to 3 defining delay cycles of 0 to 3 multiples of the t_{SCLK} shift clock period. The three parameters are:

1. Number of leading delay cycles (t_{SLSOL} = SSOTC.LEAD × t_{SCLK})
2. Number of trailing delay cycles (t_{SLSOT} = SSOTC.TRAIL × t_{SCLK})
3. Number of inactive delay cycles (t_{SLSOI} = SSOTC.INACT × t_{SCLK})

If SSOTC.INACT = 00_B and register TB has already been loaded with the data for the next data frame, the next chip select period is started with its leading delay phase without SLSOn going inactive. If, in this case, TB has not been loaded in time with the data for the next data frame, SLSOn becomes inactive again.

Slave Select Output Control

Each slave select output SLSOn can be enabled individually. When SSOC.OENn = 1, SLSOn is enabled. Furthermore, active and inactive levels of the SLSOn outputs are programmable. Bit SSOC.AOLn determines the state of the active level of SLSOn.

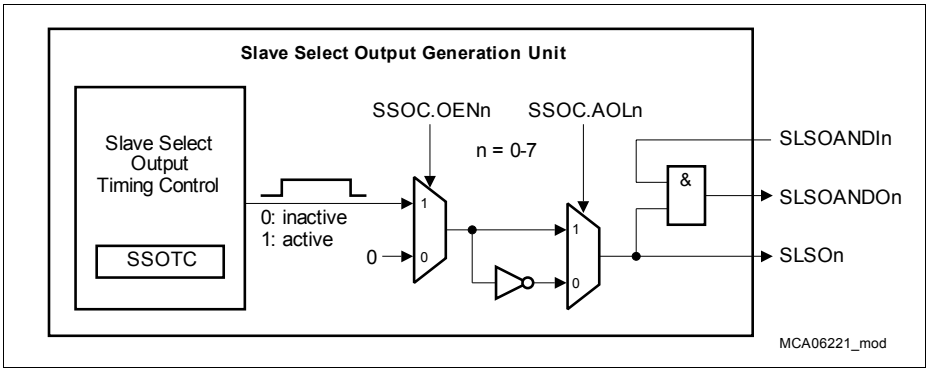

Figure 21-10 Slave Select Output Control Logic

As a special feature, each SLSOn output signal can be combined (ANDed) by an external signal SLSOANDIn coming from another SSC to an output signal SLSANDOn. This AND gate can be used for example to combine two slave select output signals from two SSCs to one common SLSOn output signal. Note that this functionality only works for low active SLSOn signals (SSOC.AOLn = 0).

Slave Select Output 7 Delayed Mode

In the SLSO7 delayed mode (SSOTC.SLSO7MOD = 1), the timing of the slave select output SLSO7 as programmed by the three parameters in SSOTC (number of trailing, leading, and inactive delay clock cycles) is delayed by one shift clock period for the inactive-to-active edge. The active-to-inactive edge is not delayed. The timing of SLSO7 in the delayed mode is shown in **Figure 21-11**. The bold lines show the timing of SLSO7 in normal operating mode, and the dotted lines show the timing of SLSO7 in delayed mode.

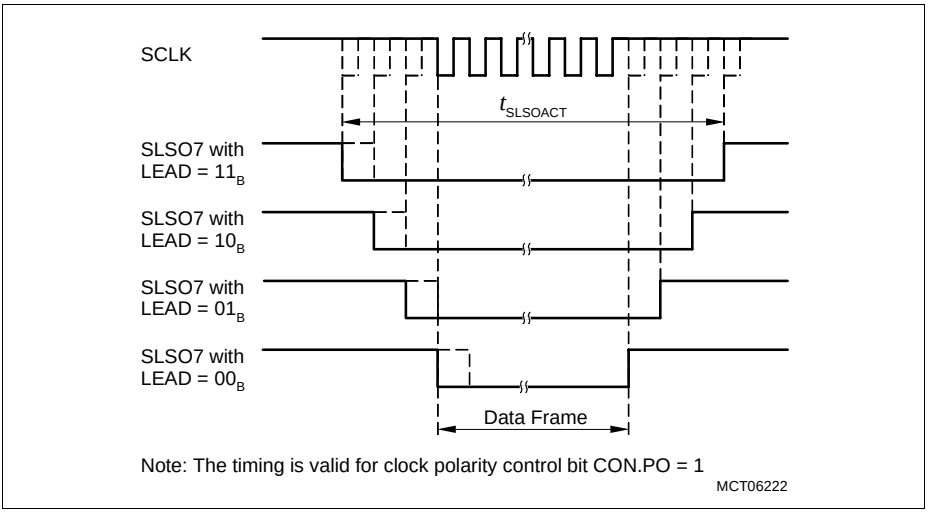

Figure 21-11 SLSO7 Delayed Mode

Slave Select Register Update

At the start of an internal transmit sequence (with the TB register write operation), the parameters in registers SSOC and SSOTC are latched. This means that they remain stable while a serial transmission is in progress. Therefore, it is always guaranteed that the data of one serial transmission is always transmitted with a constant slave select configuration setup. A configuration change by reprogramming SSOC or SSOTC during a serial transmission will first become valid with the start of the subsequent serial transmission.

21.1.2.10 Error Detection Mechanisms

The SSC is able to detect four different error conditions. Receive Error and Phase Error are detected in all modes, while Transmit Error and Baud Rate Error apply to Slave Mode only. In case of a Transmit Error or Receive Error, the respective error flags are always set and the error interrupt requests will be generated by activating the EIR line only if the corresponding error enable bits have been set (see **Figure 21-12**). The error interrupt handler may then check the error flags to determine the cause of the error interrupt. The error flags are not cleared automatically, but must be cleared via register EFM after servicing. This allows servicing of some error conditions via interrupt, while others may be polled by software. The error status flags can be set and cleared by software via the error flag modification register EFM.

Note: The error interrupt handler must clear the associated (enabled) error flag(s) to prevent repeated interrupt requests. The setting of an error flag by software does not generate an interrupt request.

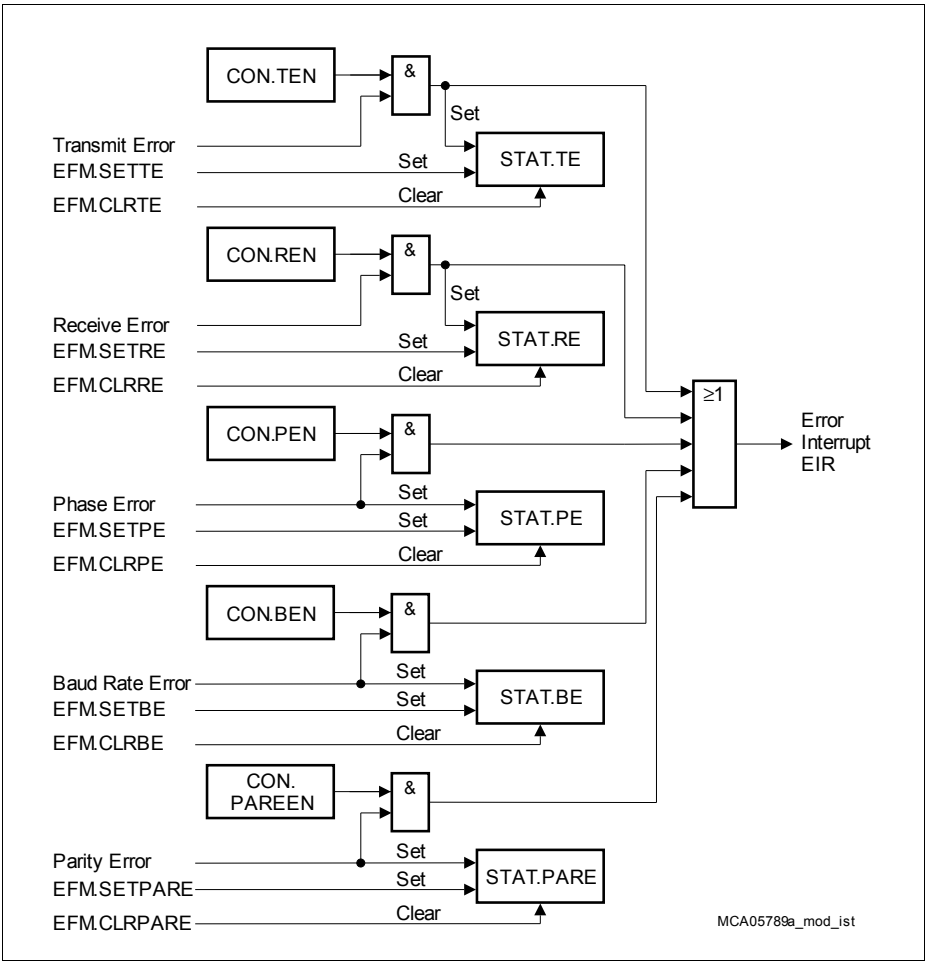

Figure 21-12 SSC Error Interrupt Control

A **Receive Error** (Master or Slave mode) is detected when a new data frame is completely received, but the previous data was not read out of the receive buffer register RB. If enabled via CON.REN, this condition sets the error flag STAT.RE and activates the error interrupt request line EIR. This condition sets the error flag STAT.RE and, if enabled via CON.REN, sets the error interrupt request line EIR. The old data in the receive buffer RB will be overwritten with the new value and is irretrievably lost.

A **Phase Error** (Master or Slave Mode) is detected when the incoming data at pin MRST (Master Mode) or MTSR (Slave Mode), sampled with the same frequency as the module

clock, changes between one cycle before and two cycles after the latching edge of the shift clock signal SCLK. This condition sets the error status flag STAT.PE and, if enabled via CON.PEN, the error interrupt request line EIR.

Note: When CON.PH = 1, the data output signal may be disturbed shortly when the slave select input signal is changed after a serial transmission, resulting in a phase error.

A **Baud Rate Error** (Slave Mode) is detected when the incoming clock signal deviates from the programmed baud rate (shift clock) by more than 100%, meaning it is either more than double or less than half the expected baud rate. This condition sets the error status flag STAT.BE and, if enabled via CON.BEN, the EIR line. Using this error detection capability requires that the slave's shift clock generator is programmed to the same baud rate as the master device. This feature detects false additional pulses or missing pulses on the clock line (within a certain frame).

Note: If this error condition occurs and bit CON.AREN = 1, an automatic reset of the SSC will be performed. This is done to re-initialize the SSC, if too few or too many clock pulses have been detected.

Note: The baud rate error can occur in slave mode after any transfer if the communication is stopped by the master. This is the case due to the fact that SSC module supports back-to-back transfers for multiple transfers. In order to handle this the baud rate detection logic expects after a finished transfer immediately a next clock cycle for a new transfer.

If baud rate error is enabled and the transmit buffer of the slave SSC is loaded with a new value for the next data frame while the current data frame is not yet finished (while STAT.BSY = 1), the slave SSC expects continuation of the clock pulses for the next data frame transmission immediately after finishing the current data frame. Any write to TBUF of the slave SSC while STAT.BSY = 1 initiates or sustains a continuous transmission in the slave. Therefore, the master (shift) clock must be continued after the current frame transmission. Otherwise, the slave SSC will detect a baud rate error. Note that the master SSC does not necessarily send out a continuous shift clock in the case that its transmit buffer is not yet filled with new data or transmission delays occur. Further details on continuous transfers are described in **Section 21.1.2.4** on **Page 21-10**.

A **Transmit Error** (Slave Mode) is detected when a transfer was initiated by the master (shift clock gets active), but the transmit buffer (TB) of the slave was not updated since the last transfer. If enabled via CON.TEN, this condition sets the error status flag STAT.TE and activates the EIR line. This condition sets the error status flag STAT.TE and, if enabled via CON.TEN, the EIR line. If a transfer starts while the transmit buffer is not updated, the slave will shift out the 'old' contents of the shift register, which is normally the data received during the last transfer. This may lead to the corruption of the data on the transmit/receive line in half-duplex mode (open drain configuration) if this slave is not selected for transmission. This mode requires that slaves not selected for

transmission only shift out ones; thus, their transmit buffers must be loaded with $FFFF_H$ prior to any transfer.

A **Parity Error** (Master or Slave Mode) is detected when the data frame is completely received and the generated parity bit for the received data is not equal to the calculated parity bit. This condition sets the error status flag STAT.PARE and, if enabled via CON.PAREEN, the error interrupt request line EIR.

Note: A slave with push/pull output drivers not selected for transmission will normally have its output drivers switched off. However, to avoid possible conflicts or misinterpretations, it is recommended to always load the slave's transmit buffer prior to any transfer.

The cause of an error interrupt request (receive, phase, baud rate, transmit error) can be identified by the error status flags in control register CON.

Note: In contrast to the EIR line, the error status flags STAT.TE, STAT.RE, STAT.PE, and STAT.BE, are not automatically cleared upon entry into the error interrupt service routine, but must be cleared by software.

21.1.2.11 Queued SSC Mode

In queued SSC mode, the enable/disable control of the SSC is possible by two bit locations, one control bit in register CON and one additional control bit in register SSOTC. This double-enable control capability allows control and data operations of the SSC to be completely handled by a DMA controller.

The bits for queued SSC mode are:

- Bit SSCTC.QSMEN: Queued SSC Mode Enable
- Bit SSCTC.EN: Enable SSC (functionality identical with bit CON.EN)

Table 21-2 Queued SSC Mode Control

Write SSOTC Register		SSC Module Enable/Disable Control	
Bit QSMEN	**Bit EN**		
0	X	Enable/disable control of SSC is only possible via bit CON.EN (queued SSC mode disabled).	
1	0	Enable/disable control of SSC is possible via bits SSOTC.EN and CON.EN (queued SSC mode enabled).	SSC is disabled
	1		SSC is enabled

Note: Both register bits, CON.EN and SSOTC.EN, control one common flip-flop for enable/disable control.

Figure 21-13 shows how the Queued SSC Mode control logic. Reading SSOTC returns the state of CON.EN for SSOTC.EN. Writing to SSOTC with QSMEN = 1, sets CON.EN if SSOTC.EN is written with 1 and clears CON.EN if SSOTC.EN is written with 0.

Compared to the timing parameters stored in register SSOTC (LEAD, TRAIL, INACT, and SLSO7MOD), the Queued SSC Mode control bits QSMEN and EN are a not latched and directly control the receive/transmit functionality. But note that CON.EN should only be cleared by software (either by a CON or SSOTC write operation) while no transfer is in progress (STAT.BSY = 0).

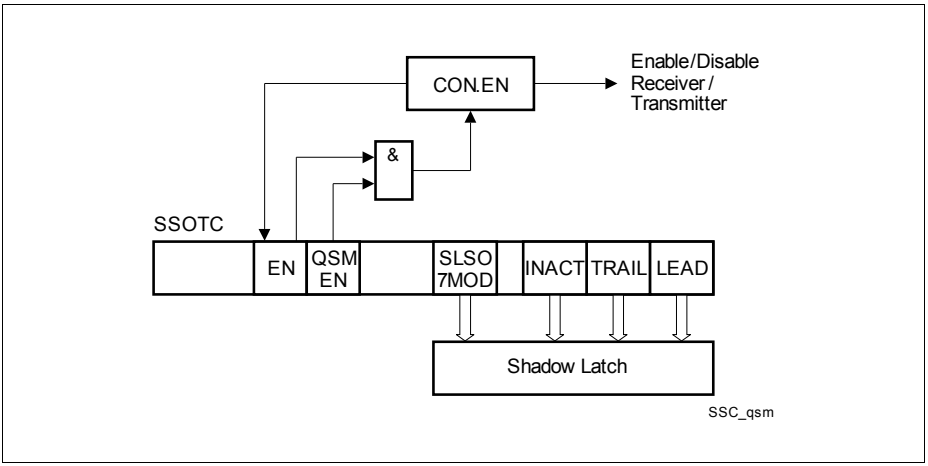

Figure 21-13 Queued SSC Mode Control

Application for Queued SSC Mode

Example: the SSC operates in master mode and controls multiple SSC slave devices with different frame settings and baud rates.

For controlling such an application task, that can be time critical when CPU is used for SSC control, the queued SSC mode is applicable. In this case, the control and data handling for an SSC slave is handled by three DMA channels.

- **DMA Channel 1**
  One DMA transaction consists of four consecutive DMA write transfers, programming registers CON, BR, SSOC, and SSOTC. All these registers are on consecutive addresses with an offset of 4.
  With the CON write operation, CON.EN is set to 0 (SSC disabled). The BR, SSOC, and SSOTC write operations program the SSC slave parameters such as baud rate, frame layout, and slave select output timing. The fourth write operation to SSOTC enables again the SSC by writing SSOTC.QSMEN = 1 and SSOTC.EN = 1. After DMA channel 1 has finished this 4-byte control setup transaction it can be programmed to start automatically data transactions via DMA channel 2 or 3 (depending on the application).
- **DMA Channel 2**
  This DMA channel is setup to write the transmit buffer register TB.
- **DMA Channel 3**
  This DMA channel is setup to read the receive buffer register RB.

Depending on the details of the application, the write or read DMA channel may be unnecessary.

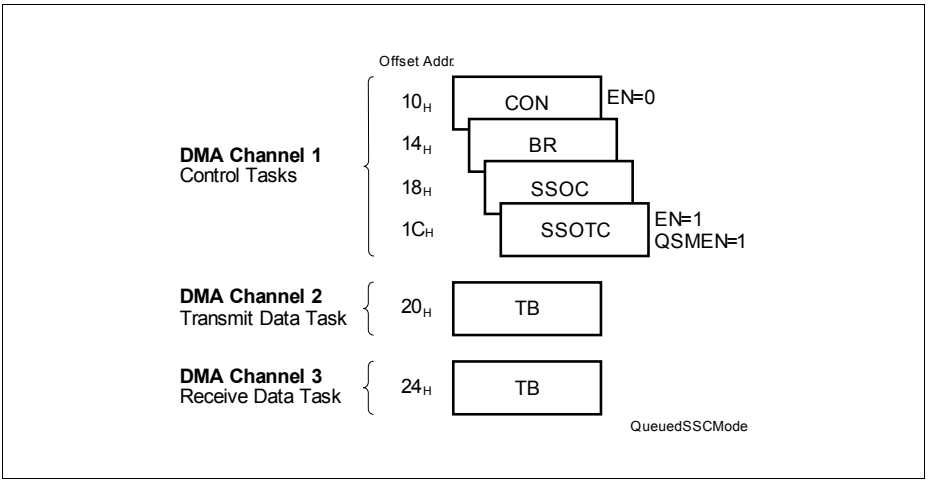

Figure 21-14 SSC Error Interrupt Control

21.2 SSC Kernel Registers

This section describes the kernel registers of the SSC module. All SSC kernel register names described in this section will be referenced in other parts of the TC1798 User´s Manual by the module name prefix “SSC0_” for the SSC0 interface and “SSC1_” for the SSC1 interface.

All registers in the SSC address spaces are reset with the application reset (definition see SCU section “Reset Operation”).

SSC Kernel Register Overview

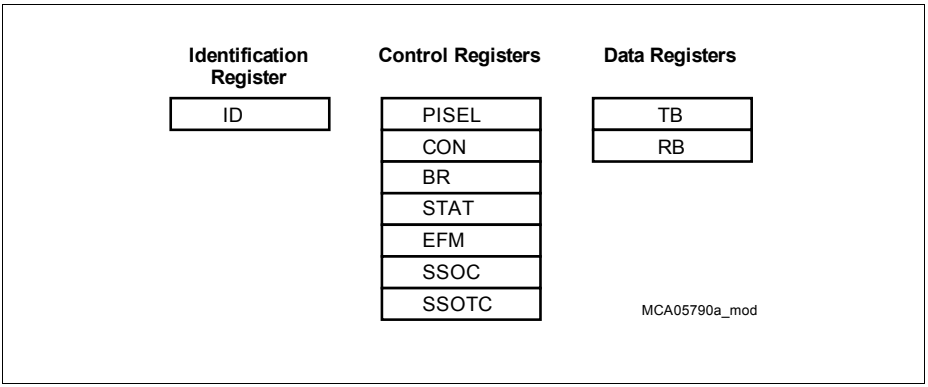

Figure 21-15 SSC Kernel Registers

The complete and detailed address map of the SSC modules is described at the end of this chapter.

Table 21-3 Registers Address Space - SSC Kernel Registers

Module	Base Address	End Address	Note
SSC0	$F031\ 0000_H$	$F031\ 00FF_H$	–
SSC1	$F031\ 0100_H$	$F031\ 01FF_H$	–
SSC2	$F031\ 0200_H$	$F031\ 02FF_H$	–
SSC3	$F031\ 0300_H$	$F031\ 03FF_H$	–

Table 21-4 Registers Overview - SSC Kernel Registers

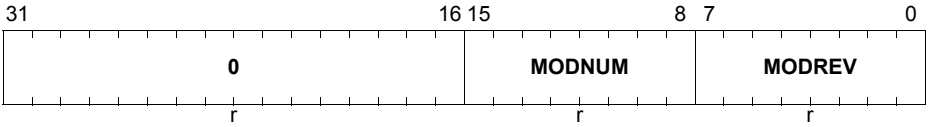
Register Short Name	Register Long Name	Offset Address[1)]	Description see
PISEL	Port Input Select Register	04_H	Page 21-29
ID	Module Identification Register	08_H	Page 21-28
CON	Control Register	10_H	Page 21-31
BR	Baud Rate Timer Reload Register	14_H	Page 21-41
STAT	Status Register	28_H	Page 21-34
EFM	Error Flag Modification Register	$2C_H$	Page 21-36
SSOC	Slave Select Output Control Register	18_H	Page 21-38
SSOTC	Slave Select Output Timing Control Register	$1C_H$	Page 21-39
TB	Transmit Buffer Register	20_H	Page 21-42
RB	Receive Buffer Register	24_H	Page 21-42

1) The absolute register address is calculated as follows:
Module Base Address (Table 21-3) + Offset Address (shown in this column)

21.2.1 Module Identification Register

The SSC Module Identification Register ID contains read-only information about the module version.

ID
Module Identification Register **(08_H)** **Reset Value: 0000 45XX$_H$**



Field	Bits	Type	Description
MODREV	[7:0]	r	**Module Revision Number** MODREV defines the module revision number. The value of a module revision starts with 01_H (first revision).
MODNUM	[15:8]	r	**Module Number Value** This bit field defines the module identification number for the SSC: 45_H

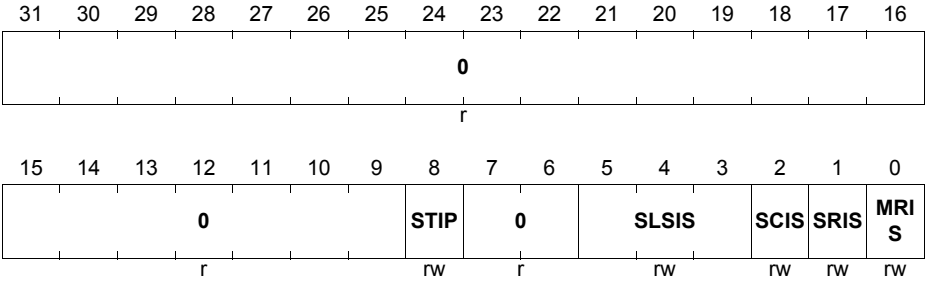
Field	Bits	Type	Description
0	[31:16]	r	**Reserved** Read as 0.

Note: Implementation specific details (e.g. reset value) see ***"Module Identification Registers" on Page 21-43****.*

21.2.2 Control Registers

The PISEL register controls the input signal selection of the SSC module. Each input of the module kernel receive, transmit and clock signals has associated two input lines (marked by suffix A and B).

PISEL
Port Input Select Register **(04_H)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
MRIS	0	rw	**Master Mode Receive Input Select** MRIS selects the receive input line in Master Mode. 0_B Receive input line MRSTA is selected 1_B Receive input line MRSTB is selected
SRIS	1	rw	**Slave Mode Receive Input Select** SRIS selects receive input line in Slave Mode. 0_B Receive input line MTSRA is selected 1_B Receive input line MTSRB is selected
SCIS	2	rw	**Slave Mode Clock Input Select** SCIS selects the module kernel SCLK input line that is used as clock input line in slave mode. 0_B Slave Mode clock input line SCLKA is selected 1_B Slave Mode clock input line SCLKB is selected

Field	Bits	Type	Description
SLSIS	[5:3]	rw	**Slave Mode Slave Select Input Selection** 000_B Slave select input lines are deselected; SSC is operating without slave select input functionality. 001_B $\overline{SLSI}$ input line 1 is selected for operation. 010_B $\overline{SLSI}$ input line 2 is selected for operation. 011_B $\overline{SLSI}$ input line 3 is selected for operation. 100_B $\overline{SLSI}$ input line 4 is selected for operation. 101_B $\overline{SLSI}$ input line 5 is selected for operation. 110_B $\overline{SLSI}$ input line 6 is selected for operation. 111_B $\overline{SLSI}$ input line 7 is selected for operation. In the TC1798, other combinations of SLSIS except 000_B and 001_B are reserved and must not be used.
STIP	8	rw	**Slave Transmit Idle State Polarity** This bit determines the logic level of the Slave Mode transmit signal MRST when the SSC slave select input signals are inactive (PISEL.SLSIS $\neq 000_B$). 0_B MRST = 0 when SSC is deselected in Slave Mode. 1_B MRST = 1 when SSC is deselected in Slave Mode.
0	[7:6], [31:9]	r	**Reserved** Read as 0; should be written with 0.

The operating modes of the SSC are controlled by the Control Register CON. This register contains control bits for mode and error check selection.

Note: Whenever operating mode parameters in the CON register are changed by software, no transfer should be in progress (STAT.BSY = 0) and the SSC should be disabled (CON.EN = 0) and afterwards enabled again (CON.EN = 1).

CON
Control Register **(10_H)** **Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Bits	Type	Description
BM	[3:0]	rw	**Frame Width Selection** BM determines the number of bits of the serial frame. PAREN = 0, parity mode disabled: 0000_B Reserved; do not use this combination. 0001_B Frame width is 2 bits (2 data bits). 0010_B Frame width is 3 bits (3 data bits). $\cdots_B$ ... 1110_B Frame width is 15 bits (15 data bits). 1111_B Frame width is 16 bits (16 data bits). PAREN = 1, parity mode enabled: 0000_B Reserved; do not use this combination. 0001_B Frame width is 2 bits (1 data bit + parity bit. 0010_B Frame width is 3 bits (2 data bits + parity bit). $\cdots_B$ ... 1110_B Frame width is 15 bits (14 data bits + parity bit). 1111_B Frame width is 16 bits (15 data bits + parity bit).

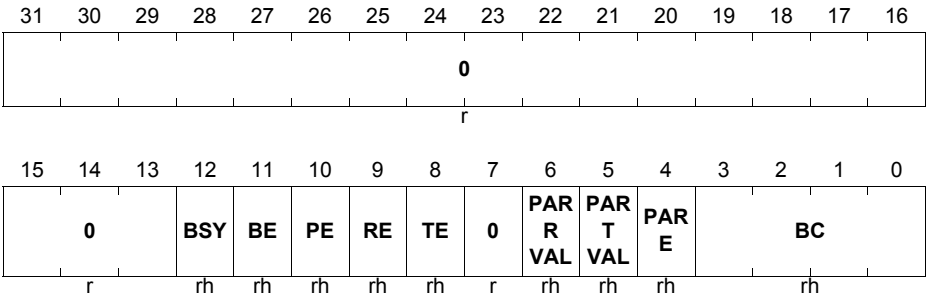
Field	Bits	Type	Description
HB	4	rw	**Heading Bit Control** 0_B Transmit/Receive LSB First 1_B Transmit/Receive MSB First
PH	5	rw	**Clock Phase Control** 0_B Shift transmit data on the leading clock edge, latch on trailing edge 1_B Latch receive data on leading clock edge, shift on trailing edge
PO	6	rw	**Clock Polarity Control** 0_B Idle clock line is low, the leading clock edge is low-to-high transition 1_B Idle clock line is high, the leading clock edge is high-to-low transition
LB	7	rw	**Loop-Back Control** 0_B Normal output 1_B Receive input is connected to transmit output (Half-duplex Mode)
TEN	8	rw	**Transmit Error Enable** 0_B Ignore transmit errors 1_B Check transmit errors
REN	9	rw	**Receive Error Enable** 0_B Ignore receive errors 1_B Check receive errors
PEN	10	rw	**Phase Error Enable** 0_B Ignore phase errors 1_B Check phase errors
BEN	11	rw	**Baud Rate Error Enable** 0_B Ignore baud rate errors 1_B Check baud rate errors
AREN	12	rw	**Automatic Reset Enable** 0_B No additional action upon a baud rate error 1_B SSC is automatically reset on a baud rate error

Field	Bits	Type	Description
MS	14	rw	**Master Select** 0_B Slave Mode. Operate on shift clock received via SCLK 1_B Master Mode. Generate shift clock and output it via SCLK The inverted state of this bit is available on module output line “M/S selected” (see **Figure 21-2**).
EN	15	rw	**Enable Bit** 0_B Transmission and reception are disabled. 1_B Transmission and reception are enabled. This bit is available as module output line “SSC enabled” (see **Figure 21-2**). Note that EN should only be cleared by software while no transfer is in progress (STAT.BSY = 0). Note that the transmission/reception enable can also be controlled in queued SSC mode by bit SSOTC.EN (see **Page 21-24**).
PARTEN	16	rw	**Parity Transmit Enable Bit** This bit enables the parity mode for the transmission of frames. 0_B Parity mode for transmission is disabled. 1_B Parity mode for transmission is enabled.
PARREN	17	rw	**Parity Receive Enable Bit** This bit enables the parity mode for the reception of frames. 0_B Parity mode for reception is disabled. 1_B Parity mode for reception is enabled.
PARTYP	18	rw	**Parity Type Bit** If PAREN = 1, this bit defines the type of parity to be generated or checked. 0_B Even parity is selected (parity bit = 1 on odd number of 1s in data, parity bit = 0 on even number of 1s in data). 1_B Odd parity selected (parity bit = 1 on even number of 1s in data, parity bit = 0 on odd number of 1s in data)
PAREEN	19	rw	**Parity Error Enable** 0_B Ignore receive parity errors 1_B Check receive parity errors

Field	Bits	Type	Description
0	13, [31:20]	r	**Reserved** Read as 0; should be written with 0.

The Status Register STAT contains status flags for error identification, the busy flag, and a bit field that indicates the current shift counter status.

STAT
Status Register **(28_H)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
BC	[3:0]	rh	**Bit Count Status** BC indicates the current status of the shift counter. The shift counter is updated with every shifted bit.
PARE	4	rh	**Parity Error Flag** 0_B No error 1_B Received parity bit is wrong.
PARTVAL	5	rh	**Parity Transmit Value** If parity mode is enabled, this bit indicates the calculated parity bit for the transmission of the actual serial frame. PARTVAL is written with the transmit parity value when the shift register is loaded from TB. PARTVAL is reset when CON.PAREN is reset.
PARRVAL	6	rh	**Parity Receive Value** if parity mode is enabled, this bit PARRVAL is loaded when the received data is written into RB. PARRVAL is reset when CON.PAREN is reset.

Field	Bits	Type	Description
TE	8	rh	**Transmit Error Flag** 0_B No error 1_B Transfer starts with the slave's transmit buffer not being updated
RE	9	rh	**Receive Error Flag** 0_B No error 1_B Reception completed before the receive buffer was read
PE	10	rh	**Phase Error Flag** 0_B No error 1_B Received data changes during the sampling clock edge
BE	11	rh	**Baud Rate Error Flag** 0_B No error 1_B There is more than factor 2 or less than factor 0.5 between the slave's actual and the expected baud rate.
BSY	12	rh	**Busy Flag** BSY is set while a transfer is in progress.
0	7, [31:13]	r	**Reserved** Read as 0; should be written with 0.

The Error Flag Modification Register EFM is required for clearing or setting the four error flags which are located in register STAT.

EFM
Error Flag Modification Register (2C$_H$) Reset Value: 0000 0000$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

SETBE	SETPE	SETRE	SETTE	CLRBE	CLRPE	CLRRE	CLRTE	0			SETPARE	0			CLRPARE
w	w	w	w	w	w	w	w	r			w	r			w

Field	Bits	Type	Description
CLRPARE	0	w	**Clear Parity Error Flag** 0_B No effect 1_B Bit STAT.PARE is cleared. Bit is always read as 0.
SETPARE	4	w	**Set Parity Error Flag** 0_B No effect 1_B Bit STAT.PARE is set. Bit is always read as 0.
CLRTE	8	w	**Clear Transmit Error Flag** 0_B No effect 1_B Bit STAT.TE is cleared. Bit is always read as 0.
CLRRE	9	w	**Clear Receive Error Flag** 0_B No effect 1_B Bit STAT.RE is cleared. Bit is always read as 0.
CLRPE	10	w	**Clear Phase Error Flag** 0_B No effect 1_B Bit STAT.PE is cleared. Bit is always read as 0.

Field	Bits	Type	Description
CLRBE	11	w	**Clear Baud Rate Error Flag** 0_B No effect 1_B Bit STAT.BE is cleared. Bit is always read as 0.
SETTE	12	w	**Set Transmit Error Flag** 0_B No effect 1_B Bit STAT.TE is set. Bit is always read as 0.
SETRE	13	w	**Set Receive Error Flag** 0_B No effect 1_B Bit STAT.RE is set. Bit is always read as 0.
SETPE	14	w	**Set Phase Error Flag** 0_B No effect 1_B Bit STAT.PE is set. Bit is always read as 0.
SETBE	15	w	**Set Baud Rate Error Flag** 0_B No effect 1_B Bit STAT.BE is set. Bit is always read as 0.
0	[3:1], [7:5], [31:16]	r	**Reserved** Read as 0; should be written with 0.

Note: When the set and clear bits for an error flag are set at the same time during an EFM write operation (e.g SETPE = CLRPE = 1), the error flag in STAT is not affected.

The Slave Select Output Control Register controls the operation of the Chip Select Output Generation Unit.

SSOC

Slave Select Output Control Register (18_H) **Reset Value: $0000\ 0000_H$**

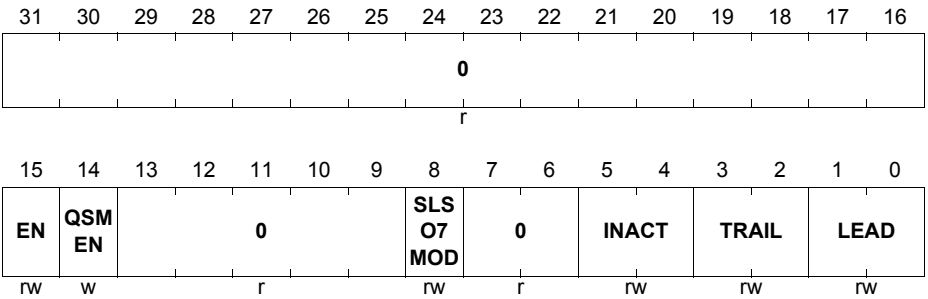
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
AOLn (n = 0-7)	n	rw	**Active Output Level** 0_B SLSOn is at low level during the chip select active time $t_{SLSOACT}$. The high level is the inactive level of SLSOn. 1_B SLSO line n is at high level during the chip select active time $t_{SLSOACT}$. The low level is the inactive level of SLSOn.
OENn (n = 0-7)	8 + n	rw	**Output n Enable Control** 0_B SLSOn output is disabled; SLSOn is always at inactive level as defined by AOLn. 1_B SLSOn output is enabled.
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

Note: The SSOC register content is latched by each TB register write operation and remains latched during the consecutive serial transmission.

The Slave Select Output Timing Control Register controls the operation of the Slave Select Output Generation Unit.

SSOTC
Slave Select Output Timing Control Register
($1C_H$) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
LEAD	[1:0]	rw	**Slave Output Select Leading Delay** This bit field determines the number of leading delay clock cycles. A leading delay clock cycle is always a multiple of an SCLK shift clock period. 00_B Zero leading delay clock cycle selected[1)] 01_B One leading delay clock cycle selected 10_B Two leading delay clock cycles selected 11_B Three leading delay clock cycles selected
TRAIL	[3:2]	rw	**Slave Output Select Trailing Delay** This bit field determines the number of trailing delay clock cycles. A trailing delay clock cycle is always a multiple of an SCLK shift clock period. 00_B Zero trailing delay clock cycle selected[1)] 01_B One trailing delay clock cycle selected 10_B Two trailing delay clock cycles selected 11_B Three trailing delay clock cycles selected

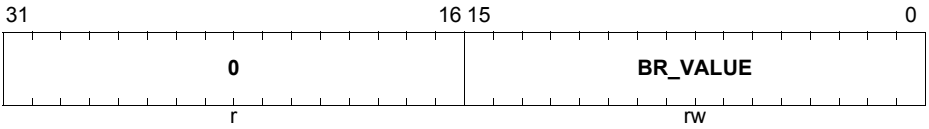
Field	Bits	Type	Description
INACT	[5:4]	rw	**Slave Output Select Inactive Delay** This bit field determines the number of inactive delay clock cycles. An inactive delay clock cycle is always a multiple of an SCLK shift clock period. 00_B Zero inactive delay clock cycle selected[1)] 01_B One inactive delay clock cycle selected 10_B Two inactive delay clock cycles selected 11_B Three inactive delay clock cycles selected
SLSO7MOD	8	rw	**SLSO7 Delayed Mode Selection** This bit selects the delayed mode for the SLSO7 slave select output. 0_B Normal mode selected for SLSO7 1_B Delayed mode selected for SLSO7
QSMEN	14	w	**Queued SSC Mode Enabled** 0_B When QSMEN is written with 0, the state of bit SSOTC.EN is don't care. In this case, the enable/disable of the SSC is controlled by bit CON.EN only. Note that EN should only be cleared by software while no transfer is in progress (STAT.BSY = 0). 1_B When QSMEN is written with 1, queued SSC mode is enabled, and the state of bit SSOTC.EN is copied to CON.EN. QSMEN is always read as 0.
EN	15	rw	**Enable Bit** 0_B Transmission and reception are disabled. 1_B Transmission and reception are enabled. Note that the transmission/reception enable can also be controlled in queued SSC mode by bit CON.EN.
0	[7:6], [13:9], [31:16]	r	**Reserved** Read as 0; should be written with 0.

1) For getting a best case timing with no timing delays (see **Figure 21-9**), this bit field value should be set when the SLSOn outputs are disabled (SSOC.OENn bits set to 0).

Note: The SSOTC register timing parameters LEAD, TRAIL, INACT, and SLSO7MOD are latched by each TB register write operation and remain latched during a consecutive serial transmission. Bits QSMEN and EN of register SSOTC are not latched.

The Baud Rate Timer Reload Register BR contains the 16-bit reload value for the baud rate timer.

BR
Baud Rate Timer Reload Register (14_H) Reset Value: 0000 0000_H

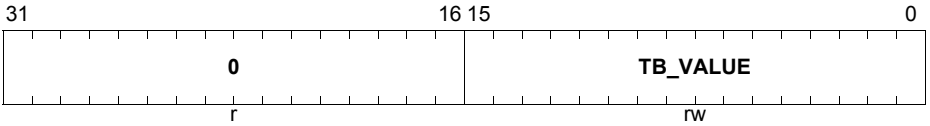


Field	Bits	Type	Description
BR_VALUE	[15:0]	rw	**Baud Rate Timer/Reload Register Value** Reading BR returns the 16-bit content of the baud rate timer. Writing BR loads the baud rate timer reload register with BR_VALUE.
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

21.2.3 Data Registers

The Transmit Buffer Register TB contains the transmit data value. A TB write operation latches all timing parameters stored in register SSOTC.

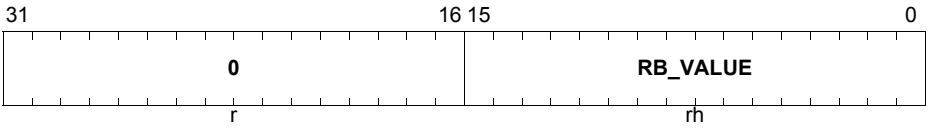
TB
Transmit Buffer Register **(20_H)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
TB_VALUE	[15:0]	rw	**Transmit Data Register Value** Register TB stores the data value to be transmitted TB_VALUE. Unused bits of TB_VALUE (as defined by CON.BM) are ignored during transmission.
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

The Receive Buffer Register RB contains the receive data value.

RB
Receive Buffer Register **(24_H)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
RB_VALUE	[15:0]	rh	**Receive Data Register Value** Register RB contains the received data value RB_VALUE (without the parity bit in parity mode) right aligned. Unused bits of RB_VALUE (as defined by CON.BM) will not be valid and should be ignored.
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

21.3 SSC0/SSC1/SSC2/SSC3 Module Implementation

This section describes SSC0/SSC1/SSC2/SSC3 module interfaces with the clock control, port connections, interrupt control, and address decoding.

21.3.1 Module Identification Registers

The reset values of the SSCx_ID module identification registers are 0000 4512_H.

21.3.2 Interfaces of the SSC Modules

Figure 21-16 and **Figure 21-17** show the TC1798-specific implementation details and interconnections of the SSC0/SSC1/SSC2/SSC3 modules.

Each of the SSC modules is supplied with a separate clock control, interrupt control, and address decoding logic. Two interrupt outputs can be used to generate DMA requests. The SSC0/SSC1/SSC2/SSC3 I/O lines are connected to Port 1, Port 2, Port 4, Port 6, Port 7, Port 10 and Port 18.

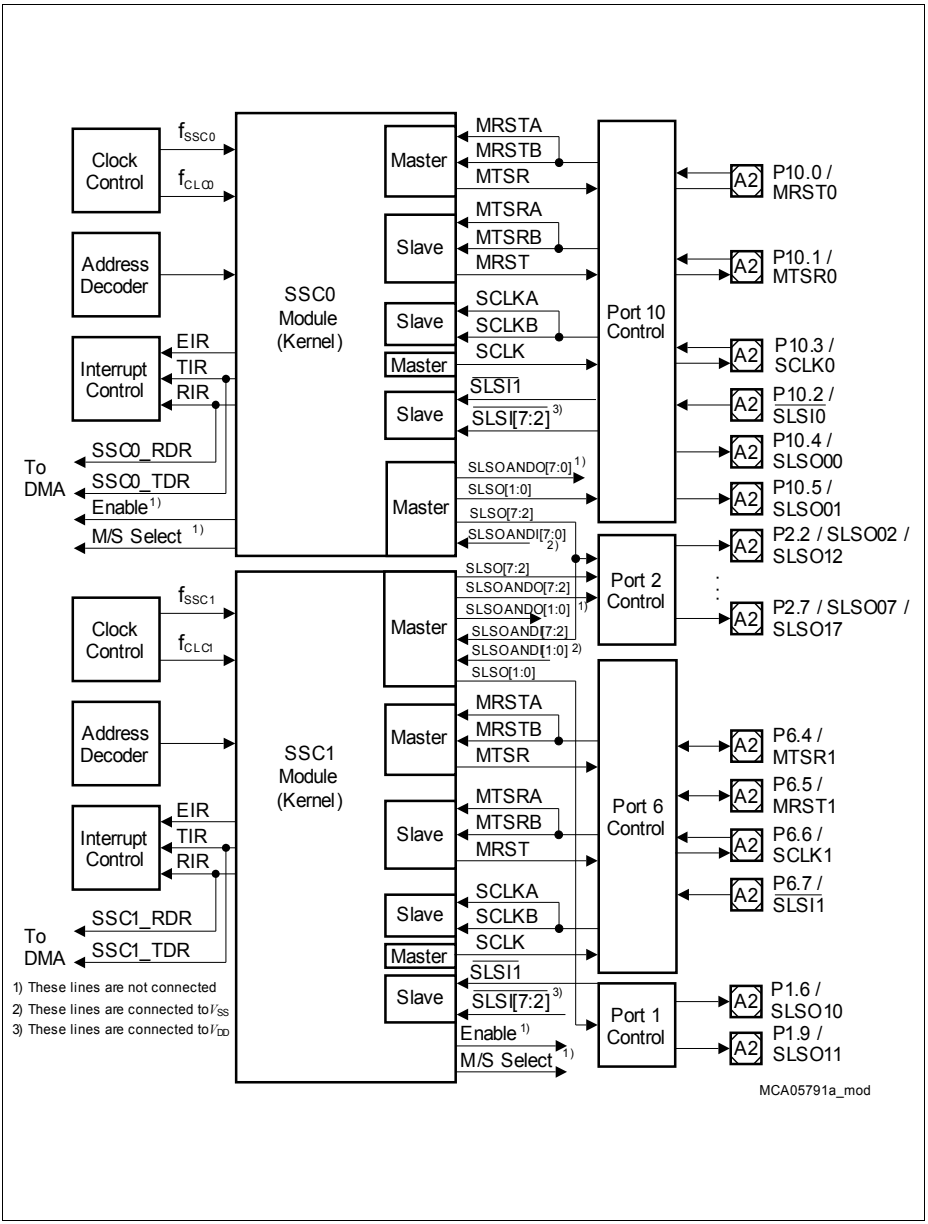


Figure 21-16 SSC0/SSC1 Module Implementation and Interconnections

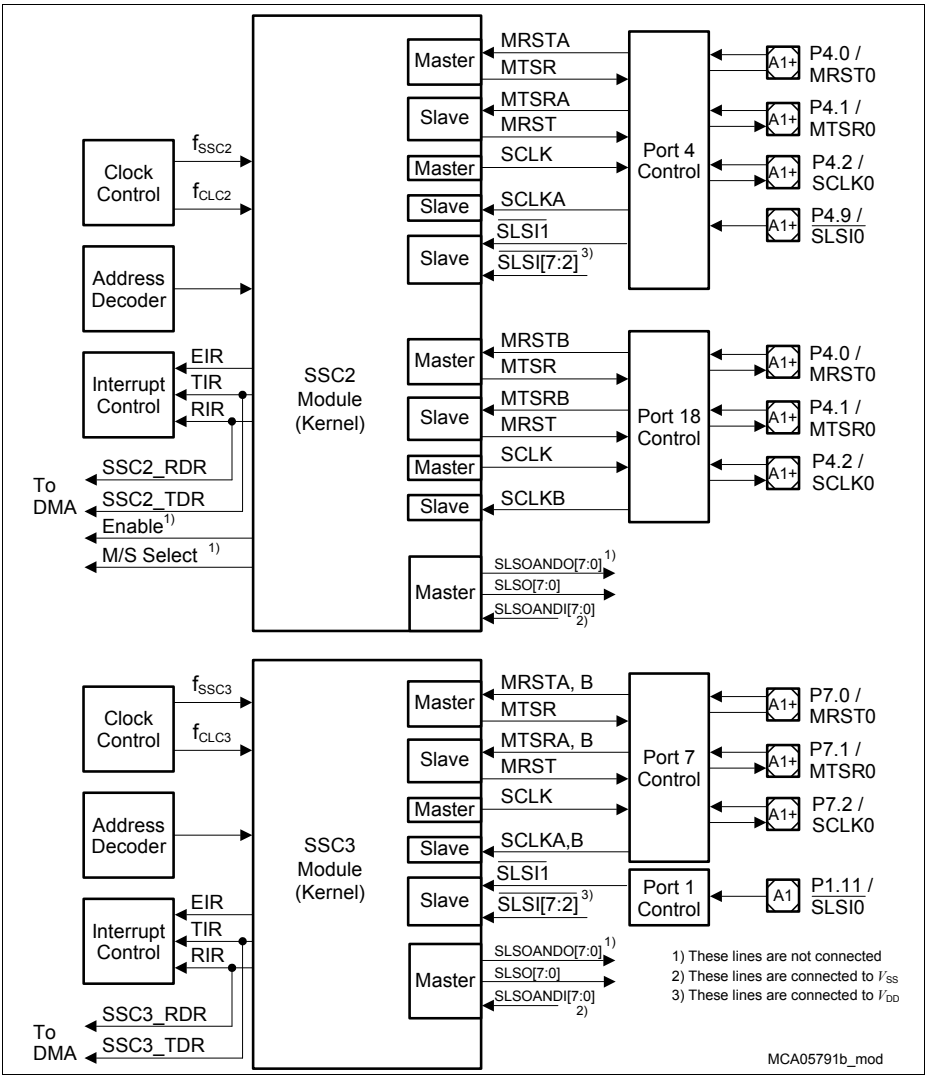

Figure 21-17 SSC2/SSC3 Module Implementation and Interconnections

21.3.3 On-Chip Connections

This section describes the on-chip connections of the SSC0/SSC1/SSC2 modules.

DMA Requests

The DMA request lines of the SSC0/SSC1/SSC2 modules become active whenever the related interrupt line is activated. The DMA request lines are connected to the DMA controller as shown in **Table 21-5**.

Table 21-5 DMA Request Lines of SSC0/SSC1/SSC2/SSC3

Module	SSC Interrupt Request Line	DMA Request Line	Description
SSC0	RIR	SSC0_RDR	DMA Channel 00 Request Input 4
			DMA Channel 06 Request Input 4
	TIR	SSC0_TDR	DMA Channel 02 Request Input 4
			DMA Channel 04 Request Input 4
SSC1	RIR	SSC1_RDR	DMA Channel 01 Request Input 4
			DMA Channel 07 Request Input 4
	TIR	SSC1_TDR	DMA Channel 03 Request Input 4
			DMA Channel 05 Request Input 4
SSC2	RIR	SSC2_RDR	DMA Channel 00 Request Input 13
	TIR	SSC2_TDR	DMA Channel 02 Request Input 13
SSC3	RIR	SSC2_RDR	DMA Channel 07 Request Input 12
	TIR	SSC2_TDR	DMA Channel 06 Request Input 12

21.3.4 SSC0/SSC1/SSC2/SSC3 Module Related External Registers

Figure 21-18 summarizes the module-related external registers which are required for SSC0/SSC1/SSC2/SSC3 programming (see also **Figure 21-15** for the module kernel specific registers).

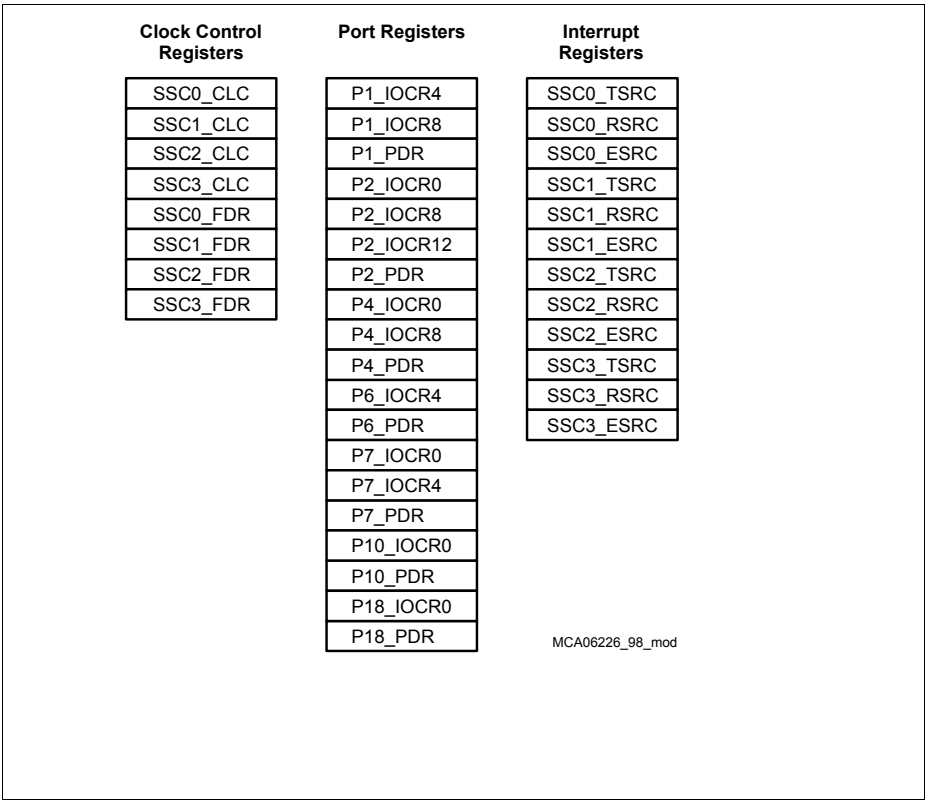

Figure 21-18 SSC0/SSC1/SSC2/SSC3 Implementation-specific Special Function Registers

21.3.4.1 Clock Control

Each SSC module has two clock signals (x = 0-3):

- f_{CLCx}
  This is the module clock that is used inside the SSC kernel for control purposes such as clocking of control logic and register operations. The frequency of f_{CLCx} is always identical to the system clock frequency f_{FPI}. The clock control registers SSCx_CLC make it possible to enable/disable f_{CLCx} under certain conditions.
- f_{SSCx}
  This clock is the module clock that is used in the SSCx as input clock of the baud rate generator, which finally determines the baud rate of the serial data. The fractional divider registers SSCx_FDR control the frequency of f_{SSCx} and make it possible to enable/disable it independently of f_{CLCx}.
  The Baud Rate Timer Reload Register SSCx_BR define serial data baud rate dependent from the frequency of f_{SSCx}.

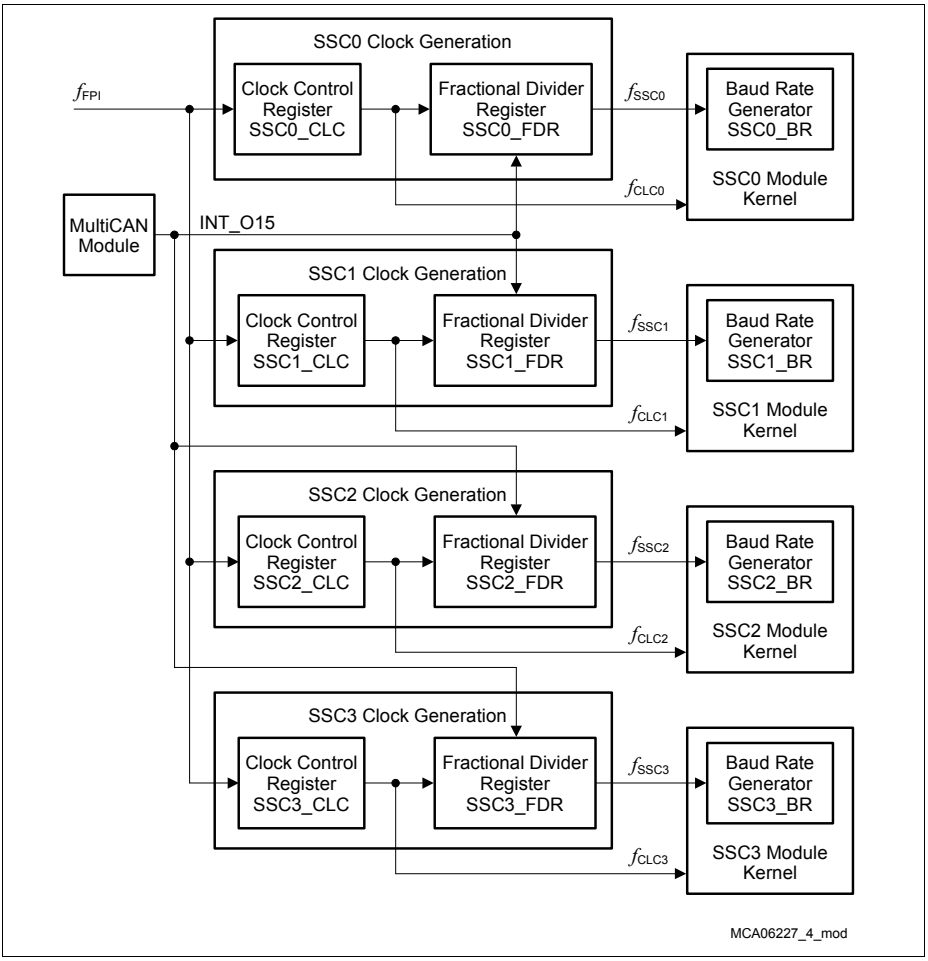

Figure 21-19 SSC Clock Generation

Output signal CAN_INT_O15 of the MultiCAN module can be used for external clock enable control of the fractional divider.

The following formulas define the frequency of f_{SSCx}.

$$f_{SSCx} = f_{FPI} \times \frac{1}{n} \text{ with n = 1024 - FDR.STEP} \quad (21.2)$$

$$f_{SSCx} = f_{FPI} \times \frac{n}{1024} \text{ with n = 0-1023} \quad (21.3)$$

Note: In SSC Master Mode, the maximum shift clock frequency is $f_{SSCx}/2$. In SSC Slave Mode, the maximum shift clock frequency is $f_{SSCx}/4$.

Combined with the formulas of the baud rate generator (see **Page 21-14**) and the fractional divider, the resulting serial data baud rate is defined by:

$$\text{Baud rate}_{SSC} = \frac{f_{FPI}}{2 \times (\text{BR.BR\_VALUE} + 1) \times (1024 - \text{FDR.STEP})} \quad (21.4)$$

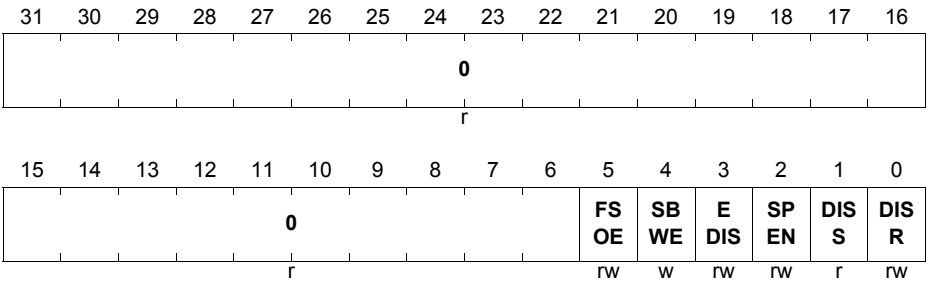
$$\text{Baud rate}_{SSC} = \frac{f_{FPI} \times \text{FDR.STEP}}{2 \times (\text{BR.BR\_VALUE} + 1) \times 1024} \text{ with FDR.STEP = 0-1023} \quad (21.5)$$

*Note: **Equation (21.2)** and **Equation (21.4)** apply to normal divider mode of the fractional divider (FDR.DM = 01_B). **Equation (21.3)** and **Equation (21.5)** apply to fractional divider mode (FDR.DM = 10_B).*

Clock Control Register

Each SSC has its own clock control register. The Clock Control Registers SSCx_CLC make it possible to control (enable/disable) the clock signals f_{CLCx} under certain conditions.

SSC0_CLC
SSC0_Clock Control Register **(00_H)** **Reset Value: 0000 0003$_H$**
SSC1_CLC
SSC1 Clock Control Register **(00_H)** **Reset Value: 0000 0003$_H$**
SSC2_CLC
SSC2 Clock Control Register **(00_H)** **Reset Value: 0000 0003$_H$**
SSC3_CLC
SSC3 Clock Control Register **(00_H)** **Reset Value: 0000 0003$_H$**



Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module.
DISS	1	r	**Module Disable Status Bit** Bit indicates the current status of the module.
SPEN	2	rw	**Module Suspend Enable for OCDS** Used to enable the suspend mode.
EDIS	3	rw	**Sleep Mode Enable Control** Used to control module's sleep mode.
SBWE	4	w	**Module Suspend Bit Write Enable for OCDS** Determines whether SPEN and FSOE are write-protected.
FSOE	5	rw	**Fast Switch Off Enable** Used to switch off fast clock in Suspend Mode.

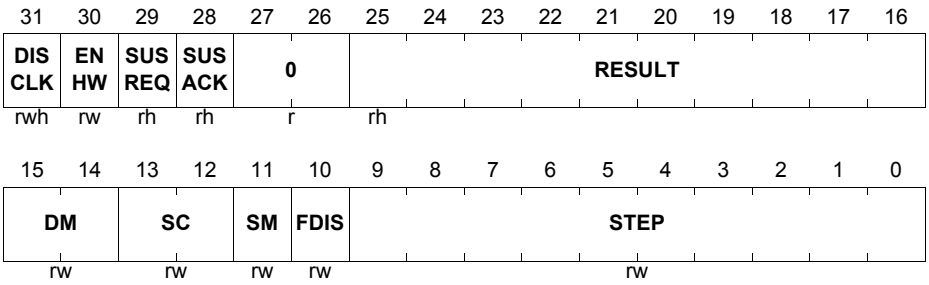
Field	Bits	Type	Description
0	[31:6]	r	**Reserved** Read as 0; should be written with 0.

Note: After a hardware reset operation, the f_{CLCx} clocks are disabled, and therefore also the SSC modules are disabled (DISS set).

Fractional Divider Register

Each SSC has its own fractional divider register. The Fractional Divider Registers SSCx_FDR control the clock rate of the shift clocks f_{SSCx}.

SSC0_FDR
SSC0 Fractional Divider Register (0C$_H$) Reset Value: 1000 0000$_H$
SSC1_FDR
SSC1 Fractional Divider Register (0C$_H$) Reset Value: 1000 0000$_H$
SSC2_FDR
SSC2 Fractional Divider Register (0C$_H$) Reset Value: 1000 0000$_H$
SSC3_FDR
SSC3 Fractional Divider Register (0C$_H$) Reset Value: 1000 0000$_H$



Field	Bits	Type	Description
STEP	[9:0]	rw	**Step Value** Reload or addition value for RESULT.
FDIS	10	rw	**Freeze Disable** This bit controls the freeze function for this module. 0_B Module operates on corrected clock, with reduced modulation jitter. 1_B Module operates on uncorrected clock, with full modulation jitter.

Field	Bits	Type	Description
SM	11	rw	**Suspend Mode** SM selects between granted or immediate suspend mode.
SC	[13:12]	rw	**Suspend Control** This bit field determines the behavior of the fractional divider in suspend mode.
DM	[15:14]	rw	**Divider Mode** This bit field selects normal divider mode, fractional divider mode, and off-state.
RESULT	[25:16]	rh	**Result Value** Bit field for the addition result.
SUSACK	28	rh	**Suspend Mode Acknowledge** Indicates state of SPNDACK signal.
SUSREQ	29	rh	**Suspend Mode Request** Indicates state of SPND signal.
ENHW	30	rw	**Enable Hardware Clock Control** Controls operation of ECEN input and DISCLK bit.
DISCLK	31	rwh	**Disable Clock** Hardware-controlled disable for f_{OUT} signal.
0	[27:26]	r	**Reserved** Read as 0; should be written with 0.

21.3.4.2 Port Control

Note: The SSCs in the TC1798 do not directly control the I/O functionality of pins. Therefore, control bits CON.EN and CON.MS have no functionality.

The interconnections between the SSC modules and the I/O lines/pins are controlled by software in the port logics. The SSC0/SSC1/SSC2 I/O functionality must be selected by the following port control operations (additionally to the PISEL programming):

- Input/output function selection (IOCR registers)
- Pad driver characteristics selection for the outputs (PDR registers)

The SSC0/SSC1/SSC2 port input/output control registers contain the bit fields that select the digital output and input driver characteristics such as pull-up/down devices, port direction (input/output), open-drain, and alternate output selections.

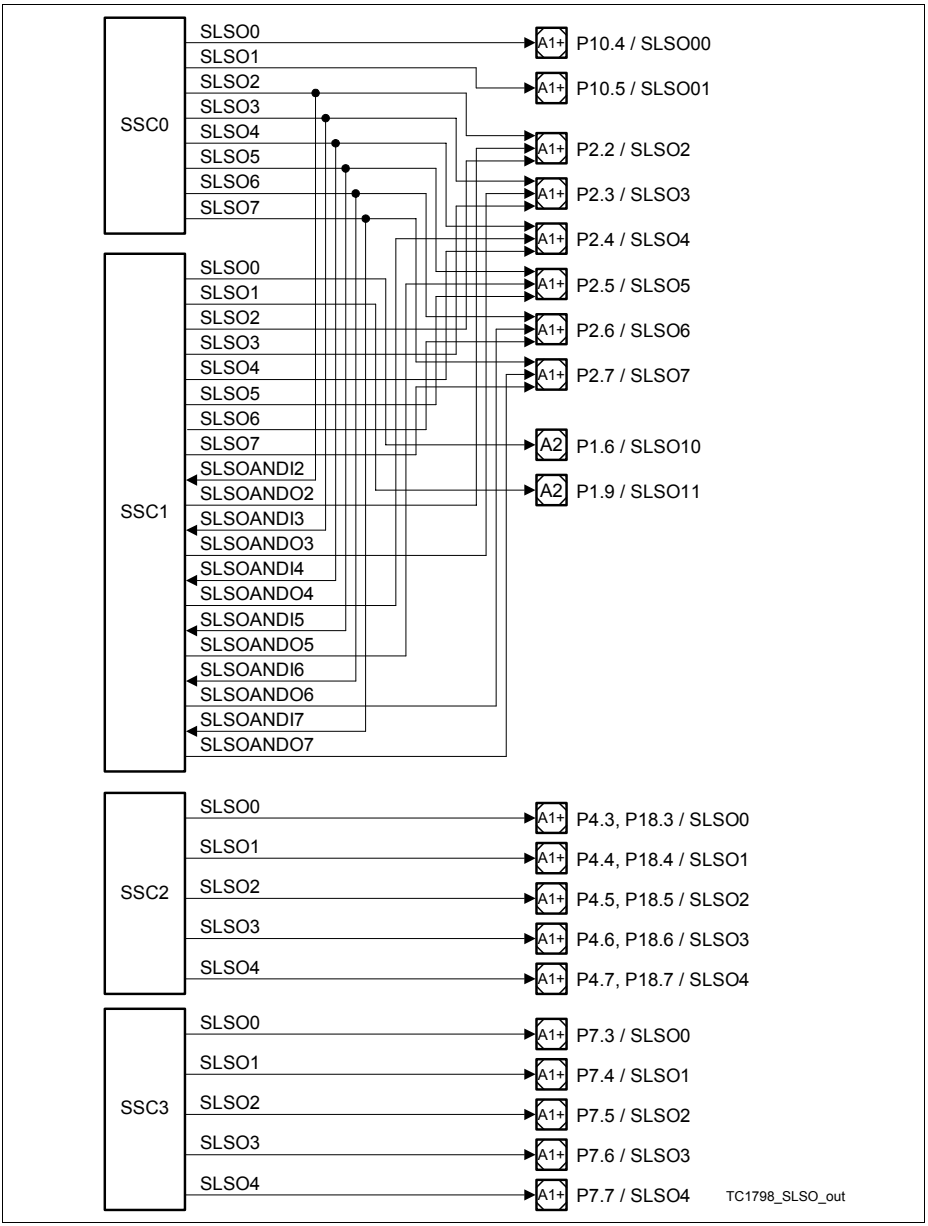


Figure 21-20 SLSI and SLSO Input/Output Connections

Table 21-6 shows how bits and bit fields must be programmed for the required I/O functionality of the SSC I/O lines.

Table 21-6 SSC I/O Line Selection and Setup

Module	Port Lines	Input/Output Control Register Bits	I/O

21.3.4.3 Interrupt Control Registers

The 3 × 3 interrupts of the SSC0/SSC1/SSC2 modules are controlled by the following service request control registers:

- SSCx_TSRC (x = 0-3) controls the transmit interrupts of the SSCx module
- SSCx_RSRC (x = 0-3) controls the receive interrupts of the SSCx module
- SSCx_ESRC (x = 0-3) controls the error interrupts of the SSCx module

TSRC

22 Synchronous Serial Interface Guardian (SSCG)

This chapter describes one SSCG module in top-down fashion. The chapter consists of the following sections:

- Overview - providing a description of the subsystem consisting of one SSC module and the corresponding SSCG module.
- Kernel description, describing how the SSCG module works and how it is to be used.
- Registers description, providing detailed information on each SSCG specific register.
- TC1798 implementation description.

22.1 Overview

Figure 22-1 shows a sub-system consisting of
- one SSC module SSC0
- one SSCG module SSCG0

This sub-system can be analyzed independently of the rest of the chip. One chip can contain one or more such subsystems.

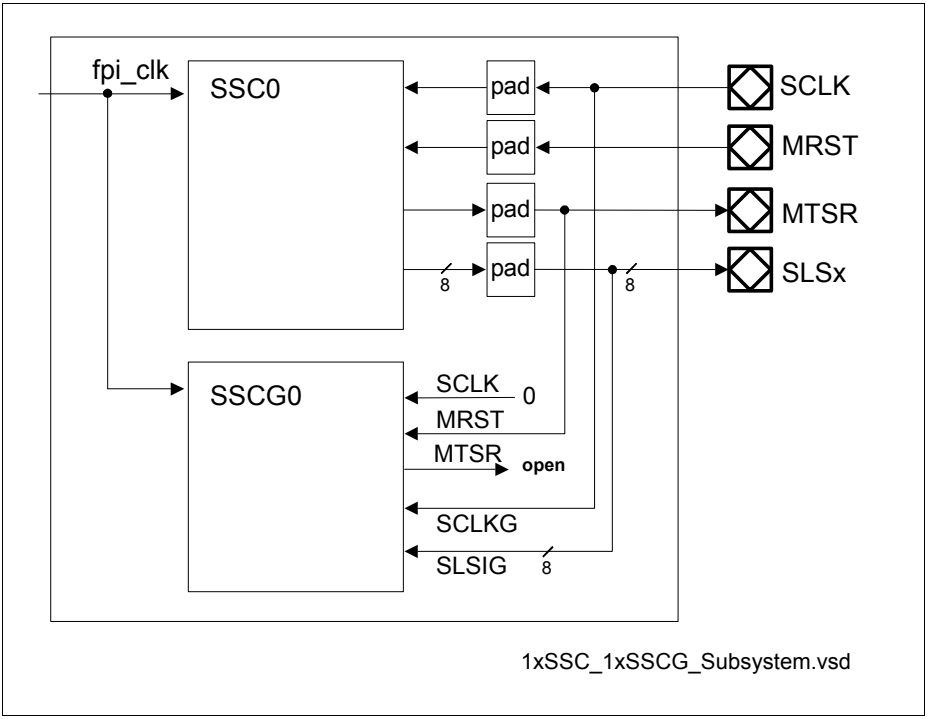

Figure 22-1 General Block Diagram of an SSC / SSCG Sub-System

22.1.1 General Operation

One SSCG monitors one SSC module. The SSCG itself can be considered as an SSC module, extended with some additional logic and registers. It is always configured in master mode, that is, the same as the monitored SSC. On the serial communication side, it receives all messages transmitted by the SSC module. On the FPI bus side, its registers inherited from the SSC module are always written in parallel to the registers of the SSC and contain identical values. The SSCG has an additional compare logic with additional registers which compares a copy of the ideal transmit message with the message that really appears on the pin. If a mismatch occurs, an interrupt is raised.

A user software can access the SSCG by reading / writing in two address ranges: one address range common to SSC and SSCG, and one dedicated to SSCG only. The extended SSCG registers can be accessed only through the dedicated address range.

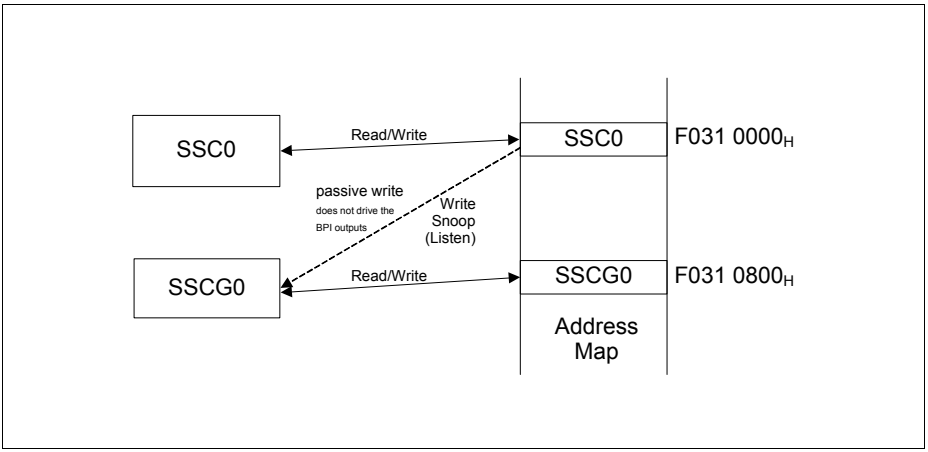

Figure 22-2 An Address Map of an SSC / SSCG Sub-System

22.2 SSCG Kernel Description

This chapter describees the additional functionality provided by the guardian.

22.2.1 Details on the Operation Principles and the Architecture

The SSCG module generates its own clock the same way the SSC does, by using identical but independent hardware. SSCG is initialized in parallel to the SSC using the same write accesses for initializing the SSC. The parallel register accesses insure cycle accurate parallel operation of the both modules.

Once all the common registers are initialized and the SSC starts to operate, the guardian immediately and transparently to the user starts with comparing the outgoing messages on the pin to the ideally programmed messages written in the transmit buffers of the SSC and the SSCG.

The SSC and the guardian both transmit the same message in parallel with their state machines operating cycle-synchronously, but whereas the SSC receives messages from the outside world, the SSCG receives the message being sent by its SSC.

A write to the transmit buffer of the SSCG copies in parallel the message to two locations: to the shift register and to the TB1 register. The message shifted out of the guardian ends nowhere, but the SSC transmitted message, which should be the identical one, is shifted into the guardian. The received message is copied from the shift register to the receive buffer and with this copy event a comparison between the sent and the received message is triggered.

If a difference is detected, an interrupt is raised, the contents of the TB1 and RB are copied to the snapshot registers TB1SNAP and RBSNAP, and at the same time the sticky error flag SNAPF is set. The hardware can only set the bit SNAPF, and the software can reset (or set) this flag. Reading this flag by software does not reset this flag automatically. It is reset by a second memory access, a write to the GEFM register.

Message Length

The message length can vary according to the settings from 2 to 16 bits. The padding bits not belonging to the message filling the maximum length of 16 are undefined, and shall be masked out when performing the comparison.

Parity Bit

If the parity bit is set, than the effective message length is one bit shorter, and the total length includes the concatenated parity bit. Parity error shall be raised by the guardian using the normal parity check mechanisms. The guardian comparison shall be done on effective message length, taking the parity out.

Snapshots

The SSCG keeps a snapshot of the information of the last error message in the registers TB1SNAP and RBSNAP. The SNAPF bit flags that error occurred. The snapshot is sticky, that is it is not destroyed by the consequent correct messages. Only a new error message overwrites the snapshot of an old error message. A lost snapshot is not flagged.

Interrupts

The three SSC interrupts, the Rx and Tx and Error interrupts, are not used.

There is a dedicated SSCG interrupt node, signaling a comparison error and parity error.

Both errors cause taking a sticky snapshot on TB1 and RB. Compare error sets the sticky flag GSTAT.CE. Parity error sets the sticky flag STAT.PARE.

Additionally the SSCG interupt node signals a phase error and clock and slave select compare errors.

Phase error sets the sticky flag STAT.PE. Clock and slave select errors set the sticky flags in the GSTAT register.

Data comparison error and the parity error trigger the interrupt after the data comparison has been done. The SLS and CLK comparison errors and the phase error trigger an interrupt immediately.

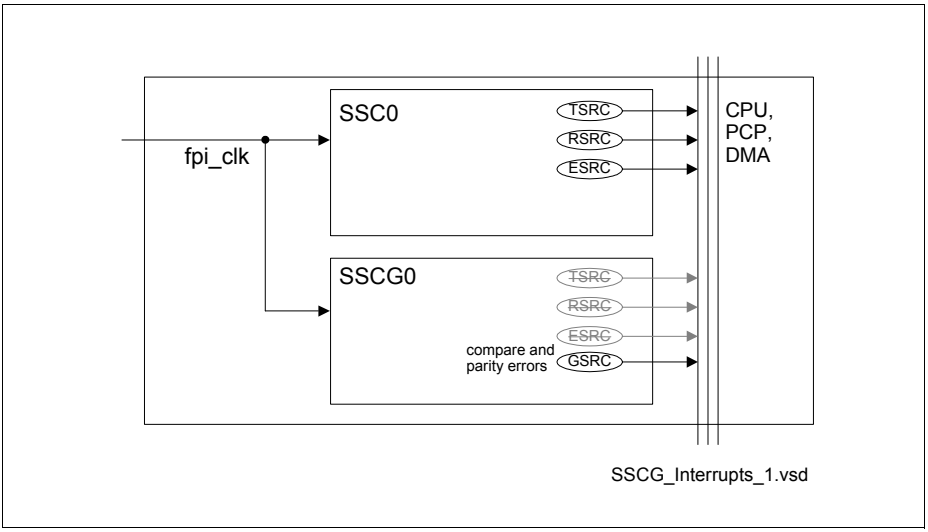

Figure 22-3 SSCG Interrupts

22.2.1.1 Monitoring the Slave Select and Serial Clock Signals

The slave select signals SLSx are monitored continuously with the same serial clock edge as the data signals. In contrast to the data signal which is sampled only during the data shift phase, all SLS signals are sampled and compared all the time: during the idle, leading delay, data shift, inter word delay, and trailing delay phases. The goal is to monitor if the SSC module operates properly and to detect stuck-at and other failiures in the hardware of the module.

The clock signal SCLK is monitored continuously in the middle of each half-period. This is achieved by using a double frequency, which is generated by a dedicated clock divider, similar to the main baud-rate generator. The purpose of the monitoring is to assure the corect operation of the SSC baud-rate generator and quickly detect hardware failiures.

This concept covers the hardware operation with focus on the digital functionality. Checking the timing constraints is not a subject of the monitoring, due to the wide variation of the timings and their dependency on process, voltage, temperature and the capacitive load at the lines. Therefore the baud rates are limited to single digit Mbaud rates, which is necessary in order to have robust monitoring without timing violations and with stable signals arround the sample points. Communication disturbances due to signal glitches and EMI effects can not be covered sufficiently using monitoring with digital sampling, and therefore they are not covered. They are covered with the parity bit and taken care of by the customer during the design of the printed circuit board.

Each of the eight SLS signals and the one SCLK is associated to a sticky flag signaling an occurence of a mismatch between an SSC signal and the corresponding SSCG signal. It is set by hardware and can be reset only by software. For test purposes these flags can be set by software, using the GEFM register.

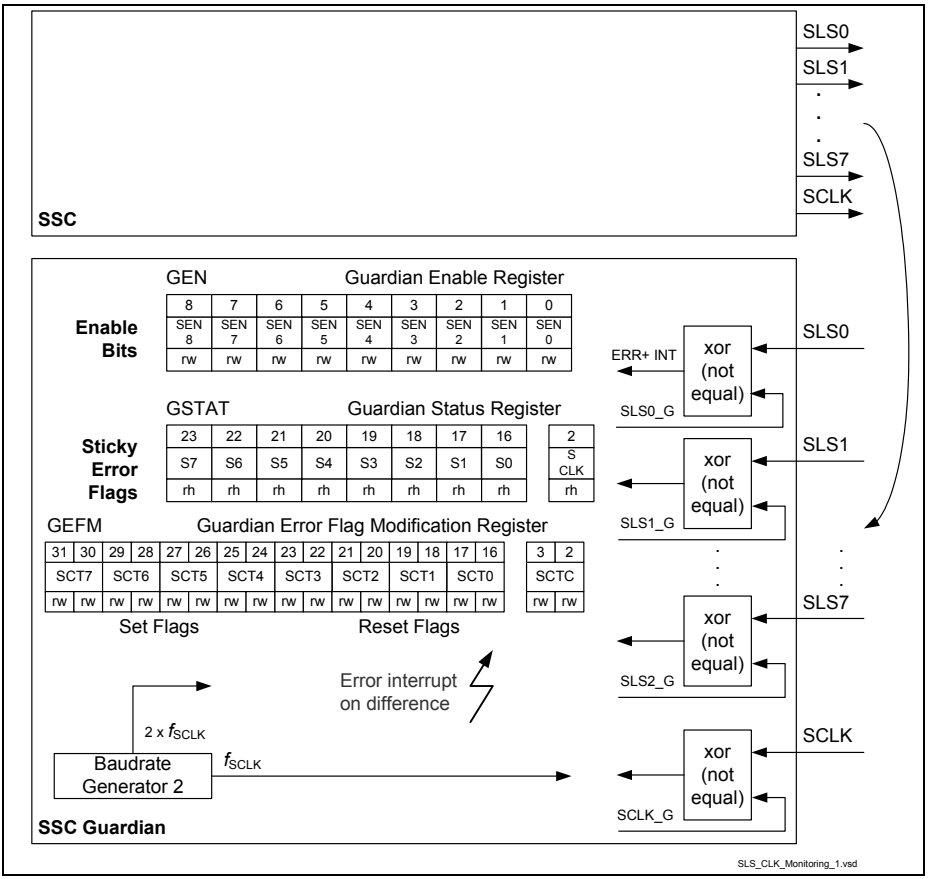

Figure 22-4 Implementation of the SLSx and SCLK monitoring registers

22.3 SSCG Kernel Registers, inherited from SSC

This section describes the kernel registers of the SSC module. All SSC kernel register names described in this section will be referenced in other parts of the TC1798 User´s Manual by the module name prefix “SSCG0_” for the SSCG0 interface, “SSCG1, 2, 3_” for the SSCG1, 2, 3 interfaces.

All registers in the SSCG address spaces are reset with the application reset (definition see SCU section “Reset Operation”).

SSC Kernel Register Overview

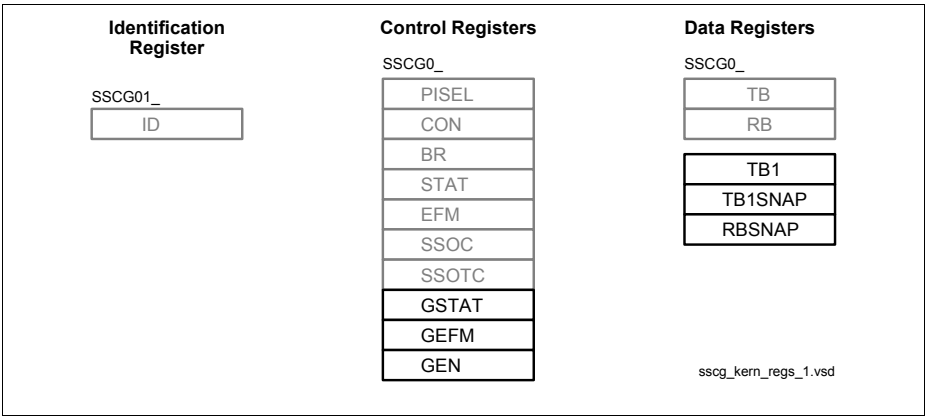

Figure 22-5 SSCG Kernel Registers

The complete address map of the SSC modules is described in **Table 22-5** on **Page 22-41**.

Table 22-1 Registers Address Space - SSC Kernel Registers

Module	Base Address	End Address	Note
SSCG0	F031 0800$_H$	F031 09FF$_H$	–
SSCG1	F031 0A00$_H$	F031 0BFF$_H$	–
SSCG2	F031 0C00$_H$	F031 0DFF$_H$	–
SSCG3	F031 0E00$_H$	F031 0FFF$_H$	–

Table 22-2 Registers Overview - SSC Kernel Registers

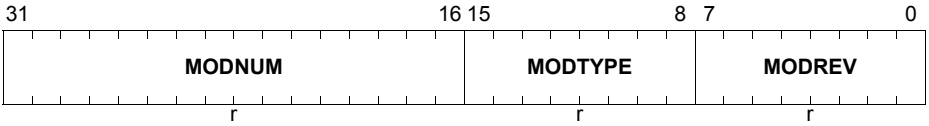
1) The absolute register address is calculated as follows:
Module Base Address (Table 22-1) + Offset Address (shown in this column)

22.3.1 Module Identification Register

The SSC Module Identification Register ID contains read-only information about the module version.

ID

Module Identification Register **(08_H)** **Reset Value: 0085 C0XX$_H$**



Field	Bits	Type	Description
MODREV	[7:0]	r	**Module Revision Number** This bit field defines the module revision number..
MODTYPE	[15:8]	r	**Module Type** This bit field defines the module as a 32-bit module: $C0_H$
MODNUM	[31:16]	r	**Module Number Value** This bit field defines the module identification number for the SSCG: 0085_H

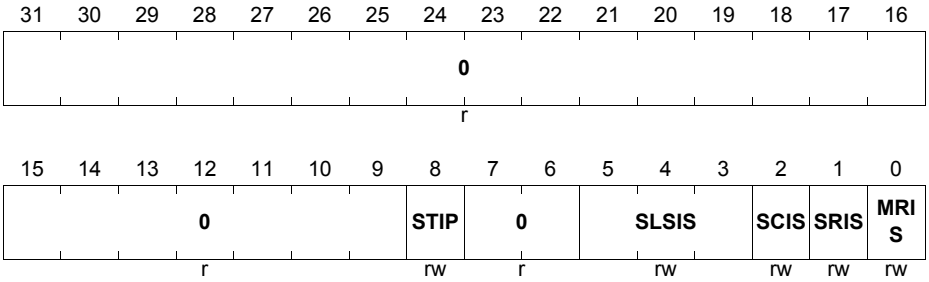
22.3.2 Control Registers

The PISEL register controls the input signal selection of the SSGC module. Each input of the module kernel receive, transmit and clock signals has associated two input lines (marked by suffix A and B).

Note: They may need to be programmed / initialized differently for SSC / SSCG module, depending on the top level connections to the ports and pins. In general, such situation should be avoided, if possible.

PISEL

Port Input Select Register **(04_H)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
MRIS	0	rw	**Master Mode Receive Input Select** MRIS selects the receive input line in Master Mode. 0_B Receive input line MRSTA is selected 1_B Receive input line MRSTB is selected
SRIS	1	rw	**Slave Mode Receive Input Select** SRIS selects receive input line in Slave Mode. 0_B Receive input line MTSRA is selected 1_B Receive input line MTSRB is selected
SCIS	2	rw	**Slave Mode Clock Input Select** SCIS selects the module kernel SCLK input line that is used as clock input line in slave mode. 0_B Slave Mode clock input line SCLKA is selected 1_B Slave Mode clock input line SCLKB is selected

Field	Bits	Type	Description
SLSIS	[5:3]	rw	**Slave Mode Slave Select Input Selection** 000_B Slave select input lines are deselected; SSC is operating without slave select input functionality. 001_B $\overline{SLSI}$ input line 1 is selected for operation. 010_B $\overline{SLSI}$ input line 2 is selected for operation. 011_B $\overline{SLSI}$ input line 3 is selected for operation. 100_B $\overline{SLSI}$ input line 4 is selected for operation. 101_B $\overline{SLSI}$ input line 5 is selected for operation. 110_B $\overline{SLSI}$ input line 6 is selected for operation. 111_B $\overline{SLSI}$ input line 7 is selected for operation. In the TC1798, other combinations of SLSIS except 000_B and 001_B are reserved and must not be used.
STIP	8	rw	**Slave Transmit Idle State Polarity** This bit determines the logic level of the Slave Mode transmit signal MRST when the SSC slave select input signals are inactive (PISEL.SLSIS $\neq 000_B$). 0_B MRST = 0 when SSC is deselected in Slave Mode. 1_B MRST = 1 when SSC is deselected in Slave Mode.
0	[7:6], [31:9]	r	**Reserved** Read as 0; should be written with 0.

The operating modes of the SSC are controlled by the Control Register CON. This register contains control bits for mode and error check selection.

Note: Whenever operating mode parameters in the CON register are changed by software, no transfer should be in progress (STAT.BSY = 0) and the SSC should be disabled (CON.EN = 0) and afterwards enabled again (CON.EN = 1).

CON
Control Register **(10_H)** **Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	r	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw			

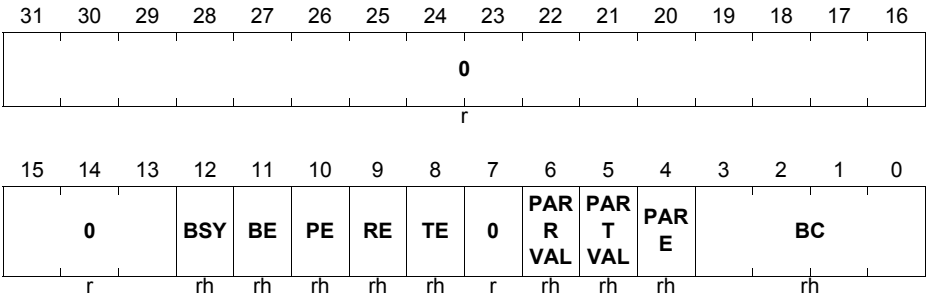
Field	Bits	Type	Description
BM	[3:0]	rw	**Frame Width Selection** BM determines the number of bits of the serial frame. Frame width without parity: 0000_B Reserved; do not use this combination. 0001_B Frame width is 2 bits (2 data bits). 0010_B Frame width is 3 bits (3 data bits). $\cdots_B$ ... 1110_B Frame width is 15 bits (15 data bits). 1111_B Frame width is 16 bits (16 data bits). Frame width with parity: 0000_B Reserved; do not use this combination. 0001_B Frame width is 2 bits (1 data bit + parity bit. 0010_B Frame width is 3 bits (2 data bits + parity bit). $\cdots_B$ ... 1110_B Frame width is 15 bits (14 data bits + parity bit). 1111_B Frame width is 16 bits (15 data bits + parity bit).
HB	4	rw	**Heading Bit Control** 0_B Transmit/Receive LSB First 1_B Transmit/Receive MSB First

Field	Bits	Type	Description
PH	5	rw	**Clock Phase Control** 0_B Shift transmit data on the leading clock edge, latch on trailing edge 1_B Latch receive data on leading clock edge, shift on trailing edge
PO	6	rw	**Clock Polarity Control** 0_B Idle clock line is low, the leading clock edge is low-to-high transition 1_B Idle clock line is high, the leading clock edge is high-to-low transition
LB	7	rw	**Loop-Back Control** 0_B Normal output 1_B Receive input is connected to transmit output (Half-duplex Mode)
TEN	8	rw	**Transmit Error Enable** 0_B Ignore transmit errors 1_B Check transmit errors
REN	9	rw	**Receive Error Enable** 0_B Ignore receive errors 1_B Check receive errors
PEN	10	rw	**Phase Error Enable** 0_B Check phase errors 1_B Check phase errors In the SSC Guardian module, the phase error is always checked, independent of the setting of the enable bit.
BEN	11	rw	**Baud Rate Error Enable** 0_B Ignore baud rate errors 1_B Check baud rate errors
AREN	12	rw	**Automatic Reset Enable** 0_B No additional action upon a baud rate error 1_B SSC is automatically reset on a baud rate error
MS	14	rw	**Master Select** 0_B Slave Mode. Operate on shift clock received via SCLK 1_B Master Mode. Generate shift clock and output it via SCLK The inverted state of this bit is available on module output line “M/S selected”.

Field	Bits	Type	Description
EN	15	rw	**Enable Bit** 0_B Transmission and reception are disabled. 1_B Transmission and reception are enabled. This bit is available as module output line “SSC enabled”. Note that EN should only be cleared by software while no transfer is in progress (STAT.BSY = 0). Note that the transmission/reception enable can also be controlled in queued SSC mode by bit SSOTC.EN.
PARTEN	16	rw	**Parity Transmit Enable Bit** This bit enables the parity mode for transmit frames. 0_B Parity mode for transmit frames is disabled. 1_B Parity mode for transmit frames is enabled.
PARREN	17	rw	**Parity Receive Enable Bit** This bit enables the parity mode for receive frames. 0_B Parity mode for receive frames is disabled. 1_B Parity mode for receive frames is enabled.
PARTYP	18	rw	**Parity Type Bit** If PAREN = 1, this bit defines the type of parity to be generated or checked. 0_B Even parity is selected (parity bit = 1 on odd number of 1s in data, parity bit = 0 on even number of 1s in data). 1_B Odd parity selected (parity bit = 1 on even number of 1s in data, parity bit = 0 on odd number of 1s in data)
PAREEN	19	rw	**Parity Error Enable** 0_B Ignore receive parity errors 1_B Check receive parity errors
0	13, [31:20]	r	**Reserved** Read as 0; should be written with 0.

The Status Register STAT contains status flags for error identification, the busy flag, and a bit field that indicates the current shift counter status.

STAT
Status Register **(28_H)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
BC	[3:0]	rh	**Bit Count Status** BC indicates the current status of the shift counter. The shift counter is updated with every shifted bit.
PARE	4	rh	**Parity Error Flag** 0_B No error 1_B Received parity bit is wrong.
PARTVAL	5	rh	**Parity Transmit Value** If parity mode is enabled, this bit indicates the calculated parity bit for the transmission of the actual serial frame. PARTVAL is written with the transmit parity value when the shift register is loaded from TB. PARTVAL is reset when CON.PAREN is reset.
PARRVAL	6	rh	**Parity Receive Value** if parity mode is enabled, this bit PARRVAL is loaded when the received data is written into RB. PARRVAL is reset when CON.PAREN is reset.
TE	8	rh	**Transmit Error Flag** 0_B No error 1_B Transfer starts with the slave's transmit buffer not being updated
RE	9	rh	**Receive Error Flag** 0_B No error 1_B Reception completed before the receive buffer was read

Field	Bits	Type	Description
PE	10	rh	**Phase Error Flag** 0_B No error 1_B Received data changes during the sampling clock edge
BE	11	rh	**Baud Rate Error Flag** 0_B No error 1_B There is more than factor 2 or less than factor 0.5 between the slave's actual and the expected baud rate.
BSY	12	rh	**Busy Flag** BSY is set while a transfer is in progress.
0	7, [31:13]	r	**Reserved** Read as 0; should be written with 0.

The Error Flag Modification Register EFM is required for clearing or setting the four error flags which are located in register STAT.

EFM
Error Flag Modification Register (2C$_H$) Reset Value: 0000 0000$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SETBE	SETPE	SETRE	SETTE	CLRBE	CLRPE	CLRRE	CLRTE	0			SETPARE	0			CLRPARE
w	w	w	w	w	w	w	w	r			w	r			w

Field	Bits	Type	Description
CLRPARE	0	w	**Clear Parity Error Flag** 0_B No effect 1_B Bit STAT.PARE is cleared. Bit is always read as 0.
SETPARE	4	w	**Set Parity Error Flag** 0_B No effect 1_B Bit STAT.PARE is set. Bit is always read as 0.
CLRTE	8	w	**Clear Transmit Error Flag** 0_B No effect 1_B Bit STAT.TE is cleared. Bit is always read as 0.
CLRRE	9	w	**Clear Receive Error Flag** 0_B No effect 1_B Bit STAT.RE is cleared. Bit is always read as 0.
CLRPE	10	w	**Clear Phase Error Flag** 0_B No effect 1_B Bit STAT.PE is cleared. Bit is always read as 0.

Field	Bits	Type	Description
CLRBE	11	w	**Clear Baud Rate Error Flag** 0_B No effect 1_B Bit STAT.BE is cleared. Bit is always read as 0.
SETTE	12	w	**Set Transmit Error Flag** 0_B No effect 1_B Bit STAT.TE is set. Bit is always read as 0.
SETRE	13	w	**Set Receive Error Flag** 0_B No effect 1_B Bit STAT.RE is set. Bit is always read as 0.
SETPE	14	w	**Set Phase Error Flag** 0_B No effect 1_B Bit STAT.PE is set. Bit is always read as 0.
SETBE	15	w	**Set Baud Rate Error Flag** 0_B No effect 1_B Bit STAT.BE is set. Bit is always read as 0.
0	[3:1], [7:5], [31:16]	r	**Reserved** Read as 0; should be written with 0.

Note: When the set and clear bits for an error flag are set at the same time during an EFM write operation (e.g SETPE = CLRPE = 1), the error flag in STAT is not affected.

The Slave Select Output Control Register controls the operation of the Chip Select Output Generation Unit.

SSOC

Slave Select Output Control Register (18_H) **Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
EN	QSM EN	0					SLS O7 MOD	0		INACT		TRAIL		LEAD	
rw	w	r					rw	r		rw		rw		rw	

Field	Bits	Type	Description
LEAD	[1:0]	rw	**Slave Output Select Leading Delay** This bit field determines the number of leading delay clock cycles. A leading delay clock cycle is always a multiple of an SCLK shift clock period. 00_B Zero leading delay clock cycle selected[1)] 01_B One leading delay clock cycle selected 10_B Two leading delay clock cycles selected 11_B Three leading delay clock cycles selected
TRAIL	[3:2]	rw	**Slave Output Select Trailing Delay** This bit field determines the number of trailing delay clock cycles. A trailing delay clock cycle is always a multiple of an SCLK shift clock period. 00_B Zero trailing delay clock cycle selected[1)] 01_B One trailing delay clock cycle selected 10_B Two trailing delay clock cycles selected 11_B Three trailing delay clock cycles selected

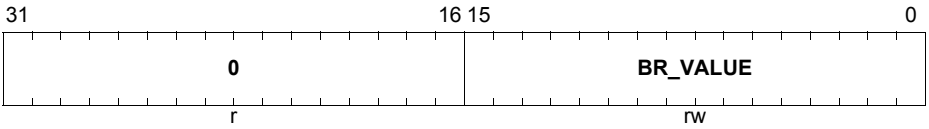
Field	Bits	Type	Description
INACT	[5:4]	rw	**Slave Output Select Inactive Delay** This bit field determines the number of inactive delay clock cycles. An inactive delay clock cycle is always a multiple of an SCLK shift clock period. 00_B Zero inactive delay clock cycle selected[1)] 01_B One inactive delay clock cycle selected 10_B Two inactive delay clock cycles selected 11_B Three inactive delay clock cycles selected
SLSO7MOD	8	rw	**SLSO7 Delayed Mode Selection** This bit selects the delayed mode for the SLSO7 slave select output. 0_B Normal mode selected for SLSO7 1_B Delayed mode selected for SLSO7
QSMEN	14	w	**Queued SSC Mode Enabled** 0_B When QSMEN is written with 0, the state of bit SSOTC.EN is don't care. In this case, the enable/disable of the SSC is controlled by bit CON.EN only. Note that EN should only be cleared by software while no transfer is in progress (STAT.BSY = 0). 1_B When QSMEN is written with 1, queued SSC mode is enabled, and the state of bit SSOTC.EN is copied to CON.EN. QSMEN is always read as 0.
EN	15	rw	**Enable Bit** 0_B Transmission and reception are disabled. 1_B Transmission and reception are enabled. Note that the transmission/reception enable can also be controlled in queued SSC mode by bit CON.EN.
0	[7:6], [13:9], [31:16]	r	**Reserved** Read as 0; should be written with 0.

1) For getting a best case timing with no timing delays, this bit field value should be set when the SLSOn outputs are disabled (SSOC.OENn bits set to 0).

Note: The SSOTC register timing parameters LEAD, TRAIL, INACT, and SLSO7MOD are latched by each TB register write operation and remain latched during a consecutive serial transmission. Bits QSMEN and EN of register SSOTC are not latched.

The Baud Rate Timer Reload Register BR contains the 16-bit reload value for the baud rate timer.

BR
Baud Rate Timer Reload Register (14_H) Reset Value: 0000 0000_H

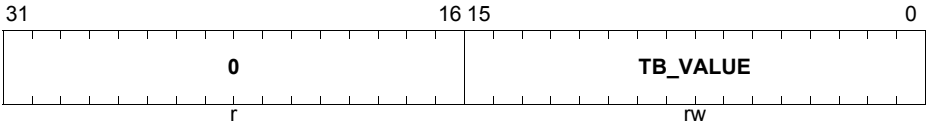


Field	Bits	Type	Description
BR_VALUE	[15:0]	rw	**Baud Rate Timer/Reload Register Value** Reading BR returns the 16-bit content of the baud rate timer. Writing BR loads the baud rate timer reload register with BR_VALUE.
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

22.3.3 Data Registers

The Transmit Buffer Register TB contains the transmit data value. A TB write operation latches all timing parameters stored in register SSOTC.

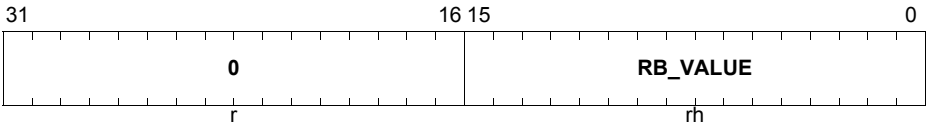
TB
Transmit Buffer Register **(20_H)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
TB_VALUE	[15:0]	rw	**Transmit Data Register Value** Register TB stores the data value to be transmitted TB_VALUE. Unused bits of TB_VALUE (as defined by CON.BM) are ignored during transmission.
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

The Receive Buffer Register RB contains the receive data value.

RB
Receive Buffer Register **(24_H)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
RB_VALUE	[15:0]	rh	**Receive Data Register Value** Register RB contains the received data value RB_VALUE (without the parity bit in parity mode) right aligned. Unused bits of RB_VALUE (as defined by CON.BM) will not be valid and should be ignored.
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

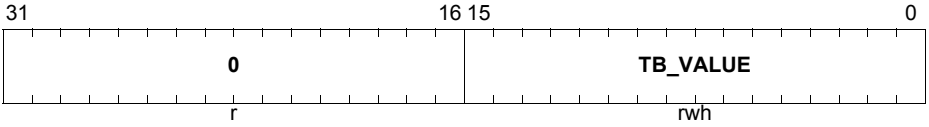
22.3.4 SSCG Specific Registers

The Transmit Buffer Compare Register TB1 contains a copy of the currently transmitted data value.

This register can be written by software. A software write triggers automatically a compare with the receive buffer. This is used for error injection for test purposes, and should not be performed during a real application.

This register is writen also by hardware. When transferring the TB value to the shift register, at the same time in parallel, the same data is written to the TB1 register.

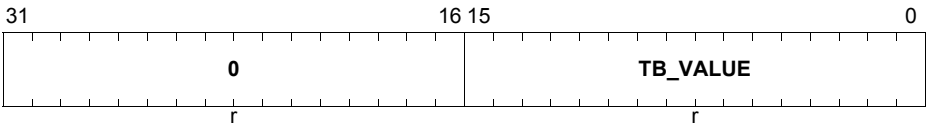
TB1
Transmit Buffer Compare Register (100_H) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
TB_VALUE	[15:0]	rwh	**Transmit Data Register Value** Register TB stores the data value to be transmitted TB_VALUE. Unused bits of TB_VALUE (as defined by CON.BM) are ignored during transmission.
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

The Transmit Buffer Snapshot Register TB1SNAP contains the last erroneous transmitted data value. This is a read only register

TB1SNAP
Transmit Buffer Snapshot Register (104_H) **Reset Value: 0000 0000$_H$**

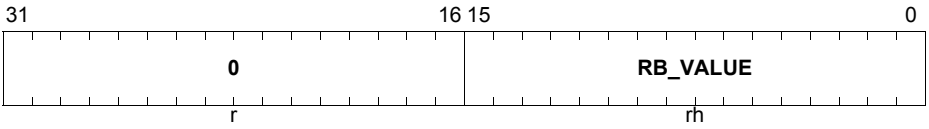


Field	Bits	Type	Description
TB_VALUE	[15:0]	rw	**Transmit Data Snapshot Value** Register TB1SNAP stores the last erroneous transmitted data TB_VALUE. Unused bits of TB_VALUE (as defined by CON.BM) are ignored during transmission.
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

The Receive Buffer Snapshot Register RBSNAP contains the last erroneous received data value. This is a read only register.

RBSNAP

Receive Buffer Snapshot Register (108_H) Reset Value: 0000 0000_H



Field	Bits	Type	Description
RB_VALUE	[15:0]	rh	**Receive Snapshot Register Value** Register RB contains the last received erroneous data value RB_VALUE right aligned. Unused bits of RB_VALUE (as defined by CON.BM) will not be valid and should be ignored.
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

The Status Register GSTAT contains sticky status flags for error identification. They are set by hardware in case of an error, and can be cleared only by software, using the GEFM register. They can be set and cleared by software, but can not be cleared by hardware.

Phase error and parity error are flaged in the STAT register and generate an interrupt.

GSTAT
Guardian Status Register **($10C_H$)** **Reset Value: $0000\ 0000_H$**

22.4 SSCG0 Module Implementation

This section describes SSC / SSCG modules interfaces with the clock control, port connections, interrupt control, and address decoding.

22.4.1 Module Identification Registers

The reset values of the SSCGx_ID module identification register is 0085 C0XX$_H$.

22.4.2 Interfaces of the SSCG Modules

Figure 22-6 shows the interconnections of the SSC / SSCG subsystem.

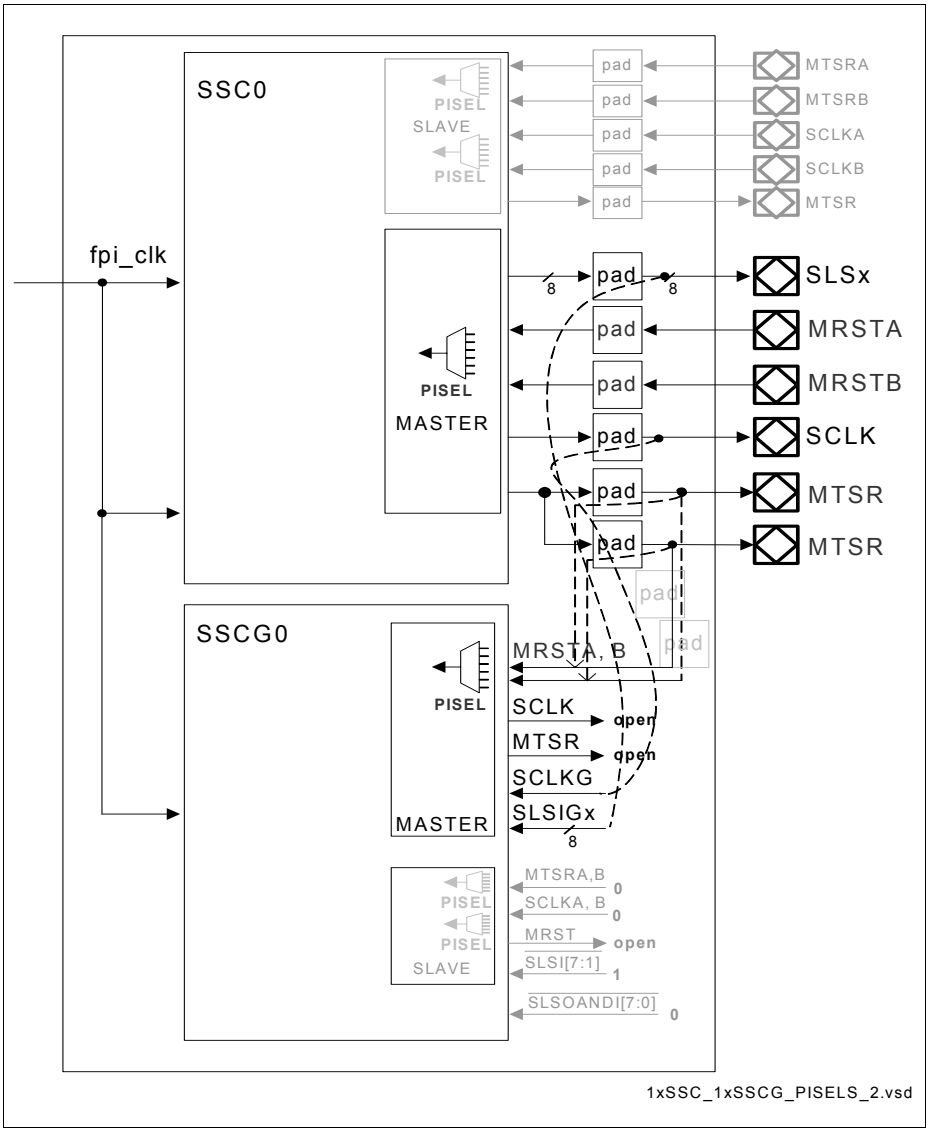

Figure 22-6 SSC0/SSC1/SSCG01 Subsystem Interconnections

The PISEL register of the SSCG0 select the particular output used by the SSC in an application which is to be monitored. On the other hand, the PISEL registers of the SSC0 selects the inputs of the SSC module which are used in the application.

22.4.3 On-Chip Connections

This section describes the on-chip connections of the SSC0/SSCG0 modules.

DMA Requests

The SSCG does not have its own DMA requests. It is always served in parallel by the SSC requests.

22.4.3.1 Receive Input Selection

The MRSTG inputs (master receive) of the SSC Guardian module are mapped to some pins where the MTSR (master transmit) outputs of the corresponding SSC are connected. The alternative inputs A/B of each MRSTG are selected via the corresponding PISEL register of the SSC Guardian.

The PISEL register of the SSCG is normally programmed in parallel with the PISEL register of the SSC, but it can be reprogammed afterwards, if needed.

Table 22-3 Receive Input Selection

Receive Input	Connected to	Selected by
SSCG0_MRSTG0 (A/B)	P10.1	SSCG0_PISEL.MRIS = X_B
SSCG1_MRSTG1 (A/B)	P6.4	SSCG1_PISEL.MRIS = X_B

22.4.4 SSC0/SSC1 Module Related External Registers

Figure 22-7 summarizes the module-related external registers which are required for SSC0/SSC1 programming (see also **Figure 22-5** for the module kernel specific registers).

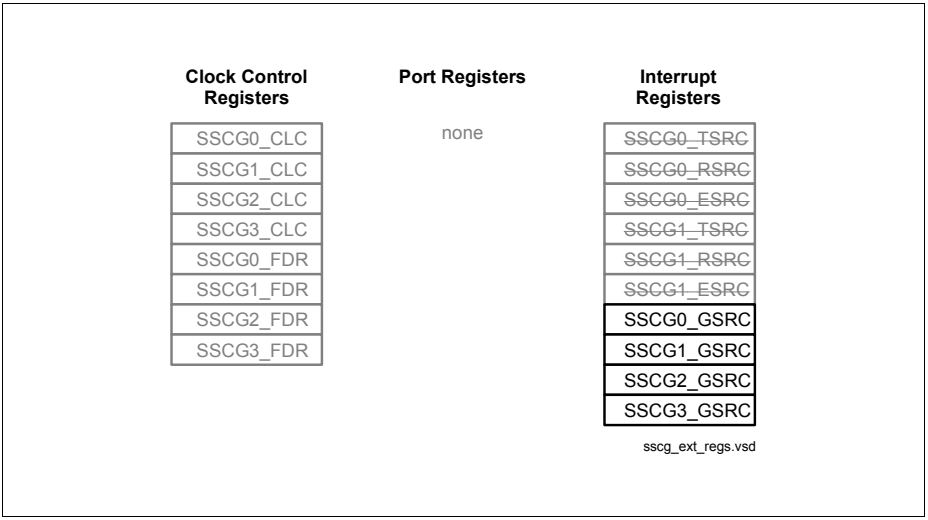

Figure 22-7 SSC0/SSC1 Implementation-specific Special Function Registers

22.4.4.1 Clock Control

Each SSCG module has two clock signals:

- f_{CLC0}
  This is the module clock that is used inside the SSC kernel for control purposes such as clocking of control logic and register operations. The frequency of f_{CLC0} and f_{CLC1} is always identical to the system clock frequency f_{FPI} The clock control registers SSC0_CLC and SSC1_CLC make it possible to enable/disable f_{CLC0} and f_{CLC1} under certain conditions.
- f_{SSCG0}
  This clock is the module clock that is used in the SSCG as input clock of the baud rate generator, which finally determines the baud rate of the serial data. The fractional divider registers SSCG0_FDR and SSCG1_FDR control the frequency of f_{SSCG0} and f_{SSC1} and make it possible to enable/disable it independently of f_{CLC0} and f_{CLC1}.
  The Baud Rate Timer Reload Register SSCG0_BR and SSCG1_BR define serial data baud rate dependent from the frequency of f_{SSCG0} and f_{SSCG1}.

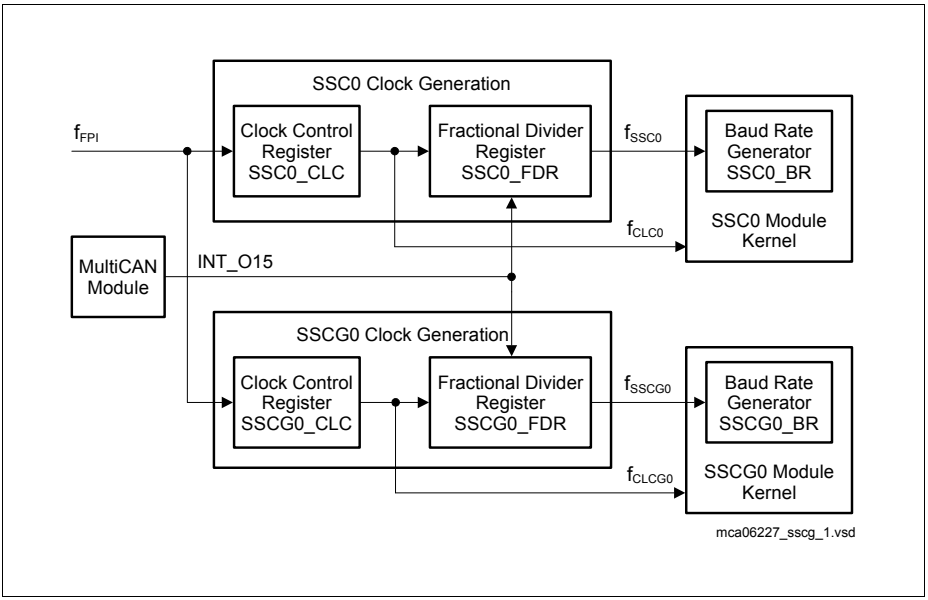

Figure 22-8 SSC Clock Generation

Output signal CAN_INT_O15 of the MultiCAN module can be used for external clock enable control of the fractional divider.

The following formulas define the frequency of f_{SSC0} or f_{SSC1}

$$f_{SSCx} = f_{FPI} \times \frac{1}{n} \text{ with n = 1024 - FDR.STEP} \quad (22.1)$$

$$f_{SSCx} = f_{FPI} \times \frac{n}{1024} \text{ with n = 0-1023} \quad (22.2)$$

Note: In SSC Master Mode, the maximum shift clock frequency is $f_{SSCx}/2$. In SSC Slave Mode, the maximum shift clock frequency is $f_{SSCx}/4$.

Combined with the formulas of the baud rate generator and the fractional divider, the resulting serial data baud rate is defined by:

$$\text{Baud rate}_{SSC} = \frac{f_{FPI}}{2 \times (\text{BR.BR\_VALUE} + 1) \times (1024 - \text{FDR.STEP})} \quad (22.3)$$

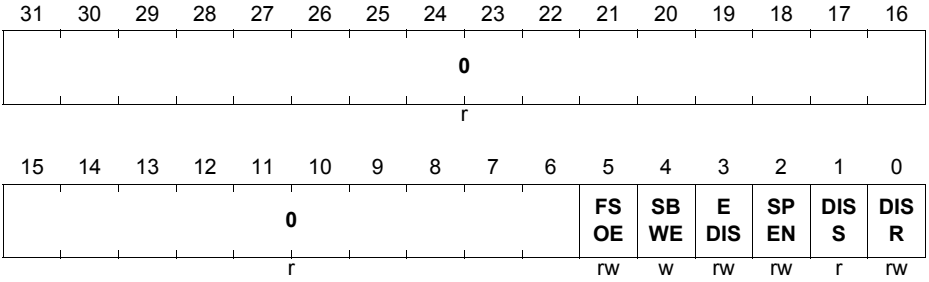
$$\text{Baud rate}_{SSC} = \frac{f_{FPI} \times \text{FDR.STEP}}{2 \times (\text{BR.BR\_VALUE} + 1) \times 1024} \text{ with FDR.STEP = 0-1023} \quad (22.4)$$

*Note: **Equation (22.1)** and **Equation (22.3)** apply to normal divider mode of the fractional divider (FDR.DM = 01_B). **Equation (22.2)** and **Equation (22.4)** apply to fractional divider mode (FDR.DM = 10_B).*

Clock Control Register

The Clock Control Register SSCG0_CLC makes it possible to control (enable/disable) the clock signal f_{CLC0} under certain conditions. Each SSC has its own clock control register.

CLC
Clock Control Register **(00_H)** **Reset Value: 0000 0003$_H$**



Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module.
DISS	1	r	**Module Disable Status Bit** Bit indicates the current status of the module.
SPEN	2	rw	**Module Suspend Enable for OCDS** Used to enable the suspend mode.
EDIS	3	rw	**Sleep Mode Enable Control** Used to control module's sleep mode.
SBWE	4	w	**Module Suspend Bit Write Enable for OCDS** Determines whether SPEN and FSOE are write-protected.
FSOE	5	rw	**Fast Switch Off Enable** Used to switch off fast clock in Suspend Mode.
0	[31:6]	r	**Reserved** Read as 0; should be written with 0.

Note: After a hardware reset operation, the f_{CLCx} clocks are disabled, and therefore the SSC modules are disabled (DISS set) also.

Fractional Divider Register

The Fractional Divider Registers SSCG0_FDR and SSCG1_FDR control the clock rate of the shift clock f_{SSCG0} and f_{SSCG1}. Each SSCG has its own fractional divider register.

FDR
Fractional Divider Register **($0C_H$)** **Reset Value: $1000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DISCLK	ENHW	SUSREQ	SUSACK	0		RESULT									
rwh	rw	rh	rh	r		rh									

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DM		SC		SM	FDIS	STEP									
rw		rw		rw	rw	rw									

Field	Bits	Type	Description
STEP	[9:0]	rw	**Step Value** Reload or addition value for RESULT.
FDIS	10	rw	**Freeze Disable** This bit controls the freeze function for this module. 0_B Module operates on corrected clock, with reduced modulation jitter. 1_B Module operates on uncorrected clock, with full modulation jitter.
SM	11	rw	**Suspend Mode** SM selects between granted or immediate suspend mode.
SC	[13:12]	rw	**Suspend Control** This bit field determines the behavior of the fractional divider in suspend mode.
DM	[15:14]	rw	**Divider Mode** This bit field selects normal divider mode, fractional divider mode, and off-state.
RESULT	[25:16]	rh	**Result Value** Bit field for the addition result.
SUSACK	28	rh	**Suspend Mode Acknowledge** Indicates state of $\overline{\text{SPNDACK}}$ signal.

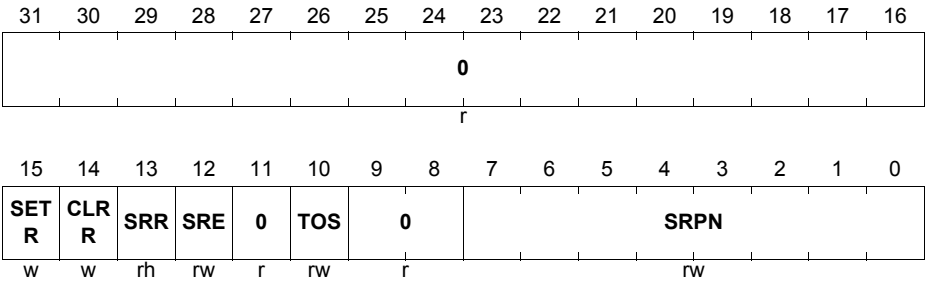
Field	Bits	Type	Description
SUSREQ	29	rh	**Suspend Mode Request** Indicates state of SPND signal.
ENHW	30	rw	**Enable Hardware Clock Control** Controls operation of ECEN input and DISCLK bit.
DISCLK	31	rwh	**Disable Clock** Hardware-controlled disable for f_{OUT} signal.
0	[27:26]	r	**Reserved** Read as 0; should be written with 0.

22.4.4.2 Interrupt Control Registers

The SSC service request control registers are removed from the guardian module. Their read value is constant FFFF FFFF$_H$.´

There is a dedicated guardian service request register GSRC.

GSRC
Guardian Interrupt Service Request Control Register
(1FC$_H$) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
SRPN	[7:0]	rw	**Service Request Priority Number**
TOS	10	rw	**Type of Service Control**
SRE	12	rw	**Service Request Enable**
SRR	13	rh	**Service Request Flag**
CLRR	14	w	**Request Clear Bit**
SETR	15	w	**Request Set Bit**
0	[9:8], 11, [31:16]	r	**Reserved** Read as 0; should be written with 0.

22.4.5 SSCG Address Map

An absolute register address is given by the offset address of the register (given in Table 22-2) plus the module base address (given in Table 22-1).

SSCG has two chip-selects, one common with the SSC module, and one common and dedicated at the same time, OR-ed inside the module to select the address decoder. Additionally, the read signal is combined with the common chip select to suppres a read access parallel to the SSC read access. The common interrupt registers can be read as FFFF FFFF$_H$, but they are not functionally available. Write access has no effect and does not cause a bus error.

Table 22-4 SSCG Address Overview

Module	Base Address	End Address	Note
SSCG0	F031 0000$_H$	F031 00FF$_H$	shared with SSC0
SSCG1	F031 0100$_H$	F031 01FF$_H$	shared with SSC1
SSCG2	F031 0200$_H$	F031 02FF$_H$	shared with SSC2

23 Micro Second Channel (MSC)

This chapter describes the Micro Second Channel Interface s, MSC0 and MSC1, of the TC1798. It contains the following sections:

- Functional description of the MSC kernel (see **Page 23-3**)
- MSC kernel register descriptions (see **Page 23-36**)
- TC1798 implementation-specific details and registers of the MSC module (port connections and control, interrupt control, address decoding, and clock control, see **Page 23-62**)

*Note: The MSC kernel register names described in **Section 23.2** are also referenced in the TC1798 User´s Manual by the module name prefix “MSC0_” for the MSC0 module and by “MSC1_” for the MSC1 module.*

MSC Applications

The MSC is a serial interface that is especially designed to connect external power devices to the TC1798. The serial data transmission capability minimizes the number of pins required to connect such external power devices. Parallel data information (coming from the timer units) or command information is sent out to the power device via a high-speed synchronous serial data stream (downstream channel). The MSC receives data and status back from the power device via a low-speed asynchronous serial data stream (upstream channel).

Figure 23-1 shows a typical TC1798 application in which an MSC interface controls two power devices. Output data is provided by the GPTA module.

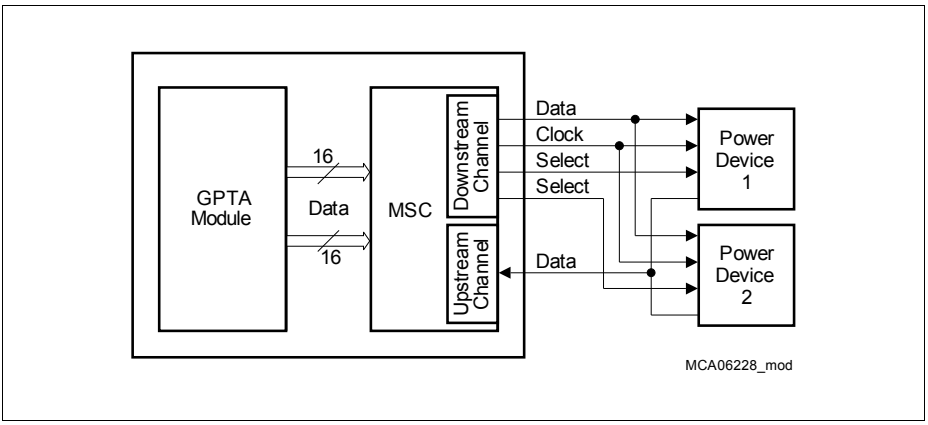

Figure 23-1 MSC to External Power Device Connection

Some applications are:

- Control of the external power switching unit via the downstream channel
- Receiving information back from power switching unit
- Serial connections of the TC1798 to other peripheral devices

23.1 MSC Kernel Description

This section describes the functionality of the MSC kernel.

23.1.1 Overview

The MSC interface provides a serial communication link typically used to connect power switches or other peripheral devices. The serial communication link includes a fast synchronous downstream channel and a slow asynchronous upstream channel. **Figure 23-2** shows a global view of the MSC interface signals.

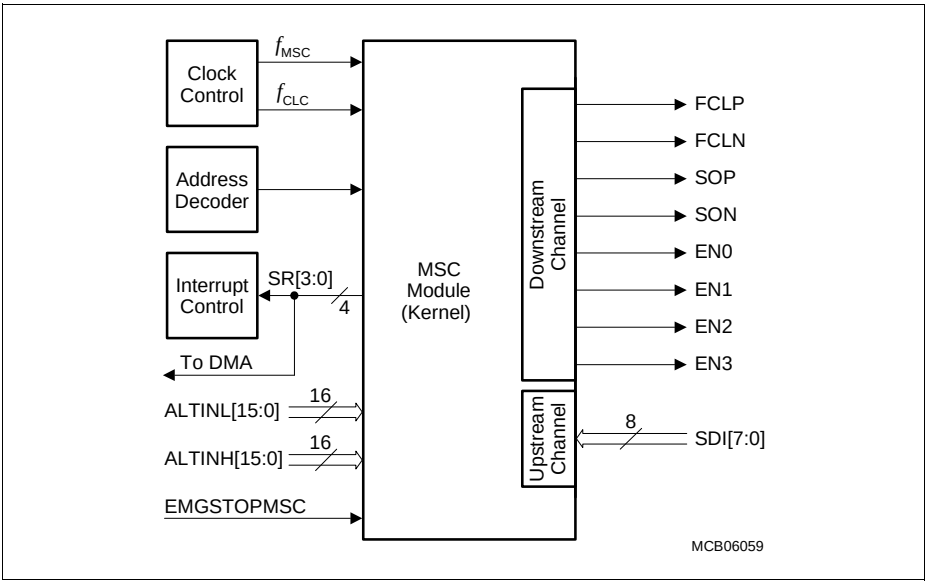

Figure 23-2 General Block Diagram of the MSC Interface

The downstream and upstream channels of the MSC module communicate with the external world via nine I/O lines. Eight output lines are required for the serial communication of the downstream channel (clock, data, and enable signals). One out of eight input lines SDI[7:0] is used as serial data input signal for the upstream channel. The source of the serial data to be transmitted by the downstream channel can be MSC register contents or data that is provided at the ALTINL/ALTINH input lines. These input lines are typically connected to other on-chip peripheral units (for example with a timer unit like the GPTA). An emergency stop input signal makes it possible to set bits of the serial data stream to dedicated values in emergency case.

Clock control, address decoding, and interrupt service request control are managed outside the MSC module kernel. Service request outputs are able to trigger an interrupt or a DMA request.

Features

- Fast synchronous serial interface to connect power switches in particular, or other peripheral devices via serial buses
- High-speed synchronous serial transmission on downstream channel
  - Serial output clock frequency: $f_{FCL} = f_{MSC}/2$ (f_{MSCmax} = 110 MHz)
  - Fractional clock divider for precise frequency control of serial clock f_{MSC}
  - Command, data, and passive frame types
  - Start of serial frame: Software-controlled, timer-controlled, or free-running
  - Transmission with or without SEL bit
  - Flexible chip select generation indicates status during serial frame transmission
  - Emergency stop without CPU intervention
- Low-speed asynchronous serial reception on upstream channel
  - Baud rate: f_{MSC} divided by 4, 8, 16, 32, 64, 128, or 256 (f_{MSCmax} = 110 MHz)
  - Standard asynchronous serial frames
  - Programmable upstream data frame length (16 or 12 bits)
  - Parity error checker
  - 8-to-1 input multiplexer for SDI lines
  - Built-in spike filter on SDI lines
- Selectable pin types of downstream channel interface:
  four LVDS differential output drivers or four digital GPIO pins

23.1.2 Downstream Channel

The downstream channel performs a high-speed synchronous serial transmission of data to external devices. Its 32-bit shift register is divided into two 16-bit parts, SRL and SRH. Each bit of SRL and SRH can be selected to be delivered by the downstream data register DD, by the Downstream Command Register DC, or by two 16-bit wide input signal buses ALTINL and ALTINH.

Figure 23-3 is a diagram of the MSC downstream channel.

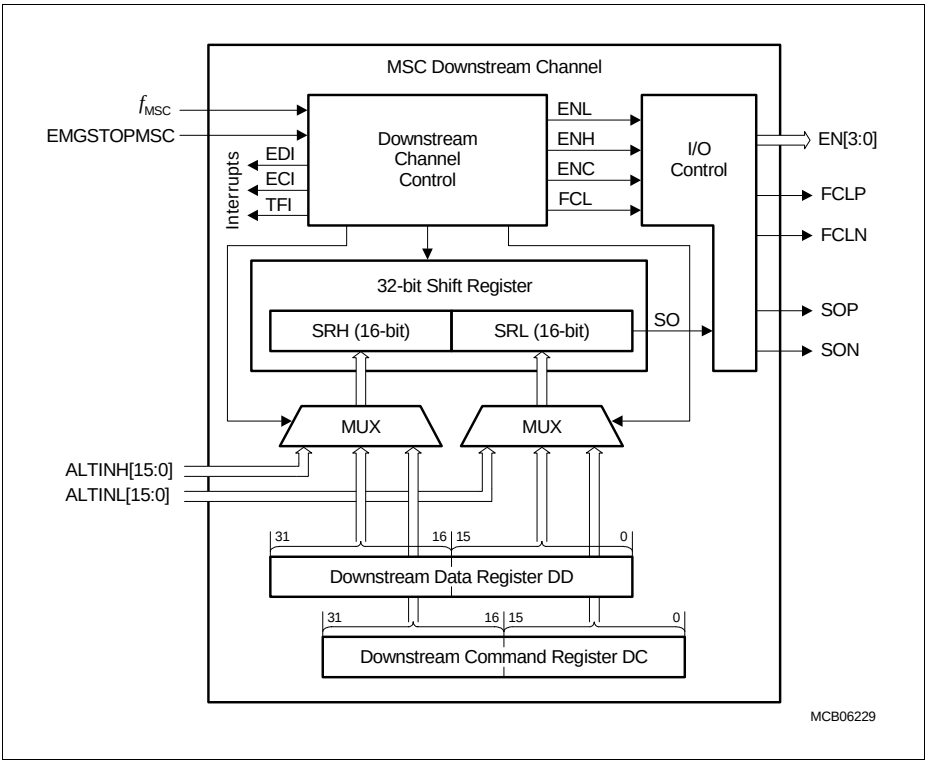

Figure 23-3 Downstream Channel Block Diagram

The enable signals ENL, ENH, and ENC indicate certain phases of the serial transmission in relation to the serial clock FCL. In the I/O control logic, these signals can be combined to four enable/select outputs EN[3:0]. For supporting differential output drivers, the serial clock output FCL and the serial data output SO are available in both polarities, indicated by the signal name suffix “P” and “N”.

The emergency stop input line EMGSTOPMSC is used to indicate an emergency stop condition of a power device. In emergency case, shift register bits can be loaded bit-wise from the downstream data register instead from the ALTINL and ALTINH buses.

23.1.2.1 Frame Formats and Definitions

This section describes the frame formats and definitions of the MSC.

Basic Definitions

Figure 23-4 shows the layout and definitions of a downstream frame. A downstream frame is composed of an active phase and a passive phase. During the active phase, data transmission takes place and during the passive phase no data is transmitted at SO. The active phase is split into two parts: The SRL active phase in which the content of the shift register low part SRL is transmitted, and the SRH active phase in which the content of the shift register high part SRH is transmitted. At the beginning of the SRL and SRH active phase, a selection bit (SELL) can be optionally inserted into the serial data stream. In the frame shown in **Figure 23-4**, SELL is generated at the beginning of the SRL active phase (not for the SRH active phase). The least significant bits of SRL and SRH are sent out first.

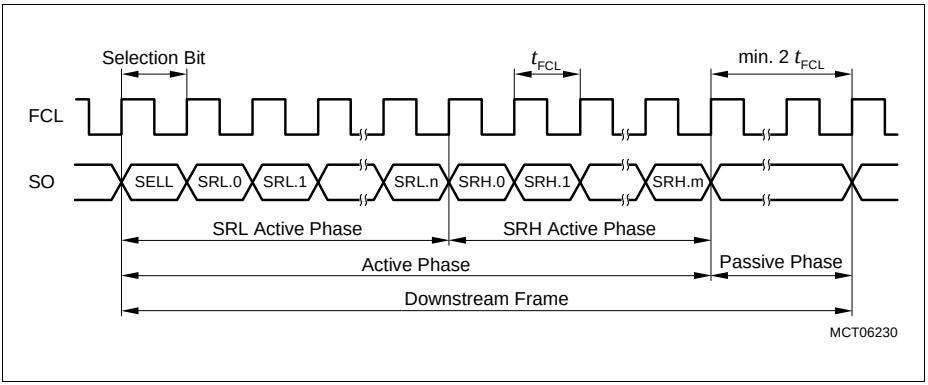

Figure 23-4 Downstream Channel Frame

The MSC downstream channel uses three types of frame formats for operation:

- Command frames, indicated by SELL = 1
- Data frames, indicated by SELL = 0 or SELL bit insertion disabled
- Passive time frame, indicated by ENL = ENH = 0

Command Frames

A command frame has two active phase parts, SRL active phase and SRH active phase. The command frame always starts with a high-level selection bit, independently whether the selection bit insertion (as defined by bit DSC.ENSELL) is enabled or not. The number of the bits transmitted during SRL and SRH active phases (except the selection bit) is defined by bit field DSC.NBC. SRL and SRH are combined to a 32-bit value whose length can be selected from 0 up to 32 bits. In other words, whenever bits of SRH are transmitted, they are always preceded by the transmission of the complete SRL content.

During the active phase of a command frame, the enable output signal ENC becomes active. The enable output signals ENL and ENH remain inactive.

The passive phase of a command frame always has a fixed length of $2 \times t_{FCL}$. The diagram shown in **Figure 23-5** assumes that the FCL clock is only generated during the active phase of the command frame (OCR.CLKCTRL = 0).

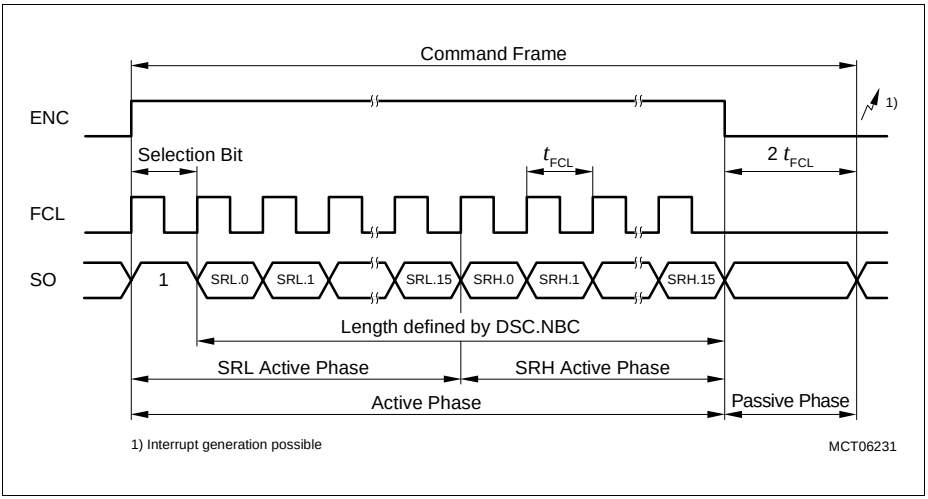

Figure 23-5 Command Frame Layout

Table 23-1 shows the programming of the bits to be transmitted and the resulting length of the complete command frame.

Table 23-1 Command Frame Length

DSC.NBC	SRL/SRH Bits that are Transmitted in Active Phase	Command Frame Length in t_{FCL} Periods
000000_B	No bit shifted out	1 + 0 + 2 = 3
000001_B	SRL[0] shifted out	1 + 1 + 2 = 4
000010_B	SRL[1:0] shifted out	1 + 2 + 2 = 5
000011_B	SRL[2:0] shifted out	1 + 3 + 2 = 6
…	…	…
001111_B	SRL[14:0] shifted out	1 + 15 + 2 = 18
010000_B	SRL[15:0] shifted out	1 + 16 + 2 = 19
010001_B	SRL[15:0] and SRH[0] shifted out	1 + 17 + 2 = 20
010010_B	SRL[15:0] and SRH[1:0] shifted out	1 + 18 + 2 = 21
010011_B	SRL[15:0] and SRH[2:0] shifted out	1 + 19 + 2 = 22
…	…	…
011111_B	SRL[15:0] and SRH[14:0] shifted out	1 + 31 + 2 = 34
100000_B	SRL[15:0] and SRH[15:0] shifted out	1 + 32 + 2 = 35
Other NBC combinations	Reserved; do not use these bit combinations.	

Data Frames

A data frame has two active phase parts, SRL active phase and SRH active phase. The number of bits that are transmitted can be programmed separately for each of these two phases. Bit field DSC.NDBL determines the number of SRL bits that are transmitted during the SRL active phase and DSC.NDBH determines the number of SRH bits that are transmitted during the SRH active phase.

SRL and SRH active phases can start with a low-level selection bit when enabled by bits DSC.ENSELL or DSC.ENSELH.

During the SRL active phase of a data frame, the enable output signal ENL becomes active and during the SRH active phase of a data frame, the enable output signal ENH becomes active. The enable output signal ENC remains inactive.

The length of the data frame's passive phase is variable and is defined by bit field DSC.PPD. It can be within a range of $2 \times t_{FCL}$ up to $31 \times t_{FCL}$. The diagram shown in **Figure 23-6** assumes that the FCL clock is only generated during the active phase of the data frame (OCR.CLKCTRL = 0).

Table 23-2, **Table 23-3**, and **Table 23-4** show the definitions of the five data frame parameters that determine the layout of the data frame.

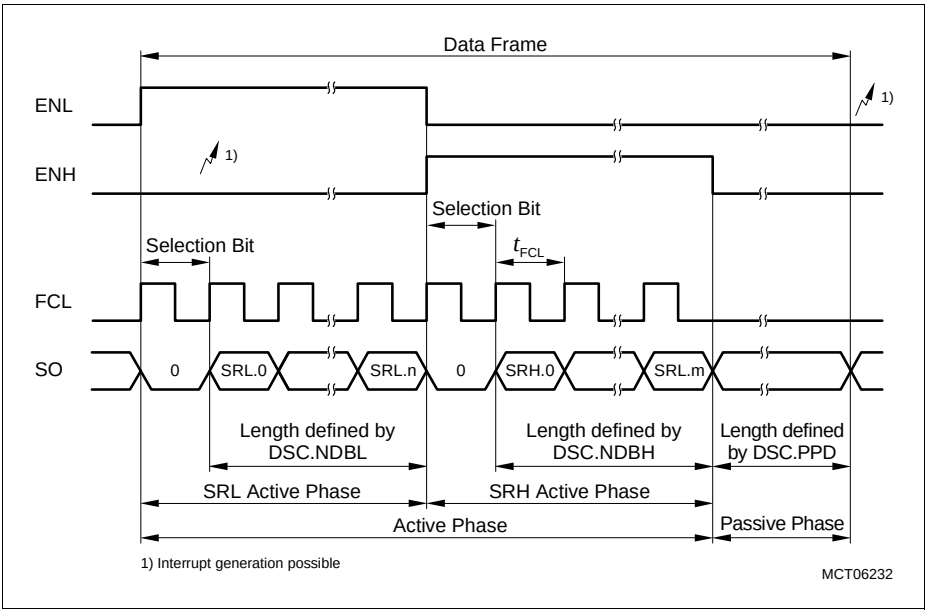

Figure 23-6 Data Frame Layout

Table 23-2 Data Frame Selection Bit Parameters

DSC.ENSELL	Selection Bit	DSC.ENSELH	Selection Bit
0	No selection bit inserted at the beginning of the SRL active phase	0	No selection bit inserted at the beginning of the SRH active phase
1	A low level selection bit is inserted at the beginning of the SRL active phase	1	A low level selection bit is inserted at the beginning of the SRH active phase

Table 23-3 Data Frame SRL/SRH Length Parameters

DSC.NDBL	SRL Bits Transmitted in SRL Active Phase	DSC.NDBH	SRH Bits Transmitted in SRH Active Phase
00000_B	No SRL bit transmitted	00000_B	No SRH bit transmitted
00001_B	SRL[0]	00001_B	SRHL[0]
00010_B	SRL[1:0]	00010_B	SRH[1:0]
00011_B	SRL[2:0]	00011_B	SRH[2:0]
…	…	…	…
01111_B	SRL[14:0]	01111_B	SRH[14:0]
10000_B	SRL[15:0]	10000_B	SRH[15:0]
Other bit combinations	Reserved; do not use these bit combinations.	Other bit combinations	Reserved; do not use these bit combinations.

Table 23-4 Data Frame Passive Phase Length

DSC.PPD	Passive Phase Length
00000_B	$2 \times t_{FCL}$
00001_B	$2 \times t_{FCL}$
00010_B	$2 \times t_{FCL}$
00011_B	$3 \times t_{FCL}$
…	…
01110_B	$30 \times t_{FCL}$
01111_B	$31 \times t_{FCL}$

The following formula determines the number of t_{FCL} cycles of a data frame: All parameters (bits and bit fields) are located in register DSC.

$$\text{Number of cycles} = \text{ENSELL} + \text{NDBL} + \text{ENSELH} + \text{NDBH} + \text{PPD} \quad (23.1)$$

Note that in the formula above, PPD must be set to 2 when DSC.PPD $\leq 00010_B$.

Passive Time Frames

A passive time frame has the length defined by the five data frame parameters according **Equation (23.1)**. They are generated only in Data Repetition Mode. Under special conditions (command frame insertion), passive time frames can be shortened (see **Figure 23-9**).

During passive time frames, the data output SO have to be considered as invalid at the receiving device and the clock output FCL may toggle or not (as selected by bit OCR.CLKCTRL). The ENL and ENH enable signals remain at low level during a passive time frame.

23.1.2.2 Shift Register Operation

This section describes the SRL and SRH shift register loading.

SRL Shift Register Loading

During the SRL/SRH shift register load operation at the beginning of each downstream frame transmission, several parameters determine which information is loaded into the bits of the shift register. **Figure 23-7** shows the logic that is implemented for the SRL shift register loading operation. The logic for the SRH shift register loading operation is equivalent to the one for the SRL register. Its differences in data sources and register controls are described later in this section.

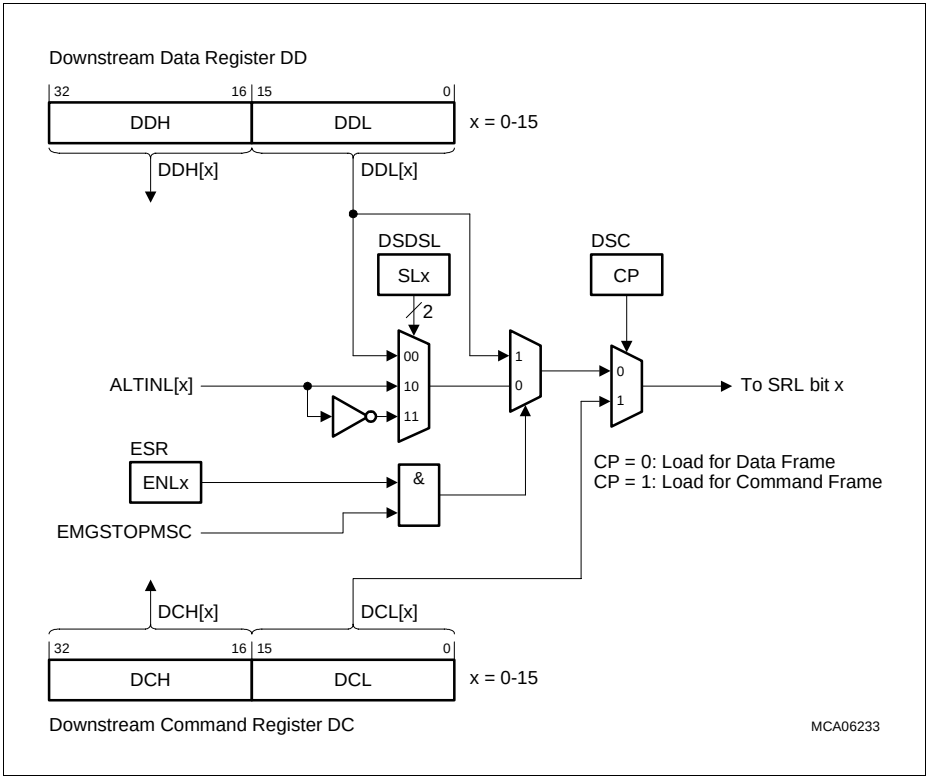

Figure 23-7 SRL Shift Register Data Loading Control

Four data sources can be selected for each SRL bit by using several control bits and one control signal:

- ALTINL input line (non-inverted)
- ALTINL input line (inverted)
- Bit of DD.DDL (downstream data register)
- Bit of DC.DCL (downstream control register)

When SRL is loaded for data frame transmission (DSC.CP = 0), bit fields DSDSL.SLx determine bit-wise which data is loaded into SRL bit x. The data source selection as controlled by DSDSL.SLx will only be effective when EMGSTOPMSC is inactive (at low level). When EMGSTOPMSC = 1 (active) during the load operation, all SRL[x] bits that are enabled for the emergency stop feature (bit ESR.ENLx = 1) are loaded directly with the corresponding bit DDL[x] of the downstream data register DD.

When SRL is loaded for command frame transmission (DSC.CP = 1), always the lower 16-bit part DCL of the downstream control register is loaded completely into SRL.

Table 23-5 summarizes all SRL data source selection capabilities (x = 0-15).

Table 23-5 SRL Data Source Selection Capabilities

DSC.CP	DSDSL.SLx	ESR.ENLx	EMGSTOPMSC	Selection
0	00_B	0	–	Bit DD.DDL[x] is loaded into SRL[x].
	01_B			Reserved.
	10_B			State of ALTINL[x] input is loaded into SRL[x].
	11_B			Inverted state of ALTINL[x] input is loaded into SRL[x].
	XX_B	1	1	Bit DD.DDL[x] is loaded into SRL[x].
1	XX_B	X	X	Bit fields DCL and DCH are completely loaded into SRL and SRH, respectively.

SRH Shift Register Loading

The SRH shift register load operation is equivalent to the SRL shift register load operation. The following differences must be taken into account for SRH shift register loading:

- Input lines ALTINH are connected instead of ALTINL input lines.
- DSDSH register bits control data source selection instead of DSDSL register.
- Emergency stop is enabled by ESR.ENHx bits instead of ESR.ENLx bits.
- Bits of the downstream data register high part DDH are selected instead of DDL.
- Downstream control register high part DCH is selected instead of DCL.

23.1.2.3 Transmission Modes

The downstream channel of the MSC makes it possible to select between two transmission modes:

- Triggered Mode, selected by DSC.TM = 0, or
- Data Repetition Mode, selected by DSC.TM = 1

Triggered Mode

In Triggered Mode, command frames or data frames are sent out as a result of a software event. When a frame transmission has been finished and no further frame transmission has been requested, the downstream channel returns to idle state and waits for the next frame transmission to be triggered by software.

When the Downstream Command Register DC is written, the command pending bit DSC.CP becomes set and a command frame will be immediately started and sent out if the downstream channel is idle. If a data or command frame is currently processed and output, the command frame transmission is delayed, and started when the active downstream frame has been finished. The command pending bit DSC.CP becomes cleared by hardware when the first bit of the command frame is sent out.

If the downstream channel is idle and the data pending bit DSC.DP is set by writing bit ISC.SDP with 1, a data frame will be immediately started and sent out if the downstream channel is idle. If a data frame or a command frame is currently processed and output, the data frame transmission is delayed and started when the active downstream frame has been finished. The data pending bit DSC.DP becomes cleared by hardware when the first bit of the data frame is sent out.

A command frame always has priority over the data frame. This means that if both frame pending bits are set (DSC.DP = DSC.CP = 1), the command frame will always be sent first. Therefore, a pending data frame transmission will be delayed as long as no further command frame transmission is running or requested.

Figure 23-8 is a flow diagram of the Triggered Mode. This diagram especially shows the behavior of the data and command pending bits DSC.DP and DSC.CP. If both frame pending bits are set (DSC.DP = DSC.CP = 1), the command frame will always be sent first, followed by the data frame (assuming no further command frame has been requested).

The type of the active frame that is currently processed and output is indicated by two status flags: DSS.DFA is set during a data frame transmission and DSS.CFA is set during a command frame transmission. Further, the downstream counter DSS.DC indicates the number of shift clock periods that have been elapsed since the start of the current frame.

In Triggered Mode, the shift register loading event as described in **Section 23.1.2.2** occurs just before a command or data frame transmission is started.

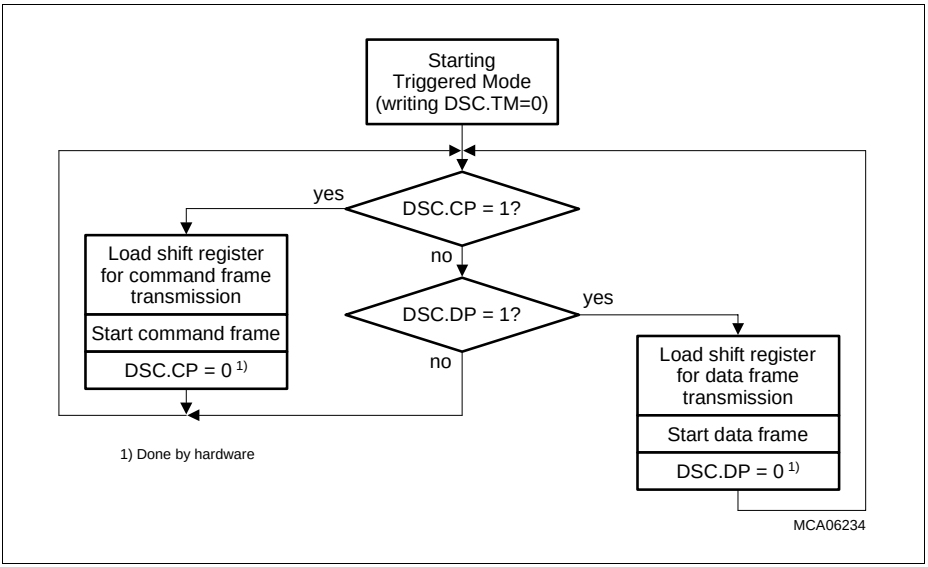

Figure 23-8 Triggered Mode Flow Diagram

Data Repetition Mode

In Data Repetition Mode, data frames are sent out continuously without any software interaction. In the time gap between two consecutive data frames, passive time frames can be inserted. The number of passive time frames to be inserted (0 to 15) is defined by bit field DSS.NPTF. The duration of data frame (t_{DF}) and passive time frames (t_{PTF}) is determined by the five data frame parameters (see **Equation (23.1)**). These parameters determine time reference points (TRP) at which a data or passive time frames is started (see diagram A in **Figure 23-9**).

The automatic data frame generation is controlled by the data pending bit DSC.DP. This bit is set near the end of the last transmitted passive time frame. At the next TRP, a data frame is started (if no command frame has been requested) and DSC.DP is cleared again by hardware after the data frame has been started. Data Frames are always aligned to time reference points. This means they always start at a TRP. Passive time frames can be shortened. This is especially the case when command frames are inserted.

Continuous data frame transmission can be interrupted by insertion of command frames. Command frames are initiated by software. When the downstream control register DSC is written, the command pending bit DSC.CP is set by hardware. CP = 1 indicates that the MSC starts a command frame at the next TRP, independently of whether a data

frame (indicated by DSC.DP = 1) or passive time frame should be started with the next TRP. This means also that command frames are always aligned to time reference points.

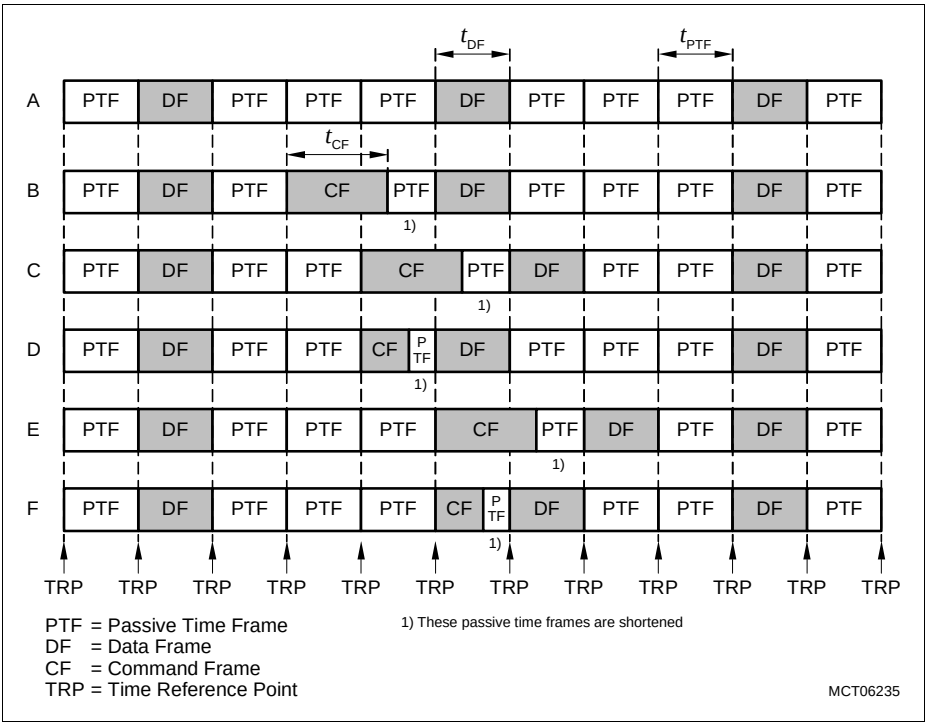

Figure 23-9 Data Repetition Mode Frame Examples with DSS.NPTF = 0011_B

Diagrams B to F in **Figure 23-9** show the command frame insertion in Data Repetition Mode.

In diagram B, a command frame has been requested during the first passive time frame after the data frame, and is inserted at the next TRP. In diagrams C and D, a command frame has been requested during the second passive time frame, and is inserted at the time reference point of the last nominal passive time frame.

When the command frame and data frame is not of the same length (this is the case in diagram B to F), a shortened passive time frame is inserted until the next TRP is reached. This ensures that the next data or normal passive time frame is again aligned to a TRP.

Figure 23-10 is a flow diagram of the Data Repetition Mode. This diagram especially shows the behavior of the data and command pending bits DSC.DP and DSC.CP. If both frame pending bits are set (DSC.DP = DSC.CP = 1), the command frame will always be

sent first, followed by the data frame when the next TRP is reached (assuming no further command frame has been requested).

When the last passive frame is transmitted, DSC.DP becomes set by hardware. This triggers the start of a data frame when the next TRP is reached.

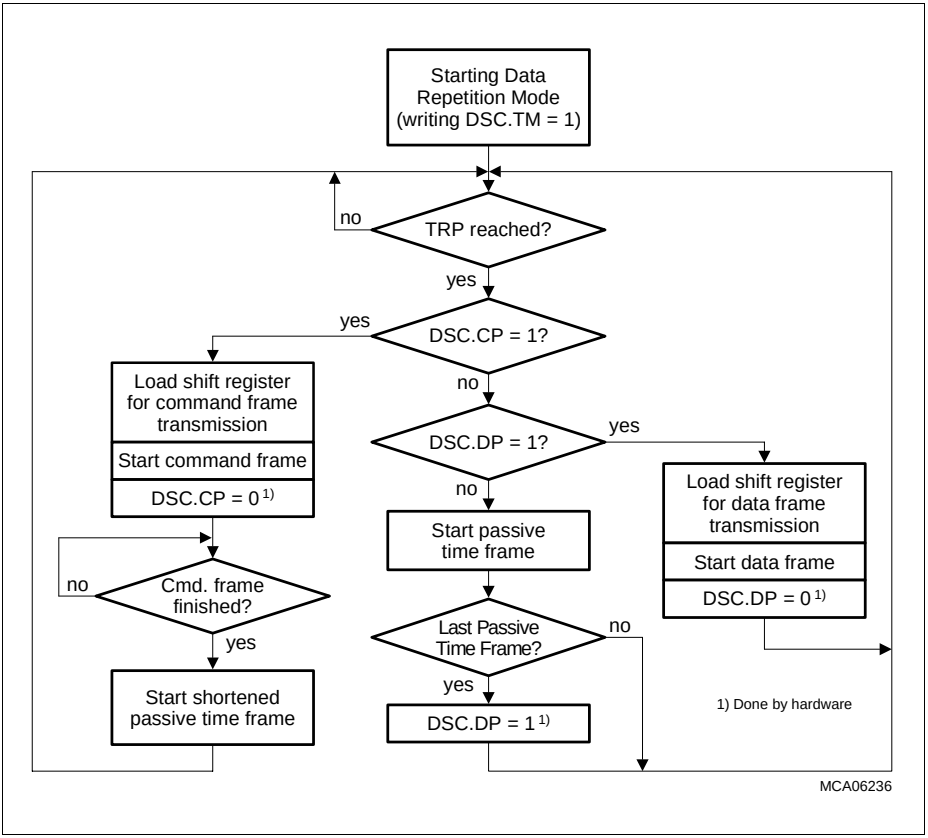

Figure 23-10 Data Repetition Mode Flow Diagram

The type of the active frame (data or command frame) that is currently processed and output is indicated by two status flags: DSS.DFA is set during a data frame transmission and DSS.CFA is set during a command frame transmission. Further, the downstream counter DSS.DC indicates the number of shift clock periods that have been elapsed since the start of the current data, command, or passive time frame.

As in Triggered Mode, the shift register loading event as described in **Section 23.1.2.2** occurs in Data Repetition Mode just before a TRP, this means shortly before a command or data frame transmission is started.

Passive Frame Counter in Data Repetition Mode

In Data Repetition Mode, a passive time frame counter DSS.PFC indicates how many time frames have been already transmitted after the last regular data frame occurrence. The passive time frame counter counts up from 0000_B to the value which has been written into bit field DSS.NPTF (number of passive time frames). DSS.PFC = 0000_B indicates that a data frame is requested for transmission.

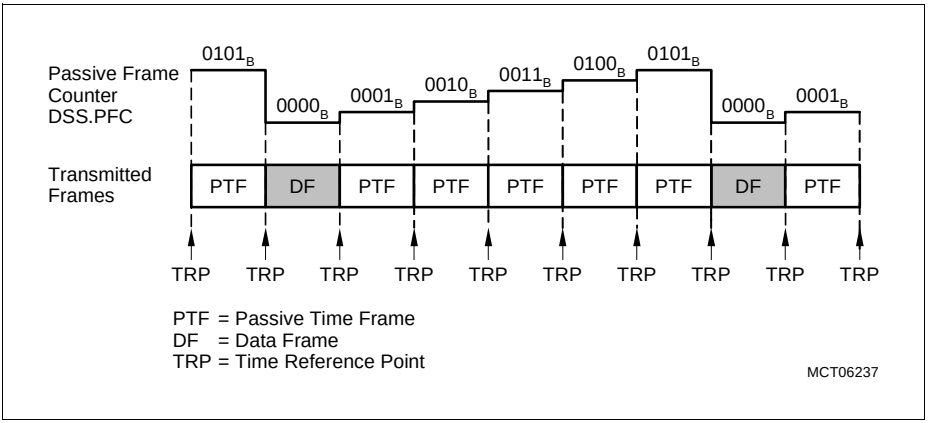

Figure 23-11 Passive Frame Counter Operation (with DSS.NPTF = 0101_B)

23.1.2.4 Downstream Counter and Enable Signals

During downstream channel operation, a 7-bit downstream counter DSS.DC is counting FCL shift clock periods. With the loading of the shift register, the downstream counter is reset to 00_H and started for counting up to the end of the downstream frame (end of passive phase).

In Triggered Mode, the downstream counter stops counting at the end of the passive phase and waits until a new downstream frame is started.

In Repetition Mode, the downstream counter does not stop at the end of the passive phase but is reset and starts counting up again with the next frame, independently whether a data frame, command frame, or passive time frame is started as next frame.

Figure 23-12 shows an example of downstream channel data frame transmission. In this example, the selection bit for the SRL active frame is enabled (ENSELL = 1), and the selection bit for the SRH active frame is disabled (ENSELH = 0). With loading of the shift register SRL/SRH, the downstream counter is reset and then starts counting up with each FCL clock until the end of the passive phase. ENL is set to high level at the beginning of the SRL active frame selection bit.

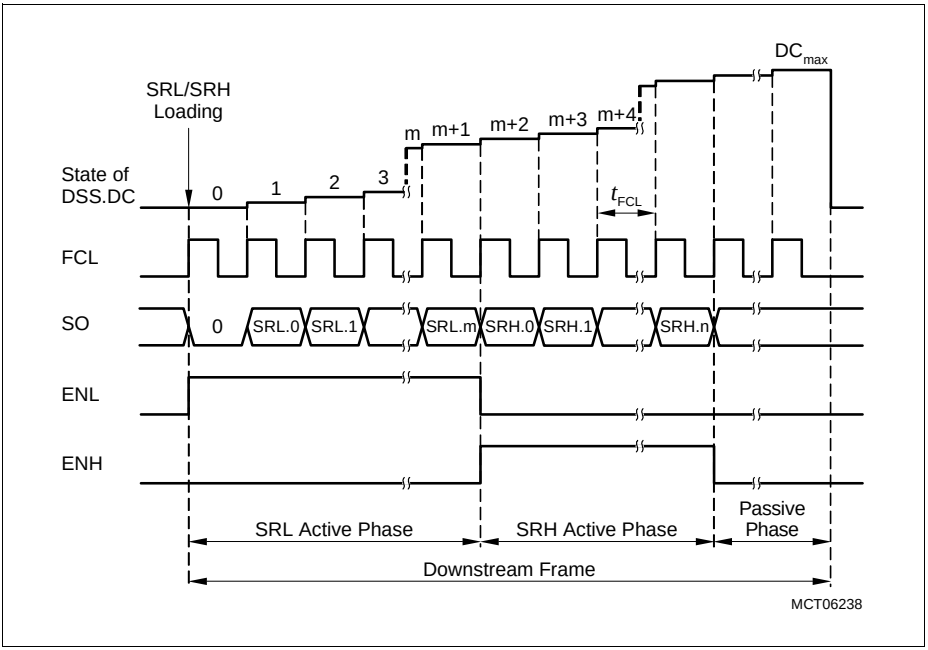

Figure 23-12 Shift Clock Counting: Data Frame with ENSELL = 1 and ENSELH = 0

When the selection bit for the SRL active frame is disabled (ENSELL = 0, see **Figure 23-13**), the loading of the shift register SRL/SRH (and reset of the downstream counter) occurs one FCL clock cycle before the first data bit SRL.0 is output. ENL is set to high level with the beginning of the first data bit SRL.0.

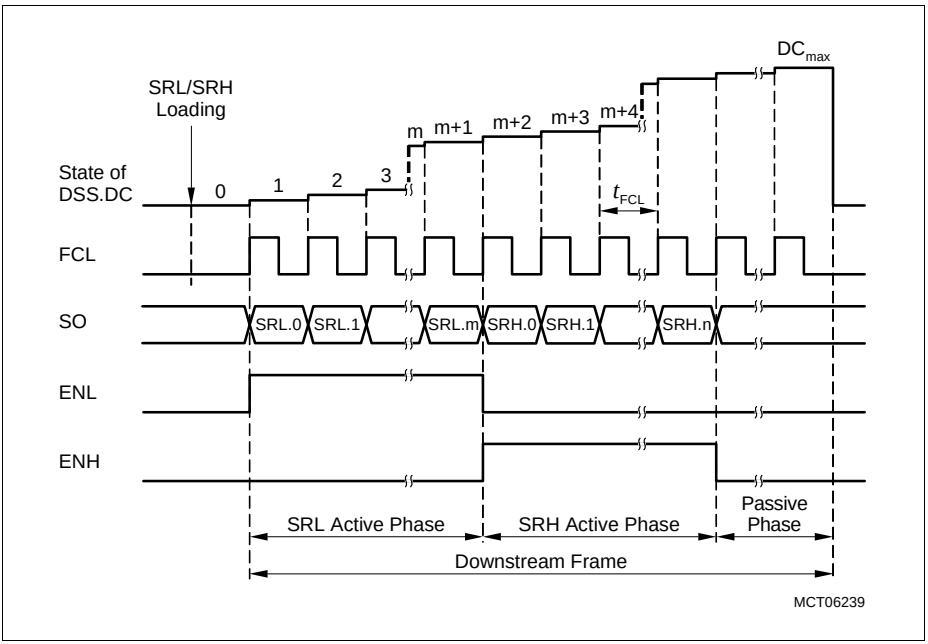

Figure 23-13 Shift Clock Counting: Data Frame with ENSELL = 0 and ENSELH = 0

23.1.2.5 Baud Rate

The baud rate of the downstream channel's serial transmission is defined by the frequency of the serial clock FCL, and is always $f_{MSC}/2$. The f_{MSC} generation is device specific and depends on the implementation of the MSC module. The TC1798 specific clock generation is described on **Page 23-65**.

23.1.2.6 Abort of Frames

Only a reset condition of the device can abort a current transmission. The MSC module does not start a new frame transmission when the downstream channel becomes disabled, the suspend mode is requested, or the sleep mode is entered. If one of these three conditions becomes active during a running frame transmission, the frame transmission is completely finished before the requested abort state is entered. Note that in this case no time frame finished interrupt is generated any more.

23.1.3 Upstream Channel

The MSC upstream channel is an asynchronous serial receiver based on the standard asynchronous data transfer protocol. It is dedicated to receive a serial data stream from a peripheral device via its serial data input SDI, using two specific data frame formats.

Figure 23-14 is a block diagram of the MSC upstream channel.

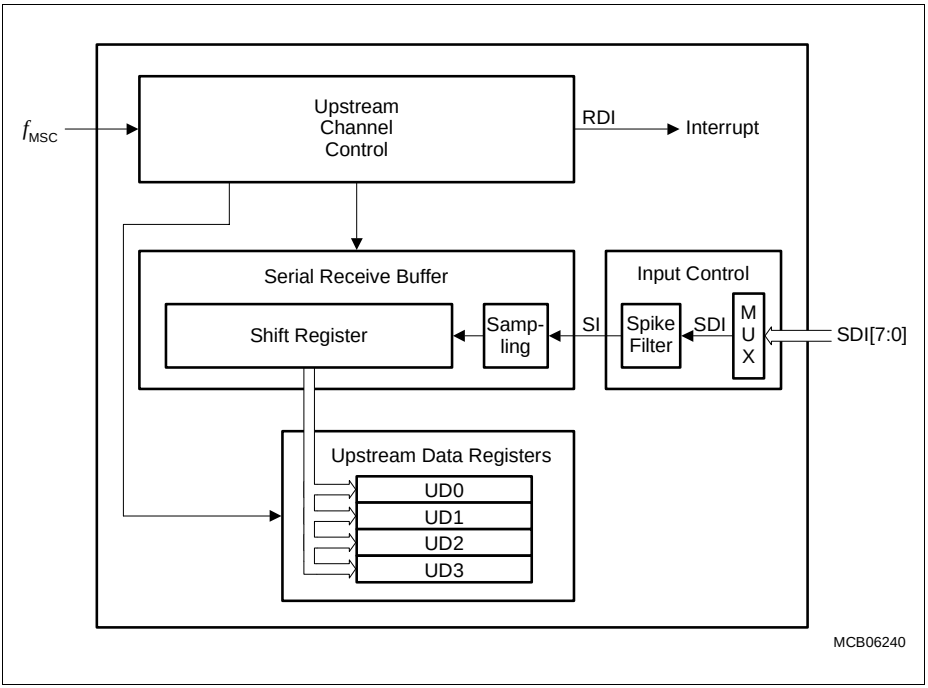

Figure 23-14 Upstream Channel Block Diagram

The incoming data at SI is sampled after it has been filtered for spikes. The detected logic states of the serial input are clocked into a shift register. After the complete reception of the serial data frame, the content of the shift register is transferred into one of the four data registers, and an interrupt can be generated optionally.

The reception baud rate is directly coupled to the module clock f_{MSC}, and can be within a range of $f_{MSC}/4$ up to $f_{MSC}/256$.

23.1.3.1 Data Frames

The asynchronous data frames used by the upstream channel include four basic parts:

1. One start bit, always at low level
2. An 8-bit data field D[7:0] with LSB first
3. An optional 4-bit address field A[3:0] with LSB first
4. One parity bit and two stop bits, that are always at high level

As shown in **Figure 23-15**, the 16-bit upstream data frame includes an additional 4-bit address field. The upstream frame type is selected by bit USR.UFT.

- USR.UFT = 0: 12-bit upstream data frame selected
- USR.UFT = 1: 16-bit upstream data frame with 4-bit address field selected

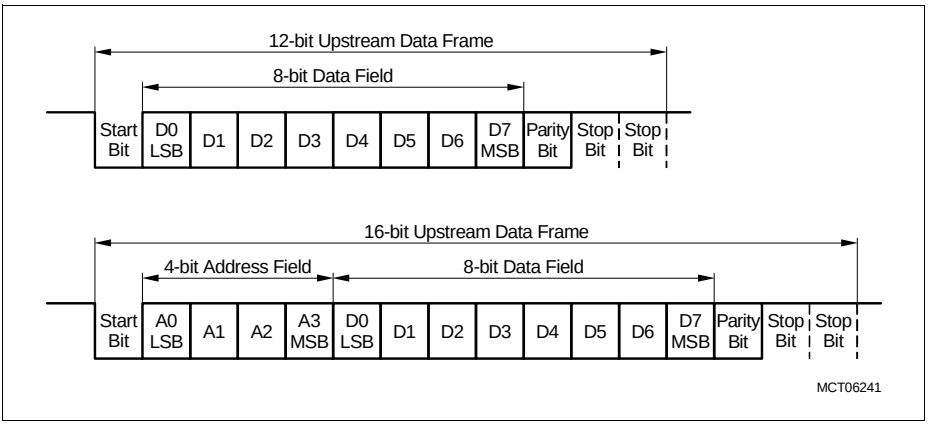

Figure 23-15 Upstream Channel Frame Types

23.1.3.2 Parity Checking

The incoming parity bit of the data frames can be checked by the upstream channel. When a parity error is detected, the parity error flag PERR in the related Upstream Data Register UDx is set. Note that a setting of the parity error flag PERR does not generate an interrupt. The PERR bits must be checked by software. The UDx registers also store the parity bit of the incoming data frame (UDx.P) and the parity bit that is generated internally (UDx.IPF).

Bit USR.PCTR determines the parity mode, even or odd, that is selected for parity checking. With USR.PCTR = 0, even parity mode is selected. Even parity means that the parity bit is set on an odd number of 1s in the data field (12-bit upstream data frame) or in the address plus data field (16-bit upstream data frame). With USR.PCTR = 1, odd parity mode is selected. In odd parity mode, the parity bit is set on an even number of 1s of the related data.

The parity checking logic in the upstream channel also controls whether start bit and the two stop bits of the upstream data frame are at correct logic level. If the start bit is not at low level and the two stop bits are not at high level at the end of the frame reception, the parity error flag UDx.PERR is set, too.

23.1.3.3 Data Reception

The reception of the upstream frame is started with a falling edge (1-to-0 transition) on the SI line. When the start bit is detected, serial reception is enabled and the receive circuit begins to sample the incoming serial data and to buffer it in the receive buffer. After the second stop bit has been detected, the content of the receive buffer is transferred to one of four upstream data registers UDx. The receive circuit then waits for the next start bit (1-to-0 transition) at the SI line. When the content of the receive buffer has been transferred to UDx, the valid bit UDx.V is set by hardware, and a receive interrupt can be generated.

*Note: The SI input line is the filtered non-inverted (OCR.ILP = 0) or inverted (OCR.ILP = 1) SDI input signal. The SI input signal selection is described on **Page 23-30**).*

Frame Reception with Address Field

Frame reception for a 16-bit data frame (see **Figure 23-16**) is selected by USR.UFT = 1. When the content of the receive buffer has been received completely, it is transferred to one of the four UDx registers. The two most significant address bits A[3:2] of the received 4-bit address field select the number x of register UDx in which the received frame content is stored. Register UDx is loaded with the two least significant address bits A0 and A1 (UDx.LABF), the 8-bit data (UDx.DATA), the received parity bit (UDx.P), the calculated parity bit (UDx.IPF), and the parity checking result (UDx.PERR). Finally, the valid bit UDx.V is set to indicate that the UDx register contains valid data.

The current state of the frame reception is indicated by the content of an upstream counter that is readable via bit field USR.UC. The upstream counter is a 5-bit counter that counts the upstream frame bits during reception. As shown in **Figure 23-16**, the upstream counter is loaded with 10000_B at the detection of a start bit. It counts down and is again at 00000_B when the second stop bit has been detected and the frame reception is finished.

The state of the serial input data line SI is sampled in the middle of a bit cell and shifted into the receive buffer at the end of the bit cell. The frequency of the shift clock f_{SHIFT} depends the selected baud rate (see **Page 23-25**).

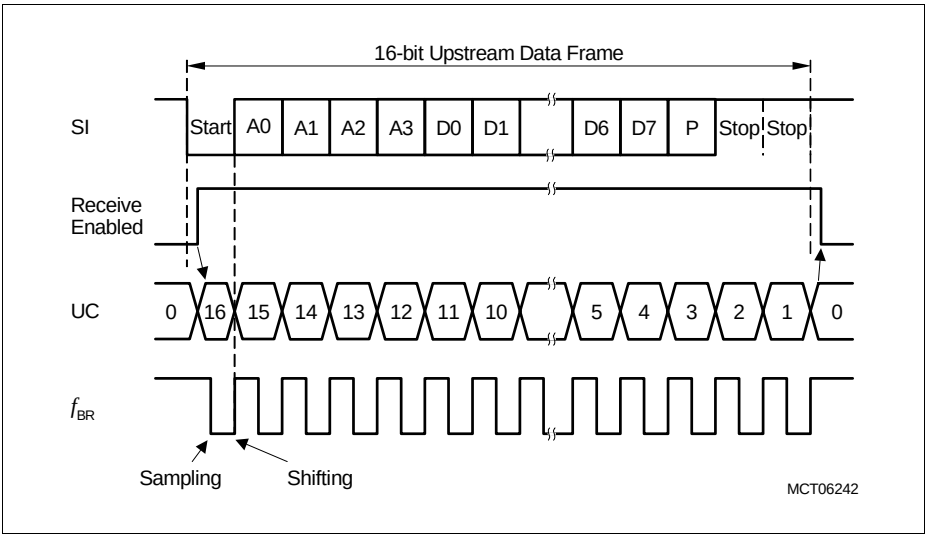

Figure 23-16 16-bit Upstream Reception

Data Reception without Address Field

Frame reception for a 12-bit data frame is selected by USR.UFT = 0. The reception scheme is comparable with that of the 16-bit data frame reception but there are a few differences:

- The upstream counter is initially loaded with 01100_B.
- The received frame content is always stored in register UD0.
- Bit field UD0.LABF is always loaded with 00_B when the frame is stored.

23.1.3.4 Baud Rate

The baud rate of the upstream channel is derived from the MSC module clock f_{MSC}. Figure 23-17 shows the configuration of the upstream channel clock circuitry.

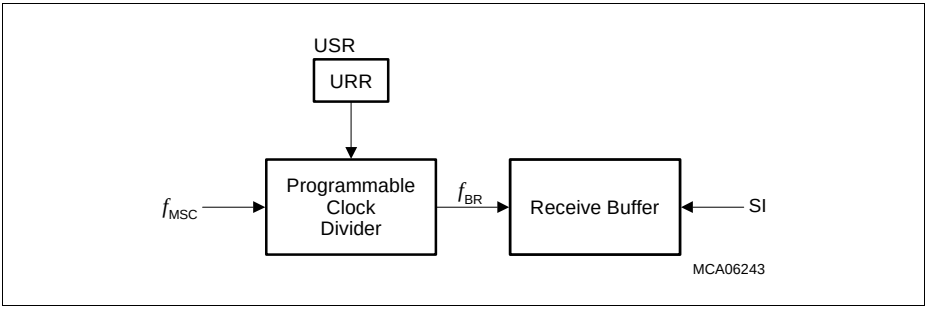

Figure 23-17 Upstream Channel Clock Circuitry

The serial data input SI is evaluated with the baud rate clock f_{BR} in the middle of each bit cell, and latched in case of a data bit. The baud rate clock f_{BR} is derived from f_{MSC} by a programmable clock divider. The frequency of f_{BR} determines the width of a received bit cell and therefore the baud rate for the received data. The content of bit field USR.URR selects the baud rate according Table 23-6. The resulting baud rate formula is:

$$\text{Baud rate}_{\text{MSC Upstream Channel}} = \frac{f_{MSC}}{DF} \quad (23.2)$$

Table 23-6 Upstream Channel Divide Factor DF Selection & Baud Rate

USR.URR	Divide Factor DF	Baud Rate
000_B	reception disabled	–
001_B	4	$f_{MSC}/4$
010_B	8	$f_{MSC}/8$
011_B	16	$f_{MSC}/16$
100_B	32	$f_{MSC}/32$
101_B	64	$f_{MSC}/64$
110_B	128	$f_{MSC}/128$
111_B	256	$f_{MSC}/256$

Note: With the USR.URR = 000_B the upstream channel is disabled and data reception is not possible.

The content of bit field USR.URR determines the operation of an internal sampling reload counter that is clocked with f_{MSC}. **Figure 23-18** shows the operation of the sampling counter at the beginning of an upstream frame with a divide factor DF of 8 (USR.URR = 010_B is equal to DF = 8) which means eight sampling clocks per each frame bit cell.

When the upstream channel is in idle state, it waits for a falling edge (1-to-0 transition) at SI. Therefore, the sample counter starts counting up and is reset when the selected divide factor DF as shown in **Table 23-6** is reached. In the middle of the sampling counter's count range, the logic state at SI is evaluated and, in case of a data bit, latched in the receive buffer's shift register. With the reload of the sampling counter, the shift register is shifted by one bit position.

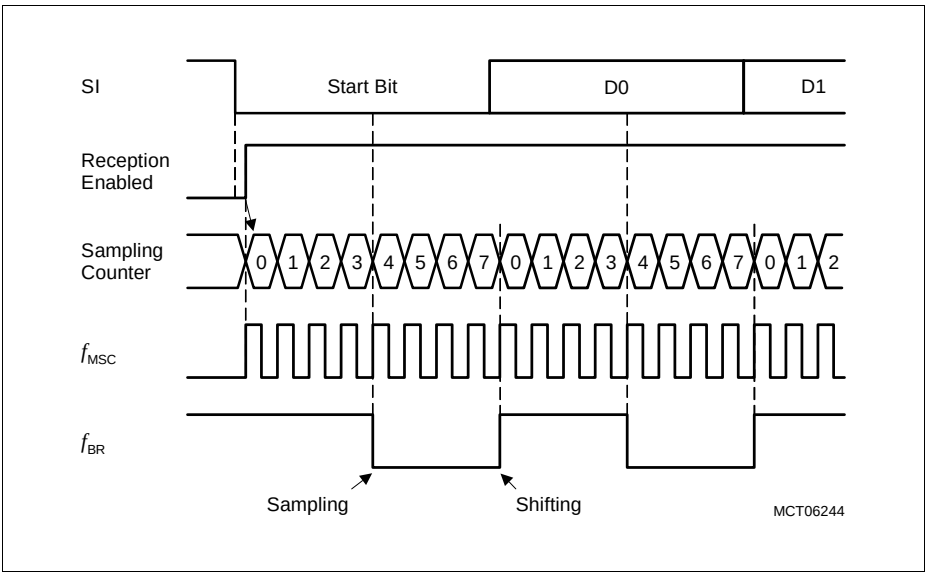

Figure 23-18 Upstream Channel Sampling with URR = 010_B

23.1.3.5 Spike Filter

The upstream channel input line SDI is sampled using a built-in spike filter with synchronization stage, both clocked with f_{MSC}. The spike filter is a chain of flip-flops with a majority decision logic (2 out of 3). A sampled value that is found at least twice in three samples is taken as data input value for SI.

23.1.4 I/O Control

The types of I/O control logic for the MSC module I/O lines are shown in **Figure 23-19**. The downstream channel generates five output signals that control eight MSC module outputs, split into four chip select outputs, two clock outputs, and two serial data outputs. The upstream channel has one input signal.

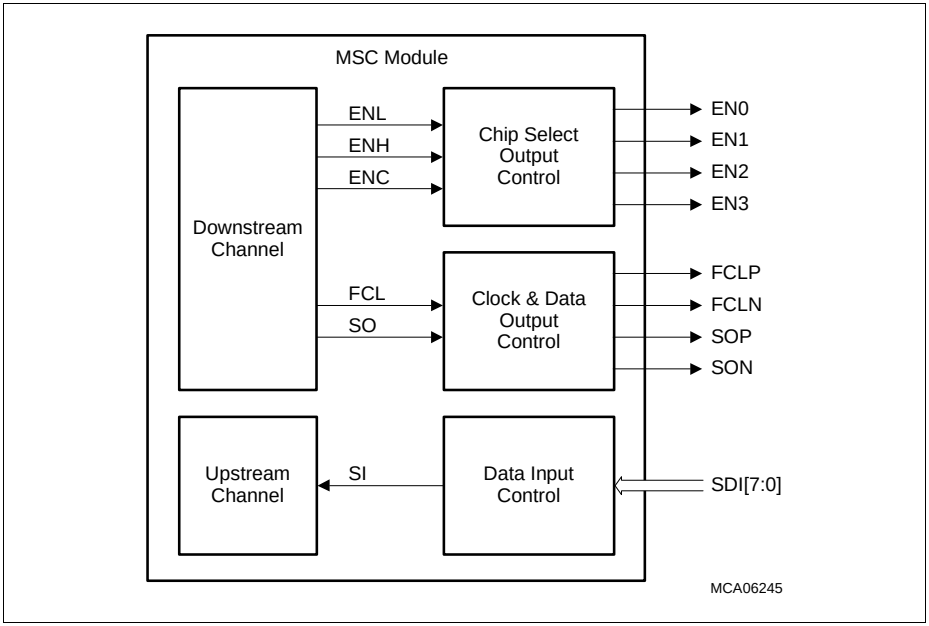

Figure 23-19 I/O Control

The MSC module I/O signals is controlled by bit fields that are located in the Output Control Register OCR.

23.1.4.1 Downstream Channel Output Control

As shown in **Figure 23-5** and **Figure 23-6**, the active phases during downstream channel operation are indicated by three enable signals:

- ENL indicates the SRL active phase of a data frame
- ENH indicates the SRH active phase of a data frame
- ENC indicates the active phase of a command frame

The chip select output control logic of the MSC uses a signal compressing scheme (similar to the interrupt request compressing scheme in **Figure 23-27**) that allows each of the three enable signals to be directed via a 2-bit selector to one of the four chip enable

outputs EN[3:0]. This also makes it possible to connect more than one internal enable signal (ENL, ENH, ENC) to one chip enable output ENx. Three bit fields in register OCR (CSL, CSH, and CSC) determine which chip enable output becomes active on a valid internal enable signal.

In the MSC, enable signals are high-level active signals. If required in a specific application, all chip enable outputs ENx can be assigned for low-level active polarity by setting bit OCR.CSLP.

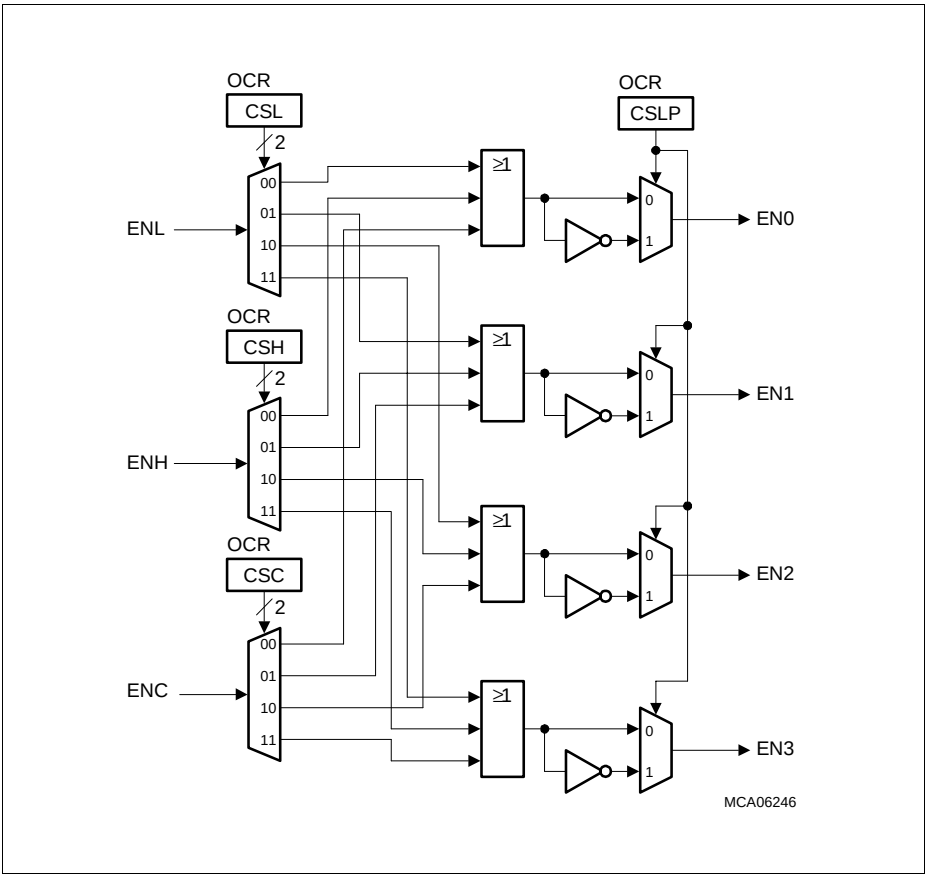

Figure 23-20 Downstream Channel: Chip Enable Output Control

At the MSC downstream channel, the internal serial clock output FCL and data output line SO are available outside the MSC module as two signal pairs with inverted signal polarity, FCLP/FCLN and SOP/SON. Both, clock and data outputs, are generated from the module internal signals FCL and SO according to **Figure 23-21**.

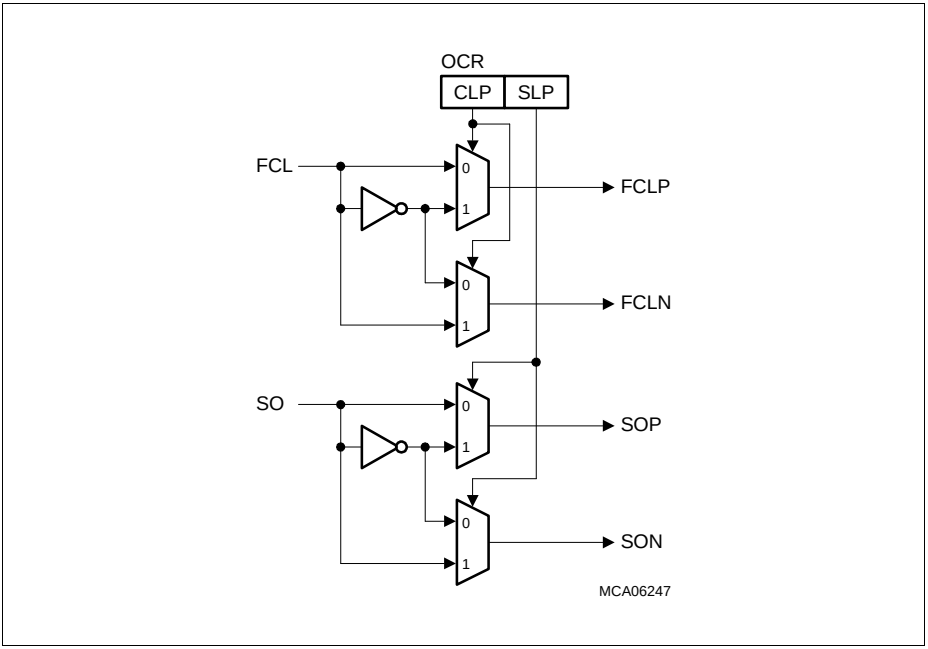

Figure 23-21 Downstream Channel: Clock and Data Output Control

With OCR.CLP = 0, FCLP has identical and FCLN has inverted polarity compared to FCL. Setting OCR.CLP, exchanges the signal polarities of FCLP and FCLN. An equivalent control capability is available for the SOP and SON data outputs (controlled by OCR.SLP).

One additional control capability not shown in **Figure 23-21** is available for the FCL signal. With OCR.CLKCTRL = 1, the FCL clock signal will always be generated, independently whether a downstream frame is currently transmitted or not. If OCR.CLKCTRL = 0, FCL becomes only active during the active phases of data or command frames (not during passive time frames).

23.1.4.2 Upstream Channel

As shown in **Figure 23-22**, the MSC upstream channel can be connected to up to eight SDI[7:0] serial inputs. Bit field OCR.SDISEL selects one out of these input lines (input signal SDI). If OCR.ILP = 0, SDI is directly connected to the serial receive buffer input SI. If OCR.ILP = 1, SDI is connected to input SI via an inverter.

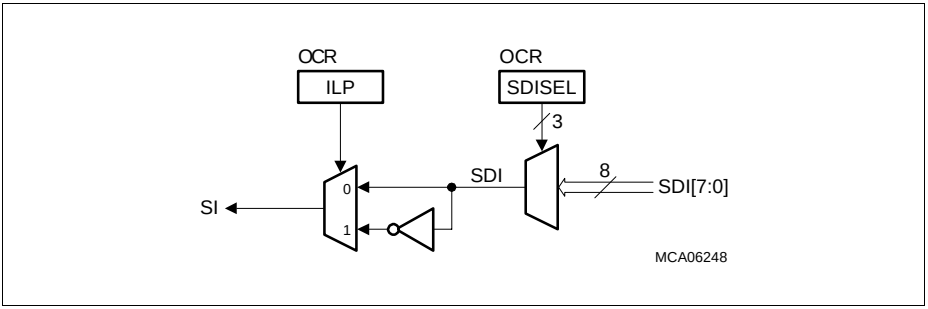

Figure 23-22 Upstream Channel Serial Data Input Control

23.1.5 MSC Interrupts

The MSC module has four interrupt sources and four service request outputs. A service request output is able to generate interrupts (controlled by a service request control register) or DMA requests. The service request output assignment, interrupt or DMA request, is specific for each microcontroller that is using the MSC. In this section, the term “interrupt request” has the meaning of “service request” that is able to handle interrupt or DMA requests.

Each interrupt source is provided with a status flag, enable bit(s) with software set/clear capability, and an interrupt node pointer. An interrupt event, internally generated as a request pulse, is always stored in an interrupt status flag that is located in the Interrupt Status Register ISR. All interrupt status flag can be set or cleared individually by software via the interrupt Set Clear Register ISC. Software-controlled interrupt generation can be initiated by setting the interrupt status flag of the corresponding interrupt. Each interrupt source can be enabled or disabled individually. When an interrupt event is enabled, a 2-bit interrupt node pointer determines which of the service request outputs will be activated.

Table 23-7 shows the four MSC interrupt sources.

Table 23-7 MSC Interrupts

Interrupt Type	Generated by
Data frame interrupt	Downstream Channel
Command frame interrupt	
Time frame finished interrupt	
Receive data interrupt	Upstream Channel

23.1.5.1 Data Frame Interrupt

A data frame interrupt can be generated when either the first or the last data bit of the downstream channel is shifted out and becomes available at the SO output line (see also **Figure 23-6**). Bit ICR.EDIEI selects which case is selected.

Note: If ICR.EDIE = 10_B, an interrupt at the first data bit is only generated if DSC.NDBL is not equal 00000_B. This means, at least one SRL bit must be shifted out for the first data bit shifted interrupt to become active.

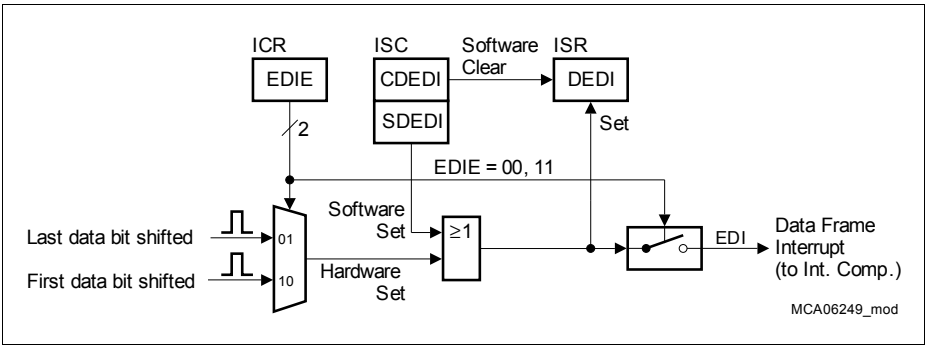

Figure 23-23 Data Frame Interrupt Control

23.1.5.2 Command Frame Interrupt

A command frame interrupt can be generated at the end of a downstream channel command frame (see also **Figure 23-5**).

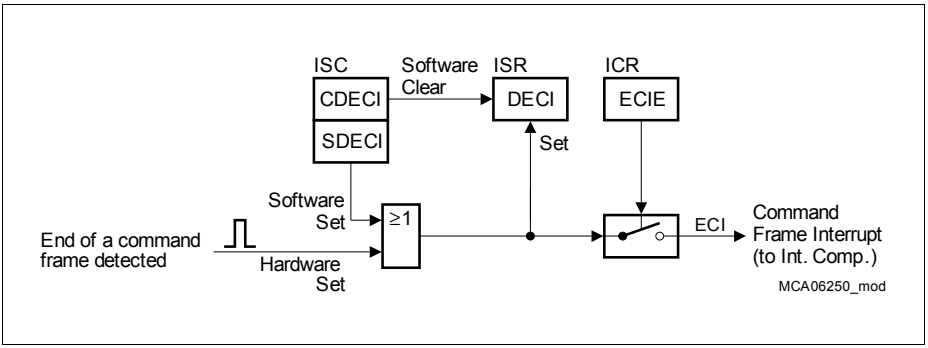

Figure 23-24 Command Frame Interrupt Control

23.1.5.3 Time Frame Finished Interrupt

A time frame finished interrupt can be generated at the end of a downstream channel passive time phase.

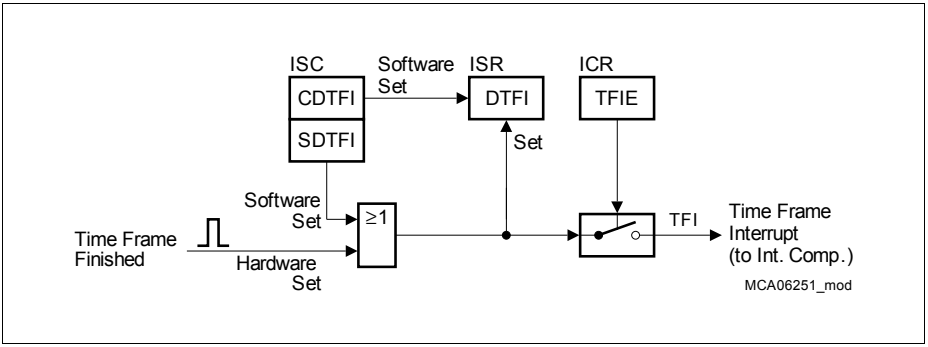

Figure 23-25 Time Frame Interrupt Control

23.1.5.4 Receive Data Interrupt

Whenever the upstream channel receives data in registers UDx (x = 0-3), the MSC is able to generate an interrupt. Three interrupt generation conditions can be selected for the receive data interrupt:

- Each update of UDx (x = 0-3) generates a receive data interrupt.
- Each update of UDx (x = 0-3) generates a receive data interrupt when the updated value is not equal 00_H.
- Only an update of register UD3 generates a receive data interrupt.

The selection of the interrupt generation condition is controlled by bit field ICR.RDIE. Setting ICR.RDIE = 0 disables the receive data interrupt in general. ISR.URDI is the interrupt status flag that can be set or clear when writing bits ISC.SURDI or ISC.CURDI with a 1.

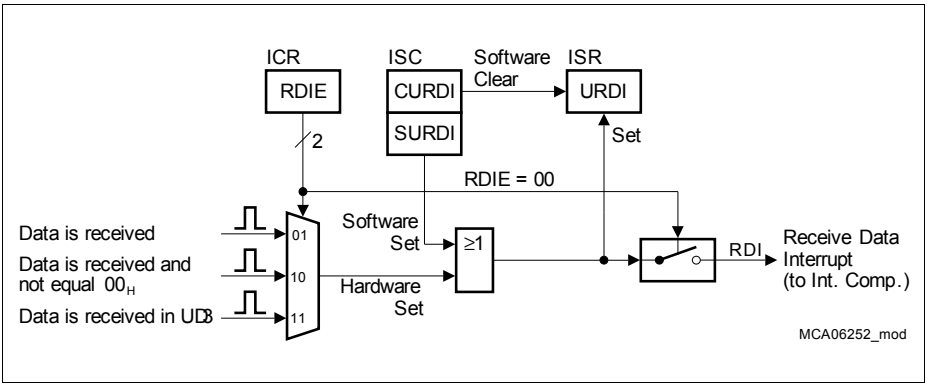

Figure 23-26 Receive Data Interrupt Control

23.1.5.5 Interrupt Request Compressor

The interrupt control logic of the MSC uses an interrupt compressing scheme that allows high flexibility in interrupt processing. Each of the four interrupt sources can be directed via a 2-bit interrupt node pointer to one of the four service request outputs SR[3:0]. This also makes it possible to connect more than one interrupt source to one interrupt output SRx.

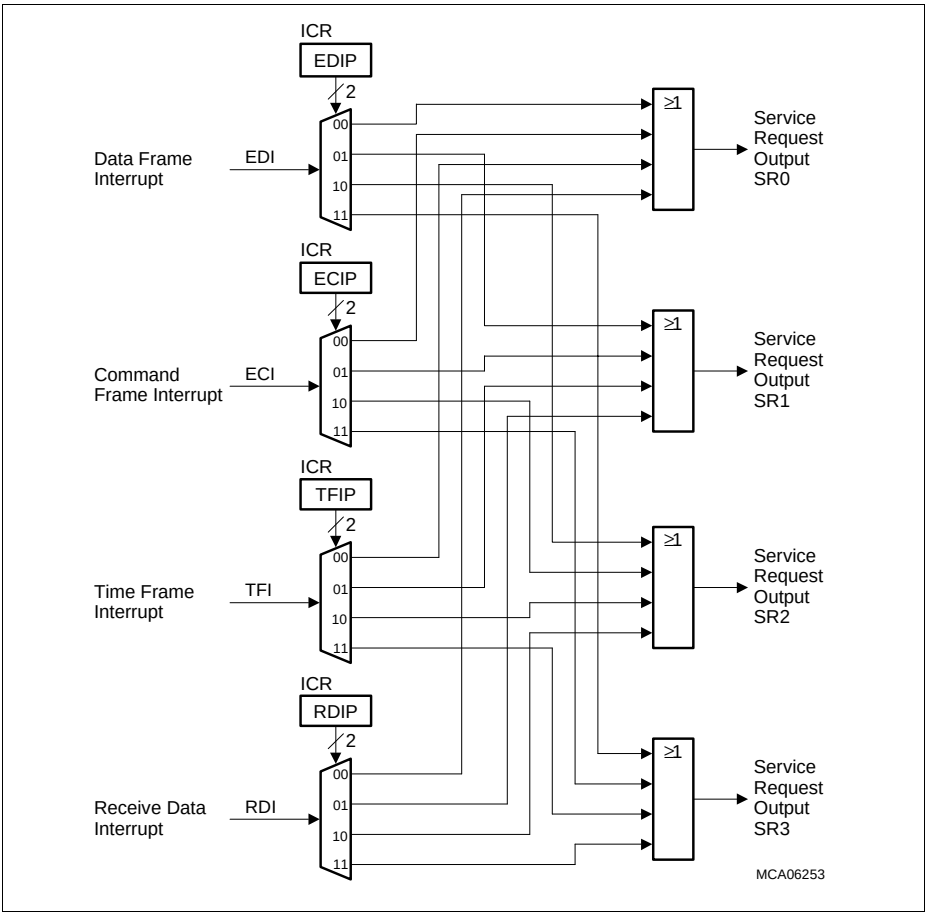

Figure 23-27 MSC Interrupt Request Compressor

*Note: The number of available MSC interrupt outputs depends on the implementation of the MSC module(s) in the specific product (see **Page 23-74** for TC1798 details).*

23.2 MSC Kernel Registers

This section describes the kernel registers of the MSC module. All MSC kernel register names described in this section will be referenced in other parts of the TC1798 User´s Manual by the module name prefix “MSC0_” for the MSC0 interface and “MSC1_” for the MSC1 interface.

All registers in the MSC address spaces are reset with the application reset (definition see SCU section “Reset Operation”).

MSC Kernel Register Overview

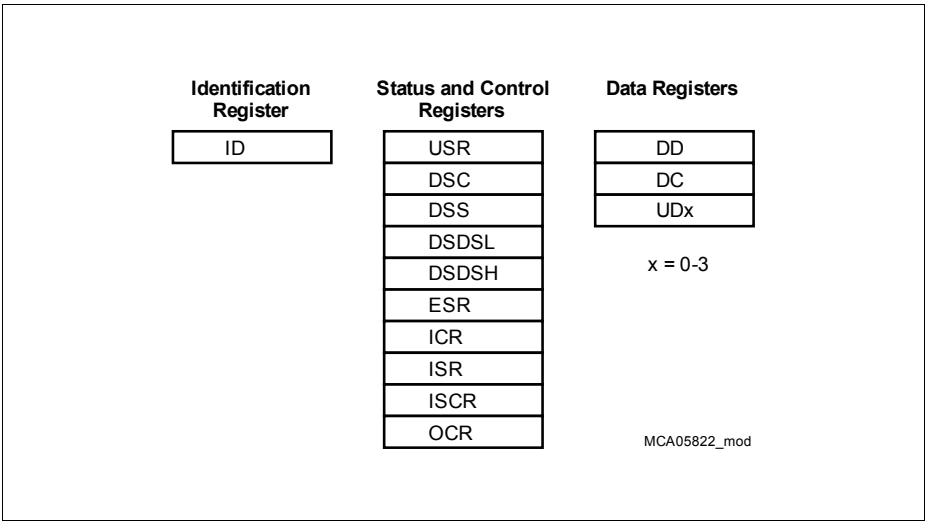

Figure 23-28 MSC Kernel Registers

The complete and detailed address map of the MSC0 module is described in Table 23-12 on Page 23-75.

Table 23-8 Registers Address Space - MSC0 Kernel Registers

Module	Base Address	End Address	Note
MSC0	$F000\ 0800_H$	$F000\ 08FF_H$	–
MSC1	$F000\ 0900_H$	$F000\ 09FF_H$	–

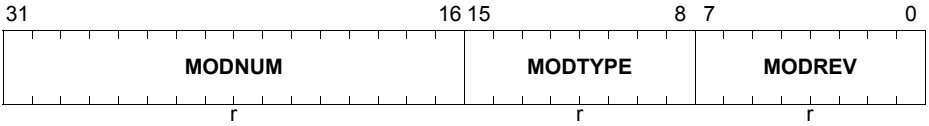
1) The absolute register address is calculated as follows:
Module Base Address (Table 23-8) + Offset Address (shown in this column)

23.2.1 Module Identification Register

The MSC Module Identification Register ID contains read-only information about the module version.

ID
Module Identification Register **(08_H)** **Reset Value: $0028\ C0XX_H$**

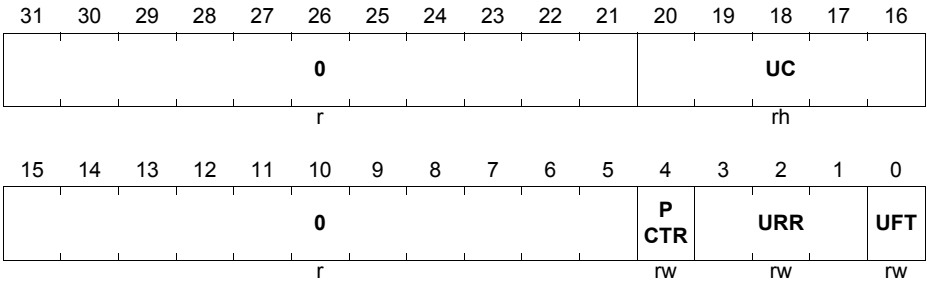


Field	Bits	Type	Description
MODREV	[7:0]	r	**Module Revision Number** This bit field defines the module revision number. The value of a module revision starts with 01_H (first revision).
MODTYPE	[15:8]	r	**Module Type** This bit field defines the module as a 32-bit module: $C0_H$
MODNUM	[31:16]	r	**Module Number Value** This bit field defines the module identification number for the MSC: 0028_H

23.2.2 Status and Control Registers

The Upstream Status Register is used to configure the upstream channel data format, baud rate, and parity type. It also provides the status information of the upstream counter (UC).

USR
Upstream Status Register **(10_H)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
UFT	0	rw	**Upstream Channel Frame Type** This bit determines the frame type used by the upstream channel for data reception. 0_B 12-bit upstream frame selected 1_B 16-bit upstream frame selected (with 4-bit address field)
URR	[3:1]	rw	**Upstream Channel Receiving Rate** This bit field determines the baud rate for the upstream channel. 000_B Upstream channel disabled; no reception is possible 001_B Baud rate = $f_{MSC}/4$ 010_B Baud rate = $f_{MSC}/8$ 011_B Baud rate = $f_{MSC}/16$ 100_B Baud rate = $f_{MSC}/32$ 101_B Baud rate = $f_{MSC}/64$ 110_B Baud rate = $f_{MSC}/128$ 111_B Baud rate = $f_{MSC}/256$

Field	Bits	Type	Description
PCTR	4	rw	**Parity Control** This bit determines the parity mode used by the upstream channel for data reception. 0_B Even parity mode is selected. A parity bit is set on an odd number of 1s in the serial address/data stream. 1_B Odd parity mode is selected. A parity bit is set on an even number of 1s in the serial address/data stream.
UC	[20:16]	rh	**Upstream Counter** This bit field indicates the content of the upstream counter that counts the bits during upstream channel reception.
0	[15:5], [31:21]	r	**Reserved** Read as 0; should be written with 0.

The Downstream Control Register is used to control the operation mode and frame layout of the downstream channel transmission. It also contains the two pending status bits.

DSC
Downstream Control Register (14_H) Reset Value: $0000\ 0000_H$

DS DIS	EN SEL H	EN SEL L	NDBH					NDBL					DP	CP	TM
rh	rw	rw	rw					rw					rh	rh	rw

Field	Bits	Type	Description
TM	0	rw	**Transmission Mode** This bit selects the transmission mode of the downstream channel. 0_B Triggered Mode selected 1_B Data Repetition Mode selected
CP	1	rh	**Command Pending** This bit is set when the downstream command register DC is written. CP is cleared when the first bit of the related command frame is sent out.
DP	2	rh	**Data Pending** In Triggered Mode, this bit is set when the set data pending bit ISC.SDP is set by software. In Data Repetition Mode, this bit is set by hardware at the last passive time frame. At the start of the data frame, DP is cleared by hardware.

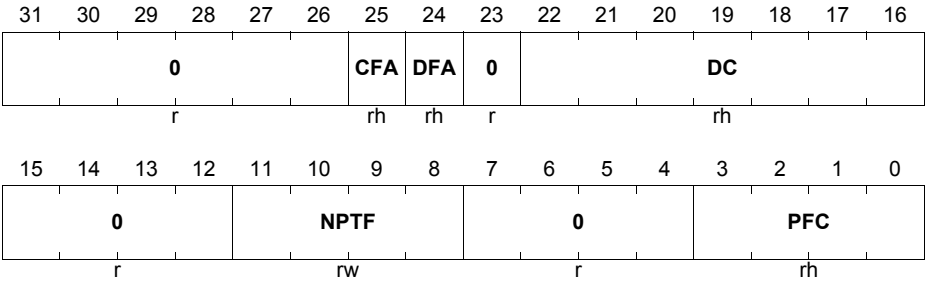
Field	Bits	Type	Description
NDBL	[7:3]	rw	**Number of SRL Bits Shifted at Data Frames** NDBL determines the number of shift register low part (SRL) bits that are shifted out on SO during a data frame. 00000_B No SRL bit shifted 00001_B SRL[0] shifted 00010_B SRL[1:0] shifted $...B$ ... 01111_B SRL[14:0] shifted 10000_B SRL[15:0] shifted Other bit combinations are reserved; do not use these bit combinations.
NDBH	[12:8]	rw	**Number of SRH Bits Shifted at Data Frames** NDBH determines the number of shift register high part (SRH) bits that are shifted out on SO during a data frame. 00000_B No SRH bit shifted; no selection bit is generated, the SRH active phase is completely skipped. 00001_B SRH[0] shifted 00010_B SRH[1:0] shifted $...B$ ... 01111_B SRH[14:0] shifted 10000_B SRH[15:0] shifted Other bit combinations are reserved; do not use these bit combinations.
ENSELL	13	rw	**Enable SRL Active Phase Selection Bit** This bit determines whether a low level selection bit is inserted at the beginning of a data frame's SRL active phase. 0_B No selection bit inserted. 1_B Low level selection bit inserted.
ENSELH	14	rw	**Enable SRH Active Phase Selection Bit** This bit determines whether a low level selection bit is inserted at the beginning of a data frame's SRH active phase. 0_B No selection bit inserted. 1_B Low level selection bit inserted.

Field	Bits	Type	Description
DSDIS	15	rh	**Downstream Disable** This bit indicates the state of the downstream channel operation. 0_B The downstream channel is enabled. A frame transmission can take place (Triggered Mode) or takes place (Data Repetition Mode). 1_B Downstream Counter becomes disabled. No new frame transmission is started. A running frame transmission is always completed.
NBC	[21:16]	rw	**Number of Bits Shifted at Command Frames** This bit field determines how many bits of the SRL/SRH shift registers are shifted out during transmission of a command frame. 000000_B No bit shifted 000001_B SRL[0] shifted 000010_B SRL[1:0] shifted 000011_B SRL[2:0] shifted $\cdots_B$ ... 010000_B SRL[15:0] shifted 010001_B SRL[15:0] and SRH[0] shifted 010010_B SRL[15:0] and SRH[1:0] shifted $\cdots_B$ ... 011111_B SRL[15:0] and SRH[14:0] shifted 100000_B SRL[15:0] and SRH[15:0] shifted Other bit combinations are reserved; do not use these bit combinations
PPD	[28:24]	rw	**Passive Phase Length at Data Frames** This bit field determines the length of the passive phase of a data frame. 00000_B Passive phase length is $2 \times t_{FCL}$ 00001_B Passive phase length is $2 \times t_{FCL}$ 00010_B Passive phase length is $2 \times t_{FCL}$ 00011_B Passive phase length is $3 \times t_{FCL}$ $\cdots_B$ ... 11111_B Passive phase length is $31 \times t_{FCL}$
0	[23:22], [31:29]	r	**Reserved** Read as 0; should be written with 0.

Note: The "rw" bits in the DSC register are buffered in a shadow buffer at the start of a corresponding frame transmission.

The Downstream Status Register DSS contains counter bit fields, status bits, and indicates the number of passive time frames.

DSS
Downstream Status Register (18_H) Reset Value: $0000\ 0000_H$

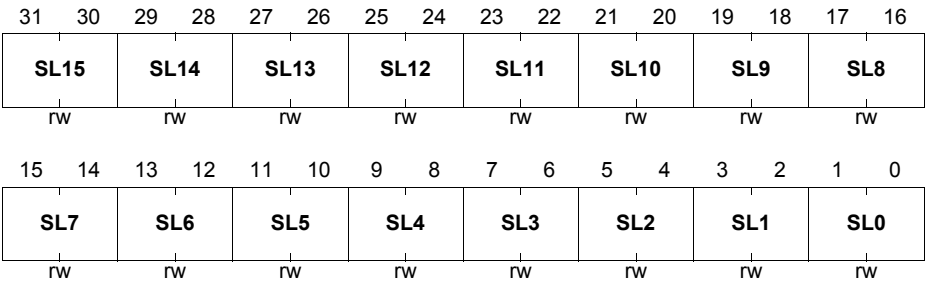


Field	Bits	Type	Description
PFC	[3:0]	rh	**Passive Time Frame Counter** In Data Repetition Mode, this bit field indicates the count of passive time frames that are currently transmitted. In Triggered Mode PFC remains at 0000_B. 0000_B Data frame is transmitted. 0001_B First passive time frame is transmitted. 0010_B Second passive time frame is transmitted. $\ldots_B$ ... 1111_B Fifteenth passive time frame is transmitted.
NPTF	[11:8]	rw	**Number Of Passive Time Frames** This bit field indicates the number of passive time frames that are inserted in Data Repetition Mode between two data frames. 0000_B No passive time frame inserted. 0001_B One passive time frame inserted. 0010_B Two passive time frames inserted. $\ldots_B$ ... 1111_B Fifteen passive time frames inserted. *Note: NPTF is buffered in a shadow buffer at the start of each data frame.*

Field	Bits	Type	Description
DC	[22:16]	rh	**Downstream Counter** This bit field indicates the number of downstream shift clock periods that have been elapsed since the start of the current frame. 00_H No shift clock elapsed (after counter reset). 01_H 1 shift clock elapsed. …$_H$ … $7F_H$ 127 shift clocks elapsed. DC is reset at the end of a downstream frame.
DFA	24	rh	**Data Frame Active** This bit indicates if a data frame is currently sent out. 0_B No data frame is currently sent out. 1_B A data frame is currently sent out.
CFA	25	rh	**Command Frame Active** This bit indicates if a command frame is currently sent out. 0_B No command frame is currently sent out. 1_B A command frame is currently sent out.
0	[7:4], [15:12], 23, [31:26]	r	**Reserved** Read as 0; should be written with 0.

The bit fields of the Downstream Select Data Low Register DSDSL determine the data source for each bit in shift register SRL.

DSDSL
Downstream Select Data Source Low Register
(24_H) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
SLx **(x = 0-15)**	[2*x+1: 2*x]	rw	**Select Source for SRL** SLx determines which data source is used for the shift register bit SRL[x] during data frame transmission. 00_B SRL[x] is taken from data register DD.DDL[x]. 01_B Reserved. 10_B SRL[x] is taken from the ALTINL input line x. 11_B SRL[x] is taken from the ALTINL input line x in inverted state.

The bit fields of the Downstream Select Data Source High Register DSDSH determine the data source for each bit in shift register SRH.

DSDSH
Downstream Select Data Source High Register

Field	Bits	Type	Description
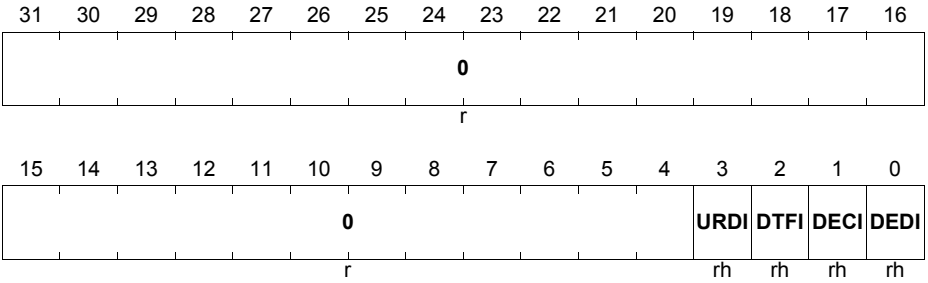
RDIE	[15:14]	rw	**Receive Data Interrupt Enable** This bit field determines the enable conditions for the receive data interrupt. 00_B Interrupt generation disabled. 01_B An interrupt is generated when data is received and written into the upstream data registers UDx (x = 0-3). 10_B An interrupt is generated as with RDIE = 01_B but only if the received data is not equal to 00_H. 11_B An interrupt is generated when data is received and written into register UD3.
0	6, 10, [31:16]	r	**Reserved** Read as 0; should be written with 0.

The Interrupt Status Register ISR holds the interrupt status flags that indicate an interrupt occurrence in downstream and upstream channels.

ISR

Interrupt Status Register **(44_H)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
DEDI	0	rh	**Data Frame Interrupt Flag** This flag is always set by hardware when a downstream channel data frame interrupt is generated. DEDI can be set or cleared by software when writing to register ISC with the appropriate bits ISC.SDEDI or ISC.CDEDI set.
DECI	1	rh	**Command Frame Interrupt Flag** This flag is always set by hardware when a downstream channel command frame interrupt is generated, whether or not it is enabled. DECI can be set or cleared by software when writing to register ISC with the appropriate bits SDECI or CDECI set.
DTFI	2	rh	**Time Frame Interrupt Flag** This flag is always set by hardware when a downstream channel time frame interrupt is generated, whether or not it is enabled. DTFI can be set or cleared by software when writing to register ISC with the appropriate bits SDTFI or CDTFI set.

Field	Bits	Type	Description
URDI	3	rh	**Receive Data Interrupt Flag** This flag is always set by hardware when an upstream channel receive data interrupt is generated, whether or not it is enabled. URDI can be set or cleared by software when writing to register ISC with the appropriate bits SURDI or CURDI set.
0	[31:4]	r	**Reserved** Read as 0; should be written with 0.

The Interrupt Set Clear Register ISC is used to set or clear the MSC interrupt flags located in the Interrupt Status Register ISR. Reading ISC always returns 0000 0000$_H$.

ISC
Interrupt Set Clear Register **(48$_H$)** **Reset Value: 0000 0000$_H$**

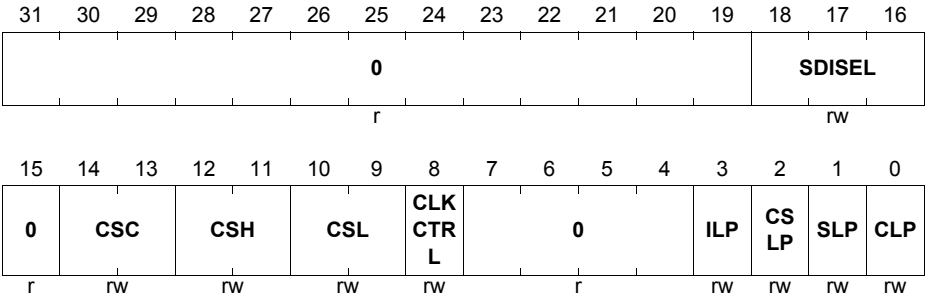
Note: When the ISC register is written with both bits (set and reset bit) for a specific interrupt flag, the clear operation takes place and the set operation is ignored.

The Output Control Register OCR determines the MSC input/output signal polarities, the chip select output signal assignment, and the serial output clock generation.

OCR
Output Control Register **($4C_H$)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
CLP	0	rw	**FCLP Line Polarity** 0_B FCLP and FCL signal polarity is identical. FCLN signal has inverted FCL signal polarity. 1_B FCLP signal has inverted FCL signal polarity. FCLN and FCL signal polarities are identical.
SLP	1	rw	**SOP Line Polarity** 0_B SOP and SO signal polarity is identical. SON signal has inverted SO signal polarity. 1_B SOP signal has inverted SO signal polarity. SON and SO signal polarities are identical.
CSLP	2	rw	**Chip Selection Lines Polarity** 0_B EN[3:0] and ENL, ENH, ENC signal polarities are identical (high active). 1_B EN[3:0] signal polarities are inverted (low active) to the ENL, ENH, ENC signal polarities. Bit CSLP is buffered during a frame transmission. This means that any change of CSLP becomes valid first with the start of the next frame transmission.
ILP	3	rw	**SDI Line Polarity** 0_B SDI and SI signal polarities are identical. 1_B SDI and SI signal polarities are inverted.

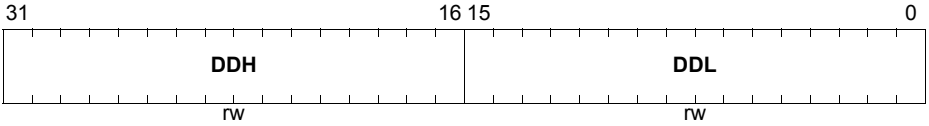
Field	Bits	Type	Description
CLKCTRL	8	rw	**Clock Control** This bit determines the activation of clock output FCL. 0_B FCL is activated only during the active phases of data or command frames (not during passive time frames). 1_B FCL is always active whether or not a downstream frame is currently transmitted.
CSL	[10:9]	rw	**Chip Enable Selection for ENL** This bit field selects the chip enable output ENx that becomes active during the SRL active phase (ENL = 1) of a data frame. The active level of ENx is defined by bit CSLP. 00_B EN0 line is selected for ENL. 01_B EN1 line is selected for ENL. 10_B EN2 line is selected for ENL. 11_B EN3 line is selected for ENL.
CSH	[12:11]	rw	**Chip Enable Selection for ENH** This bit field selects the chip enable output ENx that becomes active during the SRH active phase (ENH = 1) of a data frame. The active level of ENx is defined by bit CSLP. 00_B EN0 line is selected for ENH. 01_B EN1 line is selected for ENH. 10_B EN2 line is selected for ENH. 11_B EN3 line is selected for ENH.
CSC	[14:13]	rw	**Chip Enable Selection for ENC** This bit field selects the chip enable output ENx that becomes active during the active phase (ENC = 1) of a command frame. The active level of ENx is defined by bit CSLP. 00_B EN0 line is selected for ENC. 01_B EN1 line is selected for ENC. 10_B EN2 line is selected for ENC. 11_B EN3 line is selected for ENC.

Field	Bits	Type	Description
SDISEL	[18:16]	rw	**Serial Data Input Selection** This bit field selects the source for the serial data input SDI of the upstream channel. 000_B SDI0 input is selected for SDI. 001_B SDI1 input is selected for SDI. 010_B SDI2 input is selected for SDI. 011_B SDI3 input is selected for SDI. 100_B SDI4 input is selected for SDI. 101_B SDI5 input is selected for SDI. 110_B SDI6 input is selected for SDI. 111_B SDI7 input is selected for SDI.
0	[7:4], 15, [31:19]	r	**Reserved** Read as 0; should be written with 0.

23.2.3 Data Registers

The Downstream Data Register DD contains data to be transmitted during data frames.

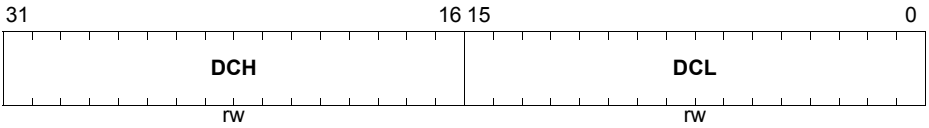
DD
Downstream Data Register **($1C_H$)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
DDL	[15:0]	rw	**Downstream Data for SRL Shift Register** Contains the data bits to be transmitted during the SRL active phase of a data frame.
DDH	[31:16]	rw	**Downstream Data for SRH Shift Register** Contains the data bits to be transmitted during the SRH active phase of a data frame.

The Downstream Command Register DC contains command information to be transmitted during command frames.

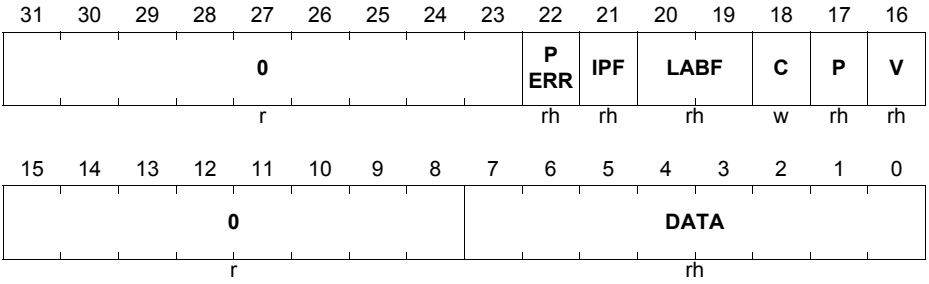
DC
Downstream Command Register **(20_H)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
DCL	[15:0]	rw	**Downstream Command for SRL Shift Register** Contains the data bits to be transmitted during the SRL active phase of a command frame.
DCH	[31:16]	rw	**Downstream Command for SRH Shift Register** Contains the data bits to be transmitted during the SRH active phase of a command frame.

The four Upstream Data Registers UDx store the content (data, addresses, received and calculated parity bit, parity error bit) of a received upstream channel data frame.

UDx (x = 0-3)
Upstream Data Register x **(30_H+x*4_H)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
DATA	[7:0]	rh	**Received Data** This bit field contains the 8-bit receive data.
V	16	rh	**Valid Bit** This bit is set by hardware when the received data is written to UDx. Writing bit C = 1 clears V. If hardware setting and software clearing of the valid bit occur simultaneously, bit V will be cleared.
P	17	rh	**Parity Bit** This flag contains the parity bit that has been received with the data frame.
C	18	w	**Clear Bit** 0_B No operation. 1_B Bit V is cleared. C is always read as 0.
LABF	[20:19]	rh	**Lower Address Bit Field** This bit field contains the two address bits A[1:0] of the 4-bit address field (16-bit data frame). If 12-bit data frame is selected, LABF is always set to 00_B.
IPF	21	rh	**Internal Parity Flag** This bit contains the parity bit that has been calculated in the MSC during data frame reception.

Field	Bits	Type	Description
PERR	22	rh	**Parity Error** This bit indicates if a start bit error, parity error, or stop bit error occurred during frame reception. 0_B No error detected. 1_B Error detected.
0	[15:8], [31:23]	r	**Reserved** Read as 0; should be written with 0.

23.3 MSC Module Implementation

This section describes the MSC module interface as implemented in the TC1798. It especially covers clock control, port and on-chip connections, interrupt control, and address decoding.

23.3.1 Interface Connections of the MSC Modules

Figure 23-29 shows the TC798-specific implementation details and interconnections of the MSC0 and MSC1 modules.

Each MSC module is supplied with a separate clock control, address decoding, and interrupt control logic. Two of the four modules' service request outputs are connected with interrupt nodes, and two with the DMA controller. Outputs of the GPTA module are connected to the alternate input buses ALTINL/ALTINH. The emergency stop output from the SCU controls the corresponding inputs of both MSC modules.

The serial data and clock outputs of the downstream channels of each MSC module are connected to combined GPIO/LVDS differential output drivers. Details about these eight Port 5 pins are defined in the ports chapter (see also **Table 23-10**).

Additionally, the positive serial clock (FCLP) and positive data output (SOP) are available at GPIO lines of Port 9. The device select outputs (ENxy) are wired to GPIO lines of Port 5 and Port 9. One Port 5 input line is connected to the upstream channel serial data input.

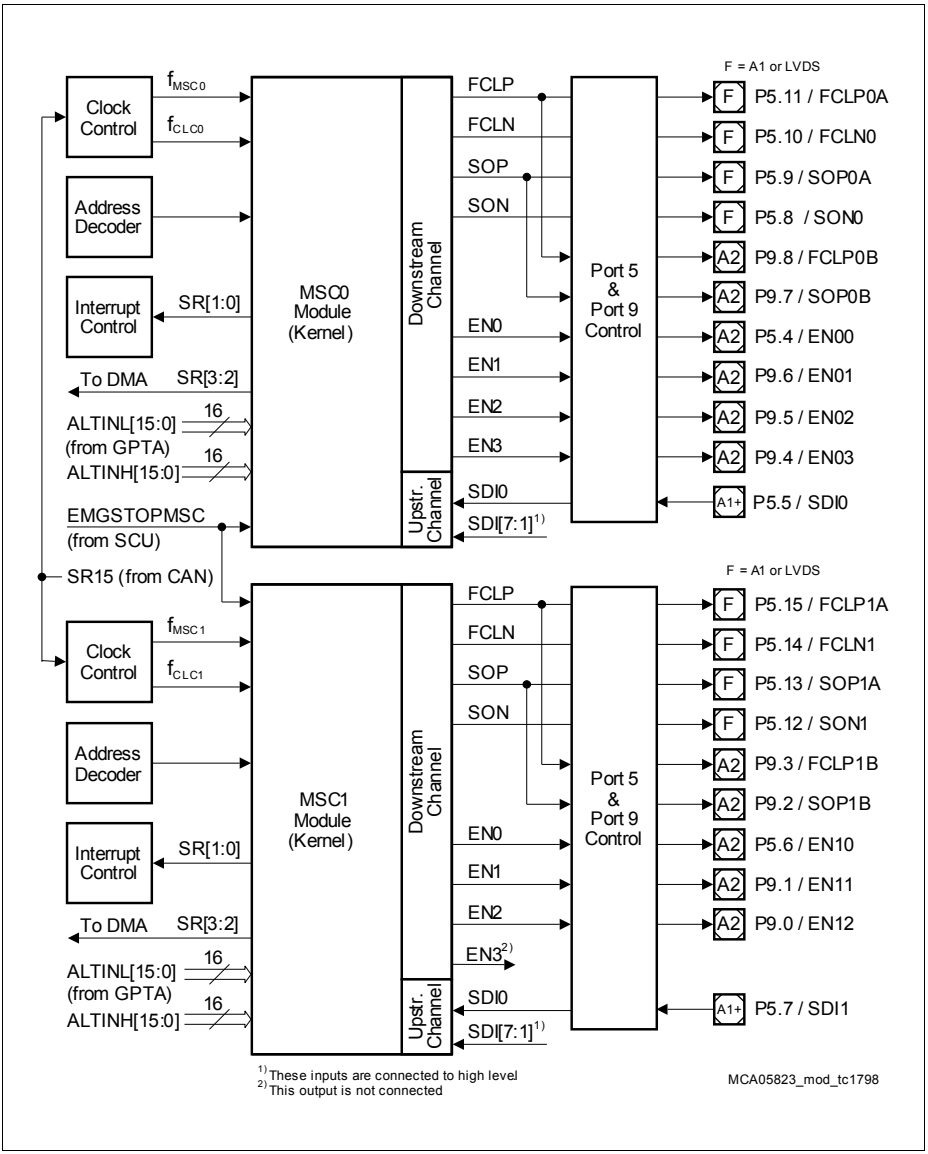


Figure 23-29 MSC0 and MSC1 Module Implementations and Interconnections

23.3.2 MSC0/MSC1 Module-Related External Registers

Figure 23-30 summarizes the module-related external registers which are required for MSC programming (see also **Figure 23-28** for the module kernel specific registers). These registers are described in the following sections.

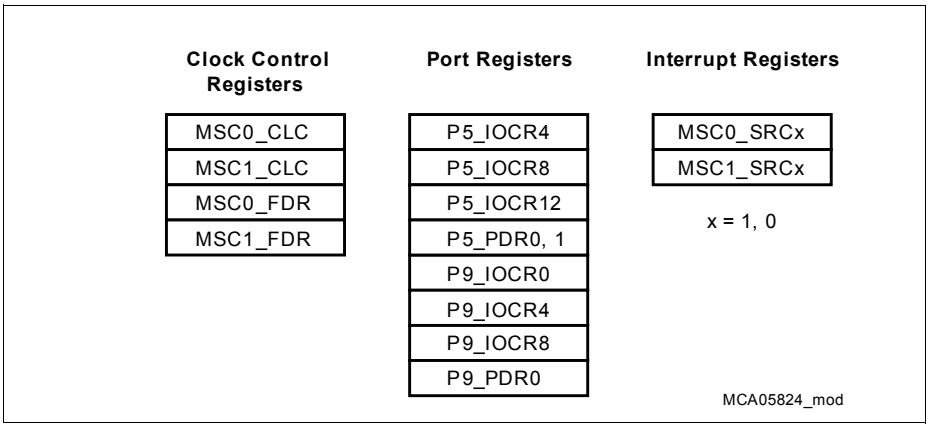

Figure 23-30 MSC Implementation-specific Special Function Registers

23.3.3 Clock Control

The MSC modules are provided with two independent clock signals (**Figure 23-31**):

- f_{CLC0} and f_{CLC1}
  These are the module clocks that are used inside the MSC kernel for control purposes such as clocking of control logic and register operations. The frequency of f_{CLC0} and f_{CLC1} is always identical to the system clock frequency f_{FPI}. The clock control registers MSC0_CLC and MSC1_CLC make it possible to enable/disable f_{CLC0} and f_{CLC1} under certain conditions.
- f_{MSC0} and f_{MSC1}
  These clocks are the module clocks that are used inside the MSC for baud rate generation of the serial upstream and downstream channel. The fractional divider registers MSC0_FDR and MSC1_FDR control the frequency of f_{MSC0} and f_{MSC1} and make it possible to enable/disable it independently of f_{CLC0} and f_{CLC1}.

For module test purposes only, the service request output SR15 of the MultiCAN controller makes it possible to synchronize the fractional divider clock generation of both MSC modules to external events. This feature should not be used for normal MSC operation.

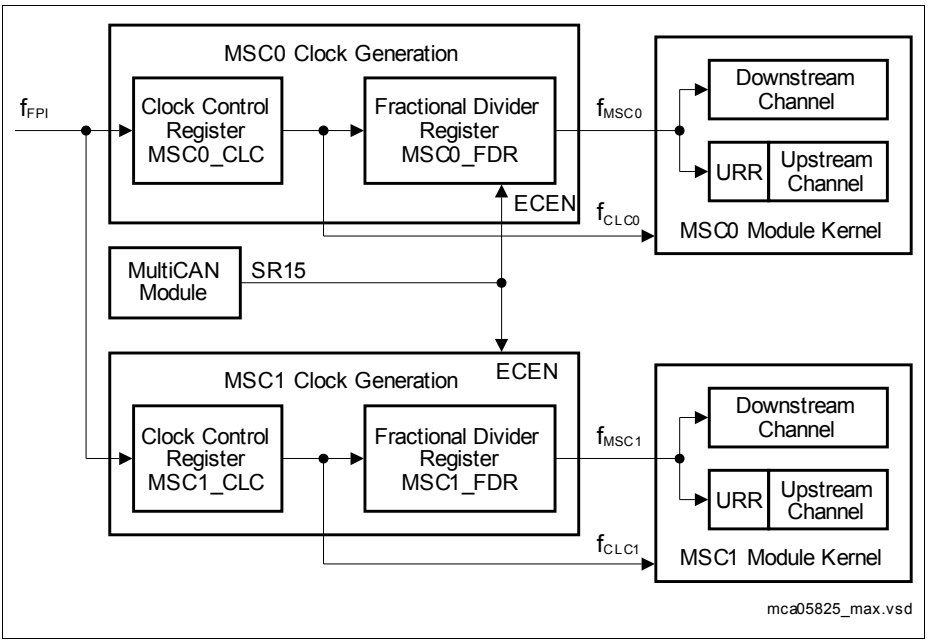

Figure 23-31 MSC Module Clock Generation

The following two formulas define the frequency of f_{MSC0}:

$$f_{MSC0} = f_{FPI} \times \frac{1}{n} \text{ with n = 1024 - MSC0.FDR.STEP} \quad (23.3)$$

$$f_{MSC0} = f_{FPI} \times \frac{n}{1024} \text{ with n = 0-1023} \quad (23.4)$$

Downstream Channel Baud Rate

As the clock signal FCL of the synchronous downstream channel is always half the frequency of f_{MSC0}, the resulting downstream channel baud rate is defined by:

$$\text{Baud rate}_{MSC0} = f_{FPI} \times \frac{1}{2 \times (1024 - \text{MSC0.FDR.STEP})} \quad (23.5)$$

$$\text{Baud rate}_{MSC0} = f_{FPI} \times \frac{\text{MSC0.FDR.STEP}}{2 \times 1024} \quad (23.6)$$

Upstream Channel Baud Rate

The baud rate of the asynchronous upstream channel is derived from the module clock f_{MSC0} by a programmable clock divider selected by bit field MSC0_USR.URR (see also **Equation (23.2)** on **Page 23-25**). The divide factor DF can be at minimum 4 and at maximum 256.

$$\text{Baud rate}_{MSC0} = f_{FPI} \times \frac{1}{DF \times (1024 - \text{MSC0.FDR.STEP})} \quad (23.7)$$

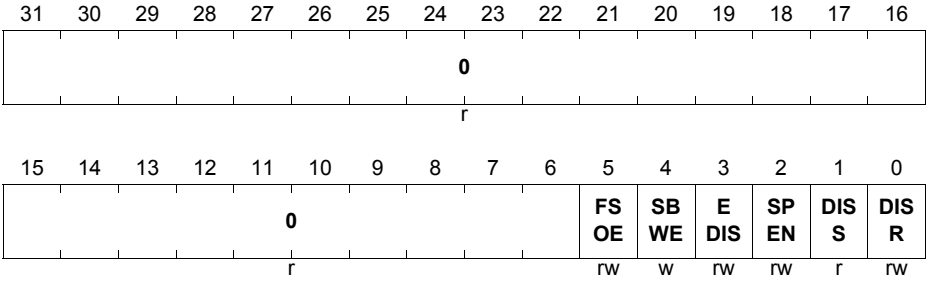
$$\text{Baud rate}_{MSC0} = f_{FPI} \times \frac{\text{MSC0.FDR.STEP}}{DF \times 1024} \quad (23.8)$$

Equation (23.3), **Equation (23.5)**, and **Equation (23.7)** are valid for normal divider mode (MSC0.FDR.DM = 01_B). **Equation (23.4)**, **Equation (23.6)**, and **Equation (23.8)** are valid for fractional divider mode (MSC0.FDR.DM = 10_B).

23.3.3.1 Clock Control Register

The Clock Control Register allows the programmer to control (enable/disable) the clock signals to the MSC0 module under certain conditions. The diagram below shows the clock control register functionality as is implemented for the MSC0 and MSC1 modules.

MSC0_CLC
MSC0 Clock Control Register **(00_H)** **Reset Value: $0000\ 0003_H$**
MSC1_CLC
MSC1 Clock Control Register **(00_H)** **Reset Value: $0000\ 0003_H$**



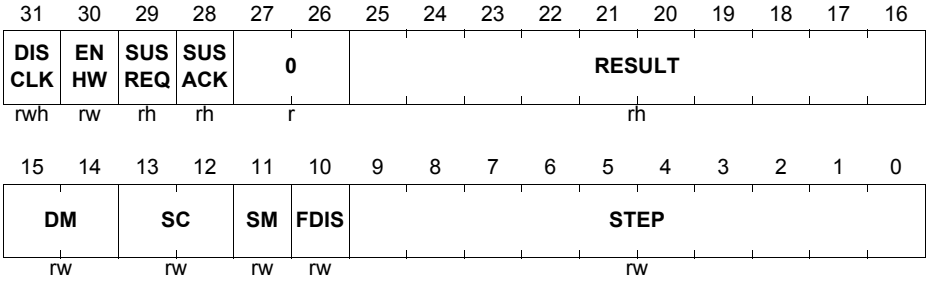
Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module.
DISS	1	r	**Module Disable Status Bit** Bit indicates the current status of the module.
SPEN	2	rw	**Module Suspend Enable for OCDS** Used to enable the suspend mode
EDIS	3	rw	**Sleep Mode Enable Control** Used to control module's sleep mode.
SBWE	4	w	**Module Suspend Bit Write Enable for OCDS** Determines whether SPEN and FSOE are write-protected.
FSOE	5	rw	**Fast Switch Off Enable** Used to switch off fast clock in Suspend Mode.
0	[31:6]	r	**Reserved** Read as 0; should be written with 0.

Note: After a hardware reset operation, the f_{CLC0} and f_{MSC0} clocks are switched off and the MSC modules are disabled (DISS set).

23.3.3.2 Fractional Divider Register

The Fractional Divider Registers control the clock rate of the shift clock f_{MSC0} and f_{MSC1}. Each MSC module has its own fractional divider register.

MSC0_FDR
MSC0 Fractional Divider Register ($0C_H$) Reset Value: 0000 0000$_H$
MSC1_FDR
MSC1 Fractional Divider Register ($0C_H$) Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
STEP	[9:0]	rw	**Step Value** Reload or addition value for RESULT.
FDIS	10	rw	**Freeze Disable** This bit controls the freeze function for this module. 0_B Module operates on corrected clock, with reduced modulation jitter. 1_B Module operates on uncorrected clock, with full modulation jitter.
SM	11	rw	**Suspend Mode** SM selects between granted or immediate suspend mode.
SC	[13:12]	rw	**Suspend Control** This bit field determines the behavior of the fractional divider in suspend mode.
DM	[15:14]	rw	**Divider Mode** DM selects normal or fractional divider mode.
RESULT	[25:16]	rh	**Result Value** Bit field for the addition result.

Field	Bits	Type	Description
SUSACK	28	rh	**Suspend Mode Acknowledge** Indicates state of $\overline{\text{SPNDACK}}$ signal.
SUSREQ	29	rh	**Suspend Mode Request** Indicates state of SPND signal.
ENHW	30	rw	**Enable Hardware Clock Control** Controls operation of ECEN input and DISCLK bit.
DISCLK	31	rwh	**Disable Clock** Hardware controlled disable for f_{OUT} signal.
0	[27:26]	r	**Reserved** Read as 0; should be written with 0.

23.3.4 Port Control

MSC0 and MSC1 clock and data output lines are connected to dedicated differential output drivers. Some of the MSC module I/O lines are connected to I/O ports and therefore controlled in the port logic (see also **Figure 23-29**). The following port control operations selections must be executed for these I/O lines:

- Input/output function selection (IOCR registers)
- Pad driver characteristics selection for the outputs (PDR registers)

23.3.4.1 Input/Output Function Selection

The port input/output control registers contain the bit fields that select the digital output and input driver characteristics such as port direction (input/output) with alternate output selection, pull-up/down devices, and open-drain selections. The I/O lines for the MSC modules are controlled by the Port 5 and Port 9 input/output control registers.

Table 23-10 shows in an overview how bits and bit fields must be programmed for the required I/O functionality of the MSC I/O lines.

Table 23-10 MSC0 and MSC1 I/O Line Selection and Setup

Module	Port Lines	Input/Output Control Register Bits	I/O
MSC0	P5.8 / SON0	P5_IOCR8.PC8 = $1X01_B$ P5_PDR1.PD8 = $0XX_B$	CMOS Output[1)]
		P5_IOCR8.PC8 = $1XXX_B$ P5_PDR1.PD8 = $1XX_B$	LVDS Output

1) Default after reset.

2) For the upstream channel serial data inputs, additionally bit fields MSC0_OCR.SDISEL (for SDI0) and MSC1_OCR.SDISEL (for MSC1) must be set to 000_B.

3) Chip enable output 3 (EN3) of the MSC1 module is not connected in the TC1798.

23.3.5 On-Chip Connections

This section describes the on-chip connections of the MSC0/MSC1 modules.

23.3.5.1 EMGSTOPMSC Signal (from SCU)

The emergency stop input signals EMGSTOPMSC of both MSC modules are connected to the output signal of the emergency stop input control logic. This logic is located in the SCU. Its functionality is controlled by the SCU emergency stop register.

23.3.5.2 ALTINH and ALTINL Connections

In the TC1798, output lines of GPTA0, GPTA1, and LTCA2 are connected to ALTINH and ALTINL inputs of the MSC0/MSC1 downstream channels as shown in **Figure 23-32**. The setting of the GPTA-to-MSC multiplexer determines which output of the three GPTA sub-modules is connected to a specific ALTINL/ALTINH line.

Please note that the upper eight MSC1 input lines ALTINH[15:8] are connected to logic 0 level.

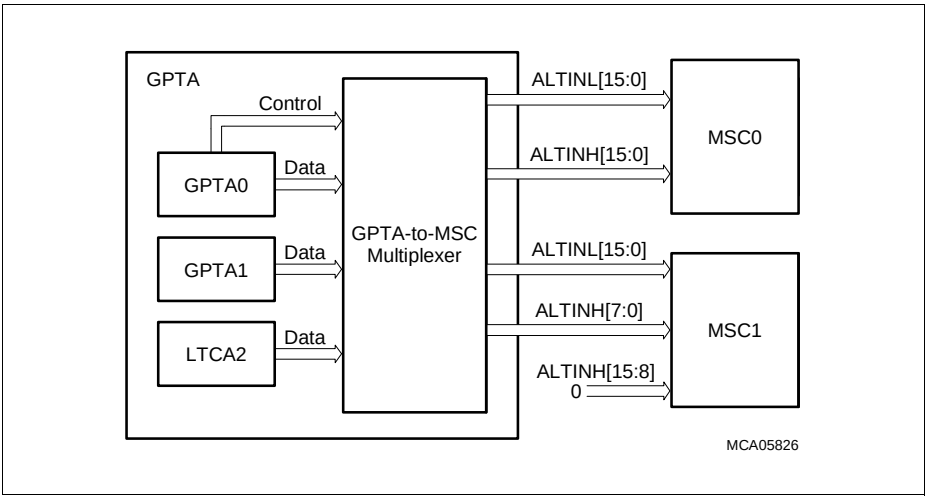

Figure 23-32 ALTINL/ALTINH Connections of the MSC0/MSC1

23.3.5.3 DMA Controller Service Requests

Two service request outputs (SR[3:2]) of each MSC module are connected as DMA request input to the DMA controller. The DMA request lines are connected to the DMA controller as shown in **Table 23-11**.

Table 23-11 Service Request Lines of MSC0/MSC1

Module	Service Request Line	Connected to	Description
MSC0	SR0	MSC0_SRC0	MSC0 Service Request Node 0
	SR1	MSC0_SRC1	MSC0 Service Request Node 1
	SR2	CH02_REQI6	DMA Channel 02 Request Input 6
		CH04_REQI6	DMA Channel 04 Request Input 6
	SR3	CH03_REQI6	DMA Channel 03 Request Input 6
		CH05_REQI6	DMA Channel 05 Request Input 6
MSC1	SR0	MSC1_SRC0	MSC1 Service Request Node 0
	SR1	MSC1_SRC1	MSC1 Service Request Node 1
	SR2	CH12_REQI14	DMA Channel 12 Request Input 14
		CH14_REQI14	DMA Channel 14 Request Input 14
	SR3	CH13_REQI14	DMA Channel 13 Request Input 14
		CH15_REQI14	DMA Channel 15 Request Input 14

23.3.6 Interrupt Control Registers

In the TC1798, the two service request outputs SR[1:0] of each MSC module are connected to one interrupt node. The upper two service request outputs SR[3:2] of each MSC module are not connected to interrupt nodes, but can be used as DMA requests (see **Table 23-11**).

24 Controller Area Network Controller (MultiCAN)

This chapter describes the MultiCAN controller of the TC1798. It contains the following sections:

- CAN basics (see **Page 24-2**)
- Overview of the CAN Module in the TC1798 (see **Page 24-14**)
- Functional description of the MultiCAN Kernel (see **Page 24-18**)
- MultiCAN Kernel register description (see **Page 24-60**)
- Functional description of the TTCAN extension (see **Page 24-117**)
- TTCAN extension register description (see **Page 24-157**)
- TC1798 implementation-specific details (port connections and control, interrupt control, address decoding, clock control, see **Page 24-202**).

Note: The MultiCAN register names described in this chapter are referenced in the TC1798 User´s Manual by the module name prefix “CAN_”.

Table 24-1 Fixed Module Constants

Constant	Description
n_objects	**Number of Message Objects available.**
n_interrupts	**Number of Interrupt Output Lines available.**
n_pendings **n_pendingregs**	**Number of Message Pending Bits available.** There are n_pendings/32 message pending registers.
n_lists	**Number of Lists available for allocation of Message Objects.**
n_nodes	**Number of CAN Nodes available** As each CAN node has it’s own list in addition to the list of un-allocated elements, the relation n_nodes < n_lists is true.

24.1 CAN Basics

CAN is an asynchronous serial bus system with one logical bus line. It has an open, linear bus structure with equal bus participants called nodes. A CAN bus consists of two or more nodes.

The bus logic corresponds to a “wired-AND” mechanism. Recessive bits (equivalent to the logic 1 level) are overwritten by dominant bits (logic 0 level). As long as no bus node is sending a dominant bit, the bus is in the recessive state. In this state, a dominant bit from any bus node generates a dominant bus state. The maximum CAN bus speed is, by definition, 1 Mbit/s. This speed limits the CAN bus to a length of up to 40 m. For bus lengths longer than 40 m, the bus speed must be reduced.

The binary data of a CAN frame is coded in NRZ code (Non-Return-to-Zero). To ensure re-synchronization of all bus nodes, bit stuffing is used. This means that during the transmission of a message, a maximum of five consecutive bits can have the same polarity. Whenever five consecutive bits of the same polarity have been transmitted, the transmitter will insert one additional bit (stuff bit) of the opposite polarity into the bit stream before transmitting further bits. The receiver also checks the number of bits with the same polarity and removes the stuff bits from the bit stream (= destuffing).

24.1.1 Addressing and Bus Arbitration

In the CAN protocol, address information is defined in the identifier field of a message. The identifier indicates the contents of the message and its priority. The lower the binary value of the identifier, the higher is the priority of the message.

For bus arbitration, CSMA/CD with NDA (Carrier Sense Multiple Access/Collision Detection with Non-Destructive Arbitration) is used. If bus node A attempts to transmit a message across the network, it first checks that the bus is in the idle state (“Carrier Sense”) i.e. no node is currently transmitting. If this is the case (and no other node wishes to start a transmission at the same moment), node A becomes the bus master and sends its message. All other nodes switch to receive mode during the first transmitted bit (Start-Of-Frame bit). After correct reception of the message (acknowledged by each node), each bus node checks the message identifier and stores the message, if required. Otherwise, the message is discarded.

If two or more bus nodes start their transmission at the same time (“Multiple Access”), bus collision of the messages is avoided by bit-wise arbitration (“Collision Detection / Non-Destructive Arbitration” together with the “Wired-AND” mechanism, dominant bits override recessive bits). Each node that sends also reads back the bus level. When a recessive bit is sent but a dominant one is read back, bus arbitration is lost and the transmitting node switches to receive mode. This condition occurs for example when the message identifier of a competing node has a lower binary value and therefore sends a message with a higher priority. In this way, the bus node with the highest priority message wins arbitration without losing time by having to repeat the message. Other nodes that lost arbitration will automatically try to repeat their transmission once the bus

returns to idle state. Therefore, the same identifier can be sent in a Data Frame only by one node in the system. There must not be more than one node programmed to send Data Frames with the same identifier.

Standard message identifier has a length of 11 bits. CAN specification 2.0B extends the message identifier lengths to 29 bits, i.e. the extended identifier.

24.1.2 CAN Frame Formats

There are three types of CAN frames:

- Data Frames
- Remote Frames
- Error Frames

A Data Frame contains a Data Field of 0 to 8 bytes in length. A Remote Frame contains no Data Field and is typically generated as a request for data (e.g. from a sensor). Data and Remote Frames can use an 11-bit “Standard” identifier or a 29-bit “Extended” identifier. An Error Frame can be generated by any node that detects a CAN bus error.

24.1.2.1 Data Frames

There are two types of Data Frames defined (see **Figure 24-1**):

- Standard Data Frame
- Extended Data Frame

Standard Data Frame

A Data Frame begins with the Start-Of-Frame bit (SOF = dominant level) for hard synchronization of all nodes. The SOF is followed by the Arbitration Field consisting of 12 bits, the 11-bit identifier (reflecting the contents and priority of the message), and the RTR (Remote Transmission Request) bit. With RTR at dominant level, the frame is marked as Data Frame. With RTR at recessive level, the frame is defined as a Remote Frame.

The next field is the Control Field consisting of 6 bits. The first bit of this field is the IDE (Identifier Extension) bit and is at dominant level for the Standard Data Frame. The following bit is reserved and defined as a dominant bit. The remaining 4 bits of the Control Field are the Data Length Code (DLC) that specifies the number of bytes in the Data Field. The Data Field can be 0 to 8 bytes wide. The Cyclic Redundancy (CRC) Field that follows the data bytes is used to detect possible transmission errors. It consists of a 15-bit CRC sequence, completed by a recessive CRC delimiter bit.

The final field is the Acknowledge Field. During the ACK Slot, the transmitting node sends out a recessive bit. Any node that has received an error free frame acknowledges the correct reception of the frame by sending back a dominant bit, regardless of whether or not the node is configured to accept that specific message. This behavior assigns the

CAN protocol to the “in-bit-response” group of protocols. The recessive ACK delimiter bit, which must not be overwritten by a dominant bit, completes the Acknowledge Field.

Seven recessive End-of-Frame (EOF) bits finish the Data Frame. Between any two consecutive frames, the bus must remain in the recessive state for at least 3 bit times (called Inter Frame Space). If after the Inter Frame Space, no other nodes attempt to transmit the bus remains in idle state with a recessive level.

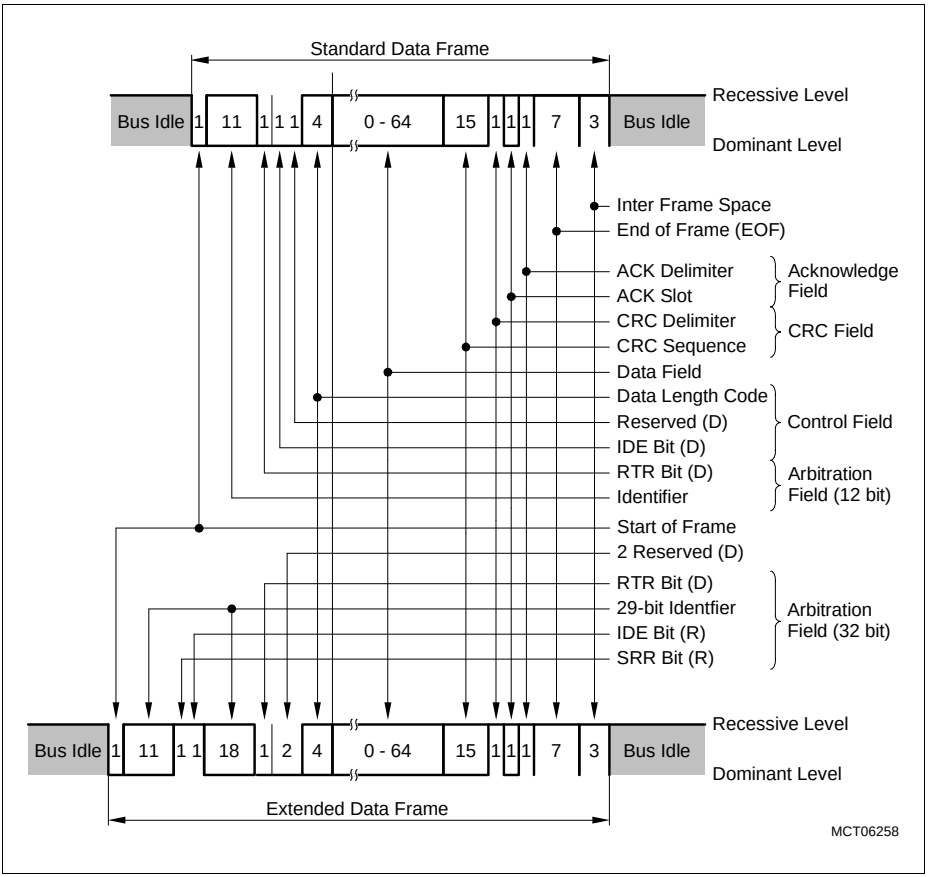

Figure 24-1 CAN Data Frame

Extended Data Frame

In the Extended CAN Data Frame, the message identifier of the standard frame has been extended to 29-bit. A split of the extended identifier into two parts, an 11-bit least

significant section (as in standard CAN frame) and an 18-bit most significant section, ensures that the Identifier Extension bit (IDE) can remain at the same bit position in both standard and extended frames.

In the Extended CAN Data Frame, the SOF bit is followed by the 32-bit Arbitration Field. The first 11 bits are the least significant bits of the 29-bit Identifier (“Base-ID”). These 11 bits are followed by the recessive Substitute Remote Request (SRR) bit. The SRR is further followed by the recessive IDE bit, which indicates the frame to be an Extended CAN frame. If arbitration remains unresolved after transmission of the first 11 bits of the identifier, and if one of the nodes involved in arbitration is sending a Standard CAN frame, then the Standard CAN frame will win arbitration due to the assertion of its dominant IDE bit. Therefore, the SRR bit in an Extended CAN frame is recessive to allow the assertion of a dominant RTR bit by a node that is sending a Standard CAN Remote Frame. The SRR and IDE bits are followed by the remaining 18 bits of the extended identifier and the RTR bit.

Control field and frame termination is identical to the Standard Data Frame.

24.1.2.2 Remote Frames

Normally, data transmission is performed on an autonomous basis with the data source node (e.g. a sensor) sending out a Data Frame. It is also possible, however, for a destination node (or nodes) to request the data from the source. For this purpose, the destination node sends a Remote Frame with an identifier that matches the identifier of the required Data Frame. The appropriate data source node will then send a Data Frame as a response to this remote request.

There are 2 differences between a Remote Frame and a Data Frame.

- The RTR bit is in the recessive state in a Remote Frame.
- There is no Data Field in a Remote Frame.

If a Data Frame and a Remote Frame with the same identifier are transmitted at the same time, the Data Frame wins arbitration due to the dominant RTR bit following the identifier. In this way, the node that transmitted the Remote Frame receives the requested data immediately. The format of a Standard and Extended Remote Frames is shown in **Figure 24-2**.

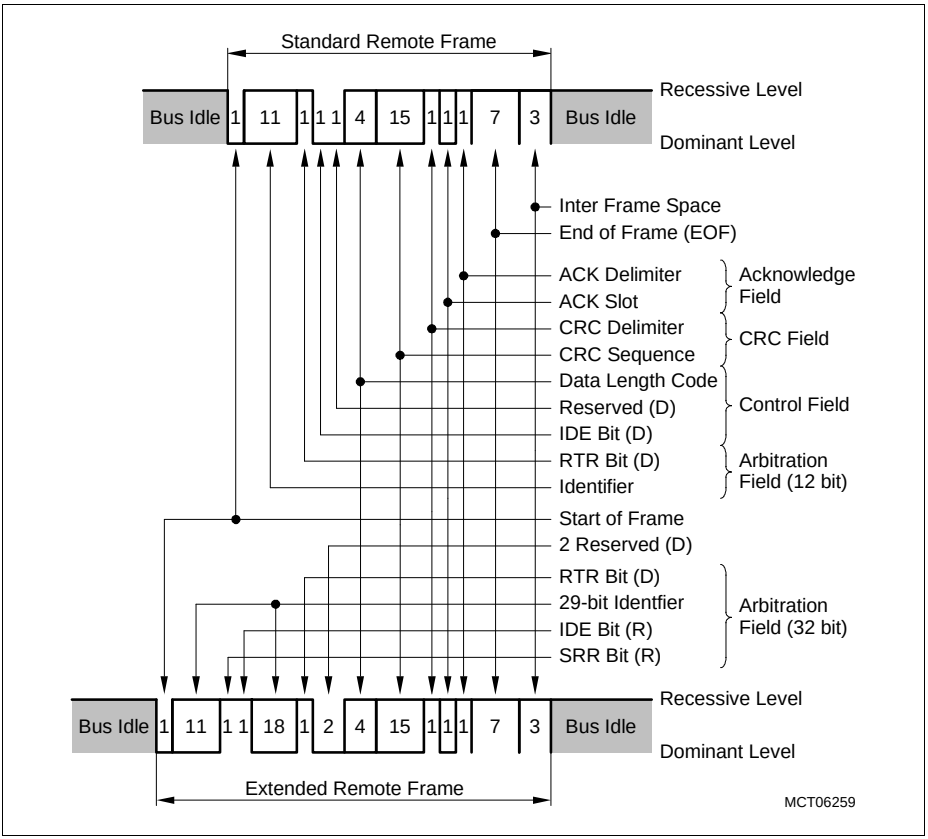

Figure 24-2 CAN Remote Frame

24.1.2.3 Error Frames

An Error Frame is generated by any node that detects a bus error. An Error Frame consists of two fields, an Error Flag field followed by an Error Delimiter field. The Error Delimiter Field consists of 8 recessive bits and allows the bus nodes to restart bus communications after an error. There are, however, two forms of Error Flag fields. The form of the Error Flag field depends on the error status of the node that detects the error.

When an error-active node detects a bus error, the node generates an Error Frame with an active-error flag. The error-active flag is composed of six consecutive dominant bits that actively violate the bit-stuffing rule. All other stations recognize a bit-stuffing error and generate Error Frames themselves. The resulting Error Flag field on the CAN bus therefore consists of six to twelve consecutive dominant bits (generated by one or more nodes). The Error Delimiter field completes the Error Frame. After completion of the Error Frame, bus activity returns to normal and the interrupted node attempts to re-send the aborted message.

If an error-passive node detects a bus error, the node transmits an error-passive flag followed, again, by the Error Delimiter field. The error-passive flag consists of six consecutive recessive bits, and therefore the Error Frame (for an error-passive node) consists of 14 recessive bits (i.e. no dominant bits). Therefore, the transmission of an Error Frame by an error-passive node will not affect any other node on the network, unless the bus error is detected by the node that is actually transmitting (i.e. the bus master). If the bus master node generates an error-passive flag, this may cause other nodes to generate Error Frames due to the resulting bit-stuffing violation. After transmission of an Error Frame an error-passive node must wait for 6 consecutive recessive bits on the bus before attempting to rejoin bus communications.

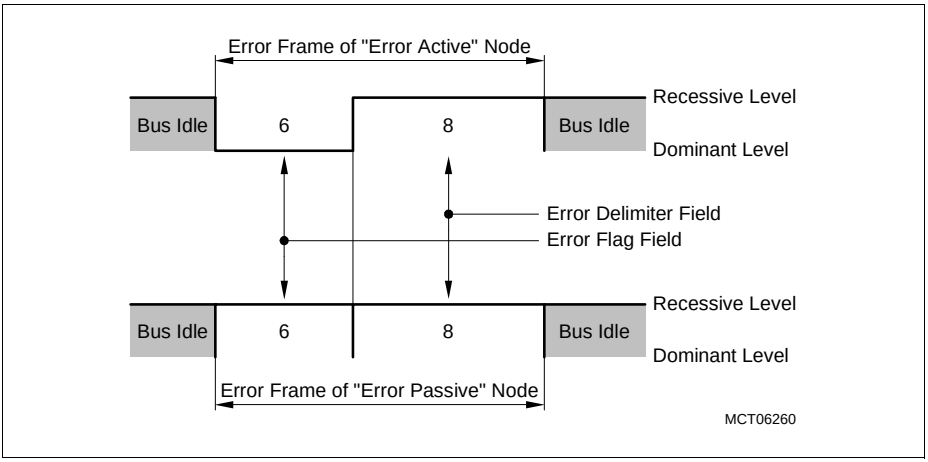

Figure 24-3 CAN Error Frames

24.1.3 The Nominal Bit Time

One bit cell (this means one high or low pulse of the NRZ code) is composed by four segments. Each segment is an integer multiple of Time Quanta t_Q. The Time Quanta is the smallest discrete timing resolution used by a CAN node. The nominal bit time definition with its segments is shown in **Figure 24-4**.

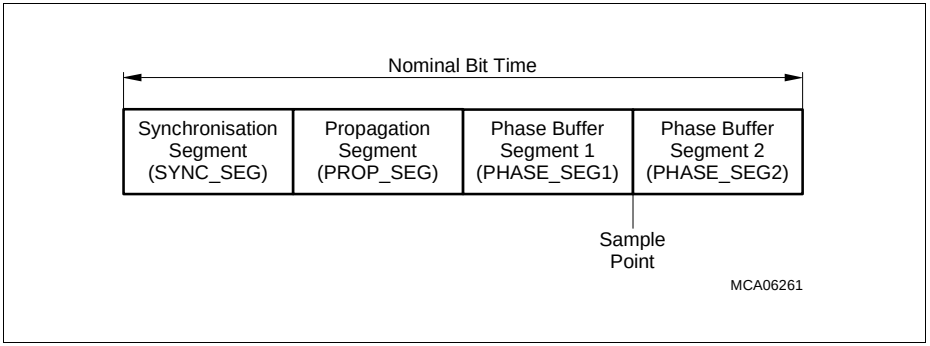

Figure 24-4 Partition of Nominal Bit Time

The Synchronization Segment (SYNC_SEG) is used to synchronize the various bus nodes. If there is a bit state change between the previous bit and the current bit, then the bus state change is expected to occur within this segment. The length of this segment is always 1 t_Q.

The Propagation Segment (PROP_SEG) is used to compensate for signal delays across the network. These delays are caused by signal propagation delay on the bus line and through the electronic interface circuits of the bus nodes.

The Phase Segments 1 and 2 (PHASE_SEG1, PHASE_SEG2) are used to compensate for edge phase errors. These segments can be lengthened or shortened by re-synchronization. PHASE_SEG2 is reserved for calculation of the subsequent bit level, and is $\geq 2\ t_Q$. At the sample point, the bus level is read and interpreted as the value of the bit cell. It occurs at the end of PHASE_SEG1.

The total number of t_Q in a bit time is between 8 and 25.

As a result of re-synchronization, PHASE_SEG1 can be lengthened or PHASE_SEG2 can be shortened. The amount of lengthening or shortening the phase buffer segments has an upper limit given by the re-synchronization jump width. The re-synchronization jump width may be between 1 and 4 t_Q, but it may not be longer than PHASE_SEG1.

24.1.4 Error Detection and Error Handling

The CAN protocol has sophisticated error detection mechanisms. The following errors can be detected:

- **Cyclic Redundancy Check (CRC) Error**
  With the Cyclic Redundancy Check, the transmitter calculates special check bits for the bit sequence from the start of a frame until the end of the Data Field. This CRC sequence is transmitted in the CRC Field. The receiving node also calculates the CRC sequence using the same formula, and performs a comparison to the received sequence. If a mismatch is detected, a CRC error has occurred and an Error Frame is generated. The message is repeated.
- **Acknowledge Error**
  In the Acknowledge Field of a message, the transmitter checks whether a dominant bit is read during the Acknowledge Slot (that is sent out as a recessive bit). If not, no other node has received the frame correctly, an Acknowledge Error has occurred, and the message must be repeated. No Error Frame is generated.
- **Form Error**
  If a transmitter detects a dominant bit in one of the four segments End of Frame, Interframe Space, Acknowledge Delimiter, or CRC Delimiter, a Form Error has occurred, and an Error Frame is generated. The message is repeated.
- **Bit Error**
  A Bit Error occurs if a) a transmitter sends a dominant bit and detects a recessive bit or b) if the transmitter sends a recessive bit and detects a dominant bit when monitoring the actual bus level and comparing it to the just transmitted bit. In case b), no error occurs during the Arbitration Field (ID, RTR, IDE) and the Acknowledge Slot.
- **Stuff Error**
  If between Start of Frame and CRC Delimiter, six consecutive bits with the same polarity are detected, the bit-stuffing rule has been violated. A stuff error occurs and an Error Frame is generated. The message is repeated.

Detected errors are made public to all other nodes via Error Frames (except Acknowledge Errors). The transmission of the erroneous message is aborted and the frame is repeated as soon as possible. Furthermore, each CAN node is in one of the three error states (error-active, error-passive or bus-off) according to the value of the internal error counters. The error-active state is the usual state where the bus node can transmit messages and active-error frames (made of dominant bits) without any restrictions. In the error-passive state, messages and passive-error frames (made of recessive bits) may be transmitted. The bus-off state makes it temporarily impossible for the node to participate in the bus communication. During this state, messages can be neither received nor transmitted.

Basic CAN, Full CAN

There is one more CAN characteristic that is related to the interface of a CAN module (controller) and the host CPU: Basic-CAN and Full-CAN functionality.

In Basic-CAN devices, only basic functions of the protocol are implemented in hardware, such as the generation and the check of the bit stream. The decision, whether a received message has to be stored or not (acceptance filtering), and the complete message management must be done by software. Normally, the CAN device also provides only one transmit buffer and one or two receive buffers. Therefore, the host CPU load is quite high when using Basic-CAN modules. The main advantage of Basic-CAN is a reduced chip size leading to low costs of these devices.

Full-CAN devices (this is the case for the MultiCAN controller as implemented in TC1798) manage the whole bus protocol in hardware, including the acceptance filtering and message management. Full-CAN devices contain message objects that handle autonomously the identifier, the data, the direction (receive or transmit) and the information of Standard CAN/Extended CAN operation. During the initialization of the device, the host CPU determines which messages are to be sent and which are to be received. The host CPU is informed by interrupt if the identifier of a received message matches with one of the programmed (receive-) message objects. The CPU load of Full-CAN devices is greatly reduced. When using Full-CAN devices, high baud rates and high bus loads with many messages can be handled.

24.2 TTCAN Basics

In general, a CAN network is event-oriented due to the error handling and bus arbitration. The exact time for a message to be transferred is difficult to determine. In order to allow deterministic message transfers, the event-driven mechanism has been changed into a time-driven mechanism by a TTCAN extension, with “TT” standing for Time-Triggered.

TTCAN is a higher-layer protocol above the standard CAN protocol that synchronizes the communication schedules of all CAN nodes in a CAN network, and that provides a global system time. When CAN nodes are synchronized, messages can be transmitted at a specific time slot, without competing with other messages for the bus. Thus, the loss of arbitration is avoided, and the latency time becomes predictable. Apart from the synchronized communication schedule, TTCAN-compliant nodes operate according to the standard CAN protocol as defined by ISO 11898-4.

24.2.1 Time Reference

In TTCAN networks, a global time reference makes it possible to synchronize the activities of all CAN nodes. Each CAN node has its own local time represented by a counter that is incremented with each network time unit (NTU). The NTU is derived from the node’s local clock and local Time Unit Ratio (TUR).

In TTCAN, synchronization is achieved by a periodic transmission of a reference message. This reference message (transmitted by a time master) restarts the cycle time in each node. The reference message can be easily recognized by its identifier. Within TTCAN level 1, the reference message holds control information in one byte of the message Data Field. In TTCAN level 2, the reference message provides additional control information in four bytes of the message Data Field (e.g. the global time information of the current TTCAN time master) with downwards compatibility.

24.2.2 Basic Cycle

A reference message starts a new basic cycle and resets the cycle time. The cycle time counts the time since the start of the basic cycle. A basic cycle consists of several non-overlapping time windows of different sizes. The sequence of the time windows is described by time marks that determine when a time window begins. Time marks are compared to the cycle time, and particular actions are triggered when the cycle time matches the time mark.

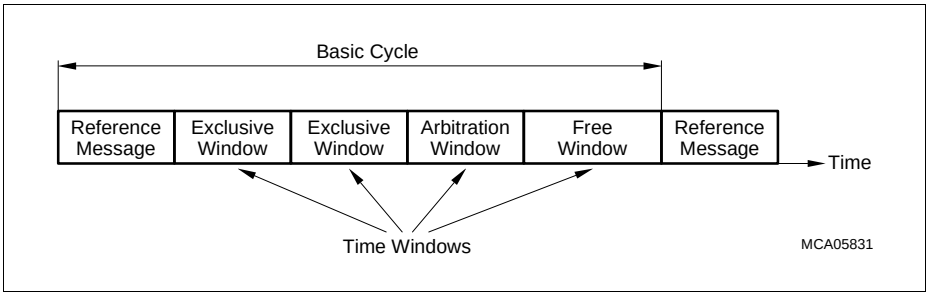

Figure 24-5 TTCAN Basic Cycle

The structure of the basic cycle is defined once for the whole TTCAN network. Several different basic cycles are combined to build a matrix cycle or the system matrix. The sequence of basic cycles in the matrix cycle is controlled by the reference messages.

All possible messages in the TTCAN system are assigned to time windows of the system matrix. A time window can be:

- An exclusive time window, in which only one particular message can be transmitted.
- An arbitrating time window, in which messages can arbitrate for bus access.
- A free time window, reserved for future extensions.

In exclusive time windows automatic retransmission of messages is disabled. This guarantees that messages are not delayed by other bus traffic.

24.2.3 Global System Time

Level 2 of TTCAN supports a global system time. The time master establishes its own local time as global time by transmitting reference message. The other CAN nodes in the network operate as time slaves that calculate their local time offset to the global time by comparing their local time with the received global time. To compensate for slightly different clock drifts in the CAN nodes and to provide a consistent view of the global time, the nodes can perform a drift compensation operation. They compare the length of the basic cycle in local time to the length of the basic cycle in global time. The difference (quotient) of the two values gives the adapted TUR.

24.2.4 The System Matrix

Typical CAN applications include many control loops and tasks with different periods. All of them need individual sending patterns for their information. One TTCAN basic cycle would not offer enough flexibility to satisfy this needs. Therefore, the TTCAN specification also makes it possible to use more than one basic cycle to build the communication matrix or system matrix. Several different basic cycles are connected together to build the matrix cycle. Most combinations of basic cycles are possible, such

as sending every basic cycle, sending every second basic cycle, or sending only once within the matrix cycle.

24.2.5 Generation of the Network Time Unit (NTU)

The granularity of any timing information within TTCAN is the NTU. The cycle time is measured in NTU that is based on the nominal CAN bit time (TTCAN level 1), or on the Time Quantum t_Q (TTCAN level 2), or on the CAN input frequency. In level 2, the node's local relation between the physical oscillator of a TTCAN controller and the system wide NTU must be established. A clock signal in the node provides the system clock to a frequency divider. This frequency divider generates the system-wide NTU while a node local TUR takes care for the correct relationship between the system clock and NTU. NTU now can be used to calculate a local time and to build the global time.

24.2.6 Global Time Generation and Drift Correction

The node sending the reference message is the time master in the TTCAN network. The reference message includes the time master's (by definition correct) global time value for frame synchronization. All nodes take a snap-shot of their time values at the SOF bit sample point of the received reference message. After reference message reception, each node can calculate its local offset that indicates the difference between the master global time value and the own local time value. In the current basic cycle, the node can compute the global time for the next basic cycle by:

global time = local time + local offset

This equation ensures that all nodes have a consistent global time. Due to slightly different clock drifts of the different nodes in a CAN network, a mechanism is established that guarantees that local and global time run in parallel. This mechanism is the continuous update of the TUR. The initial value of TUR is locally known in the node by the node clock signal specification. During node operation, the node locally measures the length between two successive reference messages in number of oscillator periods and in local time. The quotient of these two values gives the actual TUR. The achievable precision determines a reasonable choice of the NTU value in physical seconds.

24.3 Overview

This section describes the serial communication module called MultiCAN (CAN = Controller Area Network) of the TC1798. A MultiCAN module can contain between two and eight independent CAN nodes, depending on the device, each representing one serial communication interface.

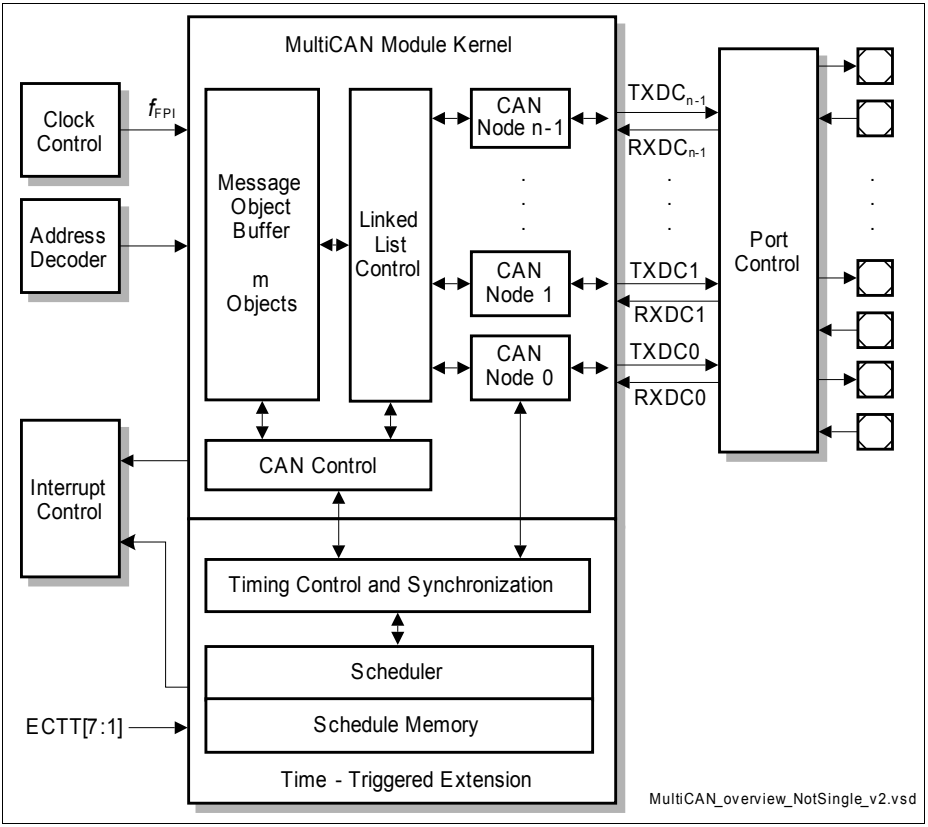

Figure 24-6 Overview of the MultiCAN Module with TTCAN extension

24.3.1 MultiCAN Module

The MultiCAN module contains independently operating CAN nodes with Full-CAN functionality that are able to exchange Data and Remote Frames via a gateway function. Transmission and reception of CAN frames is handled in accordance with CAN specification V2.0 B (active). Each CAN node can receive and transmit standard frames with 11-bit identifiers as well as extended frames with 29-bit identifiers.

Both CAN nodes share a common set of message objects. Each message object can be individually allocated to one of the CAN nodes. Besides serving as a storage container for incoming and outgoing frames, message objects can be combined to build gateways between the CAN nodes or to setup a FIFO buffer.

The message objects are organized in double-chained linked lists, where each CAN node has its own list of message objects. A CAN node stores frames only into message objects that are allocated to the message object list of the CAN node, and it transmits only messages belonging to this message object list. A powerful, command-driven list controller performs all message object list operations.

The bit timings for the CAN nodes are derived from the module timer clock (f_{CAN}), and are programmable up to a data rate of 1 Mbit/s. External bus transceivers are connected to a CAN node via a pair of receive and transmit pins.

Features

- Compliant with ISO 11898
- CAN functionality according to CAN specification V2.0 B active
- Dedicated control registers for each CAN node
- Data transfer rates up to 1 Mbit/s
- Flexible and powerful message transfer control and error handling capabilities
- Advanced CAN bus bit timing analysis and baud rate detection for each CAN node via a frame counter
- Full-CAN functionality: A set of message objects can be individually
  - Allocated (assigned) to any CAN node
  - Configured as transmit or receive object
  - Set up to handle frames with 11-bit or 29-bit identifier
  - Identified by a timestamp via a frame counter
  - Configured to remote monitoring mode
- Advanced acceptance filtering
  - Each message object provides an individual acceptance mask to filter incoming frames
  - A message object can be configured to accept standard or extended frames or to accept both standard and extended frames
  - Message objects can be grouped into four priority classes for transmission and reception

  - The selection of the message to be transmitted first can be based on frame identifier, IDE bit and RTR bit according to CAN arbitration rules, or according to its order in the list
- Advanced message object functionality
  - Message objects can be combined to build FIFO message buffers of arbitrary size, limited only by the total number of message objects
  - Message objects can be linked to form a gateway that automatically transfers frames between two different CAN buses. A single gateway can link any two CAN nodes. An arbitrary number of gateways can be defined.
- Advanced data management
  - The message objects are organized in double-chained lists
  - List reorganizations can be performed at any time, even during full operation of the CAN nodes
  - A powerful, command-driven list controller manages the organization of the list structure and ensures consistency of the list
  - Message FIFOs are based on the list structure and can easily be scaled in size during CAN operation
  - Static allocation commands offer compatibility with TwinCAN applications that are not list-based
- Advanced interrupt handling
  - Up to 16 interrupt output lines are available. Interrupt requests can be routed individually to one of the 16 interrupt output lines
  - Message post-processing notifications can be mapped flexibly using dedicated registers consisting of notification bits

24.4 Time-Triggered Extension (TTCAN)

In addition to the event-driven CAN functionality, a deterministic behavior can be achieved for CAN node 0 by an extension module that supports TTCAN functionality. The TTCAN protocol is compliant with the confirmed standardization proposal for ISO 11898-4 and fully conforms to the existing CAN protocol.

The time-triggered functionality is added as higher-layer extension (session layer) to the CAN protocol in order to be able to operate in safety-critical applications. The new features allow for deterministic behavior of a CAN network and the synchronization of networks. Global time information is available. The time-triggered extension is based on a scheduler mechanism with a timing control unit and a dedicated timing data part.

TTCAN Features

- Full support of basic cycle and system matrix functionality
- Support of reference messages level 1 and level 2
- Usable as time master
- Arbitration windows supported in time-triggered mode
- Global time information available
- CAN node 0 can be configured either for event-driven or time-triggered mode
- Built-in scheduler mechanism and a timing synchronization unit
- Write protection for scheduler timing data memory
- Timing-related interrupt functionality
- Parity protection for scheduler memory

24.5 MultiCAN Kernel Functional Description

This section describes the functionality of the MultiCAN module.

24.5.1 Module Structure

Figure 24-7 shows the general structure of the MultiCAN module.

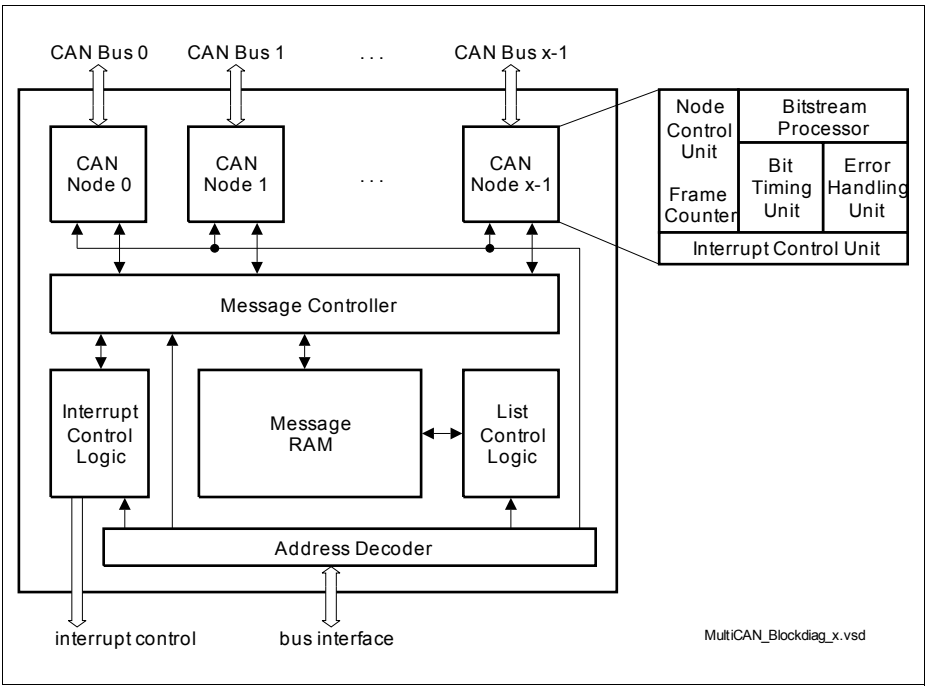

Figure 24-7 MultiCAN Block Diagram

CAN Nodes

Each CAN node consists of several sub-units.

- **Bitstream Processor**
  The Bitstream Processor performs data, remote, error and overload frame processing according to the ISO 11898 standard. This includes conversion between the serial data stream and the input/output registers.
- **Bit Timing Unit**
  The Bit Timing Unit determines the length of a bit time and the location of the sample point according to the user settings, taking into account propagation delays and phase shift errors. The Bit Timing Unit also performs resynchronization.

- **Error Handling Unit**
  The Error Handling Unit manages the receive and transmit error counter. Depending on the contents of both counters, the CAN node is set into an error-active, error passive or bus-off state.
- **Node Control Unit**
  The Node Control Unit coordinates the operation of the CAN node:
  – Enable/disable CAN transfer of the node
  – Enable/disable and generate node-specific events that lead to an interrupt request (CAN bus errors, successful frame transfers etc.)
  – Administration of the Frame Counter
- **Interrupt Control Unit**
  The Interrupt Control Unit in the CAN node controls the interrupt generation for the different conditions that can occur in the CAN node.

Message Controller

The Message Controller handles the exchange of CAN frames between the CAN nodes and the message objects that are stored in the Message RAM. The Message Controller performs several functions:

- Receive acceptance filtering to determine the correct message object for storing of a received CAN frame
- Transmit acceptance filtering to determine the message object to be transmitted first, individually for each CAN node
- Transfer contents between message objects and the CAN nodes, taking into account the status/control bits of the message objects
- Handling of the FIFO buffering and gateway functionality
- Aggregation of message-pending notification bits

List Controller

The List Controller performs all operations that lead to a modification of the double-chained message object lists. Only the list controller is allowed to modify the list structure. The allocation/deallocation or reallocation of a message object can be requested via a user command interface (command panel). The list controller state machine then performs the requested command autonomously.

Interrupt Control

The general interrupt structure is shown in **Figure 24-9**. The interrupt event can trigger the interrupt generation. The interrupt pulse is generated independently of the interrupt flag in the interrupt status register. The interrupt flag can be reset by software by writing a 0 to it.

If enabled by the related interrupt enable bit in the interrupt enable register, an interrupt pulse can be generated at one of the 16 interrupt output lines INT_Om of the MultiCAN

module. If more than one interrupt source is connected to the same interrupt node pointer (in the interrupt node pointer register), the requests are combined to one common line.

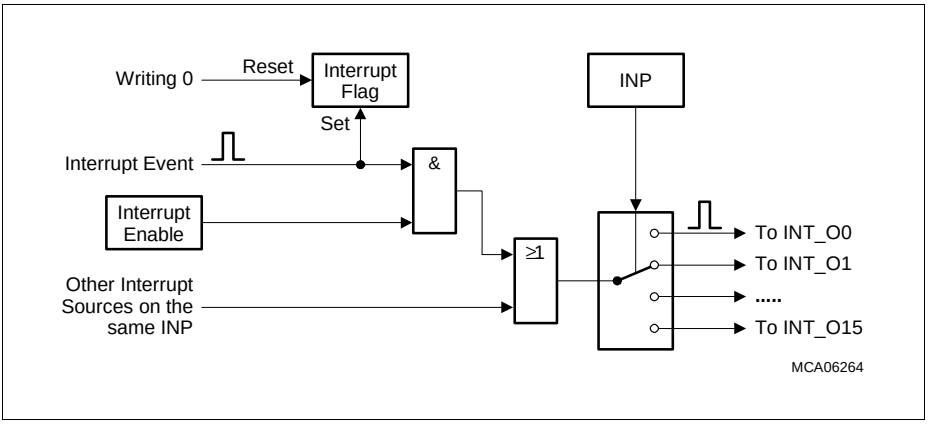

Figure 24-8 General Interrupt Structure

24.5.2 Clock Control

The CAN module timer clock f_{CAN} of the functional blocks of the MultiCAN module is derived from the module control clock f_{CLC}. The Fractional Divider is used to generate f_{CAN} used for bit timing calculation, the generation of the NTU, and the local time of the TTCAN part. The frequency of f_{CAN} is identical for all CAN nodes. The register file and the TTCAN scheduler operate with the module control clock f_{CLC}. See also **"Module Clock Generation" on Page 24-204**.

The output clock f_{CAN} of the Fractional Divider is based on the system clock f_{CLC}, but only every n-th clock pulse is taken. The suspend signal (coming as acknowledge from the MultiCAN module in response to a OCDS suspend request) freezes or resets the Fractional Divider.

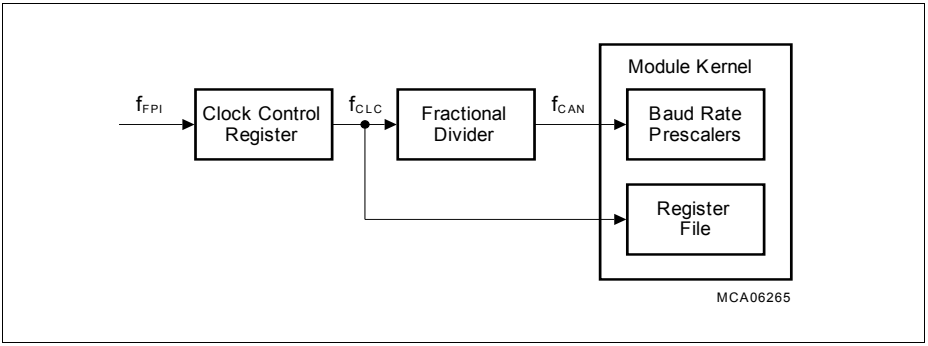

Figure 24-9 MultiCAN Clock Generation

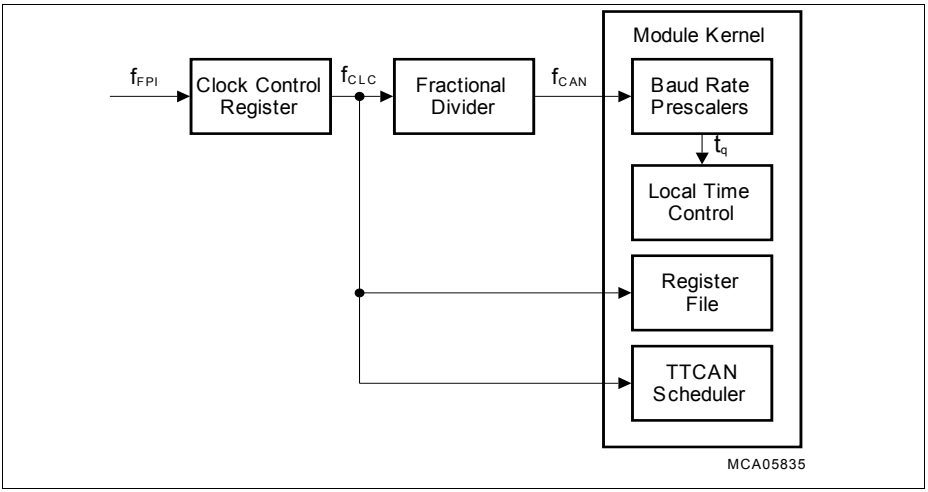

Figure 24-10 MultiCAN with TTCAN Clock Generation

Table 24-2 indicates the minimum operating frequencies in MHz for f_{CLC} that are required for a baud rate of 1 Mbit/s for the active CAN nodes. If a lower baud rate is desired, the values can be scaled linearly (e.g. for a maximum of 500 kbit/s, 50% of the indicated value are required).

The values imply that the CPU (or DMA) executes maximum accesses to the MultiCAN module. The values may contain rounding effects.

Table 24-2 Minimum Operating Frequencies [MHz]

Number of allocated message objects MO[1], with or without TTCAN functionality	1 CAN node active	2 CAN nodes active	3 CAN nodes active	4 CAN nodes active
16 MO, without TTCAN	12	19	26	33
16 MO, with 1 TTCAN	14	21	28	35
32 MO, without TTCAN	15	23	30	37
32 MO, with 1 TTCAN	17	25	32	39
64 MO, without TTCAN	21	28	37	46
64 MO, with 1 TTCAN	23	30	39	48
128 MO, without TTCAN	40	45	50	55
128 MO, with 1 TTCAN	42	47	52	57

1) Only those message objects have to be taken into account that are allocated to a CAN node. The unallocated message objects have no influence on the minimum operating frequency.

The baud rate generation of the MultiCAN being based on f_{FPI}, this frequency has to be chosen carefully to allow correct CAN bit timing. The required value of f_{FPI} is given by an integer multiple (n) of the CAN baud rate multiplied by the number of time quanta per CAN bit time. For example, to reach 1 Mbit/s with 20 tq per bit time, possible values of f_{FPI} are given by formula [n × 20] MHz, with n being an integer value, starting at 1.
In order to minimize jitter, it is not recommended to use the fractional divider mode for high baud rates.

24.5.3 Port Input Control

It is possible to select the input lines for the RXDCANx inputs for the CAN nodes. The selected input is connected to the CAN node and is also available to wake-up the system. More details are defined in **Section 24.11.4.2** on **Page 24-208**.

24.5.4 Suspend Mode

The Suspend Mode can be triggered by the OCDS in order to freeze the state of the module and to permit access to the registers (at least for read actions). The MultiCAN module provides two types of Suspend Modes:

- All actions are immediately stopped (Hard Suspend Mode):
  The module clocks f_{CLC} and f_{CAN} are switched off as soon as the suspend request becomes active. Read and write operations to the module are no longer possible. This means that the CAN registers cannot be accessed anymore. In this mode, there is a very high probability that the communication with other CAN devices is made

impossible, and that the CAN bus is blocked (e.g. if the suspended CAN module just sends a dominant level). A reset operation must be executed to leave Hard Suspend Mode.

- The current action is finished (Soft Suspend Mode):
  The module clock f_{CLC} keeps running. Module functions are stopped automatically after internal actions have been finished (for example, after a CAN frame has been sent out). The end of the internal actions is indicated to the fractional divider by a suspend mode acknowledged signal. Due to this behavior, the communication network is not blocked. Furthermore, all registers are accessible for read and write actions. As a result, the debugger can stop the module actions and modify registers. These modifications are taken into account after the Suspend Mode is left.

The Hard Suspend Mode can be enabled/disabled only for the complete MultiCAN module. The Soft Suspend Mode can be individually enabled for each CAN node.

The fractional divider disables module clock f_{CAN} only if all CAN nodes signal that they can be suspended. A CAN node that is not active can always be suspended.

The user has to be aware that the Soft Suspend Mode can corrupt the TTCAN timing values, because the counter clock can be disabled. In order to guarantee correct TTCAN behavior, a TTCAN node should not enter any Suspend Mode if the consistency of the timing data must be ensured.

24.5.5 CAN Node Control

Each CAN node may be configured and run independently of the other CAN node. Each CAN node is equipped with its own node control logic to configure the global behavior and to provide status information.

Note: In the following descriptions, index “x” stands for the node number and index “n” represents the message object number.

Configuration Mode is activated when bit NCRx.CCE is set to 1. This mode allows CAN bit timing parameters and the error counter registers to be modified.

CAN Analyze Mode is activated when bit NCRx.CALM is set to 1. In this operation mode, Data And Remote Frames are monitored without active participation in any CAN transfer (CAN transmit pin is held on recessive level). Incoming Remote Frames are stored in a corresponding transmit message object, while arriving data frames are saved in a matching receive message object.

In CAN Analyze Mode, the entire configuration information of the received frame is stored in the corresponding message object, and can be evaluated by the CPU to determine their identifier, XTD bit information and data length code (ID and DLC optionally if the Remote Monitoring Mode is active, bit MOFCRn.RMM = 1). Incoming frames are not acknowledged, and no Error Frames are generated. If CAN Analyze Mode is enabled, Remote Frames are not responded to by the corresponding Data Frame, and Data Frames cannot be transmitted by setting the transmit request bit MOSTATn.TXRQ. Receive interrupts are generated in CAN Analyze Mode (if enabled) for all error free received frames.

The node-specific interrupt configuration is also defined by the Node Control Logic via the NCRx register bits TRIE, ALIE and LECIE:

- If control bit TRIE is set to 1, a transfer interrupt is generated when the NSRx register has been updated (after each successfully completed message transfer).
- If control bit ALIE is set to 1, an error interrupt is generated when a “bus-off” condition has been recognized or the Error Warning Level has been exceeded or under-run. Additionally, list or object errors lead to this type of interrupt.
- If control bit LECIE is set to 1, a last error code interrupt is generated when an error code > 0 is written into bit field NSRx.LEC by hardware.

The Node x Status Register NSRx provides an overview about the current state of the respective CAN node x, comprising information about CAN transfers, CAN node status, and error conditions.

The CAN frame counter can be used to check the transfer sequence of message objects or to obtain information about the instant a frame has been transmitted or received from the associated CAN bus. CAN frame counting is performed by a 16-bit counter, controlled by register NFCRx. Bit fields NFCRx.CFMOD and NFCRx.CFSEL determine the operation mode and the trigger event incrementing the frame counter.

24.5.5.1 Bit Timing Unit

According to the ISO 11898 standard, a CAN bit time is subdivided into different segments (**Figure 24-11**). Each segment consists of multiples of a time quantum t_q. The magnitude of t_q is adjusted by Node x Bit Timing Register bit fields NBTRx.BRP and NBTRx.DIV8, both controlling the baud rate prescaler (register NBTRx is described on **Page 24-87**). The baud rate prescaler is driven by the module timer clock f_{CAN} (generation and control of f_{CAN} is described on **Page 24-204**).

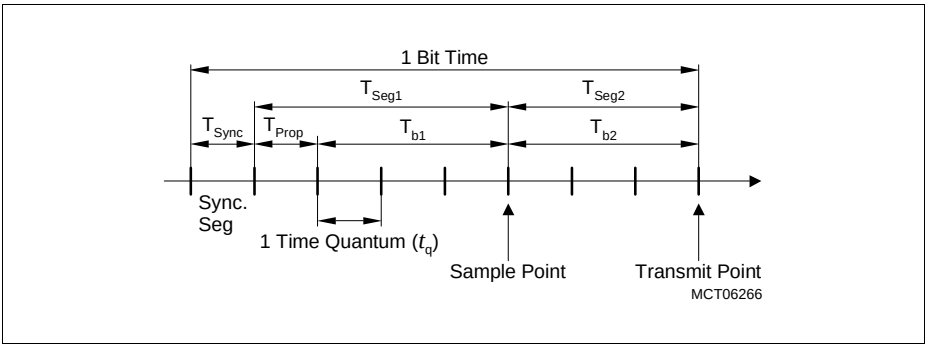

Figure 24-11 CAN Bus Bit Timing Standard

The Synchronization Segment (T_{Sync}) allows a phase synchronization between transmitter and receiver time base. The Synchronization Segment length is always one t_q. The Propagation Time Segment (T_{Prop}) takes into account the physical propagation delay in the transmitter output driver on the CAN bus line and in the transceiver circuit. For a working collision detection mechanism, T_{Prop} must be two times the sum of all propagation delay quantities rounded up to a multiple of t_q. The phase buffer segments 1 and 2 (T_{b1}, T_{b2}) before and after the signal sample point are used to compensate for a mismatch between transmitter and receiver clock phases detected in the synchronization segment.

The maximum number of time quanta allowed for re-synchronization is defined by bit field NBTRx.SJW. The Propagation Time Segment and the Phase Buffer Segment 1 are combined to parameter T_{Seg1}, which is defined by the value NBTRx.TSEG1. A minimum of 3 time quanta is demanded by the ISO standard. Parameter T_{Seg2}, which is defined by the value of NBTRx.TSEG2, covers the Phase Buffer Segment 2. A minimum of 2 time quanta is demanded by the ISO standard. According to ISO standard, a CAN bit time, calculated as the sum of T_{Sync}, T_{Seg1} and T_{Seg2}, must not fall below 8 time quanta.

Calculation of the bit time:

t_q	= (BRP + 1) / f_{CAN}	if DIV8 = 0
	= 8 × (BRP + 1) / f_{CAN}	if DIV8 = 1
T_{Sync}	= 1 × t_q	
T_{Seg1}	= (TSEG1 + 1) × t_q	(min. 3 t_q)
T_{Seg2}	= (TSEG2 + 1) × t_q	(min. 2 t_q)
bit time	= T_{Sync} + T_{Seg1} + T_{Seg2}	(min. 8 t_q)

To compensate phase shifts between clocks of different CAN controllers, the CAN controller must synchronize on any edge from the recessive to the dominant bus level. If the hard synchronization is enabled (at the start of frame), the bit time is restarted at the synchronization segment. Otherwise, the re-synchronization jump width T_{SJW} defines the maximum number of time quanta, a bit time may be shortened or lengthened by one re-synchronization. The value of SJW is defined by bit field NBTRx.SJW.

T_{SJW}	= (SJW + 1) × t_q
T_{Seg1}	≥ T_{SJW} + T_{prop}
T_{Seg2}	≥ T_{SJW}

The maximum relative tolerance for f_{CAN} depends on the Phase Buffer Segments and the re-synchronization jump width.

df_{CAN}	≤ min (T_{b1}, T_{b2}) / 2 × (13 × bit time - T_{b2})	AND
df_{CAN}	≤ T_{SJW} / 20 × bit time	

A valid CAN bit timing must be written to the CAN Node Bit Timing Register NBTR before resetting the INIT bit in the Node Control Register, i.e. before enabling the operation of the CAN node.

The Node Bit Timing Register may be written only if bit CCE (Configuration Change Enable) is set in the corresponding Node Control Register.

24.5.5.2 Bitstream Processor

Based on the message objects in the message buffer, the Bitstream Processor generates the remote and Data Frames to be transmitted via the CAN bus. It controls the CRC generator and adds the checksum information to the new remote or Data Frame. After including the SOF bit and the EOF field, the Bitstream Processor starts the CAN

bus arbitration procedure and continues with the frame transmission when the bus was found in idle state. While the data transmission is running, the Bitstream Processor continuously monitors the I/O line. If (outside the CAN bus arbitration phase or the acknowledge slot) a mismatch is detected between the voltage level on the I/O line and the logic state of the bit currently sent out by the transmit shift register, a CAN error interrupt request is generated, and the error code is indicated by the Node x Status Register bit field NSRx.LEC.

The data consistency of an incoming frame is verified by checking the associated CRC field. When an error has been detected, a CAN error interrupt request is generated and the associated error code is presented in the Node x Status Register NSRx. Furthermore, an Error Frame is generated and transmitted on the CAN bus. After decomposing a faultless frame into identifier and data portion, the received information is transferred to the message buffer executing remote and Data Frame handling, interrupt generation and status processing.

24.5.5.3 Error Handling Unit

The Error Handling Unit of a CAN node x is responsible for the fault confinement of the CAN device. Its two counters, the Receive Error Counter REC and the Transmit Error Counter TEC (bit fields of the Node x Error Counter Register NECNTx, see **Page 24-89**) are incremented and decremented by commands from the Bitstream Processor. If the Bitstream Processor itself detects an error while a transmit operation is running, the Transmit Error Counter is incremented by 8. An increment of 1 is used when the error condition was reported by an external CAN node via an Error Frame generation. For error analysis, the transfer direction of the disturbed message and the node that recognizes the transfer error are indicated for the respective CAN node x in register NECNTx. Depending on the values of the error counters, the CAN node is set into error-active, error-passive, or bus-off state.

The CAN node is in error-active state if both error counters are below the error-passive limit of 128. The CAN node is in error-passive state, if at least one of the error counters is equal to or greater than 128.

The bus-off state is activated if the Transmit Error Counter is equal to or greater than the bus-off limit of 256. This state is reported for CAN node x by the Node x Status Register flag NSRx.BOFF. The device remains in this state, until the “bus-off” recovery sequence is finished. Additionally, Node x Status Register flag NSRx.EWRN is set when at least one of the error counters is equal to or greater than the error warning limit defined by the Node x Error Count Register bit field NECNTx.EWRNLVL. Bit NSRx.EWRN is reset if both error counters fall below the error warning limit again (see **Page 24-77**).

24.5.5.4 CAN Frame Counter

Each CAN node is equipped with a frame counter that counts transmitted/received CAN frames or obtains information about the time when a frame has been started to transmit or be received by the CAN node. CAN frame counting/bit time counting is performed by a 16-bit counter that is controlled by Node x Frame Counter Register NFCRx (see Page 24-90). Bit field NFCRx.CFSEL determines the operation mode of the frame counter:

- **Frame Count Mode:**
  After the successful transmission and/or reception of a CAN frame, the frame counter is copied into the CFCVAL bit field of the MOIPRn register of the message object involved in the transfer. Afterwards, the frame counter is incremented.
- **Time Stamp Mode:**
  The frame counter is incremented with the beginning of a new bit time. When the transmission/reception of a frame starts, the value of the frame counter is captured and stored to the CFC bit field of the NFCRx register. After the successful transfer of the frame the captured value is copied to the CFCVAL bit field of the MOIPRn register of the message object involved in the transfer.
- **Bit Timing Mode:**
  Used for baud rate detection and analysis of the bit timing (Chapter 24.5.7.3).

24.5.5.5 CAN Node Interrupts

Each CAN node has four hardware triggered interrupt request types that are able to generate an interrupt request upon:

- The successful transmission or reception of a frame
- A CAN protocol error with a last error code
- An alert condition: Transmit/receive error counters reach the warning limit, bus-off state changes, a List Length Error occurs, or a List Object Error occurs
- An overflow of the frame counter

Besides the hardware generated interrupts, software initiated interrupts can be generated using the Module Interrupt Trigger Register MITR. Writing a 1 to bit n of bit field MITR.IT generates an interrupt request signal on the corresponding interrupt output line INT_On. When writing MITR.IT more than one bit can be set resulting in activation of multiple INT_On interrupt output lines at the same time. See also **“Interrupt Control” on Page 24-211** for further processing of the CAN node interrupts.

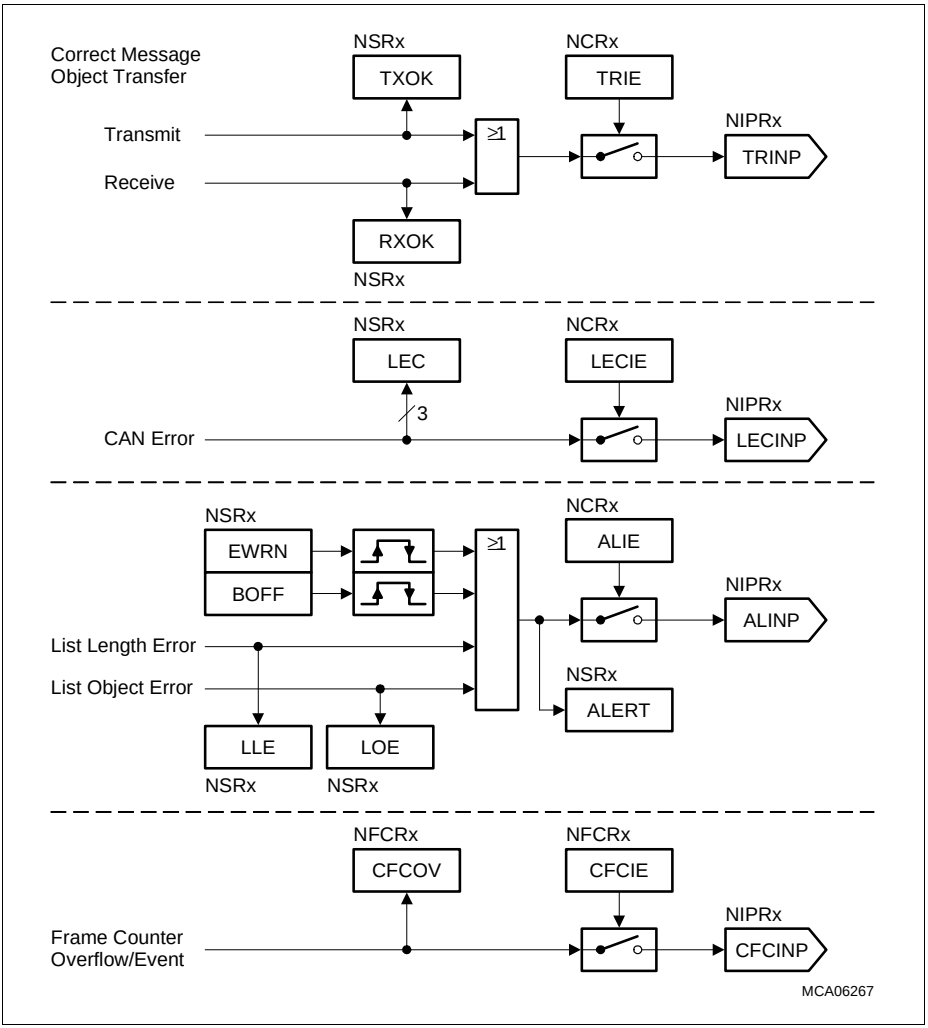

Figure 24-12 CAN Node Interrupts

24.5.6 Message Object List Structure

This section describes the structure of the message object lists in the MultiCAN module.

24.5.6.1 Basics

The message objects of the MultiCAN module are organized in double-chained lists, where each message object has a pointer to the previous message object in the list as well as a pointer to the next message object in the list. The MultiCAN module provides eight lists. Each message object is allocated to one of these lists. In the example in **Figure 24-13**, the three message objects (3, 5, and 16) are allocated to the list with index 2 (List Register LIST2).

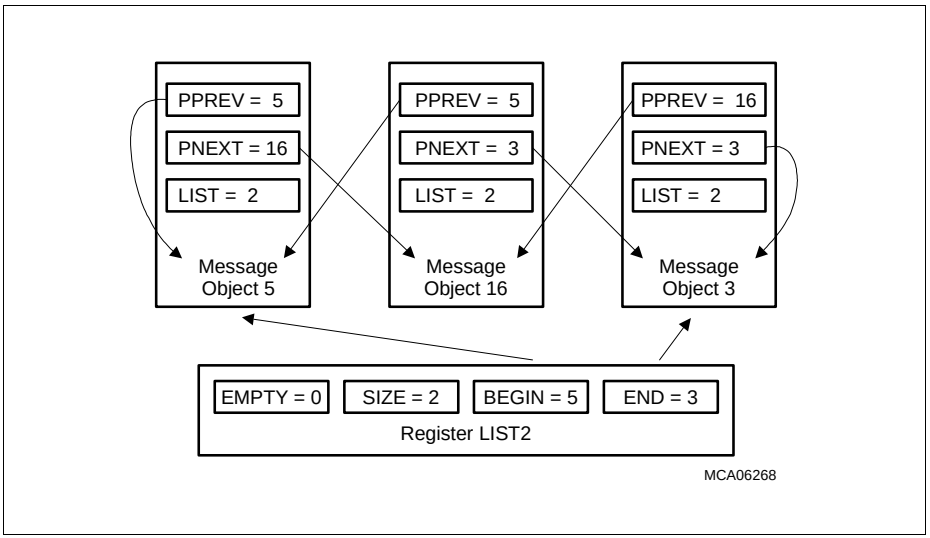

Figure 24-13 Example Allocation of Message Objects to a List

Bit field BEGIN in the List Register (for definition, see **Page 24-71**) points to the first element in the list (object 5 in the example), and bit field END points to the last element in the list (object 3 in the example). The number of elements in the list is indicated by bit field SIZE of the List Register (SIZE = number of list elements - 1, thus SIZE = 2 for the 3 elements in the example). The EMPTY bit of the List Register indicates whether or not a list is empty (EMPTY = 0 in the example, because list 2 is not empty).

Each message object n has a pointer PNEXT in its Message Object n Control Register MOCTRn (see **Page 24-94**) that points to the next message object in the list, and a pointer PPREV that points to the previous message object in the list. PPREV of the first message object points to the message object itself because the first message object has no predecessor (in the example message object 5 is the first message object in the list,

indicated by PPREV = 5). PNEXT of the last message object also points to the message object itself because the last message object has no successor (in the example, object 3 is the last message object in the list, indicated by PNEXT = 3).

Bit field MOCTRn.LIST indicates the list index number to which the message object is currently allocated. The message object of the example are allocated to list 2. Therefore, all LIST bit fields for the message objects assigned to list 2 are set to LIST = 2.

24.5.6.2 List of Unallocated Elements

The list with list index 0 has a special meaning: it is the list of all unallocated elements. An element is called unallocated if it belongs to list 0 (MOCTRn.LIST = 0). It is called allocated if it belongs to a list with an index not equal to 0 (MOCTRn.LIST > 0).

After reset, all message objects are unallocated. This means that they are assigned to the list of unallocated elements with MOCTRn.LIST = 0. After this initial allocation of the message objects caused by reset, the list of all unallocated message objects is ordered by message number (predecessor of message object n is object n-1, successor of object n is object n+1).

24.5.6.3 Connection to the CAN Nodes

Each CAN node is linked to one unique list of message objects. A CAN node performs message transfer only with the message objects that are allocated to the list of the CAN node. This is illustrated in **Figure 24-14**. Frames that are received on a CAN node may only be stored in one of the message objects that belongs to the CAN node; frames to be transmitted on a CAN node are selected only from the message objects that are allocated to that node, as indicated by the vertical arrows.

There are more lists (eight) than CAN nodes (two). This means that some lists are not linked to one of the CAN nodes. A message object that is allocated to one of these unlinked lists cannot receive messages directly from a CAN node and it may not transmit messages.

FIFO and gateway mechanisms refer to message numbers and not directly to a specific list. The user must take care that the message objects targeted by FIFO/gateway belong to the desired list. The mechanisms make it possible to work with lists that do not belong to the CAN node.

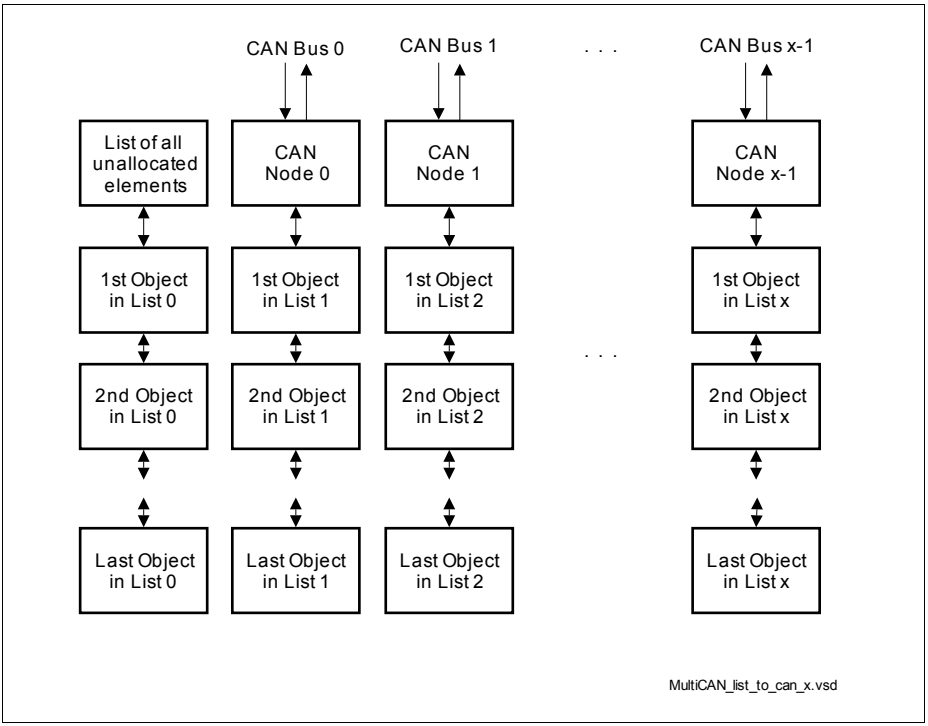

Figure 24-14 Message Objects Linked to CAN Nodes

24.5.6.4 List Command Panel

The list structure cannot be modified directly by write accesses to the LIST registers and the PPREV, PNEXT and LIST bit fields in the Message Object Control Registers, as they are read only. The list structure is managed by and limited to the list controller inside the MultiCAN module. The list controller is controlled via a command panel allowing the user to issue list allocation commands to the list controller. The list controller has two main purposes:

1. Ensure that all operations that modify the list structure result in a consistent list structure.
2. Present maximum ease of use and flexibility to the user.

The list controller and the associated command panel allows the programmer to concentrate on the final properties of the list, which are characterized by the allocation of message objects to a CAN node, and the ordering relation between objects that are allocated to the same list. The process of list (re-)building is done in the list controller.

Table 24-3 gives an overview on the available panel commands while Table 24-7 on Page 24-66 describes the panel commands in more detail.

Table 24-3 Panel Commands Overview

Command Name	Description
No Operation	No new command is started.
Initialize Lists	Run the initialization sequence to reset the CTRL and LIST field of all message objects.
Static Allocate	Allocate message object to a list.
Dynamic Allocate	Allocate the first message object of the list of unallocated objects to the selected list.
Static Insert Before	Remove a message object (source object) from the list that it currently belongs to, and insert it before a given destination object into the list structure of the destination object.
Dynamic Insert Before	Insert a new message object before a given destination object.
Static Insert Behind	Remove a message object (source object) from the list that it currently belongs to, and insert it behind a given destination object into the list structure of the destination object.
Dynamic Insert Behind	Insert a new message object behind a given destination object.

A panel command is started by writing the respective command code into the Panel Control Register bit field PANCTR.PANCMD (see Page 24-65). The corresponding command arguments must be written into bit fields PANCTR.PANAR1 and PANCTR.PANAR2 before writing the command code, or latest along with the command code in a single 32-bit write access to the Panel Control Register.

With the write operation of a valid command code, the PANCTR.BUSY flag is set and further write accesses to the Panel Control Register are ignored. The BUSY flag remains active and the control panel remains locked until the execution of the requested command has been completed. After a reset, the list controller builds up list 0. During this operation, BUSY is set and other accesses to the CAN RAM are forbidden. The CAN RAM can be accessed again when BUSY becomes inactive.

Note: The CAN RAM is automatically initialized after reset by the list controller in order to ensure correct list pointers in each message object. The end of this CAN RAM initialization is indicated by bit PANCTR.BUSY becoming inactive.

In case of a dynamic allocation command that takes an element from the list of unallocated objects, the PANCTR.RBUSY bit is also set along with the BUSY bit

(RBUSY = BUSY = 1). This indicates that bit fields PANAR1 and PANAR2 are going to be updated by the list controller in the following way:

1. The message number of the message object taken from the list of unallocated elements is written to PANAR1.
2. If ERR (bit 7 of PANAR2) is set to 1, the list of unallocated elements was empty and the command is aborted. If ERR is 0, the list was not empty and the command will be performed successfully.

The results of a dynamic allocation command are written before the list controller starts the actual allocation process. As soon as the results are available, RBUSY becomes inactive (RBUSY = 0) again, while BUSY still remains active until completion of the command. This allows the user to set up the new message object while it is still in the process of list allocation. The access to message objects is not limited during ongoing list operations. However, any access to a register resource located inside the RAM delays the ongoing allocation process by one access cycle.

As soon as the command is finished, the BUSY flag becomes inactive (BUSY = 0) and write accesses to the Panel Control Register are enabled again. Also, the “No Operation” command code is automatically written to the PANCTR.PANCMD field. A new command may be started any time when BUSY = 0.

All fields of the Panel Control Register PANCTR except BUSY and RBUSY may be written by the user. This makes it possible to save and restore the Panel Control Register if the Command Panel is used within independent (mutually interruptible) interrupt service routines. If this is the case, any task that uses the Command Panel and that may interrupt another task that also uses the Command Panel should poll the BUSY flag until it becomes inactive and save the whole PANCTR register to a memory location before issuing a command. At the end of the interrupt service routine, the task should restore PANCTR from the memory location.

Before a message object that is allocated to the list of an active CAN node shall be moved to another list or to another position within the same list, bit MOCTRn.MSGVAL (“Message Valid”) of message object n must be cleared.

24.5.7 CAN Node Analysis Features

The chapter describes the CAN node analysis capabilities of the MultiCAN module.

24.5.7.1 Analyze Mode

The CAN Analyze Mode makes it possible to monitor the CAN traffic for each CAN node individually without affecting the logical state of the CAN bus. The CAN Analyze Mode for CAN node x is selected by setting Node x Control Register bit NCRx.CALM.

In CAN Analyze Mode, the transmit pin of a CAN node is held at a recessive level permanently. The CAN node may receive frames (Data, Remote, and Error Frames) but is not allowed to transmit. Received Data/Remote Frames are not acknowledged (i.e. acknowledge slot is sent recessive) but will be received and stored in matching message objects as long as there is any other node that acknowledges the frame. The complete message object functionality is available, but no transmit request will be executed.

24.5.7.2 Loop-Back Mode

The MultiCAN module provides a Loop-Back Mode to enable an in-system test of the MultiCAN module as well as the development of CAN driver software without access to an external CAN bus.

The loop-back feature consists of an internal CAN bus (inside the MultiCAN module) and a bus select switch for each CAN node (see **Figure 24-15**). With the switch, each CAN node can be connected either to the internal CAN bus (Loop-Back Mode activated) or the external CAN bus, respectively to transmit and receive pins (normal operation). The CAN bus that is not currently selected is driven recessive; this means the transmit pin is held at 1, and the receive pin is ignored by the CAN nodes that are in Loop-Back Mode.

The Loop-Back Mode is selected for CAN node x by setting the Node x Port Control Register bit NPCRx.LBM. All CAN nodes that are in Loop-Back Mode may communicate together via the internal CAN bus without affecting the normal operation of the other CAN nodes that are not in Loop-Back Mode.

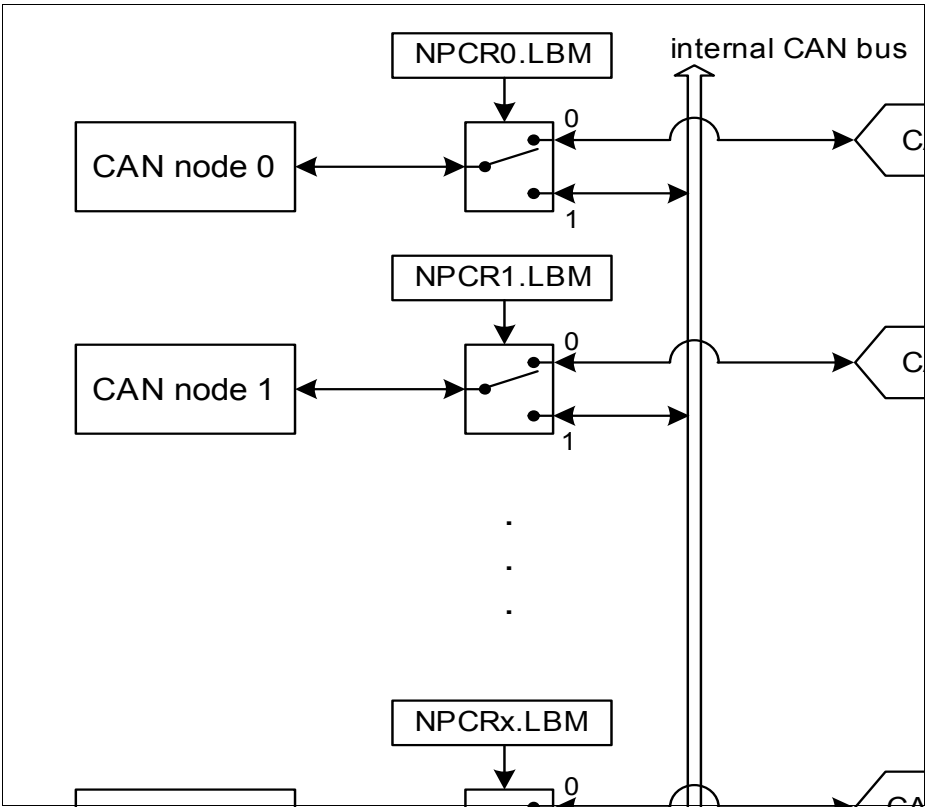

Figure 24-15 Loop-Back Mode

24.5.7.3 Bit Timing Analysis

Detailed analysis of the bit timing can be performed for each CAN node using the analysis modes of the CAN frame counter. The bit timing analysis functionality of the frame counter may be used for automatic detection of the CAN baud rate, as well as to analyze the timing of the CAN network.

Bit timing analysis for CAN node x is selected when bit field NFCRx.CFMOD = 10_B. Bit timing analysis does not affect the operation of the CAN node.

The bit timing measurement results are written into the NFCRx.CFC bit field. Whenever NFCRx.CFC is updated in bit timing analysis mode, bit NFCRx.CFCOV is also set to indicate the CFC update event. If NFCRx.CFCIE is set, an interrupt request can be generated (see **Figure 24-12**).

Automatic Baud Rate Detection

For automatic baud rate detection, the time between the observation of subsequent dominant edges on the CAN bus must be measured. This measurement is automatically performed if bit field NFCRx.CFSEL = 000_B. With each dominant edge monitored on the CAN receive input line, the time (measured in f_{CAN} clock cycles) between this edge and the most recent dominant edge is stored in the NFCRx.CFC bit field.

Synchronization Analysis

The bit time synchronization is monitored if NFCRx.CFSEL = 010_B. The time between the first dominant edge and the sample point is measured and stored in the NFCRx.CFC bit field. The bit timing synchronization offset may be derived from this time as the first edge after the sample point triggers synchronization and there is only one synchronization between consecutive sample points.

Synchronization analysis can be used, for example, for fine tuning of the baud rate during reception of the first CAN frame with the measured baud rate.

Driver Delay Measurement

The delay between a transmitted edge and the corresponding received edge is measured when NFCRx.CFSEL = 011_B (dominant to dominant) and NFCRx.CFSEL = 100_B (recessive to recessive). These delays indicate the time needed to represent a new bit value on the physical implementation of the CAN bus.

24.5.8 Message Acceptance Filtering

The chapter describes the Message Acceptance Filtering capabilities of the MultiCAN module.

24.5.8.1 Receive Acceptance Filtering

When a CAN frame is received by a CAN node, a unique message object is determined in which the received frame is stored after successful frame reception. A message object is qualified for reception of a frame if the following six conditions are met.

- The message object is allocated to the message object list of the CAN node by which the frame is received.
- Bit MOSTATn.MSGVAL in the Message Status Register (see **Page 24-97**) is set.
- Bit MOSTATn.RXEN is set.
- Bit MOSTATn.DIR is equal to bit RTR of the received frame.
  If bit MOSTATn.DIR = 1 (transmit object), the message object accepts only Remote Frames. If bit MOSTATn.DIR = 0 (receive object), the message object accepts only Data Frames.
- If bit MOAMRn.MIDE = 1, the IDE bit of the received frame becomes evaluated in the following way: If MOARn.IDE = 1, the IDE bit of the received frame must be set (indicates extended identifier). If MOARn.IDE = 0, the IDE bit of the received frame must be cleared (indicates standard identifier).
  If bit MOAMRn.MIDE = 0, the IDE bit of the received frame is “don’t care”. In this case, message objects with standard and extended frames are accepted.
- The identifier of the received frame matches the identifier stored in the Arbitration Register of the message object as qualified by the acceptance mask in the MOAMRn register. This means that each bit of the received message object identifier is equal to the bit field MOARn.ID, except those bits for which the corresponding acceptance mask bits in bit field MOAMRn.AM are cleared. These identifier bits are “don’t care” for reception. **Figure 24-16** illustrates this receive message identifier check.

Among all messages that fulfill all six qualifying criteria the message object with the highest receive priority wins receive acceptance filtering and becomes selected to store the received frame. All other message objects lose receive acceptance filtering.

The following priority scheme is defined for the message objects:

A message object a (MOa) has higher receive priority than a message object b (MOb) if the following two conditions are fulfilled (see **Page 24-113**):

1. MOa has a higher priority class than MOb. This means, the 2-bit priority bit field MOARa.PRI must be equal or less than bit field MOARb.PRI.
2. If both message objects have the same priority class (MOARa.PRI = MOARb.PRI), MOb is a list successor of MOa. This means that MOb can be reached by means of successively stepping forward in the list, starting from a.

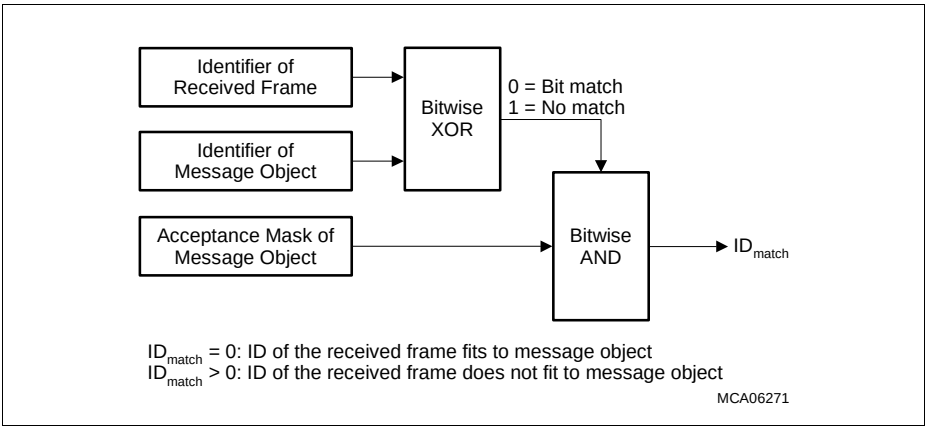

Figure 24-16 Received Message Identifier Acceptance Check

24.5.8.2 Transmit Acceptance Filtering

A message is requested for transmission by setting a transmit request in the message object that holds the message. If more than one message object have a valid transmit request for the same CAN node, one of these message objects is chosen for transmission, because only a single message object can be transmitted at one time on a CAN bus.

A message object is qualified for transmission on a CAN node if the following four conditions are met (see also **Figure 24-17**).

1. The message object is allocated to the message object list of the CAN node.
2. Bit MOSTATn.MSGVAL is set.
3. Bit MOSTATn.TXRQ is set.
4. Bit MOSTATn.TXEN0 and MOSTATn.TXEN1 are set.

A priority scheme determines which one of all qualifying message objects is transmitted first. It is assumed that message object a (MOa) and message object b (MOb) are two message objects qualified for transmission. MOb is a list successor of MOa. For both message objects, CAN messages CANa and CANb are defined (identifier, IDE, and RTR are taken from the message-specific bit fields and bits MOARn.ID, MOARn.IDE and MOCTRn.DIR).

If both message objects belong to the same priority class (identical PRI bit field in register MOARn), MOa has a higher transmit priority than MOb if one of the following conditions is fulfilled.

- PRI = 10_B and CAN message MOa has higher or equal priority than CAN message MOb with respect to CAN arbitration rules (see **Table 24-13** on **Page 24-114**).
- PRI = 01_B or PRI = 11_B (priority by list order).

- PRI = 00_B and the actual matrix position in a TTCAN network matches the matrix position(s) given in MOAMRn of MOa, i.e.
  CYCLE & MCYCLE = CYCTMR.BCC & MCYCLE and
  COLUMN & MCOLUMN = CYCTMR.CSM & MCOLUMN
  A message object with PRI = 00_B can be transmitted only by an active TTCAN node.

The message object that is qualified for transmission and has highest transmit priority wins the transmit acceptance filtering, and will be transmitted first. All other message objects lose the current transmit acceptance filtering round. They get a new chance in subsequent acceptance filtering rounds.

The three priority rules listed before are valid for normal CAN operation (without TTCAN functionality) as well as for arbitration windows within a TTCAN system matrix.

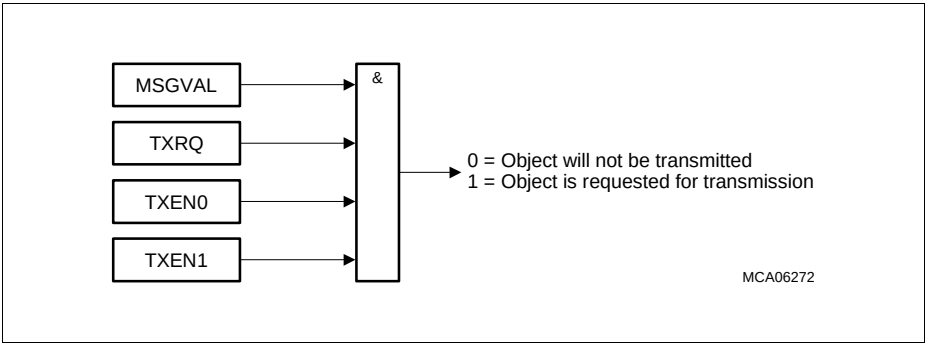

Figure 24-17 Effective Transmit Request of Message Object

Transmission Acceptance Filtering in TTCAN Exclusive Windows

In exclusive windows of a TTCAN, transmit acceptance filtering is performed as described in the previous section but with the exception that only message objects with MOARn.PRI = 00_B can be transmitted. Message objects with other PRI values are not taken into account. Hence the transmit acceptance filtering process selects the first message object in the list that meets the following conditions:

1. MOARn.PRI = 00_B
   a) MSGVAL & TXRQ & TXEN0 & TXEN1 = 1 (i.e. the message object qualifies for transmission)
   b) The actual matrix position in a TTCAN network matches the matrix position(s) given in MOAMR of MOa, i.e.
   CYCLE & MCYCLE = CYCTMR.BCC & MCYCLE and
   COLUMN & MCOLUMN = CYCTMR.CSM & MCOLUMN

24.5.9 Message Postprocessing

After a message object has successfully received or transmitted a frame, the CPU can be notified to perform a postprocessing on the message object. The postprocessing of the MultiCAN module consists of two elements:

1. Message interrupts to trigger postprocessing.
2. Message pending registers to collect pending message interrupts into a common structure for postprocessing.

24.5.9.1 Message Object Interrupts

When the storage of a received frame into a message object or the successful transmission of a frame is completed, a message interrupt can be issued. For each message object, a transmit and a receive interrupt can be generated and routed to one of the sixteen CAN interrupt output lines (see **Figure 24-18**). A receive interrupt occurs also after a frame storage event that has been induced by a FIFO or a gateway action. The status bits TXPND and RXPND in the Message Object n Status Register are always set after a successful transmission/reception, whether or not the respective message interrupt is enabled.

A third FIFO full interrupt condition of a message object is provided. If bit field MOFCRn.OVIE (Overflow Interrupt Enable) is set, the FIFO full interrupt will be activated depending on the actual message object type.

In case of a Receive FIFO Base Object (MOFCRn.MMC = 0001_B), the FIFO full interrupt is routed to the interrupt output line INT_Om as defined by the transmit interrupt node pointer MOIPRn.TXINP.

In case of a Transmit FIFO Base Object (MOFCRn.MMC = 0010_B), the FIFO full interrupt becomes routed to the interrupt output line INT_Om as defined by the receive interrupt node pointer MOIPRn.RXINP.

See also **“Interrupt Control” on Page 24-211** for further processing of the message object interrupts.

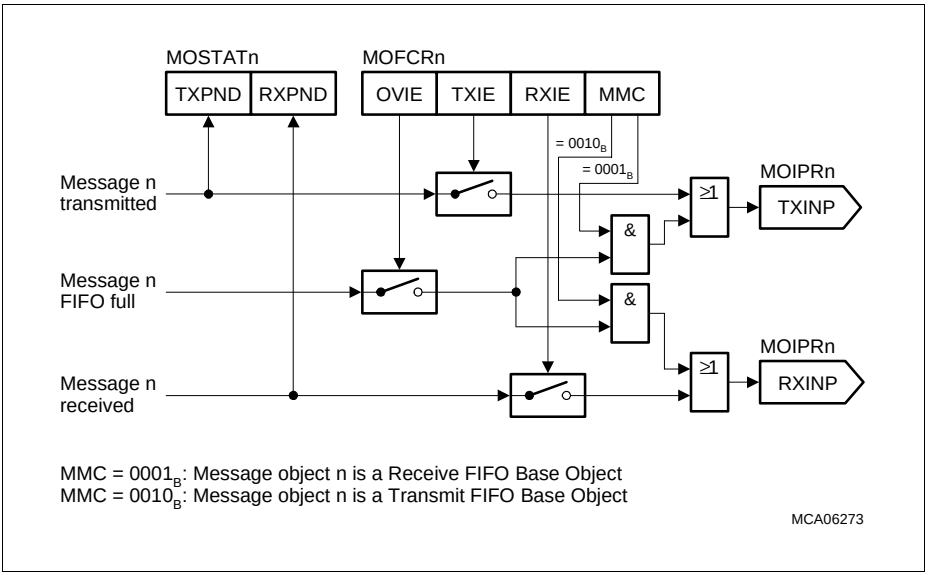

Figure 24-18 Message Interrupt Request Routing

24.5.9.2 Pending Messages

When a message interrupt request is generated, a message pending bit is set in one of the Message Pending Registers. There are 8 Message Pending Registers, MSPNDk (k = 0-7) with 32 pending bits available each. The general **Figure 24-19** shows the allocation of the message pending bits in case that the maximum possible number of eight Message Pending Registers are implemented and available on the chip.

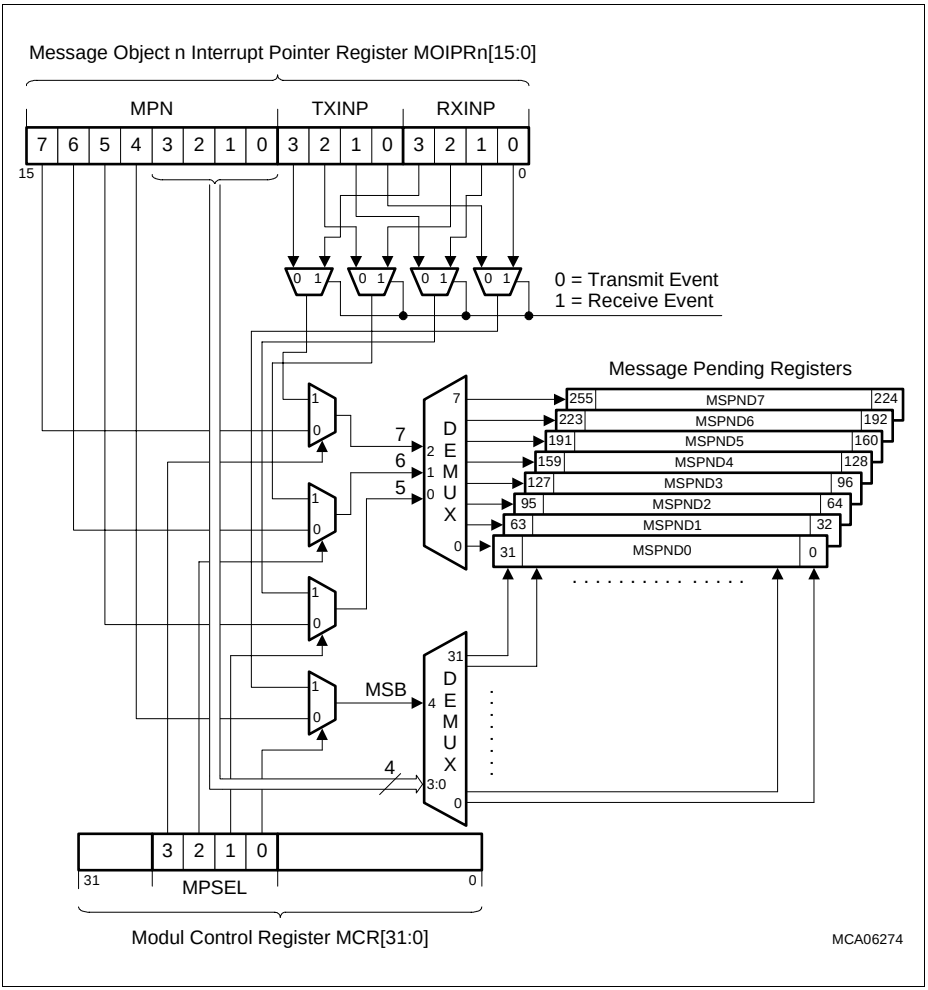

Figure 24-19 Message Pending Bit Allocation

The location of a pending bit is defined by two demultiplexers selecting the number k of the MSPNDk registers (3-bit demux), and the bit location within the corresponding MSPNDk register (5-bit demux).

Allocation Case 1

In this allocation case, bit field MCR.MPSEL = 0000_B (see **Page 24-69**). The location selection consists of 2 parts:

- The upper three bits of MOIPRn.MPN (MPN[7:5]) select the number k of a Message Pending Register MSPNDk in which the pending bit will be set.
- The lower five bits of MOIPRn.MPN (MPN[4:0]) select the bit position (0-31) in MSPNDk for the pending bit to be set.

Allocation Case 2

In this allocation case, bit field MCR.MPSEL is taken into account for pending bit allocation. Bit field MCR.MPSEL makes it possible to include the interrupt request node pointer for reception (MOIPRn.RXINP) or transmission (MOIPRn.TXINP) for pending bit allocation in such a way that different target locations for the pending bits are used in receive and transmit case. If MPSEL = 1111_B, the location selection operates in the following way:

- At a transmit event, the upper 3 bits of TXINP determine the number k of a Message Pending Register MSPNDk in which the pending bit will be set. At a receive event, the upper 3 bits of RXINP determine the number k.
- The bit position (0-31) in MSPNDk for the pending bit to be set is selected by the lowest bit of TXINP or RXINP (selects between low and high half-word of MSPNDk) and the four least significant bits of MPN.

General Hints

The Message Pending Registers MSPNDk can be written by software. Bits that are written with 1 are left unchanged, and bits which are written with 0 are cleared. This makes it possible to clear individual MSPNDk bits with a single register write access. Therefore, access conflicts are avoided when the MultiCAN module (hardware) sets another pending bit at the same time when software writes to the register.

Each Message Pending Register MSPNDk is associated with a Message Index Register MSIDk (see **Page 24-74**) which indicates the lowest bit position of all set (1) bits in Message Pending Register k. The MSIDk register is a read-only register that is updated immediately when a value in the corresponding Message Pending Register k is changed by software or hardware.

24.5.10 Message Object Data Handling

This chapter describes the handling capabilities for the Message Object Data of the MultiCAN module.

24.5.10.1 Frame Reception

After the reception of a message, it is stored in a message object according to the scheme shown in **Figure 24-20**. The MultiCAN module not only copies the received data into the message object, and it provides advanced features to enable consistent data exchange between MultiCAN and CPU.

MSGVAL

Bit MSGVAL (Message Valid) in the Message Object n Status Register MOSTATn is the main switch of the message object. During the frame reception, information is stored in the message object only when MSGVAL = 1. If bit MSGVAL is reset by the CPU, the MultiCAN module stops all ongoing write accesses to the message object. Now the message object can be re-configured by the CPU with subsequent write accesses to it without being disturbed by the MultiCAN.

RTSEL

When the CPU re-configures a message object during CAN operation (for example, clears MSGVAL, modifies the message object and sets MSGVAL again), the following scenario can occur:

1. The message object wins receive acceptance filtering.
2. The CPU clears MSGVAL to re-configure the message object.
3. The CPU sets MSGVAL again after re-configuration.
4. The end of the received frame is reached. As MSGVAL is set, the received data is stored in the message object, a message interrupt request is generated, gateway and FIFO actions are processed, etc.

After the re-configuration of the message object (after step 3 above) the storage of further received data may be undesirable. This can be achieved through bit MOCTRn.RTSEL (Receive/Transmit Selected) that makes it possible to disconnect a message object from an ongoing frame reception.

When a message object wins the receive acceptance filtering, its RTSEL bit is set by the MultiCAN module to indicate an upcoming frame delivery. The MultiCAN module checks RTSEL whether it is set on successful frame reception to verify that the object is still ready for receiving the frame. The received frame is then stored in the message object (along with all subsequent actions such as message interrupts, FIFO & gateway actions, flag updates) only if RTSEL = 1.

When a message object is invalidated during CAN operation (resetting bit MSGVAL), RTSEL should be cleared before setting MSGVAL again (latest with the same write

access that sets MSGVAL) to prevent the storage of a frame that belongs to the old context of the message object. Therefore, a message object re-configuration should consist of the following steps:

1. Clear MSGVAL bit
2. Re-configure the message object while MSGVAL = 0
3. Clear RTSEL bit and set MSGVAL again

RXEN

Bit MOSTATn.RXEN enables a message object for frame reception. A message object can receive CAN messages from the CAN bus only if RXEN = 1. The MultiCAN module evaluates RXEN only during receive acceptance filtering. After receive acceptance filtering, RXEN is ignored and has no further influence on the actual storage of a received message in a message object.

Bit RXEN enables the “soft phase out” of a message object: after clearing RXEN, a currently received CAN message for which the message object has won acceptance filtering is still stored in the message object but for subsequent messages the message object no longer wins receive acceptance filtering.

RXUPD, NEWDAT and MSGLST

An ongoing frame storage process is indicated by the RXUPD (Receive Updating) flag in the MOSTATn register. RXUPD is set with the start and cleared with the end of a message object update, which consists of frame storage as well as flag updates.

After storing the received frame (identifier, IDE bit, DLC; including the Data Field for Data Frames), the NEWDAT (New Data) bit of the message object is set. If NEWDAT was already set before it becomes set again, bit MSGLST (Message Lost) is set to indicate a data loss condition.

The RXUPD and NEWDAT flags can help to read consistent frame data from the message object during an ongoing CAN operation. The following steps are recommended to be executed:

1. Clear NEWDAT bit.
2. Read message content (identifier, data etc.) from the message object.
3. Check that both, NEWDAT and RXUPD, are cleared. If this is not the case, go back to step 1.
4. When step 3 was successful, the message object contents are consistent and has not been updated by the MultiCAN module while reading.

Bits RXUPD, NEWDAT and MSGLST have the same behavior for the reception of Data as well as Remote Frames.

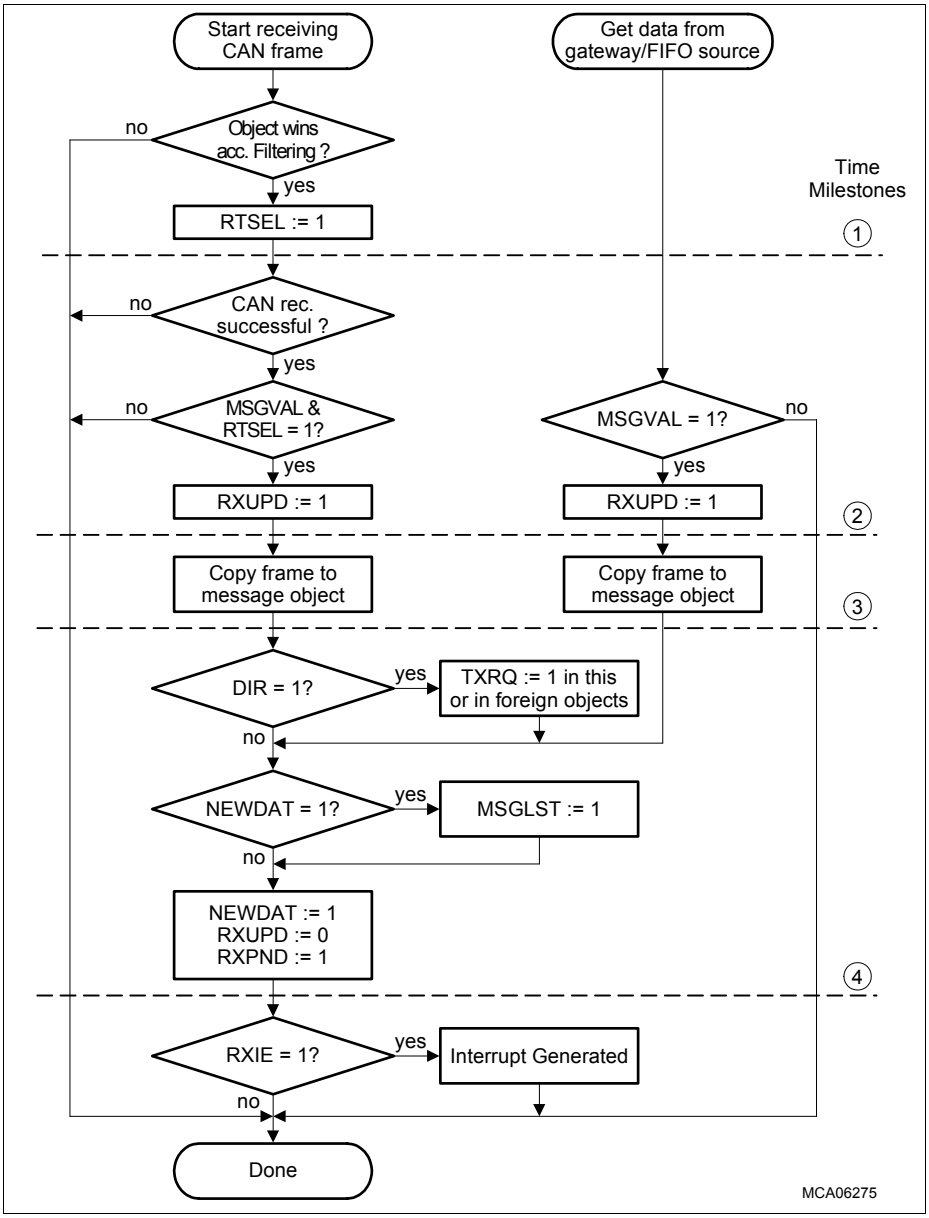

Figure 24-20 Reception of a Message Object

24.5.10.2 Frame Transmission

The process of a message object transmission is shown in **Figure 24-21**. Along with the copy of the message object content to be transmitted (identifier, IDE bit, RTR = DIR bit, DLC, including the Data Field for Data Frames) into the internal transmit buffer of the assigned CAN node, several status flags are also served and monitored to control consistent data handling.

The transmission process of a message object starting after the transmit acceptance filtering is identical for Remote and Data Frames.

MSGVAL, TXRQ, TXEN0, TXEN1

A message can only be transmitted if all four bits in registers MOSTATn, MSGVAL (Message Valid), TXRQ (Transmit Request), TXEN0 (Transmit Enable 0), TXEN1 (Transmit Enable 1) are set as shown in **Figure 24-17**. Although these bits are equivalent with respect to the transmission process, they have different semantics:

Table 24-4 Message Transmission Bit Definitions

Bit	Description
MSGVAL	**Message Valid** This is the main switch bit of the message object.
TXRQ	**Transmit Request** This is the standard transmit request bit. This bit must be set whenever a message object should be transmitted. TXRQ is cleared by hardware at the end of a successful transmission, except when there is new data (indicated by NEWDAT = 1) to be transmitted. When bit MOFCRn.STT (“Single Transmit Trial”) is set, TXRQ becomes already cleared when the contents of the message object are copied into the transmit frame buffer of the CAN node. A received remote request (after a Remote Frame reception) sets bit TXRQ to request the transmission of the requested data frame.
TXEN0	**Transmit Enable 0** This bit can be temporarily cleared by software to suppress the transmission of this message object when it writes new content to the Data Field. This avoids transmission of inconsistent frames that consist of a mixture of old and new data. Remote requests are still accepted when TXEN0 = 0, but transmission of the Data Frame is suspended until transmission is re-enabled by software (setting TXEN0).

Table 24-4 Message Transmission Bit Definitions (cont'd)

Bit	Description
TXEN1	**Transmit Enable 1** This bit is used in transmit FIFOs to select the message object that is transmit active within the FIFO structure. For message objects that are not transmit FIFO elements, TXEN1 can either be set permanently to 1 or can be used as a second independent transmission enable bit.

RTSEL

When a message object has been identified to be transmitted next after transmission acceptance filtering, bit MOCTRn.RTSEL (Receive/Transmit Selected) is set.

When the message object is copied into the internal transmit buffer, bit RTSEL is checked, and the message is transmitted only if RTSEL = 1. After the successful transmission of the message, bit RTSEL is checked again and the message postprocessing is only executed if RTSEL = 1.

For a complete re-configuration of a valid message object, the following steps should be executed:

1. Clear MSGVAL bit
2. Re-configure the message object while MSGVAL = 0
3. Clear RTSEL and set MSGVAL

Clearing of RTSEL ensures that the message object is disconnected from an ongoing/scheduled transmission and no message object processing (copying message to transmit buffer including clearing NEWDAT, clearing TXRQ, time stamp update, message interrupt, etc.) within the old context of the object can occur after the message object becomes valid again, but within a new context.

NEWDAT

When the contents of a message object have been transferred to the internal transmit buffer of the CAN node, bit MOSTATn.NEWDAT (New Data) is cleared by hardware to indicate that the transmit message object data is no longer new.

When the transmission of the frame is successful and NEWDAT is still cleared (if no new data has been copied into the message object meanwhile), TXRQ (Transmit Request) is cleared automatically by hardware.

If, however, the NEWDAT bit has been set again by the software (because a new frame should be transmitted), TXRQ is not cleared to enable the transmission of the new data.

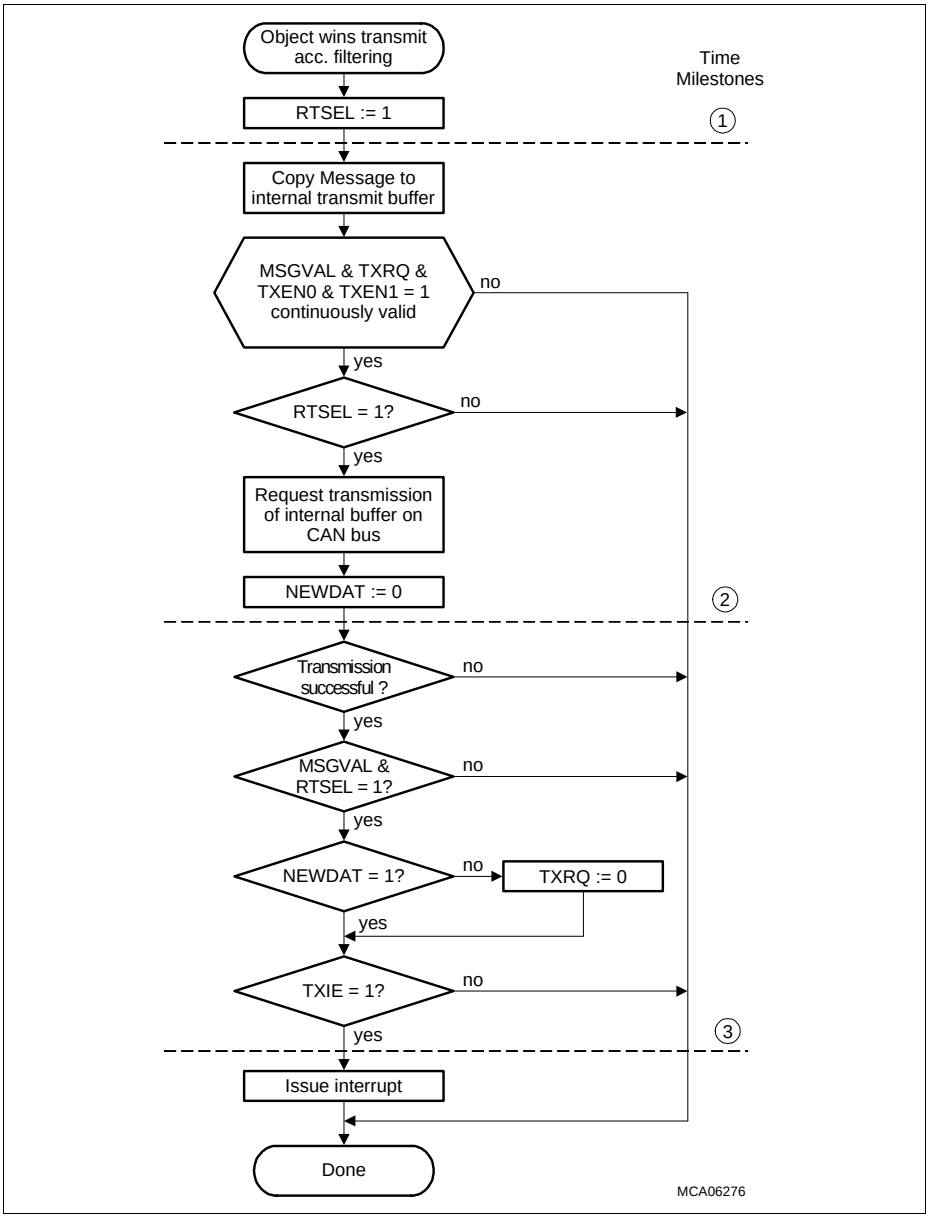

Figure 24-21 Transmission of a Message Object

24.5.11 Message Object Functionality

This chapter describes the functionality of the Message Objects in the MultiCAN module.

24.5.11.1 Standard Message Object

A message object is selected as standard message object when bit field MOFCRn.MMC = 0000_B (see **Page 24-90**). The standard message object can transmit and receive CAN frames according to the basic rules described in the previous sections. Additional services such as Single Data Transfer Mode or Single Transmit Trial (see following sections) are available and can be individually selected.

24.5.11.2 Single Data Transfer Mode

Single Data Transfer Mode is a useful feature in order to broadcast data over the CAN bus without unintended duplication of information. Single Data Transfer Mode is selected via bit MOFCRn.SDT.

Message Reception

When a received message stored in a message object is overwritten by a new received message, the contents of the first message are lost and replaced with the contents of the new received message (indicated by MSGLST = 1).

If SDT is set (Single Data Transfer Mode activated), bit MSGVAL of the message object is automatically cleared by hardware after the storage of a received Data Frame. This prevents the reception of further messages.

After the reception of a Remote Frame, bit MSGVAL is not automatically cleared.

Message Transmission

When a message object receives a series of multiple remote requests, it transmits several Data Frames in response to the remote requests. If the data within the message object has not been updated in the time between the transmissions, the same data can be sent more than once on the CAN bus.

In Single Data Transfer Mode (SDT = 1), this is avoided because MSGVAL is automatically cleared after the successful transmission of a Data Frame.

After the transmission of a Remote Frame, bit MSGVAL is not automatically cleared.

24.5.11.3 Single Transmit Trial

If the bit STT in the message object function register is set (STT = 1), the transmission request is cleared (TXRQ = 0) when the frame contents of the message object have been copied to the internal transmit buffer of the CAN node. Thus, the transmission of the message object is not tried again when it fails due to CAN bus errors.

24.5.11.4 Message Object FIFO Structure

In case of high CPU load it may be difficult to process a series of CAN frames in time. This may happen if multiple messages are received or must be transmitted in short time.

Therefore, a FIFO buffer structure is available to avoid loss of incoming messages and to minimize the setup time for outgoing messages. The FIFO structure can also be used to automate the reception or transmission of a series of CAN messages and to generate a single message interrupt when the whole CAN frame series is done.

There can be several FIFOs in parallel. The number of FIFOs and their size are limited only by the number of available message objects. A FIFO can be installed, resized and de-installed at any time, even during CAN operation.

The basic structure of a FIFO is shown in **Figure 24-22**. A FIFO consists of one base object and n slave objects. The slave objects are chained together in a list structure (similar as in message object lists). The base object may be allocated to any list. Although **Figure 24-22** shows the base object as a separate part beside the slave objects, it is also possible to integrate the base object at any place into the chain of slave objects. This means that the base object is slave object, too (not possible for gateways). The absolute object numbers of the message objects have no impact on the operation of the FIFO.

The base object does not need to be allocated to the same list as the slave objects. Only the slave object must be allocated to a common list (as they are chained together). Several pointers (BOT, CUR and TOP) that are located in the Message Object n FIFO/Gateway Pointer Register MOFGPRn link the base object to the slave objects, regardless whether the base object is allocated to the same or to another **list** than the slave objects.

The smallest FIFO would be a single message object which is both, FIFO base and FIFO slave (not very useful). The biggest possible FIFO structure would include all message objects of the MultiCAN module. Any FIFO sizes between these limits are possible.

In the FIFO base object, the FIFO boundaries are defined. Bit field MOFGPRn.BOT of the base object points to (includes the number of) the bottom slave object in the FIFO structure. The MOFGPRn.TOP bit field points to (includes the number of) the top slave object in the FIFO structure. The MOFGPRn.CUR bit field points to (includes the number of) the slave object that is actually selected by the MultiCAN module for message transfer. When a message transfer takes place with this object, CUR is set to the next message object in the list structure of the slave objects (CUR = PNEXT of current object). If CUR was equal to TOP (top of the FIFO reached), the next update of CUR will result in CUR = BOT (wrap-around from the top to the bottom of the FIFO). This scheme represents a circular FIFO structure where the bit fields BOT and TOP establish the link from the last to the first element.

Bit field MOFGPRn.SEL of the base object can be used for monitoring purposes. It makes it possible to define a slave object within the list at which a message interrupt is

generated whenever the CUR pointer reaches the value of the SEL pointer. Thus SEL makes it possible to detect the end of a predefined message transfer series or to issue a warning interrupt when the FIFO becomes full.

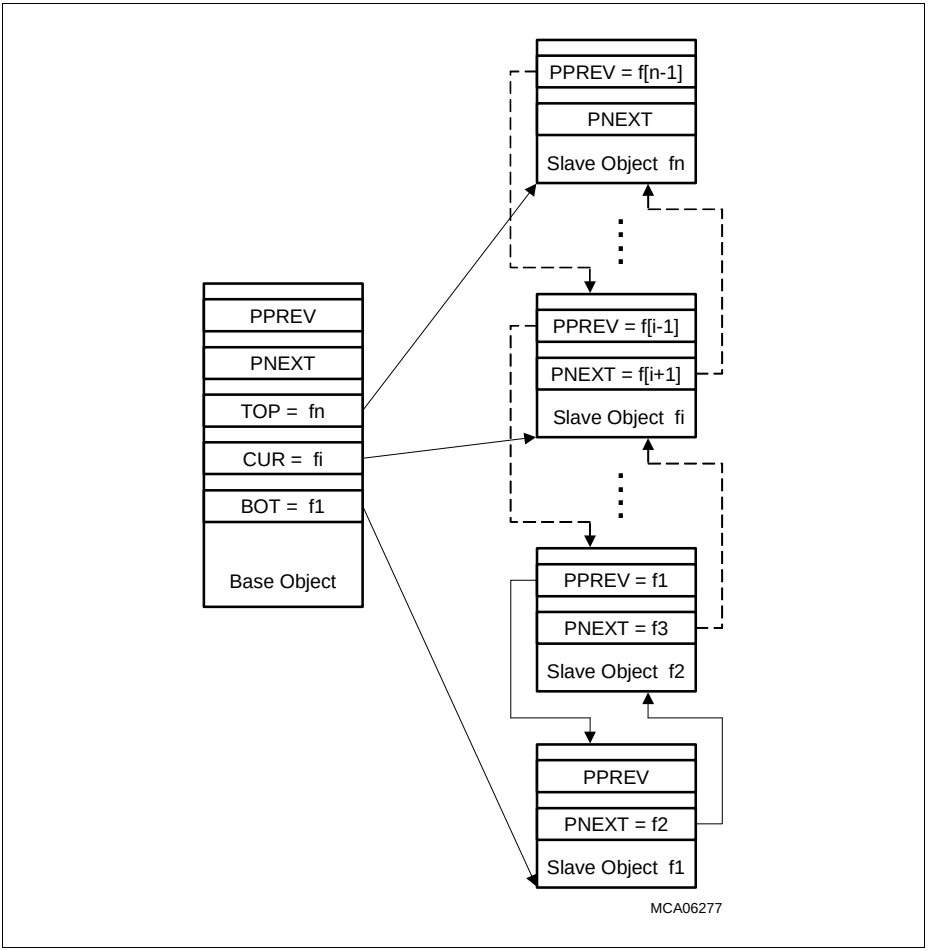

Figure 24-22 FIFO Structure with FIFO Base Object and n FIFO Slave Objects

24.5.11.5 Receive FIFO

The Receive FIFO structure is used to buffer incoming (received) Remote or Data Frames.

A Receive FIFO is selected by setting MOFCRn.MMC = 0001_B in the FIFO base object. This MMC code automatically designates a message object as FIFO base object. The message modes of the FIFO slave objects are not relevant for the operation of the Receive FIFO.

When the FIFO base object receives a frame from the CAN node it belongs to, the frame is not stored in the base object itself but in the message object that is selected by the base object's MOFGPRn.CUR pointer. This message object receives the CAN message as if it is the direct receiver of the message. However, MOFCRn.MMC = 0000_B is implicitly assumed for the FIFO slave object, and a standard message delivery is performed. The actual message mode (MMC setting) of the FIFO slave object is ignored. For the slave object, no acceptance filtering takes place that checks the received frame for a match with the identifier, IDE bit, and DIR bit.

With the reception of a CAN frame, the current pointer CUR of the base object is set to the number of the next message object in the FIFO structure. This message object will then be used to store the next incoming message.

If bit field MOFCRn.OVIE ("Overflow Interrupt Enable") of the FIFO base object is set and the current pointer MOFGPRn.CUR becomes equal to MOFGPRn.SEL, a FIFO overflow interrupt request is generated. This interrupt request is generated on interrupt node TXINP of the base object immediately after the storage of the received frame in the slave object. Transmit interrupts are still generated if TXIE is set.

A CAN message is stored in FIFO base and slave object only if MSGVAL = 1.

In order to avoid direct reception of a message by a slave message object, as if it was an independent message object and not a part of a FIFO, the bit RXEN of each slave object must be cleared. The setting of the bit RXEN is "don't care" only if the slave object is located in a list not assigned to a CAN node.

24.5.11.6 Transmit FIFO

The Transmit FIFO structure is used to buffer a series of Data or Remote Frames that must be transmitted. A transmit FIFO consists of one base message object and one or more slave message objects.

A Transmit FIFO is selected by setting MOFCRn.MMC = 0010_B in the FIFO base object. Unlike the Receive FIFO, slave objects assigned to the Transmit FIFO must explicitly set their bit fields MOFCRn.MMC = 0011_B. The CUR pointer in all slave objects must point back to the Transmit FIFO Base Object (to be initialized by software).

The MOSTATn.TXEN1 bits (Transmit Enable 1) of all message objects except the one which is selected by the CUR pointer of the base object must be cleared by software. TXEN1 of the message (slave) object selected by CUR must be set. CUR (of the base object) may be initialized to any FIFO slave object.

When tagging the message objects of the FIFO as valid to start the operation of the FIFO, then the base object must be tagged valid (MSGVAL = 1) first.

Before a Transmit FIFO becomes de-installed during operation, its slave objects must be tagged invalid (MSGVAL = 0).

The Transmit FIFO uses the TXEN1 bit in the Message Object Control Register of all FIFO elements to select the actual message for transmission. Transmit acceptance filtering evaluates TXEN1 for each message object and a message object can win transmit acceptance filtering only if its TXEN1 bit is set. When a FIFO object has transmitted a message, the hardware clears its TXEN1 bit in addition to standard transmit postprocessing (clear TXRQ, transmit interrupt etc.), and moves the CUR pointer in the next FIFO base object to be transmitted. TXEN1 is set automatically (by hardware) in the next message object. Thus, TXEN1 moves along the Transmit FIFO structure as a token that selects the active element.

If bit field MOFCRn.OVIE (“Overflow Interrupt Enable”) of the FIFO base object is set and the current pointer CUR becomes equal to MOFGPRn.SEL, a FIFO overflow interrupt request is generated. The interrupt request is generated on interrupt node RXINP of the base object after postprocessing of the received frame. Receive interrupts are still generated for the Transmit FIFO base object if bit RXIE is set.

24.5.11.7 Gateway Mode

The Gateway Mode makes it possible to establish an automatic information transfer between two independent CAN buses without CPU interaction.

The Gateway Mode operates on message object level. In Gateway mode, information is transferred between two message objects, resulting in an information transfer between the two CAN nodes to which the message objects are allocated. A gateway may be established with any pair of CAN nodes, and there can be as many gateways as there are message objects available to build the gateway structure.

Gateway Mode is selected by setting MOFCRs.MMC = 0100_B for the gateway source object s. The gateway destination object d is selected by the MOFGPRd.CUR pointer of the source object. The gateway destination object only needs to be valid (its MSGVAL = 1). All other settings are not relevant for the information transfer from the source object to the destination object.

Gateway source object behaves as a standard message object with the difference that some additional actions are performed by the MultiCAN module when a CAN frame has been received and stored in the source object (see **Figure 24-23**):

1. If bit MOFCRs.DLCC is set, the data length code MOFCRs.DLC is copied from the gateway source object to the gateway destination object.
2. If bit MOFCRs.IDC is set, the identifier MOARs.ID and the identifier extension MOARs.IDE are copied from the gateway source object to the gateway destination object.
3. If bit MOFCRs.DATC is set, the data bytes stored in the two data registers MODATALs and MODATAHs are copied from the gateway source object to the gateway destination object. All 8 data bytes are copied, even if MOFCRs.DLC indicates less than 8 data bytes.
4. If bit MOFCRs.GDFS is set, the transmit request flag MOSTATd.TXRQ is set in the gateway destination object.
5. The receive pending bit MOSTATd.RXPND and the new data bit MOSTATd.NEWDAT are set in the gateway destination object.
6. A message interrupt request is generated for the gateway destination object if its MOSTATd.RXIE is set.
7. The current object pointer MOFGPRs.CUR of the gateway source object is moved to the next destination object according to the FIFO rules as described on **Page 24-53**. A gateway with a single (static) destination object is obtained by setting MOFGPRs.TOP = MOFGPRs.BOT = MOFGPRs.CUR = destination object.

The link from the gateway source object to the gateway destination object works in the same way as the link from a FIFO base to a FIFO slave. This means that a gateway with an integrated destination FIFO may be created; in **Figure 24-22**, the object on the left is the gateway source object and the message object on the right side is the gateway destination objects.

The gateway operates equivalent for the reception of data frames (source object is receive object, i.e. DIR = 0) as well as for the reception of Remote Frames (source object is transmit object).

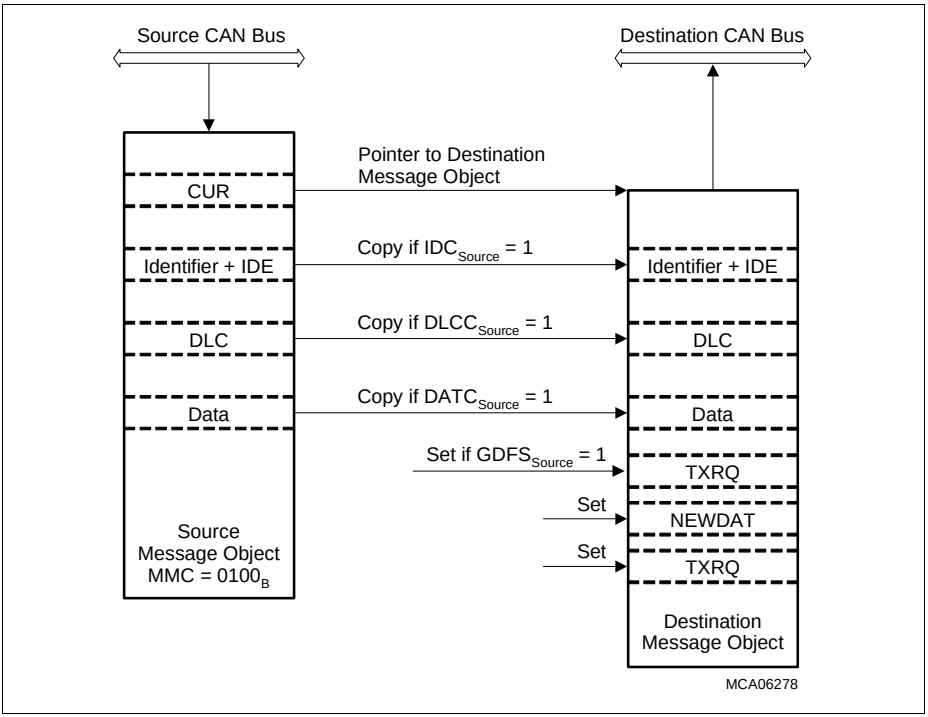

Figure 24-23 Gateway Transfer from Source to Destination

24.5.11.8 Foreign Remote Requests

When a Remote Frame has been received on a CAN node and is stored in a message object, a transmit request is set to trigger the answer (transmission of a Data Frame) to the request or to automatically issue a secondary request. If the Foreign Remote Request Enable bit MOFCRn.FRREN is cleared in the message object in which the remote request is stored, MOSTATn.TXRQ is set in the same message object.

If bit FRREN is set (FRREN = 1: foreign remote request enabled), TXRQ is set in the message object that is referenced by pointer MOFGPRn.CUR. The value of CUR is, however, not changed by this feature.

Although the foreign remote request feature works independently of the selected message mode, it is especially useful for gateways to issue a remote request on the source bus of a gateway after the reception of a remote request on the gateway destination bus. According to the setting of FRREN in the gateway destination object, there are two capabilities to handle remote requests that appear on the destination side (assuming that the source object is a receive object and the destination is a transmit object, i.e. DIR_{source} = 0 and $DIR_{destination}$ = 1):

FRREN = 0 in the Gateway Destination Object

1. A Remote Frame is received by gateway destination object.
2. TXRQ is set automatically in the gateway destination object.
3. A Data Frame with the current data stored in the destination object is transmitted on the destination bus.

FRREN = 1 in the Gateway Destination Object

1. A Remote Frame is received by gateway destination object.
2. TXRQ is set automatically in the gateway source object (must be referenced by CUR pointer of the destination object).
3. A remote request is transmitted by the source object (which is a receive object) on the source CAN bus.
4. The receiver of the remote request responds with a Data Frame on the source bus.
5. The Data Frame is stored in the source object.
6. The Data Frame is copied to the destination object (gateway action).
7. TXRQ is set in the destination object (assuming $GDFS_{source}$ = 1).
8. The new data stored in the destination object is transmitted on the destination bus, in response to the initial remote request on the destination bus.

24.6 MultiCAN Kernel Registers

This section describes the kernel registers of the MultiCAN module. All MultiCAN kernel register names described in this section are also referenced in other parts of the TC1798 User´s Manual by the module name prefix “CAN_”.

MultiCAN Kernel Register Overview

The MultiCAN Kernel include three blocks of registers:

- Global Module Registers
- Node Registers, for each CAN node x
- Message Object Registers, for each message object n

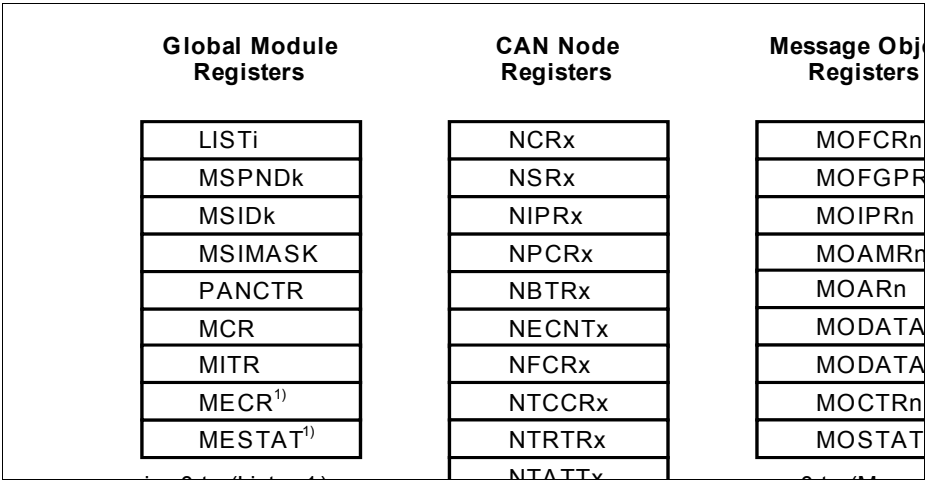

Figure 24-24 MultiCAN Kernel Registers

The registers of the MultiCAN module kernel are listed below.

Table 24-5 Registers Address Space - MultiCAN Kernel Registers

Module	Base Address	End Address	Note
CAN	F000 4000$_H$	F000 7FFF$_H$	-

Table 24-6 Registers Overview - MultiCAN Kernel Registers

Register Short Name	Register Long Name	Offset Address[1)]	Description see
LISTi	List Register i	$0100_H + i \times 4_H$	Page 24-71
MSPNDk	Message Pending Register k	$0140_H + k \times 4_H$	Page 24-73

1) The absolute register address is calculated as follows:
Module Base Address (**Table 24-5**) + Offset Address (shown in this column)
Further, the following ranges for parameters i, k, x, and n are valid: i = 0-7, k = 0-7, x = 0-3, n = 0-127.

Figure 24-25 shows the MultiCAN register address map, without TTCAN registers. They are shown in **Figure 24-38**.

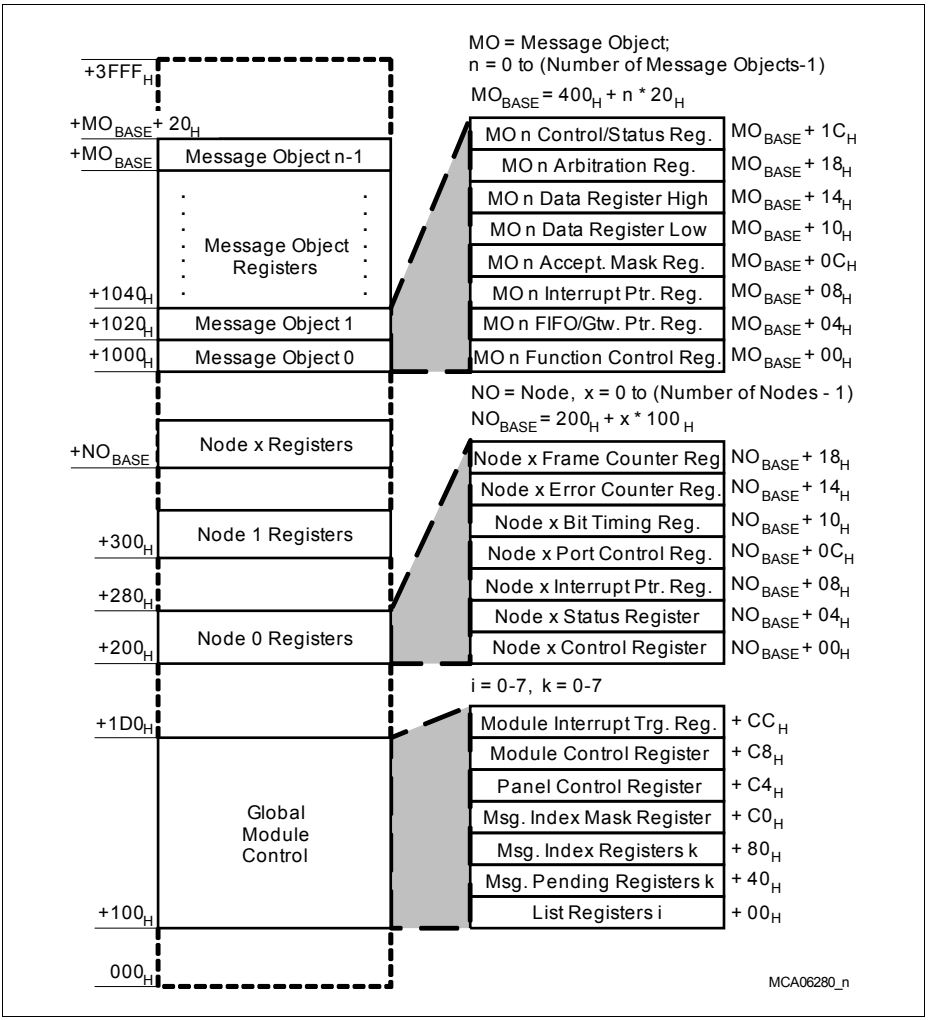

Figure 24-25 MultiCAN Register Address Map

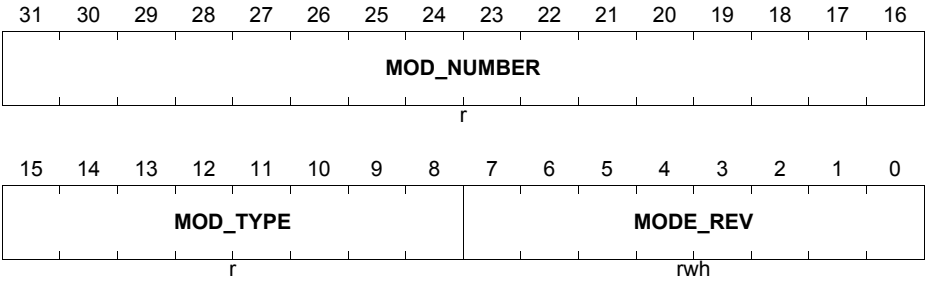
24.6.1 Global Module Registers

All list operations such as allocation, de-allocation and relocation of message objects within the list structure are performed via the Command Panel. It is not possible to modify the list structure directly by software by writing to the message objects and the LIST registers.

Module Identification Register .

ID

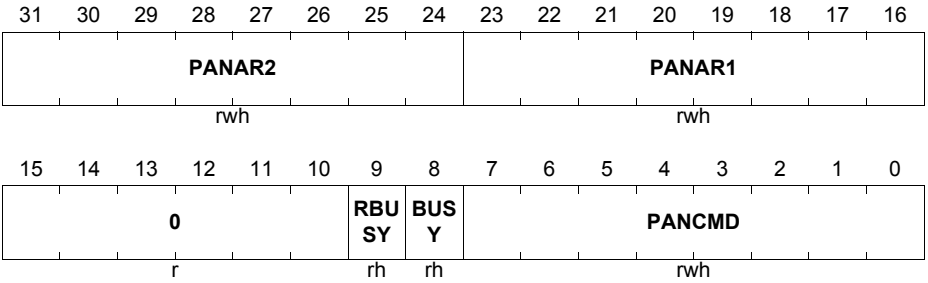
Module Identification Register (008_H) Reset Value: 002B C0XX$_H$



Field	Bits	Type	Description
MOD_REV	[7:0]	r	**Module Revision Number** MOD_REV defines the revision number. The value of a module revision starts with 01_H (first revision).
MOD_TYPE	[15:8]	r	**Module Type** $C0_H$ Define the module as a 32-bit module.
MOD_NUMBER	[31:16]	r	**Module Number Value** This bit field defines the MultiCAN module identification number (=002BH)

The Panel Control Register PANCTR is used to start a new command by writing the command arguments and the command code into its bit fields.

PANCTR
Panel Control Register **($1C4_H$)** **Reset Value: $0000\ 0301_H$**



Field	Bits	Type	Description
PANCMD	[7:0]	rwh	**Panel Command** This bit field is used to start a new command by writing a panel command code into it. At the end of a panel command, the NOP (no operation) command code is automatically written into PANCMD. The coding of PANCMD is defined in **Table 24-7**.
BUSY	8	rh	**Panel Busy Flag** 0_B Panel has finished command and is ready to accept a new command. 1_B Panel operation is in progress.
RBUSY	9	rh	**Result Busy Flag** 0_B No update of PANAR1 and PANAR2 is scheduled by the list controller. 1_B A list command is running (BUSY = 1) that will write results to PANAR1 and PANAR2, but the results are not yet available.
PANAR1	[23:16]	rwh	**Panel Argument 1** See **Table 24-7**.
PANAR2	[31:24]	rwh	**Panel Argument 2** See **Table 24-7**.
0	[15:10]	r	**Reserved** Read as 0; should be written with 0.

Panel Commands

A panel operation consists of a command code (PANCMD) and up to two panel arguments (PANAR1, PANAR2). Commands that have a return value deliver it to the PANAR1 bit field. Commands that return an error flag deliver it to bit 31 of the Panel Control Register, this means bit 7 of PANAR2.

Table 24-7 Panel Commands

PANCMD	PANAR2	PANAR1	Command Description
00_H	–	–	**No Operation** Writing 00_H to PANCMD has no effect. No new command is started.
01_H	**Result:** Bit 7: ERR Bit 6-0: undefined	–	**Initialize Lists** Run the initialization sequence to reset the CTRL and LIST fields of all message objects. List registers LIST[7:0] are set to their reset values. This results in the de-allocation of all message objects. The initialization command requires that bits NCRx.INIT and NCRx.CCE are set for all CAN nodes. Bit 7 of PANAR2 (ERR) reports the success of the operation: 0_B Initialization was successful 1_B Not all NCRx.INIT and NCRx.CCE bits are set. Therefore, no initialization is performed. The initialize lists command is automatically performed with each reset of the MultiCAN module, but with the exception that all message object registers are reset, too.
02_H	**Argument:** List Index	**Argument:** Message Object Number	**Static Allocate** Allocate message object to a list. The message object is removed from the list that it currently belongs to, and appended to the end of the list, given by PANAR2. This command is also used to deallocate a message object. In this case, the target list is the list of unallocated elements (PANAR2 = 0).

Table 24-7 Panel Commands (cont'd)

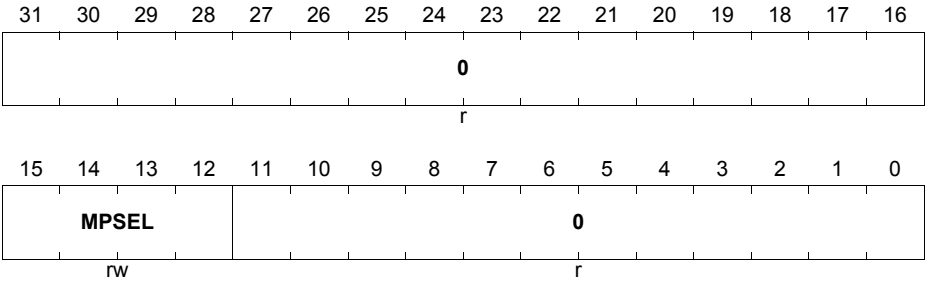
PANCMD	PANAR2	PANAR1	Command Description
03_H	**Argument:** List Index **Result:** Bit 7: ERR Bit 6-0: undefined	**Result:** Message Object Number	**Dynamic Allocate** Allocate the first message object of the list of unallocated objects to the selected list. The message object is appended to the end of the list. The message number of the message object is returned in PANAR1. An ERR bit (bit 7 of PANAR2) reports the success of the operation: 0_B Success. 1_B The operation has not been performed because the list of unallocated elements was empty.
04_H	**Argument:** Destination Object Number	**Argument:** Source Object Number	**Static Insert Before** Remove a message object (source object) from the list that it currently belongs to, and insert it before a given destination object into the list structure of the destination object. The source object thus becomes the predecessor of the destination object.
05_H	**Argument:** Destination Object Number **Result:** Bit 7: ERR Bit 6-0: undefined	**Result:** Object Number of inserted object	**Dynamic Insert Before** Insert a new message object before a given destination object. The new object is taken from the list of unallocated elements (the first element is chosen). The number of the new object is delivered as a result to PANAR1. An ERR bit (bit 7 of PANAR2) reports the success of the operation: 0_B Success. 1_B The operation has not been performed because the list of unallocated elements was empty.

Table 24-7 Panel Commands (cont'd)

PANCMD	PANAR2	PANAR1	Command Description
06_H	**Argument:** Destination Object Number	**Argument:** Source Object Number	**Static Insert Behind** Remove a message object (source object) from the list that it currently belongs to, and insert it behind a given destination object into the list structure of the destination object. The source object thus becomes the successor of the destination object.
07_H	**Argument:** Destination Object Number **Result:** Bit 7: ERR Bit 6-0: undefined	**Result:** Object Number of inserted object	**Dynamic Insert Behind** Insert a new message object behind a given destination object. The new object is taken from the list of unallocated elements (the first element is chosen). The number of the new object is delivered as result to PANAR1. An ERR bit (bit 7 of PANAR2) reports the success of the operation: 0_B Success. 1_B The operation has not been performed because the list of unallocated elements was empty.
08_H - FF_H	–	–	**Reserved**

The Module Control Register MCR contains basic settings that determine the operation of the MultiCAN module.

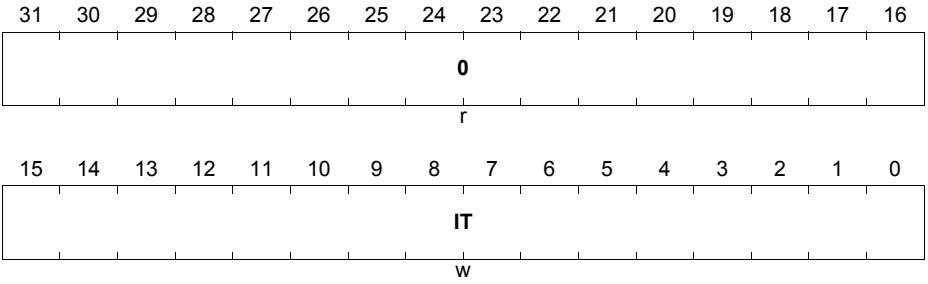
MCR
Module Control Register **($1C8_H$)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
MPSEL	[15:12]	rw	**Message Pending Selector** Bit field MPSEL makes it possible to select the bit position of the message pending bit after a message reception/transmission by a mixture of the MOIPRn register bit fields RXINP, TXINP, and MPN. Selection details are given in **Figure 24-19** on **Page 24-44**.
0	[31:16], [11:0]	r	**Reserved** Read as 0; should be written with 0.

The Interrupt Trigger Register ITR is used to trigger interrupt requests on each interrupt output line by software.

MITR
Module Interrupt Trigger Register ($1CC_H$) Reset Value: $0000\ 0000_H$



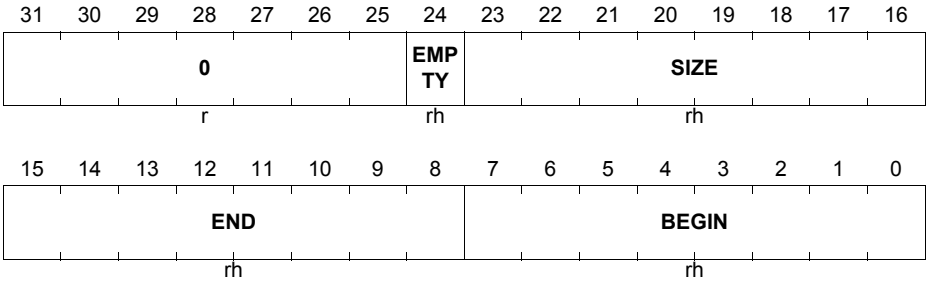
Field	Bits	Type	Description
IT	[15:0]	w	**Interrupt Trigger** Writing a 1 to IT[n] (n = 0-15) generates an interrupt request on interrupt output line INT_O[n]. Writing a 0 to IT[n] has no effect. Bit field IT is always read as 0. Multiple interrupt requests can be generated with a single write operation to MITR by writing a 1 to several bit positions of IT.
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

List Pointer and List Register

Each CAN node has a list that determines the allocated message objects. Additionally, a list of all unallocated objects is available. Furthermore, general purpose lists are available which are not associated to a CAN node. The List Registers are assigned in the following way:

- LIST0 provides the list of all unallocated objects
- LIST1 provides the list for CAN node 0
- LIST2 provides the list for CAN node 1
- LIST3 provides the list for CAN node 2
- LIST[7:4] are not associated to a CAN node (free lists)

LIST0
List Register 0 **(100_H)** **Reset Value: 007F 7F00$_H$**
LISTx (x = 1-7)
List Register x **(100_H+x*4_H)** **Reset Value: 0100 0000$_H$**



Field	Bits	Type	Description
BEGIN	[7:0]	rh	**List Begin** BEGIN indicates the number of the first message object in list i.
END	[15:8]	rh	**List End** END indicates the number of the last message object in list i.
SIZE	[23:16]	rh	**List Size** SIZE indicates the number of elements in the list i. SIZE = number of list elements - 1 SIZE = 0 indicates that list x is empty.

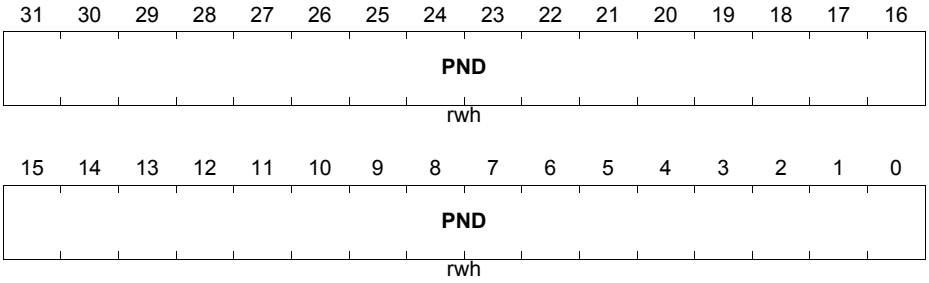
Field	Bits	Type	Description
EMPTY	24	rh	**List Empty Indication** 0_B At least one message object is allocated to list i. 1_B No message object is allocated to the list x. List x is empty.
0	[31:25]	r	**Reserved** Read as 0.

Message Notifications

When a message object n generates an interrupt request upon the transmission or reception of a message, then the request is routed to the interrupt output line selected by the bit field MOIPRn.TXINP or MOIPRn.RXINP of the message object n. As there are more message objects than interrupt output lines, an interrupt routine typically processes requests from more than one message object. Therefore, a priority selection mechanism is implemented in the MultiCAN module to select the highest priority object within a collection of message objects.

The Message Pending Register MSPNDk contains the pending interrupt notification of list i.

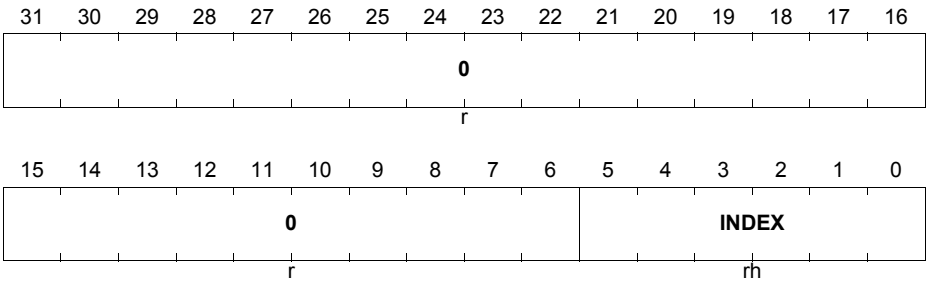
MSPNDk (k = 0-7)
Message Pending Register k **(140_H+k*4_H)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
PND	[31:0]	rwh	**Message Pending** When a message interrupt occurs, the message object sets a bit in one of the MSPND register, where the bit position is given by the MPN[4:0] field of the IPR register of the message object. The register selection n is given by the higher bits of MPN. The register bits can be cleared by software (write 0). Writing a 1 has no effect.

Each Message Pending Register has a Message Index Register MSIDk associated with it. The Message Index Register shows the active (set) pending bit with lowest bit position within groups of pending bits.

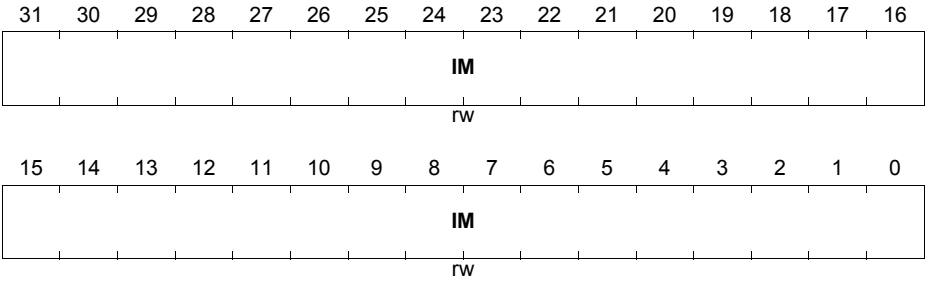
MSIDk (k = 0-7)
Message Index Register k **(180_H+k*4_H)** **Reset Value: 0000 0020_H**



Field	Bits	Type	Description
INDEX	[5:0]	rh	**Message Pending Index** The value of INDEX is given by the bit position i of the pending bit of MSPNDk with the following properties: 1. MSPNDk[i] & IM[i] = 1 2. i = 0 or MSPNDk[i-1:0] & IM[i-1:0] = 0 If no bit of MSPNDk satisfies these conditions then INDEX reads 100000_B. Thus INDEX shows the position of the first pending bit of MSPNDk, in which only those bits of MSPNDk that are selected in the Message Index Mask Register are taken into account.
0	[31:6]	r	**Reserved** Read as 0; should be written with 0.

The Message Index Mask Register MSIMASK selects individual bits for the calculation of the Message Pending Index. The Message Index Mask Register is used commonly for all Message Pending registers and their associated Message Index registers.

MSIMASK
Message Index Mask Register **($1C0_H$)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
IM	[31:0]	rw	**Message Index Mask** Only those bits in MSPNDk for which the corresponding Index Mask bits are set contribute to the calculation of the Message Index.

24.6.2 CAN Node Registers

The CAN node registers are built in for each CAN node of the MultiCAN module. They contain information that is directly related to the operation of the CAN nodes and are shared among the nodes.

The Node Control Register contains basic settings that determine the operation of the CAN node.

NCRx (x = 0-3)
Node x Control Register **(200_H+x*100_H)** **Reset Value: 0000 0001_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0							SUSEN	CALM	CCE	0	CANDIS	ALIE	LECIE	TRIE	INIT
r							rw	rw	rw	r	rw	rw	rw	rw	rwh

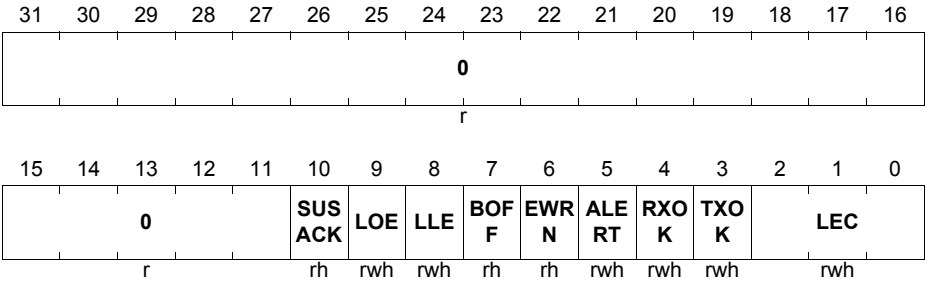
Field	Bits	Type	Description
INIT	0	rwh	**Node Initialization** 0_B Resetting bit INIT enables the participation of the node in the CAN traffic. If the CAN node is in the bus-off state, the ongoing bus-off recovery (which does not depend on the INIT bit) is continued. With the end of the bus-off recovery sequence the CAN node is allowed to take part in the CAN traffic. If the CAN node is not in the bus-off state, a sequence of 11 consecutive recessive bits must be detected before the node is allowed to take part in the CAN traffic. 1_B Setting this bit terminates the participation of this node in the CAN traffic. Any ongoing frame transfer is cancelled and the transmit line goes recessive. If the CAN node is in the bus-off state, then the running bus-off recovery sequence is continued. If the INIT bit is still set after the successful completion of the bus-off recovery sequence, i.e. after detecting 128 sequences of 11 consecutive recessive bits (11×1), then the CAN node leaves the bus-off state but remains inactive as long as INIT remains set. Bit INIT is automatically set when the CAN node enters the bus-off state (see **Page 24-28**).
TRIE	1	rw	**Transfer Interrupt Enable** TRIE enables the transfer interrupt of CAN node x. This interrupt is generated after the successful reception or transmission of a CAN frame in node x. 0_B Transfer interrupt is disabled. 1_B Transfer interrupt is enabled. Bit field NIPRx.TRINP selects the interrupt output line which becomes activated at this type of interrupt.

Field	Bits	Type	Description
LECIE	2	rw	**LEC Indicated Error Interrupt Enable** LECIE enables the last error code interrupt of CAN node x. This interrupt is generated with each update of bit field NSRx.LEC with LEC > 0 (CAN protocol error). 0_B Last error code interrupt is disabled. 1_B Last error code interrupt is enabled. Bit field NIPRx.LECINP selects the interrupt output line which becomes activated at this type of interrupt.
ALIE	3	rw	**Alert Interrupt Enable** ALIE enables the alert interrupt of CAN node x. This interrupt is generated by any one of the following events: • A change of bit NSRx.BOFF • A change of bit NSRx.EWRN • A List Length Error, which also sets bit NSRx.LLE • A List Object Error, which also sets bit NSRx.LOE • A Bit INIT is set by hardware 0_B Alert interrupt is disabled. 1_B Alert interrupt is enabled. Bit field NIPRx.ALINP selects the interrupt output line which becomes activated at this type of interrupt.
CANDIS	4	rw	**CAN Disable** Setting this bit disables the CAN node. The CAN node first waits until it is bus-idle or bus-off. Then bit INIT is automatically set, and an alert interrupt is generated if bit ALIE is set.
CCE	6	rw	**Configuration Change Enable** 0_B The Bit Timing Register, the Port Control Register, and the Error Counter Register may only be read. All attempts to modify them are ignored. 1_B The Bit Timing Register, the Port Control Register, and the Error Counter Register may be read and written.
CALM	7	rw	**CAN Analyze Mode** If this bit is set, then the CAN node operates in Analyze Mode. This means that messages may be received, but not transmitted. No acknowledge is sent on the CAN bus upon frame reception. Active-error flags are sent recessive instead of dominant. The transmit line is continuously held at recessive (1) level. Bit CALM can be written only while bit INIT is set.

Field	Bits	Type	Description
SUSEN	8	rw	**Suspend Enable** This bit makes it possible to set the CAN node into Suspend Mode via OCDS (on chip debug support): 0_B An OCDS suspend trigger is ignored by the CAN node. 1_B An OCDS suspend trigger disables the CAN node: As soon as the CAN node becomes bus-idle or bus-off, bit INIT is internally forced to 1 to disable the CAN node. The actual value of bit INIT remains unchanged. Bit SUSEN is reset via OCDS Reset.
0	[31:9], 5	r	**Reserved** Read as 0; should be written with 0.

The Node Status Register NSRx reports errors as well as successfully transferred CAN frames.

NSRx (x = 0-3)
Node x Status Register **(204_H+x*100_H)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
LEC	[2:0]	rwh	**Last Error Code** This bit field indicates the type of the last (most recent) CAN error. The encoding of this bit field is described in **Table 24-8**.
TXOK	3	rwh	**Message Transmitted Successfully** 0_B No successful transmission since last (most recent) flag reset. 1_B A message has been transmitted successfully (error-free and acknowledged by at least another node). TXOK must be reset by software (write 0). Writing 1 has no effect.
RXOK	4	rwh	**Message Received Successfully** 0_B No successful reception since last (most recent) flag reset. 1_B A message has been received successfully. RXOK must be reset by software (write 0). Writing 1 has no effect.

Field	Bits	Type	Description
ALERT	5	rwh	**Alert Warning** The ALERT bit is set upon the occurrence of one of the following events (the same events which also trigger an alert interrupt if ALIE is set): • A change of bit NSRx.BOFF • A change of bit NSRx.EWRN • A List Length Error, which also sets bit NSRx.LLE • A List Object Error, which also sets bit NSRx.LOE • Bit INIT has been set by hardware ALERT must be reset by software (write 0). Writing 1 has no effect.
EWRN	6	rh	**Error Warning Status** 0_B No warning limit exceeded. 1_B One of the error counters REC or TEC reached the warning limit EWRNLVL.
BOFF	7	rh	**Bus-off Status** 0_B CAN controller is not in the bus-off state. 1_B CAN controller is in the bus-off state.
LLE	8	rwh	**List Length Error** 0_B No List Length Error since last (most recent) flag reset. 1_B A List Length Error has been detected during message acceptance filtering. The number of elements in the list that belongs to this CAN node differs from the list SIZE given in the list termination pointer. LLE must be reset by software (write 0). Writing 1 has no effect.
LOE	9	rwh	**List Object Error** 0_B No List Object Error since last (most recent) flag reset. 1_B A List Object Error has been detected during message acceptance filtering. A message object with wrong LIST index entry in the Message Object Control Register has been detected. LOE must be reset by software (write 0). Writing 1 has no effect.

Field	Bits	Type	Description
SUSACK	10	rh	**Suspend Acknowledge** 0_B The CAN node is not in Suspend Mode or a suspend request is pending, but the CAN node has not yet reached bus-idle or bus-off. 1_B The CAN node is in Suspend Mode: The CAN node is inactive (bit NCR.INIT internally forced to 1) due to an OCDS suspend request.
0	[31:11]	r	**Reserved** Read as 0; should be written with 0.

Encoding of the LEC Bit Field

Table 24-8 Encoding of the LEC Bit Field

LEC Value	Signification
000_B	**No Error:** No error was detected for the last (most recent) message on the CAN bus.
001_B	**Stuff Error:** More than 5 equal bits in a sequence have occurred in a part of a received message where this is not allowed.
010_B	**Form Error:** A fixed format part of a received frame has the wrong format.
011_B	**Ack Error:** The transmitted message was not acknowledged by another node.
100_B	**Bit1 Error:** During a message transmission, the CAN node tried to send a recessive level (1) outside the arbitration field and the acknowledge slot, but the monitored bus value was dominant.
101_B	**Bit0 Error:** Two different conditions are signaled by this code: 1. During transmission of a message (or acknowledge bit, active-error flag, overload flag), the CAN node tried to send a dominant level (0), but the monitored bus value was recessive. 2. During bus-off recovery, this code is set each time a sequence of 11 recessive bits has been monitored. The CPU may use this code as indication that the bus is not continuously disturbed.

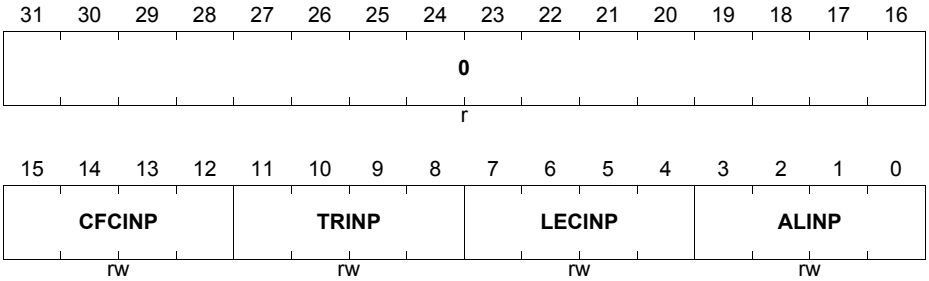
Table 24-8 Encoding of the LEC Bit Field (cont'd)

LEC Value	Signification
110_B	**CRC Error:** The CRC checksum of the received message was incorrect.
111_B	**CPU write to LEC:** Whenever the the CPU writes the value 111 to LEC, it takes the value 111. Whenever the CPU writes another value to LEC, the written LEC value is ignored.

The four interrupt pointers in the Node Interrupt Pointer Register NIPRx select one out of the sixteen interrupt outputs individually for each type of CAN node interrupt. See also **Page 24-29** for more CAN node interrupt details.

NIPRx (x = 0-3)
Node x Interrupt Pointer Register

(208_H+x*100_H) **Reset Value: 0000 0000_H**

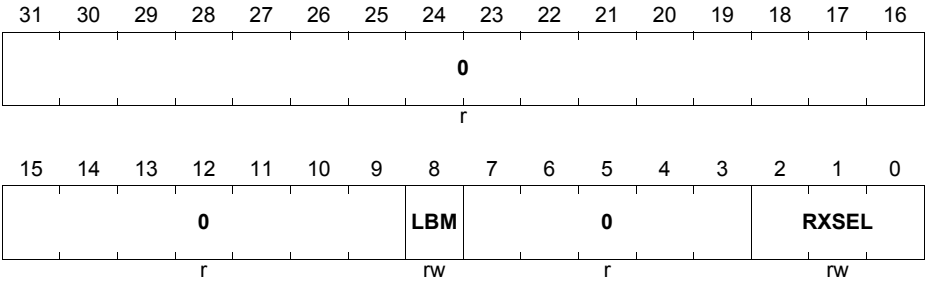


Field	Bits	Type	Description
ALINP	[3:0]	rw	**Alert Interrupt Node Pointer** ALINP selects the interrupt output line INT_Om (m = 0-15) for an alert interrupt of CAN Node x. 0000_B Interrupt output line INT_O0 is selected. 0001_B Interrupt output line INT_O1 is selected. $\ldots_B$ … 1110_B Interrupt output line INT_O14 is selected. 1111_B Interrupt output line INT_O15 is selected.
LECINP	[7:4]	rw	**Last Error Code Interrupt Node Pointer** LECINP selects the interrupt output line INT_Om (m = 0-15) for an LEC interrupt of CAN Node x. 0000_B Interrupt output line INT_O0 is selected. 0001_B Interrupt output line INT_O1 is selected. $\ldots_B$ … 1110_B Interrupt output line INT_O14 is selected. 1111_B Interrupt output line INT_O15 is selected.

Field	Bits	Type	Description
TRINP	[11:8]	rw	**Transfer OK Interrupt Node Pointer** TRINP selects the interrupt output line INT_Om (m = 0-15) for a transfer OK interrupt of CAN Node x. 0000_B Interrupt output line INT_O0 is selected. 0001_B Interrupt output line INT_O1 is selected. $\ldots_B$ … 1110_B Interrupt output line INT_O14 is selected. 1111_B Interrupt output line INT_O15 is selected.
CFCINP	[15:12]	rw	**Frame Counter Interrupt Node Pointer** CFCINP selects the interrupt output line INT_Om (m = 0-15) for a transfer OK interrupt of CAN Node x. 0000_B Interrupt output line INT_O0 is selected. 0001_B Interrupt output line INT_O1 is selected. $\ldots_B$ … 1110_B Interrupt output line INT_O14 is selected. 1111_B Interrupt output line INT_O15 is selected.
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

The Node Port Control Register NPCRx configures the CAN bus transmit/receive ports. NPCRx can be written only if bit NCRx.CCE is set.

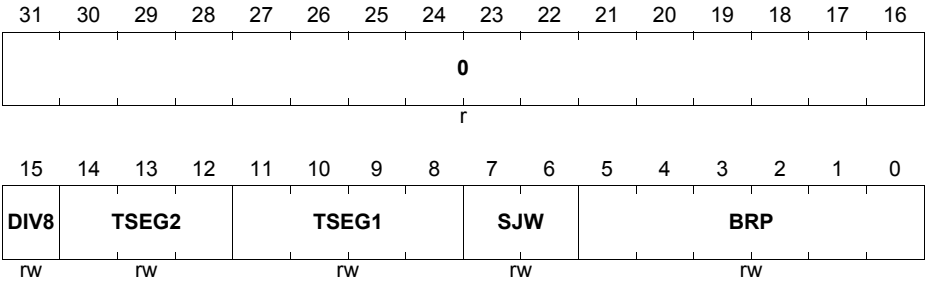
NPCRx (x = 0-3)
Node x Port Control Register **($20C_H$+x*100_H)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
RXSEL	[2:0]	rw	**Receive Select** RXSEL selects one out of 8 possible receive inputs. The CAN receive signal is performed only through the selected input. *Note: In TC1798, only specific combinations of RXSEL are available (see also **"Receive Input Selection" on Page 24-209**).*
LBM	8	rw	**Loop-Back Mode** 0_B Loop-Back Mode is disabled. 1_B Loop-Back Mode is enabled. This node is connected to an internal (virtual) loop-back CAN bus. All CAN nodes which are in Loop-Back Mode are connected to this virtual CAN bus so that they can communicate with each other internally. The external transmit line is forced recessive in Loop-Back Mode.
0	[7:3], [31:9]	r	**Reserved** Read as 0; should be written with 0.

The Node Bit Timing Register NBTRx contains all parameters to set up the bit timing for the CAN transfer. NBTRx can be written only if bit NCRx.CCE is set.

NBTRx (x = 0-3)
Node x Bit Timing Register **(210_H+x*100_H)** **Reset Value: 0000 0000_H**

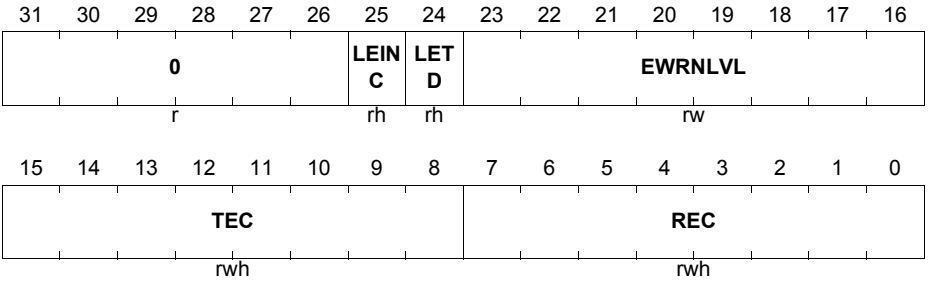


Field	Bits	Type	Description
BRP	[5:0]	rw	**Baud Rate Prescaler** The duration of one time quantum is given by (BRP + 1) clock cycles if DIV8 = 0. The duration of one time quantum is given by 8 × (BRP + 1) clock cycles if DIV8 = 1.
SJW	[7:6]	rw	**(Re) Synchronization Jump Width** (SJW + 1) time quanta are allowed for re-synchronization.
TSEG1	[11:8]	rw	**Time Segment Before Sample Point** (TSEG1 + 1) time quanta is the user-defined nominal time between the end of the synchronization segment and the sample point. It includes the propagation segment, which takes into account signal propagation delays. The time segment may be lengthened due to re-synchronization. Valid values for TSEG1 are 2 to 15.
TSEG2	[14:12]	rw	**Time Segment After Sample Point** (TSEG2 + 1) time quanta is the user-defined nominal time between the sample point and the start of the next synchronization segment. It may be shortened due to re-synchronization. Valid values for TSEG2 are 1 to 7.

Field	Bits	Type	Description
DIV8	15	rw	**Divide Prescaler Clock by 8** 0_B A time quantum lasts (BRP+1) clock cycles. 1_B A time quantum lasts 8 × (BRP+1) clock cycles.
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

The Node Error Counter Register NECNTx contains the CAN receive and transmit error counter as well as some additional bits to ease error analysis. NECNTx can be written only if bit NCRx.CCE is set.

NECNTx (x = 0-3)
Node x Error Counter Register (214_H+x*100_H) Reset Value: 0060 0000_H

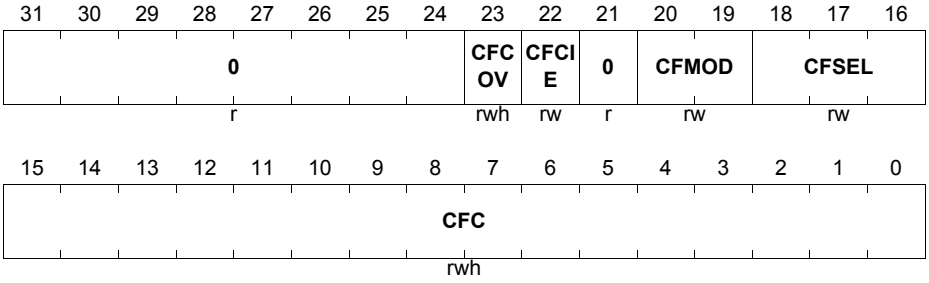


Field	Bits	Type	Description
REC	[7:0]	rwh	**Receive Error Counter** Bit field REC contains the value of the receive error counter of CAN node x.
TEC	[15:8]	rwh	**Transmit Error Counter** Bit field TEC contains the value of the transmit error counter of CAN node x.
EWRNLVL	[23:16]	rw	**Error Warning Level** Bit field EWRNLVL determines the threshold value (warning level, default 96) to be reached in order to set the corresponding error warning bit EWRN.
LETD	24	rh	**Last Error Transfer Direction** 0_B The last error occurred while the CAN node x was receiver (REC has been incremented). 1_B The last error occurred while the CAN node x was transmitter (TEC has been incremented).
LEINC	25	rh	**Last Error Increment** 0_B The last error led to an error counter increment of 1. 1_B The last error led to an error counter increment of 8.

Field	Bits	Type	Description
0	[31:26]	r	**Reserved** Read as 0; should be written with 0.

The Node Frame Counter Register NFCRx contains the actual value of the frame counter as well as control and status bits of the frame counter.

NFCRx (x = 0-3)
Node x Frame Counter Register (218_H+x*100_H) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
CFC	[15:0]	rwh	**CAN Frame Counter** In Frame Count Mode (CFMOD = 00_B), this bit field contains the frame count value. In Time Stamp Mode (CFMOD = 01_B), this bit field contains the captured bit time count value, captured with the start of a new frame. In all Bit Timing Analysis Modes (CFMOD = 10_B), CFC always displays the number of f_{CLC} clock cycles (measurement result) minus 1. Example: a CFC value of 34 in measurement mode CFSEL = 000_B means that 35 f_{CLC} clock cycles have been elapsed between the most recent two dominant edges on the receive input.

Field	Bits	Type	Description
CFSEL	[18:16]	rw	**CAN Frame Count Selection** This bit field selects the function of the frame counter for the chosen frame count mode. **Frame Count Mode** Bit 0 If Bit 0 of CFSEL is set, then CFC is incremented each time a foreign frame (i.e. a frame not matching to a message object) has been received on the CAN bus. Bit 1 If Bit 1 of CFSEL is set, then CFC is incremented each time a frame matching to a message object has been received on the CAN bus. Bit 2 If Bit 2 of CFSEL is set, then CFC is incremented each time a frame has been transmitted successfully by the node. **Time Stamp Mode** 000_B The frame counter is incremented (internally) at the beginning of a new bit time. The value is sampled during the SOF bit of a new frame. The sampled value is visible in the CFC field. **Bit Timing Mode** The available bit timing measurement modes are shown in Table 24-9. If CFCIE is set, then an interrupt on request node x (where x is the CAN node number) is generated with a CFC update.
CFMOD	[20:19]	rw	**CAN Frame Counter Mode** This bit field determines the operation mode of the frame counter. 00_B Frame Count Mode: The frame counter is incremented upon the reception and transmission of frames. 01_B Time Stamp Mode: The frame counter is used to count bit times. 10_B Bit Timing Mode: The frame counter is used for analysis of the bit timing.

Field	Bits	Type	Description
CFCIE	22	rw	**CAN Frame Count Interrupt Enable** CFCIE enables the CAN frame counter overflow interrupt of CAN node x. 0_B CAN frame counter overflow interrupt is disabled. 1_B CAN frame counter overflow interrupt is enabled. Bit field NIPRx.CFCINP selects the interrupt output line that is activated at this type of interrupt.
CFCOV	23	rwh	**CAN Frame Counter Overflow Flag** Flag CFCOV is set upon a frame counter overflow (transition from $FFFF_H$ to 0000_H). In bit timing analysis mode, CFCOV is set upon an update of CFC. An interrupt request is generated if CFCIE = 1. 0_B No overflow has occurred since last flag reset. 1_B An overflow has occurred since last flag reset. CFCOV must be reset by software.
0	21, [31:24]	r	**Reserved** Read as 0; should be written with 0.

Bit Timing Analysis Modes

Table 24-9 Bit Timing Analysis Modes (CFMOD = 10)

CFSEL	Measurement
000_B	Whenever a dominant edge (transition from 1 to 0) is monitored on the receive input, the time (measured in clock cycles) between this edge and the most recent dominant edge is stored in CFC.
001_B	Whenever a recessive edge (transition from 0 to 1) is monitored on the receive input the time (measured in clock cycles) between this edge and the most recent dominant edge is stored in CFC.
010_B	Whenever a dominant edge is received as a result of a transmitted dominant edge, the time (clock cycles) between both edges is stored in CFC.
011_B	Whenever a recessive edge is received as a result of a transmitted recessive edge, the time (clock cycles) between both edges is stored in CFC.
100_B	Whenever a dominant edge that qualifies for synchronization is monitored on the receive input, the time (measured in clock cycles) between this edge and the most recent sample point is stored in CFC.

Table 24-9 Bit Timing Analysis Modes (CFMOD = 10) (cont'd)

CFSEL	Measurement
101_B	With each sample point, the time (measured in clock cycles) between the start of the new bit time and the start of the previous bit time is stored in CFC[11:0]. Additional information is written to CFC[15:12] at each sample point: CFC[15]: Transmit value of actual bit time CFC[14]: Receive sample value of actual bit time CFC[13:12]: CAN bus information (see **Table 24-10**)
110_B	Reserved, do not use this combination.
111_B	Reserved, do not use this combination.

Table 24-10 CAN Bus State Information

CFC[13:12]	CAN Bus State
00_B	**NoBit** The CAN bus is idle, performs bit (de-) stuffing or is in one of the following frame segments: SOF, SRR, CRC, delimiters, first 6 EOF bits, IFS.
01_B	**NewBit** This code represents the first bit of a new frame segment. The current bit is the first bit in one of the following frame segments: Bit 10 (MSB) of standard ID (transmit only), RTR, reserved bits, IDE, DLC(MSB), bit 7 (MSB) in each data byte and the first bit of the ID extension.
10_B	**Bit** This code represents a bit inside a frame segment with a length of more than one bit (not the first bit of those frame segments that is indicated by NewBit). The current bit is processed within one of the following frame segments: ID bits (except first bit of standard ID for transmission and first bit of ID extension), DLC (3 LSB) and bits 6-0 in each data byte.
11_B	**Done** The current bit is in one of the following frame segments: Acknowledge slot, last bit of EOF, active/passive-error frame, overload frame. Two or more directly consecutive Done codes signal an Error Frame.

24.6.3 Message Object Registers

The Message Object Control Register MOCTRn and the Message Object Status Register MOSTATn are located at the same address offset within a message object address block (offset address $1C_H$). The MOCTRn is a write-only register that makes it possible to set/reset CAN transfer related control bits through software.

MOCTR0
Message Object 0 Control Register ($101C_H$) **Reset Value: $0100\ 0000_H$**
MOCTR127
Message Object 127 Control Register($1FFC_H$) **Reset Value: $7F7E\ 0000_H$**
MOCTRn (n = 1-126)
Message Object n Control Register
($101C_H+n*20_H$)
Reset Value: $((n+1)*01000000_H)+((n-1)*00010000_H)$

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0				RES DIR	RES TXEN1	RES TXEN0	RES TXRQ	RES RXEN	RES RTSEL	RES MSGVAL	RES MSGLST	RES NEWDAT	RES RXUPD	RES TXPND	RES RXPND
w				w	w	w	w	w	w	w	w	w	w	w	w

Field	Bits	Type	Description
RESRXPND, SETRXPND	0, 16	w	**Reset/Set Receive Pending** These bits control the set/reset condition for RXPND (see **Table 24-11**).
RESTXPND, SETTXPND	1, 17	w	**Reset/Set Transmit Pending** These bits control the set/reset condition for TXPND (see **Table 24-11**).
RESRXUPD, SETRXUPD	2, 18	w	**Reset/Set Receive Updating** These bits control the set/reset condition for RXUPD (see **Table 24-11**).
RESNEWDAT, SETNEWDAT	3, 19	w	**Reset/Set New Data** These bits control the set/reset condition for NEWDAT (see **Table 24-11**).

Field	Bits	Type	Description
RESMSGLST, SETMSGLST	4, 20	w	**Reset/Set Message Lost** These bits control the set/reset condition for MSGLST (see **Table 24-11**).
RESMSGVAL, SETMSGVAL	5, 21	w	**Reset/Set Message Valid** These bits control the set/reset condition for MSGVAL (see **Table 24-11**).
RESRTSEL, SETRTSEL	6, 22	w	**Reset/Set Receive/Transmit Selected** These bits control the set/reset condition for RTSEL (see **Table 24-11**).
RESRXEN, SETRXEN	7, 23	w	**Reset/Set Receive Enable** These bits control the set/reset condition for RXEN (see **Table 24-11**).
RESTXRQ, SETTXRQ	8, 24	w	**Reset/Set Transmit Request** These bits control the set/reset condition for TXRQ (see **Table 24-11**).
RESTXEN0, SETTXEN0	9, 25	w	**Reset/Set Transmit Enable 0** These bits control the set/reset condition for TXEN0 (see **Table 24-11**).
RESTXEN1, SETTXEN1	10, 26	w	**Reset/Set Transmit Enable 1** These bits control the set/reset condition for TXEN1 (see **Table 24-11**).
RESDIR, SETDIR	11, 27	w	**Reset/Set Message Direction** These bits control the set/reset condition for DIR (see **Table 24-11**).
0	[15:12], [31:28]	w	**Reserved** Should be written with 0.

Table 24-11 Reset/Set Conditions for Bits in Register MOCTRn

RESy Bit[1)]	SETy Bit	Action on Write
Write 0	Write 0	Leave element unchanged
	No write	
No write	Write 0	
Write 1	Write 1	

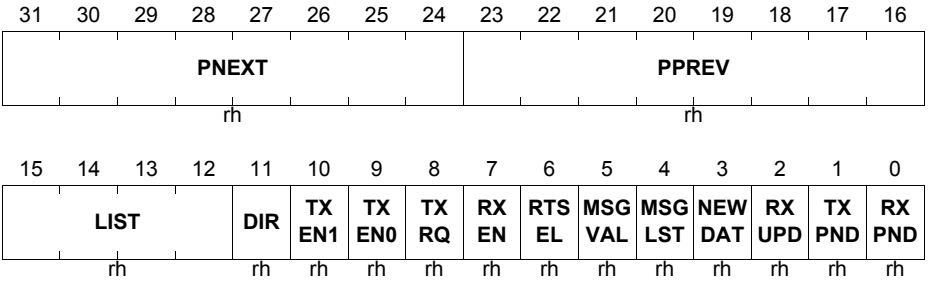
Table 24-11 Reset/Set Conditions for Bits in Register MOCTRn (cont'd)

RESy Bit[1)]	SETy Bit	Action on Write
Write 1	Write 0	Reset element
	No write	
Write 0	Write 1	Set element
No write		

1) The parameter "y" stands for the second part of the bit name ("RXPND", "TXPND", … up to "DIR").

The MOSTATn is a read-only register that indicates message object list status information such as the number of the current message object predecessor and successor message object, as well as the list number to which the message object is assigned.

MOSTAT0
Message Object 0 Status Register ($101C_H$) Reset Value: $0100\ 0000_H$
MOSTAT127
Message Object 127 Status Register ($1FFC_H$) Reset Value: $7F7E\ 0000_H$
MOSTATn (n = 1-126)
Message Object n Status Register
($101C_H+n*20_H$)
Rest Value: $((n+1)*01000000_H)+((n-1)*00010000_H)$



Field	Bits	Type	Description
RXPND	0	rh	**Receive Pending** 0_B No CAN message has been received. 1_B A CAN message has been received by the message object n, either directly or via gateway copy action. RXPND is not reset by hardware but must be reset by software.
TXPND	1	rh	**Transmit Pending** 0_B No CAN message has been transmitted. 1_B A CAN message from message object n has been transmitted successfully over the CAN bus. TXPND is reset by hardware but must be reset by software.

Field	Bits	Type	Description
RXUPD	2	rh	**Receive Updating** 0_B No receive update ongoing. 1_B Message identifier, DLC, and data of the message object are currently updated.
NEWDAT	3	rh	**New Data** 0_B No update of the message object n since last flag reset. 1_B Message object n has been updated. NEWDAT is set by hardware after a received CAN frame has been stored in message object n. NEWDAT is cleared by hardware when a CAN transmission of message object n has been started. NEWDAT should be set by software after the new transmit data has been stored in message object n to prevent the automatic reset of TXRQ at the end of an ongoing transmission.
MSGLST	4	rh	**Message Lost** 0_B No CAN message is lost. 1_B A CAN message is lost because NEWDAT has become set again when it has already been set.
MSGVAL	5	rh	**Message Valid** 0_B Message object n is not valid. 1_B Message object n is valid. Only a valid message object takes part in CAN transfers.

Field	Bits	Type	Description
RTSEL	6	rh	**Receive/Transmit Selected** 0_B Message object n is not selected for receive or transmit operation. 1_B Message object n is selected for receive or transmit operation. **Frame Reception:** RTSEL is set by hardware when message object n has been identified for storage of a CAN frame that is currently received. Before a received frame becomes finally stored in message object n, a check is performed to determine if RTSEL is set. Thus the CPU can suppress a scheduled frame delivery to this message object n by clearing RTSEL by software. **Frame Transmission:** RTSEL is set by hardware when message object n has been identified to be transmitted next. A check is performed to determine if RTSEL is still set before message object n is actually set up for transmission and bit NEWDAT is cleared. It is also checked that RTSEL is still set before its message object n is verified due to the successful transmission of a frame. RTSEL needs to be checked only when the context of message object n changes, and a conflict with an ongoing frame transfer shall be avoided. In all other cases, RTSEL can be ignored. RTSEL has no impact on message acceptance filtering. RTSEL is not cleared by hardware.
RXEN	7	rh	**Receive Enable** 0_B Message object n is not enabled for frame reception. 1_B Message object n is enabled for frame reception. RXEN is evaluated for receive acceptance filtering only.

Field	Bits	Type	Description
TXRQ	8	rh	**Transmit Request** 0_B No transmission of message object n is requested. 1_B Transmission of message object n on the CAN bus is requested. The transmit request becomes valid only if TXRQ, TXEN0, TXEN1 and MSGVAL are set. TXRQ is set by hardware if a matching Remote Frame has been received correctly. TXRQ is reset by hardware if message object n has been transmitted successfully and NEWDAT is not set again by software.
TXEN0	9	rh	**Transmit Enable 0** 0_B Message object n is not enabled for frame transmission. 1_B Message object n is enabled for frame transmission. Message object n can be transmitted only if both bits, TXEN0 and TXEN1, are set. The user may clear TXEN0 in order to inhibit the transmission of a message that is currently updated, or to disable automatic response of Remote Frames.
TXEN1	10	rh	**Transmit Enable 1** 0_B Message object n is not enabled for frame transmission. 1_B Message object n is enabled for frame transmission. Message object n can be transmitted only if both bits, TXEN0 and TXEN1, are set. TXEN1 is used by the MultiCAN module for selecting the active message object in the Transmit FIFOs.

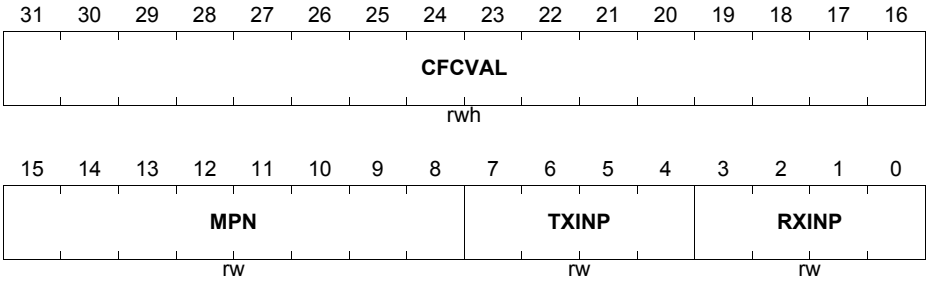
Field	Bits	Type	Description
DIR	11	rh	**Message Direction** 0_B Receive Object selected: With TXRQ = 1, a Remote Frame with the identifier of message object n is scheduled for transmission. On reception of a Data Frame with matching identifier, the message is stored in message object n. 1_B Transmit Object selected: If TXRQ = 1, message object n is scheduled for transmission of a Data Frame. On reception of a Remote Frame with matching identifier, bit TXRQ is set.
LIST	[15:12]	rh	**List Allocation** LIST indicates the number of the message list to which message object n is allocated. LIST is updated by hardware when the list allocation of the object is modified by a panel command.
PPREV	[23:16]	rh	**Pointer to Previous Message Object** PPREV holds the message object number of the previous message object in a message list structure.
PNEXT	[31:24]	rh	**Pointer to Next Message Object** PNEXT holds the message object number of the next message object in a message list structure.

Table 24-12 MOSTATn Reset Values

Message Object	PNEXT	PPREV	Reset Value
0	1	0	$0100\ 0000_H$
1	2	0	$0200\ 0000_H$
2	3	1	$0301\ 0000_H$
3	4	2	$0402\ 0000_H$
…	…	…	…
60	61	59	$3D3B\ 0000_H$
61	62	60	$3E3C\ 0000_H$
62	63	61	$3F3D\ 0000_H$
63	63	62	$3F3E\ 0000_H$

The Message Object Interrupt Pointer Register MOIPRn holds the message interrupt pointers, the message pending number, and the frame counter value of message object n.

MOIPRn (n = 0-127)
Message Object n Interrupt Pointer Register
(1008_H+n*20_H) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
RXINP	[3:0]	rw	**Receive Interrupt Node Pointer** RXINP selects the interrupt output line INT_Om (m = 0-15) for a receive interrupt event of message object n. RXINP can also be taken for message pending bit selection (see **Page 24-44**). 0000_B Interrupt output line INT_O0 is selected. 0001_B Interrupt output line INT_O1 is selected. …$_B$ … 1110_B Interrupt output line INT_O14 is selected. 1111_B Interrupt output line INT_O15 is selected.
TXINP	[7:4]	rw	**Transmit Interrupt Node Pointer** TXINP selects the interrupt output line INT_Om (m = 0-15) for a transmit interrupt event of message object n. TXINP can also be taken for message pending bit selection (see **Page 24-44**). 0000_B Interrupt output line INT_O0 is selected. 0001_B Interrupt output line INT_O1 is selected. …$_B$ … 1110_B Interrupt output line INT_O14 is selected. 1111_B Interrupt output line INT_O15 is selected.

Field	Bits	Type	Description
MPN	[15:8]	rw	**Message Pending Number** This bit field selects the bit position of the bit in the Message Pending Register that is set upon a message object n receive/transmit interrupt.
CFCVAL	[31:16]	rwh	**CAN Frame Counter Value** When a message is stored in message object n or message object n has been successfully transmitted, the CAN frame counter value NFCRx.CFC is then copied to CFCVAL.

The Message Object Function Control Register MOFCRn contains bits that select and configure the function of the message object. It also holds the CAN data length code.

MOFCRn (n = 0-127)
Message Object n Function Control Register

rw				rw	rw	rw	rw	rw				rw			

Field	Bits	Type	Description
MMC	[3:0]	rw	**Message Mode Control** MMC controls the message mode of message object n. 0000_B Standard Message Object 0001_B Receive FIFO Base Object 0010_B Transmit FIFO Base Object 0011_B Transmit FIFO Slave Object 0100_B Gateway Source Object $..._B$ Reserved
GDFS	8	rw	**Gateway Data Frame Send** 0_B TXRQ is unchanged in the destination object. 1_B TXRQ is set in the gateway destination object after the internal transfer from the gateway source to the gateway destination object. Applicable only to a gateway source object; ignored in other nodes.

Field	Bits	Type	Description
IDC	9	rw	**Identifier Copy** 0_B The identifier of the gateway source object is not copied. 1_B The identifier of the gateway source object (after storing the received frame in the source) is copied to the gateway destination object. Applicable only to a gateway source object; ignored in other nodes.
DLCC	10	rw	**Data Length Code Copy** 0_B Data length code is not copied. 1_B Data length code of the gateway source object (after storing the received frame in the source) is copied to the gateway destination object. Applicable only to a gateway source object; ignored in other nodes.
DATC	11	rw	**Data Copy** 0_B Data fields are not copied. 1_B Data fields in registers MODATALn and MODATAHn of the gateway source object (after storing the received frame in the source) are copied to the gateway destination. Applicable only to a gateway source object; ignored in other nodes.
RXIE	16	rw	**Receive Interrupt Enable** RXIE enables the message receive interrupt of message object n. This interrupt is generated after reception of a CAN message (independent of whether the CAN message is received directly or indirectly via a gateway action). 0_B Message receive interrupt is disabled. 1_B Message receive interrupt is enabled. Bit field MOIPRn.RXINP selects the interrupt output line which becomes activated at this type of interrupt.

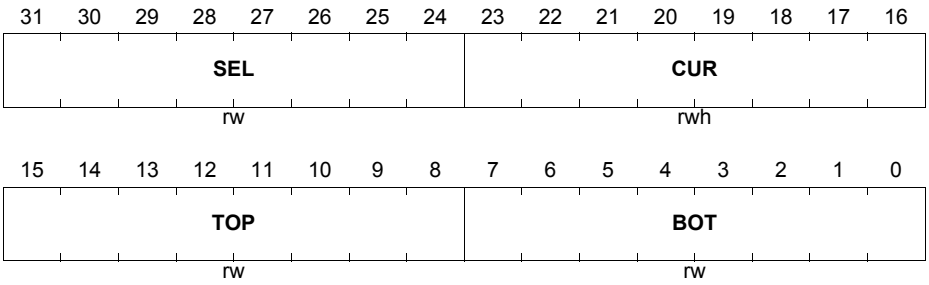
Field	Bits	Type	Description
TXIE	17	rw	**Transmit Interrupt Enable** TXIE enables the message transmit interrupt of message object n. This interrupt is generated after the transmission of a CAN message. 0_B Message transmit interrupt is disabled. 1_B Message transmit interrupt is enabled. Bit field MOIPRn.TXINP selects the interrupt output line which becomes activated at this type of interrupt.
OVIE	18	rw	**Overflow Interrupt Enable** OVIE enables the FIFO full interrupt of message object n. This interrupt is generated when the pointer to the current message object (CUR) reaches the value of SEL in the FIFO/Gateway Pointer Register. 0_B FIFO full interrupt is disabled. 1_B FIFO full interrupt is enabled. If message object n is a Receive FIFO base object, bit field MOIPRn.TXINP selects the interrupt output line which becomes activated at this type of interrupt. If message object n is a Transmit FIFO base object, bit field MOIPRn.RXINP selects the interrupt output line which becomes activated at this type of interrupt. For all other message object modes, bit OVIE has no effect.
FRREN	20	rw	**Foreign Remote Request Enable** Specifies whether the TXRQ bit is set in message object n or in a foreign message object referenced by the pointer CUR. 0_B TXRQ of message object n is set on reception of a matching Remote Frame. 1_B TXRQ of the message object referenced by the pointer CUR is set on reception of a matching Remote Frame.

Field	Bits	Type	Description
RMM	21	rw	**Transmit Object Remote Monitoring** 0_B Remote monitoring is disabled: Identifier, IDE bit, and DLC of message object n remain unchanged upon the reception of a matching Remote Frame. 1_B Remote monitoring is enabled: Identifier, IDE bit, and DLC of a matching Remote Frame are copied to transmit object n in order to monitor incoming Remote Frames. Bit RMM applies only to transmit objects and has no effect on receive objects.
SDT	22	rw	**Single Data Transfer** If SDT = 1 and message object n is not a FIFO base object, then MSGVAL is reset when this object has taken part in a successful data transfer (receive or transmit). If SDT = 1 and message object n is a FIFO base object, then MSGVAL is reset when the pointer to the current object CUR reaches the value of SEL in the FIFO/Gateway Pointer Register. With SDT = 0, bit MSGVAL is not affected.
STT	23	rw	**Single Transmit Trial** If this bit is set, then TXRQ is cleared on transmission start of message object n. Thus, no transmission retry is performed in case of transmission failure.
DLC	[27:24]	rwh	**Data Length Code** Bit field determines the number of data bytes for message object n. Valid values for DLC are 0 to 8. A value of DLC > 8 results in a data length of 8 data bytes. If a frame with DLC > 8 is received, the received value is stored in the message object.

Field	Bits	Type	Description
MSC	[31:28]	rwh	**Message Status Count (TTCAN only)** MSC can have values between 0000_B and 0111_B. An increment of MSC = 0111_B results in MSC = 0111_B (no overflow). A decrement of MSC = 0000_B results in MSC = 0000_B (no underflow). **Transmission:** When message object n is scheduled for transmission in an exclusive time window and the transmission is successful within this time window and the TTCAN is in error state S0 or S1, MSC is decremented by one. If the transmission fails, bit field MSC is incremented by one. If the TTCAN is in error state S2 and detects CAN bus-idle during the transmit enable window for message object n, MSC is decremented by one (although this message object is not transmitted). **Reception:** When message object n is scheduled for reception in an exclusive time window and the reception is successful within this time window, MSC is decremented by one. If the reception does not take place within this time window, MSC is incremented by one. If TTCAN function is not available/enabled, bit field MSC is unchanged.
0	[7:4], [15:12], 19	rw	**Reserved** Read as 0 after reset; value last written is read back; should be written with 0.

The Message Object FIFO/Gateway Pointer register MOFGPRn contains a set of message object link pointers that are used for FIFO and gateway operations.

MOFGPRn (n = 0-127)
Message Object n FIFO/Gateway Pointer Register
(1004_H+n*20_H) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
BOT	[7:0]	rw	**Bottom Pointer** Bit field BOT points to the first element in a FIFO structure.
TOP	[15:8]	rw	**Top Pointer** Bit field TOP points to the last element in a FIFO structure.
CUR	[23:16]	rwh	**Current Object Pointer** Bit field CUR points to the actual target object within a FIFO/Gateway structure. After a FIFO/gateway operation CUR is updated with the message number of the next message object in the list structure (given by PNEXT of the message control register) until it reaches the FIFO top element (given by TOP) when it is reset to the bottom element (given by BOT).
SEL	[31:24]	rw	**Object Select Pointer** Bit field SEL is the second (software) pointer to complement the hardware pointer CUR in the FIFO structure. SEL is used for monitoring purposes (FIFO interrupt generation).

Message Object n Acceptance Mask Register MOAMRn contains the mask bits for the acceptance filtering of the message object n.

MOAMRn (n = 0-127)
Message Object n Acceptance Mask Register

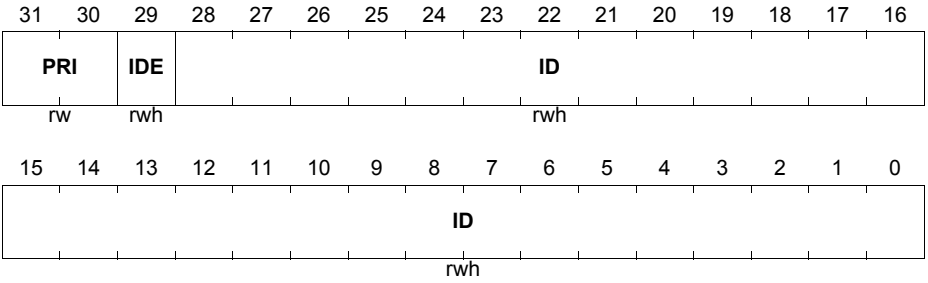
Field	Bits	Type	Description
AM	[28:0]	rw	**Acceptance Mask for Message Identifier** Bit field AM is the 29-bit mask for filtering incoming messages with standard identifiers (AM[28:18]) or extended identifiers (AM[28:0]). For standard identifiers, bits AM[17:0] are “don’t care”. For TTC based transmit acceptance filtering (MOARn.PRI = 00_B) register MOAMRn is used to specify the transmit column/row in which this message object may be transmitted in a time-triggered communication. It is then no longer used as an identifier mask. This means that all identifier bits are used for receive acceptance filtering. In this case AMR contains the following information: • MOAMR[5:0] = CYCLE • MOAMR[13:8] = MCYCLE • MOAMR[21:16] = COLUMN • MOAMR[29:24] = MCOLUMN where CYCLE is the cycle count (transmit row) and COLUMN is the transmission column of the system matrix. MCYCLE and MCOLUMN are acceptance masks for matching CYCLE and COLUMN against the actual position within the system matrix of the time-triggered communication network. Message object n may be transmitted only if CYCLE and COLUMN match the actual matrix position (given by CYCTMR.BCC and CYCTMR.CSM). If more than one object with valid transmit request matches a given matrix position, the actually transmitted message object is chosen by list order.
MIDE	29	rw	**Acceptance Mask Bit for Message IDE Bit** 0_B Message object n accepts the reception of both, standard and extended frames. 1_B Message object n receives frames only with matching IDE bit.
0	[31:30]	rw	**Reserved** Read as 0 after reset; value last written is read back; should be written with 0.

Message Object n Arbitration Register MOARn contains the CAN identifier of the message object.

MOARn (n = 0-127)
Message Object n Arbitration Register
(1018_H+n*20_H) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
ID	[28:0]	rwh	**CAN Identifier of Message Object n** Identifier of a standard message (ID[28:18]) or an extended message (ID[28:0]). For standard identifiers, bits ID[17:0] are “don’t care”.
IDE	29	rwh	**Identifier Extension Bit of Message Object n** 0_B Message object n handles standard frames with 11-bit identifier. 1_B Message object n handles extended frames with 29-bit identifier.

Field	Bits	Type	Description
PRI	[31:30]	rw	**Priority Class** PRI assigns one of the four priority classes 0, 1, 2, 3 to message object n. A lower PRI number defines a higher priority. Message objects with lower PRI value always win acceptance filtering for frame reception and transmission over message objects with higher PRI value. Acceptance filtering based on identifier/mask and list position is performed only between message objects of the same priority class. PRI also determines the acceptance filtering method for transmission: 00_B Time-Triggered CAN (TTCAN): The Message Object Mask Register specifies the position(s) within the transmission matrix at which the message object n may be transmitted. Transmit acceptance filtering is based on the list order. This means that message object n is considered for transmission only if there is no other message object with valid transmit request (MSGVAL & TXEN0 & TXEN1 = 1) that matches the actual position within the transmission matrix somewhere before this object in the list. 01_B Transmit acceptance filtering is based on the list order. This means that message object n is considered for transmission only if there is no other message object with valid transmit request (MSGVAL & TXEN0 & TXEN1 = 1) somewhere before this object in the list. 10_B Transmit acceptance filtering is based on the CAN identifier. This means, message object n is considered for transmission only if there is no other message object with higher priority identifier + IDE + DIR (with respect to CAN arbitration rules) somewhere in the list (see **Table 24-13**). 11_B Transmit acceptance filtering is based on the list order (as PRI = 01_B).

Transmit Priority of Msg. Objects based on CAN Arbitration Rules

Table 24-13 Transmit Priority of Msg. Objects Based on CAN Arbitration Rules

Settings of Arbitrarily Chosen Message Objects A and B, (A has higher transmit priority than B)	Comment
A.MOAR[28:18] < B.MOAR[28:18] (11-bit standard identifier of A less than 11-bit standard identifier of B)	Messages with lower standard identifier have higher priority than messages with higher standard identifier. MOAR[28] is the most significant bit (MSB) of the standard identifier. MOAR[18] is the least significant bit of the standard identifier.
A.MOAR[28:18] = B.MOAR[28:18] A.MOAR.IDE = 0 (send Standard Frame) B.MOAR.IDE = 1 (send Extended Frame)	Standard Frames have higher transmit priority than Extended Frames with equal standard identifier.
A.MOAR[28:18] = B.MOAR[28:18] A.MOAR.IDE = B.MOAR.IDE = 0 A.MOCTR.DIR = 1 (send Data Frame) B.MOCTR.DIR = 0 (send Remote Fame)	Standard Data Frames have higher transmit priority than standard Remote Frames with equal identifier.
A.MOAR[28:0] = B.MOAR[28:0] A.MOAR.IDE = B.MOAR.IDE = 1 A.MOCTR.DIR = 1 (send Data Frame) B.MOCTR.DIR = 0 (send Remote Frame)	Extended Data Frames have higher transmit priority than Extended Remote Frames with equal identifier.
A.MOAR[28:0] < B.MOAR[28:0] A.MOAR.IDE = B.MOAR.IDE = 1 (29-bit identifier)	Extended Frames with lower identifier have higher transmit priority than Extended Frames with higher identifier. MOAR[28] is the most significant bit (MSB) of the overall identifier (standard identifier MOAR[28:18] and identifier extension MOAR[17:0]). MOAR[0] is the least significant bit (LSB) of the overall identifier.

Message Object n Data Register Low MODATALn contains the lowest four data bytes of message object n. Unused data bytes are set to zero upon reception and ignored for transmission.

MODATALn (n = 0-127)

24.7 Time-Triggered Extension (TTCAN Controller)

24.7.1 Generation of the Local Time

The Nominal Time Unit (NTU) of the TTCAN controller is generated by the NTU timer with a clock derived from the fractional divider (an NTU timer action takes place with t_q or with a multiple of $1/f_{CAN}$). The sum of the NTU is the local time LT, which is a 16-bit value (to be considered as integer number) and a fractional part LTFR.

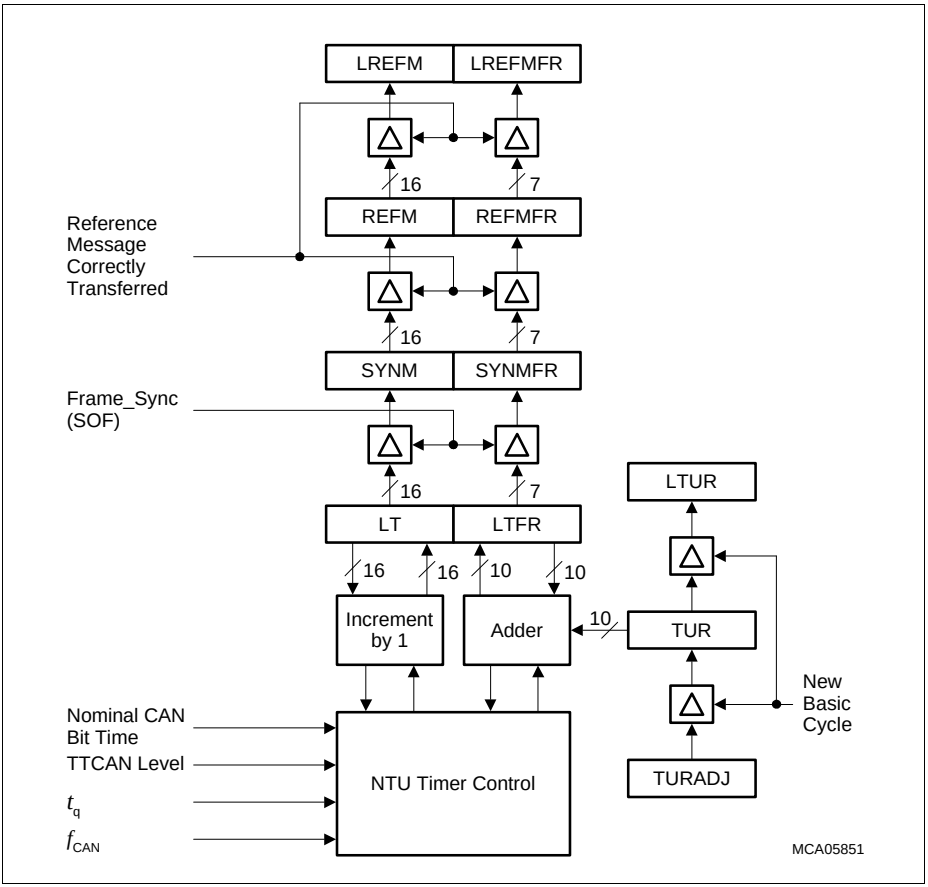

Figure 24-26 Generation of the Local Time

Note: Register LTUR is used for the internal automatic calculation of the new TURADJ value. It is not visible for the user.

In TTCAN level 1, the LT counter is incremented once per CAN bit time. The fractional part LTFR of the local time and the TUR are not taken into account.
In TTCAN level 2, the LT is extended by its fractional part LTFR. The TUR value is added to the LTFR value with the update period t_{upd} in order to generate a new LT value. If an overflow occurs (carry active) after an addition of LTFR and TUR, the value of LT is incremented by 1. As a result, the value of LT can change only in steps of 1, whereas the value of LTFR changes in steps of TUR.

In order to cover a wide range of CAN baud rates with the same counting range of the local timer, the counting can take place every CAN time quantum t_q ($t_{upd} = t_q$). If another resolution of the NTU is desired, the local time generation can also be based on the clock f_{CAN}, divided by a programmable factor that is independent from the CAN bit timing.

After the update period t_{upd} has elapsed N times, the difference in local time dt has elapsed to: dt = TURR.TUR/1024 $\times$ N $\times$ t_{upd}.

24.7.2 Automatic TUR Adjust

It is possible to automatically calculate the new value written to TURADJ for adjusting the correct value for the local time on TTCAN level 2. Each time a new reference message is correctly received, the difference is calculated between the time values in the reference message (GMR) and the previous reference message (LGMR). This difference, divided by the amount of own NTUs for a complete basic cycle multiplied by LTUR, provides the TURADJ value (including fractional parts).

TURADJ = LTUR $\times$ (GM - LGM) / (REFM - LREFM)

The automatic TUR adjust is not made when a discontinuity has been signaled between the reference messages. The automatic calculation of the new value for TURADJ takes place during the basic cycle.

The value of TUR is updated at the beginning of each basic cycle. The new value that is written to TUR to adjust the timing is stored in the bit field TURADJ.

24.7.3 Cycle Time

The cycle time is always positive and represents the time elapsed in the current basic cycle, starting from 0.

24.7.3.1 Local Time and Synchronization Marks

The cycle time is the difference between the local time (stored in bit field LT) and its last reference mark (stored in bit field REFM). The result is available in the bit field CYCTM. The value of the local time LT is captured at the start of each message as a synchronization mark SYNM. If the correctly received message has been a reference

message, the captured value becomes the reference mark REFM. The REFM value of the previous reference mark is stored in LREFM.

The cycle time is still incremented while the reference message is received. After the end of the correctly received reference message, the cycle time takes the value corresponding to the length of this reference message. As a result, the cycle time seems to start from zero each time a reference message starts (= with each new basic cycle).

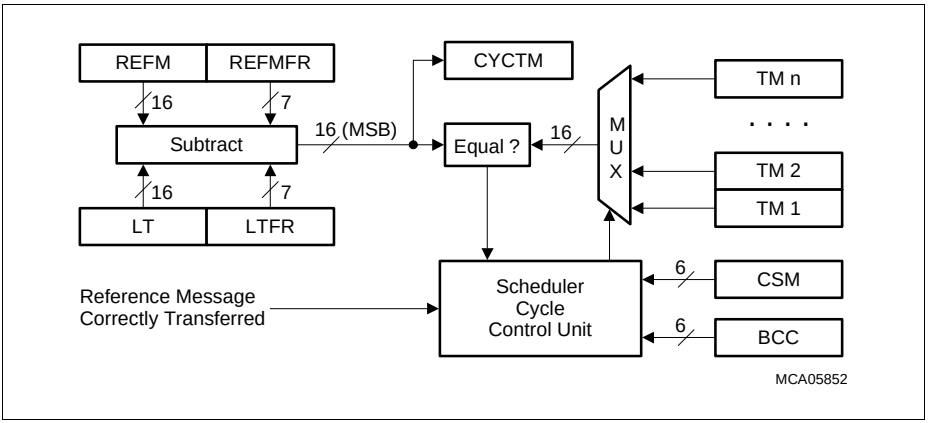

Figure 24-27 Generation of the Cycle Time

The cycle control unit also delivers the values for the basic cycle and matrix cycle handling, and provides the possibility to generate an interrupt if a new basic cycle has started or a new matrix cycle has started. If the TTCAN node receives a reference message, the value for BCC is taken from the reference message.

24.7.3.2 Time Marks

Each time a reference message is received correctly, the cycle control unit starts again comparing the cycle time to the first time mark (TM 1). If one time mark is reached, it continues with the next one. In order to be able to do an “equal-to” comparison, the time marks have to be programmed in increasing order and the first time mark must not be lower than the maximum length of the reference message plus 5 bit times.
The cycle time is used to determine the different columns of the system matrix (CSM = column of the system matrix). These columns are defined by the time marks. These time marks can be programmed and are valid for all columns of the system matrix.
The cycle control unit also checks the number of the current basic cycle that is indicated by the basic cycle count BCC. The value of BCC and the value of CSM, taken together, clearly identify each time window in the matrix cycle.

In master mode, the value BCC is transmitted as part of the reference message.

24.7.3.3 Watch Trigger

The watch trigger is used to check if the elapsed time since the last reference message was received is too long. This is done by comparing the programmed watch trigger value to the cycle time. This information can generate an interrupt to the system. The watch trigger value is defined by the scheduler entry for the end of the basic cycle.

24.7.4 Master Reference Mark (Level 2 only)

The time master sends the sum of its reference mark SYNM (integer part) and SYNMFR (fractional part) and its local offset LOF (integer part) and LOFFR (fractional part) as master reference mark (MRM), which is stored in the global mark register GMR.
If the master's clock or its local time has been corrected and a discontinuity has been introduced, the discontinuity bit DISC is automatically set until the next reference message is started. The discontinuity bit is set if a write access to LOF or LOFFR occurs. As a result, the reference message will contain the new reference mark and the discontinuity bit DISC set for the current time master.

24.7.5 Transmit Enable Window

The transmit enable window determines the number of CAN bit times that may elapse between the transmit trigger event (time marks in the scheduler) and the real start of the message on the bus. If this time expires without starting the transmission of the triggered message, no new transmission attempt will be made in this time window (if it was an exclusive one or a short arbitration one). The transmit trigger is deleted and an interrupt may be generated. If the time window is a long, merged arbitration window, the transmit enable window is not taken into account.

24.7.6 Local Offset and Global Time

On TTCAN level 2, the local offset of a TTCAN node (not of the time master) is defined as the difference between the Master_Ref_Mark (also named Global_Ref_Mark) and the node's reference mark Ref_Mark. For the time master, the sum of the local time and the local offset is stored as Global_Sync_Mark when the frame synchronization is reached. The Global_Sync_Mark (for the time master) and the Global_Ref_Mark (for all other nodes) are stored in the Global Mark Register GMR. The Local_Offset is stored in the local offset register LOR.

When a TTCAN node receives a reference message, the global mark register is updated by the received value. The value that has been received in the previous reference message is automatically transferred from the global mark register to the last global mark register. The difference between these two values represents the time elapsed between the last two reference messages from the time master's point of view.

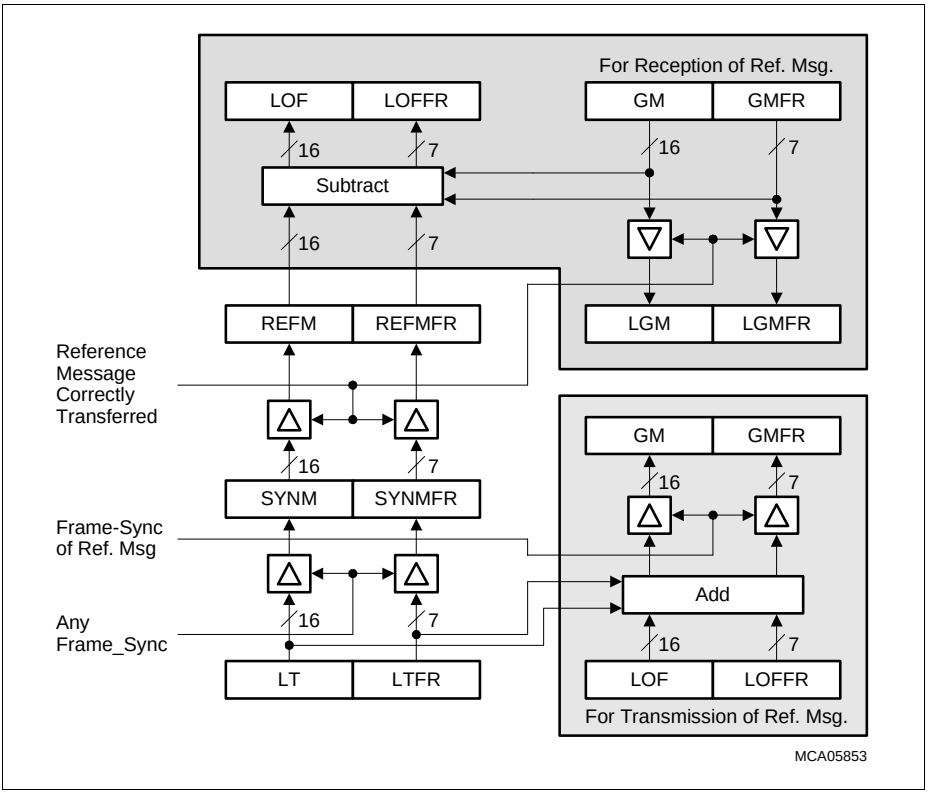

Figure 24-28 Local Offset and Global Time

Due to possible variations of the LOF values from one reference mark to the other, the current global time may contain discontinuities. In order to get a smooth (continuous) behavior, a SW filter can be used for receiving nodes. The global time can be calculated as shown below:

- Local Time + Local Offset or
- Cycle Time + Reference Mark + Local Offset

24.7.7 Transmit Trigger

The TTCAN feature of a CAN node implies the counting of transmission requests for messages to be sent in exclusive time windows. The number of messages to be transmitted in exclusive time windows is defined by system application design for the entire system matrix (expected transmit triggers EXPTT). This theoretical value is used to verify if the real TTCAN node also requests the same amount of transmissions. If fewer or more transmit triggers have been counted by the transmit trigger counter TTCNT at the end of a system matrix, a transmit trigger error interrupt can be generated (if enabled by TTIEN). This is indicated by the bits transmit trigger underflow TTUF and transmit trigger overflow TTOF.

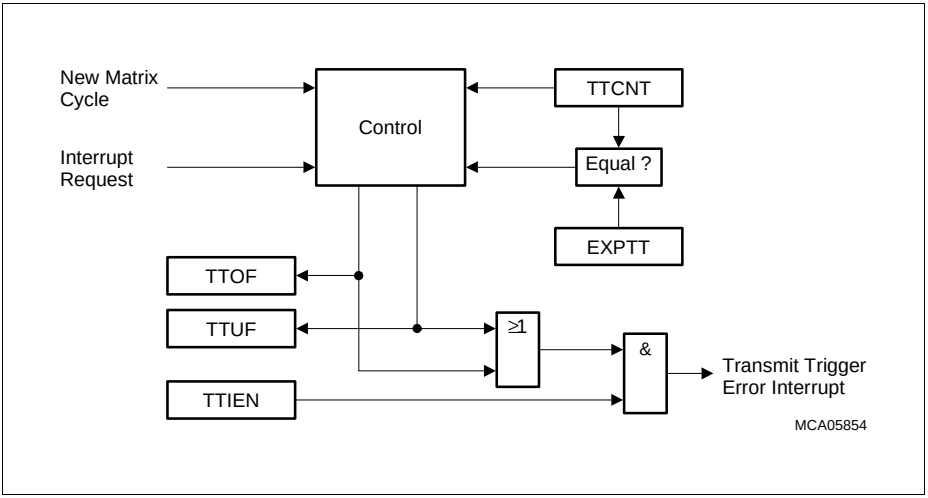

Figure 24-29 Transmit Trigger Monitoring

24.7.8 Reference Message

The reference message object has a special role in the TTCAN system. It is the first entry in the message object list for the TTCAN node (node 0 in the TC1798).

24.7.8.1 Differences to Normal CAN Messages

There are several differences between the behavior of a reference message and a normal CAN message:

- If a reference message is disturbed by an error during transmission, it is retransmitted immediately.
- If a reference message loses arbitration, it is not retransmitted, but the message on the bus is received (arbitration of potential time masters).
- For reception, no identifier bits (except the 3 least significant bits ID[2:0]) use an acceptance mask (must be set by software). The entire identifier of the latest correct reference message on the bus is stored in the reference message object.
- For reception, the 3 least significant bits of the identifier always use the acceptance mask 000_B (must be set by software).
- Its transmission request, indicated by the flag TTSR.REFTRG, is related only to a reference time mark or to an external event (for synchronization). If a correct reference message is received while REFTRG is set, REFTRG is automatically cleared.
- For transmission, the identifier bits of the reference message object are taken, except the 3 least significant bits (ID[2:0]). They are taken from the bit field TMCR.TMPRIO.
- The corresponding parts of its eight data bytes are directly connected to the TTCAN internal values (cycle_count, master_ref_mark, etc.) according to the selected level of the TTCAN protocol. The remaining bytes are available for free use.
- The DLC of a reference message to be sent out is determined by the bit field TTCR.RMDLC. This bit field must be at least 1 in TTCAN level 1 and at least 4 in TTCAN level 2.

A reference message object is used by a time master, a potential time master, and a receiving device (not a time master).

The reference message object must be initialized as a receive object (but the transmission of this object leads to the reference frame). This is due to the fact that the reception of a reference message is determined by the normal receive acceptance filtering, whereas the transmission is a specific action, triggered by the TTCAN extension.

Reference messages can also be transmitted by time masters that are in S2 error state or after the Init_Watch_Trigger has been reached.

24.7.8.2 Transmit Trigger for a Reference Message

The transmission of a reference message can be triggered by a time mark or by an external event. If it is triggered by a time mark, the “Next is Gap” bit (TTSR.NIG) of the previous reference message has been 0. If it is triggered by an external event, the “Next is Gap” bit of the previous reference message has been 1.

The software can set bit TTSR.NIG in order to initiate the synchronization of a reference message to an event. This event can be an edge at an external input or a software action (write bit TTFMR.STE = 1, software trigger event).

When TTSR.NIG is set, it will be transmitted with the next reference message in order to indicate the following synchronization gap to the other CAN nodes. The value of TTSR.NIG is copied to bit TTSR.ETR (external trigger request) and cleared automatically when the reference message has been correctly transmitted. Bit TTSR.ETR = 1 indicates that the next reference message will be transferred as soon as the corresponding time mark is reached (respecting the gap), or when the selected trigger event (ETREV) is pending. The evaluation of ETREV is started after the end of the transmit enable window of the last transfer window (valid RME found).

The transmit trigger generation logic for the reference message is shown in **Figure 24-30**. The edge detection for ECTTx contains a synchronization stage.

The trigger event can be selected by bit field ETESEL (external trigger event selection). Only trigger events are taken into account for the transfer of a reference message that have been detected after the start of the current basic cycle.

The synchronization of more than one TTCAN node to other TTCAN nodes can be achieved by setting ETESEL = 00_B. In this case, the trigger of the reference message of TTCAN nodes 0-7 (TRMCx) is used to trigger the transmission of the reference message. As a result, the reference messages can be synchronized between several TTCAN nodes of the MultiCAN/TTCAN. If not all possible TTCAN nodes are implemented, the TRMCx of not implemented nodes are 0.

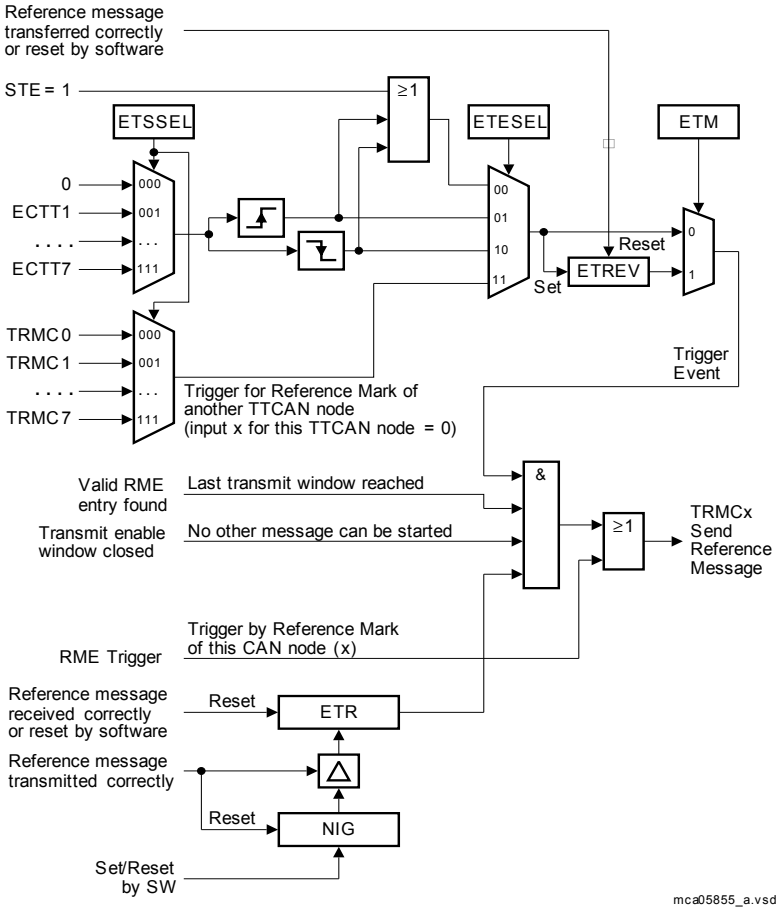

Figure 24-30 External Trigger Generation an Transmit Trigger for the Reference Message

24.8 TTCAN Scheduler

24.8.1 Overview

The message transmission and reception of the time-triggered part TTCAN is controlled by a scheduler mechanism. This scheduler is based on the cycle time and delivers the time marks. The time marks are defined by the time mark entries TMEx. Whenever a time mark is reached, programmable actions (defined by scheduler memory instruction entries INSTRxy) can take place. Typical instructions include, for example, starting the transmission of a message, checking if a message has been received, opening or closing arbitration windows, or generating interrupts.

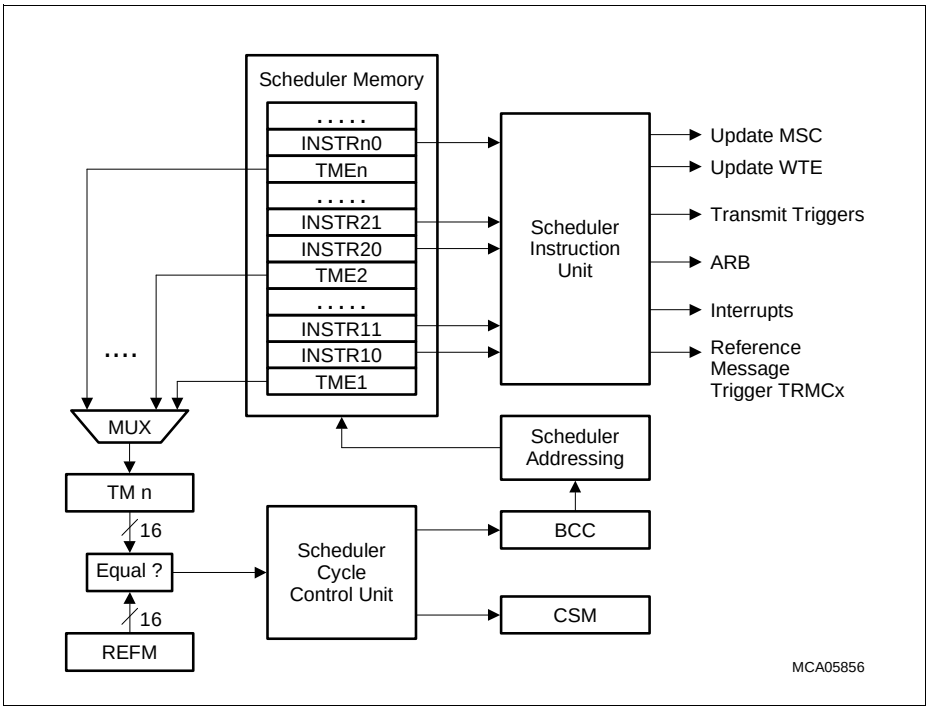

Figure 24-31 Scheduler Overview

The instructions following a time mark are read by the scheduler until the next time mark entry is found. Then, the instruction collection process is stopped until the next time mark is reached.

Note: The time mark values in the scheduler entries must be in increasing order.

24.8.2 Scheduler Memory

The scheduler contains a memory block in which the time mark entries (TMEx) and the scheduler instruction entries (INSTRnx) are stored. Each time mark entry can be followed by a number of scheduler instructions. The scheduler memory is organized as a 32-bit wide memory holding the 32-bit wide time mark entries and the 32-bit wide scheduler instruction entries.

The total number of time mark entries and scheduler instruction entries that can be stored is limited by the size of the scheduler memory. In the TC1798, the scheduler memory has a size of 128 words (32-bits).

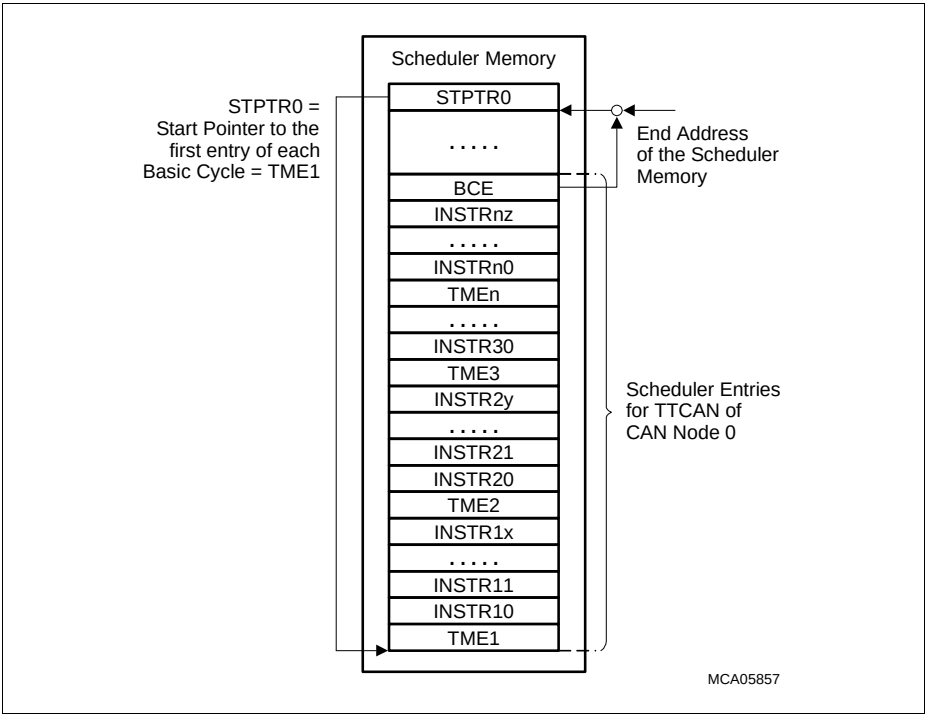

Figure 24-32 TTCAN Scheduler Memory

The last word address of the scheduler memory is reserved for the start pointer STPTR0. The value written at this address determines the start location of the first entry for the TTCAN node (= CAN node 0 in the TC1798). STPTR0 indicates how many 32-bit (word) entries below SPTR0 the first time mark entry (TME1) is located.

When the basic cycle end entry BCE (with GM = 0) is read by the scheduler, it prepares the next scheduler instructions (read from scheduler memory) starting again with TME1.

Therefore, the first entry read after BCE is STPTR0 in order to obtain the address where TME1 is located.

24.8.2.1 Scheduler Entry Types

The scheduler instruction entries are located after the time mark entry. The time mark entry determines the behavior of the TTCAN when the next time mark is reached. The scheduler instructions after the time mark entry are valid for the time mark they follow. The scheduler control reads the time mark entry and sets up the compare action (compare between the new time mark with the cycle time). Then, the scheduler reads the following instructions and sets up the transfer behavior of the TTCAN node. The scheduler stops reading from the scheduler memory when a new time mark entry is found.

The transfer behavior set up can change with each scheduler instruction. There is no built-in consistency check for scheduler instructions. Previously read scheduler instructions can be overwritten by subsequent ones. With each time mark, the settings are cleared and must be set up by new scheduler instructions (if desired).

The complete scheduler information must be finished with a basic cycle end entry that fixes the value for the watch trigger event.

Each entry in the scheduler memory contains a 4-bit wide code field that determines the type of the entry. The possible scheduler memory entry types are listed in **Table 24-14**.

Table 24-14 Scheduler Memory Entry Types

Entry Code EC Bits [31:28]	Short Name	Entry Type	Defined at
0001_B	TME	Time mark entry	see **Page 24-129**
0010_B	ICE	Interrupt control entry	see **Page 24-132**
0011_B	ARBE	Arbitration entry	see **Page 24-134**
0100_B	TCE	Transmit control entry	see **Page 24-136**
0101_B	RCE	Receive control entry	see **Page 24-139**
0110_B	RME	Reference message entry	see **Page 24-141**
0111_B	BCE	Basic cycle end entry	see **Page 24-143**
other combinations	EOS	End of scheduler memory entry	see **Page 24-144**

The general transmit trigger control for the message objects to be transmitted when a time mark is reached is performed by the message objects themselves. In order to increase the flexibility, the result of the acceptance filtering done with the message objects can be overruled by control entries. A reference message can be transmitted only when the TTCAN node is enabled as time master.

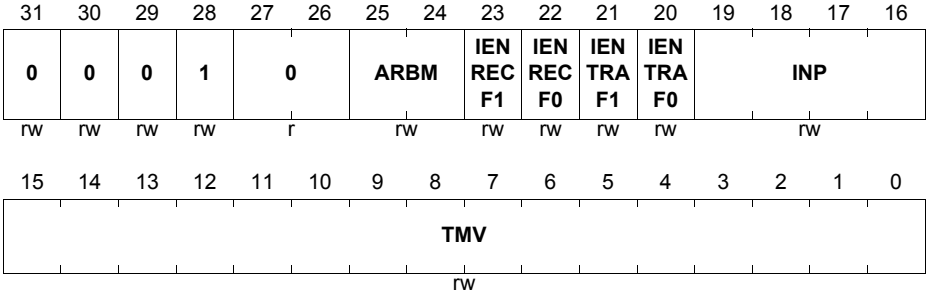
Note: The number of scheduler entries following a time mark should not exceed the number of 10. In order to minimize the required accesses to the scheduler memory by the scheduler control part, the user should set up the system carefully.

24.8.2.2 Scheduler Entry Type Description

Time Mark Entry

A time mark entry is defined as follows:

TME
Time Mark Entry



Field	Bits	Type	Description
TMV[1)]	[15:0]	rw	**Time Mark Value** This bit field determines the compare value used for the next compare action with the cycle time.
INP	[19:16]	rw	**Interrupt Node Pointer** INP selects the interrupt output line INT_Om (m = 0-15) that will be activated when a match is detected between the cycle time and the time mark value defined by TMV and if at least one of the four interrupt conditions is met and enabled. 0000_B Interrupt output line INT_O0 is selected. 0001_B Interrupt output line INT_O1 is selected. $\ldots_B$ … 1110_B Interrupt output line INT_O14 is selected. 1111_B Interrupt output line INT_O15 is selected.

Field	Bits	Type	Description
IENTRAF0	20	rw	**Interrupt Enable if TRAF = 0** This bit enables the generation of an interrupt when bit TTSR.TRAF = 0 and a match is detected between the cycle time and the time mark value defined by TMV. 0_B Interrupt generation is disabled. 1_B Interrupt generation is enabled.
IENTRAF1	21	rw	**Interrupt Enable if TRAF = 1** This bit enables the generation of an interrupt when bit TTSR.TRAF = 1 and a match is detected between the cycle time and the time mark value defined by TMV. 0_B Interrupt generation is disabled. 1_B Interrupt generation is enabled.
IENRECF0	22	rw	**Interrupt Enable if RECF = 0** This bit enables the generation of an interrupt when when bit TTSR.RECF = 0 and a match is detected between the cycle time and the time mark value defined by TMV. 0_B Interrupt generation is disabled. 1_B Interrupt generation is enabled.
IENRECF1	23	rw	**Interrupt Enable if RECF = 1** This bit enables the generation of an interrupt when when bit TTSR.RECF = 1 and a match is detected between the cycle time and the time mark value defined by TMV. 0_B Interrupt generation is disabled. 1_B Interrupt generation is enabled.

Field	Bits	Type	Description
ARBM	[25:24]	rw	**Arbitration Mode** This bit field determines the action that is taken with an arbitration window. 00_B No action taken; the status of the arbitration window is not changed. 01_B A merged (long) arbitration window will be opened. If it is already opened, it is kept open. 10_B A merged (long) transfer window will be closed. Closing a merged transfer window leads to a single (short) arbitration window (transmission possible only during the transmit enable window). The short arbitration window is automatically closed after one time window. If there is no arbitration window open, this entry will be ignored. 11_B A single (short) arbitration window (transmission possible only during the transmit enable window) is opened. A short arbitration window is automatically closed after one time window.
EC	[31:28]	rw	**Entry Code** The entry code EC = 0001_B defines this scheduler memory entry as a time mark entry.
0	[27:26]	r	**Reserved;** read as 0; should be written with 0. Bits are “don’t care” for scheduler operation when EC = 0001_B.

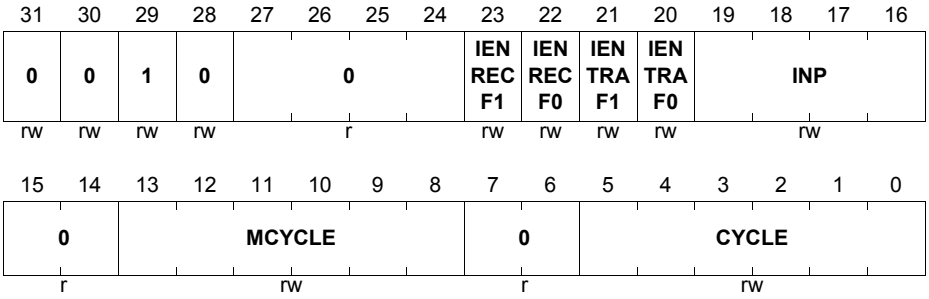
1) In order to be able to detect each time mark correctly, the first time mark of a basic cycle must not be set to a value below the length of the reference message under worst case conditions.

Note: The interrupt settings given by the time mark entry can be overruled by a subsequent valid interrupt control entry. The settings are valid until the next time mark is reached. For the time after the next time mark, the settings read from the next time mark entry become valid.

Interrupt Control Entry

An interrupt control entry is defined as follows:

ICE
Interrupt Control Entry



Field	Bits	Type	Description
CYCLE	[5:0]	rw	**Basic Cycle Number** This bit field determines the number of the basic cycle during which this interrupt control entry is valid. The value of CYCLE is compared (bit-wise) to the current value of the bit field CYCTMR.BCC. The result is then masked with the value given by the bit field MCYCLE in order to determine the repetition rate for this scheduler entry inside the matrix cycle. This bit field is equivalent to the corresponding part of the MOAMRn.AM bit field (see **Page 24-110**).
MCYCLE	[13:8]	rw	**Mask for Cycle Comparison** This bit field determines the mask that is used to determine the repetition rate for this scheduler entry. This bit field is equivalent to the corresponding part of the MOAMRn.AM bit field (see **Page 24-110**).

Field	Bits	Type	Description
INP	[19:16]	rw	**Interrupt Node Pointer** INP selects the interrupt output line INT_Om (m = 0-15) that will be activated when a match is detected between the cycle time and the time mark value defined by TMV and if at least one of the four interrupt conditions is met and enabled. 0000_B Interrupt output line INT_O0 is selected. 0001_B Interrupt output line INT_O1 is selected. … … 1110_B Interrupt output line INT_O14 is selected. 1111_B Interrupt output line INT_O15 is selected.
IENTRAF0	20	rw	**Interrupt Enable if TRAF = 0** This bit enables the generation of an interrupt when a match is detected between the cycle time and the time mark value defined by TMV and bit TRAF = 0. 0_B An interrupt will not be generated. 1_B An interrupt will be generated.
IENTRAF1	21	rw	**Interrupt Enable if TRAF = 1** This bit enables the generation of an interrupt when a match is detected between the cycle time and the time mark value defined by TMV and bit TRAF = 1. 0_B An interrupt will not be generated. 1_B An interrupt will be generated.
IENRECF0	22	rw	**Interrupt Enable if RECF = 0** This bit enables the generation of an interrupt when a match is detected between the cycle time and the time mark value defined by TMV and bit RECF = 0. 0_B An interrupt will not be generated. 1_B An interrupt will be generated.
IENRECF1	23	rw	**Interrupt Enable if RECF = 1** This bit enables the generation of an interrupt when a match is detected between the cycle time and the time mark value defined by TMV and bit RECF = 1. 0_B An interrupt will not be generated. 1_B An interrupt will be generated.
EC	[31:28]	rw	**Entry Code** The entry code EC = 0010_B defines this scheduler memory entry as an interrupt control entry.

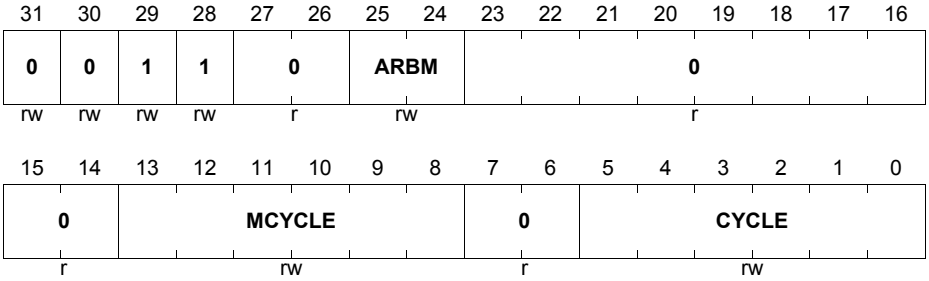
Field	Bits	Type	Description
0	[7:6], [15:14], [27:24]	r	**Reserved;** read as 0; should be written with 0. Bits are “don’t care” for scheduler operation when EC = 0011_B.

Note: The interrupt settings of a valid interrupt control entry overrule the previously stored interrupt settings for the next time mark. As a result, the use of more than one valid interrupt control entry between two time mark entries should be avoided.

Arbitration Entry

The arbitration entry is defined as follows:

ARBE
Arbitration Entry



Field	Bits	Type	Description
CYCLE	[5:0]	rw	**Basic Cycle Number** This bit field determines the number of the basic cycle during which this arbitration entry is valid. The value of CYCLE is compared (bit-wise) with the **current** value of bit field CYCTMR.BCC. The result is then masked with the value given by the bit field MCYCLE in order to determine the repetition rate for this scheduler entry inside the matrix cycle. This bit field is equivalent to the corresponding part of the MOAMRn.AM bit field (see **Page 24-110**).

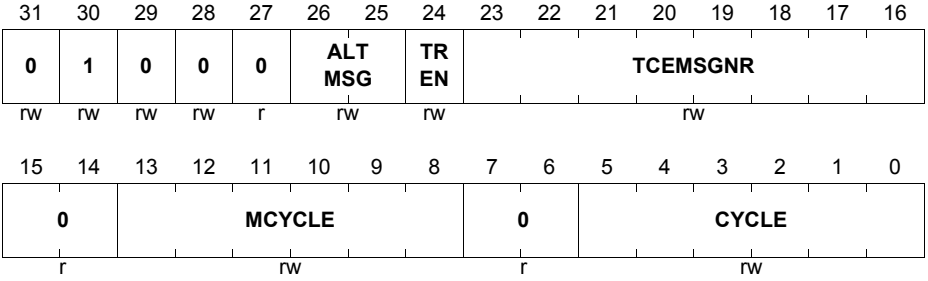
Field	Bits	Type	Description
MCYCLE	[13:8]	rw	**Mask for Cycle Comparison** This bit field determines the mask used to determine the repetition rate for this arbitration entry. This bit field is equivalent to the corresponding part of the MOAMRn.AM bit field (see **Page 24-110**).
ARBM	[25:24]	rw	**Arbitration Mode** This bit field determines the action that is taken with an arbitration window. 00_B No action is taken; the status of the window is not changed. 01_B A merged (long) arbitration window will be opened. If it is already opened, it is kept open. 10_B A merged (long) transfer window will be closed. Closing a merged transfer window leads to a single (short) arbitration window (transmission possible only during the transmit enable window). The short arbitration window is automatically closed after one time window. 11_B A single (short) arbitration window (transmission possible only during the transmit enable window) is opened. A short arbitration window is automatically closed after one time window.
EC	[31:28]	rw	**Entry Code** The entry code EC = 0011_B defines this scheduler memory entry as an arbitration entry.
0	[7:6], [23:14], [27:26]	r	**Reserved;** read as 0; should be written with 0. Bits are “don’t care” for scheduler operation when EC = 0011_B.

Note: The arbitration settings of a valid arbitration entry overrule the previously stored arbitration settings for the next time mark. As a result, the use of more than one valid arbitration entry between two time mark entries should be avoided.

Transmit Control Entry

The transmit control entry is defined as follows:

TCE
Transmit Control Entry



Field	Bits	Type	Description
CYCLE	[5:0]	rw	**Basic Cycle Number** This bit field determines the number of the basic cycle during which this transmit control entry is valid. The value of CYCLE is compared (bit-wise) to the current value of the bit field CYCTMR.BCC. The result is then masked with the value given by the bit field MCYCLE in order to determine the repetition rate for this transmit control entry inside the matrix cycle. This bit field is equivalent to the corresponding part of the MOAMRn.AM bit field (see **Page 24-110**).
MCYCLE	[13:8]	rw	**Mask for Cycle Comparison** This bit field determines the mask that is used to determine the repetition rate for this transmit control entry. This bit field is equivalent to the corresponding part of the MOAMRn.AM bit field (see **Page 24-110**).

Field	Bits	Type	Description
TCEMSGNR	[23:16]	rw	**TCE Message Number** This bit field determines the number of the message object to be transmitted when the next time mark is reached. The object will be transferred only if it is tagged valid for transmission. With this scheduler instruction, the number of the message object is defined directly, without taking into account to which CAN node it is currently assigned. Even if it is assigned to another CAN node, the selected message object will be transmitted. If the CAN message transmit acceptance filtering delivers an object number to be transmitted, it is overruled by a valid transmit control entry according to ALTMSG. If the message object delivered by the transmit control entry is not valid for transmission, no transmission will be started.
TREN	24	rw	**Transmission Enable** This bit enables transmission of a message object in the next time window due to the TTCAN transmit trigger. 0_B Neither a TTCAN transmit trigger nor the message object transmit acceptance will lead to a transmission of a message object in the next time window. 1_B If a TTCAN transmit trigger occurs or the message object transmit acceptance filtering delivers a valid message object, the transmission of a message object in the next time window is enabled.

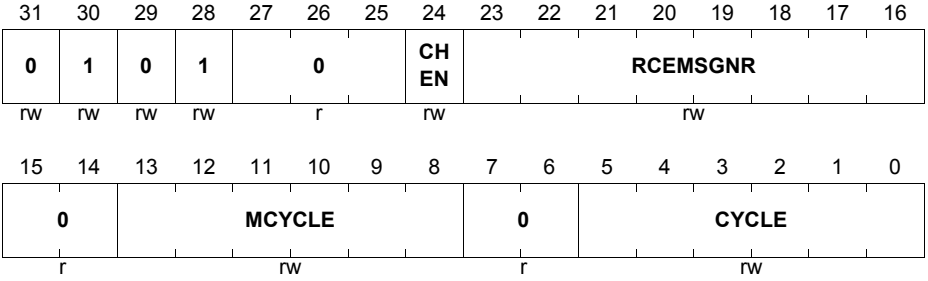
Field	Bits	Type	Description
ALTMSG	[26:25]	rw	**Alternative Message** This bit field determines which message object will be transmitted. 00_B If the message object number delivered by this entry is not valid for transmission, no message will be sent. 01_B The message object number delivered by this entry is not taken into account for transmission, the message object found by the transmit acceptance filtering will be sent if it is valid. 10_B If the message object delivered by this entry is not valid for transmission, while the message object transmit acceptance filtering delivered a valid object, the latter one will be sent out. 11_B Reserved
EC	[31:28]	rw	**Entry Code** The entry code EC = 0100_B defines this scheduler memory entry as a transmit control entry.
0	[7:6], [15:14], 27	r	**Reserved;** read as 0; should be written with 0. Bits are “don’t care” for scheduler operation when EC = 0100_B.

Note: The message transmit settings of a valid transmit control entry overrule the previously stored transmit settings and may also overrule the transmit acceptance filtering of the message objects for the next time mark (depending on bit ALTMSG). As a result, the use of more than one valid transmit control entry between two time mark entries should be avoided.

Receive Control Entry

The receive control entry is defined as follows:

RCE
Receive Control Entry



Field	Bits	Type	Description
CYCLE	[5:0]	rw	**Basic Cycle Number** This bit field determines the number of the basic cycle during which this receive control entry is valid. The value of CYCLE is compared (bit-wise) to the current value of the bit field CYCTMR.BCC. The result is then masked with the value given by the bit field MCYCLE in order to determine the repetition rate for this scheduler entry inside the matrix cycle. This bit field is equivalent to the corresponding part of the MOAMRn.AM bit field (see **Page 24-110**).
MCYCLE	[13:8]	rw	**Mask for Cycle Comparison** This bit field determines the mask that is used to determine the repetition rate for this scheduler entry. This bit field is equivalent to the corresponding part of the MOAMRn.AM bit field (see **Page 24-110**).

Field	Bits	Type	Description
RCEMSGNR	[23:16]	rw	**RCE Message Number** This bit field determines the number of the message object that is checked for correct reception of a message during the last transfer window. A received message is always stored in the message object that is determined by acceptance filtering. When reaching a new time mark, an RCE can be used to check if a desired message has actually been received in the desired message object.
CHEN	24	rw	**Check Enable** Only time windows with an active receive control entry with CHEN=1 will handle the update of the MSC bit field in the message object indicated by RCEMSGNR. If a frame has been received correctly and also stored in the indicated message object, then the reception is considered as correct; otherwise, it is an error. 0_B The MSC bit field of the indicated message object is not updated. 1_B The MSC bit field of the indicated message object is updated.
EC	[31:28]	rw	**Entry Code** The entry code EC = 0101_B defines this scheduler memory entry as a receive control entry.
0	[7:6], [15:14], [27:25]	r	**Reserved;** read as 0; should be written with 0. Bits are “don’t care” for scheduler operation when EC = 0101_B.

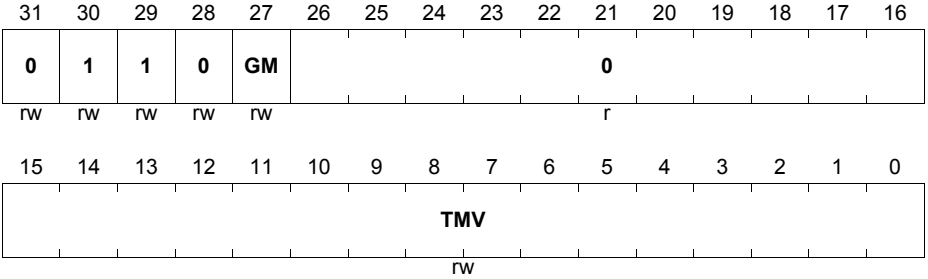
Note: The settings of a valid receive control entry overrule the previously stored information. As a result, the use of more than one valid receive control entry between two time mark entries should be avoided.

Note: If no receive control entry has been found valid for the current time window, the reception and storage of messages depends only on the message object receive acceptance filtering. Only message objects receiving messages with a valid receive control entry modify their MSC bit field accordingly. The MSC bit field of a receiving object is not modified without a valid receive control entry.

Reference Message Entry

The reference message is defined as follows:

RME
Reference Message Entry



Field	Bits	Type	Description
TMV	[15:0]	rw	**Time Mark Value** These bits determine the compare value for the next time mark. This value is used for the next compare action with the cycle time. If the CAN node is a time master, the reference message will be sent out when the time mark is reached (see also TMR.RTO).
GM	27	rw	**Gap Mode** This bit determines how the scheduler of a time master proceeds if the TTCAN node is “in a gap”. 0_B The reference message will be sent according to this RME entry (without respecting a possible gap). 1_B If the TTCAN node is “in a gap”, this RME entry is discarded and the following entries are read.
EC	[31:28]	rw	**Entry Code** The entry code EC = 0110_B defines this scheduler memory entry as a reference message entry.
0	[26:16]	r	**Reserved;** read as 0; should be written with 0. Bits are “don’t care” for scheduler operation when EC = 0110_B.

Note: This entry is taken into account for a time master. In the case that more valid reference message entries are detected, the settings of the previously found reference message entries are overruled by a subsequent one.

If the TTCAN node is not configured as time master and the scheduler reads an RME, a configuration error is generated.

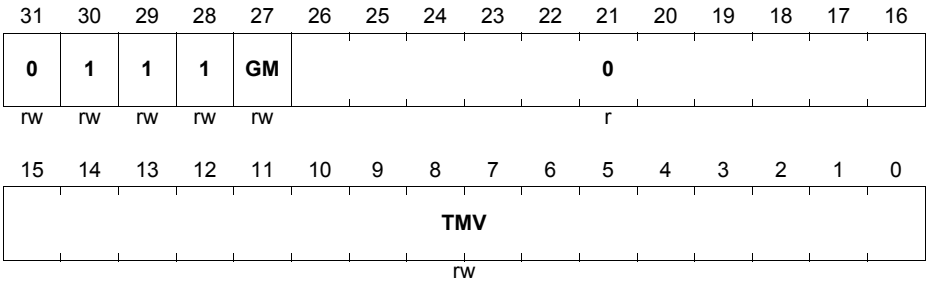
While the system is in the synchronization state, an RME entry with GM = 1 is not taken into account.

Basic Cycle End Entry

The basic cycle end entry defines the time mark value that is used as a watch trigger time mark. In the case that the TTCAN system is waiting for a reference message while the system is normally synchronized (not in a gap = not waiting for another event to synchronize). If the system is in a gap with GM set, the following entries can be read.

The basic cycle end is defined as follows:

BCE
Basic Cycle End Entry



Field	Bits	Type	Description
TMV	[15:0]	rw	**Time Mark Value** This bit field determines the compare value for the next time mark that is used for the next compare action with the cycle time. TMV determines the watch trigger that is used to generate a watch trigger event WTE when the cycle time reaches TMV. The value written into TMV must meet the condition that a minimum of one CAN frame length is in between the last time mark and the basic cycle end entry. For this calculation, the reference trigger offset TMR.RTO for the reference message entry must also be taken into account.

Field	Bits	Type	Description
GM	27	rw	**Gap Mode** This bit determines how the scheduler proceeds when the TTCAN node is “in a gap” and waits for a trigger event to send the reference message (for the current time master) or when it waits for the reception of a reference message. 0_B The watch trigger event will be generated according to this BCE entry (without respecting a possible gap). 1_B If the TTCAN node is “in a gap”, this basic cycle end entry is discarded and the following entries are read.
EC	[31:28]	rw	**Entry Code** The entry code EC = 0111_B defines this scheduler memory entry as a basic cycle end entry.
0	[26:16]	r	**Reserved;** read as 0; should be written with 0. Bits are “don’t care” for scheduler operation when EC = 0111_B.

Note: The BCE determines the end of the scheduler entries in the scheduler memory when the system is normally synchronized. When the time mark of this entry is reached, the TTCAN node will automatically enter the Configuration Mode. It will continue with the first time mark when a reference message has been correctly transferred on the CAN bus.

While the system is in the synchronization state, a BCE entry with GM = 1 is not taken into account.

24.8.2.3 End of Scheduler Memory Entry

The end of scheduler memory entry EOS is defined by entry codes EC = 0000_B or EC = $1XXX_B$ (see **Table 24-14**). An EOS immediately stops the reading of entries in the scheduler memory and sets the TTCAN node into Configuration Mode.

EOS can be regarded as a kind of emergency stop entry. It should not be used to control the scheduler itself but represents a security mechanism for the case that a scheduler entry does not show a valid EC bit field.

24.8.3 Setup of the Scheduler Entries

The entries in the scheduler memory can be set up only when all bits NCRx.CCE of the TTCAN nodes sharing the scheduler memory are set at the same time. Write actions to the scheduler memory while not all corresponding bits NCRx.CCE = 1 are not taken into account. The scheduler entries can always be read out for verification purposes.

24.8.4 Reading the Scheduler Entries

After a time mark has been reached, the scheduler instructions for the following time window are read by the scheduler. This “collected” information can be read out from the scheduler timing status and from the scheduler instruction status register. The information becomes valid when the next time mark is reached. The information collected between time mark n-1 and time mark n becomes valid when the time mark n is reached.

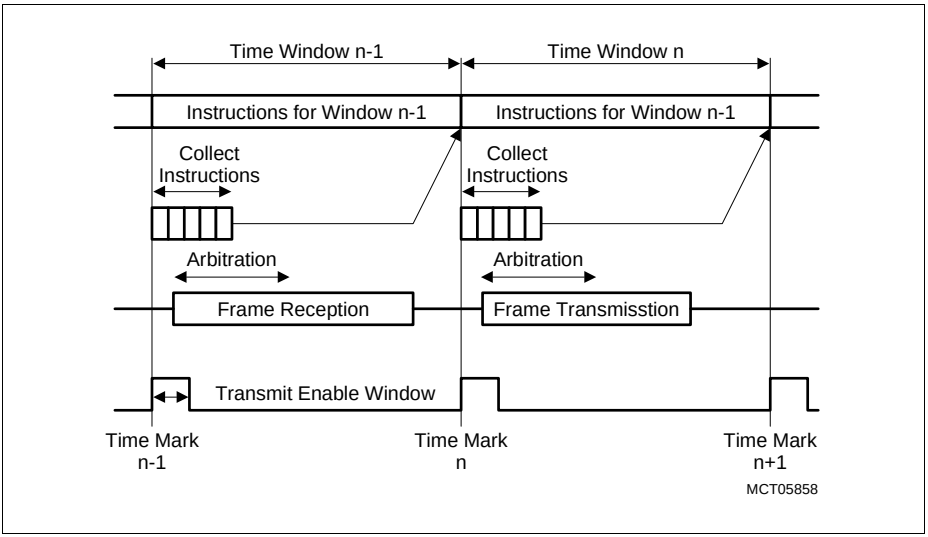


Figure 24-33 Collecting the Instructions

24.8.4.1 Instructions During a Basic Cycle

The handling of entries collected between the time marks n-1 and n is defined as follows:

- Time Mark Entry:
  The time mark value is defining the compare value for the time mark n.
- Interrupt Entry:
  Valid interrupt information (INP+ 4 enable bits) can generate an interrupt when the time mark n is reached, depending on the flags RECF and TRAF (they are

automatically cleared when the time mark is reached). As a result, this interrupt indicates that a (no) message has been sent /received in the time window between the time marks n-1 and n.

- Receive Control Entry:
  Valid receive control information (CHEN, RCEMSGNR) controls the storage of a message in the time window between the time marks n-1 and n.
- Arbitration Entry:
  Valid arbitration information (ARBM) determines the behavior of the time window starting with the time mark n.
- Transmit Control Entry:
  Valid transmit control information (TREN, ALTMSG, TCEMSGNR) defines a message to be transmitted after the time mark n. The transmission start is possible while the transmit enable window is active for an exclusive window or for a short (single) arbitration window or for the end of a merged arbitration window. For a merged (long) arbitration window, the transmission can start during the complete time window.
- Reference Message Entry:
  not used in this time window
- Basic Cycle End Entry:
  not used in this time window

The TMV value collected after time mark n-1 will become the new compare value for the time mark n.

The value of CYCTMR.CSM equals the time mark number of the last time mark reached (CSM = n after time mark n has been reached). The value of CYCTMR.BCC is number of the current basic cycle. This information is needed to correctly set up the scheduler entries (bit fields CYCLE, MCYCLE) and the message objects (bit fields CYCLE, MCYCLE, COLUMN, MCOLUMN).

24.8.4.2 Instructions at the End of a Basic Cycle

The collection of instructions for the last time window of a basic cycle starts when the time mark before is reached and stops when the entry TME2 is found. Handling of the entries collected during the last time window of a basic cycle:

- Time Mark Entry:
  After a valid BCE has been read, the first time mark TME1 is read and its value is defining the compare value for the time mark 1 (first time mark after the reference message = start of a new basic cycle).
- Interrupt Entry:
  Valid interrupt information (INP+ 4 enable bits) collected during the last time window of a basic cycle can generate an interrupt when the time mark 1 is reached, depending on the flags RECF and TRAF (they are automatically cleared when the time mark is reached). These flags do not apply to the reference message (the

transfer of a reference message does not modify these flags). As a result, this interrupt indicates that a (no) message has been sent /received in the last time window of the basic cycle. The ICE for the last time window of a basic cycle must be written into the scheduler memory after the entry TME1.

- Receive Control Entry:
  Valid receive control information (CHEN, RCEMSGNR) collected during the last time window of a basic cycle controls the storage of a message in the last time window (not applicable to reference message). The RCE for the last time window of a basic cycle must be written into the scheduler memory after the entry TME1.
- Arbitration Entry:
  Valid arbitration information (ARBM) determines the behavior of the time window starting with the time mark 1. This entry must be written into the scheduler memory after the entry TME1.
- Transmit Control Entry:
  Valid transmit control information (TREN, ALTMSG, TCEMSGNR) defines a message to be transmitted after the time mark 1. The transmission start is possible while the transmit enable window is active for an exclusive window or for a short (single) arbitration window. For a merged (long) arbitration window, the transmission can start during the complete time window. This entry must be written into the scheduler memory after the entry TME1.
- Reference Message Entry:
  The time mark value of a valid RME is defining the compare value for the reference time mark. When this reference time mark plus the reference trigger offset is reached, a reference message will be sent out (depending on the gap state of the system). This entry must be written into the scheduler memory before a valid entry BCE.
- Basic Cycle End Entry:
  The time mark value of a valid BCE is defining the compare value for the watch trigger event. When this time value is reached, a watch trigger event can be generated (depending on the gap state of the system). A valid BCE always finishes the scheduler entries for each TTCAN node.

Before the reference message has been correctly transferred:
The value of CYCTMR.CSM equals the time mark number of the last time mark reached (CSM = n after time mark n has been reached). The value of CYCTMR.BCC is number of the current basic cycle. This information is needed to correctly set up the scheduler entries RCE and ICE (bit fields CYCLE, MCYCLE).

After the reference message has been correctly transferred, but the time mark 1 has not yet been reached:
The value of CYCTMR.CSM is 0. The value of CYCTMR.BCC is number of the new basic cycle. This information is needed to correctly set up the scheduler entries ARBE and TCE (bit fields CYCLE, MCYCLE) and the message objects (bit fields CYCLE, MCYCLE, COLUMN, MCOLUMN).

As a result, the ICE and the RCE describing the reception / transmission of a message in the last time window of a basic cycle lead to actions (interrupts, etc.) when time mark 1 is reached.

24.8.5 Scheduler Instruction Sequence

24.8.5.1 BCC and CSM

In order to set up the scheduler instructions correctly, the values of CSM and BCC in register CYCTMR must be respected carefully, especially for the last time window of a basic cycle.

In order to set up the scheduler instructions correctly, the values of CSM and BCC in register CYCTMR must be respected carefully, especially for the last time window of a basic cycle. When leaving the Configuration Mode, BCC and CSM are 0 and the scheduler starts with time mark 1. The values for BCC and CSM in **Figure 24-34** represent the internal values that are updated after the correct transfer of a reference message.

The message triggered by the last time reference mark in a basic cycle is the reference message (see RME description). In **Figure 24-34**, this corresponds to the message after the time window n. The reference time mark follows after the time window n and the reference message starts a new basic cycle.

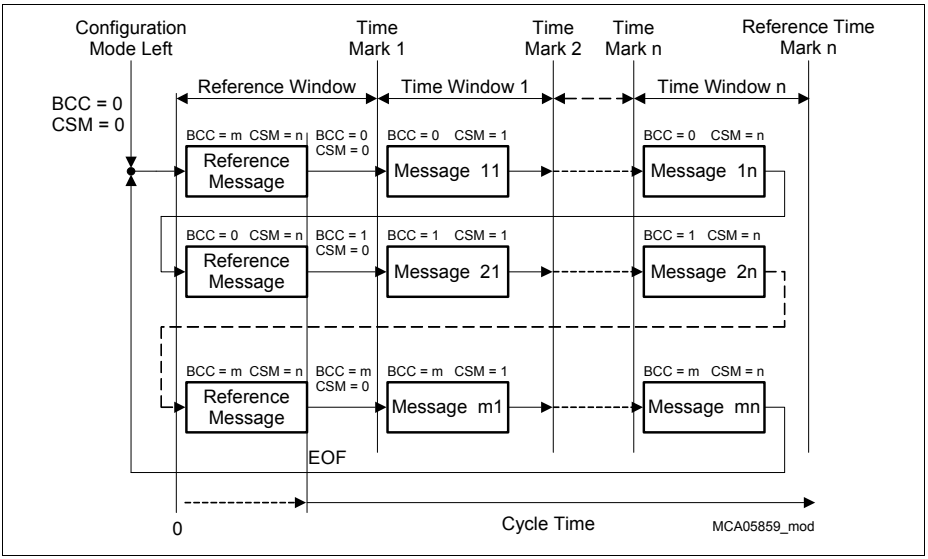

Figure 24-34 BCC and CSM in a Matrix Cycle

The cycle time of each basic cycle starts with 0 (virtual value). The start of a new basic cycle can only be detected after the correct transfer of a reference message. As a result, the cycle time value can be considered as valid after the reference message has been correctly transferred.

24.8.5.2 General Instruction Sequence Rules

The settings of already read scheduler instructions can be overwritten by following valid scheduler instructions. The following order of scheduler entry types must be respected to set up the scheduler correctly (starting with the first):

- TME then RCE or ICE or TCE or ARBE
- RME then BCE (for time masters)
- BCE (for slave devices)

The scheduler entries must always be closed with a BCE with GM = 0.

For time masters, the following sequence can be set up to close the scheduler entries:

- RME (GM = 1) then BCE (GM = 1) then RME (GM = 0) then BCE (GM = 0)
  (the entries RME(GM = 0) and BCE(GM = 0) are mandatory)

If the system is in-a-gap, the first RME and BCE entries (both with GM = 1) are not taken into account. With these entries, the standard (not in-a-gap) timing values can be adjusted. A second RME (with GM = 0) can be set up to send an emergency reference message while the system is in-a-gap and the synchronization event takes too long. The

scheduler entries are then closed again with a BCE with GM = 0 (e.g. with a longer timing value as a time-out criteria for a missing synchronization event).

24.8.5.3 Scheduler Sequence Example

The values given for CSM and BCC (both bit fields are located in register CYCTMR) lead to valid scheduler entries RCE, TCE, ICE and ARBE (bit fields CYCLE, MCYCLE) and the transmit control of the message objects (bit fields CYCLE, MCYCLE, COLUMN, MCOLUMN). In the case that the programmed values for CYCLE, MCYCLE, etc. do not match the given values of CSM and BCC, the respective entry is considered invalid and its information is not taken into account for the corresponding time window. The following example shows a scheduler instruction sequence for the basic cycle m with n time mark entries:

- TME1
- RCE, ICE (CSM = n, BCC = m-1 or CSM = BCC = 0 when the Configuration Mode is left)
- TCE, ARBE (CSM = 0, BCC = m)

- TME2
- RCE, ICE (CSM = 1, BCC = m)
- TCE, ARBE (CSM = 1, BCC = m)
- TME3
- RCE, ICE (CSM = 2, BCC = m)
- TCE, ARBE (CSM = 2, BCC = m)

- other time marks and instructions

- TMEn
- RCE, ICE (CSM = n-1, BCC = m)
- TCE, ARBE (CSM = n-1, BCC = m)

- RME (GM = 1, only for time masters)
- BCE (GM = 1, for time masters and slaves)

- RME (GM = 0, only for time masters)
- BCE (GM = 0, for time masters and slaves)

24.9 TTCAN Operation

24.9.1 Configuration

After a reset operation, the TTCAN extension must be configured. The Configuration Mode is entered automatically after reset or can be initiated through software by writing TTFMR.CFGMEL = 01_B. The Configuration Mode can be left only by software by writing TTFMR.CFGMEL = 10_B. The status flag TTSR.CFGM indicates whether or not the Configuration Mode is active. This flag is automatically set when the corresponding CAN node turns off its clock (disable request).

In Configuration Mode of the TTCAN node (CAN node 0 in TC1798), the following actions must be performed, as indicated, by software or hardware:

For all nodes:

- The local time, the global time, and the cycle time are set to 0 (hardware).
- Transmission or reception of messages of TTCAN node is not possible, because the results of the acceptance filtering are not enabled (hardware).
- An appropriate TUR value must be written to bit field TURR.TURADJ (software). This value is automatically transferred to TURR.TUR (hardware).
- The scheduler memory entries must be initialized (software).
- The TTCAN control information (ID of reference message, etc.) and the TTCAN node itself must be set up completely and enabled for CAN message transfer (software).
- After the complete configuration (software), TTFMR.CFGMEL must be set to 10_B (software).
- The local time starts after leaving the Configuration Mode (hardware).
- The synchronization phase is entered automatically when the Configuration Mode is left (hardware). This is indicated by bit field TTSR.SYNCS = 01_B (hardware).
- For time masters, the transmission of the reference messages is scheduled as in a gap while the TTCAN node is in the “synchronizing” state. The scheduler entries RME with GM = 1 are taken into account only while the TTCAN node is in the “in schedule” state.
- For time masters and for time slaves, the scheduler entries BCE with GM = 1 are taken into account only while the TTCAN node is in the “in schedule” state.

24.9.2 Configuration Error

During the scheduler actions, some conditions lead to a configuration error:

- At the end of a basic cycle, a merged arbitration window is still open.
- An RME entry is found for a slave device.
- No time mark is found during instruction collection.
- An RCE, ICE, TCE or ARBE has been found before TME1 (after start or at the end of a basic cycle).

- Another entry (except EOS) than an RME or a BCE has been found after the first RME.
- A reference message object is not valid when it is requested for transmission.

24.9.3 Synchronization Phase

When starting a TTCAN system (e.g. after reset), the entire system must be synchronized after completing the configuration phase. During the synchronization phase (indicated by bit field TTSR.SYNCS = 01_B), the following actions must be taken (or are taken automatically):

The Init_Watch_Trigger is taken into account until the first message is correctly received or transmitted. An Init_Watch_Trigger event is detected when the cycle time reaches the value of 2^{16} -1. This event is indicated by IWTE = 1 and it only leads to an interrupt.

The watch trigger value given by the basic cycle end entry is taken into account only after the first correct transfer of a message. When a watch trigger event occurs after transferring a message correctly on the bus, the transmission and the reception of Data Frames or Remote Frames are disabled (the TTCAN node is set to Configuration Mode).

During the synchronization phase, the scheduler entries RME or BCE with GM = 1 are not taken into account.

24.9.4 Time Masters

24.9.4.1 State of a Time Master

A potential time master is a device that can transmit a reference message. A backup time master is a potential time master that has received a reference message that was not its own. The current time master is the device that has successfully sent its own reference message. There is only one current time master in a TTCAN system.

If the current time master receives a reference message that is not its own, then it becomes a backup time master. If a backup time master has successfully transmitted its own reference message, it becomes the new current time master.

When a priority conflict between the TTCAN node and the actual time master is detected, the value of RTO is automatically modified (decrement by 1). This means that the priority of the actual time master (given by bits ID[2:0]) of the latest received reference message is lower than the programmed TMPRIO value.

24.9.4.2 Strictly Time-Triggered Behavior

A strictly time-triggered behavior (gaps are not allowed) can be achieved if the scheduler entries RME and BCE with GM = 0 are only used. In this case, the gap condition is “ignored” for the transfer of a reference message. In order to avoid unintentional

transfers of reference messages, the external trigger generation should be switched off in this case.

24.9.5 Error Handling

The TTCAN error handling distinguishes among four levels of error severity:

- S0:
  No Error: Normal functionality
- S1:
  Warning: Only notification of the application by an interrupt (ERRS1).
  Source: Scheduling Error 1 (MSCmax - MSCmin > 2 or when MSC of a receive object equal 7), Tx_Underflow
- S2:
  Error: Notification of the application by an interrupt (ERRS2). All transmissions are disabled (except for reference messages), TTCFGR.RTO is set to 127.
  Source: Scheduling Error 2 (MSC of a transmit object reaches 7), Tx_overflow
  Impact: The transmit enable window will not be opened (for exclusive and for arbitration windows).
- S3:
  Severe Error: Notification of the application by an interrupt (ERRS3). All CAN bus actions are stopped (no dominant values are transmitted on the bus). The configuration phase is entered automatically (CFGM is set).
  Source: Application Watchdog, Bus Off, Config Error, Watch Trigger Event
  Impact: Bit INIT of the CAN node will be set (the CAN node stops actions on the bus).

Note: Any change of the error state can generate an interrupt.

24.9.6 Application Watchdog

The application watchdog provides the possibility of checking for the TTCAN module if the main system is still running. The application watchdog counter counts in steps of 256 NTUs.

Each time 256 NTUs have elapsed, the value AWDR.AWDV is decremented by one. If the value 0 is reached after decrementing, an S3 error is signaled by bit AWDERR. The falling edge of bit LTR.LT.7 (transition from 1 to 0) indicates that the time of 256 NTUs has elapsed and the application watch dog value is decremented.
The application watchdog is serviced by the program by writing a new value to the bit field AWDR.AWDE.

24.9.7 MSC Handling

The MSC bit field is updated only for those message objects that are indicated by the valid RCE or TCE entry while the corresponding bit MSGVAL is set. The message number taken into account for an update is defined in the respective bit fields RCEMSGNR or TCEMSGNR.
Checking for the receive/transmit condition takes place when the end of the transmit enable window of the following time marks is reached. Because the transmit enable window length is known after each time mark (even if no message shall be sent out), this point in time can be used for the receive and the transmit check.
This feature makes it possible to have a positive check result even if the message in the preceding time window finishes during the transmit enable window.

A transmission attempt is defined as failed if a message object valid for transmission could not be transferred on the CAN bus. A transmit trigger being active without a valid message object being found is not considered as a transmission attempt.

24.9.8 TTCAN Interrupt Control

Figure 24-35 and **Figure 24-36** show the configurations of the three TTCAN interrupts.

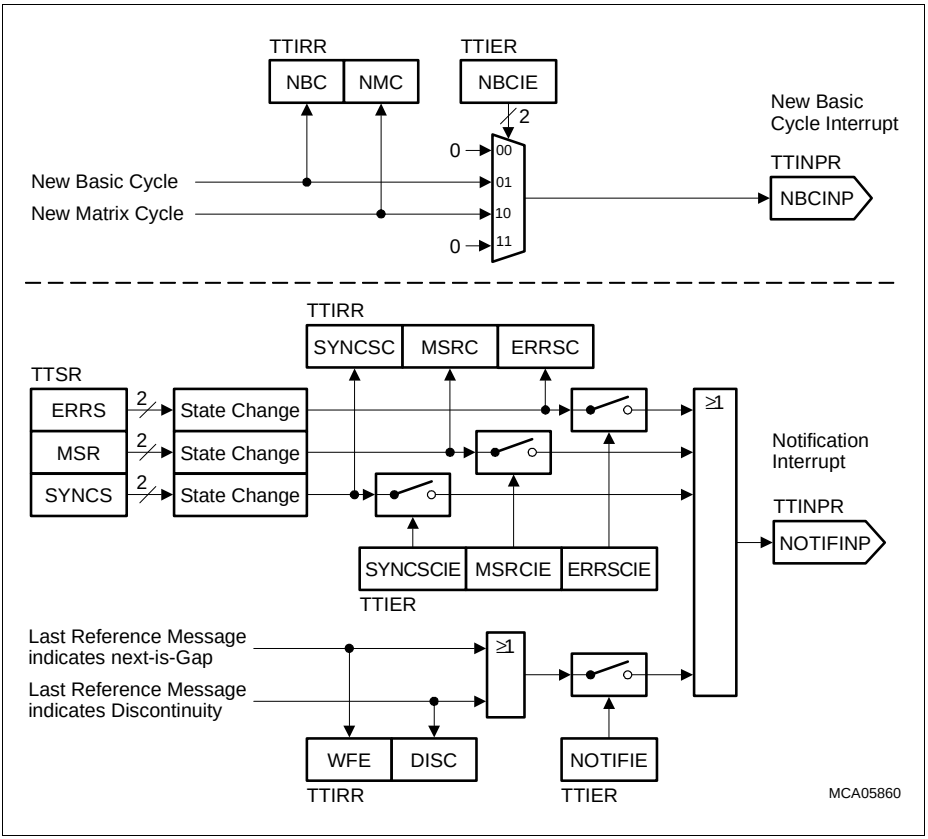

Figure 24-35 New Basic Cycle and Notification Interrupt Structure

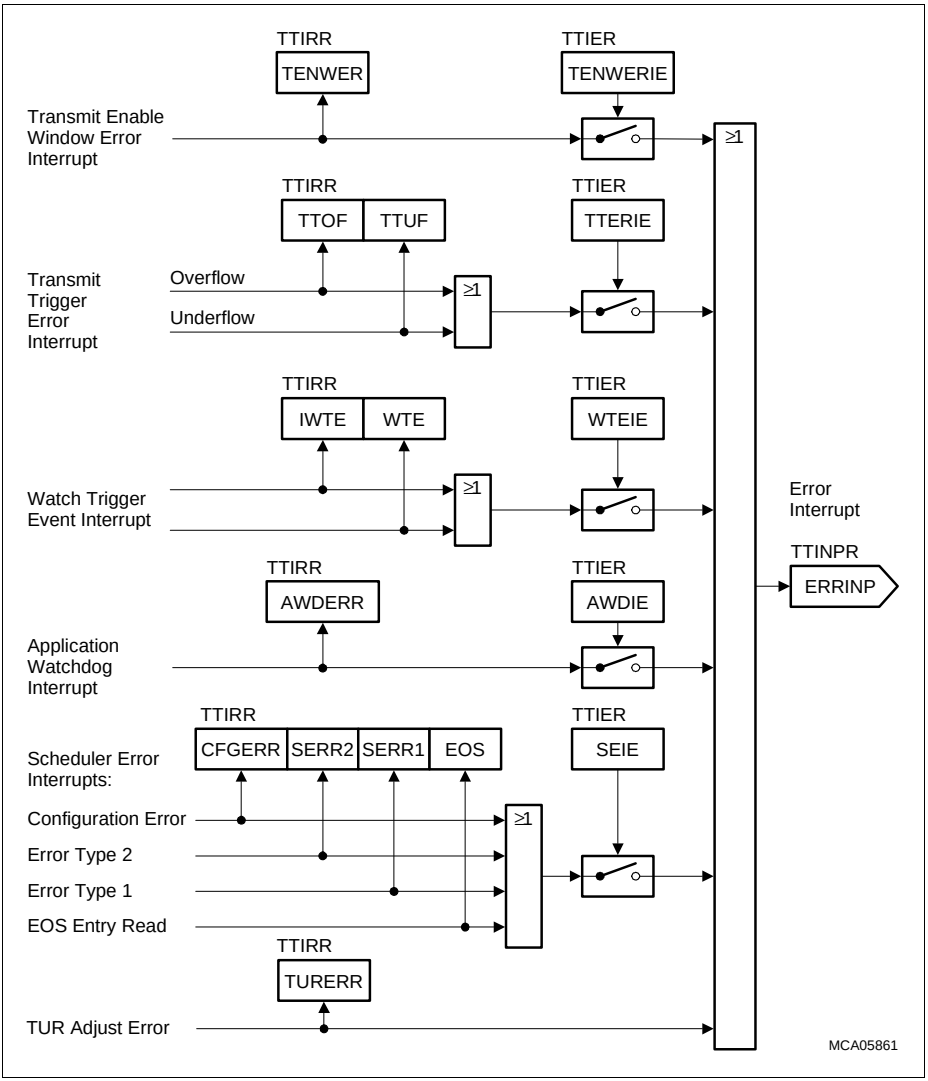

Figure 24-36 Error Interrupt Structure

See also **"Interrupt Control" on Page 24-211** for further processing of the TTCAN interrupts.

24.10 TTCAN Registers

All TTCAN register names described in this section are referenced by the module name prefix “CAN_” in other parts of the document.

TTCAN Register Overview

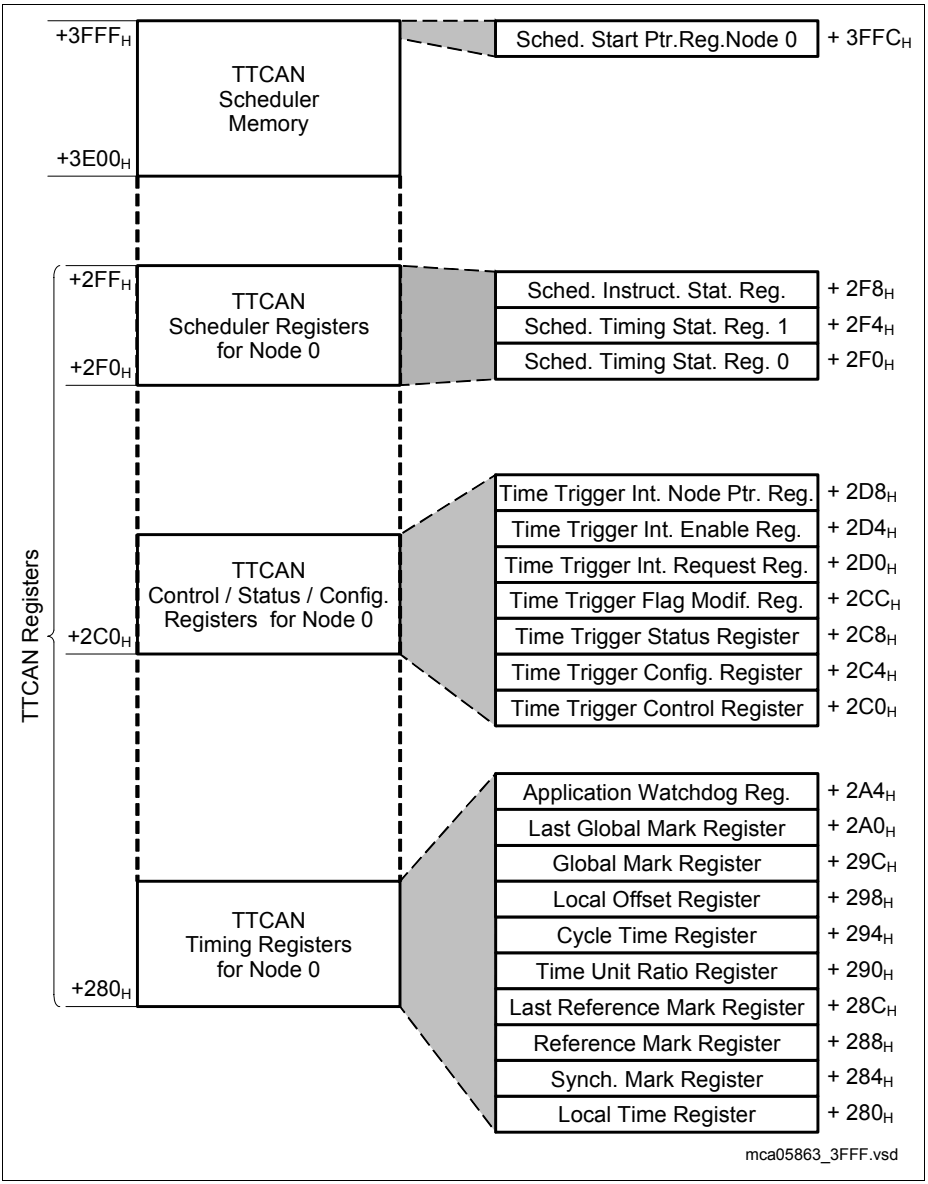

Figure 24-38 TTCAN Register Address Map

24.10.1 TTCAN Timing Registers

TURR
Time Unit Ratio Register **(290_H)** **Reset Value: $0000\ 0000_H$**

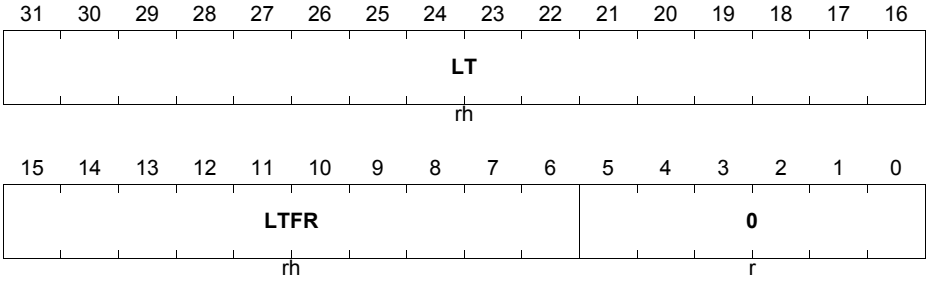
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
TUR										0	LTDIV			LTCS	VAL
rh										r	rw			rw	rh

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TURADJ										0					ADJEN
rwh										r					rwh

Field	Bits	Type	Description
ADJEN	0	rwh	**Adjust Enable** This bit enables automatic calculation of a new TURADJ value when a new reference message has been received (not for the current time master). A time unit ratio adjust error interrupt will be generated and bit ADJEN will be automatically cleared when an overflow or an underflow of the automatically calculated value occurs. 0_B The automatic TUR calculation is disabled. The new value for time unit ratio for TURADJ must be calculated and written by software. 1_B The automatic TUR calculation is enabled. After receiving a reference message, a new value for TURADJ is calculated by hardware. The calculated value is checked for overflow or underflow.
TURADJ	[15:6]	rwh	**Time Unit Ratio Adjust** This bit field holds the time unit ratio value that will be used for the next basic cycle. In the case of an automatic time unit ratio calculation with an underflow (overflow), TURADJ is written with all 0s (1s), ADJEN is cleared and a time unit ratio adjust error interrupt is generated. A hardware calculated TURADJ value can be overwritten by software.

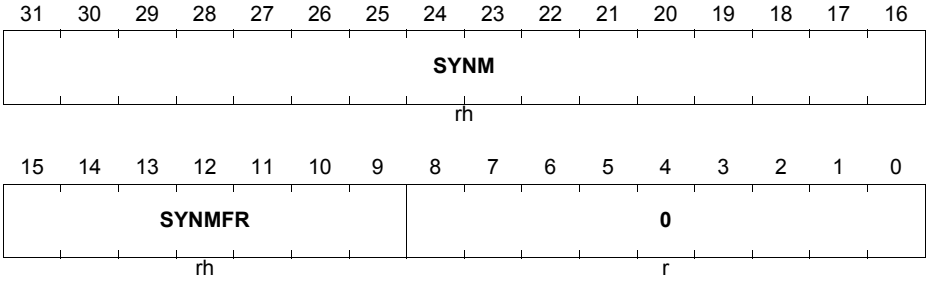
Field	Bits	Type	Description
VAL	16	rh	**Valid** This bit indicates that a new value of TURADJ is available. VAL becomes set when the hardware has finished its automatic calculation (with a correct result without overflow or underflow) or when the software writes to TURADJ. An automatic calculation does not take place while VAL = 1. VAL is cleared when the value of TURADJ is copied to TUR. 0_B The value of TURADJ has not been updated and no automatic update of TUR by the value of TURADJ takes place. 1_B The value of TURADJ has been updated by software or by hardware and it will be copied to TUR at the start of the next basic cycle.
LTCS	17	rw	**Local Time Clock Source** This bit determines the clock source for the local time generation (addition of TUR to LT, LTFR) for TTCAN level 2. 0_B A new local time value is generated with each time quantum t_q of the corresponding CAN node (depending on the CAN bit timing). 1_B The local time generation is based on the CAN module clock f_{CAN} (independent from the CAN bit timing). The update rate t_{upd} is based on the divider factor given by the bit field LTDIV according to: $t_{upd} = 2^{LTDIV} / f_{CAN}$
LTDIV	[20:18]	rw	**Local Time Divider** This bit field determines the divider factor for the local time generation (if f_{CAN} is selected by LTCS = 1). The divider factor is given by 2^{LTDIV}. 000_B Divider factor = 1 selected. 001_B Divider factor = 2 selected. $\ldots_B$ ... 111_B Divider factor = 128 selected.
TUR	[31:22]	rh	**TUR** This bit field contains the currently active time unit ratio value.
0	[5:1], 21	r	**Reserved** Read as 0; should be written with 0.

LTR
Local Time Register **(280_H)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
LTFR	[15:6]	rh	**Local Time Fraction** This bit field contains the fractional part of the NTU counter (TTCAN level 2 only). In the case of an overflow after the addition of the TUR value, the value of LT is incremented by one.
LT	[31:16]	rh	**Local Time** This bit field contains the integer part of the NTU counter. In TTCAN level 1, it is incremented with each CAN bit time, in level 2 it is incremented each time the fractional part LTFR has an overflow.
0	[5:0]	r	**Reserved** Read as 0; should be written with 0.

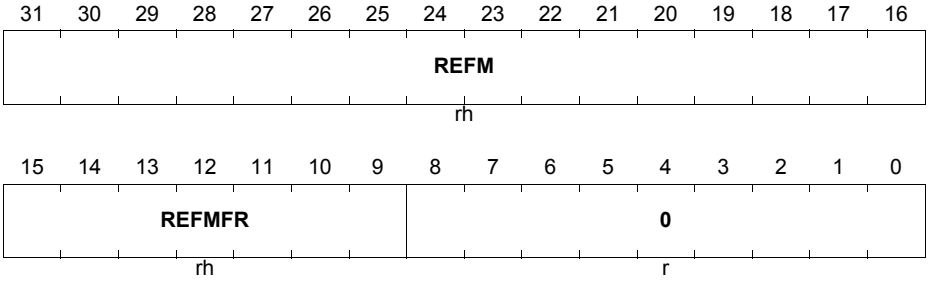
SYNMR
Synchronization Mark Register (284_H) Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
SYNMFR	[15:9]	rh	**Synchronization Mark Fraction** This bit field contains the fractional part of the synchronization mark. SYNMFR is the bit field LTR.LTFR captured with the frame synchronization pulse.
SYNM	[31:16]	rh	**Synchronization Mark** This bit field contains the integer part of the synchronization mark. SYNM is the bit field LTR.LT captured with the frame synchronization pulse.
0	[8:0]	r	**Reserved** Read as 0; should be written with 0.

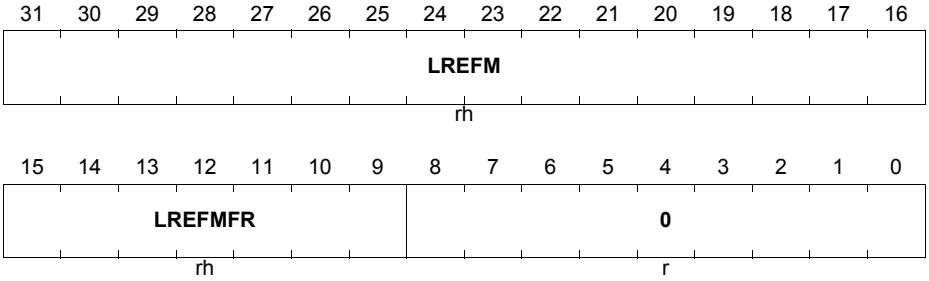
Note: If the CAN node is time master, the contents of register SYNMR are used as timing data transferred in the reference message.

REFMR
Reference Mark Register **(288_H)** **Reset Value: 0000 0000_H**



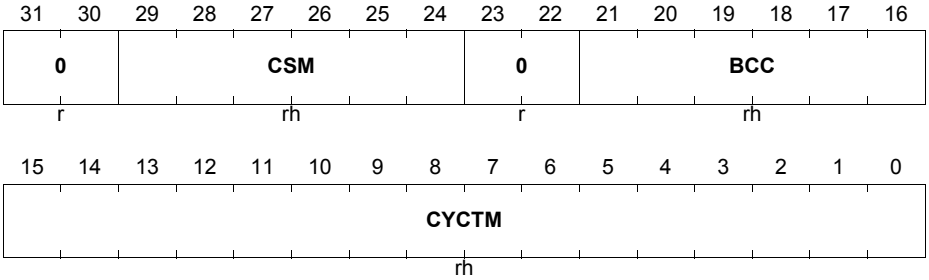
Field	Bits	Type	Description
REFMFR	[15:9]	rh	**Reference Mark Fraction** This bit field contains the fractional part of the reference mark. REFMFR is the bit field SYNMR.SYNMFR captured with the correct end of the reference message.
REFM	[31:16]	rh	**Reference Mark** This bit field contains the integer part of the reference mark. REFM is the bit field SYNMR.SYNM captured with the correct end of the reference message.
0	[8:0]	r	**Reserved** Read as 0; should be written with 0.

LREFMR
Last Reference Mark Register **($28C_H$)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
LREFMFR	[15:9]	rh	**Last Reference Mark Fraction** This bit field contains the fractional part of the last reference mark. LREFMFR is the bit field REFMR.REFMFR captured with the correct end of the reference message.
LREFM	[31:16]	rh	**Last Reference Mark** This bit field contains the integer part of the last reference mark. LREFM is the bit field REFMR.REFM captured with the correct end of the reference message.
0	[8:0]	r	**Reserved** Read as 0; should be written with 0.

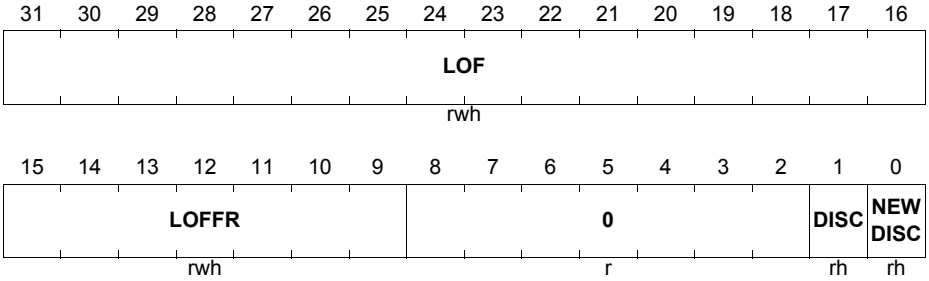
CYCTMR
Cycle Time Register **(294_H)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
CYCTM	[15:0]	rh	**Cycle Time** The cycle time indicates the time already elapsed in the current basic cycle. It is calculated by LTR.LT - REFMR.REFM. In the case of a negative result (overflow of LTR.LT), the result is corrected.
BCC	[21:16]	rh	**Basic Cycle Count** This bit field indicates the number of the current basic cycle. It is incremented after each correctly transferred reference message.
CSM	[29:24]	rh	**Column of System Matrix** This bit field indicates the number of the current column of the system matrix. It is incremented when the current cycle time becomes equal to the stored time mark (indicating the start of the next column).
0	[23:22], [31:30]	r	**Reserved** Read as 0; should be written with 0.

Note: With a reference message, the counting of the columns restarts at 0.

LOR
Local Offset Register **(298_H)** **Reset Value: 0000 0000_H**

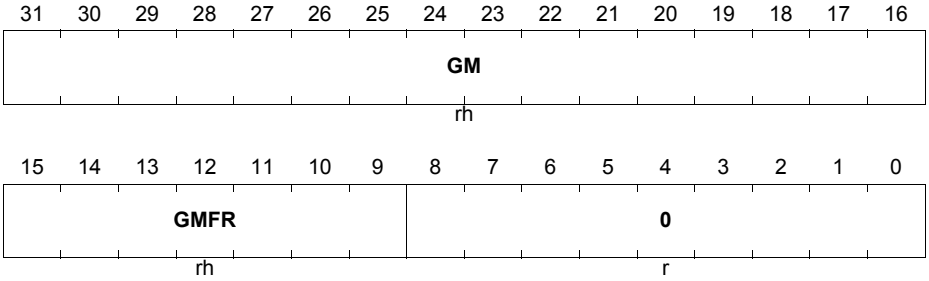


Field	Bits	Type	Description
NEWDISC	0	rh	**New Discontinuity Bit** This bit indicates that the register LOR has been the target of a write access for a time master (and that the contents of LOF or LOFFR could have been changed). This bit indicates that the next reference message will be sent with a discontinuity in the reference mark. It is set automatically when a write action to LOR is detected. It is cleared when the local time is captured (at SOF) for the transmission of the reference message. 0_B A write access to LOR has not occurred. 1_B A write access to LOR has occurred.
DISC	1	rh	**Discontinuity Bit** This bit contains the DISC bit of the reference message that is sent out (taken into account for a time master). This bit is set if the NEWDISC bit is 1 when the global time is captured (at SOF) for the transmission of the reference message. It is cleared when the reference message has been transferred correctly. 0_B The DISC bit in the reference message of the current time master is 0. 1_B The DISC bit in the reference message of the current time master is 1.
LOFFR	[15:9]	rwh	**Local Offset Fraction** This bit field contains the fractional part of the local offset.

Field	Bits	Type	Description
LOF	[31:16]	rwh	**Local Offset** This bit field contains the integer part of the local offset. Time master (transmitting reference messages): The sum of the local offset and the local time is stored as global time in the register GMR. Not time master (receiving reference messages): The local offset is the received global time information minus the local reference mark (in REFMR).
0	[8:2]	r	**Reserved** Read as 0; should be written with 0.

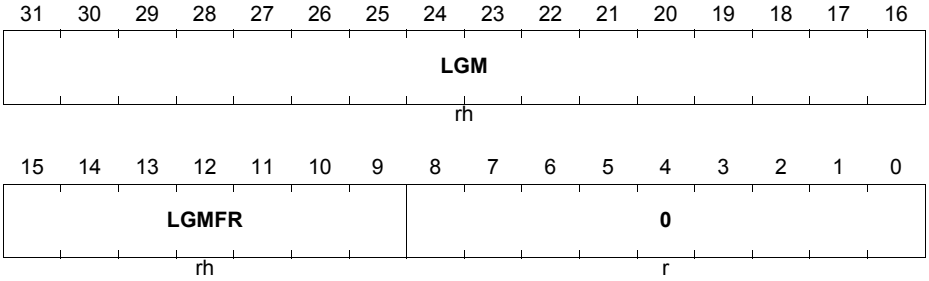
Note: Register LOR can be written by software only if the CAN node is the current time master or in Configuration Mode; otherwise, the write action is not taken into account. Because the written local offset is only taken into account for the transmission of the reference message, bit DISC is set automatically.

GMR
Global Mark Register **($29C_H$)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
GMFR	[15:9]	rh	**Global Mark Fraction** This bit field contains the fractional part of the global mark.
GM	[31:16]	rh	**Global Mark** This bit field contains the integer part of the global mark. Time master (transmitting reference messages): The sum of the local offset and the local time is stored as global time (Global_Sync_Mark) in register GMR at the beginning of the reference message. Not time master (receiving reference messages): The global time information in GMR is received as Global_Ref_Mark by reference message.
0	[8:0]	r	**Reserved** Read as 0; should be written with 0.

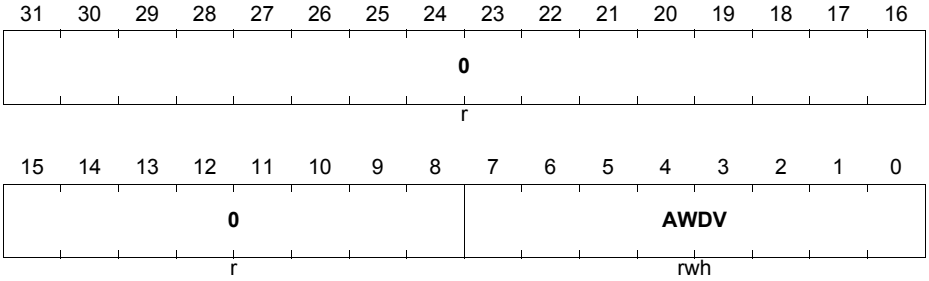
LGMR
Last Global Mark Register **($2A0_H$)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
LGMFR	[15:9]	rh	**Last Global Mark Fraction** This bit field contains the value of GMFR of the last reference mark.
LGM	[31:16]	rh	**Last Global Mark** This bit field contains the value of GM of the last reference mark.
0	[8:0]	r	**Reserved** Read as 0; should be written with 0.

Note: The difference between the actual global mark and the last one can be used to determine the value required for the TURR.TUR update (not for the actual time master).

AWDR
Application Watchdog Register ($2A4_H$) Reset Value: $0000\ 0000_H$

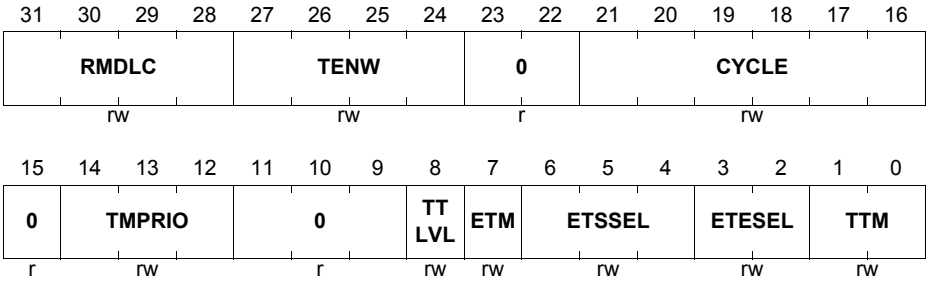


Field	Bits	Type	Description
AWDV	[7:0]	rwh	**Application Watchdog Value** This bit field contains the current value of the application watchdog. The falling edge of bit LTR.LT[7] (1-to-0 transition) indicates that the time of 256 NTUs has elapsed and the application watchdog value is automatically decremented by 1. If the value 0 is reached after decrementing, an S3 error is signaled by bit TTIRR.AWDERR. AWDV is not decremented below 0. The application watchdog is serviced by the program by writing a new value to the bit field AWDV. In the case of a collision between the write by software and the automatic decrement, the write is taken into account. Due to the fact that the counter counting the NTU (register LTR) is not reset when the application watchdog is serviced, the total time between the write to AWDV and the signaling of an S3 error has an uncertainty of one step of AWDV.
0	[31:8]	r	**Reserved** Read as 0; should be written with 0.

The application watchdog event occurs when the value of AWDV is decremented and reaches zero. When writing 0 to AWDV by software, the application watchdog is switched off without generating an application watchdog event.

24.10.2 TTCAN Control / Status / Configuration Registers

TTCR
Time Trigger Control Register **($2C0_H$)** **Reset Value: $0000\ 0000_H$**



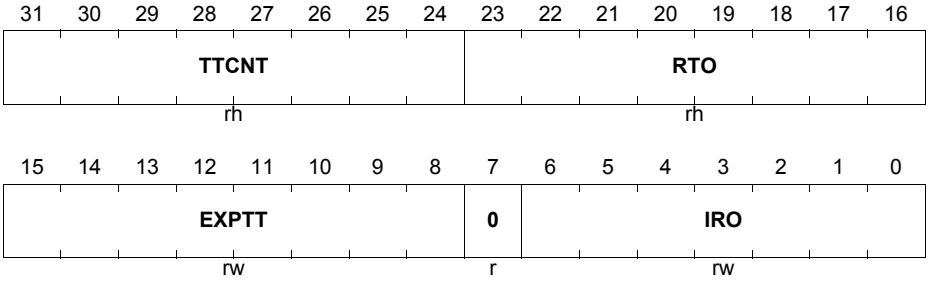
Field	Bits	Type	Description
TTM	[1:0]	rw	**Time Trigger Mode** This bit determines the behavior of the TTCAN node concerning the time trigger and the time master functionality. 00_B CAN node is disabled for TTCAN operation and operates in event triggered mode (other settings for TTCAN are inactive). The reference message object operates for reception or transmission as any other message object. 01_B CAN node is enabled for TTCAN operation as a receiving device. Reference messages cannot be transmitted by the CAN node. 10_B CAN node is enabled for TTCAN operation as the actual or a potential time master. The CAN node is able to transmit the reference message. 11_B Reserved; do not use this combination.

Field	Bits	Type	Description
ETESEL	[3:2]	rw	**External Trigger Event Selection** This bit field determines the source of the external trigger event that can be used to trigger a transmission of the reference message. The transmission of the reference message will be triggered only when the external event is detected and the external trigger request bit TTSR.ETR is set (= 1). 00_B Reserved; external trigger does not trigger the transmission of the reference message. 01_B A negative edge at an external trigger input ECTTx (as selected by ETSSEL) triggers the transmission of the reference message. 10_B A positive edge at an external trigger input ECTTx (as selected by ETSSEL) triggers the transmission of the reference message. 11_B A negative or positive edge at an external trigger input ECTTx (as selected by ETSSEL) triggers the transmission of the reference message.
ETSSEL	[6:4]	rw	**External Trigger Source Selection** This bit fields selects the input source for the external reference message trigger. 000_B No external trigger possible. 001_B External trigger input line ECTT1 selected. 010_B External trigger input line ECTT2 selected. 010_B External trigger input line ECTT3 selected. 100_B External trigger input line ECTT4 selected. 101_B External trigger input line ECTT5 selected. 110_B External trigger input line ECTT6 selected. 111_B External trigger input line ECTT7 selected.

Field	Bits	Type	Description
ETM	7	rw	**External Trigger Mode** This bit determines the external trigger mode. The transfer of a reference message is started if the selected trigger condition is met when the bus is idle after the end of the transmit enable window of the last time window of a basic cycle. The trigger event is stored in ETREV. 0_B The trigger event itself is taken into account if it occurs after the end of the transmit enable window of the last time window of a basic cycle. 1_B The trigger event stored in ETREV is taken into account after the end of the transmit enable window of the last time window of a basic cycle.
TTLVL	8	rw	**Time Trigger Level** This bit determines the level of the TTCAN functionality. 0_B TTCAN level 1 is selected. 1_B TTCAN level 2 is selected.
TMPRIO	[14:12]	rw	**Time Master Priority** This bit field determines the priority of the potential time master. This value will be used for the transmission of the ID bits [2:0] of the reference message. In the case that the TTCAN node looses arbitration against another reference mark on the bus or receives a reference mark while its own reference trigger is set, the reference trigger is reset and the received ID is stored in the reference message object's ID bit field.
CYCLE	[21:16]	rw	**Basic Cycle Number** This bit field determines the number of the last basic cycle in the matrix cycle. For time masters, the value of CYCLE is compared to the current value of the bit field CYCTMR.BCC. If the comparison detects a match, the reference message is sent out with a new basic cycle count of 0. For slave devices, the value is used to detect the expected end of a matrix cycle.

Field	Bits	Type	Description
TENW	[27:24]	rw	**Transmit Enable Window** This bit field determines how many CAN bit times can elapse before a pending transmit trigger is discarded. 0000_B One CAN bit time can elapse. 0001_B Two CAN bit times can elapse. $\cdots_B$ ... 1110_B Fifteen CAN bit times can elapse. 1111_B Sixteen CAN bit times can elapse.
RMDLC	[31:28]	rw	**Reference Message DLC** This bit field determines the data length code DLC of reference messages sent out by this CAN node if it is a time master. The DLC bit field in the reference message object contains the DLC of the previously received reference message. Note that RMDLC must be programmed only to values from 1 to 8 for TTCAN level 1 and to values from 4 to 8 for TTCAN level 2. Other values must not be programmed.
0	[11:9], 15, [23:22]	r	**Reserved** Read as 0; should be written with 0.

TTCFGR
Time Trigger Configuration Register (2C4$_H$) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
IRO	[6:0]	rw	**Initial Reference Offset** This bit field determines the initial reference trigger offset. The value is considered as 2's complement and can reach values between 0 and 127.
EXPTT	[15:8]	rw	**Expected Transmit Triggers** This bit field determines how many transmit requests are expected in a matrix cycle.
RTO	[23:16]	rh	**Reference Trigger Offset** This bit field indicates the actual reference trigger offset. This value is considered as 2's complement and can reach values between -127 and 127. It is added to the time mark (given by the basic cycle end entry in the scheduler memory) for the trigger of the reference message. The modification and the corresponding conditions are listed in **Table 24-16**.
TTCNT	[31:24]	rh	**Transmit Trigger Counter** The transmit trigger counter is incremented by 1 each time a transmit trigger is requested for a TTCAN node. When reaching the value of EXPTT, it is no longer incremented and further transmit requests are not serviced (messages are not transferred). It is reset at the beginning of each new matrix cycle (after correct transfer on the reference message of basic cycle 0).

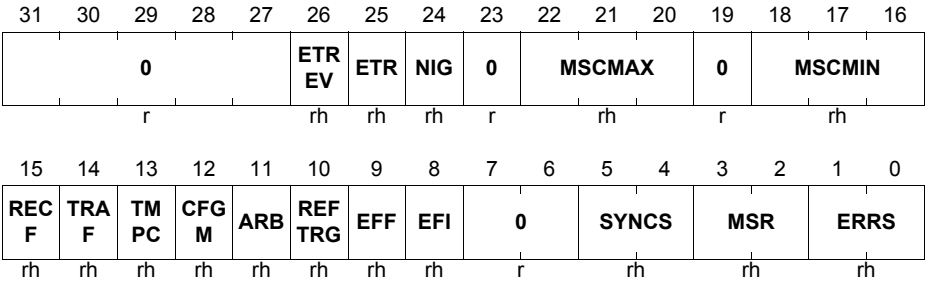
Field	Bits	Type	Description
0	7	r	**Reserved** Read as 0; should be written with 0.

Table 24-16 Modification by Hardware of Bit Field RTO

Modification	Condition
Set to TTCFGR.IRO	During reset (TTCFGR.IRO = 0) and Configuration Mode (write of TTCFGR.IRO by software)
Set to TTCFGR.IRO	Each time a potential time master receives a reference message with a higher priority than its own
Decrement by 1	Each time a potential time master receives a reference message with a lower priority than its own until -127 is reached
Set to 127	When the S2 state is entered
Set to 0	When the TTCAN node has correctly transmitted its reference message (it is the current time master) or when a potential master receives a reference message with a priority lower than its own and its RTO is positive

The Time Trigger Status Register TTSR contains the time trigger status information that does not lead directly to interrupt events.

TTSR
Time Trigger Status Register **($2C8_H$)** **Reset Value: $0000\ 1000_H$**



Field	Bits	Type	Description
ERRS	[1:0]	rh	**Error State** This bit field indicates the current error severity level. 00_B No error 01_B Warning 10_B Error 11_B Severe error
MSR	[3:2]	rh	**Master-Slave Relation** This bit field indicates the current master to slave relation of the TTCAN node. 00_B Master off 01_B Slave (receiving device) 10_B Potential time master 11_B Current time master
SYNCS	[5:4]	rh	**Synchronization State** This bit field indicates the current synchronization state of the TTCAN node. 00_B Sync off 01_B Synchronizing 10_B In gap 11_B In schedule

Field	Bits	Type	Description
EFI	8	rh	**Error Frame Indication** This bit is set when an error condition in the bitstream of a CAN frame is detected and an Error Frame will be sent out. It is automatically cleared when the next time mark is reached and its status at this moment is monitored by bit EFF. 0_B Since the last time mark, the CAN node has detected no error condition in the CAN bitstream. 1_B Since the last time mark, the CAN node has detected an error condition in the CAN bitstream. When EFI becomes set, a LEC interrupt can be generated by the CAN node.
EFF	9	rh	**Error Frame Flag** This bit monitors the Error Frame indication EFI when a time mark is reached. 0_B No CAN error has been detected in the last time window. 1_B A CAN error has been detected in the last time window.
REFTRG	10	rh	**Reference Trigger Flag** This bit is set when the reference message of a TTCAN node is intended to be sent. It is cleared when the reference message has been sent out correctly or a reference message has been received correctly (sent by another time master).
ARB	11	rh	**Arbitration Window Flag** This bit is set when an arbitration window is opened. It is cleared when the arbitration window is closed. 0_B The current time window is a time-triggered window. 1_B The current time window is an arbitration window.

Field	Bits	Type	Description
CFGM	12	rh	**Configuration Mode Flag** This bit indicates whether or not Configuration Mode is active. 0_B The TTCAN node is not in Configuration Mode. 1_B The TTCAN node is in Configuration Mode. It will not transmit messages and it will not update the MSC bit fields.
TMPC	13	rh	**Time Master Priority Conflict** This bit indicates if there is a priority conflict between the current time master and this TTCAN node. A priority conflict occurs if the current time master has a lower priority than the TTCAN node itself (potential time master). 0_B A priority conflict has not been detected for the last reference message. 1_B The TTCAN node is a potential time master with a priority conflict (the last reference message has been received with a lower priority than TTCR.TMPRIO).
TRAF	14	rh	**Transmission Finished Flag** This bit is set when the CAN node correctly finishes a transmission of a message that is not the reference message. It is reset when the next time mark is reached. This flag is used for the interrupt generation of the time mark entries and the interrupt entries. 0_B Since the last time mark has been reached, the CAN node has not yet correctly finished a transmission. 1_B Since the last time mark has been reached, the CAN node has correctly finished a transmission (it is not set by the transmission of a reference message).

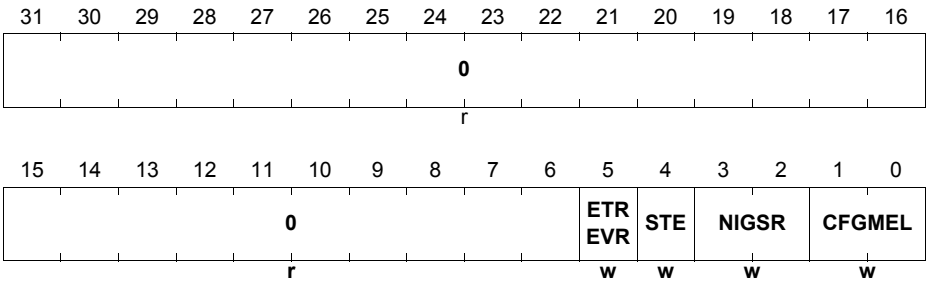
Field	Bits	Type	Description
RECF	15	rh	**Reception Finished Flag** TThis bit is set when the CAN node correctly finishes a reception of a message (= a correct message has been seen on the bus) that is not the reference message. It is reset when the next time mark is reached. This flag is used for the interrupt generation of the time mark entries and the interrupt entries. 0_B Since the last time mark has been reached, the CAN node has not yet received a message. 1_B Since the last time mark has been reached, the CAN node has received a message (it is not set by the reference message).
MSCMIN	[18:16]	rh	**Minimum of MSC Bit Fields** This bit field indicates the minimum value of the MSC bit fields of the message objects activated in exclusive time windows. This value is set to 7 at the beginning of a new matrix cycle. It is updated according to: *Note: if MSC_cur < MSCMIN then* *MSCMIN:= MSC_cur* The value MSC_cur is the MSC value of the currently activated message object.
MSCMAX	[22:20]	rh	**Maximum of MSC Bit Fields** This bit field indicates the maximum value of the MSC bit fields of the message objects activated in exclusive time windows. This value is set to 0 at the beginning of a new matrix cycle. It is updated according to: *Note: if MSC_cur > MSCMAX then* *MSCMAX:= MSC_cur* The value MSC_cur is the MSC value of the currently activated message object.

Field	Bits	Type	Description
NIG	24	rh	**Next Is Gap** This bit indicates the condition leading to the transmission of the reference message coming after the next one (only for the current time master). This bit will be transmitted with the next reference message. 0_B The reference message after the next one will be transmitted when the corresponding time mark is reached. 1_B The reference message after the next one will be transmitted when the selected trigger event occurs. Bit NIG will be cleared and bit ETR will be set when the next reference message is correctly transferred (received or transmitted).
ETR	25	rh	**External Trigger Request** This bit indicates the condition leading to the transmission of the next reference message (only for the current time master).The value of NIG is copied to ETR when a reference message is correctly transmitted. It will be cleared automatically when the next reference message is correctly received. 0_B The next reference message will be transmitted when the corresponding time mark is reached. 1_B The next reference message will be transmitted when the selected trigger or the RME trigger event occurs.
ETREV	26	rh	**External Trigger Event** This bit indicates that the external trigger event has been detected. It is automatically cleared when a reference message has been transferred correctly on the bus. 0_B The selected external trigger event has not yet been detected. 1_B The selected external trigger event has been detected.
0	[7:6], 19, 23, [31:27]	r	**Reserved** Read as 0; should be written with 0.

TTCAN status bits/flags can be modified when executing a write operation to the Time Trigger Flag Modification Register TTFMR.

TTFMR
Time Trigger Flag Modification Register

($2CC_H$) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
CFGMEL	[1:0]	w	**Configuration Mode Enter/Leave** This bit field is used to enter/leave the Configuration Mode. 00_B No action 01_B The Configuration Mode will be entered (set TTSR.CFGM). 10_B The Configuration Mode will be left (clear TTSR.CFGM). 11_B No action
NIGSR	[3:2]	w	**Next Is Gap Flag Set/Reset** This bit field can set/clear the bit TTSR.NIG and can clear the bit TTSR.ETR. 00_B No action 01_B Bit TTSR.NIG will be set. 10_B Bits TTSR.NIG and TTSR.ETR will be cleared. 11_B No action

Field	Bits	Type	Description
STE	4	w	**Software Trigger Event** This bit can be used to synchronize a TTCAN node by software. 0_B No action 1_B The transmission of a reference message is triggered if TTCR.ETESEL = 11 and the system is in-a-gap.
ETREVR	5	w	**Reset External Trigger Event** This bit clears the external trigger event flag. 0_B No action. 1_B The bit TTSR.ETREV is cleared.
0	[31:6]	r	**Reserved** Read as 0; should be written with 0.

The Time Trigger Interrupt Request Register TTIRR contains the time trigger status information related to interrupt events. Note that all bits in TTIRR can be cleared by software by writing 0 to it. Writing a 1 to the bits has no effect.

TTIRR
Time Trigger Interrupt Request Register

($2D0_H$) **Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh

Field	Bits	Type	Description
NMC	0	rwh	**New Matrix Cycle** This bit indicates that a new matrix cycle has started. It is set when a reference message with the cycle count = 0 has been transferred correctly. 0_B A new matrix cycle has not yet been detected. 1_B A new matrix cycle has been detected.
NBC	1	rwh	**New Basic Cycle** This bit indicates that a new basic cycle has started. 0_B A new basic cycle has not yet been detected. 1_B A new basic cycle has been detected.
TENWER	2	rwh	**Transmit Enable Window Error** This bit indicates that the specified time elapsed after the transmit trigger without starting the transmission of a message. 0_B The triggered messages have been sent out before the transmit enable window elapsed. 1_B A triggered message was not started before the transmit enable window elapsed.

Field	Bits	Type	Description
TTUF	3	rwh	**Transmit Trigger Underflow** This bit indicates that fewer transmit triggers have been requested during a matrix cycle than specified in TTCFGR.EXPTT. 0_B The expected number or more transmit triggers have been requested. 1_B Less transmit triggers have been requested.
TTOF	4	rwh	**Transmit Trigger Overflow** This bit indicates that more transmit triggers have been requested during a matrix cycle than specified in TTCFGR.EXPTT. 0_B The expected number or less transmit triggers have been requested. 1_B More transmit triggers have been requested.
WTE	5	rwh	**Watch Trigger Event**[1)] This bit indicates a watch trigger event WTE. This event is detected when the cycle time in CYCTMR.CYCTM becomes equal to the watch trigger value given by the time mark of the BCE entry. 0_B The cycle time has not been equal to WTV. 1_B The cycle time has been equal to WTV.
IWTE	6	rwh	**Init Watch Trigger Event**[2)] This bit indicates a watch trigger event WTE with the value of the Init_Watch_Trigger. This event is detected when the cycle time in CYCTMR.CYCTM becomes equal to the init watch trigger value of 2^{16} - 1. 0_B The cycle time has not been equal to 2^{16} - 1. 1_B The cycle time has been equal to 2^{16} - 1.
AWDERR	7	rwh	**Application Watchdog Error** This bit indicates that the application watchdog has been decremented to 0 without being serviced. 0_B AWDR.AWDV has not yet reached 00_H. 1_B AWDR.AWDV has reached 00_H. This is an S3 error condition.

Field	Bits	Type	Description
ERRSC	8	rwh	**Error State Change** This bit indicates that the bit field TTSR.ERRS has changed. 0_B TTSR.ERRS has not changed. 1_B TTSR.ERRS has changed.
MSRC	9	rwh	**Master-Slave Relation Change** This bit indicates that the bit field MSR has changed. 0_B TTSR.MSR has not changed. 1_B TTSR.MSR has changed.
SYNCSC	10	rwh	**Synchronization State Change** This bit indicates that the bit field TTSR.SYNCS has changed. 0_B TTSR.SYNCS has not changed. 1_B TTSR.SYNCS has changed.
EOS	11	rwh	**End Of Scheduler Entry Flag** This bit is set when the TTCAN scheduler reads an EOS entry. In this case, bit TTSR.CFGM is automatically set. 0_B The TTCAN scheduler has not yet read an EOS entry. 1_B The TTCAN scheduler has read an EOS entry.
WFE	12	rwh	**Wait For Event Flag** This bit is set when a reference message is received indicating a next-is-gap (not for the current time master). This event can generate a notification interrupt. 0_B The last reference message received was not indicating next-is-gap. 1_B The last reference message received was indicating next-is-gap.
DISC	13	rwh	**Discontinuity Flag** This bit is set when a reference message is received indicating a discontinuity (not for the current time master). This event can generate a notification interrupt. 0_B The last reference message received was not indicating a discontinuity. 1_B The last reference message received was indicating a discontinuity.

Field	Bits	Type	Description
SERR1	14	rwh	**Scheduler Error 1 Flag** This bit is set when a scheduler error type 1 is detected. The scheduler error can change the TTCAN error state and, as a result, can be indicated by an error state change interrupt. 0_B A scheduler error type 1 has not been detected. 1_B A scheduler error type 1 has been detected.
SERR2	15	rwh	**Scheduler Error 2 Flag** This bit is set when a scheduler error type 2 is detected. The scheduler error can change the TTCAN error state and, as a result, can be indicated by an error state change interrupt. 0_B A scheduler error type 2 has not been detected. 1_B A scheduler error type 2 has been detected.
CFGERR	16	rwh	**Configuration Error** This bit indicates that a configuration error has been detected by the scheduler. A configuration error is detected when an arbitration window is not closed when the BCE is reached. When RME.TMV is reached, no other scheduler entries as RME and BCE are allowed. See also EOSERR. 0_B A configuration error has not been detected. 1_B A configuration error has been detected (S3 error condition).
TURERR	17	rwh	**TUR Adjust Error** This bit indicates that a TUR adjust error has been detected. A TUR adjust error is detected when the automatic TUR adjustment is enabled and an overflow or an underflow of the calculated TURADJ value occurs. 0_B A TUR adjust error has not been detected. 1_B A TUR adjust error has been detected.
0	[31:18]	r	**Reserved** Read as 0; should be written with 0.

1) The WTE can be generated only after the first message has been transferred on the bus.

2) The IWTE can be generated only until the first message has been transferred on the bus.

TTIER

Time Trigger Interrupt Enable Register

(2D4$_H$) **Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r			rw	rw	rw	rw	rw	rw	rw	r		rw	rw	rw	

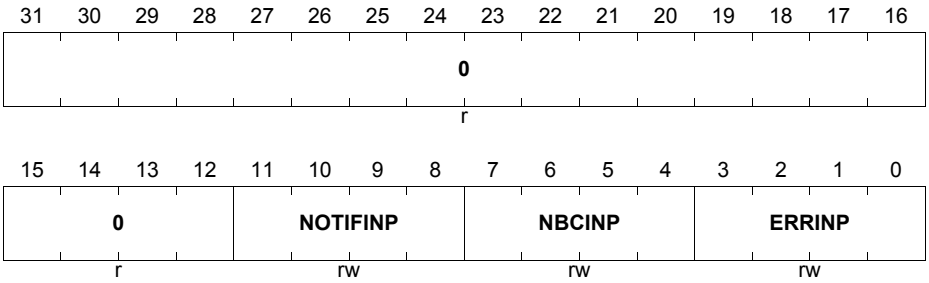
Field	Bits	Type	Description
NBCIE	[1:0]	rw	**New Basic Cycle Interrupt Enable** NBCIE enables the new basic or matrix cycle interrupt. This interrupt is generated when either bit TTIRR.NBC or bit TTIRR.NMC become set (independent of its current state). 00_B A new basic or matrix cycle interrupt is disabled. 01_B A basic cycle interrupt is generated whenever TTIRR.NBC becomes set. 10_B A matrix cycle interrupt is generated whenever TTIRR.NMC becomes set. 11_B Reserved Bit field TTINPR.NBCINP selects the interrupt output line that becomes activated at this type of interrupt.
TENWERIE	2	rw	**Transmit Enable Window Error Interrupt Enable** TENWERIE enables the transmit enable window error interrupt. This interrupt is generated when bit TTIRR.TENWER is set. 0_B Transmit enable window error interrupt is disabled. 1_B Transmit enable window error interrupt is enabled. Bit field TTINPR.ERRINP selects the interrupt output line that becomes activated at this type of interrupt.

Field	Bits	Type	Description
TTERIE	3	rw	**Transmit Trigger Error Interrupt Enable** TTERIE enables the transmit trigger error interrupt. This interrupt is generated when TTIRR.TTOF or TTIRR.TTUF become set (independent of its current state). 0_B Transmit trigger error interrupt is disabled. 1_B Transmit trigger error interrupt is enabled. Bit field TTINPR.ERRINP selects the interrupt output line that becomes activated at this type of interrupt.
WTEIE	6	rw	**Watch Trigger Event Interrupt Enable** WTEIE enables the watch trigger event interrupt. This interrupt is generated when TTIRR.IWTE or TTIRR.WTE become set (independent of its current state). 0_B Watch trigger event interrupt is disabled. 1_B Watch trigger event interrupt is enabled. Bit field TTINPR.ERRINP selects the interrupt output line that becomes activated at this type of interrupt.
AWDIE	7	rw	**Application Watchdog Interrupt Enable** AWDIE enables the application watchdog interrupt. This interrupt is generated when TTIRR.AWDERR becomes set (independent of its current state). 0_B Application watchdog interrupt is disabled. 1_B Application watchdog interrupt is enabled. Bit field TTINPR.ERRINP selects the interrupt output line that becomes activated at this type of interrupt.
ERRSCIE	8	rw	**Error State Change Interrupt Enable** ERRSCIE enables the error state change interrupt. This interrupt is generated when bit field TTSR.ERRSC changes its state. 0_B Error state change interrupt is disabled. 1_B Error state change interrupt is enabled. Bit field TTINPR.NOTIFINP selects the interrupt output line that becomes activated at this type of interrupt.

Field	Bits	Type	Description
MSRCIE	9	rw	**Master Slave Relation Change Interrupt Enable** MSRSCIE enables the master slave relation change interrupt. This interrupt is generated when bit field TTSR.MSRC changes its state. 0_B Master slave relation change interrupt is disabled. 1_B Master slave relation change interrupt is enabled. Bit field TTINPR.NOTIFINP selects the interrupt output line that becomes activated at this type of interrupt.
SYNCSCIE	10	rw	**Synchronization State Change Interrupt Enable** SYNCSCIE enables the synchronization state change interrupt. This interrupt is generated when bit field TTSR.SYNCSC changes its state. 0_B Synchronization state change interrupt is disabled. 1_B Synchronization state change interrupt is enabled. Bit field TTINPR.NOTIFINP selects the interrupt output line that becomes activated at this type of interrupt.
SEIE	11	rw	**Scheduler Error Interrupt Enable** SEIE enables the scheduler error interrupt. This interrupt is generated whenever bits EOS or SERR1 or SERR2 or CFGERR of register TTSR are set by hardware. 0_B Scheduler error interrupt generation is disabled. 1_B Scheduler error interrupt generation is enabled. Bit field TTINPR.ERRINP selects the interrupt output line that becomes activated at this type of interrupt.

Field	Bits	Type	Description
NOTIFIE	12	rw	**Notification Interrupt Enable** NOTIFIE enables the notification interrupt. This interrupt is generated whenever bits TTIRR.WFE or TTIRR.DISC are set by hardware. 0_B Notification interrupt is disabled. 1_B Notification interrupt is enabled. Bit field TTINPR.NOTIFINP selects the interrupt output line which becomes activated at this type of interrupt.
0	[5:4], [31:13]	r	**Reserved** Read as 0; should be written with 0.

TTINPR
Time Trigger Interrupt Node Pointer Register
($2D8_H$) **Reset Value: $0000\ 0000_H$**



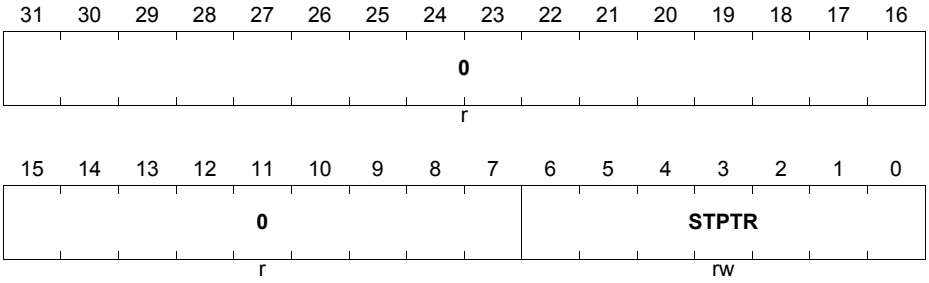
Field	Bits	Type	Description
ERRINP	[3:0]	rw	**Error Interrupt Node Pointer** ERRINP selects the interrupt output line INT_Om (m = 0-15) for an error interrupt. Possible error events for this interrupt node pointer are: • Transmit enable window error event • Transmit trigger error event • (Initial) Watch trigger event • Application watchdog event • TUR adjust error • Scheduler error event 0000_B Interrupt output line INT_O0 is selected. 0001_B Interrupt output line INT_O1 is selected. $\cdots_B$ … 1110_B Interrupt output line INT_O14 is selected. 1111_B Interrupt output line INT_O15 is selected.
NBCINP	[7:4]	rw	**New Basic Cycle Interrupt Node Pointer** NBCINP selects the interrupt output line INT_Om (m = 0-15) for a new basic or matrix cycle interrupt. 0000_B Interrupt output line INT_O0 is selected. 0001_B Interrupt output line INT_O1 is selected. $\cdots_B$ … 1110_B Interrupt output line INT_O14 is selected. 1111_B Interrupt output line INT_O15 is selected.

Field	Bits	Type	Description
NOTIFINP	[11:8]	rw	**Notification Interrupt Node Pointer** NOTIFINP selects the interrupt output line INT_Om (m = 0-15) for a notification interrupt. Possible notification events for this interrupt node pointer are: • bit field TTSR.ERRS changes • bit field TTSR.MSR changes • bit field TTSR.SYNCS changes • bit TTIRR.WFE is set • bit TTIRR.DISC is set 0000_B Interrupt output line INT_O0 is selected. 0001_B Interrupt output line INT_O1 is selected. $\ldots_B$ … 1110_B Interrupt output line INT_O14 is selected. 1111_B Interrupt output line INT_O15 is selected.
0	[31:12]	r	**Reserved** Read as 0; should be written with 0.

24.10.3 Scheduler Registers

STPTR0
Scheduler Start Pointer Node 0 Register

(3FFC$_H$) **Reset Value: 0000 0000$_H$**

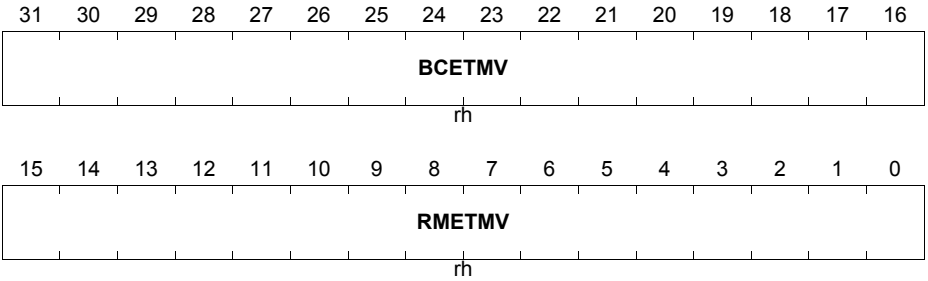


Field	Bits	Type	Description
STPTR	[6:0]	rh	**Start Pointer** This bit field determines the location of the first scheduler entry for TTCAN node 0. The value determines how many entries (counted in units of 32 bits) the first TME entry (TME1) for this TTCAN node is located below the last address of the scheduler memory. If two or more TTCAN nodes are implemented, all start pointers refer to the end (last address) of the scheduler memory.
0	[31:7]	r	**Reserved** Read as 0; should be written with 0.

The TMV bit fields in the scheduler timing status registers monitor the time mark information for the start of the next time window after the instruction collection phase of the scheduler (collected from the TME, RME or BCE entries).

STSRL
Scheduler Timing Status Register Low

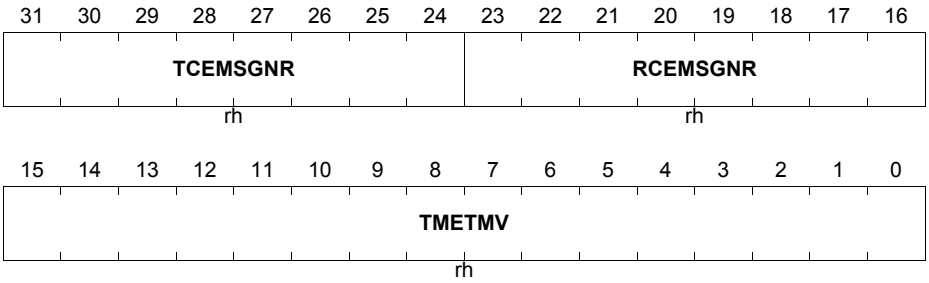
($2F0_H$) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
RMETMV	[15:0]	rh	**Time Mark Value from RME** This bit field indicates the compare value for the next time mark defined by an RME. This value is valid only if SISR.ICF = 1 and SISR.RMEV = 1.
BCETMV	[31:16]	rh	**Time Mark Value from BCE** This bit field indicates the compare value for the next time mark defined by an BCE. This value is valid only if SISR.ICF = 1 and SISR.BCEV = 1.

STSRH
Scheduler Timing Status Register High

(2F4$_H$) Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
TMETMV	[15:0]	rh	**Time Mark Value from TME** This bit field indicates the compare value for the next time mark defined by an TME. This value is valid only if SISR.ICF = 1 and SISR.TMEV = 1.
RCEMSGNR	[23:16]	rh	**Receive Control Entry Message Number** This bit field indicates the collected RCEMSGNR information from an RCE. This value is taken into account only if SISR.ICF = 1 and SISR.RCEV = 1.
TCEMSGNR	[31:24]	rh	**Transmit Control Entry Message Number** This bit field indicates the collected TCEMSGNR information from an TCE. This value is taken into account only if SISR.ICF = 1 and SISR.TCEV = 1.

The bits in the scheduler instruction status register monitor the information during and after the instruction collection phase of the scheduler. These values will become valid when the next time mark is reached.

SISR
Scheduler Instruction Status Register

($2F8_H$) **Reset Value: $0000\ 0000_H$**

Field	Bits	Type	Description
INP	[3:0]	rh	**Interrupt Node Pointer** This bit field indicates the collected INP information. This value is taken into account only when at least one of the four interrupt requests is enabled.
IENTRAF0	4	rh	**Interrupt Enable if TRAF = 0** This bit field indicates the collected IENTRAF0 information.
IENTRAF1	5	rh	**Interrupt Enable if TRAF = 1** This bit field indicates the collected IENTRAF1 information.
IENRECF0	6	rh	**Interrupt Enable if RECF = 0** This bit field indicates the collected IENRECF0 information.
IENRECF1	7	rh	**Interrupt Enable if RECF = 1** This bit field indicates the collected IENRECF1 information.
CHEN	8	rh	**Check Enable** This bit field indicates the collected CHEN information from an RCE.

Field	Bits	Type	Description
TREN	9	rh	**Transmit Enable** This bit field indicates the collected TREN information from an TCE.
ALTMSG	[11:10]	rh	**Alternative Message** This bit field indicates the collected ALTMSG information from an TCE.
ARBM	[13:12]	rh	**Arbitration Mode** This bit field indicates the collected ARBM information from an TME or an ARBE.
GM	14	rh	**Gap Mode** This bit field indicates the collected GM information from an RME or an BCE (only valid if RME or a BCE has been found).
ICF	15	rh	**Instruction Collection Finished** This bit field indicates that the instruction collection is finished for a time window. It is automatically cleared when a time mark is reached. It is set when the instruction collection is terminated. 0_B The instruction collection is not yet terminated. All other values in registers SISR, STSRL and STSR4 are invalid. 1_B The instruction collection is terminated. All other values in registers SISR, STSRL and STSRH are valid.
RCEV	16	rh	**Receive Control Entry Valid** This bit indicates that a valid receive control information has been found during the instruction collection for this time window. It is automatically cleared when a time mark is reached. 0_B The bit fields CHEN and RCEMSGNR are invalid. They are not taken into account for the next time window. 1_B The bit fields CHEN and RCEMSGNR are valid. They are taken into account for the next time window.

Field	Bits	Type	Description
TCEV	17	rh	**Transmit Control Entry Valid** This bit indicates that valid transmit control information has been found during the instruction collection for this time window. It is automatically cleared when a time mark is reached. 0_B The bit fields TREN, ALTMSG and TCEMSGNR are invalid. They are not taken into account for the next time window. 1_B The bit fields TREN, ALTMSG and TCEMSGNR are valid. They are taken into account for the next time window.
ICEV	18	rh	**Interrupt Control Entry Valid** This bit indicates that a valid interrupt control entry has been found during the instruction collection for this time window. It is automatically cleared when a time mark is reached. 0_B No valid ICE has been found 1_B A valid ICE has been found
ARBV	19	rh	**Arbitration Entry Valid** This bit indicates that a valid arbitration entry has been found during the instruction collection for this time window. It is automatically cleared when a time mark is reached. 0_B No valid ARBE has been found 1_B A valid ARBE has been found
TMEV	20	rh	**Time Mark Entry Valid** This bit indicates that a valid time mark entry has been found during the instruction collection for this time window. It is automatically cleared when a time mark is reached. 0_B No valid TME has been found 1_B A valid TME has been found
RMEV	21	rh	**Reference Mark Entry Valid** This bit indicates that a valid reference mark entry has been found during the instruction collection for this time window. It is automatically cleared when a time mark is reached. 0_B No valid RME has been found 1_B A valid RME has been found

Field	Bits	Type	Description
BCEV	22	rh	**Basic Cycle End Entry Valid** This bit indicates that a valid basic cycle end entry has been found during the instruction collection for this time window. It is automatically cleared when a time mark is reached. 0_B No valid BCE has been found 1_B A valid BCE has been found
0	[31:23]	r	**Reserved** Read as 0; should be written with 0.

Note: This register is reset at the start of a new instruction collection phase.

24.11 MultiCAN Module Implementation

This section describes CAN module interfaces with the clock control, port connections, interrupt control, and address decoding.

24.11.1 Interfaces of the MultiCAN Module

Figure 24-39 shows the TC1798 specific implementation details and interconnections of the MultiCAN module. The four I/O lines of the MultiCAN module (two I/O lines of each CAN node) are connected to I/O lines of Port 3. The MultiCAN module is also supplied by clock control, interrupt control, and address decoding logic. MultiCAN interrupts can be directed to the DMA controller and the GPTA modules. CAN interrupts are able to trigger DMA transfers and GPTA operations.

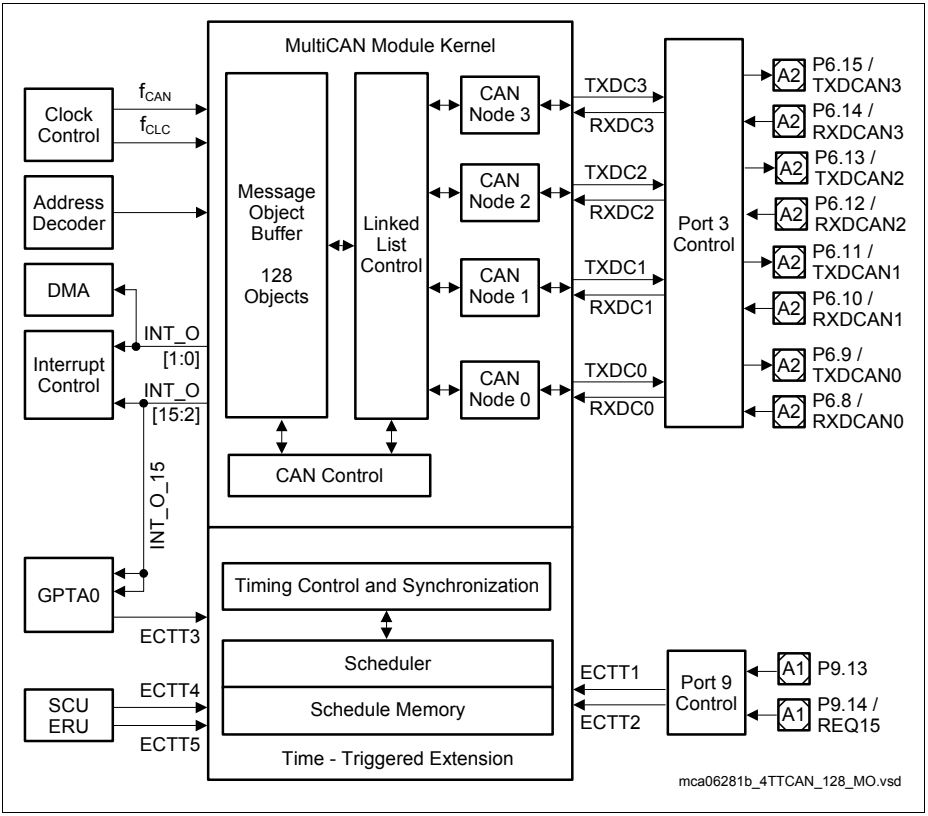

Figure 24-39 CAN with TTCAN Extension, Implementation / Interconnections

24.11.2 MultiCAN Module External Registers

The registers listed in **Figure 24-40** are not included in the MultiCAN module kernel but must be programmed for proper operation of the MultiCAN module.

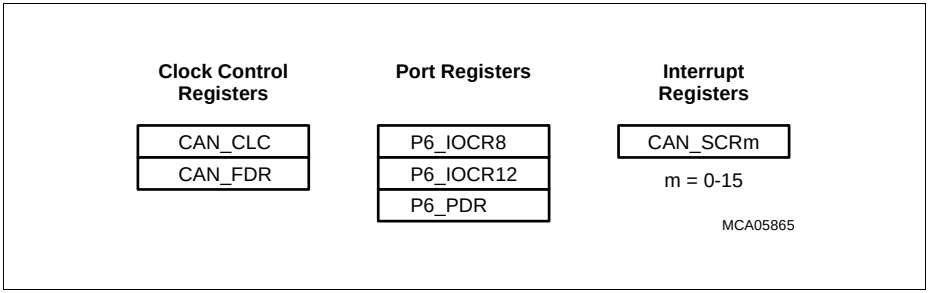

Figure 24-40 CAN Implementation-specific Special Function Registers

24.11.3 Module Clock Generation

As shown in **Figure 24-41**, the clock signals for the MultiCAN module are generated and controlled by a clock control unit. This clock generation unit is responsible for the enable/disable control, the clock frequency adjustment, and the debug clock control. This unit includes two registers:

- CAN_CLC: generation of the module control clock f_{CLC}
- CAN_FDR: frequency control of the module timer clock f_{CAN}

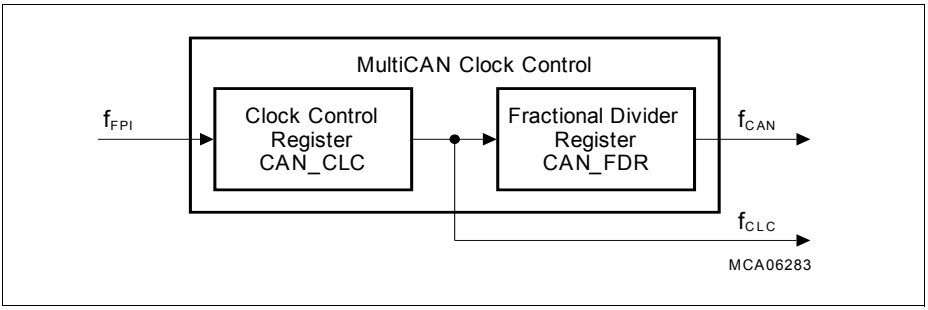

Figure 24-41 MultiCAN Module Clock Generation

The module control clock f_{CLC} is used inside the MultiCAN module for control purposes such as clocking of control logic and register operations. The frequency of f_{CLC} is identical to the system clock frequency f_{FPI}. The clock control register CAN_CLC makes it possible to enable/disable f_{CLC} under certain conditions.

The module timer clock f_{CAN} is used inside the MultiCAN module as input clock for all timing relevant operations (e.g. bit timing). The settings in the CAN_FDR register determine the frequency of the module timer clock f_{CAN} according the following two formulas:

$$f_{CAN} = f_{FPI} \times \frac{1}{n} \quad \text{with n = 1024 - CAN\_FDR.STEP} \qquad (24.1)$$

$$f_{CAN} = f_{FPI} \times \frac{n}{1024} \quad \text{with n = 0-1023} \qquad (24.2)$$

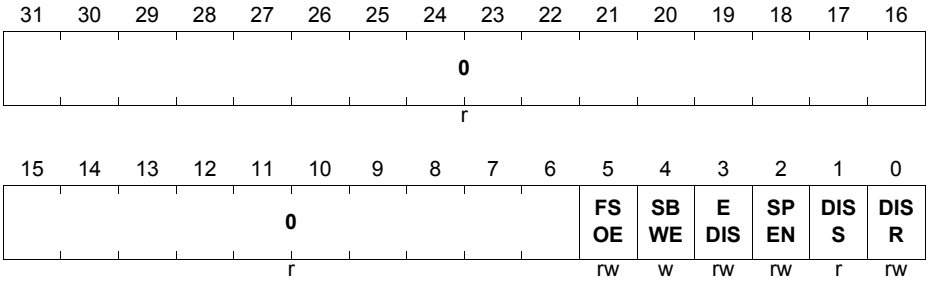
Equation (24.1) applies to normal divider mode (CAN_FDR.DM = 01_B) of the fractional divider. **Equation (24.2)** applies to fractional divider mode (CAN_FDR.DM = 10_B).

Note: The CAN module is disabled after reset. In general, after reset, the module control clock f_{CLC} must be switched on (writing to register CAN_CLC) before the frequency of the module timer clock f_{CAN} is defined (writing to register CAN_FDR).

24.11.3.1 CAN Clock Control Register

The clock control registers makes it possible to control (enable/disable) the module control clock f_{CLC}.

CAN_CLC
CAN Clock Control Register **(000_H)** **Reset Value: 0000 0003$_H$**

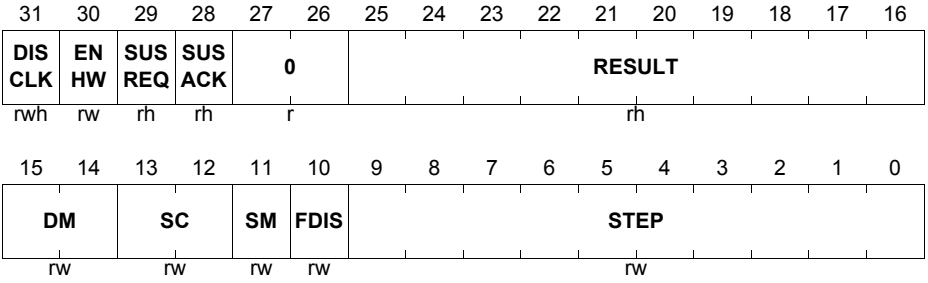


Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module.
DISS	1	r	**Module Disable Status Bit** Bit indicates the current status of the module.
SPEN	2	rw	**Module Suspend Enable for OCDS** Used to enable the suspend mode.
EDIS	3	rw	**Sleep Mode Enable Control** Used to control module's sleep mode.
SBWE	4	w	**Module Suspend Bit Write Enable for OCDS** Determines whether SPEN and FSOE are write-protected.
FSOE	5	rw	**Fast Switch Off Enable** Used to switch off fast clock in Suspend Mode.
0	[31:6]	r	**Reserved** Read as 0; should be written with 0.

Note: In disabled state, no registers of CAN module can be read or written except the CAN_CLC register.

The fractional divider register allows the programmer to control the clock rate of the module timer clock f_{CAN}.

CAN_FDR
CAN Fractional Divider Register ($00C_H$) Reset Value: $0000\ 0000_H$



Field	Bits	Type	Description
STEP	[9:0]	rw	**Step Value** Reload or addition value for RESULT.
FDIS	10	rw	**Freeze Disable** This bit controls the freeze function for this module. 0_B Module operates on corrected clock, with reduced modulation jitter. 1_B Module operates on uncorrected clock, with full modulation jitter.
SM	11	rw	**Suspend Mode** SM selects between granted or immediate Suspend Mode.
SC	[13:12]	rw	**Suspend Control** This bit field determines the behavior of the fractional divider in Suspend Mode.
DM	[15:14]	rw	**Divider Mode** This bit field selects normal divider mode, fractional divider mode, and off-state.
RESULT	[25:16]	rh	**Result Value** Bit field for the addition result.
SUSACK	28	rh	**Suspend Mode Acknowledge** Indicates state of SPNDACK signal.
SUSREQ	29	rh	**Suspend Mode Request** Indicates state of SPND signal.

Field	Bits	Type	Description
ENHW	30	rw	**Enable Hardware Clock Control** Controls operation of ECEN input and DISCLK bit.
DISCLK	31	rwh	**Disable Clock** Hardware controlled disable for f_{OUT} signal.
0	[27:26]	r	**Reserved** Read as 0; should be written with 0.

24.11.4 Port and I/O Line Control

The interconnections between the MultiCAN module and the port I/O lines are controlled in the port logic. Additionally to the port input selection, the following port control operations must be executed:

- Input/output function selection (IOCR registers)
- Pad driver characteristics selection for the outputs (PDR registers)

24.11.4.1 Input/Output Function Selection in Ports

The port input/output control registers contain the bit fields that select the digital output and input driver characteristics such as pull-up/down devices, port direction (input/output), open-drain, and alternate output selections. The I/O lines for the MultiCAN module are controlled by the port input/output control registers P6_IOCR8 and P6_IOCR12.

Table 24-17 shows how bits and bit fields must be programmed for the required I/O functionality of the CAN I/O lines.

Table 24-17 MultiCAN I/O Control Selection and Setup

Module	Port Lines	Input/Output Control Register Bits	I/O
CAN	P6.8 / RXDCAN0	P6_IOCR8.PC8 = $0XXX_B$	Input
	P6.9 / TXDCAN0	P6_IOCR8.PC9 = $1X01_B$	Output
	P6.10 / RXDCAN1	P6_IOCR8.PC10 = $0XXX_B$	Input
	P6.11 / TXDCAN1	P6_IOCR8.PC11 = $1X01_B$	Output
	P6.12 / RXDCAN2	P6_IOCR12.PC12 = $0XXX_B$	Input
	P6.13 / TXDCAN2	P6_IOCR12.PC13 = $1X01_B$	Output
	P6.14 / RXDCAN3	P6_IOCR12.PC14 = $0XXX_B$	Input
	P6.15 / TXDCAN3	P6_IOCR12.PC15 = $1X01_B$	Output

24.11.4.2 Node Receive Input Selection

Additionally to the I/O control selection, as defined in **Table 24-17**, the selection of a CAN node's receive input line requires that bit field RXSEL in its node port control register NPCRx must be set according to **Table 24-18**. Values for NPCRx.RXSEL other than those of **Table 24-18** result in a recessive receive input for node x.

This feature allows, for example, a CAN node which operates in analyzer mode to monitor the receive operations of its neighbor CAN node. The default setting after reset of a node's NPCRx.RXSEL bit field connect node x with RXDCANx I/O line (x = 0-2).

Table 24-18 Receive Input Selection

Receive Input of	Connected to	Selected by
CAN Node 0	P6.8 / RXDCAN0	NPCR0.RXSEL = 000_B
	P6.10 / RXDCAN1	NPCR0.RXSEL = 001_B
CAN Node 1	P6.10 / RXDCAN1	NPCR1.RXSEL = 000_B
	P6.12 / RXDCAN2	NPCR1.RXSEL = 001_B
CAN Node 2	P6.12 / RXDCAN2	NPCR2.RXSEL = 000_B
	P6.14 / RXDCAN3	NPCR2.RXSEL = 001_B
CAN Node 3	P6.14 / RXDCAN3	NPCR3.RXSEL = 000_B
	P6.8 / RXDCAN0	NPCR3.RXSEL = 001_B

24.11.4.3 External CAN Time Trigger Inputs

The external CAN time trigger inputs ECTT[7:1] can be used as a transmit trigger for a reference message. In the TC1798, these input lines are connected as shown in **Table 24-19**.

Table 24-19 External CAN Time Trigger Inputs

Receive Input	Connected to	From Module
ECTT1	P9.13	Port 9
ECTT2	P9.14 / REQ15 Input	Port 9 / External Request Unit (SCU)
ECTT3	Output OUT5	GPTA0
ECTT4	Output IOUT2	External Request Unit (SCU)
ECTT5	Output IOUT3	External Request Unit (SCU)
ECTT6	-	-
ECTT7	-	-

24.11.4.4 DMA Request Outputs

The interrupt output lines INT_O0 to INT_O1 of the MultiCAN module can be used as a DMA requestor and are able to trigger DMA transfers. INT_O[1:0] are connected to the DMA controller as shown in **Table 24-20**.

Table 24-20 CAN-to-DMA Request Connections

DMA Channel	Connected to CAN Interrupt Output	Selected in DMA Controller by programming
06	INT_O0	CHCR06.PRSEL = 011_B
07	INT_O1	CHCR07.PRSEL = 010_B

24.11.4.5 Connectons to GPTA0 Inputs

The interrupt output line INT_O15 is connected to the GPTA module, see **Table 24-21**.

Table 24-21 CAN-to-GPTA0 Request Connections

GPTA Input	Connected to CAN Interrupt Output
INT0	INT_O15

24.11.5 Interrupt Control

The interrupt control logic in the MultiCAN module uses an interrupt compressing scheme that allows high flexibility in interrupt processing. There are 140 hardware interrupt sources and one software interrupt source available:

- CAN node interrupts:
  - Four different interrupt sources for each of the three CAN nodes = 12 interrupt sources
- Message object interrupts:
  - Two interrupt source for each message object = 128 interrupt sources
- One software initiated interrupt (register MITR)

Each of the 140 hardware initiated interrupt sources is controlled by a 4-bit interrupt pointer that directs the interrupt source to one of the sixteen interrupt outputs INT_Om (m = 0-15). This makes it possible to connect more than one interrupt source (between one and all) to one interrupt output line. The interrupt wiring matrix shown in **Figure 24-42** is built up according to the following rules:

- Each output of the 4-bit interrupt pointer demultiplexer is connected to exactly one OR-gate input of the INT_Om line. The number “m” of the corresponding selected INT_Om interrupt output line is defined by the interrupt pointer value.
- Each INT_Om output line has an input OR gate which is connected to all interrupt pointer demultiplexer outputs which are selected by an identical 4-bit pointer value.

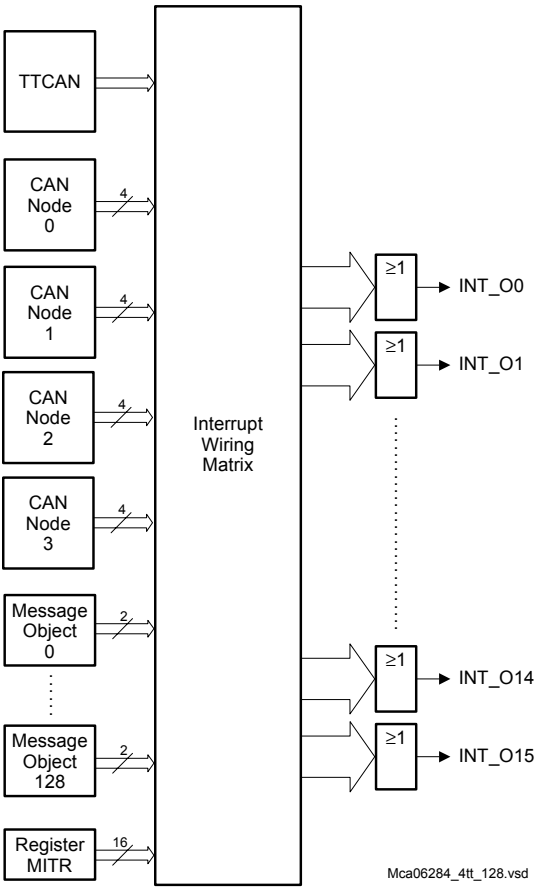


Figure 24-42 Interrupt Compressor

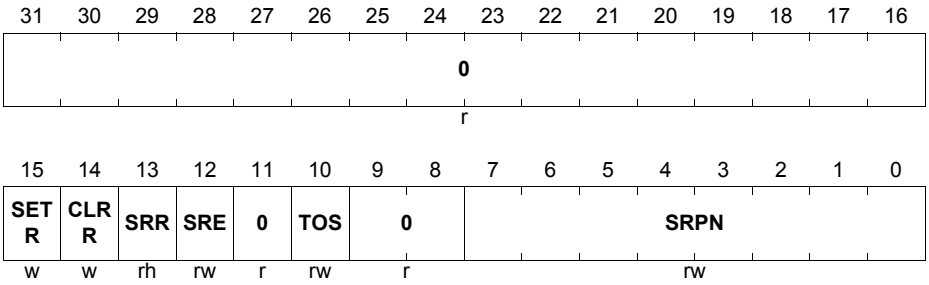
24.11.5.1 CAN Service Request Control Register

Each of the sixteen interrupt outputs INT_Om of the MultiCAN module is controlled by its service request control registers.

CAN_SRCm (m = 0-15)
CAN Service Request Control Register m
($0FC_H$-m*4_H) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
SRPN	[7:0]	rw	**Service Request Priority Number**
TOS	10	rw	**Type of Service Control**
SRE	12	rw	**Service Request Enable**
SRR	13	rh	**Service Request Flag**
CLRR	14	w	**Request Clear Bit**
SETR	15	w	**Request Set Bit**
0	[9:8], 11, [31:16]	r	**Reserved** Read as 0; should be written with 0.

Note: Additional details on service request nodes and the service request control registers are described in section "Service Request Nodes" of the TC1798 System Units part.

Some of the sixteen interrupt outputs of the MultiCAN module can be used to trigger operations in the DMA controller.

24.11.6 MultiCAN Module Register Address Map

In addition to the MultiCAN register address map from **Page 24-63**, the complete MultiCAN module register address map of **Figure 24-43** also shows the general implementation-specific registers for clock control, module identification, and interrupt service request control and adds the absolute address information. The address map of TTCAN registers only is shown in **Figure 24-38**.

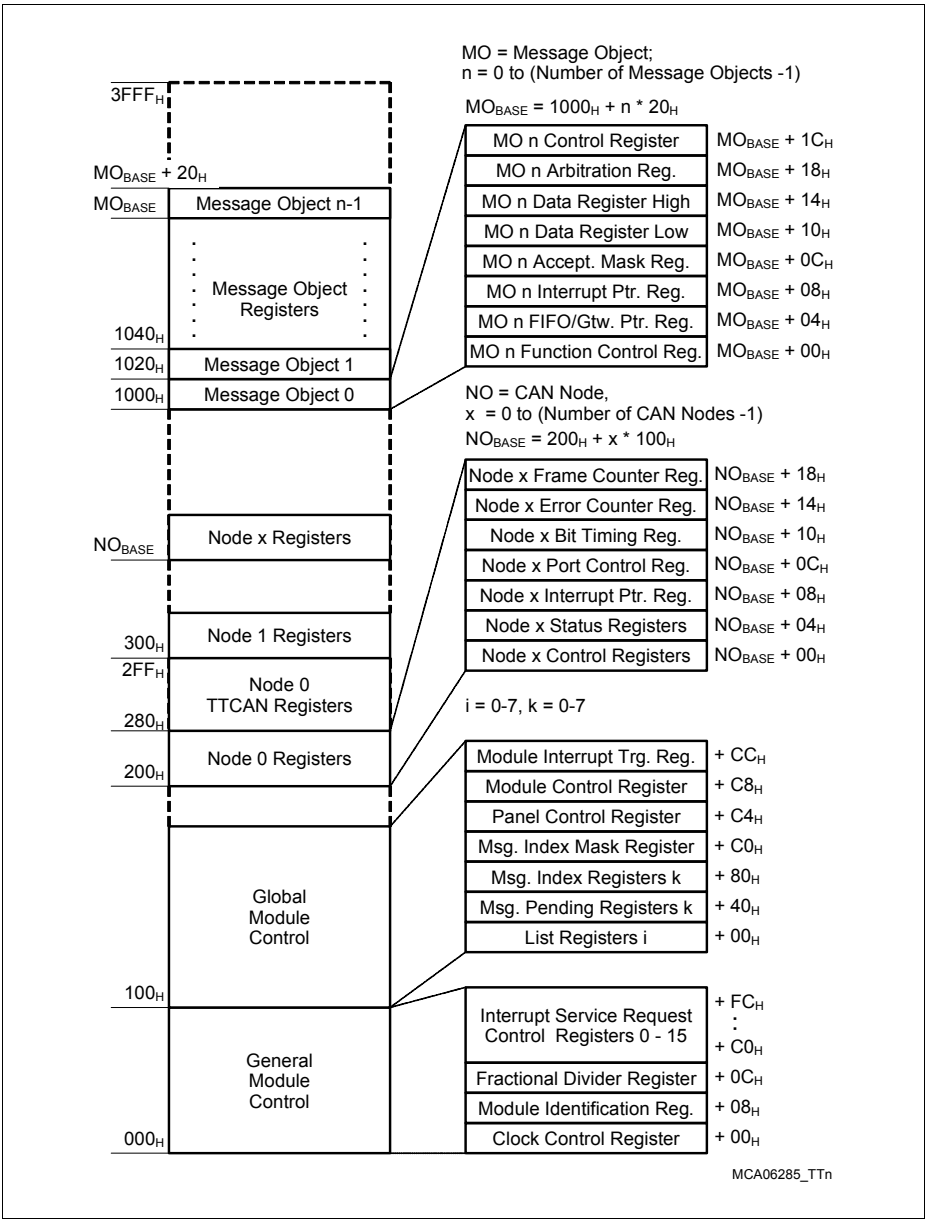


Figure 24-43 MultiCAN Module Register Map

25 Single Edge Nibble Transmission (SENT)

This chapter describes the SENT Interface of the TC1798. It contains the following sections:

- Functional description of the SENT kernel (see **"Overview" on Page 25-2**)
- SENT kernel register descriptions (see **"SENT Kernel Registers" on Page 25-22**)
- TC1798 implementation-specific details and registers of the SENT module (port connections and control, interrupt control, address decoding, and clock control, see **"SENT Module Implementation" on Page 25-64**

25.1 SENT Kernel Description

Figure 25-1 shows a global view of the SENT interface.

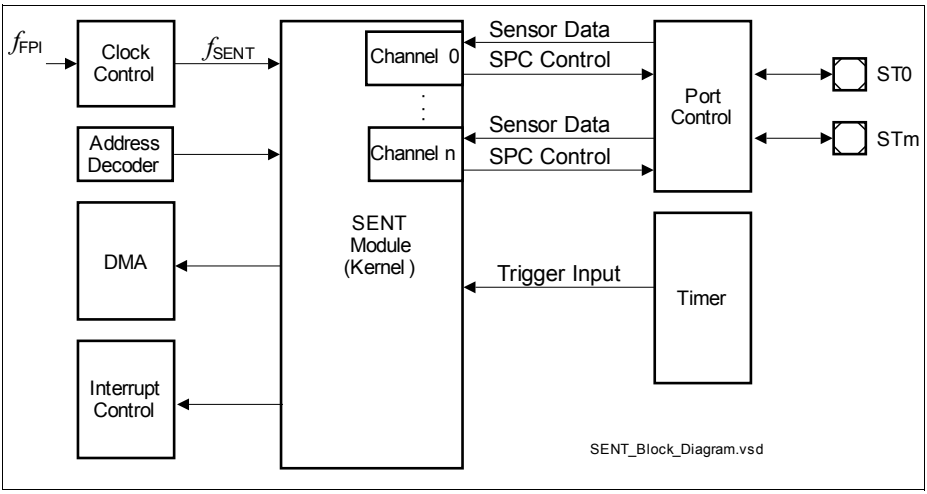

Figure 25-1 General Block Diagram of the SENT Interface

The SENT module communicates with the external world via one I/O line for each channel. The STx lines are the receive data input signals. They can overlay ADC inputs. If the optional SPC mode is used, they can be used on a port configured with an open drain transistor. This way the optional SPC data can be transmitted and the line is used bidirectionally. In case of an external transceiver, receive and transmit path can be routed to two different ports.

25.1.1 Overview

The SENT interface provides a serial communication link typically used to connect sensors or other peripheral devices.

Clock control, address decoding, and service request control are managed by the SENT module kernel.

The SENT IP-module performs communication according to the SENT specification J2716 FEB2008 Rev. 3 2009-06-24.

While staying compliant to this standard, it is able to cover as well the Short PWM Code (SPC) protocol extensions. This enhances the standardized SENT protocol defined by J2716 FEB2008 Rev. 3 2009-06-24. SPC enables the use of enhanced protocol functionality like “synchronous”, “range selection” and “ID selection” protocol mode.

Receive data on a SENT channel can be set up according to the underlying application. In particular the number of nibbles forming one value is configurable.

The message storage consists of two 32-bit registers for each channel, representing a flexible double buffer system.

In SPC mode, maintaining the sample and transmission schedule as well as providing message status information is support.

The register set of the SENT module can be accessed directly by the CPU for configuration, data read out and status query.

The SENT IP-module supports the following features:

Features

- Conformance with SENT protocol specification J2716 FEB2008 Rev. 3 2009-06-24
- Data rates of up to 65,8 kbit/s at 3 µs tick length and 6 data nibbles on each channel
- Support of standard tick times (3 µs through 90 µs) and
- Message tick time programmable between 1 µs and 90 µs
- 8 SENT channels working independently in parallel
- Status nibble optionally included in the checksum (default not included)
- Sticky interrupt flags, error interrupt optional (default disabled)
- Configurable frame length (default is 24 bit), max data size is 32 bits
- Serial data processing optional (default: disabled)
- Option for bigger frame lengths (must still be fix for each application)
- transparent mode (nibble CRCs are written to the receive control register for SW processing)
- Support of SPC
- Support of trailing Pause Nibble of any length (even longer than 70 ticks)
- Indication of system status: STOP, INITIALIZED, RUNNING, SYNCHRONIZED
- The receiver module will monitor the message for the following error conditions:
  - Calibration pulse length deviates more than +/-25% from the nominal 56 ticks
  - Too many or too few nibbles between calibration pulses.
  - Checksum error.
  - Successive calibration pulse differ by more than 1.5625%
  - Any nibble data values measured as < 0 or >15.
- When any of those errors is detected, the receiver module shall declare that a message error has occurred and ignore the entire message.
- Any of those errors shall cause the receiver to begin searching for a valid calibration pulse to re synchronize.
- Option to enable/disable the check of the next calibration pulse before validation of received data
- Digital Glitch filter suppressing noise
- Buffer overrun detection
- Optional output inversion for use of external open drain transistor
- Optional input inversion for use of external open transistor for level shifting
- Interrupt on status nibble violation
- Programmable Nibble sorting to support LSN or HSN first and relief CPU

25.1.2 General Operation

The Single Edge Nibble Transmission encoding scheme (SENT) is intended for use in applications where high resolution sensor data needs to be communicated from a sensor to an Engine Control Unit (ECU). It is intended as a replacement for the lower resolution methods of 10 bit A/D converters and PWM and as a simpler low cost alternative to CAN or LIN. The implementation assumes that the sensor is a smart sensor containing a microprocessor or dedicated logic device (ASIC) to create the signal.

Figure 25-3 shows a typical TC1798 application in which a SENT interface reads a sensor device.

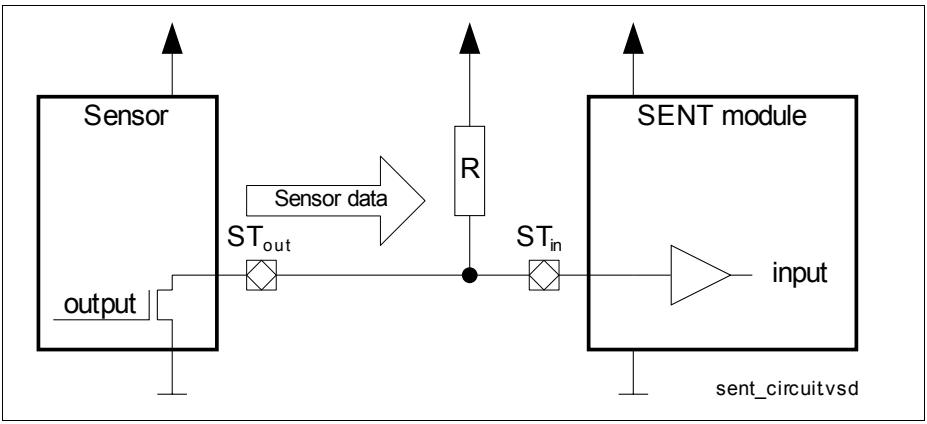

Figure 25-2 SENT to External Device Connection

SENT communication is unidirectional from sensor to controller without any synchronization. The sensor signal is transmitted as a series of PWM blocks measured as falling to falling edge times.

The Short PWM Code (SPC) extension overcomes the drawback of unidirectionality as said above while keeping conformance to the standard.

Figure 25-3 shows a typical TC1798 application in which an SPC enabled SENT ECU reads an SPC enabled SENT sensor device.

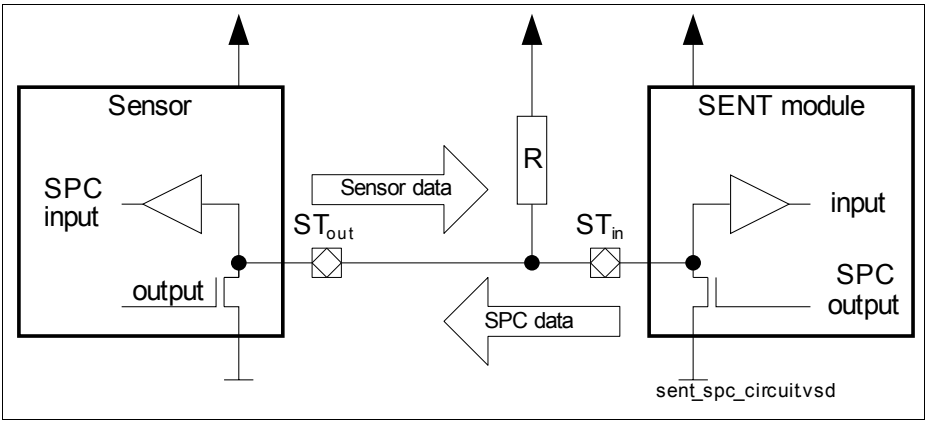

Figure 25-3 SENT SPC to External Device Connection

Some applications are:

- Read out of the external throttle position sensor (e.g. SENT enabled linear hall sensor)
- Receiving pedal position
- Synchronize sampling and read out of up to four sensors on one single line (SPC)
- Selection of 1 out of 4 sensors connected to a single SENT channel.
- Serial connections of the TC1798 to other peripheral devices

25.1.2.1 Definitions

SENT: Single Edge Nibble Transmission

Nibble: Four Bit value between 0 and 15 = half a Byte = one character in hex (0 to F)

SPC: Short PWM Code

PWM: Pulse Width Modulation

ASIC: Application Specific Integrated Circuit

CAN: Controller Area Network

LIN: Local Interconnect Network

ISO: International Organization for Standardization

ECU: Electronic Control Unit

FSM: Finite State Machine

25.1.3 Standard SENT Operation

Standard SENT Mode supports communication fully compliant to J2716 FEB2008 Rev. 3 2009-06-24, in which only the external device is sending and the ECU is receiving. In this unidirectional communication, both transmitter and receiver use the same data frame format and have the same baud rate. These settings are defined at system integration time and do not change for a given application. Data is received on pin ST. **Figure 25-4** shows the block diagram of the SENT Module when operating in Standard SENT Mode.

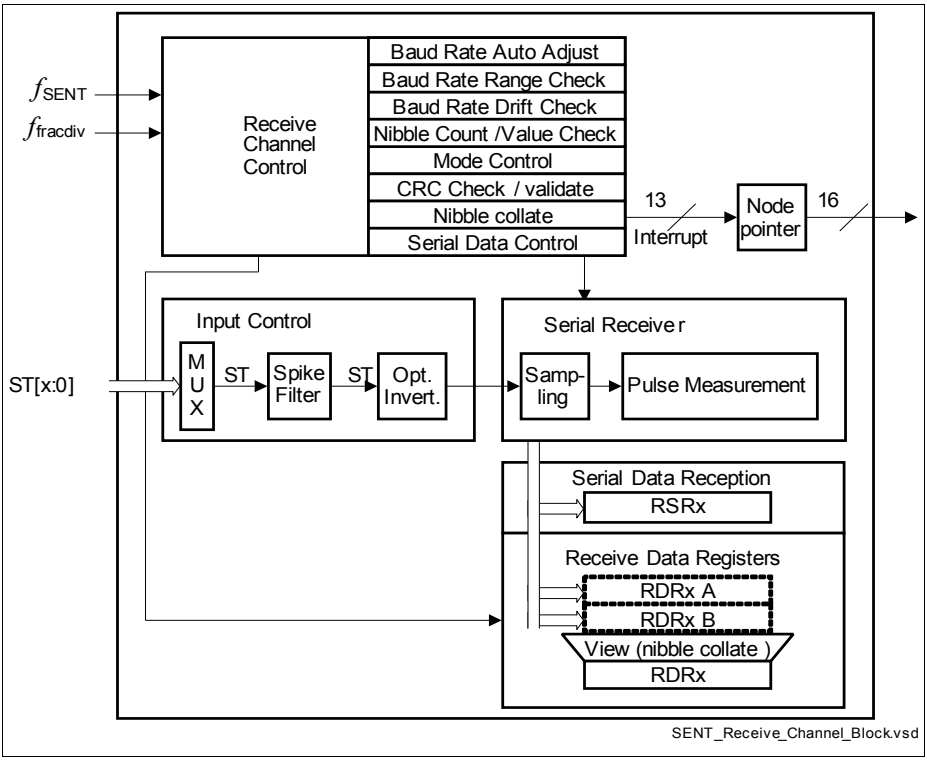

Figure 25-4 Standard SENT Mode Operation

25.1.3.1 Frame Formats and Definitions

This section describes the frame formats and definitions of the SENT protocol.

Basic Definitions

Figure 25-5 shows the layout and definitions of a standard SENT frame. Note that the SENT standard does not specify whether the most significant nibble or the least significant nibble is sent out first.

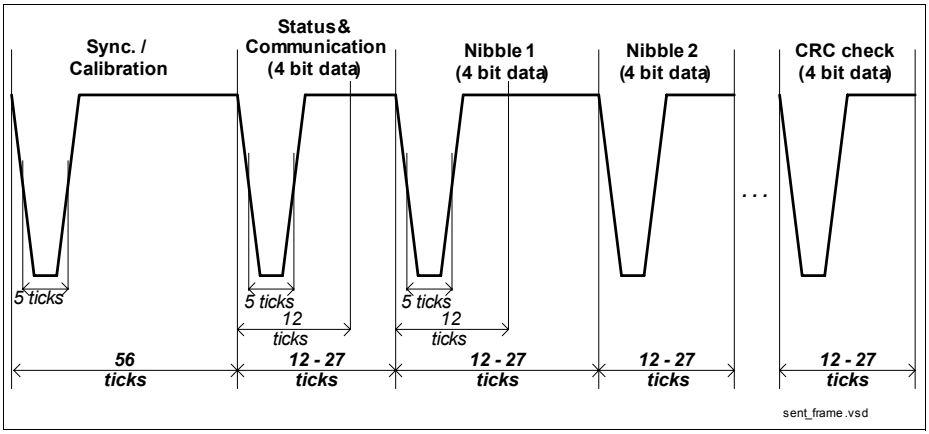

Figure 25-5 Standard Encoding Frame

Standard Serial Data Encoding

The serial data is transmitted bit wise per frame in bit 2 of the Status and Communication nibbles of consecutive messages from the transmitter.

Bit Number	Bit Function
0	Reserved for specific application
1	Reserved for specific application
2	Serial Data message bits
3	Message start = 1, otherwise = 0

Figure 25-6 Standard Serial Data Encoding

Standard Serial Data Frame

Serial data is communicated in a 16-bit sequence as shown in **Figure 25-7**. The staring bit of a serial message is indicated by a 1 in bit 3 o the Status and Communication nibble. That SENT message and the next 15 must be successfully transmitted (no errors) for the serial value to be received. The CRC generation is identical with the CRC generation on the data nibbles.

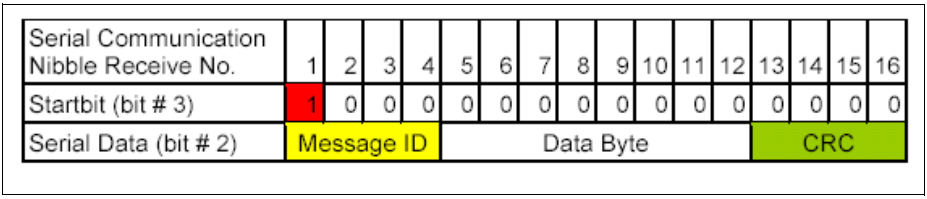

Figure 25-7 Serial Data Frame

CRC Calculation

The Signal data and the Serial data is secured with a 4 bit CRC. The standard CRC calculation method is well defined in the J2716 FEB2008 Rev. 3 2009-06-24.

Note: RCR.CRZ defines, if a zero nibble is added for calculation or not.

The alternative checksum nibble is a 4-bit CRC of the data nibbles (including the status nibble if RCR.SNI is set, as used in sensor TLE4998). The CRC is calculated using a polynomial x^4 +x^3 + x^2 + 1 with a seed value of 0101.

In order to facilitate CRC implementations and to avoid ambiguities, an example implementation of the alternative 4-bit CRC is given below. This is used e.g. in the sensor TLE4998 for the signal data. See **Figure 25-8** for details.

```
// Fast way for any µC with low memory and compute capabilities
// contains input data (status nibble, 6 data nibble, CRC)
char Data[8] = {…};
// required variables and LUT
char CheckSum, i;
char CrcLookup[16] = {0, 13, 7, 10, 14, 3, 9, 4, 1, 12, 6, 11, 15,
2, 8, 5};
CheckSum= 5; // initialize checksum with seed “0101”
for (i=0; i<7; i++) {
     CheckSum = CheckSum ^ Data[i];
     CheckSum = CrcLookup[CheckSum];
};
// finally check if Data[7] is equal to CheckSum
```

Note: For the “Extended Serial Message Frame Format”, an own 6-bit CRC calculation method is defined by the standard.

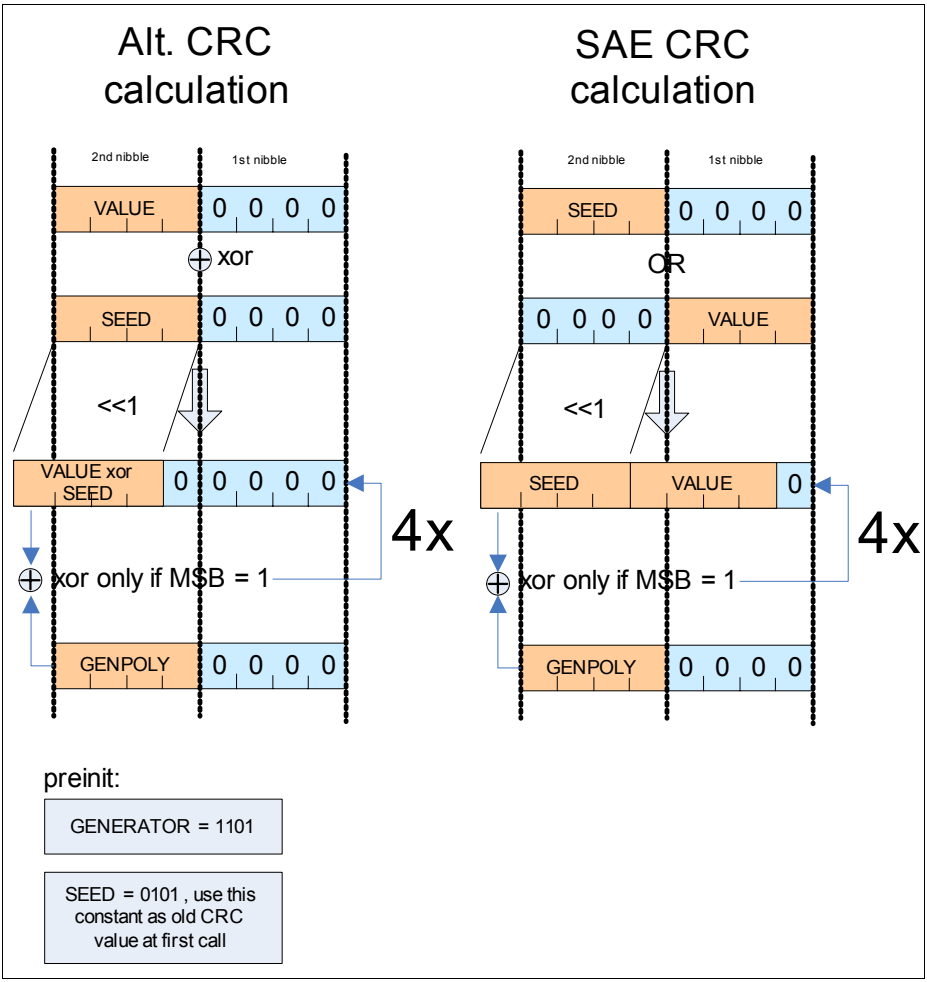

Figure 25-8 Alternate vs. SAE CRC Calculation

Extended Serial Data Encoding

The serial data is transmitted bit wise per frame in bits [3:2] of the Status and Communication nibbles of 18 consecutive messages from the transmitter.

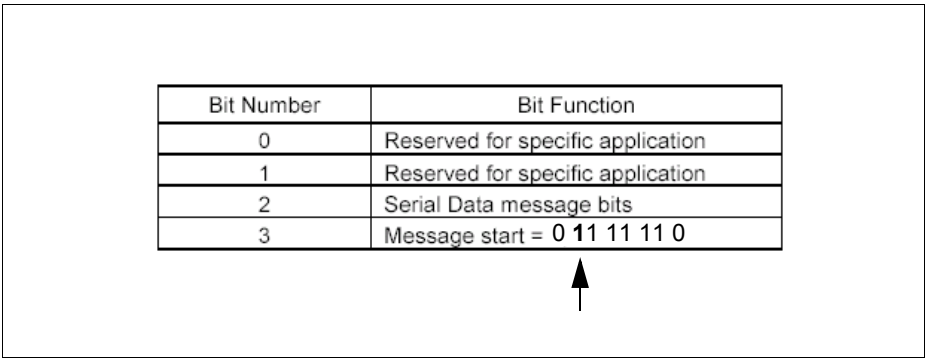

Figure 25-9 Extended Serial Data Encoding

Extended Serial Data Frame

Serial data is communicated in a 18-bit sequence as shown in **Figure 25-10**. The frame start of a serial message is indicated by the unique pattern “01111110” in bit #3 of the status and communication nibble. The first “1” in a series of six ones (after a “0”) indicates the first nibble of a serial message frame. Serial data bit #3 of serial communication nibbles 1 - 6 are set to “1”. Serial data bit #3 of serial communication nibbles 7, 13 and 18 are set to “0”. 18 consecutive SENT messages must be successfully transmitted (no errors) for the serial value to be received. The CRC generation is different from the CRC generation on the data nibbles. (See SENT Standard)

The serial message frame contains 21 bits of message data and a 6-bit frame-check sequence. Two different configurations can be chosen:

- 12-bit data and 8-bit message ID
- 16-bit data and 4-bit message ID

A configuration bit (serial data bit #3, serial communication nibble No. 8) determines the configuration of the enhanced serial message frame. It determines how the SENT module automatically interprets the serial data.

- Configuration bit = 0: 12-bit data and 8-bit message ID
- Configuration bit = 1: 16-bit data and 4-bit message ID

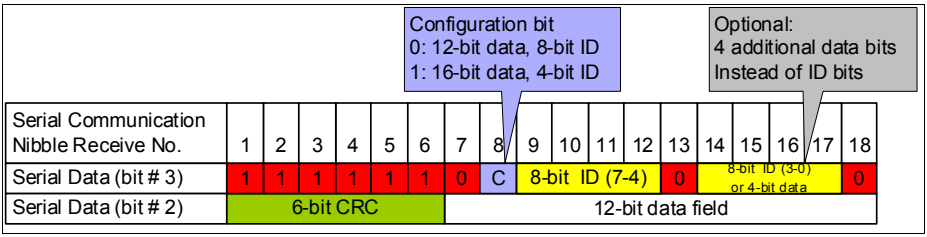

Figure 25-10 Extended Serial Data Frame

Figure 25-11 shows in detail the frame structure for Extended Serial Data Frames with Configuration Bit = 0.

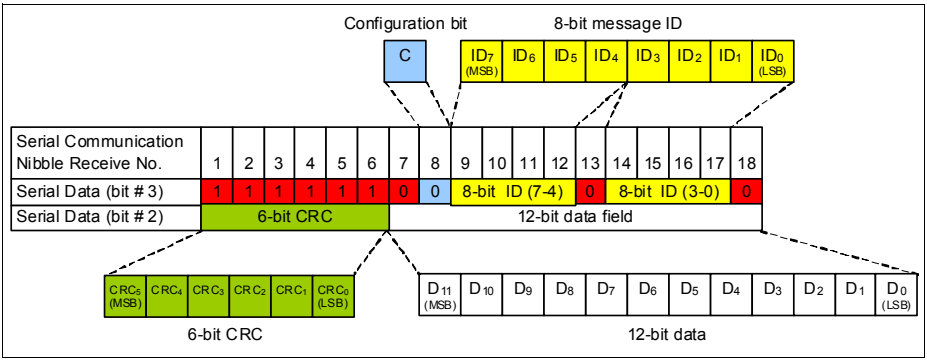

Figure 25-11 Configuration Bit = 0

Figure 25-12 shows in detail the frame structure for Extended Serial Data Frames with Configuration Bit = 1.

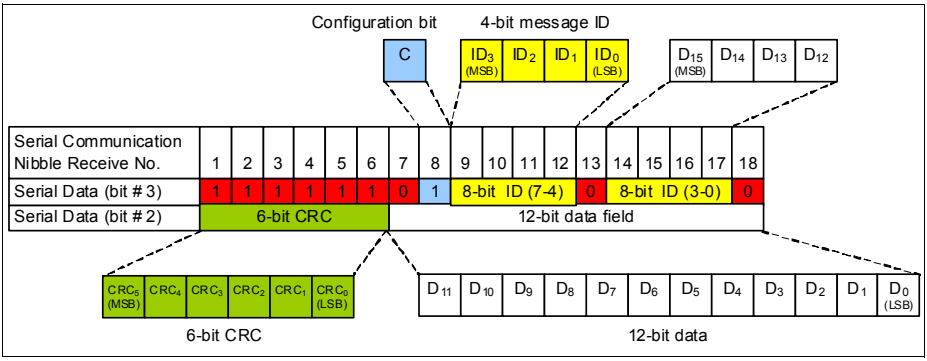

Figure 25-12 Configuration Bit = 1

25.1.4 SPC Operation

The module supports a SPC (Short PWM Code) protocol, which enhances the standardized SENT protocol (Single Edge Nibble Transmission) defined by J2716 FEB2008 Rev. 3 2009-06-24. SPC enables the use of enhanced protocol functionality due to the ability to select between “synchronous”, “range selection” and “ID selection” protocol mode or even “bidirectional transmit mode”.

25.1.4.1 Synchronous Transmission

In the “synchronous” mode, the sensor (slave) starts to transfer a complete data frame only after a low pulse is forced by the master on the OUT pin. This means that the data line is bidirectional - an open drain output of the micro controller (master) sends the trigger pulse. The sensor then initiates a sync pulse and starts to calculate the new output data value. After the synchronization period, the data follows in form of a standard SENT frame, starting with the status, data and CRC nibbles. At the end, an end pulse allows the CRC nibble decoding and indicates that the data line is idle again. The timing diagram in **Figure 25-13** visualizes a synchronous transmission

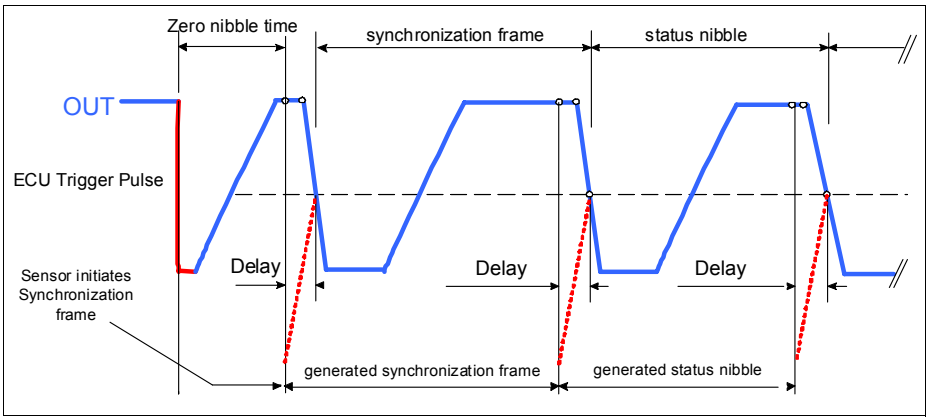

Figure 25-13 Synchronous Transmission (SPC)

25.1.4.2 Range Selection

The low time duration of the master can be used to select the range of the sensor in SPC dynamic range selection mode.

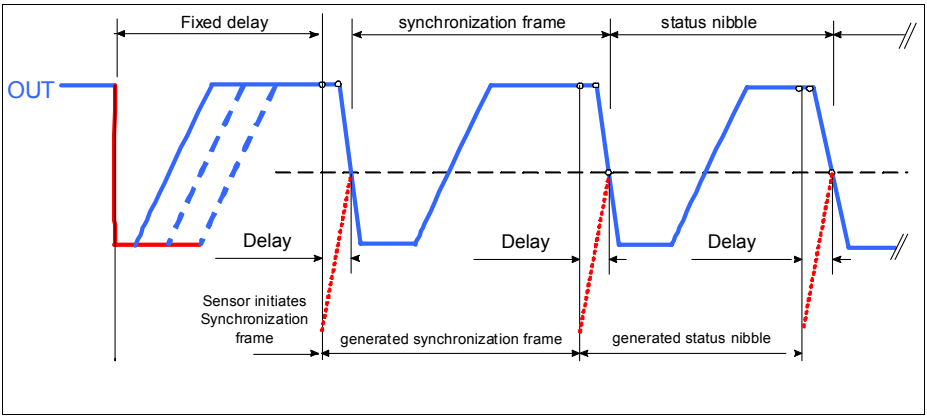

Figure 25-14 Range (SPC)

25.1.4.3 ID Selection

This functionality is similar to the previous mode, but instead of switching the range of one sensor, one of up to four sensors are selectable on a bus (bus mode, 1 master with up to 4 slaves). This allows parallel connection of up to 4 sensors using only three lines (VDD, GND, OUT), as illustrated in **Figure 25-15**.

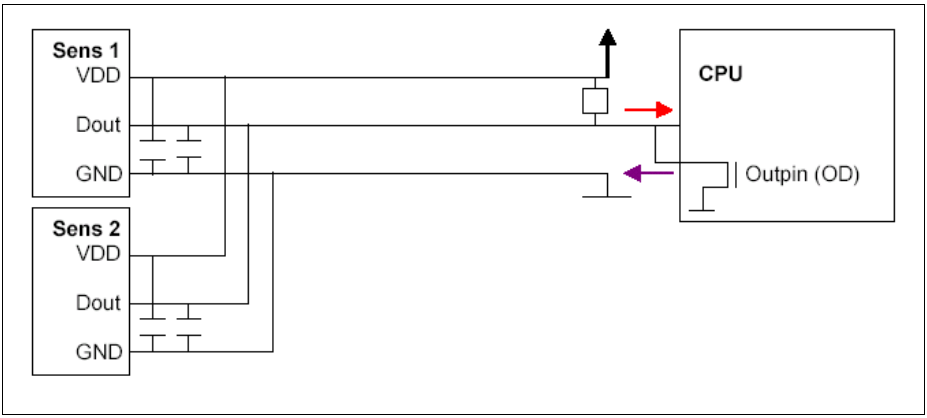

Figure 25-15 ID Selection (SPC)

25.1.4.4 Bidirectional Transmit Mode

After addressing the sensor the ECU interrupts the sensor sync pulse by pulling down the line. The ECU starts to transmit own nibbles on the time base of the selected sensor. The ECU has to adapt the sensors timing from an earlier received cycle.

The sensor detects the falling edge that infringes the protocol and switches to receive mode as illustrated in **Figure 25-16**.

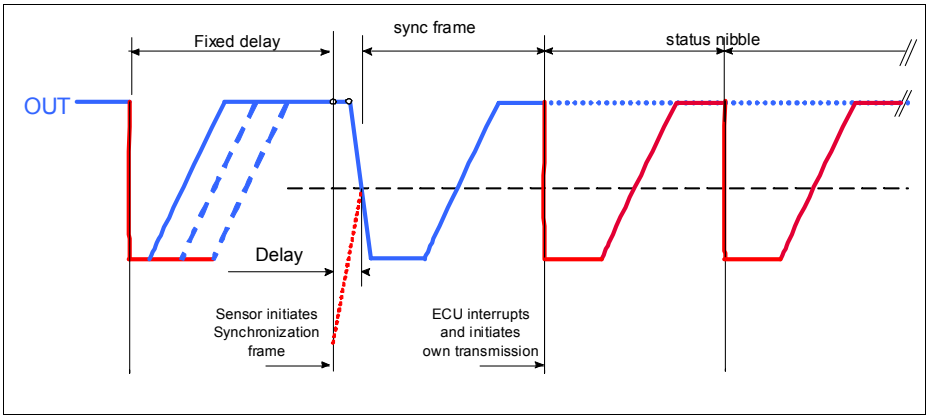

Figure 25-16 Bidirectional Transmit Mode (SPC)

25.1.4.5 SPC Timing

An SPC transmission is initiated by a Master pulse on the OUT pin. To detect a low level on the OUT pin, the voltage must be below a threshold Vthf. The sensor detects that the OUT line has been released as soon as Vthr is crossed. **Figure 25-17** shows the timing definitions for the master pulse. The master low time tmlow as well as the total trigger time tmtr are individual for the different SPC modes and are given in the sensors specifications.It is recommended to chose the typical master low time exactly between the minimum and the maximum possible time given by the connected sensor: tmlow,typ = (tmlow,min + tmlow,max) / 2.

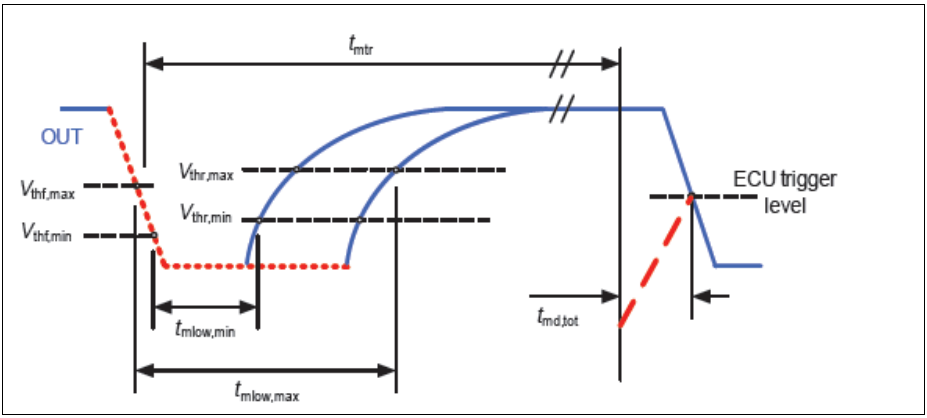

Figure 25-17 Timing (SPC)

25.1.4.6 Abort of Frames

Only a reset condition of the device or choosing Mode 0 by clearing bit field SCRx.TRIG can abort a current transmission. The SENT module does not start a new frame transmission when the channel becomes disabled, the suspend mode is requested, or the sleep mode is entered. If one of these three conditions becomes active during a running frame transmission, the frame transmission is completely finished before the requested abort state is entered. Note that in this case no frame finished interrupt is generated any more.

Note: Received frames are aborted immediately on a disable, suspend or sleep request.

25.1.5 Baud Rate Generation

The nominal baud rate of each channel is individually adjustable. This is required as it is depending from the connected sensor and its current deviation from nominal frequency.

The actual baud rate of the channel follows automatically the baud rate of the connected device and its current deviation from nominal frequency. The adaptation range is +- 25% as specified in J2716 FEB2008 Rev. 3 2009-06-24.

Chapter 25.1.5 shows in detail how the baud rate for each channel is adjusted. 1 / f_{tick_x} defines the resulting tick length.

In the first stage, a global fractional divider serves as pre divider. Its intermediate frequency $f_{fracdiv}$ can be set up so that it is handy as input frequency for the different SENT channels. The clock signal f_{pdiv} of a channel must always be at least 20 times the nominal tick frequency of the channel. This is to allow for the highly flexible and big tolerance of +-25% versus the sending device. In addition the module must be able to detect a deviation in the length of 2 consecutive Synchronization / Calibration pulses of 1.5625% (1/64) and adapt the own baud rate. The tick time is typically 3 µs but can vary by standard and take values up to 10 µs. Future application might require even shorter tick times for higher repetition rates. This is why this implementation allows for an even extended range of 1 … 90 µs. To achieve this each channel has its own fractional divider. This allows to downscale the frequency of f_{tick} precisely to the required tick frequency. For details on the principles of a fractional divider, please refer to the SCU chapter of TC1798 section “Clock Control”.

The SENT module provides two clock signals to the channels (**Figure 25-18**):

- f_{SENT}
  This is the module clock that is used inside the SENT kernel for control purposes such as clocking of control logic and register operations. The frequency of f_{SENT} is always identical to the system clock frequency f_{FPI}. The clock control register SENT_CLC makes it possible to enable/disable f_{SENT} under certain conditions.
- $f_{fracdiv}$
  This clock is the module clock that is used inside the SENT kernel for baud rate generation of the serial channels. The fractional divider register SENT_FDR controls the frequency of $f_{fracdiv}$. Usually not required and set to 1.

The channels generate two local clock signals:

- f_{pdiv_x}
  This clock is the channel clock that is used inside the SENT channel x for baud rate generation of the serial channel. The divider register SENT_CPDRx controls the frequency of f_{pdiv_x}.
- f_{tick_x}
  This clock is the channel clock that is used inside the SENT channel as the baud rate frequency. The fractional divider register SENT_CFDRx controls the frequency of

f_{tick_x}.The higher the value of DIV the higher the precision with which the Synchronization / Calibration pulse and the deviation in the length of 2 consecutive Synchronization / Calibration pulses (drift) can be measured.
DIV must be set in an interval of [560, 3276].

•

Each time a Synchronization / Calibration pulse starts DIVM is measured. DIVM is the result of measuring the calibration pulse duration with f_{pdiv_x}. At the end of the Synchronization / Calibration pulse this value is taken as new divider of the CFDR.

Each time a pulse starts, the internal accumulator of the CFDR is preset with DIVM / 2. This is required to center the data eye and to make the margin symmetrical.

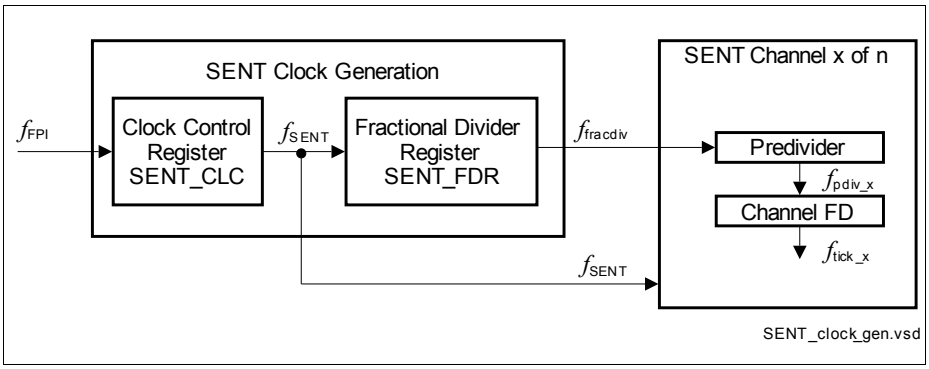

Figure 25-18 SENT Module Clock Generation

The following two formulas define the frequency of $f_{fracdiv}$:

$f_{fracdiv} = f_{SENT}$ / (1024 - SENT_FDR.STEP); FDR.DM = 01_B (25.1)

$f_{fracdiv} = f_{SENT}$ x SENT_FDR.STEP / 1024 with STEP = 0 … 1023; FDR.DM = 10_B (25.2)

The following formula defines the frequency of f_{pdiv_x}:

$f_{pdiv\_x} = f_{fracdiv}$ / (SENT_CPDRx.PDIV + 1) (25.3)

The following formula defines the nominal frequency of f_{tick_x}. For the actual frequency of f_{tick_x} DIV is replaced by DIVM after the current sensor frequency was validly measured.

$f_{tick\_x} = f_{pdiv\_x}$ x 56 / SENT_CFDRx.DIV with DIV = 560 … 3276 (25.4)

25.1.6 Error Detection Capabilities

Each SENT channel can detect and signal the following error conditions:

Protocol Level:

- Calibration pulse length deviates more than +/-25% from the nominal 56 ticks
- Too many or too few nibbles between calibration pulses
- Checksum error
- Successive calibration pulse differ by more than 1.5625%
- Any nibble data values measured as < 0 or >15
- Wrong Status and Communication nibbles
- Serial Communication CRC error

Transfer Management Level:

- Receive Data Buffer Overrun
- SPC Data Buffer Underrun

25.1.7 Digital Glitch Filter

Very slow slopes and signal noise can lead to fast transitions of the input signal. These unwanted transitions are suppressed by a digital glitch filter similar to a Filter and Prescaler Cell (FPC) of Infineons GPTA® in Delayed Debounce Filter Mode with up and down (no reset).

It is built for filtering very fast transitions only. The filter calculates the integral of the signal. If the integral reaches a programmable saturation point, the signal change is notified to the pulse measurement unit. Thus it helps to find the exact pulse length for said slow slopes in noisy environment.

The glitch filter is clocked with f_{pdiv}. If the state of the input sample differs from the current output signal value, the internal counter is incremented by one. When the state of the input sample matches the current output signal value and the timer is not in idle, the timer is decremented by one. When the timer matches the compare value stored in IOCRx.DEPTH, the level of the output signal line is inverted. The timer will be reset and set to idle state again.

The depth of the filter can be programmed to a value between 1 and 15. Typically a depth of 3 to 5 T_{pdiv} is sufficient. By default it is cleared. If IOCRx.DEPTH is cleared the filter is inactive. Nevertheless, the input signal is sampled with f_{pdiv}.

The internal signal after the filter will change value not before the new value was sampled DEPTH times. If during this period a spike occurs, it takes 2 x T_{pdiv} times longer for the internal signal to change value. The filters principal implies a delay of the signal by (DEPTH x T_{pdiv}).

Upon detection of glitch during rising or falling edge, IOCRx.REG or IOCRx.FEG is set. The rising / falling edge glitch flags must be reset by software.

Figure 25-19 shows the digital glitch filter:

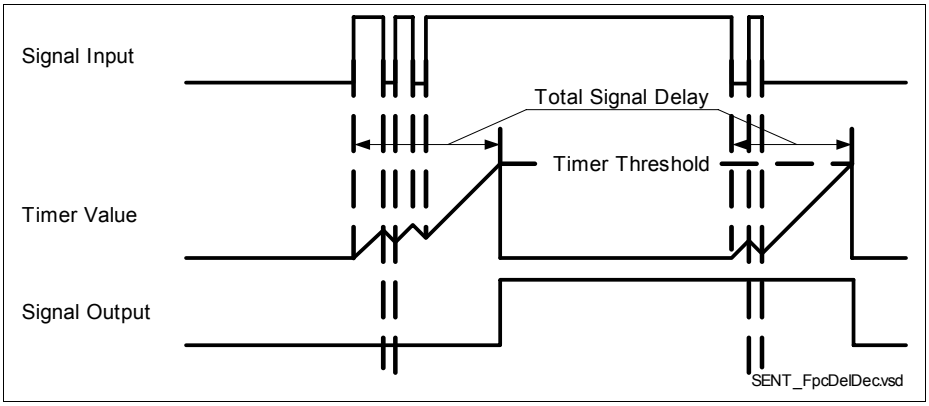

Figure 25-19 Digital Glitch Filter

25.1.8 Interrupts

4 Interrupt sources are available for the SENT module. Four interrupt sources for any 8 channels are provided by the SENT Module.

RDI indicates a receive data interrupt. It is activated when a received frame is moved to a Receive Data Register RDR. RSI indicates a receive frame success interrupt, i.e. the CRC was successful. Both RDI and RSI will be issued together in normal use cases where the frame size is not bigger than 8 nibbles and CRC is correct. RBI indicates a receive buffer overrun interrupt. It is activated when a new frame is transferred to a Receive Data Register RDR while the old value was still not read by the host (“overwrite”), i.e. the kernel wants to set any of the two interrupts RSI and RDI and finds any of these two interrupts already set. TDI indicates a transmit interrupt. It is activated when data is moved from a SCR to a transmit shift register. TBI indicates a transfer buffer under run interrupt. It is set after data has been completely transferred (PLEN exceeded) and no new data was written to SCRx. In addition the protocol error interrupts are available: FRI, FDI, NNI, NVI, CRCI. If one of the protocol interrupts is activated, data is to be treated as invalid according to J2716 FEB2008 Rev. 3 2009-06-24. WSI, SDI SCRI treat the interrupts referring to the Status and Communication nibble.

For acceleration of the interrupt service routine, a Register INTOV for any 32 channels is implemented that holds a flag for each channel. This flag is automatically set if there is an interrupt pending for the channel which is enabled. It is automatically reset, if no more enabled interrupt is pending for this channel.

The interrupt structure is shown in **Figure 25-20**. The interrupt request or the corresponding interrupt set bit (in register INTSET) can trigger the interrupt generation at the selected interrupt node. The service request pulse is generated independently from the interrupt flag in register INTSTATx. The interrupt flag can be cleared by software by writing to the corresponding bit in register INTCLR.
If more than one interrupt source is connected to the same interrupt node pointer (in register INPx), the requests are combined to one common line.

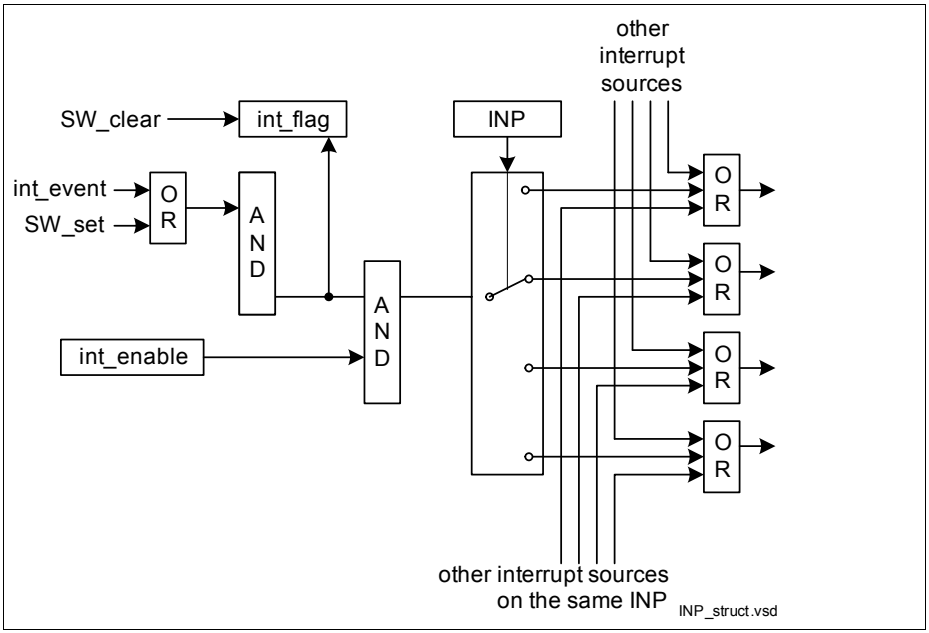

Figure 25-20 Interrupt Generation

25.1.9 Trigger Outputs

Any interrupt source can be used as trigger output TRIGO outside the module. Each TRIGO is connected to a DMA input. See **Table 25-3 "Service Request Lines of SENT" on Page 25-65**.

25.2 SENT Kernel Registers

This section describes the kernel registers of the SENT module. All SENT kernel register names described in this section will be referenced in other parts of the TC1798 User´s Manual by the module name prefix “SENT_” for the SENT interface.

All registers in the SENT address spaces are reset with the application reset (definition see SCU section “Reset Operation”).

SENT Kernel Register Overview

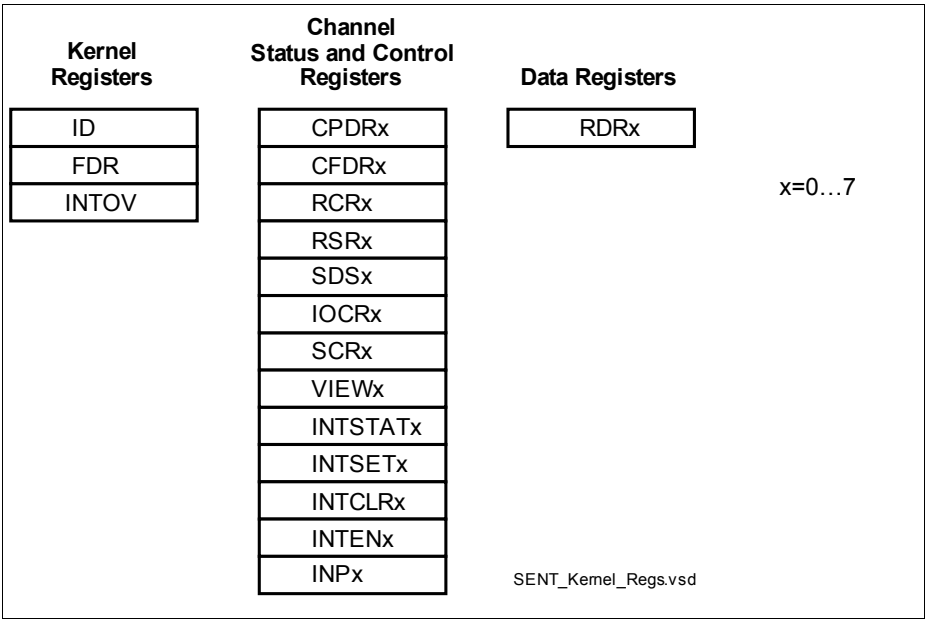

Figure 25-21 SENT Kernel Registers

The complete and detailed address map of the SENT module is described in **Table 25-1** on **Page 25-22**.

Note: x can take the values 0 … 7

Table 25-1 Registers Address Space - SENT Kernel Registers

Module	Base Address	End Address	Note

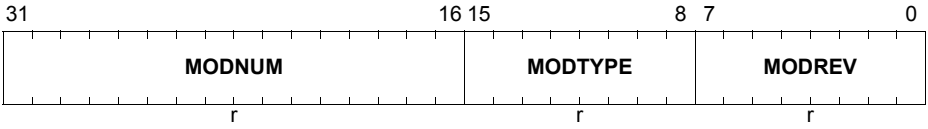
1) The absolute register address is calculated as follows:
Module Base Address (Table 25-1) + Offset Address (shown in this column)

25.2.1 Module Control

Module Identification Register

The SENT Module Identification Register ID contains read-only information about the module version.

ID
Module Identification Register **(08_H)** **Reset Value: $0080\ C0XX_H$**

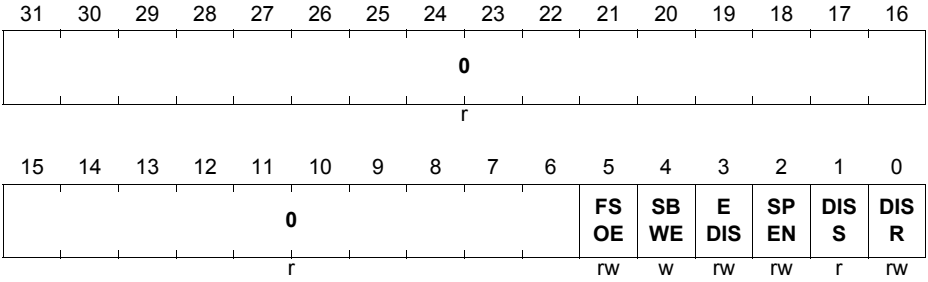


Field	Bits	Type	Description
MODREV	[7:0]	r	**Module Revision Number** This bit field defines the module revision number. The value of a module revision starts with 01_H (first revision).
MODTYPE	[15:8]	r	**Module Type** This bit field defines the module as a 32-bit module: $C0_H$
MODNUM	[31:16]	r	**Module Number Value** This bit field defines the module identification number for the SENT: 0080_H

Clock Control Register

This chapter summarizes the features of clock control. CLC controls in general switching on and off of the module. Please refer to Chapter “Module Clock Generation” of TC1798 for more details.

SENT_CLC
SENT Clock Control Register **(00_H)** **Reset Value: 0000 0003$_H$**



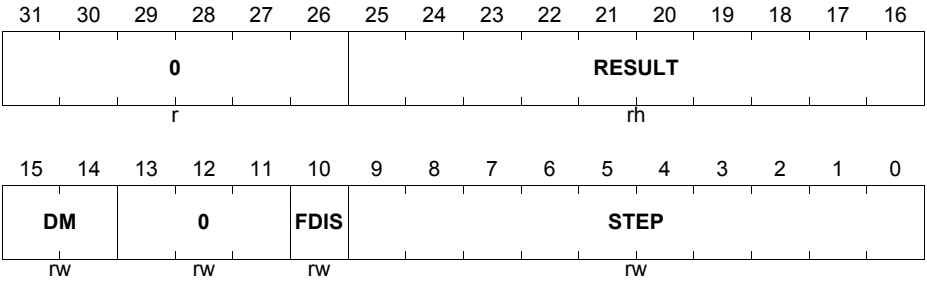
Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module.
DISS	1	r	**Module Disable Status Bit** Bit indicates the current status of the module.
SPEN	2	rw	**Module Suspend Enable for OCDS** Used to enable the suspend mode
EDIS	3	rw	**Sleep Mode Enable Control** Used to control module’s sleep mode.
SBWE	4	w	**Module Suspend Bit Write Enable for OCDS** Determines whether SPEN and FSOE are write-protected.
FSOE	5	rw	**Fast Switch Off Enable** Used to switch off fast clock in Suspend Mode.
0	[31:6]	r	**Reserved** Read as 0; should be written with 0.

Note: After a hardware reset operation, the f_{SENT} and $f_{fracdiv}$ clocks are switched off and the SENT module is disabled (DISS set).

Fractional Divider Register

The Fractional Divider Register controls the input clock $f_{fracdiv}$ of all SENT channels.

SENT_FDR
SENT Fractional Divider Register ($0C_H$) Reset Value: $0000\ 0000_H$



Field	Bits	Type	Description
STEP	[9:0]	rw	**Step Value** Reload or addition value for RESULT.
FDIS	10	rw	**Freeze Disable** This bit controls the freeze function for this module. For more details please refer to SCU chapter, section Clock Control. 0_B Module operates on corrected clock, with reduced modulation jitter (default) 1_B Module operates on uncorrected clock with full modulation jitter
DM	[15:14]	rw	**Divider Mode** DM selects normal or fractional divider mode. 00_B Fractional divider is switched off; no output clock is generated. The Reset External Divider signal is 1. RESULT is not updated (default after System Reset). 01_B Normal Divider Mode selected. 10_B Fractional Divider Mode selected. 11_B Fractional divider is switched off; no output clock is generated. RESULT is not updated.
RESULT	[25:16]	rh	**Result Value** Bit field for the addition result.

Field	Bits	Type	Description
0	[13:11], [31:26]	r	**Reserved** Read as 0; should be written with 0.

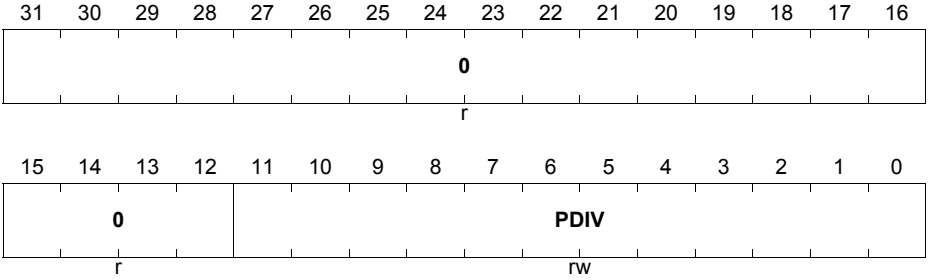
25.2.2 Channel Baud Rate Registers

Channel Pre Divider Register

The Channel Pre Divider Register CPDRx contains the pre divider that is related to the SENT channel baud rate.

See **Equation (25.3)**

CPDRx (x = 0-7)
Channel Pre Divider Register x **(100_H+40_H*x)** **Reset Value: 0000 0000_H**



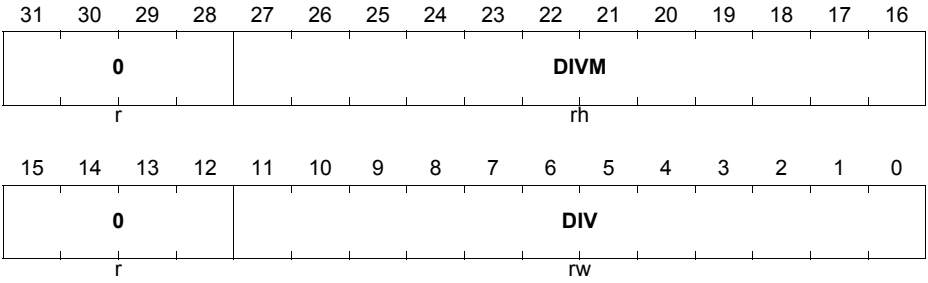
Field	Bits	Type	Description
PDIV	[11:0]	rw	**Divider Factor of Pre Divider for Channel x** Divides $f_{fracdiv}$ by (PDIV + 1) and delivers f_{pdiv_x} to the Channel Fractional Divider. RCR.CEN must be cleared before changing CPDR.PDIV or CFDR.DIV.
0	[31:12]	r	**Reserved** Read as 0; should be written with 0.

Channel Fractional Divider Register

The Channel Fractional Divider Register CFDRx contains control bits/bit fields that are related to the SENT channel baud rate.

See **Equation (25.4)** in **Chapter 25.1.5** for a detailed description.

CFDRx (x = 0-7)
Channel Fractional Divider Register x(104_H+40_H*x) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
DIV	[11:0]	rw	**Divider Value** Initial and reference divider value for the CFDR. DIV must be programmed > 0. If cleared, DIV becomes 1. If written, DIVM is updated automatically with the same value.RCR.CEN must be cleared before changing CPDR.PDIV or CFDR.DIV.
DIVM	[27:16]	rh	**Measured Divider Value** DIVM is automatically updated by HW to adjust the receiver frequency to the current sender frequency. This value is kept automatically in the range of 75% DIV < DIVM < 125% DIV Write data is ignored.
0	[15:12], [31:28]	r	**Reserved** Read as 0; should be written with 0.

25.2.3 Receiver Control and Status Registers

Receiver Control Register

The Receiver Control Register RCRx contains control bits/bit fields that are related to the SENT receiver operation.

RCRx (x = 0-7)
Receiver Control Register x **(108_H+40_H*x)** **Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0												SUS EN	IDE	ESF	CRZ
r												rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FRL								CFC	CDIS	SC DIS	SDP	SNI	ACE	IEP	CEN
rw								rw	rw	rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
CEN	0	rw	**Channel Enable** When CEN is set, the receiver of channel x is enabled. The internal receiver state machine can be initialized by switching the channel off and on. This does not change the current register content. 0_B channel x disabled (default) 1_B channel x enabled
IEP	1	rw	**Ignore End Pulse** When IEP is set, an end pulse is ignored. An end pulse can be generated in SPC mode or as pause pulse. 0_B End Pulse not ignored (default) 1_B End Pulse ignored For systems with an end pulse, during synchronize or re-synchronize of reception, if calibration pulses are detected one immediately following the other, the first calibration pulse shall be ignored as it may be a pause pulse with duration matching the calibration pulse range.

Field	Bits	Type	Description
ACE	2	rw	**Alternative CRC Mode Enable** When ACE is set, the CRC is calculated in an alternative way for both: fast (signal) and slow (serial message) data path. *Note: If ESF is set, the standard 6 bit CRC is always used for the serial message and ACE is ignored.* 0_B Serial CRC calculation as specified in J2716 FEB2008 Rev. 3 2009-06-24 (default) 1_B Alternative: 4 bit in parallel CRC calculation as used e.g. in hall sensor TLE4998C.
SNI	3	rw	**Status Nibble Included in CRC** When SNI is set, the status Nibble is included in (signal data) CRC. 0_B Status Nibble not included in CRC (default) 1_B Status Nibble included in CRC (as used e.g. in hall sensor TLE4998C).
SDP	4	rw	**Serial Data Processing Mode** This bit switches automatic serial data processing on. 0_B Automatic Serial Data Processing is disabled. Status and Communication nibble can be read from RSRx for SW processing. (default) 1_B Automatic Serial Data Processing is enabled. Status and Communication nibble can be read from RSRx; Message ID, Serial Data and SCRC can be read from SDSx after serial data interrupt SDI is activated.
SCDIS	5	rw	**CRC for Serial Data Disabled Mode** This bit selects the CRC disabled mode. 00_B CRC is enabled (default) 01_B CRC is disabled CRC nibble can be read from SDSx. The CPU must perform the CRC on the current data by SW.

Field	Bits	Type	Description
CDIS	6	rw	**CRC Disabled Mode** This bit selects the CRC disabled mode. 00_B CRC is enabled (default) 01_B CRC is disabled CRC nibble can be read from RSRx. The CPU must perform the CRC on the current data by SW.

Field	Bits	Type	Description
CFC	7	rw	**Consecutive Frame Check** This bit determines the way the most recently received frame buffer is indicated as valid. 0_B **Check against Past Sync Pulse** The current Synchronization / Calibration Pulse is compared to the Synchronization / Calibration Pulse received immediately before. The whole frame is invalid if the Synchronization / Calibration Pulse length differs from the length of the Synchronization / Calibration Pulse before by more than 1.5625%. In this case of error, its length is not used as new reference. In case the check passes and no other error occurs the Frame Buffer is indicated valid immediately after CRC calculation result is correct. Resynchronization: On the third successive calibration pulse error, the current calibration pulse value is considered as valid and the message accepted unless the message frame contains other errors. In both cases a receive data interrupt (RDI), or a referring error interrupt is issued. 1_B **Check against Future Sync Pulse** The current Synchronization / Calibration Pulse is compared with the Synchronization / Calibration Pulse received immediately after the current frame. The whole frame is invalid if the Synchronization / Calibration Pulse length differs from the length of the following Synchronization / Calibration Pulse by more than 1.5625%. Resynchronization: In this case of error, the current length is used as new reference. Note: The whole frame can be indicated valid only after additionally measuring the Synchronization / Calibration Pulse of the successive frame.

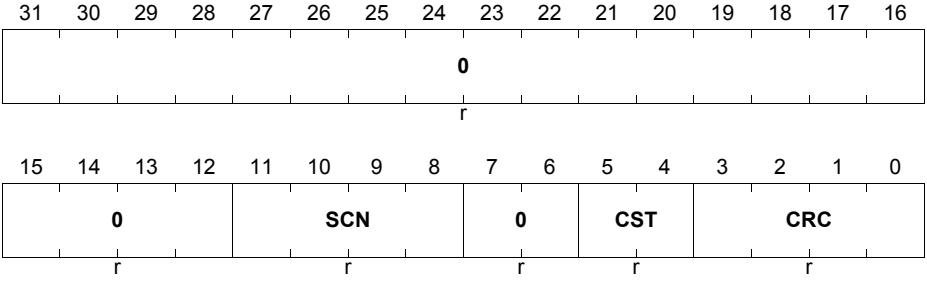
Field	Bits	Type	Description
FRL	[15:8]	rw	**Frame Length** FRL determines the number of data nibbles per frame that the SENT channel x is setup for. Note that FRL does not include the Synchronization / Calibration Pulse, the Status and Communication nibble, the CRC nibble nor the additional zero length nibble that might be introduced by use of SPC. 00000000_B No data nibble 00000001_B 1 data nibble 00000010_B 2 data nibbles 00000011_B 3 nibbles …B … 00001000_B 8 nibbles Maximum in normal length mode …B … 11111111_B 255 nibbles If more than 8 nibbles are configured, please note: In addition to the receive success interrupt RSI at the successfully received end of a frame, a receive data interrupt RDI is issued each time 8 nibbles have been transferred to the Receive Data Register RDRx. At the end of a frame, RDI is issued if RSI is issued. If an error occurred, RDI is not set at the end of a frame. If no CRC has been received at the point in time where RDI is issued, the receive data interrupt is no indication whether or not the transfer was successful so far. A CRC Error Interrupt is issued at the end of the frame if Automatic CRC check is enabled and the CRC is wrong.
CRZ	16	rw	**CRC with Zero Nibble for Serial Data** This bit selects the CRC method. If set, a ZERO NIBBLE at the end of CRC calculation (and only in calculation) is added. E.g. as 7th nibble (in case of 6 data nibbles) 00_B Trailing zero nibble added in calculation, recommended by standard (default) 01_B NO trailing zero nibble added in calculation, legacy mode by standard. Background: if the common slope of last nibble and CRC moves in error, the error correction is worse for the last nibble than for all other nibbles. Setting CRZ overcomes this problem.

Field	Bits	Type	Description
ESF	17	rw	**Extended Serial Frame Mode** This bit selects the serial frame structure. 0_B standard (16 frames, 4 bit ID, 8 bit data, 4 bit CRC) 1_B extended (18 frames, 4 or 8 bit ID, 12 or 16 bit data, 6 bit CRC)
IDE	18	rw	**Ignore Drift Error Mode** This bit selects if drift errors lead to frame rejection and if an interrupt (INTSTAT.FDI) is generated. Used, if sensors are triggered by SPC. During a long pause period the accumulated drift could be more than 1.5625%. In this special case setting IDE is useful. 0_B Drift Errors enabled (default) 1_B Drift Errors disabled
SUSEN	19	rw	**Suspend Enable** This bit makes it possible to set the SENT channel into Suspend Mode via OCDS (on chip debug support): 0_B An OCDS suspend trigger is ignored by this SENT channel. 1_B An OCDS suspend trigger disables the SENT channel: As soon as the SPC sender logic of the SENT channel becomes idle, the module is stopped while all registers of the channel stay readable. The receiver is stopped unconditionally. A partly received frame is discarded. Bit SUSEN is reset via OCDS Reset.
0	[31:20]	r	**Reserved** Read as 0; should be written with 0.

Receiver Status Register

The Receive Status Register provides the status information of channel x.

RSRx (x = 0-7)
Receive Status Register x **($10C_H$+40_H*x)** **Reset Value: 0000 0000_H**

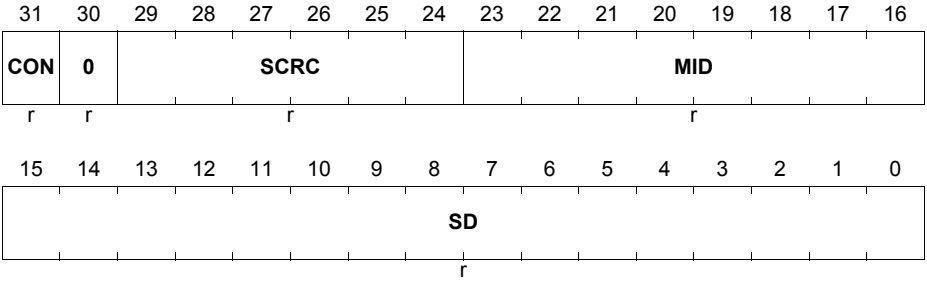


Field	Bits	Type	Description
CRC	[3:0]	r	**CRC** of last frame. CRC_0 is on bit position 0.
CST	[5:4]	r	**Channel Status** CST shows the current status of channel x. 00_B STOP Channel is disabled and can be configured 01_B INITIALIZED Channel is configured and enabled and no Synchronization / Calibration Pulse was received since last enable. 10_B RUNNING one or more Synchronization / Calibration Pulses were received and Frequency Range or Frequency Drift not or no longer in range. Fallback status from SYNCHRONIZED. 11_B SYNCHRONIZED Frequency Range and Frequency Drift in range
SCN	[11:8]	r	**Status and Communication Nibble** of last frame. SCN_0 is on bit position 8.
0	[7:6], [31:12]	r	**Reserved** Read as 0; should be written with 0.

Serial Data and Status Register

The Serial (Receive) Data and Status Register provides the data and status information of channel x.

SDSx (x = 0-7)
Serial Data and Status Register x (110_H+40_H*x) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
SD	[15:0]	r	**Serial Data** of last serial data frame. SD_0 is on bit position 0. If RCR.ESF is cleared 8 bits of data are available and bits [15:8] are zero. If RCR.ESF is set and if SDS.CON is cleared 12 bits of data are available and bits [15:12] are zero.
MID	[23:16]	r	**Message ID** of last serial data frame. ID_0 is on bit position 16. If RCR.ESF is cleared, or if SDS.CON is set, bits [23:20] are zero.
SCRC	[29:24]	r	**SCRC** CRC of last serial data frame. CRC_0 is on position 24. If RCR.ESF is cleared, bits [29:28] are always zero.
CON	31	r	**Configuration bit** of last serial frame. 0_B 12-bit data and 8-bit message ID 1_B 16-bit data and 4-bit message ID
0	30	r	**Reserved** Read as 0; should be written with 0.

25.2.4 Input and Output Control

Input and Output Control Register Functions

The Input and Output Control Register IOCRx determines for the SENT channel x:

for the receiver:

- the alternate input
- the filter depth
- the input signal polarity

for the SPC Unit

- the trigger source
- the output signal polarity

IOCRx (x = 0-7)
Input and Output Control Register x(114_H+40_H*x) **Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Bits	Type	Description
ALTI	[1:0]	rw	**Alternate Input Select** Selects the alternate input for channel y: 0000_BAlternate Input 0 selected 0001_BAlternate Input 1 selected …$_B$ … 0011_BAlternate Input 3 selected

Field	Bits	Type	Description
DEPTH	[7:4]	rw	**Digital Glitch Filter Depth** DEPTH determines the number of port input samples clocked with f_{pdiv} that are taken into account for the calculation of the floating average. The higher DEPTH is chosen to be, the longer the glitches that are suppressed and the longer the delay of the input signal introduced by this filter. 0000_B off, default 0001_B 1 T_{pdiv} 0010_B 2 0011_B 3 …B … 1111_B 15
OIE	8	rw	**Output Inverter Enable Channel x** Selects the Pulse Polarity of the output of channel x 0_B Pulse polarity is active low 1_B Pulse polarity is active high
IIE	9	rw	**Input Inverter Enable Channel x** Selects the Pulse Polarity of the input of channel x 0_B Pulse polarity is active low 1_B Pulse polarity is active high
REG	12	rh	**Rising Edge Glitch Flag for Channel x** Shows the status of the glitch detection of channel x 0_B No Glitch detected on rising edge 1_B Glitch detected on rising edge REG is cleared by setting CREG.
FEG	13	rh	**Falling Edge Glitch Flag for Channel x** Shows the status of the glitch detection of channel x 0_B No Glitch detected on falling edge 1_B Glitch detected on falling edge FEG is cleared by setting CFEG.
CREG	14	rw	**Clear Rising Edge Glitch Flag for Channel x** Clears the status flag REG 0_B REG is not cleared 1_B REG is cleared CREG always read zero.

Field	Bits	Type	Description
CFEG	15	rw	**Clear Falling Edge Glitch Flag for Channel x** Clears the status flag FEG 0_B FEG is not cleared 1_B FEG is cleared CFEG always read zero.
ETS	[18:16]	rw	**External Trigger Select** Selects the external trigger line if SCRx.TRIG is programmed to 11_B. 000_B TRIG0 001_B TRIG1 …B … 111_B TRIG7
CTR	28	rw	**Clear Trigger Monitor Flag for Channel x** Clears the status flag TRM 0_B TRM is not cleared 1_B TRM is cleared CTR always read zero.
TRM	29	rh	**Trigger Monitor Flag for Channel x** Shows the status of the trigger detection of channel x 0_B No Trigger detected 1_B Trigger detected (one or several) TRM is cleared by setting CTR.
RXM	30	rh	**Receive Monitor for Channel x** Shows the status of the receive signal of channel x after glitch filtering and inverted as specified by IIE. 0_B Current signal is low. 1_B Current signal is high.
TXM	31	rh	**Transmit Monitor for Channel x** Shows the status of the transmit signal of channel x inverted as specified by OIE. 0_B Current signal is low. 1_B Current signal is high.
0	[3:2], [11:10], [27:19]	r	**Reserved** Read as 0; should be written with 0.

25.2.5 Receive Data Registers

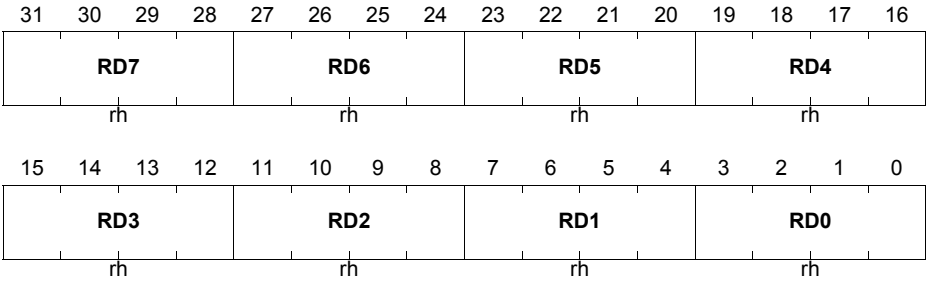
Receive Data Registers RDRx

The Receive Data Registers RDRx for channel x shows the data content of a received data frame. Register VIEWx is used to sort the nibbles.

Note: Register VIEW must be set up correctly to see all data nibbles of the frame! By default the application software set VIEW to 7654 3210$_H$.

Note: The internal receive buffer is always cleared (0x0000 0000$_H$) at each frame start. Thus unused nibbles are always read as zero.

RDRx (x = 0-7)
Receive Data Register x **(80_H+x*4_H)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
RDy (y = 0-7)	[4*y+3 :4*y]	rh	**Receive Data Nibble y** RDy shows the nibble from the received frame that is sorted to this position. It can be selected by any of VIEWx.RDNPy (y = 0-7). By default all nibbles are sorted to RD0 as the reset value of VIEW is 0x0000 0000_H. I.e. at the end of frame reception RD0 contains the last data nibble of the frame.

Receive Data View Register VIEWx

The Receive Data View Registers VIEWx stores the nibble pointers. They determine the sequence in which the received data nibbles are presented to the host. This reduces the SW effort to sort the nibbles.
The data nibble that is received first in the received frame is moved to the location given in register VIEW.RDNP0, the second to VIEW.RDNP1 and so on until VIEW.RDNP7.
If more than one VIEW.RDNPx point to a certain location in RDR, the last one will overwrite the previous ones.
Example: two 12 bit values are transmitted. One with highest significant nibble first and one with lowest significant nibble first. The frame looks like this: 456321_H. Note that the 1 is received as first data nibble and the 4 comes in as last data nibble.
The actual signal values are $0x123_H$ and $0x456_H$. By using VIEWx this can be sorted out into two 16bit values by HW. In the example VIEWx would be set to: 73 654 012_H. 73 is a dummy value and is not regarded if not more than 6 nibbles are received in a frame. The Register RDRx looks like this: 0x0456 0123_H to the host.

In the example RDR nibbles 3 and 7 contain $0x0000_B$ as the Receive Buffer is always cleared (0x0000 0000_H) before new data is received.

If a frame contains more than eight nibbles and the sorting can not be specified statically, VIEW can be set to e.g. 7654 3210_H.

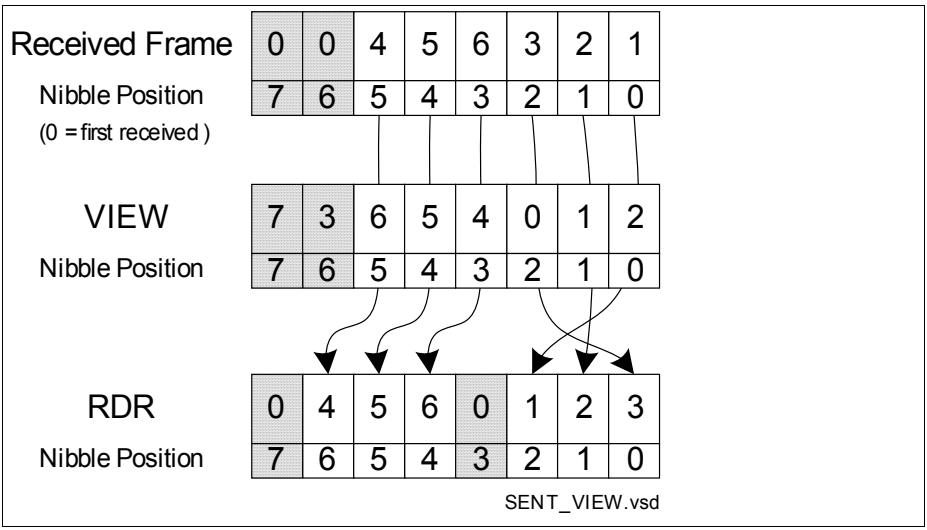


Figure 25-22 Functionality of VIEW Register

Nibble 0 is the first data nibble in the frame. It gets moved to the position defined in RDNP0. And on. 000_B Nibble 0 selected 001_B Nibble 1 selected $\ldots_B$ … 111_B Nibble 7 selected *Note: RDNPy must be written before first frame reception. All RDNPy must have different values. (Higher RDNPy overwrite lower RDNPy.)*
0	3, 7, 11, 15, 19, 23, 27, 31	r	**Reserved** Read as 0; should be written with 0.

25.2.6 SPC Control

SPC Control Registers SCRx

The SPC Control Register SCR contains data to be transmitted during the sync pulse of the data frames. It contains as well the trigger control bits required for sending nibbles from the SENT module to the sensor / external SENT device.

The SPC Control Register is used to control the trigger mode and time base of the SPC channel transmission.

Data and the control bits are collected in this single register to ease transfer of multiple pulses in cases where dynamic switching of the trigger condition is required.

The SPC Control Register is build to control single pulse transfers only.

Thus it is possible to change the control settings of an individual channel from pulse to pulse as it is required in SPC mode “Bidirectional transmit”. Here it might be considered useful to change trigger mode between Mode 1 (immediately) and Mode 2 (falling edge of next Synchronization / Calibration Pulse with programmable delay).

In addition repeating transfers with the same control settings are supported. For a pulse transfer to be initiated a synchronization signal can be sufficient and no further SW intervention is required. Here the data can be changed (“ID-Selection” Mode) or simply left constant (“Sync” Mode). Only a HW trigger needs to be set up.

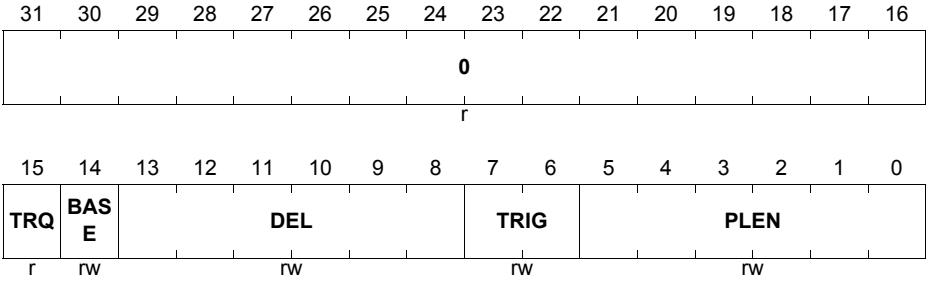
In Mode 0, SPC is deactivated for this channel. A write access to SCRx does not initiate an SPC pulse transmission. All state transmitter machines are initialized.

In Mode 1, an SPC pulse is sent, each time SPC Control Register SCRx is written to. If a transfer is ongoing, the channel waits automatically until the internal transmission register is ready. Transmit Buffer Underflow bit TBIx is set after data has been completely transferred (PLEN exceeded) and no new data was written to SCRx. After the data was transferred to the internal transmission register, interrupt TDIx signals that a new value can be written. INTSTATx.TDIx must be cleared by SW. Independently from this interrupt pending bit, a new interrupt pulse is generated on each transfer of an SPC pulse.
This mode is important for back to back transfers of several nibbles as in bidirectional SPC mode.

In Mode 2, an SPC pulse is sent, each time the first falling edge of any Synchronization / Calibration Pulse is received. In this mode, the programmable delay DEL is most useful. In SPC mode “Bidirectional Transmit” this mode is useful to synchronize the transmission. TDIx and TBIx work as in Mode 1.

In Mode 3, an SPC pulse is sent (with current DEL and PLEN) after each external trigger event (defined by IOCRx.ETS). This is most useful in SPC “sync” mode. TDIx and TBIx work as in Mode 1.

SCRx (x = 0-7)
SPC Control Register x **(118_H+40_H*x)** **Reset Value: 0000 0000_H**

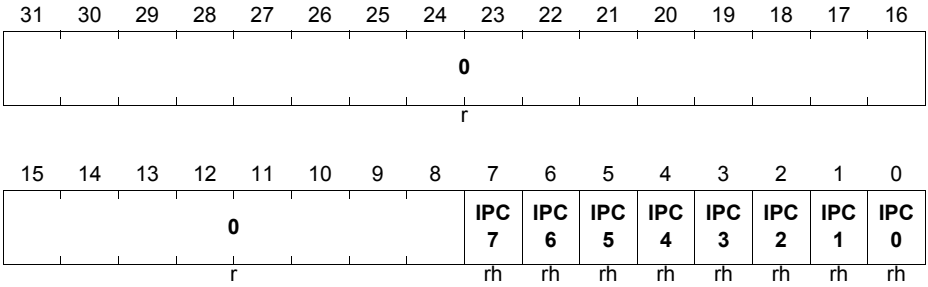


Field	Bits	Type	Description
PLEN	[5:0]	rw	**Pulse Length** Defines the length of the pulse in tick times. The time base is the measured tick time of the latest received frame if selected so by BASE. In case this measured tick time was invalid or not already available after enable of the channel, the nominal time base of the module is used. 000000_B Pulse length is 0 ticks 000001_B Pulse length is 1 tick ... ... 111111_B Pulse length is 63 ticks

Field	Bits	Type	Description
TRIG	[7:6]	rw	**Trigger Source and Mode Selection** Selects the Trigger Source and Mode. The internal sender state machine can be initialized by switching the channel off (TRIG is cleared) and on. This does not change the current register content. 00_B No Pulse is generated, OFF When cleared, an ongoing transfer is stopped immediately and the transmit output is driven recessive. 01_B Pulse starts immediately (no auto repetition) 10_B Pulse starts each time the first falling edge of any Synchronization / Calibration Pulse is received (auto repetition on next Sync. / Cal. Pulses) 11_B Pulse starts after each external trigger event. (auto repetition on next trigger) IOCRx.ETS selects the source of this event.
DEL	[13:8]	rw	**Delay Length** Selects how long the SPC pulse is delayed after the trigger condition. The time base is the measured tick time of the latest received frame if selected so by BASE. In case this measured tick time was invalid or not already available after enable of the channel, the nominal time base of the module is used. 000000_B Pulse is not delayed 000001_B Pulse is delayed by 1 tick ... ... 111111_B Pulse is delayed by 63 ticks
BASE	14	rw	**Time Base** Selects the Pulse Time Base 0_B Pulse is based on measured frequency of last Synchronization/Calibration Pulse 1_B Pulse is based on nominal frequency
TRQ	15	r	**Transfer Request in Progress** While an SPC Pulse is being sent this bit is set. Write access is ignored.
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

25.2.7 Interrupt Control Registers

INTOV
Interrupt Overview Register **(14_H)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
IPCy (y = 0-7)	y	rh	**Interrupt Pending on Channel y** If any interrupt requested flag is set for channel y in register INTSTATy AND the referring interrupt is enabled in INTENx then IPCy is set. It is automatically reset if all flags in INTSTATy are cleared for which the referring interrupt is enabled in INTENx.
0	[31:8]	r	**Reserved** Read as 0.

Interrupt Status Register

The Interrupt Status Register INTSTATx contains status bits that show the status of any interrupt of SENT channel x.

Note: The bits are set independently from the referring Interrupt Enable in Register INTENx. Thus they can be used as status bits as well e.g. by a SW based on polling.

INTSTATx (x = 0-7)
Interrupt Status Register x **(120_H+40_H*x)** **Reset Value: 0000 0000_H**

r	r	r	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh

Field	Bits	Type	Description
RSI	0	rh	**Receive Success Interrupt Request Flag** This bit is set at the successfully received end of a frame. Depending on bit RCRx.CDIS this indicates a successful check of the CRC. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLRx.RSI. This bit can be set by bit INTSETx.RSI. This bit is set independently from INTENx.

Field	Bits	Type	Description
RDI	1	rh	**Receive Data Interrupt Request Flag** RDI is activated when a received frame is moved to a Receive Data Register RDR. Both RDI and RSI will be issued together in normal use cases where the frame size is not bigger than 8 nibbles and CRC is correct or not checked (if RCRx.CDIS is cleared). 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLRx.RDI. This bit can be set by bit INTSETx.RDI. This bit is set independently from INTENx.
RBI	2	rh	**Receive Buffer Overflow Interrupt Request Flag** This bit is set after a frame has been received while the old one was not read from RDRx. I.e. the kernel wants to set any of the two interrupts RSI and RDI and finds any of these two interrupts already set.The old data is overwritten by the new data. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit is NOT cleared by reading RDRx. This bit can be cleared by bit INTCLRx.RBI. This bit can be set by bit INTSETx.RBI. This bit is set independently from INTENx.
TDI	3	rh	**Transfer Data Interrupt Request Flag** This bit is set after the trigger condition was detected. Data to be transferred has been moved internally. Thus a new value can be written to SCRx. This can be used for back to back transfers. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit is automatically cleared by writing SCRx. This bit can be cleared by bit INTCLRx.TDI. This bit can be set by bit INTSETx.TDI. This bit is set independently from INTENx.

Field	Bits	Type	Description
TBI	4	rh	**Transmit Buffer Underflow Interrupt Request Flag** This bit is set after data has been completely transferred (PLEN exceeded) and no new data was written to SCRx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit is NOT cleared by writing SCRx. This bit can be cleared by bit INTCLRx.TBI. This bit can be set by bit INTSETx.TBI. This bit is set independently from INTENx.
FRI	5	rh	**Frequency Range Interrupt Request Flag** This bit is set after a Synchronization / Calibration pulse was received that deviates more than +- 25% from the nominal value. The referring data is ignored. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLRx.FRI. This bit can be set by bit INTSETx.FRI. This bit is set independently from INTENx.
FDI	6	rh	**Frequency Drift Interrupt Request Flag** This bit is set after a subsequent Synchronization / Calibration pulse was received that deviates more than 0.15625% (1/64) from its predecessor. (See RCR.CFC) 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLRx.FDI. This bit can be set by bit INTSETx.FRI. This bit is set independently from INTENx.

Field	Bits	Type	Description
NNI	7	rh	**Number of Nibbles Wrong Request Flag** This bit is set after a more nibbles have been received than expected or a Synchronization / Calibration Pulse is received too early thus too few nibbles have been received. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLRx.NNI. This bit can be set by bit INTSETx.NNI. This bit is set independently from INTENx.
NVI	8	rh	**Nibbles Value out of Range Request Flag** This bit is set after a too long or too short nibble pulse has been received. I.e. value < 0 or value > 15. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLRx.NVI. This bit can be set by bit INTSETx.NVI. This bit is set independently from INTENx.
CRCI	9	rh	**CRC Error Request Flag** This bit is set if the CRC fails. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLRx.CRCI. This bit can be set by bit INTSETx.CRCI. This bit is set independently from INTENx.

Field	Bits	Type	Description
WSI	10	rh	**Wrong Status and Communication Nibble Error Request Flag** In standard Serial Frame Mode (RCR.ESF is cleared), this bit is set if the Status and Communication nibble shows a start bit in a frame other than frame number n x 16. In Extended Serial Frame Mode this bit is without function. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLRx.WSI. This bit can be set by bit INTSETx.WSI. This bit is set independently from INTENx.
SDI	11	rh	**Serial Data Receive Interrupt Request Flag** This bit is set after all serial data bits have been received via the Status and Communication nibble. Depending on bit RCRx.SCDIS this indicates a successful check of the CRC. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLRx.SDI. This bit can be set by bit INTSETx.SDI. This bit is set independently from INTENx.
SCRI	12	rh	**Serial Data CRC Error Request Flag** This bit is set if the CRC of the serial message fails. In Extended Serial Message Format, this includes a check of the Serial Communication Nibble for correct 0 values of bit 3 in frames 7, 13 and 18. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLRx.SCRI. This bit can be set by bit INTSETx.SCRI. This bit is set independently from INTENx.

Field	Bits	Type	Description
0	[31:13]	r	**Reserved** Read as 0.

Interrupt Set Register

The Interrupt Set Register INTSETx contains control bits that trigger an interrupt pulse for any interrupt of SENT channel x.

INTSETx (x = 0-7)
Interrupt Set Register x **(124_H+40_H*x)** **Reset Value: 0000 0000_H**

Interrupt Node Pointer Register

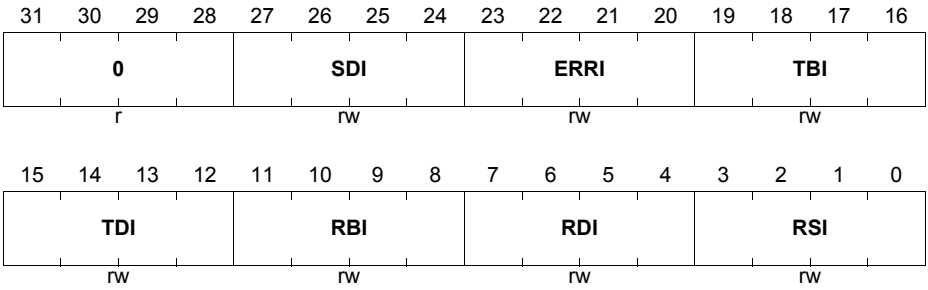
The Interrupt Node Pointer Register INPx contains the node pointers of SENT channel x.

Note: Node Pointer ERRI is one single node pointer for the following error interrupts:

- FRI
- FDI
- NNI
- NVI
- CRCI
- WSI
- SCRI

INPx (x = 0-7)

Interrupt Node Pointer Register x (130_H+40_H*x) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
RSI	[3:0]	rw	**Interrupt Node Pointer for Interrupt RSI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATx.RSI (if enabled by bit INTENx.RSI). 0000_B Interrupt node 0 is selected 0001_B Interrupt node 1 is selected 0010_B Interrupt node 2 is selected 0011_B Interrupt node 3 is selected 0100_B Trigger Output TRIGO 0 is selected 0101_B Trigger Output TRIGO 1 is selected ... ... 1101_B Trigger Output TRIGO 7 is selected 1110_B reserved ... ... 1111_B reserved

Field	Bits	Type	Description
RDI	[7:4]	rw	**Interrupt Node Pointer for Interrupt RDI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATx.RDI (if enabled by bit INTENx.RDI). For bit field definition, see RSI.
RBI	[11:8]	rw	**Interrupt Node Pointer for Interrupt RBI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATx.RBI (if enabled by bit INTENx.RBI). For bit field definition, see RSI.
TDI	[15:12]	rw	**Interrupt Node Pointer for Interrupt TDI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATx.TDI (if enabled by bit INTENx.TDI). For bit field definition, see RSI.
TBI	[19:16]	rw	**Interrupt Node Pointer for Interrupt TBI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATx.TBI (if enabled by bit INTENx.TBI). For bit field definition, see RSI.
ERRI	[23:20]	rw	**Interrupt Node Pointer for Interrupt FRI, FDI, NNI, NVI, CRCI, WSI, SCRI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATx.FRI (if enabled by bit INTENx.FRI) or INTSTATx.FDI (if enabled by bit INTENx.FDI) or INTSTATx.NNI (if enabled by bit INTENx.NNI) or INTSTATx.NVI (if enabled by bit INTENx.NVI) or INTSTATx.CRCI (if enabled by bit INTENx.CRCI) or INTSTATx.WSI (if enabled by bit INTENx.WSI) or INTSTATx.SCRI (if enabled by bit INTENx.SCRI) For bit field definition, see RSI.
SDI	[27:24]	rw	**Interrupt Node Pointer for Interrupt SDI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATx.SDI (if enabled by bit INTENx.SDI). For bit field definition, see RSI.
0	[31:28]	r	**Reserved** Read as 0; should be written with 0.

25.3 SENT Module Implementation

This section describes the SENT module interface as it is implemented in the TC1798. It especially covers clock control, port and on-chip connections, interrupt control, and address decoding.

25.3.1 Interface Connections of the SENT Module

Figure 25-23 shows the TC1798-specific implementation details and interconnections of the SENT module.

The SENT module is supplied with a separate clock control, address decoding, and interrupt control logic. The 4 modules' service request outputs are connected with interrupt nodes, and each of the 8 channels with the DMA controller. Outputs of the GPTA module are connected to the 8 timer inputs.

The serial data inputs of the receive channels of the SENT module as well as the SPC outputs (SPCn) are connected to GPIO lines. If SPC outputs are used, they are usually mapped to the same port pin like the referring SENT data input line as this minimizes the pin count requirement.

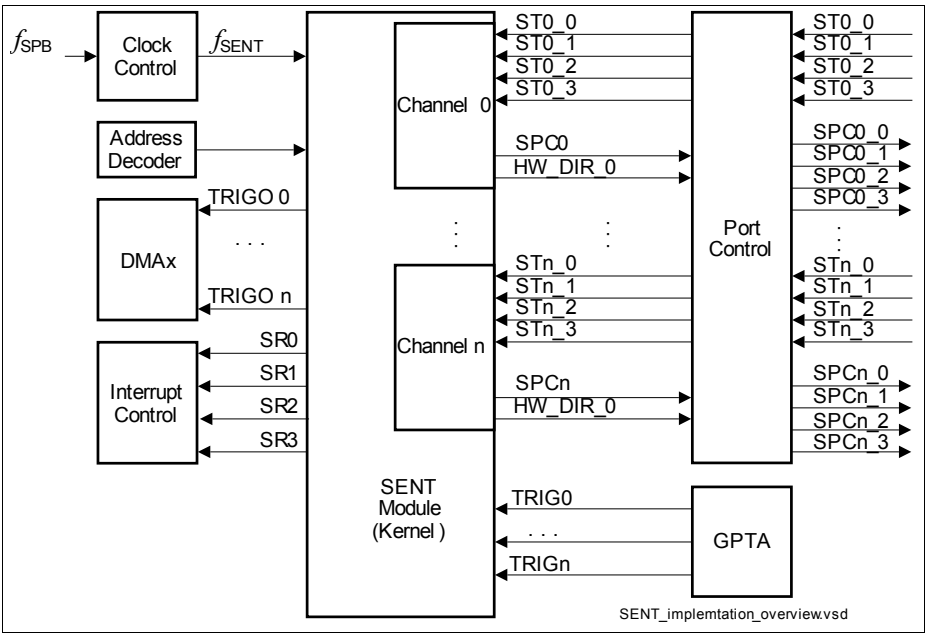


Figure 25-23 SENT Module Implementation and Interconnections

25.3.2 On-Chip Connections

This section describes the on-chip connections of the SENT module.

25.3.2.1 Interrupt and DMA Controller Service Requests

The module has 4 Service Request Nodes connecting it to the interrupt system. The trigger outputs of the SENT module are connected as DMA request input to the DMA controller. The DMA request lines are connected to the DMA controller as shown in Table 25-3.

Table 25-3 Service Request Lines of SENT

INP value	Request Line	Connected to	Description
0000_b	SR0	SENT_SRC0	SENT Service Request Node 0
0001_b	SR1	SENT_SRC1	SENT Service Request Node 1
0010_b	SR2	SENT_SRC2	SENT Service Request Node 2
0011_b	SR3	SENT_SRC3	SENT Service Request Node 3
0100_b	TRIGO0	CH00_REQI02	SDMA Channel 00 Request Input 2
0101_b	TRIGO1	CH01_REQI02	SDMA Channel 01 Request Input 2
0110_b	TRIGO2	CH02_REQI02	SDMA Channel 02 Request Input 2
0111_b	TRIGO3	CH03_REQI02	SDMA Channel 03 Request Input 2
1000_b	TRIGO4	CH04_REQI02	SDMA Channel 04 Request Input 2
1001_b	TRIGO5	CH05_REQI02	SDMA Channel 05 Request Input 2
1010_b	TRIGO6	CH06_REQI02	SDMA Channel 06 Request Input 2
1011_b	TRIGO7	CH07_REQI02	SDMA Channel 07 Request Input 2

25.3.2.2 Trigger Inputs

The module has 8 Sent Channels and the same number of trigger inputs which can be randomly chosen by programming IOCRx.ETS. The trigger inputs (TRIG[7:0]) of the SENT module are connected to the GPTA as shown in **Table 25-4**.

Table 25-4 Trigger Input Lines of SENT

Request Line	Connected to	Description
TRIG0	TRIG0	GPTA Trigger Line TRIG0
TRIG1	TRIG1	GPTA Trigger Line TRIG1
TRIG2	TRIG2	GPTA Trigger Line TRIG2
TRIG3	TRIG3	GPTA Trigger Line TRIG3
TRIG4	TRIG4	GPTA Trigger Line TRIG4
TRIG5	TRIG5	GPTA Trigger Line TRIG5
TRIG6	TRIG6	GPTA Trigger Line TRIG6
TRIG7	TRIG7	GPTA Trigger Line TRIG7

25.3.3 SENT Module-Related External Registers

The registers listed in **Figure 25-24** are not included in the SENT module kernel but must be programmed for proper operation of the SENT module.

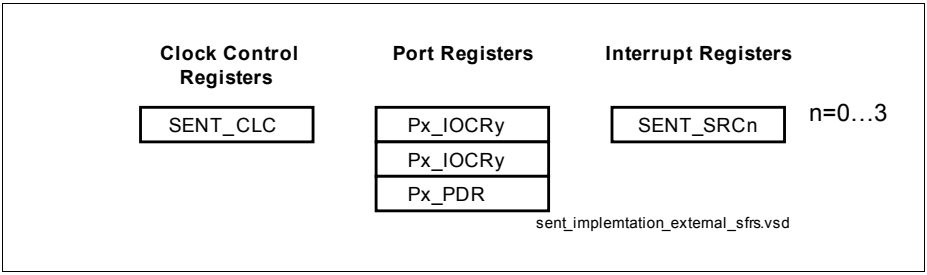

Figure 25-24 SENT Implementation-specific Special Function Registers

25.3.3.1 Port Control

The SENT input channels are overlaid with standard ADC channels as they are replacing former analog signals. Each channel is connected to two ADC channels that can be chosen alternatively. In addition each channel is connected to general purpose I//O lines as well. Each channel is connected to two different general purpose I/O lines that can be chosen alternatively. The selection from on of these 4 alternatives is done by application SW by programming SENT_IOCRx.ALTI respectively.

The SPC output lines are connected to the same I/O ports as the referring input channel. The ADC channels do not provide output functionality. The SPC I/O ports are controlled in the port logic (see also **Figure 25-23**). The following port control operations and selections must be executed for these I/O lines:

- Input/output function selection (Port IOCR registers)
- Pad driver characteristics selection for the outputs (Port PDR registers)

Input/Output Function Selection

SENT can be used in three different ways:

- ADC input (dedicated for ADC) overlaid with SENT digital input and no output option on this pin.
- SENT configured digital I/O lines (open drain, no push/pull, uses SDIR, single pin hardware direction control HW_DIR, SDIR is controlled by the data value: 0 = active out, 1 = passive/open drain, input)
- Standard general purpose input/output function on two lines for each channel (input on ADC alternative 1 or 2, or on I/O port alternative 1 while the output is chosen to be on I/O ports alternative 2.

The SENT module overlays dedicated analog to digital converter (ADC) pins as digital input port.

Note: Note that only the ADC input pins are 5V capable while the standard digital I/O provides 3.3V inputs.

The SENT module can be configured to use input/output ports configured for use with SENT. These control settings for the port pins differ from the standard general purpose I/O lines in so far as

- they are controlled by the SENT module output data via their HW_DIR line
- they are configured to use no push/pull devices and to work in open drain mode if the output function is selected by the HW_DIR line of the port

The SENT module can be configured to use standard (push pull) general purpose I/O lines as well. Different port pins can be selected for input and for output. This allows the use of external transceiver devices.

The port input/output control registers contain the bit fields that select the digital output and input driver characteristics such as port direction (input/output) with alternate output selection, pull-up/down devices, and open-drain selections. The I/O lines for the SENT module are controlled by the Port input/output control registers shown below.

Table 25-5 shows an overview how bits and bit fields must be programmed for the required I/O functionality of the SENT I/O lines.

Table 25-5 SENT I/O Control Selection and Setup

SENT Channel	Port Lines	Input Select Register	Input/Output Control Register Bits	I/O
0	ST0/AN8	SENT_IOCR0.ALTI = 0000_B	P17_PDISC.PDIS0 = 0_B	I

0	[9:8], 11, [31:16]	r	**Reserved** Read as 0; should be written with 0.

25.3.4 SENT Register Address Map

The SENT register map shown in **Figure 25-25**.

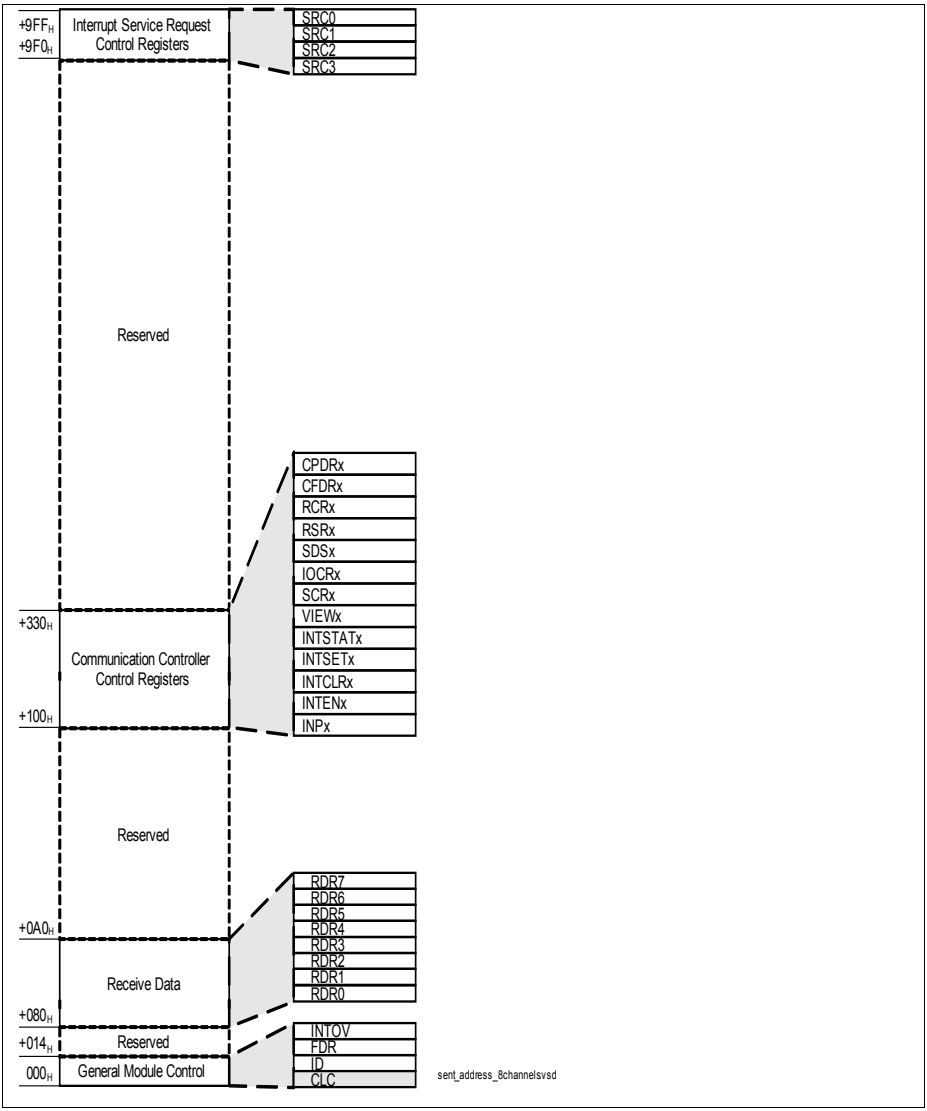

Figure 25-25 SENT Register Map

25.4 Revision History

This User´s Manual is based on: SAE Standard “SENT **Revision J2716 FEB2008 Rev. 3 2009-06-24**”.

Table 25-6 Revision History

Version Number	Changes to Previous Version
Rev_0.1D	First Draft (Bullet Points ++)
Rev_0.2D	Second Draft (Bullet Points ++)
Rev_0.3D	First Review Version
Rev_0.4D	• RCRx.NINT removed as unnecessary FIFO support • Spelling Checked • Renamed INTNP to INP (request DE) • One common error node pointer in INP for FRI, FDI, NNI, NVI, CRCI, WSI, SCRI (reduce DE effort) • Interrupt Node Pointer in INPx increased from 2 bit to 4 bit • Renamed PVAL to PDIV in register CPDRx • RCRx.ASP “Additional Sync/Cal Pulse expected” deleted, not required • RCRx.ACE “Alternate CRC Mode” added, request customer • cleanup Register SCR • ISR0 (Input select register) deleted • AltIn and Filter DEPTH moved to IOCRx • SCRx.DEL moved to SDRx • SCRx deleted, BASE and TRQ moved to SDR • Restructured Chapters (interrupts after functional registers, implementation chapter cleaned up) • Simplified Baud rate generation (Fdtick removed)
Rev_0.5D	• Clean up Glitch filter Chapter • Detailed Baud Rate Generation • Added Address overview table

Table 25-6 Revision History (cont'd)

Version Number	Changes to Previous Version
Rev_0.6D	• Channel **Fractional Divider with variable divider** instead of variable dividend • Glitch filter based on F_pdiv and no longer on F_sent • Glitch detection added • Pre divider = PDIV and no longer PDIV + 1 • Compressed address overview table • Interrupt generation updated **Figure 25-20 "Interrupt Generation" on Page 25-21** • Trigger outputs renamed (RSI and SDI, no more TRIGO) and completed • RDI simplified - now independent from RSI • ETS wording corrected • INTOV now only updated for enabled interrupts (before: any change) • Renamed "SPC Data Register SDR" to "SPC Control Register SCR", it contains both data and control information • TDI wording optimized • External Registers Overview corrected • KSCFG removed
Rev_1.0D	First complete revision (To be done)
Rev_1.1D	• Moved Base Address to F032_1000 - F032_19FF (10x256 bytes) • Serial message ID added. SDSx.SCN moved to [19:16], SDSx.SCRC moved to [15:12], SDSx.MID placed at [11:8]. • RSI and TDI as trigger outputs replaced by 8 Trigger Outputs programmable in the INPs. • implemented first port mapping proposal from product
Rev_1.2	• Added hint to RCR.CEN that FSMs are initialized during enable • Port mapping updated to latest changes of CW08/47

Table 25-6 Revision History (cont'd)

Version Number	Changes to Previous Version
Rev_1.3	• Fixed INTENx Bit descriptions: all bits are rw and high active (typo) • added to feature list: "Programmable Nibble sorting to support LSN or HSN first and relief CPU" (was missing) • SENT_FDR.DM[1:0] added description of all 4 states of this bit field. (same as system level) • IOCR.DEPTH corrected f_{SENT} sent to f_{pdiv} (longer glitch tolerance) • Add Freeze-Disable Bit [10] to SENT_FDR (system requirement) • Pre divider factor is (PDIV + 1) and no longer PDIV (ease design) • Resulting Channel Fractional Divider is (DIV + 1) and no longer DIV • Add IOCR.TXM, RXM and TRM monitor bits (ease of validation) • RDRx added explanation: unused nibbles are shown as '0' (for clarity) • RDI and RSI: Read clears these bits NOT (request from AE) • Renamed Transmit Buffer Overflow to UNDER-Flow with change to respective functionality (data completely transmitted without new write) • RCRx.CFC: Wording improved and details added
Rev_1.4	• Added column Access Modes to Register Table • Updated **Figure 25-2**, **Figure 25-3**, **Figure 25-4** (beautification) • The clock signal f_{pdiv} of a channel must always be at least 20 (old value 10) times the nominal tick frequency, to cater for worst case. • INPx: Added reserved values • Corrected **Figure 25-20**, no more separate DMA TRIGO lines. • RCRx, VIEWx and CFDRx Reset value corrected to 0x0000 0000 hex • Added explanations to RDRx and VIEWx • AI00050230 - SENT_FDR register located at "unusual" address: Moved CLC to offset 0x0Ch for consistency with other modules • Reduced ETS to 3 bit and ALTI to 2 bit width • "Zero Nibble Insertion in CRC" covered. See RCR.CRZ. • UTP AI00050205 - "Extended Serial Frame" covered. Added description of extended serial frame. SDS.SCN moved to RSR.SCN (Allows for an aligned representation of ID and Data as well as a fixed position for SCN) SDS.SD, SDS.MID, SDS.SCRC enlarged (to 16, 8 and 6 bit width) SDS.CON and RCR.ESF added • Resulting Channel Fractional Divider is DIV and no longer (DIV + 1)

Table 25-6 Revision History (cont'd)

Version Number	Changes to Previous Version
Rev_1.5	• Corrected TBIx description on Page 50. • SCR.TRQ corrected (deleted "Reads back zero") • Added hint to definition of Alternate CRC Mode (ACE) • Detailed RBI behavior. It is set if kernel wants to set RSI or RDI and finds RSI or RDI already set. • Detailed that RCR.CEN resets the receiver state machines only while SCR.TRIG resets the sender state machines. • RCR.WSI updated wrt. the special case "extended serial frame" (2009-06-24) • INSTAT.SCRI detailed wrt.: CRC check must include check for correct 0 values in Extended Serial Frame Format (2009-06-24) • Message tick time prolonged to 90 µs according to new standard (2009-06-24) • RCR.CFC (successive calibration pulse detection) adopted to new standard. (2009-06-24) • Updated INTSTAT.FDI wrt.: new additional error diagnostics (total frame length variation and ration calibration pulse/total frame length) in new standard. (2009-06-24)
Rev_1.6	• Added bit RCR.IDE (Ignore Drift Error) to cater for rare triggers by SPC. • Removed SV protection from SENT_FDR. • VIEW.RDNP must be set before reception. • SCR.TRQ spec' ed not active from request to pulse start. • Added "alternative CRC" spec from TLE4998 . • Changed wording for RBI. • New additional error diagnostics (total frame length variation and ration calibration pulse/total frame length) removed.
Rev_1.7	• Added note: RCR.CEN must be cleared before changing CPDR.PDIV or CFDR.DIV. • SCRI typo: frame 8, not 7 contains a zero value. • **Chapter 25.1.5** typo corrected: replaced f_{SENT} with $f_{fracdiv}$ • **Chapter 25.1.3.1** note added on *RCR.CRZ.* • Added hint to Chapter "Module Clock Generation" for details on CLC. • Updated Port connections and Trigger Output connections
Rev_1.8	• Changed functionality of VIEW. • Changed functionality of WSI.

26 FlexRay™ Protocol Controller (E-Ray)

The E-Ray IP-module performs communication according to the FlexRay™ [1] protocol specification v2.1. With maximum specified clock the bitrate can be programmed to values up to 10 Mbit/s. Additional bus driver (BD) hardware is required for connection to the physical layer.

26.1 E-Ray Kernel Description

Figure 26-1 shows a global view of the E-Ray interface.

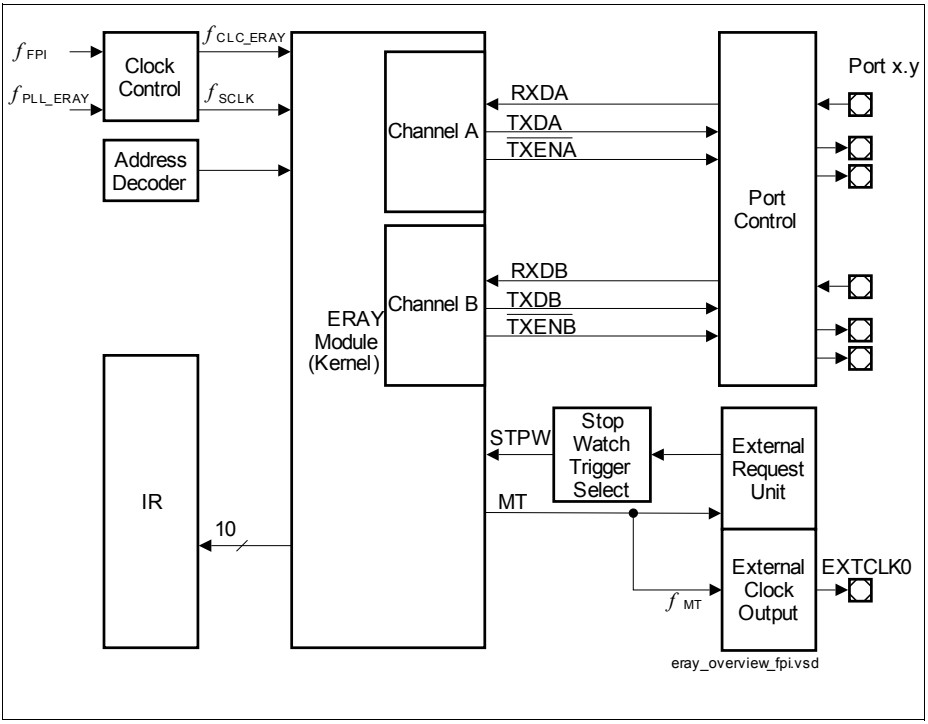

Figure 26-1 General Block Diagram of the E-Ray Interface

The E-Ray module communicates with the external world via three I/O lines each channel. The RXDAx and RXDBx lines are the receive data input signals, TXDA and

1) *Infineon®, Infineon Technologies®, are trademarks of Infineon Technologies AG. FlexRay™* is a trademark of FlexRay Consortium.

TXDB lines are the transmit output signals, $\overline{\text{TXENA}}$ and $\overline{\text{TXENB}}$ the transmit enable signals.

Clock control, address decoding, and service request control are managed outside the E-Ray module kernel.

26.2 Overview

For communication on a FlexRay™ network, individual Message Buffers with up to 254 data byte are configurable. The message storage consists of a single-ported Message RAM that holds up to 128 Message Buffers. All functions concerning the handling of messages are implemented in the Message Handler. Those functions are the acceptance filtering, the transfer of messages between the two FlexRay™ Channel Protocol Controllers and the Message RAM, maintaining the transmission schedule as well as providing message status information.

The register set of the E-Ray IP-module can be accessed directly by an external Host via the module's Host interface. These registers are used to control/configure/monitor the FlexRay™ Channel Protocol Controllers, Message Handler, Global Time Unit, System Universal Control, Frame and Symbol Processing, Network Management, Service Request Control, and to access the Message RAM via Input / Output Buffer.

The E-Ray IP-module supports the following features:

- Conformance with FlexRay™ protocol specification v2.1
- Data rates of up to 10 Mbit/s on each channel
- Up to 128 Message Buffers configurable
- 8 Kbyte of Message RAM for storage of e.g. 128 Message Buffers with max. 48 byte data field or up to 30 Message Buffers with 254 byte Data Sections
- Configuration of Message Buffers with different payload lengths possible
- One configurable receive FIFO
- Each Message Buffer can be configured as receive buffer, as transmit buffer or as part of the receive FIFO
- Host access to Message Buffers via Input and Output Buffer.
  Input Buffer: Holds message to be transferred to the Message RAM
  Output Buffer: Holds message read from the Message RAM
- Filtering for slot counter, cycle counter, and channel
- Maskable module service requests
- Network Management supported
- Four service request lines
- Automatic delayed read access to Output Command Request Register (OBCR) if a data transfer from Message RAM to Output Shadow Buffer (initiated by a previous write access to the OBCR) is ongoing.
- Automatic delayed read access to Input Command Request Register (IBCR) if a data transfer from Input Shadow Buffer to Message RAM to (initiated by a previous write access to the IBCR) is ongoing.

- Four Input Buffer for building up transmission Frames in parallel.
- Flag indicating which Input Buffer is currently accessible by the host.

26.3 Definitions

FlexRay™ Frame: Header Segment + Payload Segment

Message Buffer: Header Section + Data Section

Message RAM: Header Partition + Data Partition

Data Frame: FlexRay™ Frame that is not a NULL Frame

26.4 Block Diagram

The E-Ray is built up by the following main submodules:

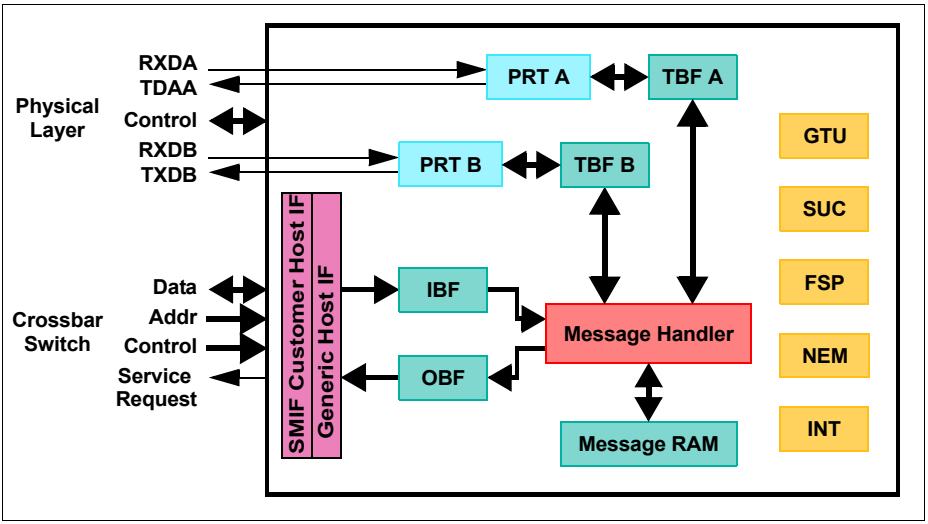

Figure 26-2 E-Ray Block Diagram

Customer Host Interface (CIF)

Connects the FPI Bus to the E-Ray IP-module via the Generic Host Interface.

Generic Host Interface (GIF)

The E-Ray IP-module is provided with an 8/16/32-bit Generic Host Interface prepared for the connection to a wide range of customer-specific Hosts. Configuration registers, status registers, and service request registers are attached to the respective blocks and can be accessed via the Generic Host Interface.

Input Buffer (IBF)

For write access to the Message Buffers configured in the Message RAM, the Host can write the Header and Data Section for a specific Message Buffer to the Input Buffer. The Message Handler then transfers the data from the Input Buffer to the selected Message Buffer in the Message RAM.

Because the Input Buffer (IBF) Scheme does only allow to write the entire Message Frame, not only parts of it, the number of IBF has been increased from originally 2 to 4. This enables to fill the buffer partly and at the end request transfer into Message RAM. Therefore 2 extra bits allow to switch between the two banks of IBF and one status bit signals the IBF currently active for Host writes.

Output Buffer (OBF)

For read access to a Message Buffer configured in the Message RAM the Message Handler transfers the selected Message Buffer to the Output Buffer. After the transfer has completed, the Host can read the Header and Data Section of the transferred Message Buffer from the Output Buffer.

Message Handler (MHD)

The E-Ray Message Handler controls data transfers between the following components:

- Input / Output Buffer and Message RAM
- Transient Buffer RAMs of the two FlexRay™ Protocol Controllers and Message RAM

Message RAM (MRAM)

The Message RAM consists of a single-ported RAM that stores up to 128 FlexRay™ Message Buffers together with the related configuration data (Header and Data Partition).

Transient Buffer RAM (TBF 1/2)

Stores the Data Section of two complete messages.

FlexRay™ Channel Protocol Controller (PRT A/B)

The FlexRay™ Channel Protocol Controllers consist of shift register and FlexRay™ protocol FSM. They are connected to the Transient Buffer RAMs for intermediate message storage and to the physical layer via bus driver BD.

They perform the following functionality:

- Control and check of bit timing
- Reception and transmission of FlexRay™ Frames and symbols
- Check of Header CRC
- Generation / check of Frame CRC

- Interfacing to bus driver

The FlexRay™ Channel Protocol Controllers have interfaces to:

- Physical Layer (bus driver)
- Transient Buffer RAM
- Message Handler
- Global Time Unit
- System Universal Control
- Frame and Symbol Processing
- Network Management
- Service Request Control

Global Time Unit (GTU)

The Global Time Unit performs the following functions:

- Generation of Microtick
- Generation of Macrotick
- Fault tolerant clock synchronization by FTM algorithm
  - Rate correction
  - Offset correction
- Cycle counter
- Timing control of static segment
- Timing control of dynamic segment (minislotting)
- Support of external clock correction

System Universal Control (SUC)

The System Universal Control controls the following functions:

- Configuration
- Wakeup
- Startup
- Normal Operation
- Passive Operation
- Monitor Mode

Frame and Symbol Processing (FSP)

The Frame and Symbol Processing controls the following functions:

- Checks the correct timing of Frames and symbols
- Tests the syntactical and semantical correctness of received Frames
- Sets the slot status flags

Network Management (NEM)

Handles of the Network Management vector

Service Request Control (INT)

The Service Request Controller performs the following functions:

- Provides error and status service request flags
- Enables and disables service request sources
- Assignment of service request sources to one of the two module service request lines
- Enables and disables module service request lines
- Manages the two service request timers
- Stop watch time capturing

26.5 Programmer's Model

The programmer's model of the E-Ray module follows the principle of memory mapped peripheral. Some portion of the memory follows the principle of segmented/paged memory organization.

26.5.1 Register Map

The E-Ray module allocates an address space of 4 Kbyte (000_H to $FFFF_H$). The registers are organized as 32-bit registers. 8/16-bit accesses are also supported. Host access to the Message RAM is done via the Input and Output Buffers. They buffer data to be transferred to and from the Message RAM under control of the Message Handler, avoiding conflicts between Host accesses and message reception / transmission. Addresses 0004_H - $000F_H$,$03C8_H$ - $03EC_H$ and 0800_H - $0FFF_H$ are reserved for customer specific purposes. All functions related to these addresses are located in the Customer Host Interface. The test registers located on address 0010_H and 0014_H are writable only under the conditions described in **"Special Registers" on Page 26-23**.

The assignment of the Message Buffers is done according to the scheme shown in **Table 26-1** below. The number N of available Message Buffers depends on the payload length of the configured Message Buffers. The maximum number of Message Buffers is 128. The maximum payload length supported is 254 byte.

The Message Buffers are separated into three consecutive groups:

- Static Buffers: Transmit / Receive Buffers assigned to static segment
- Static and Dynamic Buffers: Transmit / Receive Buffers assigned to static or dynamic segment
- FIFO- Receive FIFO

The Message Buffer separation configuration can be changed only in "DEFAULT_CONFIG" or "CONFIG" state only by programming the Message RAM Configuration register (MRC).

The first group starts with Message Buffer 0 and consists of static Message Buffers only. Message Buffer 0 is dedicated to hold the startup / SYNC Frame or the single slot Frame, if node transmit one, as configured by SUCC1.TXST, SUCC1.TXSY, and SUCC1.TSM

in the SUC Configuration Register 1 (SUCC1). In addition, Message Buffer 1 may be used for SYNC Frame transmission in case that SYNC Frames or single-slot Frames should have different payloads on the two channels. In this case bit MRC.SPLM has to be programmed to 1 and Message Buffers 0 and 1 have to be configured with the key slot ID and can be (re)configured in “DEFAULT_CONFIG” or “CONFIG” state only.

The second group consists of Message Buffers assigned to the static or to the dynamic segment. Message Buffers belonging to this group may be reconfigured during run time from dynamic to static or vice versa depending on the state of MRC.SEC.

The Message Buffers belonging to the third group are concatenated to a single receive FIFO.

Table 26-1 Assignment of Message Buffers

Message Buffer 0	⇓ Static Buffers	
Message Buffer 1		
…		
	⇓ Static + Dynamic Buffers	⇐ **FDB**
	⇓ FIFO	⇐ **FFB**
Message Buffer N-1		
Message Buffer N		⇐ **LCB**

26.5.2 E-Ray Kernel Registers

This chapter describes all registers of the E-Ray kernel.

1) The absolute register address is calculated as follows:
Module Base Address + Offset Address (shown in this column)

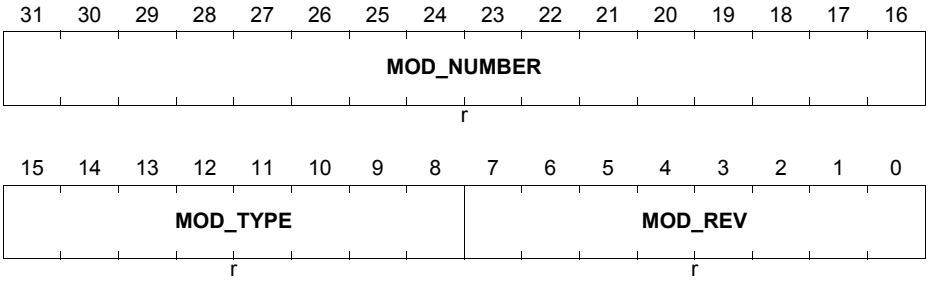
26.5.2.1 Customer Registers

The addresses 0004_H - $000F_H$,$03C8_H$ - $03EC_H$ and 0800_H - $0FFF_H$ are reserved for customer-specific registers.

Module Identification Register (ID)

This register contains bit fields identifying the E-Ray module in Infineons Module portfolio and is read only.

ID
Module Identification Register (0008_H) Reset Value: 0044 C0XX$_H$



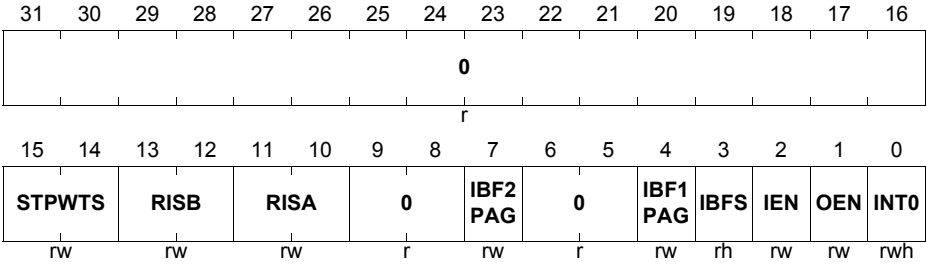
Field	Bits	Type	Description
MOD_REV	[7:0]	r	**Module Revision Number** MOD_REV defines the module revision number. The value of a module revision starts with 01_H (first revision).
MOD_TYPE	[15:8]	r	**Module Type** The value of this bit field is $C0_H$. It defines the module as a 32-bit module.
MOD_NUMBER	[31:16]	r	**Module Number Value** This bit field defines a module identification number. For the E-Ray module the module identification number is 44_H.

Busy Control Register (CUST1)

The Busy Control Register enables the automatic delay scheme. Furthermore it signals a time-out service request for the automatic delay scheme.

CUST1
Busy and Input Buffer Control Register

(0004_H) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
INT0	0	rwh	**CIF Timeout Service Request Status** INT0 will be set if a timeout has occurred during the auto delay scheme and must be reset by writing zero to INT0. *Note: In case hardware sets INT0 and at the same point of time software clears INT0, INT0 is cleared.*
OEN	1	rw	**Enable auto delay scheme for Output Buffer Control Register (OBCR)** This control bit controls the delay scheme for Output Buffer Control Register (OBCR) read accesses. 0_B Disable auto delay scheme for Output Buffer Control Register (OBCR) 1_B Enable auto delay scheme for Output Buffer Control Register (OBCR)
IEN	2	rw	**Enable auto delay scheme for Input Buffer Control Register (IBCR)** This control bit controls the auto delay scheme for Input Buffer Control Register (IBCR) read accesses. 0_B Disable auto delay scheme for Input Buffer Control Register (IBCR) 1_B Enable auto delay scheme for Input Buffer Control Register (IBCR)

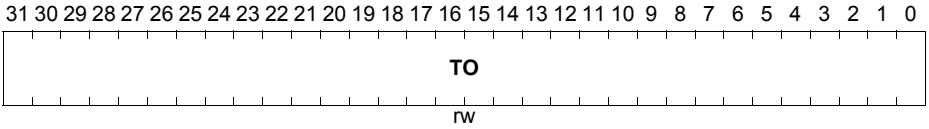
Field	Bits	Type	Description
IBFS	3	rh	**Input Buffer Status Register** This status bit indicates which of the two Input Buffer RAMs (IBF) is accessible by the host (via CIF) as Input Buffer. The other non accessible buffer RAM is currently used as shadow buffer RAM by the ERAY message handler and therefore not accessible by the host. 0_B Input Buffer RAM 2 (IBF2) is accessible as Input Buffer by the host (CIF) 1_B Input Buffer RAM 1 (IBF1) is accessible as Input Buffer by the host (CIF)
IBF1PAG	4	rw	**Input Buffer 1 Page Select Register** This control bit selects if the upper page or lower page of Input Buffer 1 (IBF1) currently active. Read: 0_B Lower Page (256 Bytes) of Input Buffer RAM 1 selected 1_B Upper Page (256 Bytes) of Input Buffer RAM 1 selected Write: 0_B Select Lower Page (256 Bytes) of Input Buffer RAM 1 1_B Select Upper Page (256 Bytes) of Input Buffer RAM 1 *Note: Write is only possible, if Input Buffer RAM 1 is currently accessible by the host (via CIF) and therefore IBFS set.*
IBF2PAG	7	rw	**Input Buffer 2 Page Select Register** This control bit selects if the upper page or lower page of Input Buffer 2 (IBF2) currently active. Read: 0_B Lower Page (256 Bytes) of Input Buffer RAM 2 selected 1_B Upper Page (256 Bytes) of Input Buffer RAM 2 selected Write: 0_B Select Lower Page (256 Bytes) of Input Buffer RAM 2 1_B Select Upper Page (256 Byte) of Input Buffer RAM 2 *Note: Write is only possible, if Input Buffer RAM 2 is currently accessible by the host (via CIF) and therefore IBFS cleared.*

Field	Bits	Type	Description
RISA	[11:10]	rw	**Receive Input Select Channel A** 00_B Channel A receiver input RXDA0 selected 01_B Channel A receiver input RXDA1 selected 10_B Channel A receiver input RXDA2 selected 11_B Channel A receiver input RXDA3 selected
RISB	[13:12]	rw	**Receive Input Select Channel B** 00_B Channel B receiver input RXDB0 selected 01_B Channel B receiver input RXDB1 selected 10_B Channel B receiver input RXDB2 selected 11_B Channel B receiver input RXDB3 selected
STPWTS	[15:14]	rw	**Stop Watch Trigger Input Select** 00_B Stop Watch Trigger input STPWT0 selected 01_B Stop Watch Trigger input STPWT1 selected 10_B Stop Watch Trigger input STPWT2 selected 11_B Stop Watch Trigger input STPWT3 selected
0	[6:5], [9:8], [31:16]	r	**Reserved** Returns 0 if read; should be written with 0.

Customer Interface Time-out Counter Register (CUST3)

The Time-out Counter Register is realizing the time-out counter reload (startup) value for the automatic delay scheme (not the time-out down counter itself).

CUST3
Customer Interface Timeout Counter ($000C_H$) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
TO	[31:0]	rw	**CIF Timeout Reload Value** The 32-bit down counter reload (start-up) value must be setup for the automatic delay scheme.

Automatic Delayed Write Access to OBCR and IBCR

Write and read accesses to the Output Buffer Control Register (OBCR) can be automatically stalled due to a ongoing transfer from the Message Buffer to the Output Buffer. Also write and read accesses to the Input Buffer Control Register (IBCR) may be automatically delayed due to a ongoing transfer from the Input Buffer to the Message Buffer.

This delay scheme can be controlled (enabled or disabled) by CUST1.IEN and CUST1.OEN. The maximum time to stall a write or read access is determined by a single time-out counter preluded with the 32-bit value specified in the bit field CUST3.TO. If the time-out counter counts down to zero before the transfer to/from the Message Buffer is completed, the access (read or write) will be canceled and a service request will be generated. A canceled read access provides a 0 value. A canceled write access does not modify any bits in the OBCR or IBCR. In addition the bit CUST1.INT0 of the service request status register will be set and must be reset by the host to disable the service request line.

The read and write access to the Output Buffer Control Register (OBCR) may be configured without automatic delay by clearing CUST1.OEN. Setting OBCR.REQ and immediately afterwards reading or writing OBCR, e.g. to set OBCR.VIEW will lead to a canceled read or write operation, e.g. OBCR.VIEW remains cleared, and an error is signalled by a set EIR.IOBA. Besides canceling the erroneous read or write operation, and setting the error bit, no further state change happens. So full operation is granted. OBCR remains read and write inaccessible until the transfer of data from the Message Buffer to the Output Buffer (MBF⇒OBF) is completed. During this time span all read and

write accesses to the Output Buffer Control Register (OBCR) are canceled. The transfer is completed when OBCR.OBSYS is cleared. Additionally signal TOBC may be used, e.g. for service request triggering, DMA triggering, or driving a pin, to communicate the access status.

The read and write access to the Output Buffer Control Register (OBCR) may be configured to be automatic delayed by setting CUST1.OEN and configuring CUST3.TO to the maximum stall time acceptable to the system. If setting OBCR.REQ and immediately afterwards reading or writing to OBCR, e.g. to set the OBCR.VIEW bit, this read or write will be stalled until either the maximum delay time elapsed (in this case the read or write operation is cancelled after the stall time, e.g. OBCR.VIEW remains cleared, and an error is signalled by setting EIR.IOBA) or the read or write completes normally, e.g. set OBCR.VIEW after the transfer of data from the Message Buffer to the Output Buffer (MBF⇒OBF) is finalized. During this time the bus is locked and no further access to the E-Ray module is possible due to the ongoing stalled read or write operation. Because no access is possible to the E-Ray module, read or write stall may only be detected through the signal TOBC or due to other not processed read or write accesses to the E-Ray module.

The read and write access to the Input Buffer Control Register (IBCR) may also be configured without automatic delay by clearing CUST1.IEN. By writing to IBCR.IBRH the Input Buffers are swapped (shadow IBF changes to host IBF and host IBF to shadow IBF), the content of the shadow IBF is copied into the MBF (IBF⇒MBF), and IBCR.IBSYS is set. Writing to IBCR.IBRH a second time while IBCR.IBSYS remained set (previously initiated copy process IBF⇒MBF ongoing) will correctly update IBCR.IBRH and set IBCR.IBSYH. This will set the signal IBUSY. A third access, read or write, to IBCR while IBCR.IBSYH remains set will cancel this third access and an error is signalled by setting EIR.IIBA. Besides canceling this last access to IBCR and setting the error bit, no further state change happens. So full operation is granted. IBCR remains read and write inaccessible until the transfer of data from the Input Shadow Buffer to the Message Buffer (IBF⇒MBF) is completed and once more the Input Buffers are swapped (shadow IBF changes to host IBF and host IBF to shadow IBF). During this time span all read and write accesses to the Input Buffer Control Register (IBCR) are canceled. The transfer is completed when IBCR.IBSYH is cleared. Additionally signal TIBC may be used, e.g. for service request triggering, DMA triggering, or driving a pin, to communicate the access status.

The read and write access to the Input Buffer Control Register (IBCR) may be configured for being automatically delayed by setting CUST1.IEN and configuring CUST3.TO to the maximum stall time acceptable to the system. By writing to IBCR.IBRH the Input Buffers are swapped (shadow IBF changes to host IBF and host IBF to shadow IBF), the content of the shadow IBF copied into the MBF, and IBCR.IBSYS is set. Writing to IBCR.IBRH a second time while IBCR.IBSYS remains set (previously initiated copy process ongoing) will correctly update IBCR.IBRH and set IBCR.IBSYH. A third access to IBCR while IBCR.IBSYH remains set will stall this read or write until either the maximum delay

time elapsed (in this case the read or write operation is cancelled after the stall time and an error is signalled by setting EIR.IOBA) or the read or write completes normally, after the transfer of data from the Input Shadow Buffer to the Message Buffer (IBF⇒MBF) is finalized and once more the Input Buffers are swapped (shadow IBF changes to host IBF and host IBF to shadow IBF). During this time the bus is locked and no further access to E-Ray module is possible due to the ongoing stalled read or write operation. Because no access is possible to the E-Ray module, read or write stall may only be detected through the signal TIBC or due to other not processed read or write accesses to the E-Ray module.

So setting CUST3.TO = $FFFFFFFF_H$, CUST1.IEN = 1, and CUST1.OEN = 1 will always grant a consistent data access of the host to the Output and Input Buffers without the need of reading and taking into account the status of OBCR.OBSYS or IBCR.IBSYH. But this simplified access may cause system latencies and system performance loss.

26.5.2.2 Special Registers

Test Register 1 (TEST1)

The Test Register 1 holds the control bits to configure the test modes of the E-Ray module. Write access to these bits is only possible if bit TEST1.WRTEN is set.

The Test Register 1 bits therefore can be used to test the interface to the physical layer (connectivity test) by driving / reading the respective pins.

When the E-Ray IP is operated in one of its test modes that requires TEST1.WRTEN to be set (RAM Test Mode, I/O Test Mode, Asynchronous Transmit Mode, and Loop Back Mode) only the selected test mode functionality is available.

The test functions are not available in addition to the normal operational mode functions, they change the functions of parts of the E-Ray module. Therefore normal operation as specified outside this chapter and as required by the FlexRay™ protocol specification and the FlexRay™ conformance test is not possible. Test mode functions may not be combined with each other or with FlexRay™ protocol functions.

The test mode features are intended for hardware testing or for FlexRay™ bus analyzer tools. They are not intended to be used in FlexRay™ applications

TEST1
Test Register 1 **(0010_H)** **Reset Value: $0000\ 0300_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CERB				CERA				0		TXENB	TXENA	TXB	TXA	RXB	RXA

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0						AOB	AOA	0		TMC		0		ELBE	WRTEN
r						rh	rh	r		rw		r		rw	rw

Field	Bits	Type	Description
WRTEN	0	rw	**Write Test Register Enable** Enables write access to the test registers. To set the bit from 0 to 1 the test mode key has to be written as defined on **"Lock Register (LCK)" on Page 26-39**. The unlock sequence is not required when TEST1.WRTEN is kept at 1 while other bits of the register are changed. The bit can be reset to 0 at any time. 0_B Write access to test registers disabled. 1_B Write access to test registers enabled.

Field	Bits	Type	Description
ELBE	1	rw	**External Loop Back Enable** There are two possibilities to perform a loop back test. External loop back via physical layer or internal loop back for in-system self-test (default). In case of an internal loop back pins TXENA and TXENB are in their inactive state, pins TXDA and TXDB are set to HIGH, pins RXDA and RXDB are not evaluated. Bit ELBE is evaluated only when POC is in loop back mode and test multiplexer control is in non multiplexed mode TMC = 00. 0_B Internal loop back (default) 1_B External loop back
TMC	[5:4]	rw	**Test Multiplexer Control** 00_B Normal signal path (default). 01_B RAM Test Mode: Internal busses are multiplexed to make all RAM blocks of the E-Ray module directly accessible by the Host. This mode is intended to enable testing of the embedded RAM blocks during production testing. 10_B I/O Test Mode: Output pins are driven to the values defined by bits TXA, TXB, TXENA, TXENB. The values applied to the input pins can be read from register bits RXA and RXB. 11_B Reserved; should not be used.
AOA	8	rh	**Activity on A** The channel idle condition is specified in the FlexRay™ protocol spec v2.1, chapter 3, BITSTRB process (zChannelIdle). 0_B No activity detected, channel A idle 1_B Activity detected, channel A not idle
AOB	9	rh	**Activity on B** The channel idle condition is specified in the FlexRay™ protocol spec v2.1, chapter 3, BITSTRB process (zChannelIdle). 0_B No activity detected, channel B idle 1_B Activity detected, channel B not idle
RXA	16	rh	**Read Channel A Receive Pin** 0_B RXDA = 0 1_B RXDA = 1

Field	Bits	Type	Description
RXB	17	rh	**Read Channel B Receive Pin** 0_B RXDB = 0 1_B RXDB = 1
TXA	18	rwh	**Read or Write to Channel A Transmit Pin** 0_B TXDA = 0 1_B TXDA = 1
TXB	19	rwh	**Read or Write to Channel B Transmit Pin** 0_B TXDB = 0 1_B TXDB = 1
TXENA	20	rwh	**Read or Write to Channel A Transmit Enable Pin** 0_B $\overline{\text{TXENA}}$= 0 1_B $\overline{\text{TXENA}}$= 1
TXENB	21	rwh	**Read or Write to Channel B Transmit Enable Pin** 0_B $\overline{\text{TXENB}}$ = 0 1_B $\overline{\text{TXENB}}$= 1
CERA	[27:24]	rh	**Coding Error Report Channel A**[1)] Set when a coding error is detected on channel A. Reset to zero when register TEST1 is read or written. Once the CERA is set it will remain unchanged until the Host accesses the TEST1 register. 0000_B No coding error detected 0001_B Header CRC error detected 0010_B Frame CRC error detected 0011_B Frame Start Sequence FSS too long 0100_B First bit of Byte Start Sequence BSS seen LOW 0101_B Second bit of Byte Start Sequence BSS seen HIGH 0110_B First bit of Frame End Sequence FES seen HIGH 0111_B Second bit of Frame End Sequence FES seen LOW 1000_B CAS / MTS symbol seen too short 1001_B CAS / MTS symbol seen too long Other combinations are reserved.

Field	Bits	Type	Description
CERB	[31:28]	rh	**Coding Error Report Channel B**[1)] Set when a coding error is detected on channel B. Reset to zero when register TEST1 is read or written. Once the CERB is set it will remain unchanged until the Host accesses the TEST1 register. 0000_B No coding error detected 0001_B Header CRC error detected 0010_B Frame CRC error detected 0011_B Frame Start Sequence FSS too long 0100_B First bit of Byte Start Sequence BSS seen LOW 0101_B Second bit of Byte Start Sequence BSS seen HIGH 0110_B First bit of Frame End Sequence FES seen HIGH 0111_B Second bit of Frame End Sequence FES seen LOW 1000_B CAS / MTS symbol seen too short 1001_B CAS / MTS symbol seen too long Other combinations are reserved.
0	[3:2], [7:6], [15:10], [23:22]	r	**Reserved** Returns 0 if read; should be written with 0.

1) Coding errors are also signalled when the Communication Controller is in “MONITOR_MODE”. The error codes regarding CAS / MTS symbols concern only the monitored bit pattern, irrelevant whether those bit patterns are seen in the symbol window or elsewhere.

Asynchronous Transmit Mode (ATM)

The asynchronous transmit mode is entered by writing 1110_B to the CHI Command Vector SUCC1.CMD in the SUC Configuration Register 1 (CHI command: ATM) while the Communication Controller is in “CONFIG” state and bit TEST1.WRTEN in the Test Register 1 is set. This write operation has to be directly preceded by two consecutive write accesses to the Configuration Lock Key (unlock sequence). When called in any other state or when bit TEST1.WRTEN is not set, SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED”. CCSV.POCS in the Communication Controller Status Vector will return 1110_B while the E-Ray module is in ATM mode. Asynchronous Transmit mode can be left by writing 0001_B (CHI command: “CONFIG”) to the CHI Command Vector SUCC1.CMD in the SUC Configuration Register 1.

In ATM mode transmission of a FlexRay™ Frame is triggered by writing the number of the respective Message Buffer to the Input Buffer Command Request register (IBCR.IBRH) while bit IBCM.STXRS in the Input Buffer Command Mask register is set to 1. In this mode wake-up, startup, and clock synchronization are bypassed. The CHI command SEND_MTS results in the immediate transmission of an MTS symbol.

The cycle counter value of Frames send in ATM mode can be programmed via MTCCV.CCV (writable in ATM and loop back mode only).

Loop Back Mode

The loop back mode is entered by writing 1111_B to the CHI Command Vector SUCC1.CMD in the SUC Configuration Register 1 (CHI command: LOOP_BACK) while the Communication Controller is in “CONFIG” state and bit TEST1.WRTEN in the Test Register 1 is set. This write operation has to be directly preceded by two consecutive write accesses to the Configuration Lock Key (unlock sequence). When called in any other state or when bit TEST1.WRTEN is not set, SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED”. CCSV.POCS in the Communication Controller Status Vector will show $0000\ 1101_H$ while the E-Ray module is in loop back mode.

Loop Back mode can be left by writing 0001_B (CHI command: “CONFIG”) to the CHI Command Vector SUCC1.CMD in the SUC Configuration Register 1.

The loop back test mode is intended to check the module’s internal data paths. Normal, time triggered operation is not possible in loop back mode.

There are two possibilities to perform a loop back test. External loop back via physical layer (TEST1.ELBE = 1) or internal loop back for in-system self-test (TEST1.ELBE = 0). In case of an internal loop back pins $\overline{\text{TXENA}}$, $\overline{\text{TXENB}}$ are in their inactive state, pins TXDA and TXDB are set to HIGH, pins RXDAn and RXDBn are not evaluated.

When the Communication Controller is in loop back mode, a loop back test is started by the Host writing a message to the Input Buffer and requesting the transmission by writing to the Input Buffer Command Request register IBCR. The Message Handler will transfer the message into the Message RAM and then into the Transient Buffer of the selected channel. The Channel Protocol Controller (PRT) will read (in 32-bit words) the message from the transmit part of the Transient Buffer and load it into its Rx / Tx shift register. The serial transmission is looped back into the shift register; its content is written into the receive part of the channels’s Transient Buffer before the next word is loaded.

The PRT and the Message Handler will then treat this transmitted message like a received message, perform an acceptance filtering on Frame ID and receive channel, and store the message into the Message RAM if it passed acceptance filtering. The loop back test ends with the Host requesting this received message from the Message RAM and then checking the contents of the Output Buffer.

Each FlexRay™ channel is tested separately. The E-Ray cannot receive messages from the FlexRay™ bus while it is in the loop back mode.

The cycle counter value of Frames used in loop back mode can be programmed via MTCCV.CCV (writable in ATM and loop back mode only).

Note that in case of an odd payload the last two bytes of the looped-back payload will be shifted by 16 bits to the right inside the last 32-bit data word.

Test Register 2 (TEST2)

The Test Register 2 holds all bits required for the RAM test of the seven embedded RAM blocks of the E-Ray module. Write access to this register is only possible when TEST1.WRTEN in the Test Register 1 is set to 1.

TEST2
Test Register 2 **(0014_H)** **Reset Value: $0000\ 0000_H$**

0	3, [13:7], 15, [31:16]	r	**Reserved** Returns 0 if read; should be written with 0.

RAM Test Mode

In RAM test mode (TEST1.TMC = 1), one of the seven RAM blocks can be selected for direct RD/WR access by programming TEST2.RS.

For external access the selected RAM block is mapped to address space 400_H to $7FF_H$ (1024 byte addresses or 256 word addresses).

Because the length of the Message RAM exceeds the available address space, the Message RAM is segmented into segments of 1024 byte. The segments can be selected by programming TEST2.SSEL in the Test Register 2.

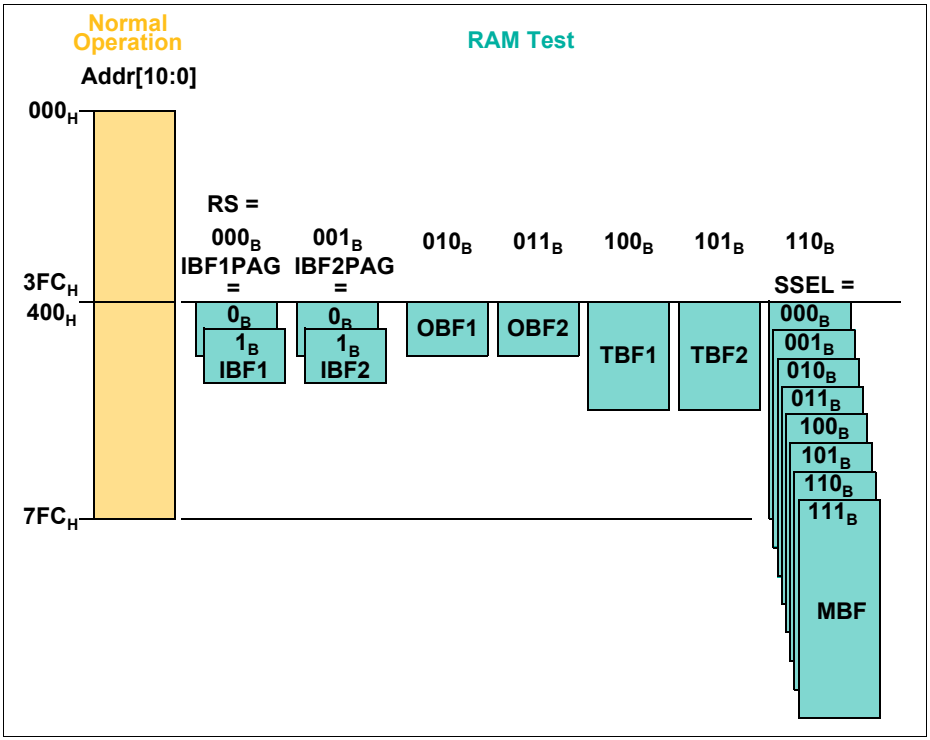

Figure 26-3 RAM test mode Access to E-Ray RAM Blocks

SECCON

The Single Bit Error Correction Control Register holds the bits required for enabling the single bit error correction for each respective RAM block of the E-Ray module. It can only be written if PRDCFG2.SENAV is set. In TC1798 this PRDCFG2 bit is reset by SSW from a parameter stored in the config sector. Thus the user has not access to turn on/off single error correction. In TC1798 the SEC bits are tied to “enabled”. It is supervisor and endinit protected.

0	[31:7]	r	**Reserved** Returns 0 if read; should be written with 0.

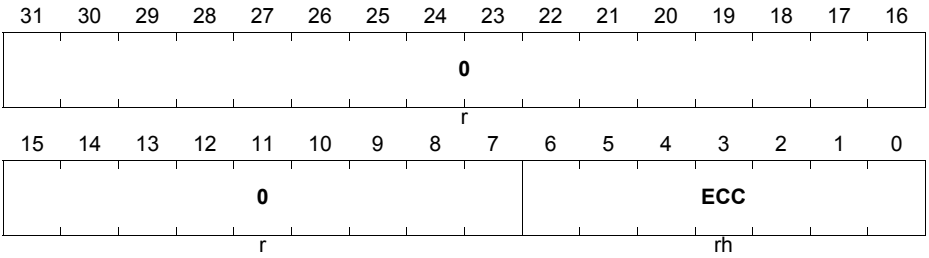
ECCR

The ECC Data Read Register always holds the ECC bits referring to the last accessed RAM address. In normal operation RAM can not be accessed by the CPU. For dedicated RAM access to selected addresses by the CPU, Test mode must be entered. See **“Test Register 2 (TEST2)” on Page 26-28**

ECCR

ECC Data Read Register **(080C$_H$)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
ECC	[6:0]	rh	**Error Correction Data of the last accessed RAM address**
0	[31:7]	r	**Reserved** Returns 0 if read; should be written with 0.

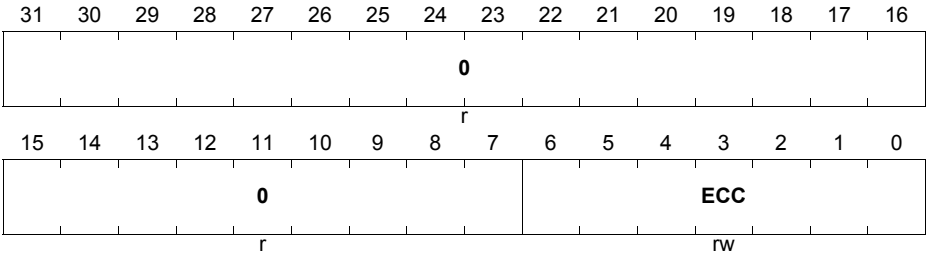
ECCW

The ECC Data Write Register holds the ECC bits to be written together with the next RAM access. These bits are written to the ECC bit field referring to the RAM address accessed next. In normal operation E-Ray RAM can not be accessed by the CPU. The content of ECCW is not transferred to the RAM ECC data field in normal operation. For ECCW to become effective (and for dedicated RAM access to selected addresses by the CPU), Test mode must be entered. See **"Test Register 1 (TEST1)" on Page 26-23**. The referring RAM must be selected. See **"Test Register 2 (TEST2)" on Page 26-28**.

Note: Content of ECCW is transferred to the RAM only if TEST2.WRECC is set!

ECCW

ECC Data Write Register (0810$_H$) Reset Value: 0000 0000$_H$

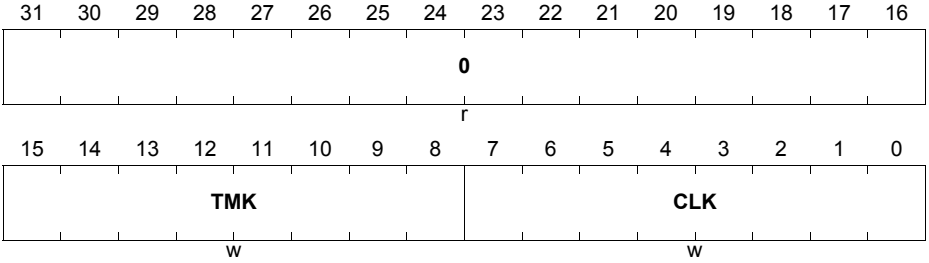


Field	Bits	Type	Description
ECC	[6:0]	rw	**Error Correction Data written with next RAM address written next**
0	[31:7]	r	**Reserved** Returns 0 if read; should be written with 0.

Lock Register (LCK)

The Lock Register is write-only. Reading the register will return 0000 0000_H.

LCK
Lock Register **($001C_H$)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
CLK	[7:0]	w	**Configuration Lock Key** To leave “CONFIG” state by writing to SUCC1.CMD commands READY, MONITOR_MODE, ATM, LOOP_BACK) in the SUC Configuration Register 1, the write operation has to be directly preceded by two consecutive write accesses to the Configuration Lock Key (unlock sequence). If the write sequence below is interrupted by other write accesses between the second write to the Configuration Lock Key and the write access to the SUCC1 register, the Communication Controller remains in “CONFIG” state and the sequence has to be repeated. First write: LCK.CLK = CE_H = $1100\ 1110_B$ Second write: LCK.CLK = 31_H = $0011\ 0001_B$ Third write: SUCC1.CMD Returns 0 if read

Field	Bits	Type	Description
TMK	[15:8]	w	**Test Mode Key** To set bit TEST1.WRTEN the write operation has to be directly preceded by two consecutive write accesses to the Test Mode Key. If the write sequence is interrupted by other write accesses between the second write to the Test Mode Key and the write access to the Test1 register, bit TEST1.WRTEN is not set to 1 and the sequence has to be repeated. First write: LCK.TMK = 75_H = 0111 0101_B Second write: LCK.TMK = $8A_H$ = 1000 1010_B Second write: TEST1.WRTEN = 1 Returns 0 if read
0	[31:16]	r	**Reserved** Returns 0 if read; should be written with 0.

Note: In case the Host uses 8/16-bit accesses to write the listed bit fields, the programmer has to ensure that no "dummy accesses" e.g. to the remaining register bytes / words are inserted by the compiler.

To exit "CONFIG" state by writing to SUCC1.CMD in the SUC Configuration Register 1, the write operation has to be directly preceded by two consecutive write accesses to the Configuration Lock Key. If this write sequence is service requested by read accesses or write accesses to other locations, the Communication Controller remains in "CONFIG" state and the sequence has to be repeated.

First write: LCK.CLK = CE_H = 1100 1110_B

Second write: LCK.CLK = 31_H = 0011 0001_B

26.5.2.3 Service Request Registers

The address space from 0020_H to $007F_H$ is reserved for service request registers.

Error Service Request Select (EIR)

The flags are set when the Communication Controller detects one of the listed error conditions. They remain set until the Host clears them. A flag is cleared by writing a 1 to the corresponding bit position. Writing a 0 has no effect on the flag. An application reset will also clear the register.

EIR
Error Service Request Register (0020_H) Reset Value: $0000\ 0000_H$

r				rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh

Field	Bits	Type	Description
PEMC	0	rwh	**POC Error Mode Changed** This flag is set whenever the error mode signalled by CCEV.ERRM in the Communication Controller Error Vector register has changed. 0_B Error mode has not changed 1_B Error mode has changed This flag is cleared by writing a 1.
CNA	1	rwh	**Command Not Accepted** The flag signals that the write access to the CHI command vector SUCC1.CMD in the SUC Configuration Register 1 was not successful because the requested command was not valid in the actual POC state, or because the CHI command was locked (CCL = 1). 0_B CHI command accepted 1_B CHI command not accepted This flag is cleared by writing a 1.

Field	Bits	Type	Description
SFBM	2	rwh	**SYNC Frames Below Minimum** This flag signals that the number of SYNC Frames received during the last communication cycle was below the limit required by the FlexRay™ protocol. May be set during startup and therefore should be cleared by the Host after the Communication Controller entered “NORMAL_ACTIVE” state. 0_B Sync node: 1 or more SYNC Frames received Non-sync node: 2 or more SYNC Frames received 1_B Less than the required minimum of SYNC Frames received This flag is cleared by writing a 1.
SFO	3	rwh	**SYNC Frame Overflow** Set when either the number of SYNC Frames received during the last communication cycle or the total number of SYNC Frames received during the last double cycle exceeds the maximum number of SYNC Frames as defined by GTUC02.SNM in the GTU Configuration Register 2. 0_B Number of received SYNC Frames ≤ GTUC02.SNM 1_B More SYNC Frames received than configured by GTUC02.SNM This flag is cleared by writing a 1.
CCF	4	rwh	**Clock Correction Failure** This flag is set at the end of the cycle whenever one of the following errors occurred: • Missing offset and / or rate correction • Clock Correction limit reached The clock correction status is monitored in registers CCEV and SFS. A failure may occur during startup, therefore bit CCF should be cleared by the Host after the Communication Controller entered “NORMAL_ACTIVE” state. 0_B Clock correction successful so far 1_B Clock correction failed This flag is cleared by writing a 1.

Field	Bits	Type	Description
CCL	5	rwh	**CHI Command Locked** The flag signals that the write access to the CHI command vector SUCC1.CMD was not successful because the execution of the previous CHI command has not yet completed. In this case bit EIR.CNA is also set to 1. 0_B CHI command accepted 1_B CHI command not accepted This flag is cleared by writing a 1.
EERR	6	rh	**ECC Error** The flag signals an ECC error to the Host. It is set whenever one of the flags MHDS.EIBF, MHDS.EOBF, MHDS.EMR, MHDS.ETBF1, MHDS.ETBF2 changes from 0 to 1. See also **“Message Handler Status (MHDS)” on Page 26-145**. 0_B No error detected 1_B Error detected
RFO	7	rh	**Receive FIFO Overrun** The flag is set by the Communication Controller when a receive FIFO overrun is detected. When a receive FIFO overrun occurs, the oldest message is overwritten with the actual received message. The actual state of the FIFO is monitored in register FSR. 0_B No receive FIFO overrun detected 1_B A receive FIFO overrun has been detected
EFA	8	rwh	**Empty FIFO Access** This flag is set by the Communication Controller when the Host requests the transfer of a message from the receive FIFO via Output Buffer while the receive FIFO is empty. 0_B No Host access to empty FIFO occurred 1_B Host access to empty FIFO occurred

Field	Bits	Type	Description
IIBA	9	rwh	**Illegal Input Buffer Access** This flag is set by the Communication Controller when the Host wants to modify a Message Buffer via Input Buffer while the Communication Controller is not in “CONFIG” or “DEFAULT_CONFIG” state and one of the following conditions applies: 1. The Host writes to the Input Buffer Command Request register to modify the: a) Header Section of Message Buffer 0, 1 if configured for transmission in key slot b) Header Section of static Message Buffers with buffer number < MRC.FDB while MRC.SEC = 01_B c) Header Section of any static or dynamic Message Buffer while MRC.SEC = $1x_B$ d) Header and / or Data Section of any message buffer belonging to the receive FIFO 2. The Host writes to any register of the Input Buffer while IBCR.IBSYS is set. 0_B No illegal Host access to Input Buffer occurred 1_B Illegal Host access to Input Buffer occurred
IOBA	10	rwh	**Illegal Output Buffer Access** This flag is set by the Communication Controller when the Host requests the transfer of a Message Buffer from the Message RAM to the Output Buffer while OBCR.OBSYS is set to 1. 0_B No illegal Host access to Output Buffer occurred 1_B Illegal Host access to Output Buffer occurred
MHF	11	rwh	**Message Handler Constraints Flag** The flag signals a Message Handler constraints violation condition. It is set whenever one of the flags MHDF.SNUA, MHDF.SNUB, MHDF.FNFA, MHDF.FNFB, MHDF.TBFA, MHDF.TBFB, MHDF.TNSA, MHDF.TNSB, MHDF.WAHP changes from 0 to 1. 0_B No Message Handler failure detected 1_B Message Handler failure detected

Field	Bits	Type	Description
EDA	16	rwh	**Error Detected on Channel A** This bit is set whenever one of the flags ACS.SEDA, ACS.CEDA, ACS.CIA, ACS.SBVA changes from 0 to 1. 0_B No error detected on channel A 1_B Error detected on channel A This flag is cleared by writing a 1.
LTVA	17	rwh	**Latest Transmit Violation Channel A** The flag signals a latest transmit violation on channel A to the Host. 0_B No latest transmit violation detected on channel A 1_B Latest transmit violation detected on channel A This flag is cleared by writing a 1.
TABA	18	rwh	**Transmission Across Boundary Channel A** The flag signals to the Host that a transmission across a slot boundary occurred for channel A. 0_B No transmission across slot boundary detected on channel A 1_B Transmission across slot boundary detected on channel A This flag is cleared by writing a 1.
EDB	24	rwh	**Error Detected on Channel B** This bit is set whenever one of the flags ACS.SEDB, ACS.CEDB, ACS.CIB, ACS.SBVB changes from 0 to 1. 0_B No error detected on channel B 1_B Error detected on channel B This flag is cleared by writing a 1.
LTVB	25	rwh	**Latest Transmit Violation Channel B** The flag signals a latest transmit violation on channel B to the Host. 0_B No latest transmit violation detected on channel B 1_B Latest transmit violation detected on channel B This flag is cleared by writing a 1.

Field	Bits	Type	Description
TABB	26	rwh	**Transmission Across Boundary Channel B** The flag signals to the Host that a transmission across a slot boundary occurred for channel B. 0_B No transmission across slot boundary detected on channel B 1_B Transmission across slot boundary detected on channel B This flag is cleared by writing a 1.
0	[15:12], [23:19], [31:27]	r	**Reserved** Returns 0 if read; should be written with 0.

Status Service Request Register (SIR)

The flags are set whenever the Communication Controller detects one of the listed events. The flags remain set until the Host clears them. A flag is cleared by writing a 1 to the corresponding bit position. Writing a 0 has no effect on the flag. An application reset will also clear the register.

SIR

Status Service Request Register (0024$_H$) Reset Value: 0000 0000$_H$

rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rh	rh	rwh	rwh	rwh	rwh	rwh

Field	Bits	Type	Description
WST	0	rwh	**Wakeup Status** This flag is set when the wakeup status vector CCSV.WSV in the Communication Controller Status Vector register changes to a value other than UNDEFINED. 0_B Wake-up status unmodified 1_B Wake-up status modified (and not UNDEFINED) This flag is cleared by writing a 1.
CAS	1	rwh	**Collision Avoidance Symbol** This flag is set by the Communication Controller during STARTUP state when a CAS or potential CAS was received. 0_B No bit pattern matching the CAS symbol received 1_B Bit pattern matching the CAS symbol received This flag is cleared by writing a 1.
CYCS	2	rwh	**Cycle Start Service Request** This flag is set by the Communication Controller when a communication cycle starts 0_B No communication cycle started 1_B Communication cycle started This flag is cleared by writing a 1.

Field	Bits	Type	Description
TXI	3	rwh	**Transmit Service Request** This flag is set by the Communication Controller at the end of Frame transmission if bit WRHS1.MBI in the respective Message Buffer is set (see **Table 26-24**). 0_B No Frame transmitted from a transmit buffer with WRHS1.MBI = 1 1_B At least one Frame was transmitted from a transmit buffer with WRHS1.MBI = 1 This flag is cleared by writing a 1.
RXI	4	rwh	**Receive Service Request** This flag is set by the Communication Controller whenever the set condition of a Message Buffer ND flag is fulfilled and if bit WRHS1.MBI of that Message Buffer is set to 1(see **Table 26-24**). 0_B No ND flag of a receive buffer with WRHS1.MBI = 1 has been set to 1 1_B At least one ND flag of a receive buffer with WRHS1.MBI = 1 has been set to 1 This flag is cleared by writing a 1.
RFNE	5	rh	**Receive FIFO Not Empty** This flag is set by the Communication Controller when a received valid Frame was stored into the empty receive FIFO.m The actual state of the receive FIFO is monitored in register FSR 0_B Receive FIFO is empty 1_B Receive FIFO is not empty
RFCL	6	rh	**Receive FIFO Critical Level** This flag is set when a valid receive FIFO fill level FSR.RFFL is equal or greater than the critical level as configured by FCL.CL. 0_B Receive FIFO below critical level 1_B Receive FIFO critical level reached
NMVC	7	rwh	**Network Management Vector Changed** This service request flag signals a change in the Network Management Vector visible to the Host. 0_B No change in the Network Management vector 1_B Network Management vector changed This flag is cleared by writing a 1.

Field	Bits	Type	Description
TI0	8	rwh	**Timer Service Request 0** This flag is set whenever timer 0 matches the conditions configured in the Timer Service Request 0 Configuration Register T0C. A Timer Service Request 0 is also signalled by TINT0SRC. 0_B No Timer Service Request 0 1_B Timer Service Request 0 occurred This flag is cleared by writing a 1.
TI1	9	rwh	**Timer Service Request 1** This flag is set whenever the conditions programmed in the Timer Service Request 1 Configuration Register T1C are met. A Timer Service Request 1 is also signalled by TINT1SRC. 0_B No Timer Service Request 1 1_B Timer Service Request 1 occurred This flag is cleared by writing a 1.
TIBC	10	rwh	**Transfer Input Buffer Completed** This flag is set whenever a transfer from Input Buffer to the Message RAM has completed and bit IBCR.IBSYS in the Input Buffer Command Request register has been reset by the Message Handler. 0_B No transfer completed 1_B Transfer between Input Buffer and Message RAM completed This flag is cleared by writing a 1.
TOBC	11	rwh	**Transfer Output Buffer Completed** This flag is set whenever a transfer from Message RAM to the Output Buffer has completed and bit OBCR.OBSYS in the Output Buffer Command Request register has been reset by the Message Handler. 0_B No transfer completed 1_B Transfer between Message RAM and the Output Buffer completed This flag is cleared by writing a 1.
SWE	12	rwh	**Stop Watch Event** This flag is set after a stop watch activation when the current cycle counter and Macrotick value are stored in the Stop Watch Register 1 (STPW1). 0_B No Stop Watch Event 1_B Stop Watch Event occurred This flag is cleared by writing a 1.

Field	Bits	Type	Description
SUCS	13	rwh	**Startup Completed Successfully** This flag is set whenever a startup completed successfully and the Communication Controller entered “NORMAL_ACTIVE” state. 0_B No startup completed successfully 1_B Startup completed successfully This flag is cleared by writing a 1.
MBSI	14	rwh	**Message Buffer Status Service Request** This flag is set by the Communication Controller when the Message Buffer status MBS has changed and if bit RDHS1.MBI of that Message Buffer is set (see **Table 26-24**). 0_B No Message Buffer status change of Message Buffer with RDHS1.MBI= 1 has changed 1_B Message Buffer status of at least one Message Buffer with RDHS1.MBI= 1 has changed This flag is cleared by writing a 1.
SDS	15	rwh	**Start of Dynamic Segment** This flag is set by the Communication Controller when the dynamic segment starts. 0_B Dynamic segment not yet started 1_B Dynamic segment started
WUPA	16	rwh	**Wakeup Pattern Channel A** This flag is set by the Communication Controller when a wakeup pattern was received on channel A. Only set when the Communication Controller is in “WAKEUP”, “READY”, or “STARTUP” state, or when in Monitor mode. 0_B No wake-up pattern received on channel A 1_B Wake-up pattern received on channel A This flag is cleared by writing a 1.
MTSA	17	rwh	**MTS Received on Channel A** (vSS!ValidMTSA) Media Access Test symbol received on channel A during the proceeding symbol window. Updated by the Communication Controller for each channel at the end of the symbol window. 0_B No MTS symbol received on channel A 1_B MTS symbol received on channel A This flag is cleared by writing a 1.

Field	Bits	Type	Description
WUPB	24	rwh	**Wakeup Pattern Channel B** This flag is set by the Communication Controller when a wakeup pattern was received on channel B. Only set when the Communication Controller is in “WAKEUP”, “READY”, or “STARTUP” state, or when in Monitor mode. 0_B No wake-up pattern received on channel B 1_B Wake-up pattern received on channel B This flag is cleared by writing a 1.
MTSB	25	rwh	**MTS Received on Channel B** (vSS!ValidMTSB) Media Access Test symbol received on channel B during the proceeding symbol window. Updated by the Communication Controller for each channel at the end of the symbol window. 0_B No MTS symbol received on channel B 1_B MTS symbol received on channel B This flag is cleared by writing a 1.
0	[23:18], [31:26]	r	**Reserved** Returns 0 if read; should be written with 0.

Error Service Request Line Select (EILS)

The Error Service Request Line Select register assigns a service request generated by a specific error service request flag from register EIR to one of the two module service request lines INT0SRC or INT1SRC:

0 = Interrupt assigned to interrupt line (INT0SRC)

1 = Interrupt assigned to interrupt line (INT1SRC)

EILS

Status Service Request Enable Set (SIES)

The settings in the Status Service Request Enable Set register determine which status changes in the Status Service Request Register will result in a service request. The enable bits are set by writing to SIES and reset by writing to SIER. Writing a 1 sets the specific enable bit, a 0 has no effect.

SIES

Status Service Request Enable Set (0038_H) **Reset Value: $0000\ 0000_H$**

Status Service Request Enable Reset (SIER)

The settings in the Status Service Request Enable Reset register determine which status changes in the Status Service Request Register will result in a service request. The enable bits are set by writing to SIES and reset by writing to SIER. Writing a 1 resets the specific enable bit, a 0 has no effect.

SIER

Status Service Request Enable Reset(003C$_H$) **Reset Value: 0000 0000$_H$**

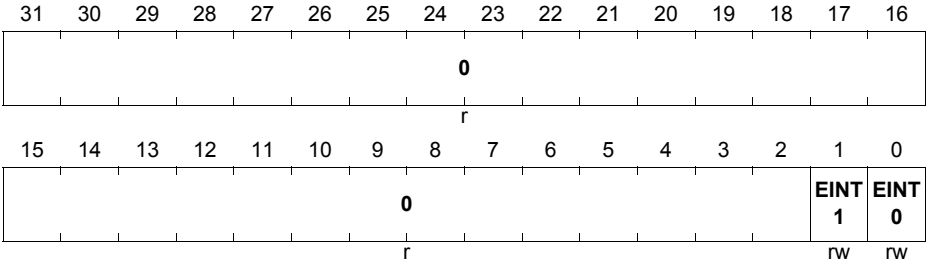
0	[23:18], [31:26]	r	**Reserved** Returns 0 if read; should be written with 0.

Service Request Line Enable (ILE)

Each of the two service request lines to the Host INT0SRC, INT1SRC can be enabled / disabled separately by programming bit EINT0 and EINT1.

ILE
Service Request Line Enable **(0040_H)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
EINT0	0	rw	**Enable Service Request Line 0** (INT0SRC) 0_B Service Request line disabled 1_B Service Request line enabled
EINT1	1	rw	**Enable Service Request Line 1** (INT1SRC) 0_B Service Request line disabled 1_B Service Request line enabled
0	[31:2]	r	**Reserved** Returns 0 if read; should be written with 0.

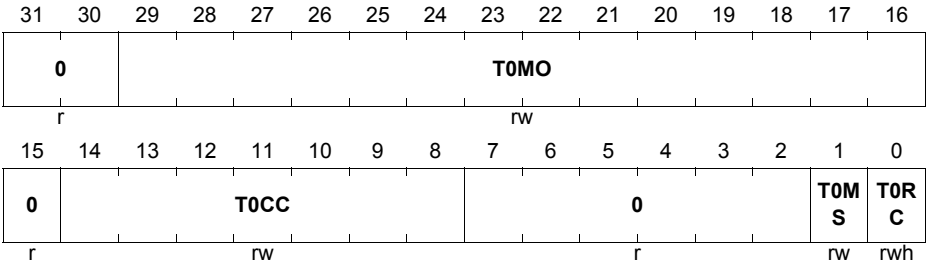
Timer 0 Configuration (T0C)

Absolute timer. Specifies in terms of cycle count and Macrotick the point in time when the timer 0 service request occurs. When the timer 0 service request is asserted, output signal TINT0SR is set to 1 for the duration of one Macrotick and SIR.TI0 is set to 1.

Timer 0 can be activated as long as the POC is either in “NORMAL_ACTIVE” state or in “NORMAL_PASSIVE” state. Timer 0 is deactivated when leaving “NORMAL_ACTIVE” state or “NORMAL_PASSIVE” state except for transitions between the two states.

Before reconfiguration of the timer, the timer has to be halted first by writing 0 to bit T0RC.

T0C
Timer 0 Configuration **(0044_H)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
T0RC	0	rwh	**Timer 0 Run Control** 0_B Timer 0 halted 1_B Timer 0 running
T0MS	1	rw	**Timer 0 Mode Select** 0_B Single-shot mode 1_B Continuous mode
T0CC	[14:8]	rw	**Timer 0 Cycle Code** The 7-bit timer 0 cycle code determines the cycle set used for generation of the timer 0 service request. For details about the configuration of the cycle code see **“Cycle Counter Filtering” on Page 26-224**.
T0MO	[29:16]	rw	**Timer 0 Macrotick Offset** Configures the Macrotick offset from the beginning of the cycle where the service request is to occur. The Timer 0 Service Request occurs at this offset for each cycle of the cycle set.

Field	Bits	Type	Description
0	[7:2], 15, [31:30]	r	**Reserved** Returns 0 if read; should be written with 0.

Note: The configuration of timer 0 is compared against the Macrotick counter value, there is no separate counter for timer 0. In case the Communication Controller leaves "NORMAL_ACTIVE" or "NORMAL_PASSIVE" state, or if timer 0 is halted by Host command, output signal TINT0SR *is reset to 0 immediately.*

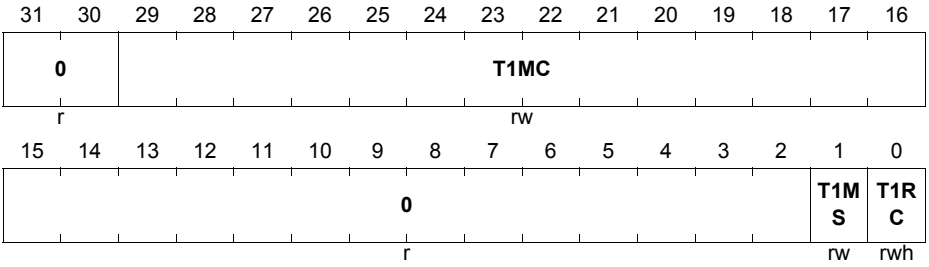
Timer 1 Configuration (T1C)

Relative timer. After the specified number of Macroticks has expired, the timer 1 service request is asserted, output signal TINT1SR is set to 1 for the duration of one Macrotick and SIR.TI1 is set to 1.

Timer 1 can be activated as long as the POC is either in “NORMAL_ACTIVE” state or in “NORMAL_PASSIVE” state. Timer 1 is deactivated when leaving “NORMAL_ACTIVE” state or “NORMAL_PASSIVE” state except for transitions between the two states.

Before reconfiguration of the timer, the timer has to be halted first by resetting bit T1RC to 0.

T1C
Timer 1 Configuration **(0048_H)** **Reset Value: $0002\ 0000_H$**



Field	Bits	Type	Description
T1RC	0	rwh	**Timer 1 Run Control** 0_B Timer 1 halted 1_B Timer 1 running
T1MS	1	rw	**Timer 1 Mode Select** 0_B Single-shot mode 1_B Continuous mode
T1MC	[29:16]	rw	**Timer 1 Macrotick Count** When the configured Macrotick count is reached the timer 1 service request is generated. Valid values are: 2_H …$3FFF_H$ Macroticks in continuous mode 1_H …$3FFF_H$ Macroticks in single-shot mode
0	[15:2], [31:30]	r	**Reserved** Returns 0 if read; should be written with 0.

Note: In case the Communication Controller leaves "NORMAL_ACTIVE" or "NORMAL_PASSIVE" state, or if timer 1 is halted by Host command, output signal TINT1SR *is reset to 0 immediately.*

Stop Watch Register 1 (STPW1)

The stop watch is activated by a rising or falling edge on signal STPW, by a service request 0 or 1 event (rising edge on signal INT0SR or INT1SR) or by the Host by writing bit STPW1.SSWT to 1. With the Macrotick counter increment following next to the stop watch activation the actual cycle counter and Macrotick value are captured in the Stop Watch Register 1 STPW1 while the slot counter values for channel A and B are captured in the Stop Watch Register 2 STPW2.

STPW1
Stop Watch Register 1 **(004C$_H$)** **Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0								SMTV

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0		SCCV						0	EINT1	EINT0	EETP	SSWT	EDGE	SWMS	ESWT
r		rh						r	rw	rw	rw	rwh	rw	rw	rwh

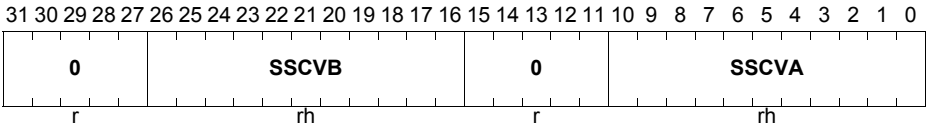
Field	Bits	Type	Description
ESWT	0	rwh	**Enable Stop Watch Trigger** If enabled an edge on input STPW or a service request 0 or 1 event (rising edge on signal INT0SR or INT1SR) activates the stop watch. In single-shot mode this bit is reset to 0 after the actual cycle counter and Macrotick value are stored in the Stop Watch register. 0_B Stop watch trigger disabled 1_B Stop watch trigger enabled
SWMS	1	rw	**Stop Watch Mode Select** It is not possible to change the Stop Watch Mode during enabled stop watch trigger (STPW1.ESWT) 0_B Single-shot mode 1_B Continuous mode
EDGE	2	rw	**Stop Watch Trigger Edge Select** 0_B Falling Edge 1_B Rising Edge

Field	Bits	Type	Description
SSWT	3	rwh	**Software Stop Watch Trigger** When the Host writes this bit to 1 the stop watch is activated. After the actual cycle counter and Macrotick value are stored in the Stop Watch register this bit is reset to 0. The bit is only writeable while ESWT = 0. 0_B Software trigger reset 1_B Stop watch activated by software trigger
EETP	4	rw	**Enable External Trigger Pin** Enables stop watch trigger event via signal STPW if ESWT = 1. 0_B Stop watch trigger via signal STPW disabled 1_B Edge on signal STPW triggers stop watch
EINT0	5	rw	**Enable Service Request 0 Trigger** Enables stop watch trigger by service request 0 event if ESWT = 1. 0_B Stop watch trigger by service request 0 disabled 1_B Service Request 0 event triggers stop watch
EINT1	6	rw	**Enable Service Request 1 Trigger** Enables stop watch trigger by service request 1 event if ESWT = 1. 0_B Stop watch trigger by service request 1 disabled 1_B Service Request 1 event triggers stop watch
SCCV	[13:8]	rh	**Stopped Cycle Counter Value** State of the cycle counter when the stop watch event occurred. Valid values are: $0…3F_H$ Valid Values
SMTV	[29:16]	rh	**Stopped Macrotick Value** State of the Macrotick counter when the stop watch event occurred. Valid values are: $0…3F_H$ Valid Values
0	7, [15:14], [31:30]	r	**Reserved** Returns 0 if read; should be written with 0.

Note: Bits ESWT and SSWT cannot be set to 1 simultaneously. In this case the write access is ignored, and both bits keep their previous values. Therefore either the external stop watch triggers or the software stop watch trigger may be used.

Stop Watch Register 2 (STPW2)

STPW2
Stop Watch Register 2 **(0050_H)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
SSCVA	[10:0]	rh	**Stop Watch Captured Slot Counter Value Channel A** State of the slot counter for channel A when the stop watch event occurred. Valid values are 0 to 2047 (0_H to $7FF_H$).
SSCVB	[26:16]	rh	**Stop Watch Captured Slot Counter Value Channel B** State of the slot counter for channel B when the stop watch event occurred. Valid values are 0 to 2047 (0_H to $7FF_H$).
0	[15:11], [31:27]	r	**Reserved** Returns 0 if read; should be written with 0.

26.5.2.4 Communication Controller Control Registers

This section describes the registers provided by the Communication Controller to allow the Host to control the operation of the Communication Controller. The FlexRay™ protocol specification requires the Host to write application configuration data in “CONFIG” state only. Please consider that the configuration registers are not locked for writing in “DEFAULT_CONFIG” state.

The configuration data is reset when “DEFAULT_CONFIG” state is entered from application reset. To change POC state from “DEFAULT_CONFIG” to “CONFIG” state the Host has to apply CHI command “CONFIG”. If the Host wants the Communication Controller to leave “CONFIG” state, the Host has to proceed as described on **“Lock Register (LCK)” on Page 26-39**.

SUC Configuration Register 1 (SUCC1)

SUCC1
SUC Configuration Register 1 (0080_H) Reset Value: $0C40\ 1080_H$

rw					r	rw	rw	rh	r			rwh			

Field	Bits	Type	Description
CMD	[3:0]	rwh	**CHI Command Vector** The host may write any CHI command at any time, but certain commands are only enabled in specific POC states. A disabled command will not be executed, the CHI command vector CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED”, and flag EIR.CNA in the Error Service Request register will be set to 1. In case the previous CHI command has not yet completed, EIR.CCL is set to 1 together with EIR.CNA; the CHI command needs to be repeated. Except for HALT state, POC state change command applied while the Communication Controller is already in the requested POC state will be ignored. 0000_B COMMAND_NOT_ACCEPTED” 0001_B CONFIG 0010_B READY 0011_B WAKEUP 0100_B RUN 0101_B ALL_SLOTS 0110_B HALT 0111_B FREEZE 1000_B SEND_MTS 1001_B ALLOW_COLDSTART 1010_B RESET_STATUS_INDICATORS 1011_B MONITOR_MODE 1100_B CLEAR_RAMS 1101_B Reserved 1110_B Reserved 1111_B Reserved Reading SUCC1.CMD shows whether the last CHI command was accepted. CCSV.POCS monitors the actual POC state. The reserved CHI commands code hardware test functions.
PBSY	7	rh	**POC Busy** Signals that the POC is busy and cannot accept a command from the Host. SUCC1.CMD is locked against write accesses. Set to 1 after hard reset during initialization of internal RAM blocks. 0_B POC not busy, SUCC1.CMD writable 1_B POC is busy, SUCC1.CMD locked

Field	Bits	Type	Description
TXST	8	rw	**Transmit Startup Frame in Key Slot**[1) 2)] (pKeySlotUsedForStartup) Defines whether the key slot is used to transmit startup Frames. The bit can be modified in “DEFAULT_CONFIG” or “CONFIG” state only. 0_B No Startup Frame transmission in key slot, node is non-coldstarter 1_B Key slot used to transmit startup Frame, node is leading or following coldstarter
TXSY	9	rw	**Transmit SYNC Frame in Key Slot**[1) 2)] (pKeySlotUsedForSync) Defines whether the key slot is used to transmit SYNC Frames. The bit can be modified in “DEFAULT_CONFIG” or “CONFIG” state only. 0_B No SYNC Frame transmission in key slot, node is neither sync nor coldstart node 1_B Key slot used to transmit SYNC Frames, node is sync node
CSA	[15:11]	rw	**Cold Start Attempts**[1)](gColdStartAttempts) Configures the maximum number of attempts that a cold starting node is permitted to try to start up the network without receiving any valid response from another node. It can be modified in “DEFAULT_CONFIG” or “CONFIG” state only. Must be identical in all nodes of a cluster. Valid values are 2 to 31.
PTA	[20:16]	rw	**Passive to Active**[1)] (pAllowPassiveToActive) Defines the number of consecutive even / odd cycle pairs that must have valid clock correction terms before the Communication Controller is allowed to transit from “NORMAL_PASSIVE” to “NORMAL_ACTIVE” state. If set to 00000_B the Communication Controller is not allowed to transit from “NORMAL_PASSIVE” to “NORMAL_ACTIVE” state. It can be modified in “DEFAULT_CONFIG” or “CONFIG” state only. Valid values are 0 to 31 even / odd cycle pairs.

Field	Bits	Type	Description
WUCS	21	rw	**Wakeup Channel Select**[1] (pWakeupChannel) With this bit the Host selects the channel on which the Communication Controller sends the Wakeup pattern. The Communication Controller ignores any attempt to change the status of this bit when not in “DEFAULT_CONFIG” or “CONFIG” state. 0_B Send wakeup pattern on channel A 1_B Send wakeup pattern on channel B
TSM	22	rw	**Transmission Slot Mode**[1] (pSingleSlotEnabled) Selects the initial transmission slot mode. In SINGLE slot mode the Communication Controller may only transmit in the preconfigured key slot. The key slot ID is configured in the Header Section of Message Buffer 0 respectively Message Buffers 0 and 1 depending on bit MRC.SPLM. In case SUCC1.TSM = 1, Message Buffer 0 respectively Message Buffers 0,1 can be (re)configured in “DEFAULT_CONFIG” or “CONFIG” state only. In ALL slot mode the Communication Controller may transmit in all slots. The bit can be written in “DEFAULT_CONFIG” or “CONFIG” state only. The communication controller changes to ALL slot mode when the Host successfully applied the ALL_SLOTS command by writing SUCC1.CMD = 0101_B in POC states “NORMAL_ACTIVE” or “NORMAL_PASSIVE”. The actual slot mode is monitored by CCSV.SLM. 0_B ALL Slot Mode 1_B SINGLE Slot Mode (default after application reset)
HCSE	23	rw	**Halt due to Clock Sync Error**[1] (pAllowHaltDueToClock) Controls the transition to “HALT” state due to a clock synchronization error. The bit can be modified in “DEFAULT_CONFIG” or “CONFIG” state only. 0_B Communication Controller will enter / remain in “NORMAL_PASSIVE” 1_B Communication Controller will enter “HALT” state
MTSA	24	rw	**Select Channel A for MTS Transmission**[1] [3] The bit selects channel A for MTS symbol transmission. The flag is reset by default and may be modified only in “DEFAULT_CONFIG” or “CONFIG” state. 0_B Channel A disabled for MTS transmission 1_B Channel A selected for MTS transmission

Field	Bits	Type	Description
MTSB	25	rw	**Select Channel B for MTS Transmission**[1) 3)] The bit selects channel B for MTS symbol transmission. The flag is reset by default and may be modified only in "DEFAULT_CONFIG" or "CONFIG" state. 0_B Channel B disabled for MTS transmission 1_B Channel B selected for MTS transmission
CCHA	26	rw	**Connected to Channel A**[1)] (pChannels) Configures whether the node is connected to channel A. 0_B Not connected to channel A 1_B Node connected to channel A (default after application reset)
CCHB	27	rw	**Connected to Channel B**[1)] (pChannels) Configures whether the node is connected to channel B. 0_B Not connected to channel B 1_B Node connected to channel B (default after application reset)
0	[6:4], 10, [31:28]	r	**Reserved** Returns 0 if read; should be written with 0.

1) This bit can be updated in "DEFAULT_CONFIG" or "CONFIG" state only!

2) The protocol requires that both bits TXST and TXSY are set for coldstart nodes.

3) MTSA and MTSB may also be changed outside "DEFAULT_CONFIG" or "CONFIG" state when the write to SUCC1 register is directly preceded by the unlock sequence as described in Lock Register (LCK). This may be combined with CHI command "SEND_MTS". If both bits MTSA and MTSB are set to 1 an MTS symbol will be transmitted on both channels when requested by writing SUCC1.CMD = 1000_B.

COMMAND_NOT_ACCEPTED

SUCC1.CMD is reset to 0000_B due to one of the following conditions:

- Illegal command applied by the Host
- Host writes command_not_accepted
- Host applied new command while execution of the previous Host command has not completed

When SUCC1.CMD is reset to 0000_B, bit EIR.CNA in the Error Service Request register is set, and - if enabled - an service request is generated. Commands which are not accepted are not executed.

CONFIG

Go to POC state "CONFIG" when called in POC states "DEFAULT_CONFIG", "READY", or in "MONITOR_MODE". When called in "HALT" state transits to POC state

"DEFAULT_CONFIG". When called in any other state, SUCC1.CMD will be reset to 0000_B = "COMMAND_NOT_ACCEPTED".

READY

Go to POC state "READY" when called in POC states "CONFIG", "NORMAL_ACTIVE", "NORMAL_PASSIVE", "STARTUP", or "WAKEUP". When called in any other state, SUCC1.CMD will be reset to 0000_B = "COMMAND_NOT_ACCEPTED".

WAKEUP

Go to POC state WAKEUP when called in POC state "READY". When called in any other state, SUCC1.CMD will be reset to 0000_B = "COMMAND_NOT_ACCEPTED".

RUN

Go to POC state "STARTUP" when called in POC state "READY". When called in any other state, SUCC1.CMD will be reset to 0000_B = "COMMAND_NOT_ACCEPTED".

ALL_SLOTS

Leave SINGLE slot mode after successful startup / integration at the next end of cycle when called in POC states "NORMAL_ACTIVE" or "NORMAL_PASSIVE". When called in any other state, SUCC1.CMD will be reset to
0000_B = "COMMAND_NOT_ACCEPTED".

HALT

Set the halt request CCSV.HRQ bit in the Communication Controller Status Vector register and go to POC state "HALT" at the next end of cycle when called in POC states "NORMAL_ACTIVE" or "NORMAL_PASSIVE". When called in any other state, SUCC1.CMD will be reset to 0000_B = "COMMAND_NOT_ACCEPTED".

FREEZE

Set the freeze status indicator CCSV.FSI and go to POC state "HALT" immediately. Can be called from any state.

SEND_MTS

Send single MTS symbol during the next following symbol window on the channel configured by SUCC1.MTSA, SUCC1.MTSB, when called in POC state "NORMAL_ACTIVE". When called in any other state, SUCC1.CMD will be reset to 0000_B = "COMMAND_NOT_ACCEPTED".

ALLOW_COLDSTART

The command resets bit CCSV.CSI to enable the node to become cold starter. When called in states “DEFAULT_CONFIG“, “CONFIG”, “HALT”, or “MONITOR_MODE“. SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED”. To become leading coldstarter it is also required that both TXST and TXSY are set.

RESET_STATUS_INDICATORS

Resets status flags CCSV.CSNI, CCSV.CSAI, CCSV.WSV to their default values. May be called in POC state READY. When called in any other state, SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED”.

MONITOR_MODE

Enter MONITOR_MODE when called in POC state CONFIG. In this mode the Communication Controller is able to receive FlexRay™ Frames and wakeup pattern. It is also able to detect coding errors. The temporal integrity of received Frames is not checked. This mode can be used for debugging purposes, e.g. in case that the startup of a FlexRay™ network fails. When called in any other state, SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED”. For details see **“MONITOR_MODE” on Page 26-208**.

CLEAR_RAMS

Sets bit MHDS.CRAM in the Message Handler Status register when called in “DEFAULT_CONFIG” or “CONFIG” state. When called in any other state, SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED”. MHDS.CRAM is also set when the Communication Controller leaves application reset. By setting MHDS.CRAM all internal RAM blocks are initialized to zero. Note that only the currently active IBF bank is cleared. To clear the 2nd bank as well, CUST1.IBF1PAG and CUST1.IBF2PAG need to be set and command CLEAR_RAMS need to be issued again. This is required in particular after an application reset. If the 2nd bank of IBF is left unused, this procedure is not required. During the initialization of the RAMs, SUCC1.PBSY will show POC busy. Access to the configuration and status registers is possible during execution of CHI command CLEAR_RAMS.

The initialization of the E-Ray internal RAM blocks requires 2048 f_{CLC_ERAY} cycles. There should be no Host access to IBF or OBF during initialization of the internal RAM blocks after application reset or after assertion of CHI command CLEAR_RAMS. Before asserting CHI command CLEAR_RAMS the Host should make sure that no transfer between Message RAM and IBF / OBF or the Transient Buffer RAMs is ongoing. This command also resets the Message Buffer Status registers MHDS, LDTS, FSR, MHDF, TXRQ1, TXRQ2, TXRQ3, TXRQ4, NDAT1, NDAT2, NDAT3, NDAT4, MBSC1, MBSC2, MBSC3, and MBSC4.

Note: All accepted commands with exception of CLEAR_RAMS and SEND_MTS will cause a change of register CCSV after at most 8 cycles of the slower of the two clocks f_{CLC_ERAY} and f_{SCLK}, assumed that POC was not busy when the command was applied and that no POC state change was forced by bus activity in that time Frame. Reading register CCSV will show data that is delayed by synchronization from f_{SCLK} to f_{CLC_ERAY} domain and by the Host-specific CPU interface.

Table 26-4 below references the CHI commands from the FlexRay™ Protocol Specification v2.1 (section 2.2.1.1, Table 2-2) to the E-Ray CHI command vector CMD.]

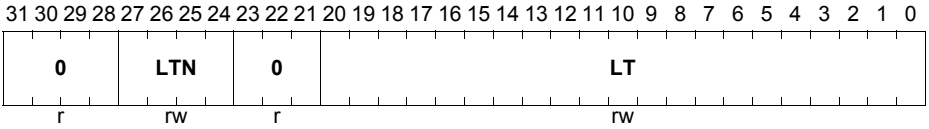
Table 26-4 Reference to CHI Host command summary from FlexRay™ protocol specification

CHI Command	Where processed (POC State)	CHI Command Vector CMD
ALL_SLOT	POC:NORMAL_ACTIVE, POC:NORMAL_PASSIVE	ALL_SLOTS
ALLOW_COLDSTART	All except POC:DEFAULT_CONFIG, POC:CONFIG, POC:HALT	ALLOW_COLDSTART
CONFIG	POC:DEFAULT_CONFIG, POC:READY	CONFIG
CONFIG_COMPLETE	POC:CONFIG	Unlock sequence & READY
DEFAULT_CONFIG	POC:HALT	CONFIG
FREEZE	All	FREEZE
HALT	POC:NORMAL_ACTIVE, POC:NORMAL_PASSIVE	HALT
READY	All except POC:DEFAULT_CONFIG, POC:CONFIG, POC:READY, POC:HALT	READY
RUN	POC:READY	RUN
WAKEUP	POC:READY	WAKEUP

SUC Configuration Register 2 (SUCC2)

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

SUCC2
SUC Configuration Register 2 (0084_H) Reset Value: 0100 0504_H



Field	Bits	Type	Description
LT	[20:0]	rw	**Listen Timeout**[1] (pdListenTimeout) Configures wakeup / startup listen timeout in Microticks. The range for wakeup / startup listen timeout (pdListenTimeout) is 1284 to 1283846 (504_H to 139706_H) Microticks
LTN	[27:24]	rw	**Listen Time-out Noise**[1] (gListenNoise - 1) Configures the upper limit for startup and wakeup listen timeout in the presence of noise expressed as a multiple of the cluster constant pdListenTimeout. The range of pdListenTimeout 2 to 16. LTN must be configured identical in all nodes of a cluster. 1_H Listen Time-out Noise is equal 2 2_H Listen Time-out Noise is equal 3 $\cdots_H$ ... F_H Listen Time-out Noise is equal 16
0	[23:21], [31:28]	r	**Reserved** Returns 0 if read; should be written with 0.

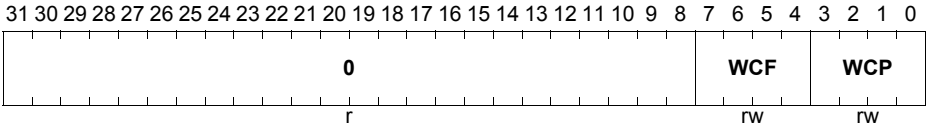
1) This bit can be updated in “DEFAULT_CONFIG” or “CONFIG” state only!

Note: The wakeup / startup noise time-out is calculated as follows:
The wakeup / startup noise time-out = pdListenTimeout • gListenNoise
= LT • (LTN+ 1)

SUC Configuration Register 3 (SUCC3)

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

SUCC3
SUC Configuration Register 3 (0088_H) Reset Value: $0000\ 0011_H$



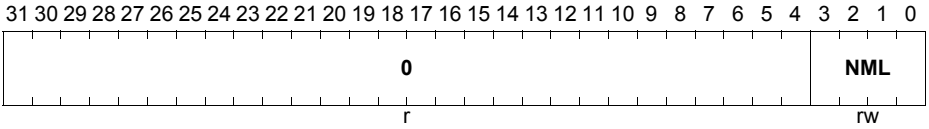
Field	Bits	Type	Description
WCP	[3:0]	rw	**Maximum Without Clock Correction Passive**[1)] (gMaxWithoutClockCorrectionPassive) Defines the number of consecutive even / odd cycle pairs with missing clock correction terms that will cause a transition from “NORMAL_ACTIVE” to “NORMAL_PASSIVE” state. Must be identical in all nodes of a cluster. Valid values are 1 to 15 (1_H to F_H) cycle pairs.
WCF	[7:4]	rw	**Maximum Without Clock Correction Fatal**[1)] (gMaxWithoutClockCorrectionFatal) Defines the number of consecutive even / odd cycle pairs with missing clock correction terms that will cause a transition from “NORMAL_ACTIVE” or “NORMAL_PASSIVE” to “HALT” state. Must be identical in all nodes of a cluster. Valid values are 1 to 15 (1_H to F_H)cycle pairs.
0	[31:8]	r	**Reserved** Returns 0 if read; should be written with 0.

1) This bit can be updated in “DEFAULT_CONFIG” or “CONFIG” state only!

NEM Configuration Register (NEMC)

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

NEMC
NEM Configuration Register (008C$_H$) Reset Value: 0000 0000$_H$



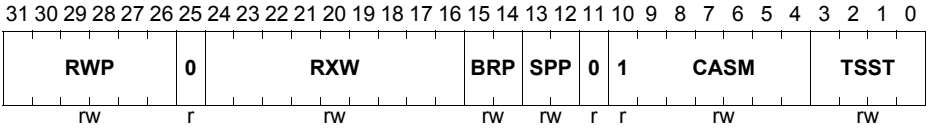
Field	Bits	Type	Description
NML	[3:0]	rw	**Network Management Vector Length**[1)] (gNetworkManagementVectorLength) These bits configure the length of the NM Vector. The configured length must be identical in all nodes of a cluster. Valid values are 0 to 12 (0_H to C_H) bytes.
0	[31:4]	r	**Reserved** Returns 0 if read; should be written with 0.

1) This bit can be updated in “DEFAULT_CONFIG” or “CONFIG” state only!

PRT Configuration Register 1 (PRTC1)

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

PRTC1
PRT Configuration Register 1 (0090_H) Reset Value: $084C\ 0633_H$



Field	Bits	Type	Description
TSST	[3:0]	rw	**Transmission Start Sequence Transmitter**[1)] (gdTSSTransmitter) Configures the duration of the Transmission Start Sequence (TSS) in terms of Bit Times (1 bit time = 4 Microticks = 100ns at 10Mbps). Must be identical in all nodes of a cluster. Valid values are 3 to 15 (3_H to F_H) Bit Times.
CASM	[10:4]	rw	**Collision Avoidance Symbol Maximum**[1)] (gdCASRxLowMax) Configures the upper limit of the acceptance window for a collision avoidance symbol (CAS). Valid values are 67 to 99 (43_H to 63_H). Most significant bit of CASM is hard wired to 1 and can not be modified.
SPP	[13:12]	rw	**Strobe Point Position**[1)] Defines the sample count value for strobing. The strobed bit value is set to the voted value when the sample count is incremented to the value configured by SPP. 00_B Sample 5 (default) 01_B Sample 4 10_B Sample 6 11_B Reserved; should not be used. *Note: The current revision 2.1 of the FlexRay™ protocol requires that SPP = 00_B. The alternate strobe point positions could be used to compensate for asymmetries in the physical layer.*

Field	Bits	Type	Description
BRP	[15:14]	rw	**Baud Rate Prescaler**[1] (gdSampleClockPeriod, pSamplePerMicrotick) The baud rate prescaler configures the baud rate on the FlexRay™ bus. The baud rates listed below are valid with a sample clock f_{SCLK}= 80 MHz. One bit time always consists of 8 samples independent of the configured baud rate. 00_B 10 Mbit/s (1 Microtick= 25 ns; twice sampled with f_{SCLK}) gdSampleClockPeriod = 12.5 ns = 1 / f_{SCLK} pSamplesPerMicrotick = 2 01_B 5 Mbit/s (1 Microtick= 25ns; single sampled with f_{SCLK} / 2) gdSampleClockPeriod = 25 ns = 2 / f_{SCLK} pSamplesPerMicrotick = 1 10_B 2.5 Mbit/s (1 Microtick = 50ns; single sampled with f_{SCLK} / 4) gdSampleClockPeriod = 50 ns = 4 / f_{SCLK} pSamplesPerMicrotick = 1 11_B Reserved; should not be used (2.5 Mbit/s (1 Microtick = 50 ns; single sampled with f_{SCLK} / 4) gdSampleClockPeriod = 50 ns = 4 / f_{SCLK} pSamplesPerMicrotick = 1
RXW	[24:16]	rw	**Wakeup Symbol Receive Window Length**[1] (gdWakeupSymbolRxWindow**)** Configures the number of Bit Times used by the node to test the duration of the received wakeup pattern. Must be identical in all nodes of a cluster. Valid values are 76 to 301 ($4C_H$ to $12D_H$) Bit Times.
RWP	[31:26]	rw	**Repetitions of Tx Wakeup Pattern**[1] (pWakeupPattern) Configures the number of repetitions (sequences) of the Tx wakeup symbol. Valid values are 2 to 63 (2_H to $3F_H$).
0	11, 25	r	**Reserved** Returns 0 if read; should be written with 0.

1) This bit can be updated in “DEFAULT_CONFIG” or “CONFIG” state only!

PRT Configuration Register 2 (PRTC2)

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

PRTC2
PRT Configuration Register 2 (0094_H) Reset Value: $0F2D\ 0A0E_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0				TXL							TXI					0				RXL						0				RXI		
r				rw							rw					r				rw						r				rw		

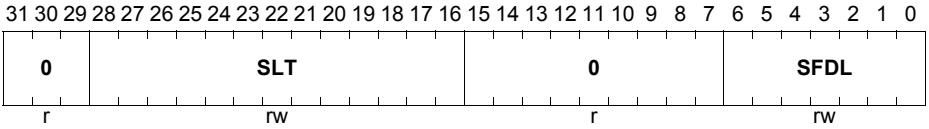
Field	Bits	Type	Description
RXI	[5:0]	rw	**Wakeup Symbol Receive Idle**[1)] (gdWakeupSymbolRxIdle) Configures the number of Bit Times used by the node to test the duration of the idle phase of the received wakeup symbol. Must be identical in all nodes of a cluster. Valid values are 14 to 59 (E_H to $3B_H$) Bit Times.
RXL	[13:8]	rw	**Wakeup Symbol Receive Low**[1)] (gdWakeupSymbolRxLow) Configures the number of Bit Times used by the node to test the duration of the low phase of the received wakeup symbol. Must be identical in all nodes of a cluster. Valid values are 10 to 55 (A_H to 37_H) Bit Times.
TXI	[23:16]	rw	**Wakeup Symbol Transmit Idle**[1)] (gdWakeupSymbolTxIdle) Configures the number of Bit Times used by the node to transmit the idle phase of the wakeup symbol. Must be identical in all nodes of a cluster. Valid values are 45 to 180 ($2D_H$ to $B4_H$)Bit Times.
TXL	[29:24]	rw	**Wakeup Symbol Transmit Low**[1)] (gdWakeupSymbolTxLow) Configures the number of Bit Times used by the node to transmit the low phase of the wakeup symbol. Must be identical in all nodes of a cluster. Valid values are 15 to 60 (F_H to $3C_H$) Bit Times.
0	[7:6], [15:14], [31:30]	r	**Reserved** Returns 0 if read; should be written with 0.

1) This bit can be updated in “DEFAULT_CONFIG” or “CONFIG” state only!

MHD Configuration Register (MHDC)

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

MHDC
MHD Configuration Register **(0098_H)** **Reset Value: $0000\ 0000_H$**



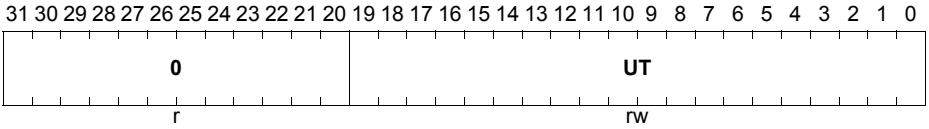
Field	Bits	Type	Description
SFDL	[6:0]	rw	**Static Frame Data Length** (gPayloadLengthStatic)[1)] Configures the cluster-wide payload length for all Frames sent in the static segment in double byte. The payload length must be identical in all nodes of a cluster. Valid values are 0 to 127 (0 to $7F_H$).
SLT	[28:16]	rw	**Start of Latest Transmit** (pLatestTx)[1)] Configures the maximum minislot value allowed before inhibiting Frame transmission in the dynamic segment of the cycle. There is no transmission dynamic segment if SLT is reset to zero. Valid values are 0 to 7981 (0 to $1F2D_H$) minislots.
0	[15:7], [31:29]	r	**Reserved** Returns 0 if read; should be written with 0.

1) This bit can be updated in “DEFAULT_CONFIG” or “CONFIG” state only!

GTU Configuration Register 1 (GTUC01)

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

GTUC01
GTU Configuration Register 1 ($00A0_H$) Reset Value: $0000\ 0280_H$



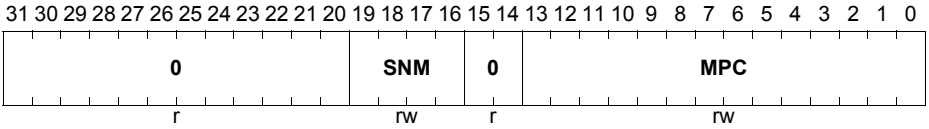
Field	Bits	Type	Description
UT	[19:0]	rw	**Microtick per Cycle** (pMicroPerCycle)[1)] Configures the duration of the communication cycle in Microticks. Valid values are 640 to 640000 (280_H to $9C400_H$) Microticks.
0	[31:20]	r	**Reserved** Returns 0 if read; should be written with 0.

1) This bit can be updated in “DEFAULT_CONFIG” or “CONFIG” state only!

GTU Configuration Register 2 (GTUC02)

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

GTUC02
GTU Configuration Register 2 ($00A4_H$) Reset Value: $0002\ 000A_H$



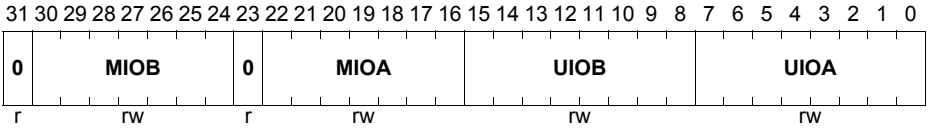
Field	Bits	Type	Description
MPC	[13:0]	rw	**Macrotick Per Cycle** (gMacroPerCycle)[1)] Configures the duration of one communication cycle in Macroticks. The cycle length must be identical in all nodes of a cluster. Valid values are 10 to 16000 (A_H to $3E80_H$) Macroticks.
SNM	[19:16]	rw	**Sync Node Max** (gSyncNodeMax)[1)] Maximum number of Frames within a cluster with SYNC Frame indicator bit SYN set to 1. Must be identical in all nodes of a cluster. Valid values are 2 to 15 (2_H to F_H).
0	[15:14], [31:20]	r	**Reserved** Returns 0 if read; should be written with 0.

1) This bit can be updated in “DEFAULT_CONFIG” or “CONFIG” state only!

GTU Configuration Register 3 (GTUC03)

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

GTUC03
GTU Configuration Register 3 (00A8$_H$) Reset Value: 0202 0000$_H$



Field	Bits	Type	Description
UIOA	[7:0]	rw	**Microtick Initial Offset Channel A**[1)] (pMicroInitialOffset[A]) Configures the number of Microticks between the actual time reference point on channel A and the subsequent Macrotick boundary of the secondary time reference point. The parameter depends on pDelayCompensation[A] and therefore has to be set for each channel independently. Valid values are 0 to 240 (0_H to $F0_H$) Microticks.
UIOB	[15:8]	rw	**Microtick Initial Offset Channel B**[1)] (pMicroInitialOffset[B]) Configures the number of Microticks between the actual time reference point on channel B and the subsequent Macrotick boundary of the secondary time reference point. The parameter depends on pDelayCompensation[B] and therefore has to be set for each channel independently. Valid values are 0 to 240 (0_H to $F0_H$) Microticks.
MIOA	[22:16]	rw	**Macrotick Initial Offset Channel A** (gMacroInitialOffset[A])[1)] Configures the number of Macroticks between the static slot boundary and the subsequent Macrotick boundary of the secondary time reference point based on the nominal Macrotick duration. Must be identical in all nodes of a cluster. Valid values are 2 to 72 (2_H to 48_H) Macroticks.
MIOB	[30:24]	rw	**Macrotick Initial Offset Channel B** (gMacroInitialOffset[B])[1)] Configures the number of Macroticks between the static slot boundary and the subsequent Macrotick boundary of the secondary time reference point based on the nominal Macrotick duration. Must be identical in all nodes of a cluster. Valid values are 2 to 72 (2_H to 48_H) Macroticks.

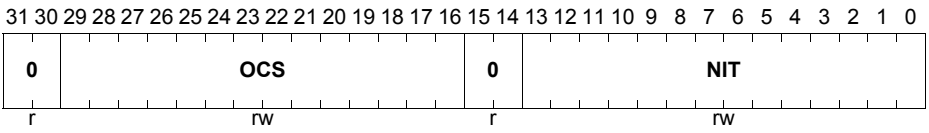
Field	Bits	Type	Description
0	23, 31	r	**Reserved** Returns 0 if read; should be written with 0.

1) This bit can be updated in “DEFAULT_CONFIG” or “CONFIG” state only!

GTU Configuration Register 4 (GTUC04)

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only. For details about configuration of NIT and OCS see **“Configuration of Network Idle Time (NIT) Start and Offset Correction Start” on Page 26-197**.

GTUC04
GTU Configuration Register 4 (00AC$_H$) Reset Value: 0008 0007$_H$



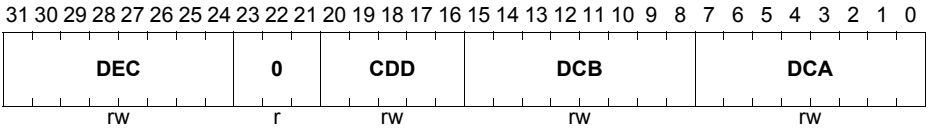
Field	Bits	Type	Description
NIT	[13:0]	rw	**Network Idle Time Start** [1] (gMacroPerCycle - gdNIT - 1) Configures the starting point of the Network Idle Time (NIT) at the end of the communication cycle expressed in terms of Macroticks from the beginning of the cycle. The start of network idle time (NIT) is recognized if Macrotick = gMacroPerCycle - gdNIT -1 and the increment pulse of Macrotick is set. Must be identical in all nodes of a cluster. Valid values are 7 to 15997 (7_H to $3E7D_H$) Macroticks.
OCS	[29:16]	rw	**Offset Correction Start**[1] (gOffsetCorrectionStart - 1) Determines the start of the offset correction within the network idle time (NIT) phase, calculated from start of cycle. Must be identical in all nodes of a cluster. For cluster consisting of E-Ray implementations only, it is sufficient to program OCS = NIT + 1. Valid values are 8 to 15998 (8_H to $3E7E_H$) Macroticks.
0	[15:14], [31:30]	r	**Reserved** Returns 0 if read; should be written with 0.

1) This bit can be updated in “DEFAULT_CONFIG” or “CONFIG” state only!

GTU Configuration Register 5 (GTUC05)

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

GTUC05
GTU Configuration Register 5 ($00B0_H$) **Reset Value: $0E00\ 0000_H$**



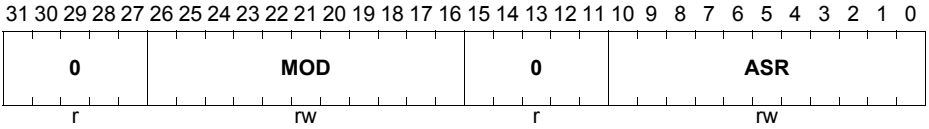
Field	Bits	Type	Description
DCA	[7:0]	rw	**Delay Compensation Channel A**[1] (pDelayCompensation[A]) Used to compensate for reception delays on channel A. This covers assumed propagation delay up to cPropagationDelayMax for Microticks in the range of 0.0125µs to 0.05µs. In practice, the minimum of the propagation delays of all sync nodes should be applied. Valid values are 0 to 200 (0_H to $C8_H$) Microticks.
DCB	[15:8]	rw	**Delay Compensation Channel B**[1] (pDelayCompensation[B]) Used to compensate for reception delays on channel B. This covers assumed propagation delay up to cPropagationDelayMax for Microticks in the range of 0.0125 to 0.05µs. In practice, the minimum of the propagation delays of all sync nodes should be applied. Valid values are 0 to 200 (0_H to $C8_H$) Microticks.
CDD	[20:16]	rw	**Cluster Drift Damping** (pClusterDriftDamping)[1] Configures the cluster drift damping value used in clock synchronization to minimize accumulation of rounding errors. Valid values are 0 to 20 (0_H to 14_H) Microticks.
DEC	[31:24]	rw	**Decoding Correction** (pDecodingCorrection)[1] Configures the decoding correction value used to determine the primary time reference point. Valid values are 14 to 143 (E_H to $8F_H$) Microticks.
0	[23:21]	r	**Reserved** Returns 0 if read; should be written with 0.

1) This bit can be updated in “DEFAULT_CONFIG” or “CONFIG” state only!

GTU Configuration Register 6 (GTUC06)

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

GTUC06
GTU Configuration Register 6 (00B4$_H$) Reset Value: 0002 0000$_H$



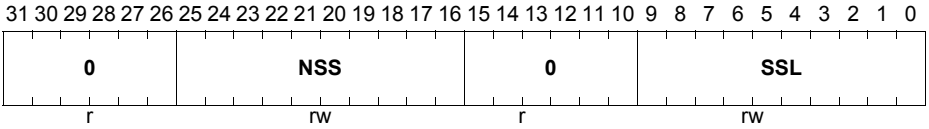
Field	Bits	Type	Description
ASR	[10:0]	rw	**Accepted Startup Range**[1] (pdAcceptedStartupRange) Number of Microticks constituting the expanded range of measured deviation for startup Frames during integration. Valid values are 0 to 1875 (0_H to 753_H) Microticks.
MOD	[26:16]	rw	**Maximum Oscillator Drift** (pdMaxDrift)[1] Maximum drift offset between two nodes that operate with unsynchronized clocks over one communication cycle in Microticks. Valid values are 2 to 1923 (2_H to 783_H) Microticks.
0	[15:11], [31:27]	r	**Reserved** Returns 0 if read; should be written with 0.

1) This bit can be updated in “DEFAULT_CONFIG” or “CONFIG” state only!

GTU Configuration Register 7 (GTUC07)

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

GTUC07
GTU Configuration Register 7 (00B8$_H$) Reset Value: 0002 0004$_H$



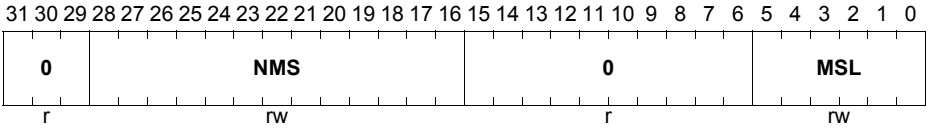
Field	Bits	Type	Description
SSL	[9:0]	rw	**Static Slot Length** (gdStaticSlot)[1)] Configures the duration of a static slot in Macroticks. The static slot length must be identical in all nodes of a cluster. Valid values are 4 to 659 (4_H to 293_H) Macroticks.
NSS	[25:16]	rw	**Number of Static Slots** (gNumberOfStaticSlots)[1)] Configures the number of static slots in a cycle. At least 2 coldstart nodes must be configured to startup a FlexRay™ network. The number of static slots must be identical in all nodes of a cluster. Valid values are 2 to 1023 (2_H to $3FF_H$).
0	[15:10], [31:26]	r	**Reserved** Returns 0 if read; should be written with 0.

1) This bit can be updated in “DEFAULT_CONFIG” or “CONFIG” state only!

GTU Configuration Register 8 (GTUC08)

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

GTUC08
GTU Configuration Register 8 (00BC$_H$) Reset Value: 0000 0002$_H$



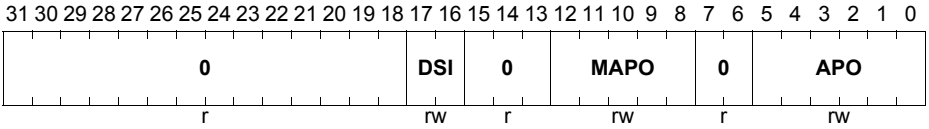
Field	Bits	Type	Description
MSL	[5:0]	rw	**Minislot Length** (gdMinislot)[1)] Configures the duration of a minislot in Macroticks. The minislot length must be identical in all nodes of a cluster. Valid values are 2 to 63 (2_H to $3F_H$) Macroticks.
NMS	[28:16]	rw	**Number of Minislots** (gNumberOfMinislots)[1)] Configures the number of minislots within the dynamic segment of a cycle. The number of minislots must be identical in all nodes of a cluster. Valid values are 0 to 7986 (0_H to $1F32_H$).
0	[15:6], [31:29]	r	**Reserved** Returns 0 if read; should be written with 0.

1) This bit can be updated in “DEFAULT_CONFIG” or “CONFIG” state only!

GTU Configuration Register 9 (GTUC09)

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

GTUC09
GTU Configuration Register 9 ($00C0_H$) Reset Value: $0000\ 0101_H$



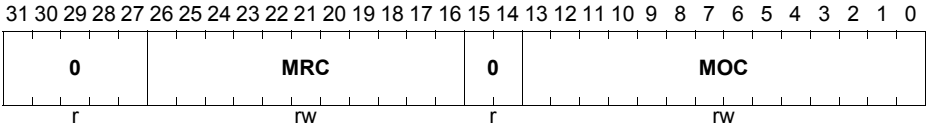
Field	Bits	Type	Description
APO	[5:0]	rw	**Action Point Offset** (gdActionPointOffset)[1)] Configures the action point offset in Macroticks within static slots and symbol window. Must be identical in all nodes of a cluster. Valid values are 1 to 63 (1_H to $3F_H$) Macroticks.
MAPO	[12:8]	rw	**Minislot Action Point Offset**[1)] (gdMinislotActionPointOffset) Configures the action point offset in Macroticks within the minislots of the dynamic segment. Must be identical in all nodes of a cluster. Valid values are 1 to 31 (1_H to $1F_H$) Macroticks.
DSI	[17:16]	rw	**Dynamic Slot Idle Phase**[1)] (gdDynamicSlotIdlePhase) The duration of the dynamic slot idle phase has to be greater or equal than the idle detection time. Must be identical in all nodes of a cluster. Valid values are 0 to 2 Minislot.
0	[7:6], [15:13], [31:18]	r	**Reserved** Returns 0 if read; should be written with 0.

1) This bit can be updated in “DEFAULT_CONFIG” or “CONFIG” state only!

GTU Configuration Register 10 (GTUC10)

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

GTUC10
GTU Configuration Register 10 (00C4$_H$) Reset Value: 0002 0005$_H$

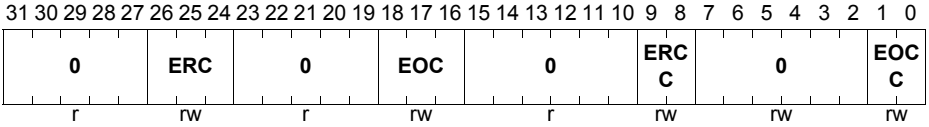


Field	Bits	Type	Description
MOC	[13:0]	rw	**Maximum Offset Correction**[1)] (pOffsetCorrectionOut) Holds the maximum permitted offset correction value to be applied by the internal clock synchronization algorithm (absolute value). The Communication Controller checks only the internal offset correction value against the maximum offset correction value. Valid values are 5 to 15266 (5_H to $3BA2_H$) Microticks.
MRC	[26:16]	rw	**Maximum Rate Correction**[1)] (pRateCorrectionOut) Holds the maximum permitted rate correction value to be applied by the internal clock synchronization algorithm. The communication controller checks only the internal rate correction value against the maximum rate correction value (absolute value). Valid values are 2 to 1923 (2_H to 783_H) Microticks.
0	[15:14], [31:27]	r	**Reserved** Returns 0 if read; should be written with 0.

1) This bit can be updated in “DEFAULT_CONFIG” or “CONFIG” state only!

GTU Configuration Register 11 (GTUC11)

GTUC11
GTU Configuration Register 11 ($00C8_H$) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
EOCC	[1:0]	rw	**External Offset Correction Control** (pExternOffsetControl) By writing to EOCC the external offset correction is enabled as specified below. Should be modified only outside network idle time (NIT). 00_B No external clock correction 01_B No external clock correction 10_B External offset correction value subtracted from calculated offset correction value 11_B External offset correction value added to calculated offset correction value
ERCC	[9:8]	rw	**External Rate Correction Control** (pExternRateControl) By writing to ERCC the external rate correction is enabled as specified below. Should be modified only outside network idle time (NIT). 00_B No external rate correction 01_B No external rate correction 10_B External rate correction value subtracted from calculated rate correction value 11_B External rate correction value added to calculated rate correction value
EOC	[18:16]	rw	**External Offset Correction**[1)] (pExternOffsetCorrection) Holds the external clock offset correction value in Microticks to be applied by the internal synchronization algorithm. The value is subtracted / added from / to the calculated offset correction value. The value is applied during network idle time (NIT). May be modified in “DEFAULT_CONFIG” or “CONFIG” state only. Valid values are 0 to 7 Microticks.

Field	Bits	Type	Description
ERC	[26:24]	rw	**External Rate Correction**[1] (pExternRateCorrection) Holds the external rate correction value in Microticks to be applied by the internal clock synchronization algorithm. The value is subtracted / added from / to the calculated rate correction value. The value is applied during network idle time (NIT). May be modified in “DEFAULT_CONFIG” or “CONFIG” state only. Valid values are 0 to 7 Microticks.
0	[7:2], [15:10], [23:19], [31:27]	r	**Reserved** Returns 0 if read; should be written with 0.

1) This bit can be updated in “DEFAULT_CONFIG” or “CONFIG” state only!

26.5.2.5 Communication Controller Status Registers

During 8/16-bit accesses to status variables coded with more than 8/16-bit, the variable might be updated by the Communication Controller between two accesses (non-atomic read accesses). The status vector may change faster than the Host can poll the status vector, depending on f_{CLC_ERAY} frequency.

Communication Controller Status Vector (CCSV)

CCSV

Communication Controller Status Vector(0100_H) **Reset Value: $0010\ 4000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0		PSL						RCA					WSV

0	CSI	CSAI	CSNI	0		SLM		HRQ	FSI	POCS					
r	rh	rh	rh	r		rh		rh	rh	rh					

Field	Bits	Type	Description
POCS	[5:0]	rh	**Protocol Operation Control Status** Indicates the actual state of operation of the Communication Controller Protocol Operation Control 000000_B “DEFAULT_CONFIG” state 000001_B “READY” state 000010_B “NORMAL_ACTIVE” state 000011_B “NORMAL_PASSIVE” state 000100_B “HALT” state 000101_B “MONITOR_MODE” state 000110_B … 001110_B are reserved. 001111_B “CONFIG” state Indicates the actual state of operation of the POC in the wakeup path 010000_B WAKEUP_STANDBY state 010001_B “WAKEUP_LISTEN” state 010010_B “WAKEUP_SEND” state 010011_B “WAKEUP_DETECT” state 010100_B … 011111_B are reserved. Indicates the actual state of operation of the POC in the startup path 100000_B “STARTUP_PREPARE” state 100001_B “COLDSTART_LISTEN” state 100010_B “COLDSTART_COLLISION_RESOLUTION state 100011_B “COLDSTART_CONSISTENCY_CHECK” state 100100_B “COLDSTART_GAP state 100101_B “COLDSTART_JOIN” State 100110_B “INTEGRATION_COLDSTART_CHECK” state 100111_B “INTEGRATION_LISTEN” state 101000_B “INTEGRATION_CONSISTENCY_CHECK” state 101001_B “INITIALIZE_SCHEDULE” state 101010_B “ABORT_STARTUP” state 101011_B “STARTUP_SUCCESS” state 101100_B … 111111_B are reserved.

Field	Bits	Type	Description
FSI	6	rh	**Freeze Status Indicator** (vPOC!Freeze**)** Indicates that the POC has entered the “HALT” state due to CHI command “FREEZE” or due to an error condition requiring an immediate POC halt. Reset by transition from “HALT” to “DEFAULT_CONFIG” state.
HRQ	7	rh	**Halt Request** (vPOC!CHIHaltRequest) Indicates that a request from the Host has been received to halt the POC at the end of the communication cycle. Reset by transition from “HALT” to “DEFAULT_CONFIG” state or when entering “READY” state.
SLM	[9:8]	rh	**Slot Mode** (vPOC!SlotMode) Indicates the actual slot mode of the POC in states READY, WAKEUP, STARTUP, NORMAL_ACTIVE, and NORMAL_PASSIVE. Default is “SINGLE”. Changes to “ALL”, depending on configuration bit SUCC1.TSM. In “NORMAL_ACTIVE” or “NORMAL_PASSIVE” state the CHI command “ALL_SLOTS” will change the slot mode from “SINGLE” over “ALL_PENDING” to “ALL”. Set to SINGLE in all other states. 00_B SINGLE 01_B Reserved 10_B ALL_PENDING 11_B ALL
CSNI	12	rh	**Coldstart Noise Indicator** (vPOC!ColdstartNoise) Indicates that the cold start procedure occurred under noisy conditions. Reset by CHI command “RESET_STATUS_INDICATORS” or by transition from “HALT” to “DEFAULT_CONFIG” state or from “READY” to “STARTUP” state.
CSAI	13	rh	**Coldstart Abort Indicator** Coldstart aborted. Reset by CHI command “RESET_STATUS_INDICATORS” or by transition from “HALT” to “DEFAULT_CONFIG” state or from “READY” to “STARTUP” state.

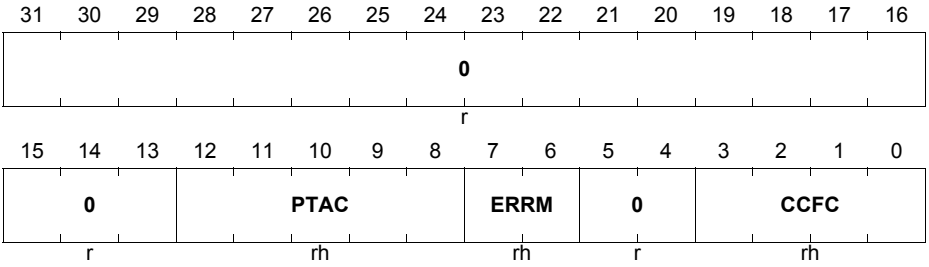
Field	Bits	Type	Description
CSI	14	rh	**Cold Start Inhibit** (vColdStartInhibit) Indicates that the node is disabled from cold starting. The flag is set whenever the POC enters “READY” state due to CHI command “READY”. The flag has to be reset under control of the Host by CHI command “ALLOW_COLDSTART” (SUCC1.CMD = 1001_B). 0_B Cold starting of node enabled 1_B Cold starting of node disabled
WSV	[18:16]	rh	**Wakeup Status** (vPOC!WakeupStatus) Indicates the status of the current wakeup attempt. Reset by CHI command “RESET_STATUS_INDICATORS” or by transition from “HALT” to “DEFAULT_CONFIG” state. 000_B UNDEFINED. Wakeup not yet executed by the Communication Controller. 001_B RECEIVED_HEADER. Set when the Communication Controller finishes wakeup due to the reception of a Frame Header without coding violation on either channel in “WAKEUP_LISTEN” state. 010_B RECEIVED_WUP. Set when the Communication Controller finishes wakeup due to the reception of a valid wakeup pattern on the configured wakeup channel in “WAKEUP_LISTEN” state. 011_B COLLISION_HEADER. Set when the Communication Controller stops wakeup due to a detected collision during wakeup pattern transmission by receiving a valid Header on either channel. 100_B COLLISION_WUP. Set when the Communication Controller stops wakeup due to a detected collision during wakeup pattern transmission by receiving a valid wakeup pattern on the configured wakeup channel. 101_B COLLISION_UNKNOWN. Set when the Communication Controller stops wakeup by leaving “WAKEUP_DETECT” state after expiration of the wakeup timer without receiving a valid wakeup pattern or a valid Frame Header. 110_B TRANSMITTED. Set when the Communication Controller has successfully completed the transmission of the wakeup pattern. 111_B Reserved

Field	Bits	Type	Description
RCA	[23:19]	rh	**Remaining Coldstart Attempts** (vRemainingColdstartAttempts) Indicates the number of remaining coldstart attempts. The RUN command resets this counter to the maximum number of coldstart attempts as configured by SUCC1.CSA.
PSL	[29:24]	rh	**POC Status Log** Status of CCSV.POCS immediately before entering “HALT” state. Set when entering “HALT” state. Set to “HALT” when FREEZE command is applied during “HALT” state. Reset to 000000_B when leaving “HALT” state.
0	[11:10], 15, [31:30]	rh	**Reserved** Returns 0 if read; should be written with 0.

Communication Controller Error Vector (CCEV)

Reset by transition from “HALT” to “DEFAULT_CONFIG” state or when entering “READY” state.

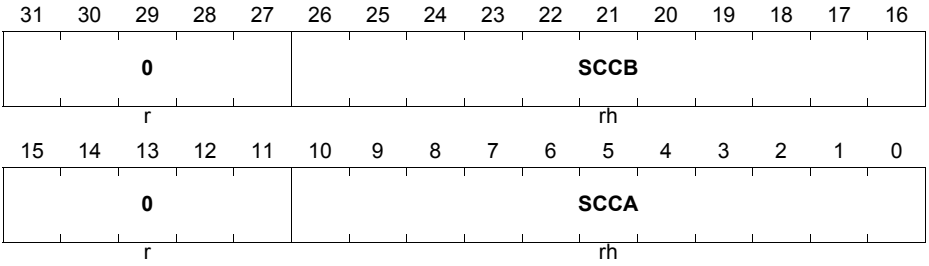
CCEV
Communication Controller Error Vector (0104_H) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
CCFC	[3:0]	rh	**Clock Correction Failed Counter** (vClockCorrectionFailed) The Clock Correction Failed Counter is incremented by one at the end of any odd communication cycle where either the missing offset correction error or missing rate correction error are active. The Clock Correction Failed Counter is reset to 0 at the end of an odd communication cycle if neither the offset correction failed nor the rate correction failed errors are active. The Clock Correction Failed Counter stops at 15.
ERRM	[7:6]	rh	**Error Mode** (vPOC!ErrorMode) Indicates the actual error mode of the POC. 00_B “ACTIVE” (green) 01_B “PASSIVE” (yellow) 10_B “COMM_HALT” (red) 11_B Reserved
PTAC	[12:8]	rh	**Passive to Active Count** (vAllowPassiveToActive) Indicates the number of consecutive even / odd cycle pairs that have passed with valid rate and offset correction terms, while the node is waiting to transit from “NORMAL_PASSIVE” state to “NORMAL_ACTIVE” state. The transition takes place when PTAC equals SUCC1.PTA.
0	[5:4], [31:13]	r	**Reserved** Returns 0 if read; should be written with 0.

Slot Counter Value (SCV)

SCV
Slot Counter Value **(0110_H)** **Reset Value: $0000\ 0000_H$**

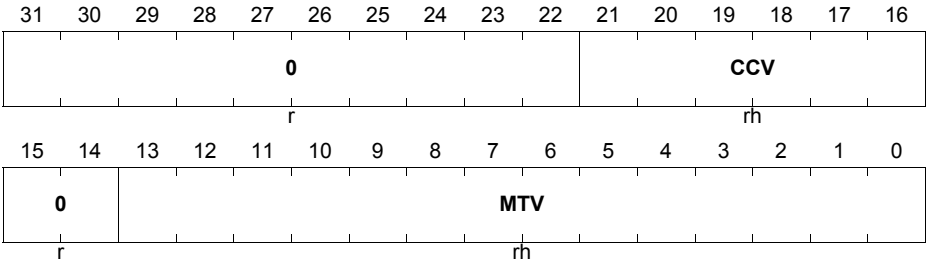


Field	Bits	Type	Description
SCCA	[10:0]	rh	**Slot Counter Channel A** (vSlotCounter[A]**)** Current slot counter value on channel A. The value is incremented by the Communication Controller and reset at the start of a communication cycle. Valid values are 0 to 2047 (0_H to $7FD_H$).
SCCB	[26:16]	rh	**Slot Counter Channel B** (vSlotCounter[B]**)** Current slot counter value on channel B. The value is incremented by the Communication Controller and reset at the start of a communication cycle. Valid values are 0 to 2047 (0_H to $7FD_H$).
0	[15:11], [31:27]	r	**Reserved** Returns 0 if read; should be written with 0.

Macrotick and Cycle Counter Value (MTCCV)

MTCCV

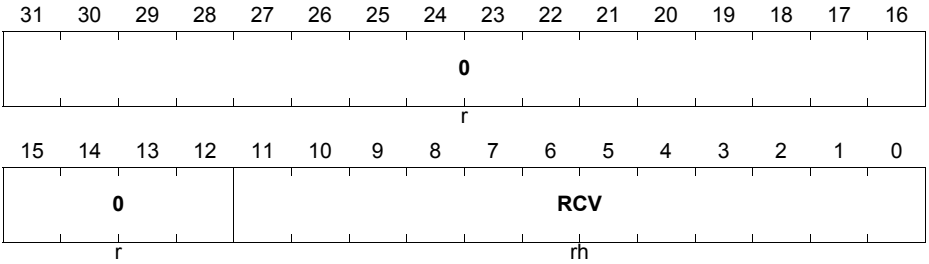
Macrotick and Cycle Counter Value (0114_H) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
MTV	[13:0]	rh	**Macrotick Value** (vMacrotick) Current Macrotick value. The value is incremented by the Communication Controller and reset at the start of a communication cycle. Valid values are 0 to 16000 (0_H to $3E80_H$).
CCV	[21:16]	rh	**Cycle Counter Value** (vCycleCounter) Current cycle counter value. The value is incremented by the Communication Controller at the start of a communication cycle. Valid values are 0 to 63 (0_H to $3F_H$).
0	[15:14], [31:22]	r	**Reserved** Returns 0 if read; should be written with 0.

Rate Correction Value (RCV)

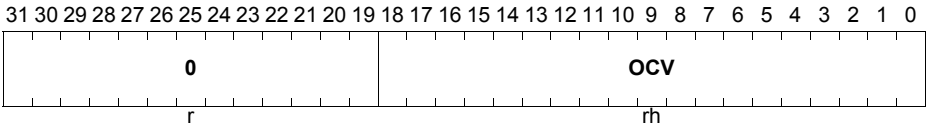
RCV
Rate Correction Value **(0118_H)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
RCV	[11:0]	rh	**Rate Correction Value** (vRateCorrection) Rate correction value (two's complement). Calculated internal rate correction value before limitation. If the RCV value exceeds the limits defined by GTUC10.MRC, flag SFS.RCLR is set to 1.
0	[31:12]	r	**Reserved** Returns 0 if read; should be written with 0.

Offset Correction Value (OCV)

OCV
Offset Correction Value **(011C$_H$)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
OCV	[18:0]	rh	**Offset Correction Value** (vOffsetCorrection) Offset correction value (two's complement). Calculated internal offset correction value before limitation. If the OCV value exceeds the limits defined by GTUC10.MOC flag SFS.OCLR is set to 1.
0	[31:19]	r	**Reserved** Returns 0 if read; should be written with 0.

Note: The external rate / offset correction value is added to the limited rate / offset correction value.

SYNC Frame Status (SFS)

The maximum number of valid SYNC Frames in a communication cycle is 15.

SFS

SYNC Frame Status **(0120_H)** **Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
VSBO				VSBE				VSAO				VSAE			
rh				rh				rh				rh			

Field	Bits	Type	Description
VSAE	[3:0]	rh	**Valid SYNC Frames Channel A, even communication cycle** Holds the number of valid SYNC Frames received on channel A in the even communication cycle. If transmission of SYNC Frames is enabled by SUCC1.TXSY the value is incremented by one. The value is updated during the network idle time (NIT) of each even communication cycle. This bit field is only valid if the channel A is assigned to the Communication Controller by SUCC1.CCHA.
VSAO	[7:4]	rh	**Valid SYNC Frames Channel A, odd communication cycle** Holds the number of valid SYNC Frames received on channel A in the odd communication cycle. If transmission of SYNC Frames is enabled by SUCC1.TXSY the value is incremented by one. The value is updated during the network idle time (NIT) of each odd communication cycle. This bit field is only valid if the channel A is assigned to the Communication Controller by SUCC1.CCHA.
VSBE	[11:8]	rh	**Valid SYNC Frames Channel B, even communication cycle** Holds the number of valid SYNC Frames received on channel B in the even communication cycle. If transmission of SYNC Frames is enabled by SUCC1.TXSY the value is incremented by one. The value is updated during the network idle time (NIT) of each even communication cycle. This bit field is only valid if the channel B is assigned to the Communication Controller by SUCC1.CCHB.

Field	Bits	Type	Description
VSBO	[15:12]	rh	**Valid SYNC Frames Channel B, odd communication cycle** Holds the number of valid SYNC Frames received on channel B in the odd communication cycle. If transmission of SYNC Frames is enabled by SUCC1.TXSY the value is incremented by one. The value is updated during the network idle time (NIT) of each odd communication cycle. This bit field is only valid if the channel B is assigned to the Communication Controller by SUCC1.CCHB.
MOCS	16	rh	**Missing Offset Correction Signal** The Missing Offset Correction flag signals to the Host, that no offset correction calculation can be performed because no SYNC Frames were received. The flag is updated by the Communication Controller at start of offset correction phase. 0_B Offset correction signal valid 1_B Missing offset correction signal
OCLR	17	rh	**Offset Correction Limit Reached** The Offset Correction Limit Reached flag signals to the Host, that the offset correction value has exceeded its limit as defined by GTUC10.MOC. The flag is updated by the Communication Controller at start of offset correction phase. 0_B Offset correction below limit 1_B Offset correction limit reached
MRCS	18	rh	**Missing Rate Correction Signal** The Missing Rate Correction Flag signals to the Host, that no rate correction calculation can be performed because no pairs of even / odd SYNC Frames were received. The flag is updated by the Communication Controller at start of offset correction phase. 0_B Rate correction signal valid 1_B Missing rate correction signal
RCLR	19	rh	**Rate Correction Limit Reached** The Rate Correction Limit Reached flag signals to the Host, that the rate correction value has exceeded its limit.as defined by GTUC10.MRC. The flag is updated by the Communication Controller at start of offset correction phase. 0_B Rate correction below limit 1_B Rate correction limit reached
0	[31:20]	r	**Reserved** Returns 0 if read; should be written with 0.

Symbol Window and network idle time (NIT) Status (SWNIT)

Symbol window related status information. Updated by the Communication Controller at the end of the symbol window for each channel. During startup the status data is not updated.

Note: MTSA and MTSB may be changed outside "DEFAULT_CONFIG" or "CONFIG" state when the write to SUC Configuration Register 1 (SUCC1) register is directly preceded by the unlock sequence as described in ***"Lock Register (LCK)" on Page 26-39****. This may be combined with CHI command SEND_MTS. If both bits MTSA and MTSB are set to 1 an MTS symbol will be transmitted on both channels when requested by writing SUCC1.CMD = 1000$_B$*

SWNIT
Symbol Window and Network Idle Time Status
(0124$_H$) **Reset Value: 0000 0000$_H$**

0	[31:12]	r	**Reserved** Returns 0 if read; should be written with 0.

1) MTSA and MTSB may also be changed outside “DEFAULT_CONFIG” or “CONFIG” state when the write to SUCC1 register is directly preceded by the unlock sequence as described in “Lock Register (LCK)”. This may be combined with CHI command SEND_MTS. If both bits MTSA and MTSB are set to 1 an MTS symbol will be transmitted on both channels when requested by writing SUCC1.CMD = 1000_B.

Aggregated Channel Status (ACS)

The aggregated channel status provides the Host with an accrued status of channel activity for all communication slots regardless of whether they are assigned for transmission or subscribed for reception. The aggregated channel status also includes status data from the symbol window and the network idle time. The status data is updated (set) after each slot and aggregated until it is reset by the Host. During startup the status data is not updated. A flag is cleared by writing a 1 to the corresponding bit position. Writing a 0 has no effect on the flag. An application reset will also clear the register.

ACS
Aggregated Channel Status **(0128_H)** **Reset Value: $0000\ 0000_H$**

SEDA	1	rwh	**Syntax Error Detected on Channel A** (vSS!SyntaxErrorA) One or more syntax errors in static or dynamic slots, symbol window, and network idle time (NIT) were observed on channel A. 0_B No syntax error observed 1_B Syntax error(s) observed on channel A
CEDA	2	rwh	**Content Error Detected on Channel A** (vSS!ContentErrorA) One or more Frames with a content error were received on channel A in any static or dynamic slot during the observation period. 0_B No Frame with content error received 1_B Frame(s) with content error received on channel A

Field	Bits	Type	Description
CIA	3	rwh	**Communication Indicator Channel A** One or more valid Frames were received on channel A in slots that also contained any additional communication during the observation period, i.e. one or more slots received a valid Frame AND had any combination of either syntax error OR content error OR slot boundary violation. 0_B No valid Frame(s) received in slots containing any additional communication 1_B Valid Frame(s) received on channel A in slots containing any additional communication
SBVA	4	rwh	**Slot Boundary Violation on Channel A** (vSS!BViolationA) One or more slot boundary violations were observed on channel A at any time during the observation period (static or dynamic slots, symbol window, and network idle time NIT). 0_B No slot boundary violation observed 1_B Slot boundary violation(s) observed on channel A
VFRB	8	rwh	**Valid Frame Received on Channel B** (vSS!ValidFrameB) One or more valid Frames were received on channel B in any static or dynamic slot during the observation period. 0_B No valid Frame received 1_B Valid Frame(s) received on channel B
SEDB	9	rwh	**Syntax Error Detected on Channel B** (vSS!SyntaxErrorB) One or more syntax errors in static or dynamic slots, symbol window, and network idle time (NIT) were observed on channel B. 0_B No syntax error observed 1_B Syntax error(s) observed on channel B
CEDB	10	rwh	**Content Error Detected on Channel B** (vSS!ContentErrorB) One or more Frames with a content error were received on channel B in any static or dynamic slot during the observation period. 0_B No Frame with content error received 1_B Frame(s) with content error received on channel B

Field	Bits	Type	Description
CIB	11	rwh	**Communication Indicator Channel B** One or more valid Frames were received on channel B in slots that also contained any additional communication during the observation period, i.e. one or more slots received a valid Frame AND had any combination of either syntax error OR content error OR slot boundary violation. 0_B No valid Frame(s) received in slots containing any additional communication 1_B Valid Frame(s) received on channel B in slots containing any additional communication
SBVB	12	rwh	**Slot Boundary Violation on Channel B** (vSS!BViolationB) One or more slot boundary violations were observed on channel B at any time during the observation period (static or dynamic slots, symbol window, and network idle time NIT). 0_B No slot boundary violation observed 1_B Slot boundary violation(s) observed on channel B
0	[7:5], [31:13]	r	**Reserved** Returns 0 if read; should be written with 0.

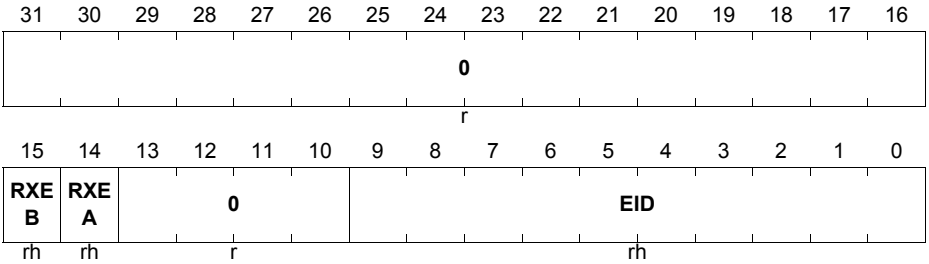
Note: The set condition of flags CIA and CIB is also fulfilled if there is only one single Frame in the slot and the slot boundary at the end of the slot is reached during the Frames channel idle recognition phase. When one of the flags SEDB, CEDB, CIB, SBVB changes from 0 to 1, service request flag EIR.EDB is set to 1.When one of the flags SEDA, CEDA, CIA, SBVA changes from 0 to 1, service request flag EIR.EDA is set to 1.

Even Sync ID [01…15] (ESIDnn)

Registers Even Sync ID nn (ESIDnn, nn=01-15) hold the Frame IDs of the SYNC Frames received in **even** communication cycles, sorted in ascending order, with register ESID01 holding the lowest received SYNC Frame ID. If the node itself transmits a SYNC Frame in an even communication cycle, register ESID01 holds the respective SYNC Frame ID as configured in Message Buffer 0 and the flags RXEA, RXEB are set. The value is updated during the network idle time (NIT) of each even communication cycle.

ESIDnn (nn = 01-15)
Even Sync ID Symbol Window nn

(012C$_H$ + nn * 4) **Reset Value: 0000 0000$_H$**



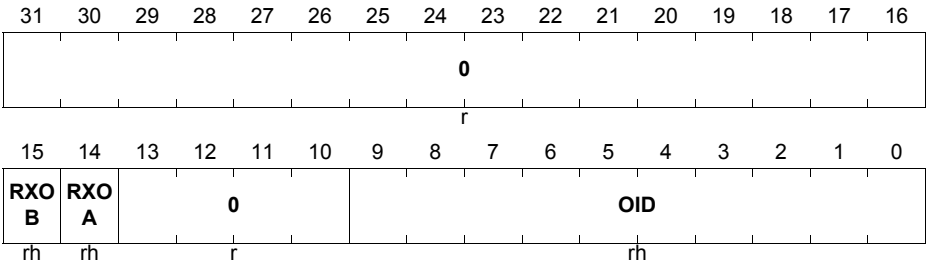
Field	Bits	Type	Description
EID	[9:0]	rh	**Even Sync ID** (vsSyncIDListA,B even) SYNC Frame ID even communication cycle.
RXEA	14	rh	**Received/Configured Even Sync ID on Channel A** Signals that a SYNC Frame corresponding to the stored even sync ID was received on channel A or that the node is configured to be a sync node with key slot = EID (ESID1 only). 0_B SYNC Frame not received on channel A / node configured to transmit SYNC Frames 1_B SYNC Frame received on channel A/ node not configured to transmit SYNC Frames
RXEB	15	rh	**Received/Configured Even Sync ID on Channel B** Signals that a SYNC Frame corresponding to the stored even sync ID was received on channel B or that the node is configured to be a sync node with key slot = EID (ESID1 only). 0_B SYNC Frame not received on channel B / node configured to transmit SYNC Frames 1_B SYNC Frame received on channel B / node not configured to transmit SYNC Frames

Field	Bits	Type	Description
0	[13:10], [31:16]	r	**Reserved** Returns 0 if read; should be written with 0.

Odd Sync ID [01…15] (OSIDnn)

he Odd Sync ID nn (OSIDnn, nn=01-15) hold the Frame IDs of the SYNC Frames received in **odd** communication cycles, sorted in ascending order, with register OSID01 holding the lowest received SYNC Frame ID. If the node itself transmits a SYNC Frame in an odd communication cycle, register OSID01 holds the respective SYNC Frame ID as configured in Message Buffer 0 and flags RXOA, RXOB are set. The value is updated during the network idle time (NIT) of each odd communication cycle.

OSIDnn (nn = 01-15)
Odd Sync ID Symbol Window nn ($016C_H$ + nn * 4) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
OID	[9:0]	rh	**Odd Sync ID** (vsSyncIDListA,B odd) SYNC Frame ID even communication cycle.
RXOA	14	rh	**Received Odd Sync ID on Channel A** Signals that a SYNC Frame corresponding to the stored odd sync ID was received on channel A or that the node is configured to be a sync node with key slot = OID (OSID1 only). 0_B SYNC Frame not received on channel A/ node configured to transmit SYNC Frames 1_B SYNC Frame received on channel A/ node not configured to transmit SYNC Frames
RXOB	15	rh	**Received Odd Sync ID on Channel B** Signals that a SYNC Frame corresponding to the stored odd sync ID was received on channel B or that the node is configured to be a sync node with key slot = OID (OSID1 only) 0_B SYNC Frame not received on channel B/ node configured to transmit SYNC Frames 1_B SYNC Frame received on channel B/ node not configured to transmit SYNC Frames

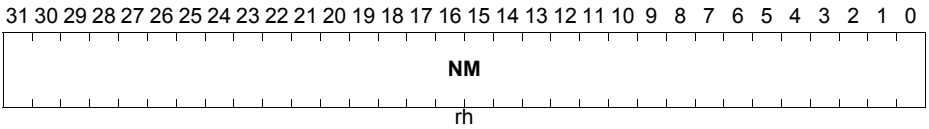
Field	Bits	Type	Description
0	[13:10], [31:16]	r	**Reserved** Returns 0 if read; should be written with 0.

Network Management Vector [1…3] (NMVx)

The three Network Management Vectors n (NMVx, x=1-3) registers hold the accrued Network Management (NM) vector (configurable 0 to 12 byte). The accrued Network Management (NM) vector is generated by the Communication Controller by bit-wise ORing each Network Management (NM) vector received (valid static Frames with PPI = 1) on each channel (see **"Network Management" on Page 26-222**). The Communication Controller updates the Network Management (NM) vector at the end of each communication cycle as long as the Communication Controller is either in "NORMAL_ACTIVE" or "NORMAL_PASSIVE" state. NMVx-bytes exceeding the configured Network Management (NM) vector length are not valid.

NMVx (x = 1-3)
Network Management Vector x

($01AC_H$ + x * 4) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
NM	[31:0]	rh	**Network Management Vector**

Table 26-5 below shows the assignment of the received payload's data byte to the Network Management vector.

Table 26-5 Assignment of Data Byte to Network Management Vector

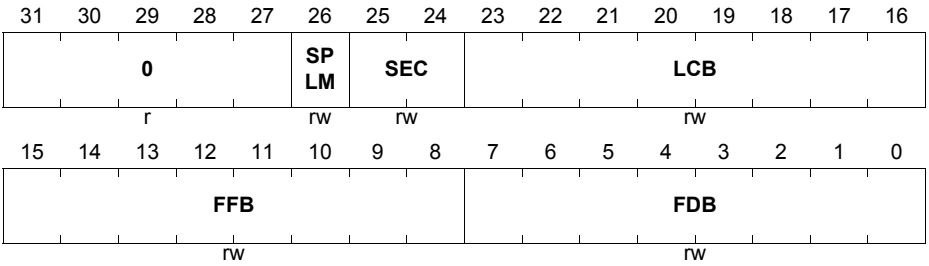
26.5.2.6 Message Buffer Control Registers

Message RAM Configuration (MRC)

The Message RAM Configuration register defines the number of Message Buffers assigned to the static segment, dynamic segment, and FIFO. The register can be written during “DEFAULT_CONFIG” or “CONFIG” state only.

MRC
Message RAM Configuration (0300_H) Reset Value: $0180\ 0000_H$



Field	Bits	Type	Description
FDB	[7:0]	rw	**First Dynamic Buffer** May be modified in “DEFAULT_CONFIG” or “CONFIG” state only. 00_H No group of Message Buffers exclusively for the static segment configured 01_H …$7F_H$ Message Buffers 0 to FDB-1 reserved for static segment 80_H …FF_H No dynamic Message Buffers configured
FFB	[15:8]	rw	**First Buffer of FIFO** May be modified in “DEFAULT_CONFIG” or “CONFIG” state only. 00_H …$7E_H$ Message Buffers from FFB to LCB assigned to the FIFO $7F_H$ All Message Buffers assigned to the FIFO 80_H …FF_H No Message Buffers assigned to the FIFO

Field	Bits	Type	Description
LCB	[23:16]	rw	**Last Configured Buffer** May be only modified in “DEFAULT_CONFIG” or “CONFIG” state. 01_H …$7F_H$ Number of Message Buffers is LCB + 1 80_H …FF_H No Message Buffer configured
SEC	[25:24]	rw	**Secure Buffers** Not evaluated when the Communication Controller is in “DEFAULT_CONFIG” or “CONFIG” state. For temporary unlocking see **“Host Handling of Errors” on Page 26-257**. 00_B Reconfiguration of Message Buffers enabled with numbers < FFB enabled. *Note: In nodes configured for SYNC Frame transmission or for single slot mode operation Message Buffer 0 (and if SPLM = 1, also Message Buffer 1) Reconfiguration of all Message Buffers is always locked* 01_B Reconfiguration of Message Buffers with numbers < FDB and with numbers ≥ FFB locked and transmission of Message Buffers for static segment with numbers ≥ FDB disabled 10_B Reconfiguration of all Message Buffers locked 11_B Reconfiguration of all Message Buffers locked and transmission of Message Buffers for static segment with numbers ≥ FDB disabled
SPLM	26	rw	**SYNC Frame Payload Multiplex** This bit is only evaluated if the node is configured as sync node (SUCC1.TXSY = 1) or for single slot mode operation (SUCC1.TSM = 1). When this bit is set to 1 Message Buffers 0 and 1 are dedicated for SYNC Frame transmission with different payload data on channel A and B. When this bit is reset to 0, SYNC Frames are transmitted from Message Buffer 0 with the same payload data on both channels. Note that the channel filter configuration for Message Buffer 0 resp. Message Buffer 1 has to be chosen accordingly. 0_B Only Message Buffer 0 locked against reconfiguration 1_B Both Message Buffers 0 and 1 are locked against reconfiguration

Field	Bits	Type	Description
0	[31:27]	r	**Reserved** Returns 0 if read; should be written with 0.

*Note: In case the node is configured as sync node (*SUCC1.*TXSY = 1) or for single slot mode operation (*SUCC1.*TSM = 1), Message Buffer 0 resp. 1 is reserved for SYNC Frames or single slot Frames and have to be configured with the node-specific key slot ID. In case the node is neither configured as sync node nor for single slot operation Message Buffer 0 resp. 1 is treated like all other Message Buffers.*

Table 26-6 Usage of the three Message Buffer Pointer

Message Buffer 0	⇓ Static Buffers		
Message Buffer 1			
	⇓ Static + Dynamic Buffers	⇐ **FDB**	
…			FIFO configured: **FFB** > **FDB**
	⇓ FIFO	⇐ **FFB**	No FIFO configured: **FFB** ≥ 128
Message Buffer N-1			**LCB** ≥ **FDB**, **LCB** ≥ **FFB**
Message Buffer N		⇐ **LCB**	

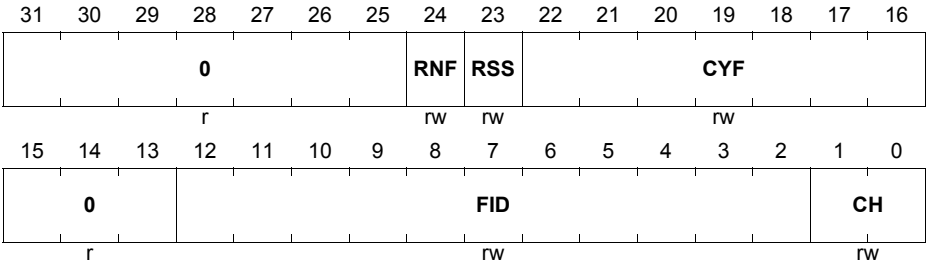
The programmer has to ensure that the configuration defined by FDB, FFB, and LCB is valid. **The Communication Controller does not check for erroneous configurations!**

Note: The maximum number of Header Sections is 128. This means a maximum of 128 Message Buffer can be configured. The maximum length of a Data Section is 254 byte. The length of the Data Section may be configured differently for each Message Buffer. For details see ***"Message RAM" on Page 26-248****.*
In case two or more Message Buffers are assigned to slot 1 by use of cycle filtering, all of them must be located either in the "Static Buffers" or at the beginning of the "Static + Dynamic Buffers" section.
The payload length configured and the length of the Data Section need to be configured identically for all Message Buffers belonging to the FIFO via WRHS2.PLC and WRHS3.DP. When the Communication Controller is not in "DEFAULT_CONFIG" or "CONFIG" state reconfiguration of Message Buffers belonging to the FIFO is locked.

FIFO Rejection Filter (FRF)

The FIFO Rejection Filter defines a user specified sequence of bits to which channel, Frame ID, and cycle count of the incoming Frames are compared. Together with the FIFO Rejection Filter Mask this register determines whether a message is rejected by the FIFO. The FRF register can be written during “DEFAULT_CONFIG” or “CONFIG” state only.

FRF
FIFO Rejection Filter **(0304_H)** **Reset Value: $0180\ 0000_H$**



Field	Bits	Type	Description
CH	[1:0]	rw	**Channel Filter** May be modified in “DEFAULT_CONFIG” or “CONFIG” state only. 00_B receive on both channels[1)] 01_B receive only on channel B 10_B receive only on channel A 11_B no reception
FID	[12:2]	rw	**Frame ID Filter** Determines the Frame ID to be rejected by the FIFO. With the additional configuration of register FRFM, the corresponding Frame ID filter bits are ignored, which results in further rejected Frame IDs. When FRFM.MFID is zero, a Frame ID filter value of zero means that no Frame ID is rejected. 000_H …$7FF_H$ Frame ID filter values

Field	Bits	Type	Description
CYF	[22:16]	rw	**Cycle Counter Filter** The 7-bit cycle counter filter determines the cycle set to which Frame ID and channel rejection filter are applied. In cycles **not** belonging to the cycle set specified by CYF, all Frames are rejected. For details about the configuration of the cycle counter filter see **“Cycle Counter Filtering” on Page 26-224**. May be modified in “DEFAULT_CONFIG” or “CONFIG” state only.
RSS	23	rw	**Reject in Static Segment** If this bit is set, the FIFO is used only be used in dynamic segment. May be modified in “DEFAULT_CONFIG” or “CONFIG” state only. 0_B FIFO also used in static segment 1_B Reject messages for static segment
RNF	24	rw	**Reject NULL Frames** If this bit is set, received NULL Frames are not stored in the FIFO. May be modified in “DEFAULT_CONFIG” or “CONFIG” state only. 0_B NULL Frames are stored in the FIFO 1_B Reject all NULL Frames
0	[15:13], [31:25]	r	**Reserved** Returns 0 if read; should be written with 0.

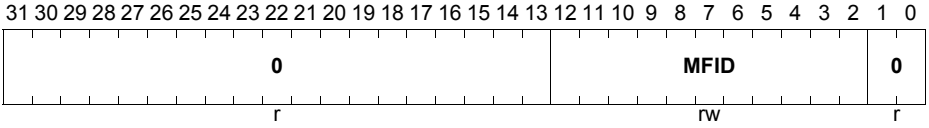
1) If reception on both channels is configured, also in static segment always both Frames (from channel A and B) are stored in the FIFO, even if they are identical.

FIFO Rejection Filter Mask (FRFM)

The FIFO Rejection Filter Mask specifies which of the corresponding Frame ID filter bits are relevant for rejection filtering. If a bit is set, it indicates that the corresponding bit in the FRF register will not be considered for rejection filtering. The FRFM register can be written during “DEFAULT_CONFIG” or “CONFIG” state only.

FRFM

FIFO Rejection Filter Mask **(0308_H)** **Reset Value: $0000\ 0000_H$**

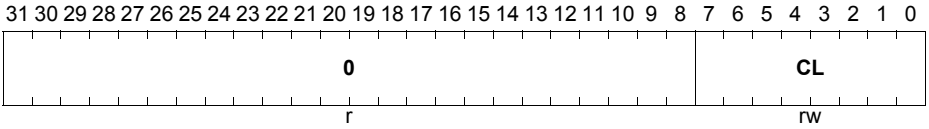


Field	Bits	Type	Description
MFID	[12:2]	rw	**Mask Frame ID Filter** May be modified in “DEFAULT_CONFIG” or “CONFIG” state only. 0_B Corresponding Frame ID filter bit is used for rejection filtering. 1_B Ignore corresponding Frame ID filter bit.
0	[1:0], [31:13]	r	**Reserved** Returns 0 if read; should be written with 0.

FIFO Critical Level (FCL)

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

FCL
FIFO Critical Level **($030C_H$)** **Reset Value: $0000\ 0080_H$**



Field	Bits	Type	Description
CL	[7:0]	rw	**Critical Level** When the receive FIFO fill level FSR.RFFL is equal or greater than the critical level configured by CL, the receive FIFO critical level flag FSR.RFCL is set. If CL is programmed to values > 128, bit FSR.RFCL is never set. When FSR.RFCL changes from 0 to 1 bit **SIR.RFCL** is set to 1, and if enabled, a service request is generated.
0	[31:8]	r	**Reserved** Returns 0 if read; should be written with 0.

26.5.2.7 Message Buffer Status Registers

Message Handler Status (MHDS)

The Message Handler Status register gives the Host access to the current state of the Message Handler. A flag is cleared by writing a 1 to the corresponding bit position. Writing a 0 has no effect on the flag. An application reset will also clear the register. If one of the flags MHDS.EIBF, MHDS.EOBF, MHDS.EMR, MHDS.ETBF1, MHDS.ETBF2 changes from 0 to 1 EIR.EERR is set.

MHDS
Message Handler Status **(0310_H)** **Reset Value: $0000\ 0080_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0	MBU							0	MBT						
r	rh							r	rh						

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	FMB							CRAM	MFMB	FMBD	ETBF2	ETBF1	EMR	EOBF	EIBF
r	rh							rh	rwh	rwh	rwh	rwh	rwh	rwh	rwh

Field	Bits	Type	Description
EIBF	0	rwh	**ECC Error Input Buffer RAM 1,2** 0_B No error 1_B Error occurred when reading Input Buffer RAM 1 or Input Buffer RAM 2
EOBF	1	rwh	**ECC Error Output Buffer RAM 1,2** 0_B No error 1_B Error occurred when reading Output Buffer RAM 1 or Output Buffer RAM 2
EMR	2	rwh	**ECC Error Message RAM** 0_B No error 1_B Error occurred when reading the Message RAM
ETBF1	3	rwh	**ECC Error Transient Buffer RAM A** 0_B No error 1_B Error occurred when reading Transient Buffer RAM A
ETBF2	4	rwh	**ECC Error Transient Buffer RAM B** 0_B No error 1_B Error occurred when reading Transient Buffer RAM B

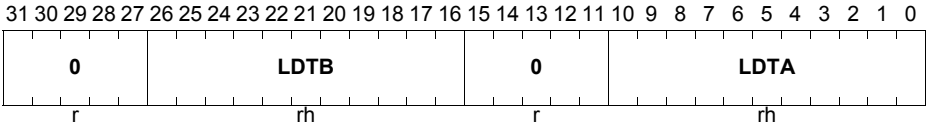
Field	Bits	Type	Description
FMBD	5	rwh	**Faulty Message Buffer Detected** 0_B No faulty Message Buffer 1_B Message Buffer referenced by MHDS.FMB holds faulty data due to a ECC error
MFMB	6	rwh	**Multiple Faulty Message Buffers detected** 0_B No additional faulty Message Buffer 1_B Another faulty Message Buffer was detected while flag MHDS.FMBD is set
CRAM	7	rh	**Clear all internal RAM's** Signals that execution of the CHI command CLEAR_RAMS is ongoing (all bits of all internal RAM blocks are written to 0). The bit is set by application reset or by CHI command CLEAR_RAMS. 0_B No execution of the CHI command CLEAR_RAMS 1_B Execution of the CHI command CLEAR_RAMS ongoing
FMB	[14:8]	rh	**Faulty Message Buffer** ECC error occurred when reading from the Message Buffer or when transferring data from Input Buffer or Transient Buffer A or Transient Buffer B to the Message Buffer referenced by MHDS.FMB. Value only valid when one of the flags MHDS.EIBF, MHDS.EMR, MHDS.ETBF1, MHDS.ETBF2, and flag MHDS.FMBD is set. Updated only after the Host has reset flag MHDS.FMBD.
MBT	[22:16]	rh	**Message Buffer Transmitted** Number of last successfully transmitted Message Buffer. If the Message Buffer is configured for single-shot mode, the respective TXR flag in the Transmission Request Registers TXRQ1 to TXRQ4 was reset. MBT is reset when the Communication Controller leaves "CONFIG" state or enters "STARTUP" state.
MBU	[30:24]	rh	**Message Buffer Updated** Number of Message Buffer that was updated last. For this Message Buffer the respective NDn (n = 0-31) to NDn (n = 96-127)and / or MBCn (n = 0-31) to MBCn (n = 96-127) flag in the New Data Registers NDAT1 to NDAT4 and the Message Buffer Status Changed MBSC1 to MBSC4 registers are also set. MBU is reset when the Communication Controller leaves "CONFIG" state or enters "STARTUP" state.

Field	Bits	Type	Description
0	15, 23, 31	r	**Reserved** Returns 0 if read; should be written with 0.

Last Dynamic Transmit Slot (LDTS)

The Last Dynamic Transmit Slot Register stores the Slot Counter value at the time of the last Frame transmission in the dynamic segment. This register is reset when the Communication Controller leaves “CONFIG” state or enters “STARTUP” state.

LDTS
Last Dynamic Transmit Slot **(0314_H)** **Reset Value: $0000\ 0000_H$**

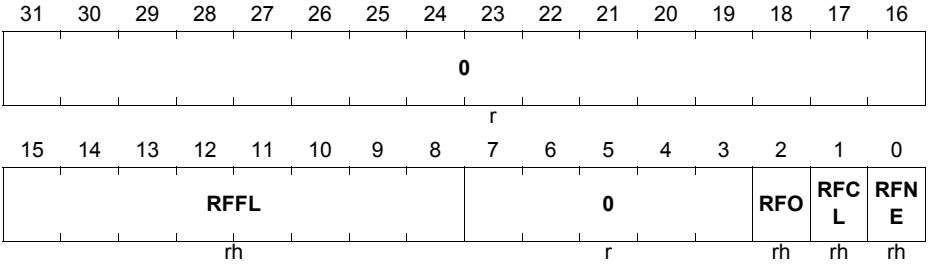


Field	Bits	Type	Description
LDTA	[10:0]	rh	**Last Dynamic Transmission Channel A** Value of (vSlotCounter[A]) at the time of the last Frame transmission on channel A in the dynamic segment of this node. It is updated at the end of the dynamic segment and is reset to zero if no Frame was transmitted during the dynamic segment.
LDTB	[26:16]	rh	**Last Dynamic Transmission Channel B** Value of (vSlotCounter[B]) at the time of the last Frame transmission on channel B in the dynamic segment of this node. It is updated at the end of the dynamic segment and is reset to zero if no Frame was transmitted during the dynamic segment.
0	[15:11], [31:27]	r	**Reserved** Returns 0 if read; should be written with 0.

FIFO Status Register (FSR)

The register is reset when the Communication Controller leaves “CONFIG” state or enters “STARTUP” state.

FSR
FIFO Status Register **(0318_H)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
RFNE	0	rh	**Receive FIFO Not Empty** This flag is set by the Communication Controller when a received valid Frame (data or NULL Frame depending on rejection mask) was stored in the FIFO. In addition, service request flag SIR.RFNE is set. The bit is reset after the Host has read all message from the FIFO. 0_B Receive FIFO is empty 1_B Receive FIFO is not empty
RFCL	1	rh	**Receive FIFO Critical Level** This flag is set when the receive FIFO fill level RFFL is equal or greater than the critical level as configured by FCL.CL. The flag is cleared by the Communication Controller as soon as RFFL drops below FCL.CL. When RFCL changes from 0 to 1 bit SIR.RFCL is set to 1, and if enabled, an service request is generated. 0_B Receive FIFO below critical level 1_B Receive FIFO critical level reached

Field	Bits	Type	Description
RFO	2	rh	**Receive FIFO Overrun** The flag is set by the Communication Controller when a receive FIFO overrun is detected. When a receive FIFO overrun occurs, the oldest message is overwritten with the actual received message. In addition, service request flag EIR.RFO is set.The flag is cleared by the next FIFO read access issued by the Host. 0_B No receive FIFO overrun detected 1_B A receive FIFO overrun has been detected
RFFL	[15:8]	rh	**Receive FIFO Fill Level** Number of FIFO buffers filled up with new data not yet read by the Host. Maximum value is 128.
0	[7:3], [31:16]	r	**Reserved** Returns 0 if read; should be written with 0.

Message Handler Constraints Flags (MHDF)

Some constraints exist for the Message Handler regarding f_{CLC_ERAY} frequency, Message RAM configuration, and FlexRay™ bus traffic. To simplify software development, constraints violations are reported by setting flags in the MHDF. The register is reset when the Communication Controller leaves “CONFIG” state or enters “STARTUP” state. A flag is cleared by setting the corresponding bit position. Clearing has no effect on the flag. If any flag in MHDFL is set, interrupt flag EIR.MHF is set.

MHDF

Message Handler Constraints Flags (031C$_H$) **Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r							rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh

Field	Bits	Type	Description
SNUA	0	rwh	**Status Not Updated Channel A** This flag is set by the Communication Controller when the Message Handler, due to overload condition, was not able to update a Message Buffer’s status MBS with respect to channel A. 0_B No overload condition occurred when updating MBS for channel A 1_B MBS for channel A not updated
SNUB	1	rwh	**Status Not Updated Channel B** This flag is set by the Communication Controller when the Message Handler, due to overload condition, was not able to update a Message Buffer’s status MBS with respect to channel B. 0_B No overload condition occurred when updating MBS for channel B 1_B MBS for channel B not updated

Field	Bits	Type	Description
FNFA	2	rwh	**Find Sequence Not Finished Channel A** This flag is set by the Communication Controller when the Message Handler, due to overload condition, was not able to finish a find sequence (scan of Message RAM for matching Message Buffer) with respect to channel A. 0_B No find sequence not finished for channel A 1_B Find sequence not finished for channel A
FNFB	3	rwh	**Find Sequence Not Finished Channel B** This flag is set by the Communication Controller when the Message Handler, due to overload condition, was not able to finish a find sequence (scan of Message RAM for matching Message Buffer) with respect to channel B. 0_B No find sequence not finished for channel B 1_B Find sequence not finished for channel B
TBFA	4	rwh	**Transient Buffer Access Failure A** This flag is set by the Communication Controller when a read or write access to Transient Buffer A requested by PRT A could not complete within the available time. 0_B No TBF A access failure 1_B TBF A access failure
TBFB	5	rwh	**Transient Buffer Access Failure B** This flag is set by the Communication Controller when a read or write access to Transient Buffer B requested by PRT B could not complete within the available time. 0_B No Transient Buffer B access failure 1_B Transient Buffer B access failure
TNSA	6	rwh	**Transmission Not Started Channel A** This flag is set by the CC when the Message Handler was not ready to start a scheduled transmission on channel A at the action point of the configured slot. 0_B No transmission not started on channel A 1_B Transmission not started on channel A
TNSB	7	rwh	**Transmission Not Started Channel B** This flag is set by the CC when the Message Handler was not ready to start a scheduled transmission on channel B at the action point of the configured slot. 0_B No transmission not started on channel B 1_B Transmission not started on channel B

Field	Bits	Type	Description
WAHP	8	rwh	**Write Attempt to Header Partition** Outside “DEFAULT_CONFIG” and “CONFIG” state this flag is set by the Communication Controller when the message handler tries to write message data into the Header Partition of the Message RAM due to faulty configuration of a Message Buffer. The write attempt is not executed, to protect the Header Partition from unintended write accesses. 0_B No write attempt to Header Partition 1_B Write attempt to Header Partition
0	[31:9]	r	**Reserved** Returns 0 if read; should be written with 0.

Transmission Request 1 (TXRQ1)

This register reflect the state of the TXR flags of the configured Message Buffers 0 to 31. The flags are evaluated for transmit buffers only. If the number of configured Message Buffers is less than 31, the remaining TXRn flags have no meaning and are read as 0.

TXRQ1
Transmission Request Register 1 (0320_H) **Reset Value: $0000\ 0000_H$**

rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh

Field	Bits	Type	Description
TXRn (n = 32-63)	n - 32	rh	**Transmission Request n (n = 32-63)** If the flag is set, the respective Message Buffer 32 to 63 is ready for transmission respectively transmission of this Message Buffer is in progress. In single-shot mode the flags are reset after transmission has completed.

Transmission Request Register 3 (TXRQ3)

This register reflect the state of the TXR flags of the configured Message Buffers 64 to 95. The flags are evaluated for transmit buffers only. If the number of configured Message Buffers is less than 95, the remaining TXRn flags have no meaning and are read as 0.

TXRQ3

Transmission Request Register 3 (0328_H) **Reset Value: $0000\ 0000_H$**

The flags are reset when the Header Section of the Message Buffer is reconfigured or when it has been transferred to the Output Buffer.

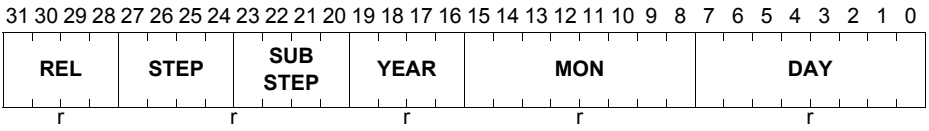
26.5.2.8 Identification Registers

Core Release Register (CREL)

This register contains bit fields about the ERAY module identification. It is read only.

CREL
Core Release Register **(03F0$_H$)** **Reset Value: XXXX XXXX$_H$**



Field	Bits	Type	Description
DAY	[7:0]	r	**Design Time Stamp, Day** Two digits, BCD-coded.
MON	[15:8]	r	**Design Time Stamp, Month** Two digits, BCD-coded.
YEAR	[19:16]	r	**Design Time Stamp, Year** One digit, BCD-coded.
SUBSTEP	[23:20]	r	**Sub-Step of Core Release** One digits, BCD-coded. 0_H Alpha, pre-Beta, pre-Beta-update, pre-Beta2, pre-Beta2-update, Beta, Beta2, Revision 1.0.0 1_H Beta_ct, Beta-ct-fix1, Revision 1.0.1 2_H Revision1.0RC1,Beta-ct-fix2, REVISION 1.0RC1
STEP	[27:24]	r	**Step of Core Release** One digits, BCD-coded. 0_H Revision 1.0.0 1_H Alpha 2_H pre-Beta 3_H pre-Beta-update 4_H pre-Beta2 5_H pre-Beta2-update 6_H Beta 7_H Beta2

Field	Bits	Type	Description
REL	[31:28]	r	**Core Release** One digit, BCD-coded. 0_B alpha…beta2ct 1_B Revision 1.0

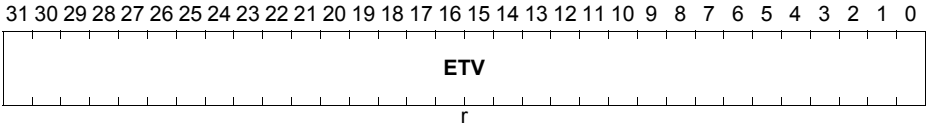
Table 26-7 Coding of releases

Release	Step	Sub-Step	Name	Release Date
0	1	0	Alpha	
0	2	0	pre-Beta	
0	3	0	pre-Beta-update	
0	4	0	pre-Beta2	
0	5	0	pre-Beta2-update	
0	6	0	Beta	
0	6	1	Beta-ct-fix1	14.10.2005
0	6	2	Beta-ct-fix2	14.12.2005
0	7	0	Beta2	03.02.2006
0	7	1	Beta2ct	24.03.2006
0	7	2	Revision 1.0RC1	07.04.2006
1	0	0	Release 1.0.0	19.05.2006
1	0	1	Release 1.0.1	2006
1	0	2	Release 1.0.2	31.10.2007

Endian Register (ENDN)

This register may be used to check, if the data of the E-Ray is handled by a host with the correct endian format. It is read only.

ENDN
Endian Register **(003F4$_H$)** **Reset Value: 8765 4321$_H$**



Field	Bits	Type	Description
ETV	[31:0]	r	**Endianness Test Value** The endianness test value.

26.5.2.9 Input Buffer

Double buffer structure consisting of Input Buffer Host and Input Buffer Shadow. While the Host can write to Input Buffer Host, the transfer to the Message RAM is done from Input Buffer Shadow. The Input Buffer holds the Header and Data Sections to be transferred to the selected Message Buffer in the Message RAM. It is used to configure the Message Buffers in the Message RAM and to update the Data Sections of transmit buffers.

When updating the Header Section of a Message Buffer in the Message RAM from the Input Buffer, the Message Buffer Status as described in **“Message Buffer Status (MBS)” on Page 26-186** is automatically reset to zero.

The Header Sections of Message Buffers belonging to the receive FIFO can only be (re)configured when the Communication Controller is in “DEFAULT_CONFIG” or “CONFIG” state. For those Message Buffers only the payload length configured and the data pointer need to be configured via WRHS2.PLC and WRHS2.DP. All information required for acceptance filtering is taken from the FIFO rejection filter and the FIFO rejection filter mask.

The data transfer between Input Buffer (IBF) and Message RAM is described in detail in **“Data Transfer from Input Buffer to Message RAM” on Page 26-233**.

Write Data Section [01 - 64] (WRDSnn (nn = 01-64))

The Write Data Section (WRDSnn, nn = 01-64) holds the data words to be transferred to the Data Section of the addressed Message Buffer. The data words (DW_n) are written to the Message RAM in transmission order from DW1 (byte0, byte1) to DW_{PL} (PL = number of data words as defined by the payload length configured by WRHS2.PLC).

WRDSnn (nn = 01-64)
Write Data Section nn **($03FC_H$ + nn * 4)** **Reset Value: $0000\ 0000_H$**

31 30 29 28 27 26 25 24	23 22 21 20 19 18 17 16	15 14 13 12 11 10 9 8	7 6 5 4 3 2 1 0
MDWBnn3	MDWBnn2	MDWBnn1	MDWBnn0
rw	rw	rw	rw

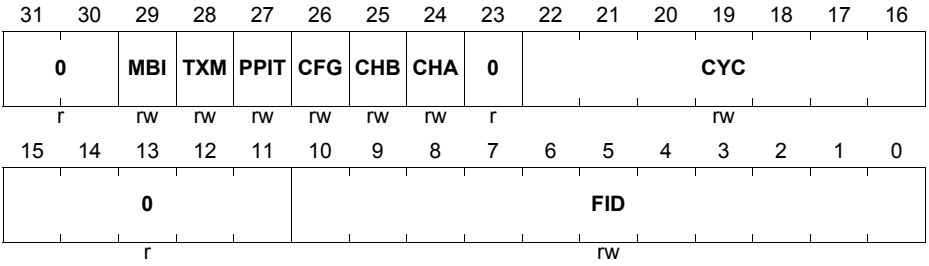
Field	Bits	Type	Description
MDWB0	[7:0]	rw	**32-Bit Word nn, Byte 0**
MDWB1	[15:8]	rw	**32-Bit Word nn, Byte 1**
MDWB2	[23:16]	rw	**32-Bit Word nn, Byte 2**
MDWB3	[31:24]	rw	**32-Bit Word nn, Byte 3**

Note: 16-bit Word 127 is located on WRDS64.MDW. In this case WRDS64.MDW is unused (no valid data). The Input Buffer RAMs are initialized to zero when leaving application reset or by CHI command CLEAR_RAMS.

Note: When writing to the WRDSnn (nn = 01-64), each 32-bit word has to be filled up by one 32-bit access OR two consecutive 16-bit accesses OR four consecutive 8-bit accesses before the transfer from the Input Buffer to the Message RAM is started by writing the number of the target Message Buffer in the Message RAM to the Input Buffer Command Request register. If a 32-bit word of the Input Buffer has been filled with less then two consecutive 16-bit accesses OR four consecutive 8-bit accesses (less then 32-bit), random data is transferred into the Input buffer for every not written 16-bit or 8-bit of a 32-bit word.

Write Header Section 1 (WRHS1)

WRHS1
Write Header Section 1 **(0500_H)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
FID	[10:0]	rw	**Frame ID** Frame ID of the selected Message Buffer. The Frame ID defines the slot number for transmission / reception of the respective message. Message Buffers with Frame ID = 0 are considered as not valid.
CYC	[22:16]	rw	**Cycle Code** The 7-bit cycle code determines the cycle set used for cycle counter filtering. For details about the configuration of the cycle code see **Section 26.6.7.3**.
CHA	24	rw	**Channel Filter Control A** The channel filtering field A associated with the buffer serves of channel A as a filter for receive buffers, and as a control field for transmit buffers
CHB	25	rw	**Channel Filter Control B** The channel filtering field B associated with the buffer serves of channel B as a filter for receive buffers, and as a control field for transmit buffers
CFG	26	rw	**Message Buffer Direction Configuration Bit** This bit is used to configure the corresponding buffer as a transmit buffer or as a receive buffer. For Message Buffers belonging to the receive FIFO the bit is not evaluated. 0_B The corresponding buffer is configured as Receive Buffer 1_B The corresponding buffer is configured as Transmit Buffer

Field	Bits	Type	Description
PPIT	27	rw	**Payload Preamble Indicator Transmit** This bit is used to control the state of the Payload Preamble Indicator in transmit Frames. If the bit is set in a static Message Buffer, the respective Message Buffer holds Network Management information. If the bit is set in a dynamic Message Buffer the first two byte of the Payload Segment may be used for message ID filtering by the receiver. Message ID filtering of received FlexRay™ Frames is not supported by the E-Ray module, but can be done by the Host. 0_B Payload Preamble Indicator not set 1_B Payload Preamble Indicator set
TXM	28	rw	**Transmission Mode** This bit is used to select the transmission mode (see **"Transmit Buffers" on Page 26-226**). 0_B Continuous mode 1_B Single-shot mode
MBI	29	rw	**Message Buffer Service Request** This bit enables the receive / transmit service request for the corresponding Message Buffer. After a dedicated receive buffer has been updated by the Message Handler, flag SIR.RXI and /or SIR.MBSI in the Status Service Request register are set. After a transmission has completed flag SIR.TXI is set. 0_B The corresponding Message Buffer service request is disabled 1_B The corresponding Message Buffer service request is enabled
0	[15:11], 23, [31:30]	r	**Reserved** Returns 0 if read; should be written with 0.

Note: The Input Buffer RAMs are initialized to zero when leaving application reset or by CHI command CLEAR_RAMS. Note that only the currently active IBF bank is cleared. To clear the 2nd bank as well, CUST1.IBF1PAG and CUST1.IBF2PAG need to be set and command CLEAR_RAMS need to be issued again. This is required in particular after an application reset. If the 2nd bank of IBF is left unused, this procedure is not required.

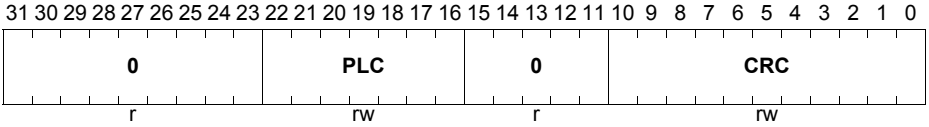
Table 26-8 Channel Filter Control Bits

CHA	CHB	Transmit Buffer transmit Frame on	Receive Buffer store Frame received from
1[1)]	1[1)]	Both Channels (static segment only)	Channel A or B (store first semantically valid Frame, static segment only)
1	0	Channel A	Channel A
0	1	Channel B	Channel B
0	0	No Transmission	Ignore Frame

1) If a Message Buffer is configured for the dynamic segment and both bits of the channel filtering field are set to 1, no Frames are transmitted resp. received Frames are ignored (same function as CHA = CHB = 0)

Write Header Section 2 (WRHS2)

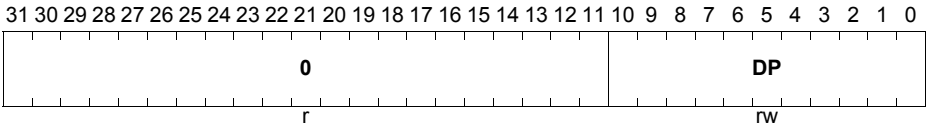
WRHS2
Write Header Section 2 **(0504_H)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
CRC	[10:0]	rw	**Header CRC** (vRF!Header!HeaderCRC) Receive Buffer: Configuration not required Transmit Buffer: Header CRC calculated and configured by the Host. For calculation of the Header CRC the payload length of the Frame send on the bus has to be considered. In static segment the payload length of all Frames is configured by MHDC.SFDL.
PLC	[22:16]	rw	**Payload Length Configured** Length of Data Section (number of 2-byte words) as configured by the Host. During static segment the static Frame payload length as configured by MHDC.SFDL in the MHD Configuration Register defines the payload length for all static Frames. If the payload length configured by PLC is shorter than this value padding byte are inserted to ensure that Frames have proper physical length. The padding pattern is logical zero.
0	[15:11], [31:23]	r	**Reserved** Returns 0 if read; should be written with 0.

Write Header Section 3 (WRHS3)

WRHS3
Write Header Section 3 **(0508_H)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
DP	[10:0]	rw	**Data Pointer** Pointer to the first 32-bit word of the Data Section of the addressed Message Buffer in the Message RAM.
0	[31:11]	r	**Reserved** Returns 0 if read; should be written with 0.

Input Buffer Command Mask (IBCM)

Configures how the Message Buffer in the Message RAM selected by the Input Buffer Command Request register IBCR is updated. If IBF Host and IBF Shadow are swapped, also masked bits IBCM.LHSH, IBCM.LDSH, and IBCM.STXRH are swapped with bits IBCM.LHSS, IBCM.LDSS, and IBCM.STXRS to keep them attached to the respective Input Buffer transfer.

IBCM
Input Buffer Command Mask **(0510_H)** **Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0													STXRS	LDSS	LHSS
r													rh	rh	rh

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0													STXRH	LDSH	LHSH
r													rwh	rwh	rwh

Field	Bits	Type	Description
LHSH	0	rwh	**Load Header Section Host** 0_B Header Section is not updated 1_B Header Section selected for transfer from Input Buffer to the Message RAM
LDSH	1	rwh	**Load Data Section Host** 0_B Data Section is not updated 1_B Data Section selected for transfer from Input Buffer to the Message RAM
STXRH	2	rwh	**Set Transmission Request Host** If this bit is set to 1, the Transmission Request flag TXRQ1.TXRn (n = 0-31) to TXRQ4.TXRn (n = 0-31) for the selected Message Buffer is set in the Transmission Request Registers to release the Message Buffer for transmission. In single-shot mode the flag is cleared by the Communication Controller after transmission has completed. TXRQ1.TXRn (n = 0-31) to TXRQ4.TXRn (n = 0-31) are evaluated for transmit buffer only. 0_B Reset Transmission Request flag 1_B Set Transmission Request flag, transmit buffer released for transmission

Field	Bits	Type	Description
LHSS	16	rh	**Load Header Section Shadow** 0_B Header Section is not updated 1_B Header Section selected for transfer from Input Buffer to the Message RAM (transfer is ongoing of finalized)
LDSS	17	rh	**Load Data Section Shadow** 0_B Data Section is not updated 1_B Data Section selected for transfer from Input Buffer to the Message RAM (transfer is ongoing of finalized)
STXRS	18	rh	**Transmission Request Shadow** If this bit is set to 1, the Transmission Request flag TXRQ1.TXRn (n = 0-31) to TXRQ4.TXRn (n = 0-31) for the selected Message Buffer is set in the Transmission Request Registers to release the Message Buffer for transmission. In single-shot mode the flag is cleared by the Communication Controller after transmission has completed. TXRQ1.TXRn (n = 0-31) to TXRQ4.TXRn (n = 0-31) are evaluated for transmit buffer only. 0_B Reset Transmission Request flag 1_B Set Transmission Request flag, transmit buffer released for transmission (operation is ongoing of finalized)
0	[15:3], [31:19]	r	**Reserved** Returns 0 if read; should be written with 0.

Input Buffer Command Request (IBCR)

When the Host writes the number of the target Message Buffer in the Message RAM to IBRH in the Input Buffer Command Request register, IBF Host and IBF Shadow are swapped. In addition the Message Buffer numbers stored under IBRH and IBRS are also swapped (see also **"Data Transfer from Input Buffer to Message RAM" on Page 26-233**).

With this write operation the IBSYS bit in the Input Buffer Command Request register is set to 1. The Message Handler then starts to transfer the contents of IBF Shadow to the Message Buffer in the Message RAM selected by IBRS.

While the Message Handler transfers the data from IBF Shadow to the target Message Buffer in the Message RAM, the Host may write the next message into the IBF Host. After the transfer between IBF Shadow and the Message RAM has completed, the IBSYS bit is set back to 0 and the next transfer to the Message RAM may be started by the Host by writing the respective target Message Buffer number to IBRH.

If a write access to IBRH occurs while IBSYS is 1, IBSYH is set to 1. After completion of the ongoing data transfer from IBF Shadow to the Message RAM, IBF Host and IBF Shadow are swapped, IBSYH is reset to 0. IBSYS remains set to 1, and the next transfer to the Message RAM is started. In addition the Message Buffer numbers stored under IBRH and IBRS are also swapped. Any write access to an Input Buffer register while both IBSYS and IBSYH are set will cause the error flag EIR.IIBA to be set. In this case the Input Buffer will not be changed.

IBCR
Input Buffer Command Request (0514_H) Reset Value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
IBSYS	0								IBRS						
rh	r								rh						

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IBSYH	0								IBRH						
rh	r								rwh						

Field	Bits	Type	Description
IBRH	[6:0]	rwh	**Input Buffer Request Host** Selects the target Message Buffer in the Message RAM for data transfer from Input Buffer. Valid values are 00_H to $7F_H$ (0…127).

Field	Bits	Type	Description
IBSYH	15	rh	**Input Buffer Busy Host** Set to 1 by writing IBRH while IBSYS is still 1. After the ongoing transfer between IBF Shadow and the Message RAM has completed, the IBSYH is set back to 0. 0_B No request pending 1_B Request while transfer between IBF Shadow and Message RAM in progress
IBRS	[22:16]	rh	**Input Buffer Request Shadow** Number of the target Message Buffer actually updated/lately updated. Valid values are 00_H to $7F_H$ (0…127).
IBSYS	31	rh	**Input Buffer Busy Shadow** Set to 1 after writing IBRH. When the transfer between IBF Shadow and the Message RAM has completed, IBSYS is set back to 0. 0_B Transfer between IBF Shadow and Message RAM completed 1_B Transfer between IBF Shadow and Message RAM in progress
0	[14:7], [30:23]	r	**Reserved** Returns 0 if read; should be written with 0.

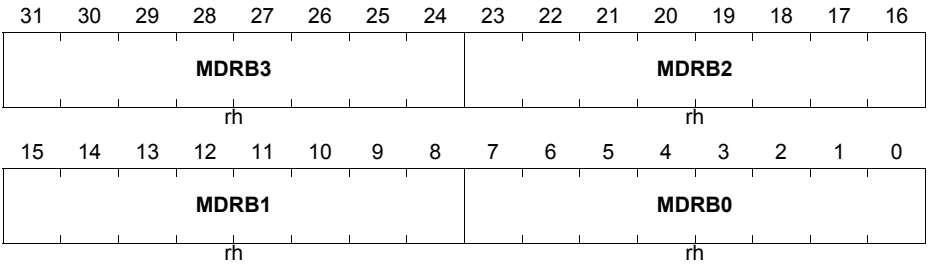
26.5.2.10 Output Buffer

Double buffer structure consisting of Output Buffer Host and Output Buffer Shadow. Used to read out Message Buffers from the Message RAM. While the Host can read from Output Buffer Host, the Message Handler transfers the selected Message Buffer from Message RAM to the respective Output Buffer Shadow. The data transfer between Message RAM and Output Buffer (OBF) is described in **"Data Transfer from Message RAM to Output Buffer" on Page 26-235**.

Read Data Section [1…64] (RDDSn)

The Read Data Section nn (RDDSnn, nn = 01-64) holds the data words read from the Data Section of the addressed Message Buffer. The data words are read from the Message RAM in reception order from DW1 (byte0, byte1) to DW_{PL} (PL = number of data words as defined by the Payload Length).

RDDSnn (nn = 01-64)
Read Data Section nn **($05FC_H$ + nn * 4)** **Reset Value: $0000\ 0000_H$**



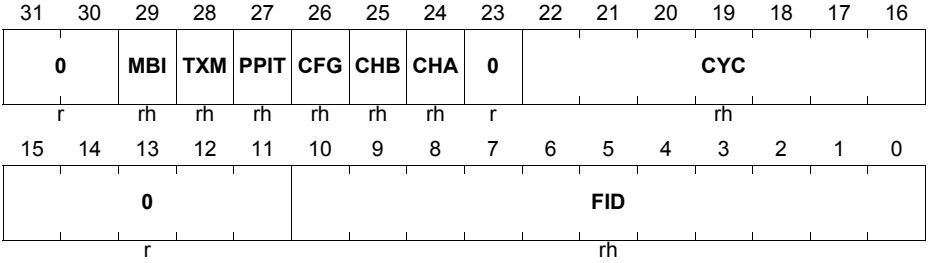
Field	Bits	Type	Description
MDRB0	[7:0]	rh	**32-Bit Word nn, Byte 0**
MDRB1	[15:8]	rh	**32-Bit Word nn, Byte 1**
MDRB2	[23:16]	rh	**32-Bit Word nn, Byte 2**
MDRB3	[31:24]	rh	**32-Bit Word nn, Byte 3**

Note: DW127 is located on RDDS64.MDW. In this case RDDS64.MDW is unused (no valid data). The Output Buffer RAMs are initialized to zero when leaving application reset or by CHI command CLEAR_RAMS.

Read Header Section 1 (RDHS1)

Values as configured by the Host via WRHS1 Register:

RDHS1
Read Header Section 1 **(0700_H)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
FID	[10:0]	rh	**Frame ID**
CYC	[22:16]	rh	**Cycle Code**
CHA	24	rh	**Channel Filter Control A**
CHB	25	rh	**Channel Filter Control B**
CFG	26	rh	**Message Buffer Direction Configuration Bit**
PPIT	27	rh	**Payload Preamble Indicator Transmit**
TXM	28	rh	**Transmission Mode**
MBI	29	rh	**Message Buffer Service Request**
0	[15:11], 23, [31:30]	r	**Reserved** Returns 0 if read; should be written with 0.

Note: In case that the Message Buffer read from the Message RAM belongs to the receive FIFO, FID holds the received Frame ID, while CYC, CHA, CHB, CFG, PPIT, TXM, and MBI are reset to zero.

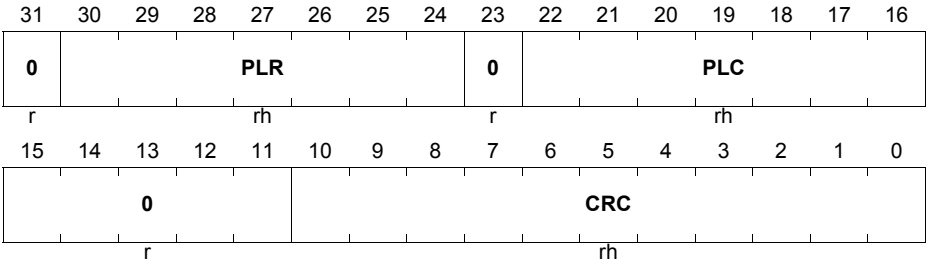
Table 26-9 Channel Filter Control Bits

CHA	CHB	Transmit Buffer transmit Frame on	Receive Buffer store Frame received from
1[1)]	1[1)]	Both Channels (static segment only)	Channel A or B (store first semantically valid Frame, static segment only)
1	0	Channel A	Channel A
0	1	Channel B	Channel B
0	0	No Transmission	Ignore Frame

1) If a Message Buffer is configured for the dynamic segment and both bits of the channel filtering field are set to 1, no Frames are transmitted resp. received Frames are ignored (same function as CHA = CHB = 0)

Read Header Section 2 (RDHS2)

RDHS2
Read Header Section 2 **(0704_H)** **Reset Value: $0000\ 0000_H$**



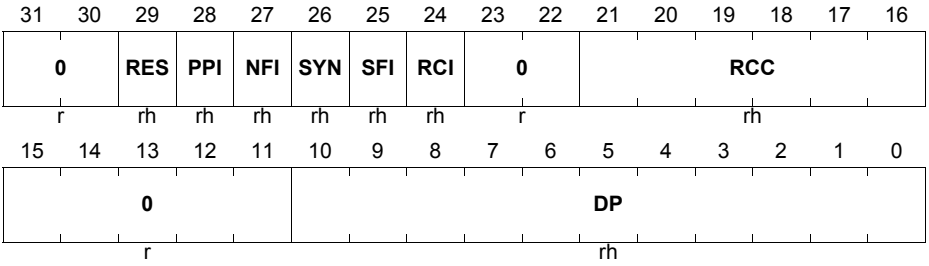
Field	Bits	Type	Description
CRC	[10:0]	rh	**Header CRC** (vRF!Header!HeaderCRC) Receive Buffer: Configuration not required. Header CRC updated from receive Data Frames. Transmit Buffer: Header CRC calculated and configured by the Host
PLC	[22:16]	rh	**Payload Length Configured** Length of Data Section (number of 2-byte words) as configured by the Host.

Field	Bits	Type	Description
PLR	[30:24]	rh	**Payload Length Received** (vRF!Header!Length) Payload length value updated from received Data Frame (exception: if Message Buffer belongs to the receive FIFO PLR is also updated from received NULL Frames). When a message is stored into a Message Buffer the following behavior with respect to payload length received and payload length configured is implemented: • **PLR > PLC:** The payload data stored in the Message Buffer is truncated to the payload length configured for even PLC or else truncated to PLC + 1. • **PLR ≤ PLC:** The received payload data is stored into the Message Buffers Data Section. The remaining data bytes of the Data Section as configured by PLC are filled with undefined data. • **PLR = 0:** The Message Buffer's Data Section is filled with undefined data. • **PLC = 0:** Message Buffer has no Data Section configured. No data is stored into the Message Buffer's Data Section.
0	[15:11], 23, 31	r	**Reserved** Returns 0 if read; should be written with 0.

Note: The Message RAM is organized in 4-byte words. When received data is stored into a Message Buffer's Data Section, the number of 2-byte data words written into the Message Buffer is PLC rounded to the next even value. PLC should be configured identical for all Message Buffers belonging to the receive FIFO. Header 2 is updated from Data Frames only.

Read Header Section 3 (RDHS3)

RDHS3
Read Header Section 3 **(0708_H)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
DP	[10:0]	rh	**Data Pointer** Pointer to the first 32-bit word of the Data Section of the addressed Message Buffer in the Message RAM.
RCC	[21:16]	rh	**Receive Cycle Count** (vRF!Header!CycleCount) Cycle counter value updated from received Data Frame.
RCI	24	rh	**Received on Channel Indicator** (vSS!Channel) Indicates the channel from which the received Data Frame was taken to update the respective receive buffer. 0_B Frame received on channel B 1_B Frame received on channel A
SFI	25	rh	**Startup Frame Indicator** (vRF!Header!SuFIndicator) A Startup Frame is marked by the Startup Frame indicator. 0_B The received Frame is not a startup Frame 1_B The received Frame is a startup Frame
SYN	26	rh	**SYNC Frame Indicator** (vRF!Header!SyFIndicator) A SYNC Frame is marked by the SYNC Frame indicator. 0_B The received Frame is not a SYNC Frame 1_B The received Frame is a SYNC Frame
NFI	27	rh	**NULL Frame Indicator** (vRF!Header!NFIndicator) Is set to 1 after storage of the first received Data Frame. 0_B Up to now no Data Frame has been stored into the respective Message Buffer 1_B At least one Data Frame has been stored into the respective Message Buffer

Field	Bits	Type	Description
PPI	28	rh	**Payload Preamble Indicator** (vRF!Header!PPIndicator) The payload preamble indicator defines whether a Network Management vector or message ID is contained within the Payload Segment of the received Frame. 0_B The Payload Segment of the received Frame does not contain a Network Management vector nor a message ID 1_B Static segment: Network Management vector in the first part of the payload Dynamic segment: Message ID in the first part of the payload
RES	29	rh	**Reserved Bit** (vRF!Header!Reserved) Reflects the state of the received reserved bit. The reserved bit is transmitted as 0.
0	[15:11], [23:22], [31:30]	r	**Reserved** Returns 0 if read; should be written with 0.

Note: Header 3 is updated from Data Frames only.

Message Buffer Status (MBS)

The Message Buffer status is updated by the Communication Controller with respect to the assigned channel(s) latest at the end of the slot following the slot assigned to the Message Buffer. The flags are updated only when the Communication Controller is in “NORMAL_ACTIVE” or “NORMAL_PASSIVE” state. If only one channel (A or B) is assigned to a Message Buffer, the channel-specific status flags of the other channel are written to zero. If both channels are assigned to a Message Buffer, the channel-specific status flags of both channels are updated. The Message Buffer status is updated only when the slot counter reached the configured Frame ID and when the cycle counter filter matched. When the Host updates a Message Buffer via Input Buffer, all MBS flags are reset to zero independent of which IBCM bits are set or not. For details about receive / transmit filtering see **“Filtering and Masking” on Page 26-222**, **“Transmit Process” on Page 26-226**, and **“Receive Process” on Page 26-229**.

Whenever the Message Handler changes one of the flags VFRA, VFRB, SEOA, SEOB, CEOA, CEOB, SVOA, SVOB, TCIA, TCIB, ESA, ESB, MLST, FTA, FTB the respective Message Buffer’s MBC flag in registers MBSC1 to MBSC4 is set

MBS

Message Buffer Status **($070C_H$)** **Reset Value: $0000\ 0000_H$**

Field	Bits	Type	Description
VFRA	0	rh	**Valid Frame Received on Channel A** (vSS!ValidFrameA) A valid Frame indication is set if a valid Frame was received on channel A. 0_B No valid Frame received on channel A 1_B Valid Frame received on channel A
VFRB	1	rh	**Valid Frame Received on Channel B** (vSS!ValidFrameB) A valid Frame indication is set if a valid Frame was received on channel B. 0_B No valid Frame received on channel B 1_B Valid Frame received on channel B

Field	Bits	Type	Description
SEOA	2	rh	**Syntax Error Observed on Channel A** (vSS!SyntaxErrorA) A syntax error was observed in the assigned slot on channel A. 0_B No syntax error observed on channel A 1_B Syntax error observed on channel A
SEOB	3	rh	**Syntax Error Observed on Channel B** (vSS!SyntaxErrorB) A syntax error was observed in the assigned slot on channel B. 0_B No syntax error observed on channel B 1_B Syntax error observed on channel B
CEOA	4	rh	**Content Error Observed on Channel A** (vSS!ContentErrorA) A content error was observed in the assigned slot on channel A. 0_B No content error observed on channel A 1_B Content error observed on channel A
CEOB	5	rh	**Content Error Observed on Channel B** (vSS!ContentErrorB) A content error was observed in the assigned slot on channel B. 0_B No content error observed on channel B 1_B Content error observed on channel B
SVOA	6	rh	**Slot Boundary Violation Observed on Channel A** (vSS!BViolationA) A slot boundary violation (channel active at the start or at the end of the assigned slot) was observed on channel A. 0_B No slot boundary violation observed on channel A 1_B Slot boundary violation observed on channel A
SVOB	7	rh	**Slot Boundary Violation Observed on Channel B** (vSS!BViolationB) A slot boundary violation (channel active at the start or at the end of the assigned slot) was observed on channel B. 0_B No slot boundary violation observed on channel B 1_B Slot boundary violation observed on channel B
TCIA	8	rh	**Transmission Conflict Indication Channel A** (vSS!TxConflictA) A transmission conflict indication is set if a transmission conflict has occurred on channel A. 0_B No transmission conflict occurred on channel A 1_B Transmission conflict occurred on channel A

Field	Bits	Type	Description
TCIB	9	rh	**Transmission Conflict Indication Channel B** (vSS!TxConflictB) A transmission conflict indication is set if a transmission conflict has occurred on channel B. 0_B No transmission conflict occurred on channel B 1_B Transmission conflict occurred on channel B
ESA	10	rh	**Empty Slot Channel A** In an empty slot there is no activity detected on the bus. The condition is checked in static and dynamic slots. 0_B Bus activity detected in the assigned slot on channel A 1_B No bus activity detected in the assigned slot on channel A
ESB	11	rh	**Empty Slot Channel B** In an empty slot there is no activity detected on the bus. The condition is checked in static and dynamic slots. 0_B Bus activity detected in the assigned slot on channel B 1_B No bus activity detected in the assigned slot on channel B
MLST	12	rh	**Message Lost** The flag is set in case the Host did not read the message before the Message Buffer was updated from a received Data Frame. Not affected by reception of NULL Frames except for Message Buffers belonging to the receive FIFO. The flag is reset by a Host write to the Message Buffer via IBF or when a new message is stored into the Message Buffer after the Message Buffers ND flag was reset by reading out the Message Buffer via OBF. 0_B No message lost 1_B Unprocessed message was overwritten
FTA	14	rh	**Frame Transmitted on Channel A** Indicates that this node has transmitted a Data Frame in the assigned slot on channel A. 0_B No transmission transmitted on channel A 1_B Data Frame transmitted on channel A in cycle defined by CCS bit field *Note: The FlexRay™ protocol specification requires that FTA can only be reset by the Host. Therefore the Cycle Count Status CCS for these bits is only valid for the cycle where the bits are set to 1*

Field	Bits	Type	Description
FTB	15	rh	**Frame Transmitted on Channel B** Indicates that this node has transmitted a Data Frame in the assigned slot on channel B. 0_B No transmission transmitted on channel B 1_B Data Frame transmitted on channel B in cycle defined by CCS bit field *Note: The FlexRay™ protocol specification requires that FTB can only be reset by the Host. Therefore the Cycle Count Status CCS for these bits is only valid for the cycle where the bits are set to 1*
CCS	[21:16]	rh	**Cycle Count Status** Cycle Count when status (MBS register) has been updated.
RCIS	24	rh	**Received on Channel Indicator Status** (vSS!Channel) Indicates the channel on which the Frame was received. 0_B Frame received on channel B 1_B Frame received on channel A *Note: For receive buffers (CFG = 0) the RCIS is updated from both valid data and NULL Frames. If no valid Frame was received, the previous value is maintained. For transmit buffers the flags have no meaning and should be ignored.*
SFIS	25	rh	**Startup Frame Indicator Status** (vRF!Header!SuFIndicator) A Startup Frame is marked by the Startup Frame indicator. 0_B No Startup Frame received 1_B The received Frame is a startup Frame *Note: For receive buffers (CFG = 0) the SFIS is updated from both valid data and NULL Frames. If no valid Frame was received, the previous value is maintained. For transmit buffers the flags have no meaning and should be ignored.*
SYNS	26	rh	**SYNC Frame Indicator Status** (vRF!Header!SyFIndicator) A Startup Frame is marked by the Startup Frame indicator. 0_B No SYNC Frame received 1_B The received Frame is a SYNC Frame *Note: For receive buffers (CFG = 0) the SYNS is updated from both valid data and NULL Frames. If no valid Frame was received, the previous value is maintained. For transmit buffers the flags have no meaning and should be ignored.*

Field	Bits	Type	Description
NFIS	27	rh	**NULL Frame Indicator Status** (vRF!Header!NFIndicator) If reset to 0 the Payload Segment of the received Frame contains no usable data. 0_B Received Frame is a NULL Frame 1_B Received Frame is not a NULL Frame *Note: For receive buffers (CFG = 0) the NFIS is updated from both valid data and NULL Frames. If no valid Frame was received, the previous value is maintained. For transmit buffers the flags have no meaning and should be ignored.*
PPIS	28	rh	**Payload Preamble Indictor Status** (vRF!Header!PPIndicator) The payload preamble indicator defines whether a Network Management vector or message ID is contained within the Payload Segment of the received Frame. Static Segment: 0_B The Payload Segment of the received Frame does not contain a Network Management vector or a message ID 1_B Network Management vector at the beginning of the payload Dynamic Segment: 0_B The Payload Segment of the received Frame does not contain a Network Management vector or a message ID 1_B Message ID at the beginning of the payload *Note: For receive buffers (CFG = 0) the PPIS is updated from both valid data and NULL Frames. If no valid Frame was received, the previous value is maintained. For transmit buffers the flags have no meaning and should be ignored.*
RESS	29	rh	**Reserved Bit Status** (vRF!Header!Reserved) Reflects the state of the received reserved bit. The reserved bit is transmitted as 0. *Note: For receive buffers (CFG = 0) the RESS is updated from both valid data and NULL Frames. If no valid Frame was received, the previous value is maintained. For transmit buffers the flags have no meaning and should be ignored.*
0	13, [23:22], [31:30]	r	**Reserved** Returns 0 if read; should be written with 0.

Output Buffer Command Mask (OBCM)

Configures how the Output Buffer is updated from the Message Buffer in the Message RAM selected by the Output Buffer Command Request register. If OBF Host and OBF Shadow are swapped, also mask bits OBCM.RDSH and OBCM.RHSH are swapped with bits OBCM.RDSS and OBCM.RHSS to keep them attached to the respective Output Buffer transfer.

OBCM
Output Buffer Command Mask **(0710_H)** **Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0														RDSH	RHSH
r														rh	rh

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0														RDSS	RHSS
r														rwh	rwh

Field	Bits	Type	Description
RHSS	0	rwh	**Read Header Section Shadow** 0_B Header Section is not read 1_B Header Section selected for transfer from Message RAM to Output Buffer
RDSS	1	rwh	**Read Data Section Shadow** 0_B Data Section is not read 1_B Data Section selected for transfer from Message RAM to Output Buffer
RHSH	16	rh	**Read Header Section Host** 0_B Header Section is not read 1_B Header Section selected for transfer from Message RAM to Output Buffer
RDSH	17	rh	**Read Data Section Host** 0_B Data Section is not read 1_B Data Section selected for transfer from Message RAM to Output Buffer
0	[15:2], [31:18]	r	**Reserved** Returns 0 if read; should be written with 0.

Note: After the transfer of the Header Section from the Message RAM to OBF Shadow has completed, the Message Buffer status changed flag MBCn (n = 0-31) to MBCn (n = 96-127) of the selected Message Buffer in the Message Buffer Changed MBSC1 to MBSC4 registers is cleared. After the transfer of the Data Section from the Message RAM to OBF Shadow has completed, the New Data flag NDn (n = 0-31) to NDn (n = 96-127) of the selected Message Buffer in the New Data NDAT1 to NDAT4 registers is cleared.

Output Buffer Command Request (OBCR)

The Message Buffer selected by OBCR.OBRS is transferred from the Message RAM to the Output Buffer as soon as the Host has set OBCR.REQ. Bit OBCR.REQ can only be set while OBCR.OBSYS is 0 (see also **"Data Transfer from Message RAM to Output Buffer" on Page 26-235**).

After setting OBCR.REQ, OBCR.OBSYS is automatically set, and the transfer of the Message Buffer selected by OBCR.OBRS from the Message RAM to Output Buffer Shadow is started. When the transfer between the Message RAM and OBF Shadow has completed, this is signalled by clearing OBCR.OBSYS. By setting OBCR.VIEW while OBCR.OBSYS is 0, OBF Host and OBF Shadow are swapped. When Output Buffer Host and Output Buffer Shadow are swapped, also mask bits OBCM.RDSH and OBCM.RHSH are swapped with bits OBCM.RDSS and OBCM.RHSS to keep them attached to the respective Output Buffer transfer. Now the Host can read the transferred Message Buffer from OBF Host. In parallel the Message Handler may transfer the next message from the Message RAM to OBF Shadow if OBCR.VIEW and OBCR.REQ are set at the same time.

Any write access to an Output Buffer register while OBCR.OBSYS is set will cause the error flag EIR.IOBA to be set. In this case the Output Buffer will not be changed.

OBCR

Output Buffer Command Request (0714$_H$) **Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0									OBRH

OBSYS	0					REQ	VIEW	0	OBRS						
rh	r					rw	rw	r	rwh						

Field	Bits	Type	Description
OBRS	[6:0]	rw	**Output Buffer Request Shadow** Number of source Message Buffer to be transferred from the Message RAM to OBF Shadow. Valid values are 00_H to $7F_H$ (0 to 127). If the number of the first Message Buffer of the receive FIFO is written to this register the Message Handler transfers the Message Buffer addressed by the GET Index Register (GIDX, **"FIFO Function" on Page 26-230**) to OBF Shadow.
VIEW	8	rw	**View Shadow Buffer** Toggles between OBF Shadow and OBF Host. Only writeable while OBCR.OBSYS = 0. 0_B No action 1_B Swap OBF Shadow and OBF Host
REQ	9	rw	**Request Message RAM Transfer** Requests transfer of Message Buffer addressed by OBCR.OBRS from Message RAM to OBF Shadow. Only writeable while OBCR.OBSYS = 0. 0_B No request 1_B Transfer to OBF Shadow requested
OBSYS	15	rh	**Output Buffer Busy Shadow** Set to 1 after setting bit OBCR.REQ. When the transfer between the Message RAM and OBF Shadow has completed, OBCR.OBSYS is cleared again. 0_B No transfer in progress 1_B Transfer between Message RAM and OBF Shadow in progress

Field	Bits	Type	Description
OBRH	[22:16]	rh	**Output Buffer Request Host** Number of Message Buffer currently accessible by the Host via RDHS1 to RDHS3, MBS, and RDDSnn (nn = 01-64). By setting OBCR.VIEW OBF Shadow and OBF Host are swapped and the transferred Message Buffer is accessible by the Host. Valid values are 00_H to $7F_H$ (01 to 27).
0	7, [14:10], [31:23]	r	**Reserved** Returns 0 if read; should be written with 0.

26.6 Functional Description

This chapter describes the E-Ray implementation together with the related FlexRay™ protocol features. More information about the FlexRay™ protocol itself can be found in the FlexRay™ protocol specification v2.1.

Communication on FlexRay™ networks is based on Frames and symbols. The wakeup symbol (WUS) and the collision avoidance symbol (CAS) are transmitted outside the communication cycle to setup the time schedule. Frames and media access test symbols (MTS) are transmitted inside the communication cycle.

26.6.1 Communication Cycle

A communication cycle in FlexRay™ consists of the following elements:

- Static Segment
- Dynamic Segment
- Symbol Window
- Network Idle Time (NIT)

Static segment, dynamic segment, and symbol window form the Network Communication Time (NCT). For each communication channel the slot counter starts at 1 and counts up until the end of the dynamic segment is reached. Both channels share the same arbitration grid which means that they use the same synchronized Macrotick.

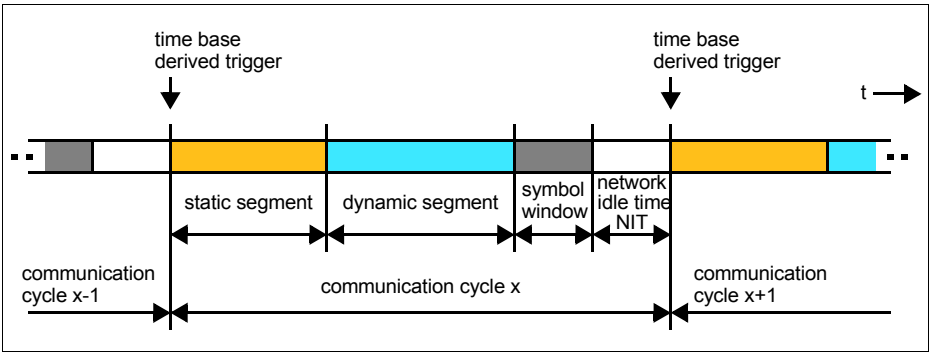

Figure 26-4 Structure of Communication Cycle

26.6.1.1 Static Segment

The Static Segment is characterized by the following features:

- Time slots of fixed length (optionally protected by bus guardian)
- Start of Frame transmission at action point of the respective static slot
- Payload length same for all Frames on both channel

Parameters: Number of Static Slots **GTUC07.NSS**, Static Slot Length **GTUC07.SSL**, Payload Length Static **MHDC.SFDL**, Action Point Offset **GTUC09.APO**.

26.6.1.2 Dynamic Segment

The Dynamic Segment is characterized by the following features:

- All controllers have bus access (no bus guardian protection possible)
- Variable payload length and duration of slots, different for both channels
- Start of transmission at minislot action point

Parameters: Number of Minislots **GTUC08.NMS**, Minislot Length **GTUC08.MSL** Minislot Action Point Offset **GTUC09.MAPO**, Start of Latest Transmit (last minislot) **MHDC.SLT**.

26.6.1.3 Symbol Window

During the symbol window only one media access test symbol (MTS) may be transmitted per channel. MTS symbols are send in “NORMAL_ACTIVE” state to test the bus guardian.

The symbol window is characterized by the following features:

- Send single symbol
- Transmission of the MTS symbol starts at the symbol windows action point

Parameters: Symbol Window Action Point Offset **GTUC09.APO** (same as for static slots), Network Idle Time Start **GTUC04.NIT**.

26.6.1.4 Network Idle Time (NIT)

During network idle time the Communication Controller has to perform the following tasks:

- Calculate clock correction terms (offset and rate)
- Distribute offset correction over multiple Macroticks
- Perform cluster cycle related tasks

Parameters: Network Idle Time Start **GTUC04.NIT**, Offset Correction Start **GTUC04.OCS**.

26.6.1.5 Configuration of Network Idle Time (NIT) Start and Offset Correction Start

The number of Macroticks per cycle (gMacroPerCycle) is assumed to be m. It is configured by programming **GTUC02.MPC** = m.

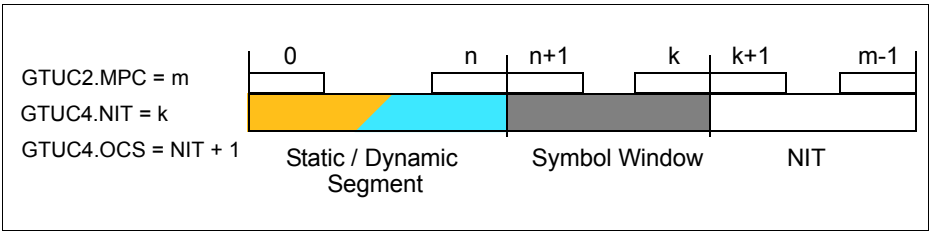

Figure 26-5 Configuration of network idle time (NIT) start and offset correction start

The static / dynamic segment starts with Macrotick 0 and ends with Macrotick n:
n = static segment length + dynamic segment offset + dynamic segment length - 1 Macrotick

n = gNumberOfStaticSlots • gdStaticSlot + dynamic segment offset
+ gNumberOfMinislots • gdMinislot - 1 Macroticks

The static segment length is configured by **GTUC07.SSL** and **GTUC07.NSS**.
The dynamic segment length is configured by **GTUC08.MSL** and **GTUC08.NMS**.

The dynamic segment offset is:

If gdActionPointOffset ≤ gdMinislotActionPointOffset:

dynamic segment offset = 0 MT

Else if gdActionPointOffset > gdMinislotActionPointOffset:

dynamic segment offset = gdActionPointOffset - gdMinislotActionPointOffset

The network idle time (NIT) starts with Macrotick k+1 and ends with the last Macrotick of cycle m-1. It has to be configured by setting **GTUC04.NIT** = k.

For the E-Ray the offset correction start is required to be

GTUC04.OCS ≥ **GTUC04.NIT** + 1 = k+1.

The length of symbol window results from the number of Macroticks between the end of the static / dynamic segment and the beginning of the NIT. It can be calculated by k - n.

26.6.2 Communication Modes

The FlexRay™ Protocol Specification v2.1 defines the Time-Triggered Distributed (TT-D) mode.

Time-triggered Distributed (TT-D)

In TT-D mode the following configurations are possible:

- **Pure static**: minimum 2 static slots + symbol window (optional)
- **Mixed static/dynamic**: minimum 2 static slots + dynamic segment + symbol window (optional)

A minimum of two coldstart nodes need to be configured for distributed time-triggered operation. Two fault-free coldstart nodes are necessary for the cluster startup. Each Startup Frame must be a SYNC Frame, therefore all coldstart nodes are sync nodes.

26.6.3 Clock Synchronization

In TT-D mode a distributed clock synchronization is used. Each node individually synchronizes itself to the cluster by observing the timing of received SYNC Frames from other nodes.

26.6.3.1 Global Time

Activities in a FlexRay™ node, including communication, are based on the concept of a global time, even though each individual node maintains its own view of it. It is the clock synchronization mechanism that differentiates the FlexRay™ cluster from other node collections with independent clock mechanisms. The global time is a vector of two values; the cycle (cycle counter) and the cycle time (Macrotick counter).

Cluster specific:

- Macrotick = basic unit of time measurement in a FlexRay™ network, a Macrotick consists of an integer number of Microticks
- Cycle length = duration of a communication cycle in units of Macroticks

26.6.3.2 Local Time

Internally, nodes time their behavior with Microtick resolution. Microticks are time units derived from the oscillator clock tick of the specific node. Therefore Microticks are controller-specific units. They may have different duration in different controllers. The precision of a node's local time difference measurements is a Microtick.

Node specific:

- Oscillator clock → prescaler → Microtick
- Microtick = basic unit of time measurement in a Communication Controller, clock correction is done in units of Microticks
- Cycle counter + Macrotick counter = nodes local view of the global time

26.6.3.3 Synchronization Process

Clock synchronization is performed by means of SYNC Frames. Only preconfigured nodes (sync nodes) are allowed to send SYNC Frames. In a two-channel cluster a sync node has to send its SYNC Frame on both channels.

For synchronization in FlexRay™ the following constraints have to be considered:

- Max. one SYNC Frame per node in one communication cycle
- Max. 15 SYNC Frames per cluster in one communication cycle
- Every node has to use all available SYNC Frames for clock synchronization
- Minimum of two sync nodes required for clock synchronization and startup

For clock synchronization the time difference between expected and observed arrival time of SYNC Frames received during the static segment, valid on both channels (two-channel cluster), is measured. The calculation of correction terms is done during network idle time (NIT) (offset: every cycle, rate: odd cycle) by using a FTA / FTM algorithm. For details see FlexRay™ protocol specification v2.1, chapter 8.

Offset (phase) Correction

- Only deviation values measured and stored in the current cycle used
- For a two channel node the smaller value will be taken
- Calculation during network idle time (NIT) of **every** communication cycle, value may be negative
- Offset correction value calculated in even cycles used for error checking only
- Checked against limit values (violation: “NORMAL_ACTIVE” → “NORMAL_PASSIVE” → “HALT”)
- Correction value is an integer number of Microticks
- Correction done in **odd** numbered cycles, distributed over the Macroticks beginning at offset correction start up to cycle end (end of network idle time (NIT)) to shift nodes next start of cycle (Macroticks lengthened / shortened)

Rate (frequency) Correction

- Pairs of deviation values measured and stored in even / odd cycle pair used
- For a two channel node the average of the differences from the two channels is used
- Calculated during network idle time (NIT) of **odd** numbered cycles, value may be negative
- Cluster drift damping is performed using global damping value

- Checked against limit values
- Correction value is a signed integer number of Microticks
- Distributed over Macroticks comprising the next **even / odd** cycle pair (Macroticks lengthened / shortened)

Synchronization Process

Clock synchronization is performed by means of SYNC Frames. Only preconfigured nodes (sync nodes) are allowed to send SYNC Frames. In a two-channel cluster a sync node has to send its SYNC Frame on both channels.

For synchronization in FlexRay™ the following constraints have to be considered:

- Max. one SYNC Frame per node in one communication cycle
- Max. 15 SYNC Frames per cluster in one communication cycle
- Every node has to use all available SYNC Frames for clock synchronization
- Minimum of two sync nodes required for clock synchronization and startup

For clock synchronization the time difference between expected and observed arrival time of SYNC Frames received during the static segment, valid on both channels (two-channel cluster), is measured. The calculation of correction terms is done during network idle time (NIT) (offset: every cycle, rate: odd cycle) by using a FTA / FTM algorithm. For details see FlexRay™ protocol specification v2.1, chapter 8.

SYNC Frame Transmission

SYNC Frame transmission is only possible from buffer 0 and 1. Message Buffer 1 may be used for SYNC Frame transmission in case that SYNC Frames should have different payloads on the two channels. In this case bit **MRC.SPLM** has to be programmed to 1.

Message Buffers used for SYNC Frame transmission have to be configured with the key slot ID and can be (re)configured in “DEFAULT_CONFIG” or “CONFIG” state only. For nodes transmitting SYNC Frames **SUCC1.TXSY** must be set to 1.

26.6.3.4 External Clock Synchronization

During normal operation, independent clusters can drift significantly. If synchronous operation across independent clusters is desired, external synchronization is necessary; even though the nodes within each cluster are synchronized. This can be accomplished with synchronous application of host-deduced rate and offset correction terms to the clusters.

- External offset / rate correction value is a signed integer
- External offset / rate correction value is added to calculated offset / rate correction value
- Aggregated offset / rate correction term (external + internal) is not checked against configured limits

26.6.4 Error Handling

The implemented error handling concept is intended to ensure that in case of a lower layer protocol error in a single node communication between non-affected nodes can be maintained. In some cases, higher layer program command activity is required for the Communication Controller to resume normal operation. A change of the error handling state will set bit **EIR.PEMC** in the Error Service Request Register and may trigger an service request to the Host if enabled. The actual error mode is signalled by **CCEV.ERRM** in the Communication Controller Error Vector register.

Table 26-10 Error Modes of the POC (Degradation Model)

Error Mode	Activity
ACTIVE (green)	**Full operation**, State: “NORMAL_ACTIVE” The Communication Controller is fully synchronized and supports the cluster wide clock synchronization. The host is informed of any error condition(s) or status change by interrupt (if enabled) or by reading the error and status interrupt flags from registers **EIR** and **SIR**.
PASSIVE (yellow)	**Reduced operation**, State: “NORMAL_PASSIVE”, Communication Controller self rescue allowed The Communication Controller stops transmitting Frames and symbols, but received Frames are still processed. Clock synchronization mechanisms are continued based on received Frames. No active contribution to the cluster wide clock synchronization. The host is informed of any error condition(s) or status change by interrupt (if enabled) or by reading the error and status interrupt flags from registers **EIR** and **SIR**.
COMM_HALT (red)	**Operation halted**, State: “HALT”, Communication Controller self rescue not allowed The Communication Controller stops Frame and symbol processing, clock synchronization processing, and the Macrotick generation. The host has still access to error and status information by reading the error and status interrupt flags from registers **EIR** and **SIR**. The bus drivers are disabled.

26.6.4.1 Clock Correction Failed Counter

When the Clock Correction Failed Counter reaches the maximum “without clock correction passive” limit defined by **SUCC3.WCP**, the POC transits from “NORMAL_ACTIVE” to “NORMAL_PASSIVE” state. When it reaches the “maximum without clock correction fatal” limit defined by **SUCC3.WCF**, it transits “NORMAL_ACTIVE” or “NORMAL_PASSIVE” to the “HALT” state. Both limits are defined in the SUC Configuration Register 3.

The Clock Correction Failed Counter **CCEV.CCFC** allows the Host to monitor the duration of the inability of a node to compute clock correction terms after the Communication Controller passed protocol startup phase. It will be incremented by one at the end of any **odd** numbered communication cycle where either the Missing Offset Correction signal **SFS.MOCS** nor the Missing Rate Correction signal **SFS.MRCS** flag is set. The two flags are located in the SYNC Frame Status register, while the Clock Correction Failed Counter is located in the Communication Controller Error Vector register.

The Clock Correction Failed Counter is reset to zero at the end of an **odd** communication cycle if neither the Missing Offset Correction signal **SFS.MOCS** nor the Missing Rate Correction signal **SFS.MRCS** flag is set.

The Clock Correction Failed Counter stops incrementing when the “maximum without clock correction fatal” value **SUCC3.WCF** as defined in the SUC Configuration Register 3 is reached (i.e. incrementing the counter at its maximum value will not cause it to “wraparound” back to zero). The Clock Correction Failed Counter is initialized to zero when the Communication Controller enters “READY” state or when “NORMAL_ACTIVE” state is entered.

26.6.4.2 Passive to Active Counter

The passive to active counter controls the transition of the POC from “NORMAL_PASSIVE” to “NORMAL_ACTIVE” state. **SUCC1.PTA** in the SUC Configuration Register 1 defines the number of consecutive even / odd cycle pairs that must have valid clock correction terms before the Communication Controller is allowed to transit from “NORMAL_PASSIVE” to “NORMAL_ACTIVE” state. If **SUCC1.PTA** is reset to zero the Communication Controller is not allowed to transit from “NORMAL_PASSIVE” to “NORMAL_ACTIVE” state.

26.6.4.3 HALT Command

In case the Host wants to stop FlexRay™ communication of the local node it can bring the Communication Controller into “HALT” state by asserting the HALT command. This can be done by writing **SUCC1.CMD** = 0110_B in the SUC Configuration Register 1. When called in “NORMAL_ACTIVE” or “NORMAL_PASSIVE” state the POC transits to “HALT” state at the end of the current cycle. When called in any other state **SUCC1.CMD** will be reset to 0000_B = “COMMAND_NOT_ACCEPTED” and bit **EIR.CNA** in the Error Service Request Register is set to 1. If enabled an service request to the Host is generated.

26.6.4.4 FREEZE Command

In case the Host detects a severe error condition it can bring the Communication Controller into “HALT” state by asserting the FREEZE command. This can be done by writing **SUCC1.CMD** = 0111_B in the SUC Configuration Register 1. The FREEZE

command triggers the entry of the “HALT” state immediately regardless of the actual POC state.

The POC state from which the transition to HALT state took place can be read from **CCSV.PSL**.

26.6.5 Communication Controller States

This chapter introduces the states of the Communication Controller.

26.6.5.1 Communication Controller State Diagram

State transitions are controlled by externals the application reset or RXDA/B, by the POC state machine, and by the CHI Command Vector **SUCC1.CMD** located in the SUC Configuration Register 1.

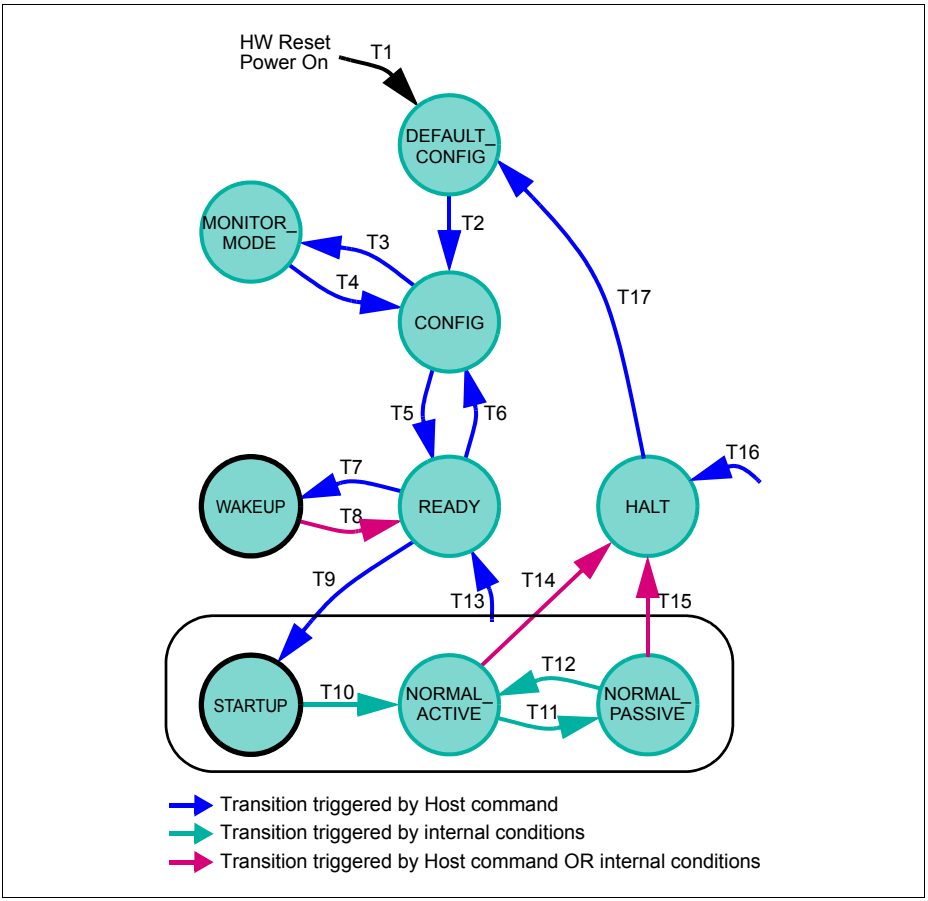

Figure 26-6 Overall State Diagram of E-Ray Communication Controller

The Communication Controller exits from all states to “HALT” state after application of the FREEZE command (SUCC1.CMD = 0111_B).

Table 26-11 State Transitions of E-Ray Overall State Machine

T#	Condition	From	To
1	application reset	HW Reset	DEFAULT_CONFIG
2	Command CONFIG, SUCC1.CMD = 0001_B	DEFAULT_CONFIG	CONFIG
3	Unlock sequence followed by command MONITOR_MODE, SUCC1.CMD = 1011_B	CONFIG	MONITOR_MODE
4	Command CONFIG, SUCC1.CMD = 0001_B	MONITOR_MODE	CONFIG
5	Unlock sequence followed by command READY, SUCC1.CMD = 0010_B	CONFIG	READY
6	Command CONFIG, SUCC1.CMD = 0001_B	READY	CONFIG
7	Command WAKEUP, SUCC1.CMD = 0011_B	READY	WAKEUP
8	Complete, non-aborted transmission of wakeup pattern OR received WUP OR received Frame Header OR command READY, SUCC1.CMD = 0010_B	WAKEUP	READY
9	Command RUN, SUCC1.CMD = 0100_B	READY	STARTUP
10	Successful startup	STARTUP	NORMAL_ACTIVE
11	Clock Correction Failed counter reached Maximum Without Clock Correction Passive limit configured by WCP in SUC Configuration Register 3	NORMAL_ACTIVE	NORMAL_PASSIVE
12	Number of valid correction terms reached the Passive to Active limit configured by PTA in SUC Configuration Register 1	NORMAL_PASSIVE	NORMAL_ACTIVE
13	Command READY, SUCC1.CMD = 0010_B	STARTUP, NORMAL_ACTIVE, NORMAL_PASSIVE	READY

Table 26-11 State Transitions of E-Ray Overall State Machine (cont'd)

T#	Condition	From	To
14	Clock Correction Failed counter reached Maximum Without Clock Correction Fatal limit configured by WCF in SUC Configuration Register 3 AND bit HCSE in the SUC Configuration Register 1 set to 1 OR command HALT, SUCC1.CMD = 0110_B	NORMAL_ACTIVE	HALT
15	Clock Correction Failed counter reached Maximum Without Clock Correction Fatal limit configured by WCF in SUC Configuration Register 3 AND bit HCSE in the SUC Configuration Register 1 set to 1 OR command HALT, SUCC1.CMD = 0110_B	NORMAL_PASSIVE	HALT
16	Command FREEZE, SUCC1.CMD = 0111_B	All States	HALT
17	Command CONFIG, SUCC1.CMD = 0001_B	HALT	DEFAULT_CONFIG

26.6.5.2 DEFAULT_CONFIG State

In "DEFAULT_CONFIG" state, the Communication Controller is stopped. All configuration registers are accessible and the pins to the physical layer are in their inactive state.

The Communication Controller enters this state

- When leaving application reset
- When exiting from "HALT" state

To leave "DEFAULT_CONFIG" state the Host has to write SUCC1.CMD = 0001_B in the SUC Configuration Register 1. The Communication Controller transits to "CONFIG" state.

CONFIG State

In "CONFIG" state, the Communication Controller is stopped. All configuration registers are accessible and the pins to the physical layer are in their inactive state. This state is used to initialize the Communication Controller configuration.

The Communication Controller enters this state

- When exiting from “DEFAULT_CONFIG” state
- When exiting from “MONITOR_MODE” or “READY” state

When the state has been entered via “HALT” and “DEFAULT_CONFIG” state, the Host can analyze status information and configuration. Before leaving “CONFIG” state the Host has to assure that the configuration is fault-free.

To leave “CONFIG” state, the Host has to perform the unlock sequence as described on **“LCK” on Page 26-39**. Directly after unlocking the “CONFIG” state the Host has to write **SUCC1.CMD** in the SUC Configuration Register 1 to enter the next state.

Internal counters and the Communication Controller status flags are reset when the Communication Controller leaves “CONFIG”.

*Note: The Message Buffer Status Registers (**MHDS**, **TXRQ1** to **TXRQ4**, **NDAT1** to **NDAT4**, **MBSC1** to **MBSC4**) and status data stored in the Message RAM and are not affected by the transition of the POC from “CONFIG” to “READY” state.*

When the Communication Controller is in “CONFIG” state it is also possible to bring the Communication Controller into a power saving mode by halting the module clocks (f_{SCLK}, f_{CLC_ERAY}). To do this the Host has to assure that all Message RAM transfers have finished before turning off the clocks.

26.6.5.3 MONITOR_MODE

After unlocking “CONFIG” state and writing **SUCC1.CMD** = 0011_B the Communication Controller enters “MONITOR_MODE”. In this mode the Communication Controller is able to receive FlexRay™ Frames and to detect wakeup pattern. The temporal integrity of received Frames is not checked, and therefore cycle counter filtering is not supported. It is not possible to distinguish between static and dynamic frames, because limited functions in Monitor Mode (FRF.RSS will be ignored, filtering not functional).This mode can be used for debugging purposes in case e.g. that startup of a FlexRay™ network fails. After writing **SUCC1.CMD** = 0001_B the Communication Controller transits back to “CONFIG” state.

In MONITOR_MODE the pick first valid mechanism is disabled. This means that a receive Message Buffer may only be configured to receive on one channel. Received Frames are stored into Message Buffers according to Frame ID and receive channel. NULL Frames are handled like Data Frames. After Frame reception only status bits **MBS.VFRA**, **MBS**, **MBS.MLST**, **MBS.RCIS**, **MBS.SFIS**, **MBS.SYNS**, **MBS.NFIS**, **MBS.PPIS**, **MBS.RESS** have valid value.

In “MONITOR_MODE” the Communication Controller is not able to distinguish between CAS and MTS symbols. In case one of these symbols is received on one or both of the two channels, the flags **SIR.MTSA** resp. **SIR.MTSB** are set. **SIR.CAS** has no function in “MONITOR_MODE”.

26.6.5.4 READY State

After unlocking “CONFIG” state and writing **SUCC1.CMD** = 0010_B the Communication Controller enters “READY” state. From this state the Communication Controller can transit to WAKEUP state and perform a cluster wakeup or to “STARTUP” state to perform a coldstart or to integrate into a running communication.

The Communication Controller enters this state

- When exiting from “CONFIG”, “WAKEUP”, “STARTUP”, “NORMAL_ACTIVE”, or “NORMAL_PASSIVE” state by writing **SUCC1.CMD** = 0010_B (READY command).

The Communication Controller exits from this state

- To “CONFIG” state by writing **SUCC1.CMD** = 0001_B (CONFIG command)
- To “WAKEUP” state by writing **SUCC1.CMD** = 0011_B (WAKEUP command)
- To “STARTUP” state by writing **SUCC1.CMD** = 0100_B (RUN command)

Internal counters and the Communication Controller status flags are reset when the Communication Controller enters “STARTUP” state.

*Note: Status bits **MHDS**, registers **TXRQ1** to **TXRQ4**, and status data stored in the Message RAM are not affected by the transition of the POC from “READY” to “STARTUP” state.*

26.6.5.5 WAKEUP State

The description below is intended to help configuring wakeup for the E-Ray IP-module. A detailed description of the wakeup procedure together with the respective SDL diagrams can be found in the FlexRay™ protocol specification v2.1, section 7.1.

The Communication Controller enters this state

- When exiting from “READY” state by writing **SUCC1.CMD** = 0011_B (WAKEUP command).

The Communication Controller exits from this state to “READY” state

- After complete non-aborted transmission of wakeup pattern
- After WUP reception
- After detecting a WUP collision
- After reception of a Frame Header
- By writing **SUCC1.CMD** = 0010_B (READY command)

The cluster wakeup must precede the communication startup in order to ensure that all mechanisms defined for the startup work properly. The minimum requirement for a cluster wakeup is that all bus drivers are supplied with power. A bus driver has the ability to wake up the other components of its node when it receives a wakeup pattern on its channel. At least one node in the cluster needs an **external** wakeup source.

The Host completely controls the wakeup procedure. It is informed about the state of the cluster by the bus driver and the Communication Controller and configures bus guardian

(if available) and Communication Controller to perform the cluster wakeup. The Communication Controller provides to the Host the ability to transmit a special wakeup pattern on each of its available channels separately. The Communication Controller needs to recognize the wakeup pattern only during “WAKEUP” state.

Wakeup may be performed on only one channel at a time. The Host has to configure the wakeup channel while the Communication Controller is in “CONFIG” state by writing bit **SUCC1.WUCS** in the SUC Configuration Register 1. The Communication Controller ensures that ongoing communication on this channel is not disturbed. The Communication Controller cannot guarantee that all nodes connected to the configured channel awake upon the transmission of the wakeup pattern, since these nodes cannot give feedback until the startup phase. The wakeup procedure enables single-channel devices in a two-channel system to trigger the wakeup, by only transmitting the wakeup pattern on the single channel to which they are connected. Any coldstart node that deems a system startup necessary will then wake the remaining channel before initiating communication startup.

The wakeup procedure tolerates any number of nodes simultaneously trying to wakeup a single channel and resolves this situation such that only one node transmits the pattern. Additionally the wakeup pattern is collision resilient, so even in the presence of a fault causing two nodes to simultaneously transmit a wakeup pattern, the resulting collided signal can still wake the other nodes.

After wakeup the Communication Controller returns to “READY” state and signals the change of the wakeup status to the Host by setting bit **SIR.WST** in the Status Service Request Register. The wakeup status vector can be read from the Communication Controller Status Vector register **CCSV.WSV**. If a valid wakeup pattern was received also either flag **SIR.WUPA** or flag **SIR.WUPB** in the Status Service Request Register is set.

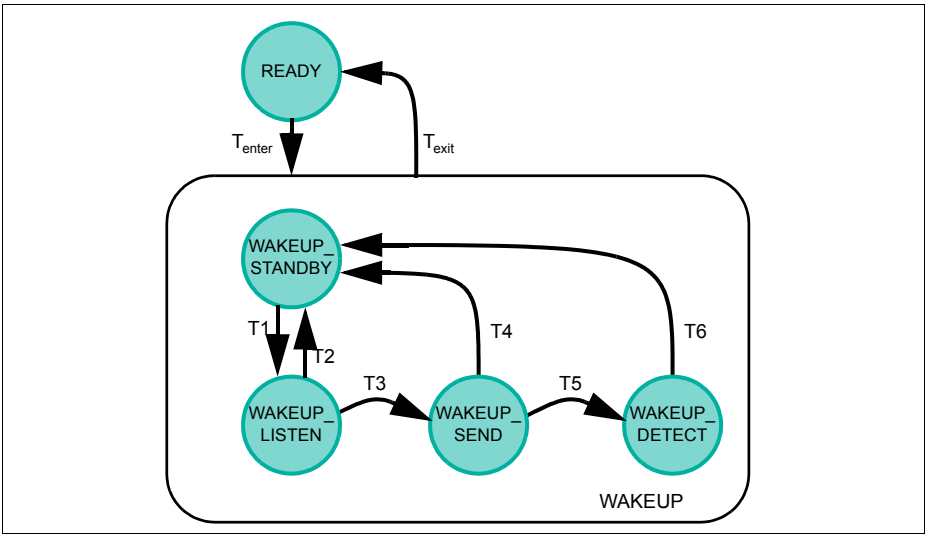

Figure 26-7 Structure of POC State WAKEUP

Table 26-12 State Transitions WAKEUP

T#	Condition	From	To
enter	Host commands change to “WAKEUP” state by writing **SUCC1.CMD** = 0011_B (WAKEUP command)	READY	WAKEUP
1	CHI command WAKEUP triggers wakeup FSM to transit to “WAKEUP_LISTEN” state	WAKEUP_ STANDBY	WAKEUP_ LISTEN
2	Received WUP on wakeup channel selected by flag **SUCC1.WUCS** in the SUC Configuration Register 1 OR Frame Header on either available channel	WAKEUP_ LISTEN	WAKEUP_ STANDBY
3	Timer event	WAKEUP_ LISTEN	WAKEUP_ SEND
4	Complete, non-aborted transmission of wakeup pattern	WAKEUP_ SEND	WAKEUP_ STANDBY

Table 26-12 State Transitions WAKEUP (cont'd)

T#	Condition	From	To
5	Collision detected	WAKEUP_ SEND	WAKEUP_ DETECT
6	Wakeup timer expired OR WUP detected on wakeup channel selected by flag **SUCC1.WUCS** in the SUC Configuration Register 1 OR Frame Header received on either available channel	WAKEUP_ DETECT	WAKEUP_ STANDBY
exit	Wakeup completed (after T2 or T4 or T6) OR Host commands change to "READY" state by writing **SUCC1.CMD** = 0010_B (READY command). This command also resets the wakeup FSM to "WAKEUP_STANDBY" state	WAKEUP	READY

The "WAKEUP_LISTEN" state is controlled by the wakeup timer and the wakeup noise timer. The two timers are controlled by the parameters listen time-out **SUCC2.LT** and listen time-out noise **SUCC2.LTN**. Both values can be configured in the SUC Configuration Register 2. listen time-out enables a fast cluster wakeup in case of a noise free environment, while listen time-out noise enables wakeup under more difficult conditions regarding noise interference.

In "WAKEUP_SEND" state the Communication Controller transmits the wakeup pattern on the configured channel and checks for collisions. After return from wakeup the Host has to bring the Communication Controller into "STARTUP" state by CHI command RUN.

In "WAKEUP_DETECT" state the Communication Controller attempts to identify the reason for the wakeup collision detected in "WAKEUP_SEND" state. The monitoring is bounded by the expiration of listen time-out as configured by **SUCC2.LT** in the SUC Configuration Register 2. Either the detection of a wakeup pattern indicating a wakeup attempt by another node or the reception of a Frame Header indication existing communication, causes the direct transition to "READY" state. Otherwise WAKEUP_DETECT is left after expiration of listen time-out; in this case the reason for wakeup collision is unknown.

The Host has to be aware of possible failures of the wakeup and act accordingly. It is advisable to delay any potential startup attempt of the node having instigated the wakeup by the minimal time it takes another coldstart node to become awake and to be configured.

The FlexRay™ Protocol Specification v2.1 recommends that two different Communication Controllers shall awake the two channels.

Host activities

The host must coordinate the wakeup of the two channels and must decide whether, or not, to wake a specific channel. The sending of the wakeup pattern is initiated by the Host and generated by the Communication Controller. The wakeup pattern is detected by the remote BDs and signalled to their local Hosts.

Wakeup procedure controlled by Host (single-channel wakeup):

- Configure the Communication Controller in “CONFIG” state
  - Select wakeup channel by programming bit **SUCC1.WUCS**
- Check local BDs whether a WUP was received
- Activate BD of selected wakeup channel
- Command Communication Controller to start wakeup on the configured channel by writing **SUCC1.CMD** = 0011_B
  - Communication Controller enters “WAKEUP
  - Communication Controller returns to “READY” state and signals status of wakeup attempt to Host
- Wait predefined time to allow the other nodes to wakeup and configure themselves
- Coldstart node: wait for WUP on the other channel
  - In a dual channel cluster wait for WUP on the other channel
  - Reset coldstart inhibit flag **CCSV.CSI** by writing **SUCC1.CMD** = 1001_B (ALLOW_COLDSTART command))
- Reset Coldstart Inhibit flag **CCSV.CSI** in the CCSV register by writing **SUCC1.CMD** = 1001_B (ALLOW_COLDSTART command), coldstart node only
- Command Communication Controller to enter startup by writing **SUCC1.CMD** = 0100_B (RUN command)

Wakeup procedure triggered by BD:

- Wakeup recognized by BD
- BD triggers power-up of Host (if required)
- BD signals wakeup event to Host
- Host configures its local Communication Controller
- If necessary Host commands wakeup of second channel and waits predefined time to allow the other nodes to wakeup and configure themselves
- Host commands Communication Controller to enter “STARTUP” state by writing **SUCC1.CMD** = 0100_B (RUN command)

Wakeup pattern (WUP)

The wakeup pattern is composed of at least two wakeup symbols (WUS). Wakeup symbol and wakeup pattern are configured by the PRT Configuration Registers **PRTC1** and **PRTC2**.

- Single channel wakeup, wakeup symbol may not be sent on both channels at the same time

- Wakeup symbol collision resilient for up to two sending nodes (two overlapping wakeup symbols still recognizable)
- Wakeup symbol must be configured identical in all nodes of a cluster
- Wakeup symbol transmit low time configured by **PRTC2.TXL**
- Wakeup symbol idle time used to listen for activity on the bus, configured by **PRTC2.TXI**
- A wakeup pattern composed of at least two Tx-wakeup symbols needed for wakeup
- Number of repetitions configurable by **PRTC1.RWP** (2 to 63 repetitions)
- Wakeup symbol receive window length configured by **PRTC1.RXW**
- Wakeup symbol receive low time configured by **PRTC2.RXL**
- Wakeup symbol receive idle time configured by **PRTC2.RXI**

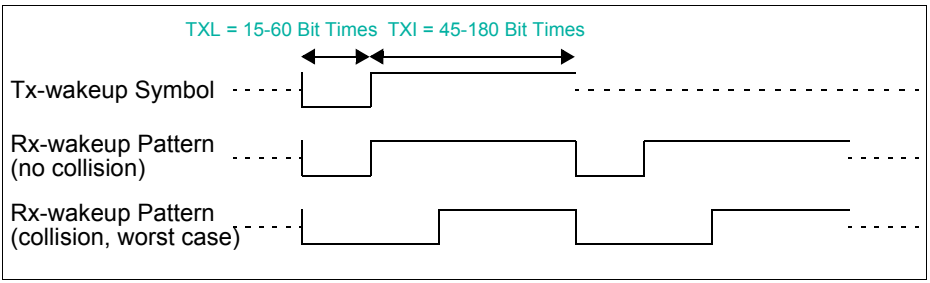

Figure 26-8 Timing of Wakeup Pattern

26.6.5.6 STARTUP State

The description below is intended to help configuring startup for the E-Ray IP-module. A detailed description of the startup procedure together with the respective SDL diagrams can be found in the FlexRay™ protocol specification v2.1, section 7.2.

Any node entering “STARTUP” state that has coldstart capability should assure that both channels attached have been awakened before initiating coldstart.

It cannot be assumed that all nodes and stars need the same amount of time to become completely awake and to be configured. Since at least two nodes are necessary to start up the cluster communication, it is advisable to delay any potential startup attempt of the node having instigated the wakeup by the minimal amount of time it takes another coldstart node to become awake, to be configured and to enter startup. It may require several hundred milliseconds (depending on the hardware used) before all nodes and stars are completely awakened and configured.

Startup is performed on all channels synchronously. During startup, a node only transmits startup Frames.

A fault-tolerant, distributed startup strategy is specified for initial synchronization of all nodes. In general, a node may enter “NORMAL_ACTIVE” state via (see **Figure 26-9**):

- Coldstart path initiating the schedule synchronization (leading coldstart node)
- Coldstart path joining other coldstart nodes (following coldstart node)
- Integration path integrating into an existing communication schedule (all other nodes)

A coldstart attempt begins with the transmission of a collision avoidance symbol (CAS). Only a coldstart node that had transmitted the CAS transmits Frames in the first four cycles after the CAS, it is then joined firstly by the other coldstart nodes and afterwards by all other nodes.

A coldstart node has the Transmit SYNC Frame in Key Slot bits **SUCC1.TXST** and **SUCC1.TXSY** in the SUC Configuration Register 1 set to 1. The Message Buffer 0 holds the key slot ID which defines the slot number where the Startup Frame is send. In the Frame Header of the Startup Frame the Startup Frame indicator bit is set.

In clusters consisting of three or more nodes, at least three nodes shall be configured to be coldstart nodes. In clusters consisting of two nodes, both nodes must be coldstart nodes. At least two fault-free coldstart nodes are necessary for the cluster to startup.

Each Startup Frame must also be a SYNC Frame; therefore each coldstart node will also be a sync node. The number of coldstart attempts is configured by **SUCC1.CSA** in the SUC Configuration Register 1.

A non-coldstart node requires at least two startup Frames from distinct nodes for integration. It may start integration before the coldstart nodes have finished their startup. It will not finish its startup until at least two coldstart nodes have finished their startup.

Both non-coldstart nodes and coldstart nodes start passive integration via the integration path as soon as they receive SYNC Frames from which to derive the TDMA schedule information. During integration the node has to adapt its own clock to the global clock (rate and offset) and has to make its cycle time consistent with the global schedule observable at the network. Afterwards, these settings are checked for consistency with all available network nodes. The node can only leave the integration phase and actively participate in communication when these checks are passed.

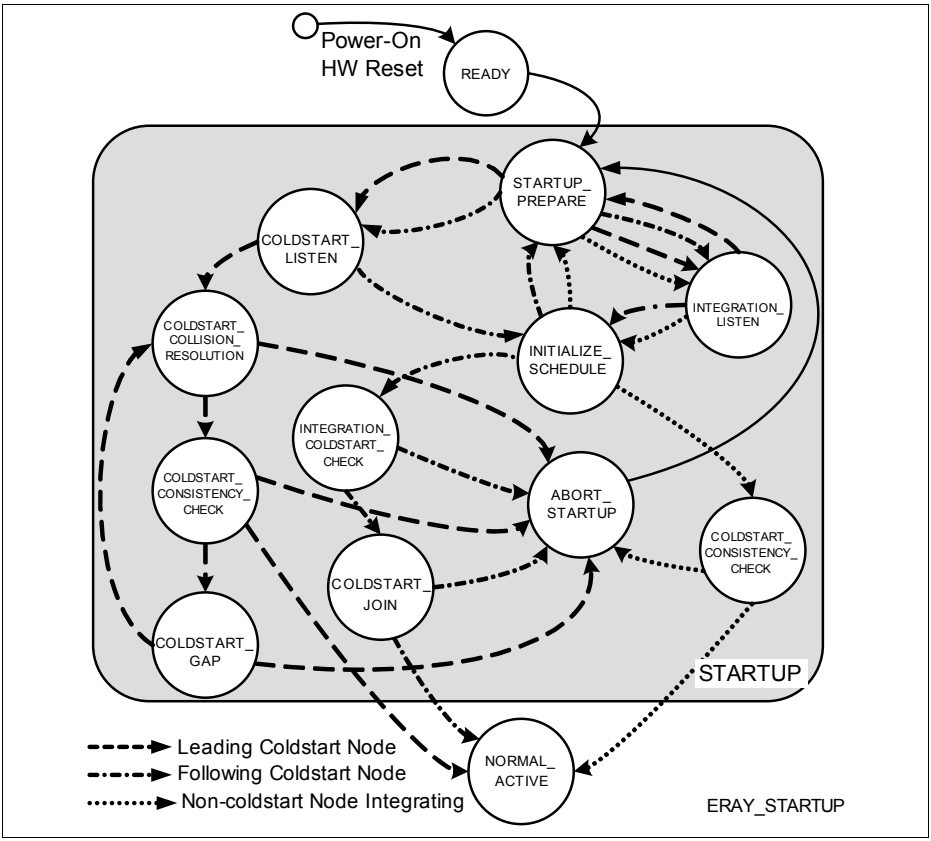

Figure 26-9 State Diagram Time-Triggered Startup

Coldstart Inhibit Mode

In coldstart inhibit mode the node is prevented from initializing the TDMA communication schedule. If bit **CCSV.CSI** in the Communication Controller Status Vector register is set, the node is not allowed to initialize the cluster communication, i.e. entering the coldstart path is prohibited. The node is allowed to integrate to a running cluster or to transmit startup Frames after another coldstart node started the initialization of the cluster communication.

The coldstart inhibit bit **CCSV.CSI** is set whenever the POC enters “READY” state. The bit has to be cleared under control of the Host by CHI command ALLOW_COLDSTART (**SUCC1.CMD** = 1001_B)

26.6.5.7 Startup Time-outs

The Communication Controller supplies two different Microtick timers supporting two time-out values, startup time-out and startup noise time-out. The two timers are reset when the Communication Controller enters the “COLDSTART_LISTEN” state. The expiration of either of these timers causes the node to leave the initial sensing phase (“COLDSTART_LISTEN” state) with the intention of starting up communication.

*Note: The startup and startup noise timers are identical with the wakeup and wakeup noise timers and use the same configuration values **SUCC2.LT** and **SUCC2.LTN** from the SUC Configuration Register 2.*

Startup Time-out

The startup time-out limits the listen time used by a node to determine if there is already communication between other nodes or at least one coldstart node actively requesting the integration of others.

The startup timer is configured by programming **SUCC2.LT** (pdListenTimeout) in the SUC Configuration Register 2.

The startup timer is restarted upon:

- Entering the “COLDSTART_LISTEN” state
- Both channels reaching idle state while in “COLDSTART_LISTEN” state

The startup timer is stopped:

- If communication channel activity is detected on one of the configured channels while the node is in the “COLDSTART_LISTEN” state
- When the “COLDSTART_LISTEN” state is left

Once the startup time-out expires, neither an overflow nor a cyclic restart of the timer is performed. The timer status is kept for further processing by the startup state machine.

Startup Noise Time-out

At the same time the startup timer is started for the first time (transition from “STARTUP_PREPARE” state to “COLDSTART_LISTEN” state), the startup noise timer is started. This additional time-out is used to improve reliability of the startup procedure in the presence of noise.

The startup noise timer is configured by programming **SUCC2.LTN** (gListenNoise - 1) in the SUC Configuration Register 2 (see **“SUC Configuration Register 2 (SUCC2)” on Page 26-96**).

The startup noise time-out is:
pdListenTimeout • ´gListenNoise = **SUCC2.LT** • (**SUCC2.LTN** + 1)

The startup noise timer is restarted upon:

- Entering the “COLDSTART_LISTEN” state
- Reception of correctly decoded Headers or CAS symbols while the node is in “COLDSTART_LISTEN” state

The startup noise timer is stopped when the “COLDSTART_LISTEN” state is left.

Once the startup noise time-out expires, neither an overflow nor a cyclic restart of the timer is performed. The status is kept for further processing by the startup state machine. Since the startup noise timer won’t be restarted when random channel activity is sensed, this time-out defines the fall-back solution that guarantees that a node will try to start up the communication cluster even in the presence of noise.

26.6.5.8 Path of leading Coldstart Node (initiating coldstart)

When a coldstart node enters “COLDSTART_LISTEN”, it listens to its attached channels.

If no communication is detected, the node enters the “COLDSTART_COLLISION_RESOLUTION” state and commences a coldstart attempt. The initial transmission of a CAS symbol is succeeded by the first regular cycle. This cycle has the number zero.

From cycle zero on, the node transmits its startup Frame. Since each coldstart node is allowed to perform a coldstart attempt, it may occur that several nodes simultaneously transmit the CAS symbol and enter the coldstart path. This situation is resolved during the first four cycles after CAS transmission.

As soon as a node that initiates a coldstart attempt receives a CAS symbol or a Frame Header during these four cycles, it re-enters the “COLDSTART_LISTEN” state. Thereby, only one node remains in this path. In cycle four, other coldstart nodes begin to transmit their startup Frames.

After four cycles in “COLDSTART_COLLISION_RESOLUTION” state, the node that initiated the coldstart enters the “COLDSTART_CONSISTENCY_CHECK” state. It collects all startup Frames from cycle four and five and performs the clock correction. If the clock correction does not deliver any errors and it has received at least one valid Startup Frame pair, the node leaves “COLDSTART_CONSISTENCY_CHECK” and enters “NORMAL_ACTIVE” state.

The number of coldstart attempts that a node is allowed to perform is configured by **SUCC1.CSA** in the SUC Configuration Register 1. The number of remaining coldstarts attempts **CCSV.RCA** can be read from Communication Controller Status Vector register. The number of remaining attempts is reduced by one for each attempted coldstart. A node may enter the “COLDSTART_LISTEN” state only if this value is larger than one and it may enter the “COLDSTART_COLLISION_RESOLUTION” state only if this value is larger than zero. If the number of coldstart attempts is one, coldstart is inhibited but integration is still possible.

Path of following Coldstart Node (responding to leading Coldstart Node)

When a coldstart node enters the “COLDSTART_LISTEN” state, it tries to receive a valid pair of startup Frames to derive its schedule and clock correction from the leading coldstart node.

As soon as a valid Startup Frame has been received the “INITIALIZE_SCHEDULE” state is entered. If the clock synchronization can successfully receive a matching second valid Startup Frame and can derive a schedule from this startup Frames, the “INTEGRATION_COLDSTART_CHECK” state is entered.

In “INTEGRATION_COLDSTART_CHECK” state it is assured that the clock correction can be performed correctly and that the coldstart node from which this node has initialized its schedule is still available. The node collects all SYNC Frames and performs clock correction in the following double-cycle. If clock correction does not signal any errors and if the node continues to receive sufficient Frames from the same node it has integrated on, the “COLDSTART_JOIN” state is entered.

In “COLDSTART_JOIN” state integrating coldstart nodes begin to transmit their own startup Frames. Thereby the node that initiated the coldstart and the nodes joining it can check if their schedules agree to each other. If for the following three cycles the clock correction does not signal errors and at least one other coldstart node is visible, the node leaves “COLDSTART_JOIN” state and enters “NORMAL_ACTIVE” state. Thereby it leaves “STARTUP” at least one cycle after the node that initiated the coldstart.

Path of Non-coldstart Node

When a non-coldstart node enters the INTEGRATION_LISTEN state, it listens to its attached channels and tries to receive FlexRay™ Frames.

As soon as a valid Startup Frame has been received the “INITIALIZE_SCHEDULE” state is entered. If the clock synchronization can successfully receive a matching second valid Startup Frame and derive a schedule from this, the INTEGRATION_CONSISTENCY_CHECK state is entered.

In “INTEGRATION_CONSISTENCY_CHECK” state it is verified that the clock correction can be performed correctly and that enough coldstart nodes (at least 2) send startup Frames that agree to the nodes own schedule. Clock correction is activated, and if any errors are signalled, the integration attempt is aborted.

During the first even cycle in this state, either two valid startup Frames or the Startup Frame of the node that this node has integrated on must be received; otherwise the node aborts the integration attempt.

During the first double-cycle in this state, either two valid Startup Frame pairs or the Startup Frame pair of the node that this node has integrated on must be received; otherwise the node aborts the integration attempt.

If after the first double-cycle less than two valid startup Frames are received within an even cycle, or less than two valid Startup Frame pairs are received within a double-cycle, the startup attempt is aborted.

Nodes in this state need to see two valid Startup Frame pairs for two consecutive double-cycles each to be allowed to leave STARTUP and enter NORMAL_OPERATION. Consequently, they leave startup at least one double-cycle after the node that initiated the coldstart and only at the end of a cycle with an odd cycle number.

26.6.5.9 NORMAL_ACTIVE State

As soon as the node that transmitted the first CAS symbol (resolving the potential access conflict and entering “STARTUP” via coldstart path) and one additional node have entered the “NORMAL_ACTIVE” state, the startup phase for the cluster has finished. In the “NORMAL_ACTIVE” state, all configured messages are scheduled for transmission. This includes all Data Frames as well as the SYNC Frames. Rate and offset measurement is started in all even cycles (even/odd cycle pairs required).

In “NORMAL_ACTIVE” state the Communication Controller supports regular communication functions

- The Communication Controller performs transmissions and reception on the FlexRay™ bus as configured
- Clock synchronization is running
- The Host interface is operational

The Communication Controller exits from that state to

- “HALT” state by writing **SUCC1.CMD** = 0110_B (HALT command, at the end of the current cycle)
- “HALT” state by writing **SUCC1.CMD** = 0111_B (FREEZE command, immediately)
- “HALT” state due to change of the error state from “ACTIVE” to “COMM_HALT”
- “NORMAL_PASSIVE” state due to change of the error state from “ACTIVE” to “PASSIVE”
- “READY” state by writing **SUCC1.CMD** = 0010_B (READY command)

26.6.5.10 NORMAL_PASSIVE State

“NORMAL_PASSIVE” state is entered from “NORMAL_ACTIVE” state when the error state changes from ACTIVE (green) to PASSIVE (yellow).

In “NORMAL_PASSIVE” state, the node is able to receive all Frames (node is fully synchronized and performs clock synchronization). In comparison to the “NORMAL_ACTIVE” state the node does not actively participate in communication, i.e. neither symbols nor Frames are transmitted.

In “NORMAL_PASSIVE” state

- The Communication Controller performs reception on the FlexRay™ bus
- The Communication Controller does not transmit any Frames or symbols on the FlexRay™ bus
- Clock synchronization is running
- The Host interface is operational

The Communication Controller exits from this state to

- “HALT” state by writing **SUCC1.CMD** = 0110_B (HALT command, at the end of the current cycle)
- “HALT” state by writing **SUCC1.CMD** = 0111_B (FREEZE command, immediately)
- “HALT” state due to change of the error state from “PASSIVE” to “COMM_HALT”
- “NORMAL_ACTIVE” state due to change of the error state from “PASSIVE” to “ACTIVE”. The transition takes place when **CCEV.PTAC** from the Communication Controller Error Vector register equals **SUCC1.PTA** - 1.
- “READY” state by writing **SUCC1.CMD** = 0010_B (READY command)

26.6.5.11 HALT State

In this state all communication (reception and transmission) is stopped.

The Communication Controller enters this state

- By writing **SUCC1.CMD** = 0110_B (HALT command) while the Communication Controller is in “NORMAL_ACTIVE” or “NORMAL_PASSIVE” state
- By writing **SUCC1.CMD** = 0111_B (FREEZE command) from all states
- When exiting from “NORMAL_ACTIVE” state because the clock correction failed counter reached the “maximum without clock correction fatal” limit
- When exiting from “NORMAL_PASSIVE” state because the clock correction failed counter reached the “maximum without clock correction fatal” limit

The Communication Controller exits from this state to “CONFIG” state

- By writing **SUCC1.CMD** = 0001_B (DEFAULT_CONFIG command)

When the Communication Controller enters “HALT” state, all configuration and status data is maintained for analyzing purposes.

When the Host writes **SUCC1.CMD** = 0110_B (HALT command) in the SUC Configuration Register 1 to 1, the Communication Controller sets bit **CCSV.HRQ** in the Communication Controller Status Vector register and enters “HALT” state after the current communication cycle has finished.

When the Host writes **SUCC1.CMD** = 0111_B (FREEZE command) in the SUC Configuration Register to 1, the Communication Controller enters “HALT” state immediately and sets the **CCSV.FSI** bit in the Communication Controller Status Vector register.

The POC state from which the transition to HALT state took place can be read from **CCSV.PSL**.

26.6.6 Network Management

The accrued Network Management (NM) vector is located in the Network Management Register 1 to Network Management Register 3 (**NMVx (x = 1-3)**). The Communication Controller performs a logical OR operation over all Network Management (NM) vectors out of all received valid Network Management (NM) Frames with the Payload Preamble Indicator (PPI) bit set. Only a static Frame may be configured to hold Network Management (NM) information. The Communication Controller updates the Network Management (NM) vector at the end of each cycle.

The length of the Network Management (NM) vector can be configured from 0 to 12 byte by NML in the NEM Configuration Register. The Network Management (NM) vector length must be configured identically in all nodes of a cluster.

To configure a transmit buffer to send FlexRay™ Frames with the PPI bit set, the PPIT bit in the Header Section of the respective transmit buffer has to be set via **WRHS1.PPIT**. In addition the Host has to write the Network Management (NM) information to the Data Section of the respective transmit buffer.

The evaluation of the Network Management (NM) vector has to be done by the application running on the Host.

*Note: In case a Message Buffer is configured for transmission / reception of Network Management Frames, the payload length configured in Header 2 of that Message Buffer should be equal or greater than the length of the NM Vector configured by **NEMC.NML**.*
When the Communication Controller transits to "HALT" state, the cycle count is not incremented and therefore the NM Vector is not updated. In this case NMV1 to NMV3 holds the value from the cycle before.

26.6.7 Filtering and Masking

Filtering is done by checking specific fields in a received Frame against the corresponding configuration constants of the valid Message Buffers and the actual slot and cycle counter values (acceptance filtering), or by comparing the configuration constants of the valid Message Buffers against the actual slot and cycle counter values (transmit filtering). A Message Buffer is only updated / transmitted if the required matches occur.

Filtering is done on the following fields:

- Channel ID
- Frame ID
- Cycle Counter

The following filter combinations for acceptance / transmit filtering are allowed:

- Frame ID + Channel ID
- Frame ID + Channel ID + Cycle Counter

In order to store a received message in a Message Buffer all configured filters must match.

Note: For the FIFO the acceptance filter is configured by the FIFO Rejection Filter and the FIFO Rejection Filter Mask.

A message will be transmitted in the time slot corresponding to the configured Frame ID on the configured channel(s). If cycle counter filtering is enabled the configured cycle filter value must also match.

26.6.7.1 Frame ID Filtering

Every transmit and receive buffer contains a Frame ID stored in the Header Section. This Frame ID is used differently for receive and transmit buffers.

Receive Buffers

A received message is stored in the first receive buffer where the received Frame ID matches the configured Frame ID, provided channel ID and cycle counter criteria are also met.

Transmit Buffers

For transmit buffers the configured Frame ID is used to determine the appropriate slot for message transmission. The Frame will be transmitted in the time slot corresponding to the configured Frame ID, provided channel ID and cycle counter criteria are also met.

26.6.7.2 Channel ID Filtering

There is a 2-bit channel filtering field (CHA, CHB) located in the Header Section of each Message Buffer in the Message RAM. It serves as a filter for receive buffers, and as a control field for transmit buffers (see **Table 26-13**).

Table 26-13 Channel Filtering Configuration

CHA	CHB	**Transmit Buffer** transmit Frame	**Receive Buffer** store valid receive Frame
1	1	on both channels (static segment only)	received on channel A or B (store first semantically valid Frame, static segment only)
1	0	on channel A	received on channel A
0	1	on channel B	received on channel B
0	0	no transmission	ignore Frame

Note: If a Message Buffer is configured for the dynamic segment and both bits of the channel filtering field are set to 1, no Frames are transmitted resp. received Frames are ignored (same function as CHA = CHB = 0)

Receive Buffers

Valid received Frames are stored if they are received on the channels specified in the channel filtering field. Only in static segment a receive buffer may be setup for reception on both channels (CHA and CHB set). Other filtering criteria must also be met.

If a valid Header Segment was stored, the respective MBC flag in the Message Buffer Status Changed register is set. If a valid Payload Segment was stored, the respective **NDn (n = 0-31)** to **NDn (n = 96-127)** flag in the New Data **NDAT1** to **NDAT4** register is set. In both cases, if bit **RDHS1.MBI** in the Header Section of the respective Message Buffer is set, the RXI flag in the Status Service Request Register is set to 1. If enabled an service request is generated.

Transmit Buffers

The content of the buffer is transmitted only on the channels specified in the channel filtering field when the Frame ID filtering and cycle counter filtering criteria are also met. Only in static segment a transmit buffer may be setup for transmission on both channels (CHA and CHB set). After transmission has completed, and if bit **WRHS1.MBI** in the Header Section of the respective Message Buffer is set, the TXI flag in the Status Service Request Register is set to 1. If enabled an service request is generated.

26.6.7.3 Cycle Counter Filtering

Cycle counter filtering is based on the notion of a cycle set. For filtering purposes, a match is detected if any one of the elements of the cycle set is matched. The cycle set is defined by the cycle code field in the Header Section of each Message Buffer.

If Message Buffer 0 is configured to hold the startup / SYNC Frame or the single slot Frame by bits TXST, TXSY, and TSM in the SUC Configuration Register 1, cycle counter filtering for Message Buffer 0 should be disabled.

*Note: Sharing of a static time slot via cycle counter filtering between different nodes of a FlexRay™ network is **not** allowed.*

The set of cycle numbers belonging to a cycle set is determined as described in **Table 26-14**.

Table 26-14 Definition of Cycle Set

Cycle Code	Matching Cycle Counter Values		
$000000x_B$	all Cycles		
$000001c_B$	every second Cycle	at (Cycle Count)mod2	= c
$00001cc_B$	every fourth Cycle	at (Cycle Count)mod4	= cc
$0001ccc_B$	every eighth Cycle	at (Cycle Count)mod8	= ccc
$001cccc_B$	every sixteenth Cycle	at (Cycle Count)mod16	= cccc
$01ccccc_B$	every thirty-second Cycle	at (Cycle Count)mod32	= ccccc
$1cccccc_B$	every sixty-fourth Cycle	at (Cycle Count)mod64	= cccccc

Table 26-15 below gives some examples for valid cycle sets to be used for cycle counter filtering:

Table 26-15 Examples for Valid Cycle Sets

Cycle Code	Matching Cycle Counter Values
0000011_B	1-3-5-7- ….-63 ↵
0000100_B	0-4-8-12- ….-60 ↵
0001110_B	6-14-22-30- ….-62 ↵
0011000_B	8-24-40-56 ↵
0100011_B	3-35 ↵
1001001_B	9 ↵

Receive Buffers

The received message is stored only if the received cycle counter matches an element of the receive buffer's cycle set. Channel ID and Frame ID criteria must also be met.

Transmit Buffers

The content of the buffer is transmitted on the configured channels when an element of the cycle set matches the current cycle counter value and the Frame ID matches the slot counter value.

26.6.7.4 FIFO Filtering

For FIFO filtering there is one rejection filter and one rejection filter mask available. The FIFO rejection filter consists of 20 bits for **Channel** (2 bits), **Frame ID** (11 bits), and **Cycle Code** (7 bits). Rejection filter and rejection filter mask can be configured in

DEFAIULT_CONGIF or “CONFIG” state only. The filter configuration in the Header Sections of Message Buffers belonging to the FIFO is ignored.

A valid received Frame is stored in the FIFO if channel ID, Frame ID, and cycle counter are not rejected by the configured rejection filter and rejection filter mask, and if there is no matching dedicated receive buffer.

26.6.8 Transmit Process

The transmit process is described in the following sections.

26.6.8.1 Static Segment

For the static segment, if there are several messages pending for transmission, the message with the Frame ID corresponding to the next sending slot is selected for transmission.

The Data Section of transmit buffers assigned to the static segment can be updated until the end of the preceding time slot. This means that a transfer from the Input Buffer has to be started by writing to the Input Buffer Command Request register latest at this time.

26.6.8.2 Dynamic Segment

In the dynamic segment, if several messages are pending, the message with the highest priority (lowest Frame ID) is selected next. Only Frame ID’s which are higher than the largest static Frame ID are allowed for the dynamic segment.

In the dynamic segment different slot counter sequences are possible (concurrent sending of different Frame ID’s on both channels). Therefore pending messages are selected according to their Frame ID and their channel configuration bit.

The Data Section of transmit buffers assigned to the dynamic segment can be updated until the end of the preceding slot. This means that a transfer from the Input Buffer has to be started by writing to the Input Buffer Command Request register latest at this time.

The start of latest transmit configured by SLT in the MHD Configuration Register 1 defines the maximum minislot value allowed before inhibiting new Frame transmission in the dynamic segment of the current cycle.

26.6.8.3 Transmit Buffers

A portion of the E-Ray Message Buffers can be configured as transmit buffers by programming bit CFG in the Header Section of the respective Message Buffer to 1. This can be done via the Write Header Section 1 register.

There exist the following possibilities to assign a transmit buffer to the Communication Controller channels:

- Static segment: channel A **or** channel B, channel A **and** channel B

- Dynamic segment: channel A **or** channel B

Message Buffer 0 is dedicated to hold the startup Frame, the SYNC Frame, or the designated single slot Frame as configured by TXST, TXSY, and TSM in the SUC Configuration Register 1. In this case it can be reconfigured in “DEFAULT_CONFIG” or “CONFIG” state only. This ensures that any node transmits at most one startup / SYNC Frame per communication cycle. Transmission of startup / SYNC Frames from other Message Buffers is not possible.

All other Message Buffers configured for transmission in static or dynamic segment are reconfigurable during runtime. Due to the organization of the Data Partition in the Message RAM (reference by data pointer), reconfiguration of the configured payload length and the data pointer in the Header Section of a Message Buffer may lead to erroneous configurations. If a Message Buffer is reconfigured during runtime it may happen that this Message Buffer is not send out in the respective communication cycle.

The Communication Controller does not have the capability to calculate the Header CRC. The Host is supposed to provide the Header CRCs for all transmit buffers. If Network Management is required the Host has to set the PPIT bit in the Header Section of the respective Message Buffer to 1 and write the Network Management information to the Data Section of the Message Buffer (see **Section 26.6.6**).

The payload length field configures the data payload length in 2-byte words. If the configured payload length of a static transmit buffer is shorter than the payload length configured for the static segment by SFDL in the Message Handler Configuration Register 1, the Communication Controller generates padding byte to ensure that Frames have proper physical length. The padding pattern is logical zero.

Each transmit buffer provides a transmission mode flag TXM that allows the Host to configure the transmission mode for the transmit buffer in the static segment. If this bit is set, the transmitter operates in the single-shot mode. If this bit is cleared, the transmitter operates in the continuous mode. In dynamic segment the transmitter always works in single-shot mode.

If a Message Buffer is configured in the continuous mode, the Communication Controller does not reset the transmission request flag TXR after successful transmission. In this case a Frame is sent out each time the Frame ID and cycle counter filter match. The TXR flag can be reset by the Host by writing the respective Message Buffer number to the Input Buffer Command Request register while bit **STXRH** in the Input Buffer Command Mask register is reset to 0.

If two or more transmit buffers are configured with the same Frame ID **and** cycle counter filter value, the transmit buffer with the lowest Message Buffer number will be transmitted in the respective slot.

26.6.8.4 Frame Transmission

To prepare a transmit buffer for transmission the following steps are required:

- Configure the Message Buffer as transmit buffer by writing bit CFG = 1 in the Write Header Section 1 register
- Write transmit message (Header and Data Section) to the Input Buffer.
- To transfer a transmit message from Input Buffer to the Message RAM proceed as described on **“Data Transfer from Input Buffer to Message RAM” on Page 26-233**.
- If configured in the Input Buffer Command Mask register the Transmission Request flag for the respective Message Buffer will be set as soon as the transfer has completed, and the Message Buffer is ready for transmission.
- Check whether the Message Buffer has been transmitted by checking the TXR bits (TXR = 0) in the Transmission Request 1,2 registers (single-shot mode only).

In single-shot mode the Communication Controller resets the TXR flag after transmission has been completed. Now the Host may update the transmit buffer with the next message. The Communication Controller does not transmit the message before the Host has indicated that the update is completed by setting the Transmission Request flag TXR again. The Host can check the actual state of the TXR flags of all Message Buffers by reading the Transmission Request registers. After successful transmission, if bit **WRHS1.MBI** in the Header Section of the respective Message Buffer is set, the transmit service request flag in the Status Service Request Register is set (TXI = 1). If enabled an service request is generated.

26.6.8.5 NULL Frame Transmission

If in static segment the Host does not set the transmission request flag before transmit time, and if there is no other transmit buffer with matching filter criteria (matching Frame ID and cycle counter filter), the Communication Controller transmits a NULL Frame with the NULL Frame indication bit reset to 0 and the payload data reset to zero.

In the following cases the Communication Controller transmits a NULL Frame with the NULL Frame indication bit reset to 0, and the rest of the Frame Header and the Frame length unchanged (payload data is reset to zero):

- All transmit buffers configured for the slot have cycle counter filters that do not match the current cycle
- There are matching Frame ID’s and cycle counter filters, but none of these transmit buffers has the transmission request flag TXR set

NULL Frames are not transmitted in the dynamic segment.

26.6.9 Receive Process

The receive process is described in the following sections.

26.6.9.1 Frame Reception

To prepare or change a Message Buffer for reception the following steps are required:

- Configure the Message Buffer as receive buffer by writing bit CFG = 0 in the Write Header Section 1 register
- Configure the receive buffer by writing the configuration data (Header Section) to the Input Buffer
- Transfer the configuration from Input Buffer to the Message RAM by writing the number of the target Message Buffer to the Input Buffer Command Request register.

Once these steps are performed, the Message Buffer functions as an active receive buffer and participates in the internal acceptance filtering process, which takes place every time the Communication Controller receives a message. The first matching receive buffer is updated from the received message. If the Message Buffer holds an unprocessed Data Section (ND = 1) it is overwritten with the new message and the MLST bit in the respective Message Buffer Status register is set.

If the payload length of a received Frame PLC is longer than the value programmed by PLC in the Header Section of the respective Message Buffer, the data field stored in the Message Buffer is truncated to that length.

If no Frame, a NULL Frame, or a corrupted Frame is received in a slot, the Data Section of the Message Buffer configured for this slot is not updated. In this case only the flags in the Message Buffer Status register are updated to signal the cause of the problem. In addition the respective MBC flag in the Message Buffer Status Changed 1,2,3,4 registers is set.

When the Data Section of a receive buffer has been updated from a received Frame, the respective New Data **NDn (n = 0-31)** to **NDn (n = 96-127)** flag in the New Data **NDAT1** to **NDAT4** registers is set. When the Message Handler has updated the Message Buffer status, the respective MBC flag in the Message Buffer Status Changed 1,2,3,4 registers is set. If bit **RDHS1.MBI** in the Header Section of the respective Message Buffer is set, the receive service request flag in the Status Service Request Register is set (RXI = 1). If enabled an service request is generated.

To read a receive buffer from the Message RAM via the Output Buffer proceed as described on **“Data Transfer from Message RAM to Output Buffer” on Page 26-235**.

Note: The ND and MBC flags are automatically cleared by the Message Handler when the received message has been transferred to the Output Buffer.

26.6.9.2 NULL Frame reception

The Payload Segment of a received NULL Frame is **not** copied into the matching receive buffer. If a NULL Frame has been received, the Header Section of the matching Message Buffer is updated from the received NULL Frame. The NULL Frame indication bit in the Header Section 3 of the respective Message Buffer is reset (NFI = 0) and the respective MBC flag in the Message Buffer Status Changed 1,2,3,4 registers is set.

In case that bit ND and / or MBC were already set before this event because the Host did not read the last received message, bit MLST in the Message Buffer Status register of the respective Message Buffer is also set.

26.6.10 FIFO Function

A group of the Message Buffers can be configured as a cyclic First-In-First-Out (FIFO). The group of Message Buffers belonging to the FIFO is contiguous in the register map starting with the Message Buffer referenced by FFB and ending with the Message Buffer referenced by LCB in the Message RAM Configuration register. Up to 128 Message Buffers can be assigned to the FIFO.

26.6.10.1 Description

Every valid incoming message not matching with any dedicated receive buffer but passing the programmable FIFO filter is stored into the FIFO. In this case Frame ID, payload length, receive cycle count, and the status bits of the addressed FIFO Message Buffer are overwritten with Frame ID, payload length, receive cycle count, and the status from the received message and can be read by the Host for message identification. Bit RFNE in the Status Service Request Register shows that the FIFO is not empty, bit RFF in the Status Service Request Register is set when the last available Message Buffer belonging to the FIFO is written, bit RFO in the Error Service Request Register shows that a FIFO overrun has been detected. If enabled, service requests are generated.

There are two index registers associated with the FIFO. The PUT Index Register (PIDX) is an index to the next available location in the FIFO. When a new message has been received it is written into the Message Buffer addressed by the PIDX register. The PIDX register is then incremented and addresses the next available Message Buffer. If the PIDX register is incremented past the highest numbered Message Buffer of the FIFO, the PIDX register is loaded with the number of the first (lowest numbered) Message Buffer in the FIFO chain. The GET Index Register (GIDX) is used to address the next Message Buffer of the FIFO to be read. The GIDX register is incremented after transfer of the contents of a Message Buffer belonging to the FIFO to the Output Buffer. The PUT Index Register and the GET Index Register are not accessible by the Host.

The FIFO is completely filled when the PUT index (PIDX) reaches the value of the GET index (GIDX). When the next message is written to the FIFO before the oldest message has been read, both PUT index and GET index are incremented and the new message

overwrites the oldest message in the FIFO. This will set FIFO overrun flag RFO in the Error Service Request Register.

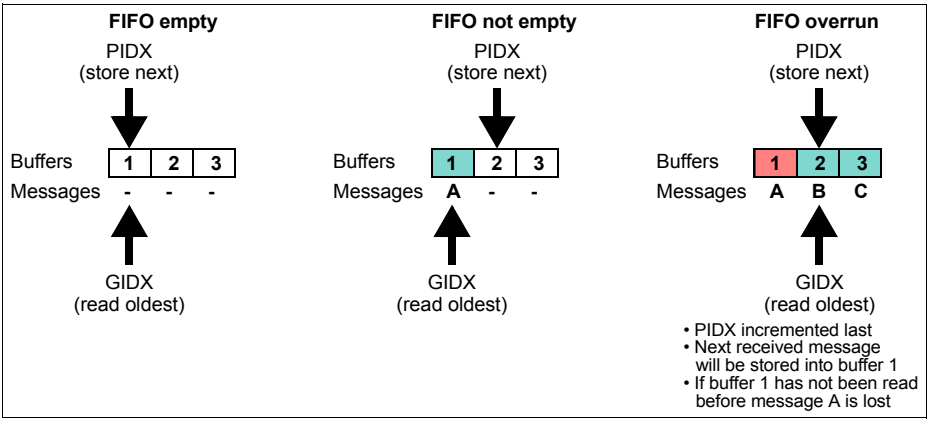

Figure 26-10 FIFO Status: Empty, Not Empty, Overrun

A FIFO non empty status is detected when the PUT index (PIDX) differs from the GET index (GIDX). In this case flag RFNE is set. This indicates that there is at least one received message in the FIFO. The FIFO empty, FIFO not empty, and the FIFO overrun states are explained in **Figure 26-10** for a three Message Buffer FIFO.

There is a programmable FIFO rejection filter for the FIFO. The FIFO Rejection Filter register (FRF) defines a filter pattern for messages to be rejected. The FIFO rejection filter consists of channel filter, Frame ID filter, and cycle counter filter. If bit RSS is set to 1 (default), all messages received in the static segment are rejected by the FIFO. If bit RNF is set to 1 (default), received NULL Frames are not stored in the FIFO.

The FIFO Rejection Filter Mask register (FRFM) specifies which bits of the Frame ID filter in the FIFO Rejection Filter register are marked “don’t care” for rejection filtering.

26.6.10.2 Configuration of the FIFO

For all Message Buffers belonging to the FIFO the data pointer to the first 32-bit word of the Data Section of the respective Message Buffer in the Message RAM has to be configured via the Write Header Section 3 register. All information required for acceptance filtering is taken from the FIFO rejection filter and the FIFO rejection filter mask and needs not be configured in the Header Sections of the Message Buffers belonging to the FIFO.

When programming the data pointers for the Message Buffers belonging to the FIFO, the payload length of all Message Buffers should be programmed to the same value.

*Note: It is recommended to program the MBI bits of the Message Buffers belonging to the FIFO to 0 via **WRHS1.MBI** to avoid generation of RX interrupts.*
*If the payload length of a received Frame is longer than the value programmed by **WRHS2.PLC** in the Header Section of the respective Message Buffer, the data field stored in a Message Buffer of the FIFO is truncated to that length.*

26.6.10.3 Access to the FIFO

To read from the FIFO the Host has to trigger a transfer from the Message RAM to the Output Buffer by writing the number of the first Message Buffer of the FIFO (referenced by FFB) to the Output Buffer Command Request register. The Message Handler then transfers the Message Buffer addressed by the GET Index Register (GIDX) to the Output Buffer. After this transfer the GET Index Register (GIDX) is incremented.

26.6.11 Message Handling

The Message Handler controls data transfers between the Input / Output Buffer and the Message RAM and between the Message RAM and the two Transient Buffer RAMs. All accesses to the internal RAM's are 32 bit accesses.

Access to the Message Buffers stored in the Message RAM is done under control of the Message Handler state machine. This avoids conflicts between accesses of the two protocol controllers and the Host to the Message RAM.

Frame IDs of Message Buffers assigned to the static segment have to be in the range from 1 to NSS as configured in the GTU Configuration Register 7. Frame IDs of Message Buffers assigned to the dynamic segment have to be in the range from NSS + 1 to 2047.

Received messages with no matching dedicated receive buffer (static or dynamic segment) are stored in the receive FIFO (if configured) if they pass the FIFO rejection filter.

26.6.11.1 Host access to Message RAM

The message transfer between Input Buffer and Message RAM as well as between Message RAM and Output Buffer is triggered by the Host by writing the number of the target / source Message Buffer to be accessed to the Input or Output Buffer Command Request register.

The Input / Output Buffer Command Mask registers can be used to write / read Header and Data Section of the selected Message Buffer separately. If bit **STXRS** in the Input Buffer Command Mask register is set (**STXRS** = 1), the transmission request flag TXR of the selected Message Buffer is automatically set after the Message Buffer has been updated.

If bit **STXRS** in the Input Buffer Command Mask register is reset (**STXRS** = 0), the transmission request flag TXR of the selected Message Buffer is reset. This can be used to stop transmission from Message Buffers operated in continuous mode.

Input Buffer (IBF) and the Output Buffer (OBF) are build up as a double buffer structure. One half of this double buffer structure is accessible by the Host (IBF Host / OBF Host), while the other half (IBF Shadow / OBF Shadow) is accessed by the Message Handler for data transfers between IBF / OBF and Message RAM.

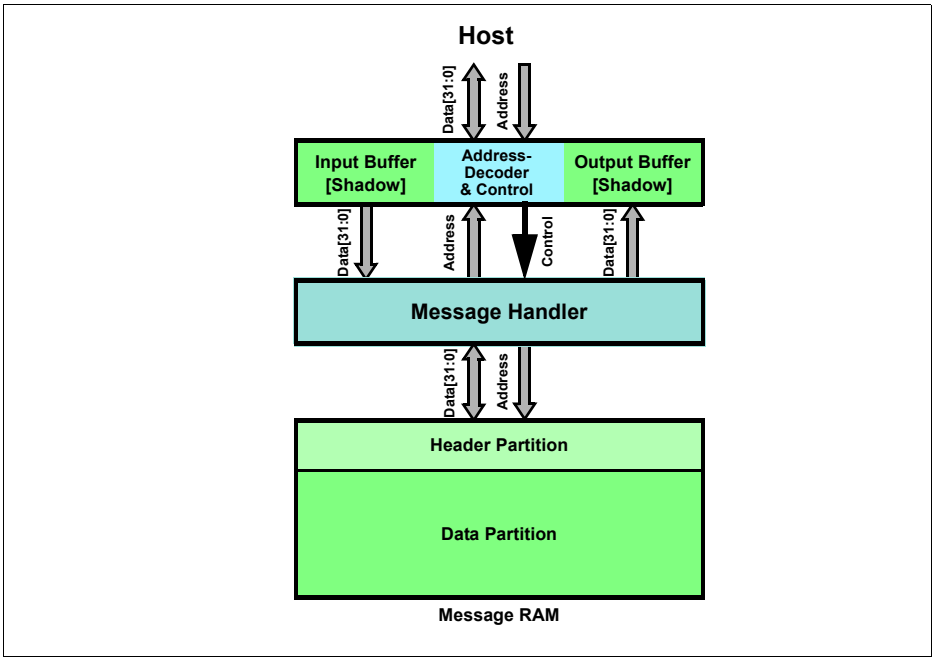

Figure 26-11 Host Access to Message RAM

Data Transfer from Input Buffer to Message RAM

To configure / update a Message Buffer in the Message RAM, the Host has to write the data to **WRDSnn (nn = 01-64)** and the Header to **WRHS1**, **WRHS2**, **WRHS3**. Two sets of **WRDSnn (nn = 01-64)** are available in parallel and selected by **CUST1.IBF1PAG**and **CUST1.IBF2PAG**. **CUST1.IBFS** shows which Input Buffer is currently used as Input Shadow Buffer and which as Input Host Buffer. **WRHS1**, **WRHS2**, and **WRHS2** does only exist once. The specific action is selected by configuring the Input Buffer Command Mask **IBCM**.

When the Host writes the number of the target Message Buffer in the Message RAM to IBRH in the Input Buffer Command Request register **IBCR**, IBF Host and IBF Shadow are swapped (see **Figure 26-12**).

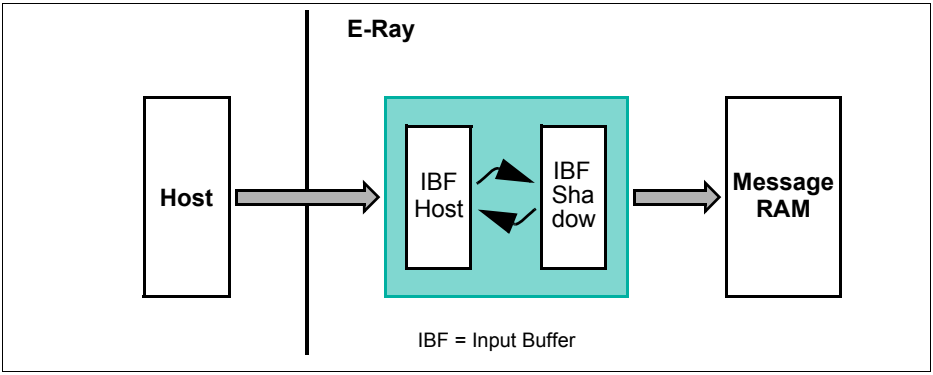

Figure 26-12 Double Buffer Structure Input Buffer

In addition the bits in the Input Buffer Command Mask and Input Buffer Command Request registers are also swapped to keep them attached to the respective IBF section (see **Figure 26-13**).

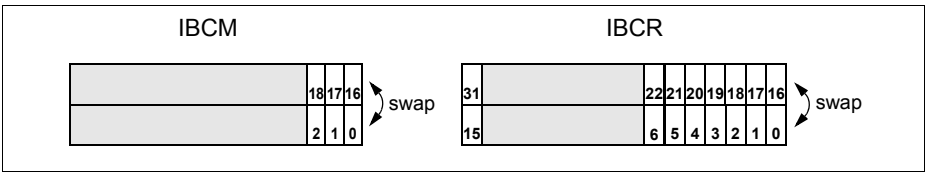

Figure 26-13 Swapping of IBCM and IBCR Bit

With this write operation the IBSYS bit in the Input Buffer Command Request register is set to 1. The Message Handler then starts to transfer the contents of IBF Shadow to the Message Buffer in the Message RAM selected by IBRS.

While the Message Handler transfers the data from IBF Shadow to the target Message Buffer in the Message RAM, the Host may write the next message to IBF Host. After the transfer between IBF Shadow and the Message RAM has completed, the IBSYS bit is set back to 0 and the next transfer to the Message RAM may be started by the Host by writing the respective target Message Buffer number to IBRH in the Input Buffer Command Request register.

If a write access to IBRH occurs while IBSYS is 1, IBSYH is set to 1. After completion of the ongoing data transfer from IBF Shadow to the Message RAM, IBF Host and IBF Shadow are swapped, IBSYH is reset to 0, IBSYS remains set to 1, and the next transfer

to the Message RAM is started. In addition the Message Buffer numbers stored under IBRH and IBRS and the Command Mask flags are also swapped.

Table 26-16 Assignment of Input Buffer Command Mask Bit

Pos.	Access	Bit	Function
18	rh	**STXRS**	Set Transmission Request Shadow
17	rh	**LDSS**	Load Data Section Shadow
16	rh	**LHSS**	Load Header Section Shadow
2	rw	**STXRH**	Set Transmission Request Host
1	rw	**LDSH**	Load Data Section Host
0	rw	**LHSH**	Load Header Section Host

Table 26-17 Assignment of Input Buffer Command Request Bit

Pos.	Access	Bit	Function
31	rh	IBSYS	**IBF Busy Shadow,** signals ongoing transfer from IBF Shadow to Message RAM
21–16	rh	IBRS	**IBF Request Shadow,** number of Message Buffer currently / last updated
15	rh	IBSYH	**IBF Busy Host,** transfer request pending for Message Buffer referenced by IBRH
5-0	rwh	IBRH	**IBF Request Host,** number of Message Buffer to be updated next

Data Transfer from Message RAM to Output Buffer

To read a Message Buffer from the Message RAM, the Host has to write to Command Request register **OBCR** to trigger the data transfer as configured in Output Buffer Command Mask **OBCM** register. After the transfer has completed, the Host can read the transferred data from **RDDSnn (nn = 01-64)**, **RDHS1**, **RDHS2**, **RDHS2**, and **MBS**.

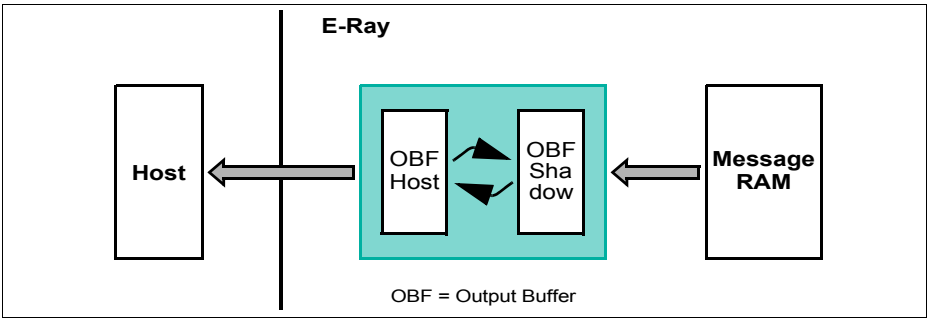

Figure 26-14 Double Buffer Structure Output Buffer

OBF Host and OBF Shadow as well as bits **OBCM.RHSS**, **OBCM.RDSS**, **OBCM.RHSH**, **OBCM.RDSH** and bits **OBCR.OBRS**, **OBCR.OBRH** are swapped under control of bits **OBCR.VIEW** and **OBCR.REQ**.

Writing bit **OBCR.REQ** to 1 copies bits **OBCM.RHSS**, **OBCM.RDSS** and bits **OBCR.OBRS** to an internal storage (see **Figure 26-15**).

After setting **OBCR.REQ** to 1, **OBCR.OBSYS** is set to 1, and the transfer of the Message Buffer selected by **OBCR.OBRS** from the Message RAM to OBF Shadow is started. After the transfer between the Message RAM and OBF Shadow has completed, the **OBCR.OBSYS** bit is set back to 0. Bits **OBCR.REQ** and **OBCR.VIEW** can only be set to 1 while **OBCR.OBSYS** is 0.

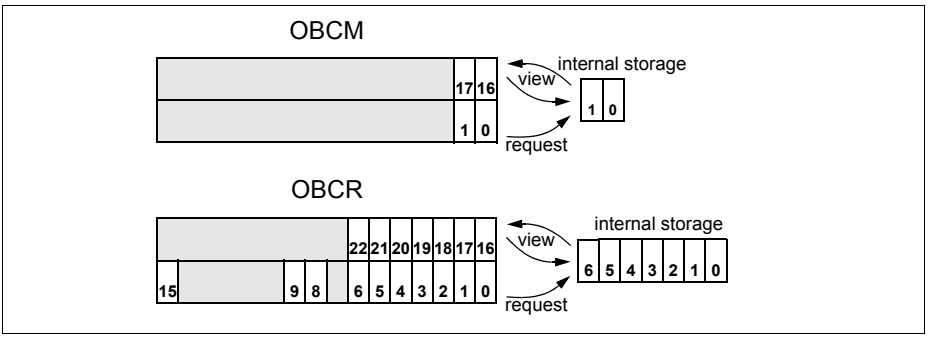

Figure 26-15 Swapping of OBCM and OBCR Bit

OBF Host and OBF Shadow are swapped by setting bit **OBCR.VIEW** to 1 while bit **OBCR.OBSYS** is 0 (see **Figure 26-14**).

In addition bits **OBCR.OBRH** and bits **OBCM.RHSH**, **OBCM.RDSH** are swapped with the registers internal storage thus assuring that the Message Buffer number stored in

OBCR.OBRH and the mask configuration stored in **OBCM.RHSH**, **OBCM.RDSH** matches the transferred data stored in OBF Host (see **Figure 26-15**).

Now the Host can read the transferred Message Buffer from OBF Host while the Message Handler may transfer the next message from the Message RAM to OBF Shadow.

Table 26-18 Assignment of Output Buffer Command Mask Bit

Pos.	Access	Bit	Function
17	rh	RDSH	Data Section available for Host access
16	rh	RHSH	Header Section available for Host access
1	rw	RDSS	Read Data Section Shadow
0	rw	RHSS	Read Header Section Shadow

Table 26-19 Assignment of Output Buffer Command Request Bit

Pos.	Access	Bit	Function
22–16	rh	OBRH	**OBF Request Host,** number of Message Buffer available for Host access
15	rh	OBSYS	**OBF Busy Shadow,** signals ongoing transfer from Message RAM to OBF Shadow
9	rw	REQ	**Request Transfer from Message RAM to OBF Shadow**
8	rwh	VIEW	**View OBF Shadow, swap OBF Shadow, and OBF Host**
6–0	rwh	OBRS	**OBF Request Shadow,** number of Message Buffer for next request

26.6.11.2 Data Transfers between IBF / OBF and Message RAM

This document uses the following terms and abbreviations:

Table 26-20 Terms and Abbreviations

Term	Meaning
MHD	Message Handler
IBF	Input Buffer 1 or 2 RAM
OBF	Output Buffer 1 or 2 RAM
MBF	Message Buffer RAM
TBF	Transient Buffer RAM Channel A (TBF1) or Channel B (TBF2)

Table 26-20 Terms and Abbreviations (cont'd)

IBF ⇒ MBF	Transfer from IBF to MBF
MBF ⇒ OBF	Transfer from MBF to OBF
MBF ⇒ TBF	Transfer from MBF to TBF
TBF ⇒ MBF	Transfer from TBF to MBF
SS	Slot Status
SS ⇒ MBF	Transfer SS to MBF

Message Handler functionality

The MHD controls the access to the MBF. It manages data-transfer between MBF and IBF, OBF, TBF1, TBF2. The data-path are shown in Figure 26-16.

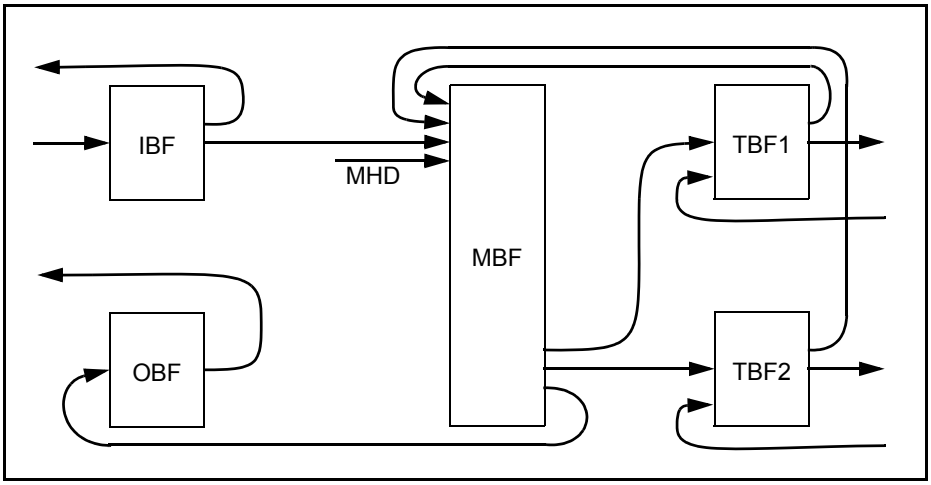

Figure 26-16 Interconnection of RAMs

Furthermore a search-algorithm allows to find the next valid message object in the MBF for transmission or reception.

Each transfer consists of a setup-time, four time steps to transfer the Header-section and a payload-length-dependent number of time steps to transfer the data-section. The internal data-busses have a width of 32 bits. Thereby it is possible to transfer two 2-byte words in one time step. If the payload consists of an odd number of 2-byte words the last time step of the data-section contains only 16 bit of valid data. If the Payload-Length (PL) is e.g. 7, the data-section consists of 4 time steps.

The maximum length for the data-section is 64 time steps, the minimum length is zero time steps.

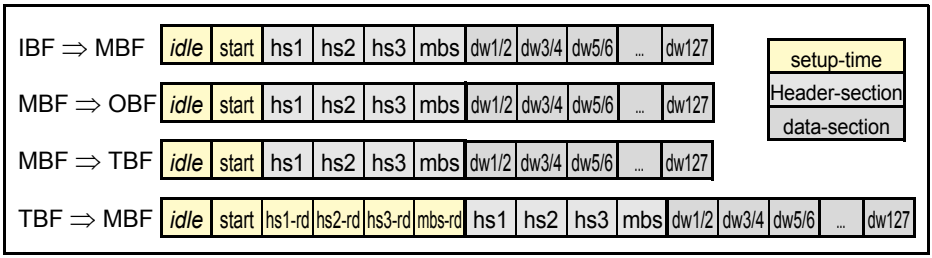

Figure 26-17 Different Possible Buffer Transfers

The update of the Slot-Status consists of a setup-time and one time-step to write the new Slot-Status.

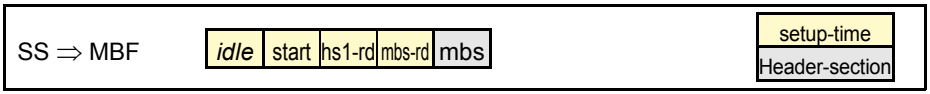

Figure 26-18 Update of Slot Status

The length of a time step depends on the number of concurrent tasks.

The following concurrent tasks are executed under control of the Message Handler:

- Data transfer between IBF or OBF and MBF
- Data transfer between TBF1 and MBF, search next TX / RX Message Buffer CHA
- Data transfer between TBF2 and MBF, search next TX / RX Message Buffer CHB

Thereby the time step length can vary between one and three f_{CLC_ERAY} periods.

Under certain conditions it is possible that a transfer is stopped or interrupted for a number of time steps until it is continued.

When a IB F⇒ MBF is started short after a TBF ⇒ MBF or SS ⇒ MBF the transfer from IBF has to wait until the setup-time of the internal transfer has finished (see Figure 26-19)

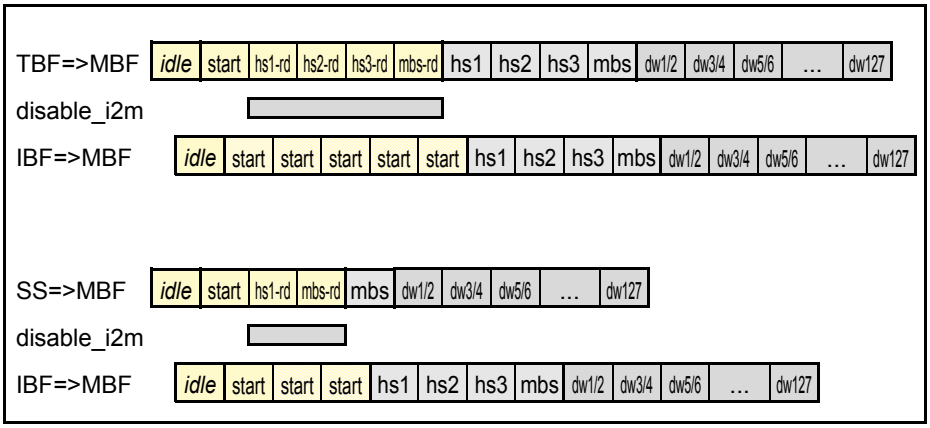

Figure 26-19 Delay start of IBF⇒MBF

The internal signal “disable_i2m” is always active when the TBF ⇒ MBF is in state “hs1-rd”, “hs2-rd”, “hs3-rd” or “mbs-rd” and when the SS ⇒ MBF is in state “hs1-rd” or “mbs-rd”.

The IBF ⇒ MBF is hold in state “start” until the internal signal “disable_i2m” gets inactive.

These additional time-steps are independent of any address-counter-values. This means, the IBF ⇒ MBF has to wait even if it writes to another buffer than the internal transfer.

Multiple requests of transfers between IBF/OBF and Message RAM

The time required to transfer the contents of a Message Buffer between IBF / OBF and Message RAM depends on the number of 4-byte words to be transferred, the number of concurrent tasks to be managed by the Message Handler, and in special cases the type and address range of the internal transfer. The number of 4-byte words varies from 4 (Header Section only) to 68 (Header + maximum Data Section) plus a short setup time to start the first transfer, while the number of concurrent task varies from one to three. The 4 Header words have to be included in calculation even if only the Data Section is requested for transfer.

The following concurrent tasks are executed under control of the Message Handler:

- Data transfer between IBF or OBF and MBF
- Data transfer between TBF1 and MBF, search next TX / RX Message Buffer CHA
- Data transfer between TBF2 and MBF, search next TX / RX Message Buffer CHB

Transfers between IBF and MBF respectively MBF and OBF can only be handled one after another. In case that e.g. a IBF ⇒ MBF has been started shortly before a

MBF ⇒ OBF is requested, the MBF ⇒ OBF has to wait until the IBF ⇒ MBF has completed.

In case that e.g. a second IBF⇒MBF is requested, a MBF⇒OBF is requested and a IBF⇒MBF is ongoing, the MBF⇒OBF has to wait until the first IBF⇒IBF has completed. The second IBF=MBF has to wait until the MBF⇒OBF has completed (see figure 26-20) independent whether MBF⇒OBF or second IBF⇒MBF is requested first.

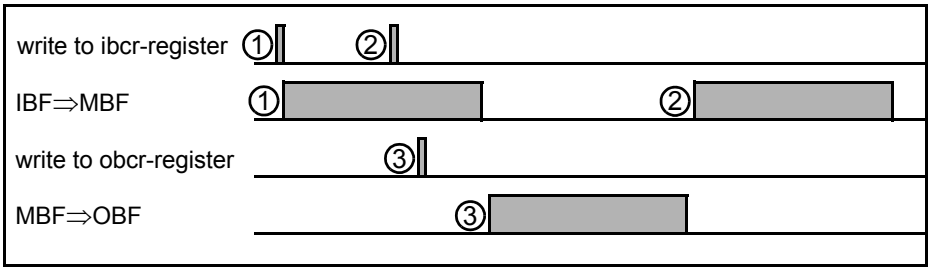

Figure 26-20 Multiple IBF/OBF Request

Worst case for single request

When a message with a large payload length is received the TBF⇒MBF is started at the begin of the next slot (n+1). If the next slot is a dynamic slot without transmission/reception (minislot), it may happen that the TBF⇒MBF has not finished until begin of the next but one slot (n+2). In this case the TBF⇒MBF will be service requested (break) to start a transmission in the next but one slot (MBF⇒TBF) and/or to update the slot status (SS⇒MBF) for the RX-buffer corresponding with next slot (n+1). After this interruption the TBF⇒MBF is continued.

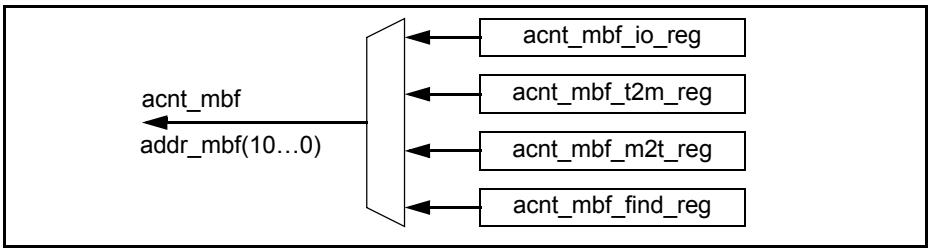

Figure 26-21 Address Counter Scheme of Message RAM (simplified)

For the transfers IBF⇒MBF / MBF⇒OBF, TBF⇒MBF and MBF⇒TBF separate address-counter are implemented (see Figure 26-21).

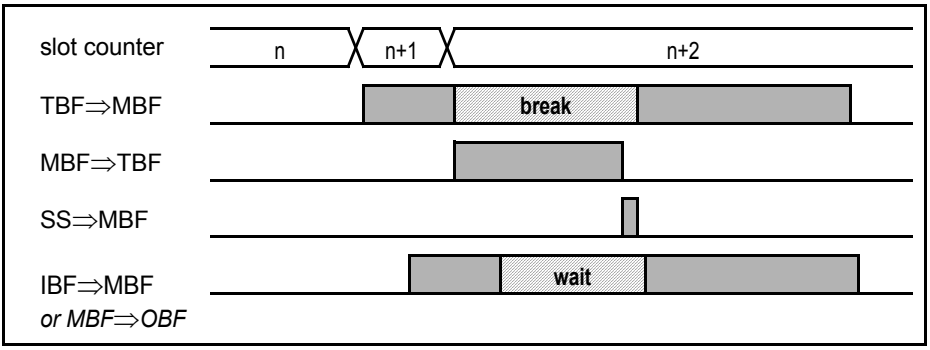

Figure 26-22 interruption of TBF⇒MBF

If the address-counter for IBF⇒MBF / MBF⇒OBF (acnt_mbf_io_reg) reaches the address of the interrupted TBF=>MBF (acnt_mbf_t2m_reg) the IBF⇒MBF / MBF⇒OBF has to wait until the TBF⇒MBF is continued (see Figure 26-22).

The relative time is measured in f_{CLC_ERAY} cycles. Absolute time depends on the actual f_{CLC_ERAY} cycle period.

tbf_to_mbf_break time$_{max}$ = (setup time + mbf_to_tbf time$_{max}$) + (setup time + ss_to_mbf)

cycles$_{req}$ = (number of concurrent tasks) × ((setup time+ (number of 4-byte words)$_{req}$) + tbf_to_mbf_break time)

setup time = 2 f_{CLC_ERAY} cycles

Worst case for one IBF⇒MBF or MBF⇒OBF:

Max. break time: tbf_to_mbf_break time$_{max}$ = (2+68) + (4+1) = 75

Max. number of f_{CLC_ERAY} cycles: cycles$_{req}$ = 3 × (6 + 68 + 75) = 435

Worst case for multiple transfers

If a second IBF⇒MBF and a MBF⇒OBF (see Figure 26-20) is requested directly after the first IBF⇒MBF has started following worst case timing could appear:

cycles$_{trans}$ = (remaining cycles of transfer running)
+ (cycles of second requested transfer)
+ (cycles of third requested transfer)

cycles$_{trans}$ = cycles$_{rem}$ + cycles$_{req_2}$+ cycles$_{req_3}$

Max. number of f_{CLC_ERAY} cycles: cycles$_{trans}$ = 447 + 435 + 447 = 1329

26.6.11.3 Minimum f_{CLC_ERAY}

To calculate the minimum f_{CLC_ERAY} the worst case scenario has to be considered.

The worst case scenario depends on the following parameters

- maximum payload length
- minimum minislot length
- number of configured Message Buffers (excluding FIFO)
- used channels (single/dual channel)

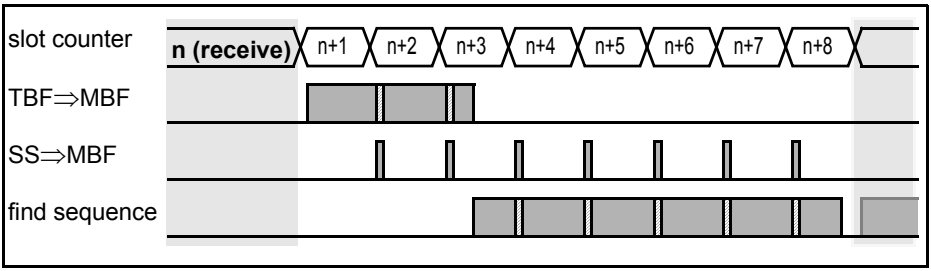

Figure 26-23 worst case scenario

Worst case scenario:

- reception of message with a maximum payload length in Slot n (n is 7,15,23,31,39,…)
- slot n+1 to n+7 are empty dynamic slots (minislot) and configured as receive buffer
- the find-sequence (usually started in slot 8,16,24,32,40,…) has to scan the maximum number of configured buffers
- the number of concurrent tasks has its maximum value of three

The find-sequence is executed each 8 Slots (slot 8,16,24,32,40,…). It has to be finished until the next find-sequence is requested.

The length of a TBF⇒MBF varies from 4 (Header Section only) to 68 (Header + maximum Data Section) time step plus a setup time of 6 time steps.

$$cycles_{t2m} = \frac{f_{CLC\_ERAY}}{\text{number of concurrent tasks}) \times (\text{setup time}_{t2m} + (\text{number of 4-byte words})_{t2m})}$$

A SS⇒MBF has a fixed length of 1 time steps plus a setup time of 4 time steps.

$$cycles_{ss2m} = \frac{f_{CLC\_ERAY}}{(\text{number of concurrent tasks}) \times 5}$$

The find sequence has a maximum length of 128 (maximum number of buffers) time steps plus a setup time of 2 time steps.

$$cycles_{find} = \frac{f_{CLC\_ERAY}}{(\text{number of concurrent tasks}) \times (\text{setup time}_{find} + (\text{number of configured buffers}))}$$

A minislot has a length of 2 to 63 Macrotick (gdMinislot). The minimum nominal Macrotick period (cdMinMTNom) is 1 µs. A sequence of 8 minislots has a length of

$$time_{8minislots} = 8 \times gdMinislot \times cdMinMTNom$$

The maximum period $T_{CLC\_ERAY} = 1/f_{CLC\_ERAY}$ can be calculated as followed:

$$time_{8minislots} \geq (f_{CLC\_ERAY}\ \text{period in}\ \mu s) \times (\ (f_{CLC\_ERAY}\ cycles_{t2m}) + 7 \times (f_{CLC\_ERAY}\ cycles_{ss2m}) + (f_{CLC\_ERAY}\ cycles_{find}))$$

$$f_{CLC\_ERAY}\ \text{period in ms} \leq \frac{time_{8mnislots}}{(\ cycles_{t2m}) + 7 \times (cycles_{ss2m}) + (cycles_{find})}$$

minimum $time_{8minislots}$ = $8 \times 2 \times 1\ \mu s = 16\ \mu s$

maximum $f_{CLC\_ERAY}\ cycles_{t2m}$ = $3 \times (6 + 68) = 222$

maximum $f_{CLC\_ERAY}\ cycles_{ss2m}$ = $3 * 5 = 15$

maximum $f_{CLC\_ERAY}\ cycles_{find}$ = $3 * (2 + 128) = 390$

$$f_{CLC\_ERAY}\ \text{period in ms} \leq \frac{16\mu s}{222 + 7 \times 15 + 390} = 22.315\ldots ns$$

The minimum f_{CLC_ERAY} frequency for this worst case scenario is 44.8125 MHz.

A too low f_{CLC_ERAY} frequency can cause a malfunction of the E-Ray.

The E-Ray can detect several malfunctions and reports this by setting the corresponding flag in the Message Handler Constraints Flags (**MHDF**) register.

Minimum f_{CLC_ERAY} for various maximum payload length

Table 26-21 summarizes the minimum required f_{CLC_ERAY} frequency for various maximum payload length assuming:

- a minimum minislot length of 2µs.
- a maximum of 128 configured Message Buffers.
- dual channels in use.

Table 26-21 Minimum f_{CLC_ERAY} for different maximum payload length

Maximum payload length of 32 bit words	4	8	16	32	64
minimum f_{CLC_ERAY}	32,82 MHz	33,57 MHz	35,07 MHz	38,07 MHz	44,82 MHz

Minimum f_{CLC_ERAY} for various minimum minislot length

Table 26-22 summarizes the minimum required f_{CLC_ERAY} frequency for various minimum minislot length assuming:

- a maximum payload length of 254 bytes / 64 four-byte-words.
- a maximum 128 configured Message Buffers.
- dual channels in use.

Table 26-22 Minimum f_{CLC_ERAY} for different minimum minislot length

gdMinislot at dMinMTNom = 1 µs	2 µs	3 µs	4 µs	7 µs	8 µs
minimum f_{CLC_ERAY}	44,82 MHz	29,88 MHz	22,412 MHz	12,8 MHz	9,96 MHz

Minimum f_{CLC_ERAY} for various amount of configured Message Buffers

Table 26-23 summarizes the minimum required f_{CLC_ERAY} frequency for various amount of configured Message Buffers assuming:

- a maximum payload length of 254 bytes / 64 four-byte-words.
- a minimum minislot length of 2 µs.
- dual channels in use.

Table 26-23 Minimum f_{CLC_ERAY} for different amount of configured Message Buffers

Configured maximum amount of Message Buffers	128	64	32
minimum f_{CLC_ERAY}	44,82 MHz	32,82 MHz	26,82 MHz

Minimum f_{CLC_ERAY} for a typical configuration

´The minimum required f_{CLC_ERAY} frequency for various assuming the following typical E-Ray configuration:

- a maximum payload length of 32 bytes / 8 four-byte-words.
- a minimum minislot length of 7 µs.
- a maximum 128 configured Message Buffers.
- dual channels in use

The minimum f_{CLC_ERAY} frequency for this typical example would be 10 MHz.

26.6.11.4 FlexRay™ Protocol Controller access to Message RAM

The two Transient Buffer RAMs (TBF 1, TBF 2) are used to buffer the data for transfer between the two FlexRay™ Protocol Controllers and the Message RAM.

Each Transient Buffer RAM is build up as a double buffer, able to store two complete FlexRay™ messages. There is always one buffer assigned to the corresponding Protocol Controller while the other one is accessible by the Message Handler.

If e.g. the Message Handler writes the next message to be send to Transient Buffer Tx, the FlexRay™ Channel Protocol Controller can access Transient Buffer Rx to store the message it is actually receiving. During transmission of the message stored in Transient Buffer Tx, the Message Handler transfers the last received message stored in Transient Buffer Rx to the Message RAM (if it passes acceptance filtering) and updates the respective Message Buffer.

Data transfers between the Transient Buffer RAMs and the shift registers of the FlexRay™ Channel Protocol Controllers are done in words of 32 bit. This enables the use of a 32 bit shift register independent of the length of the FlexRay™ messages.

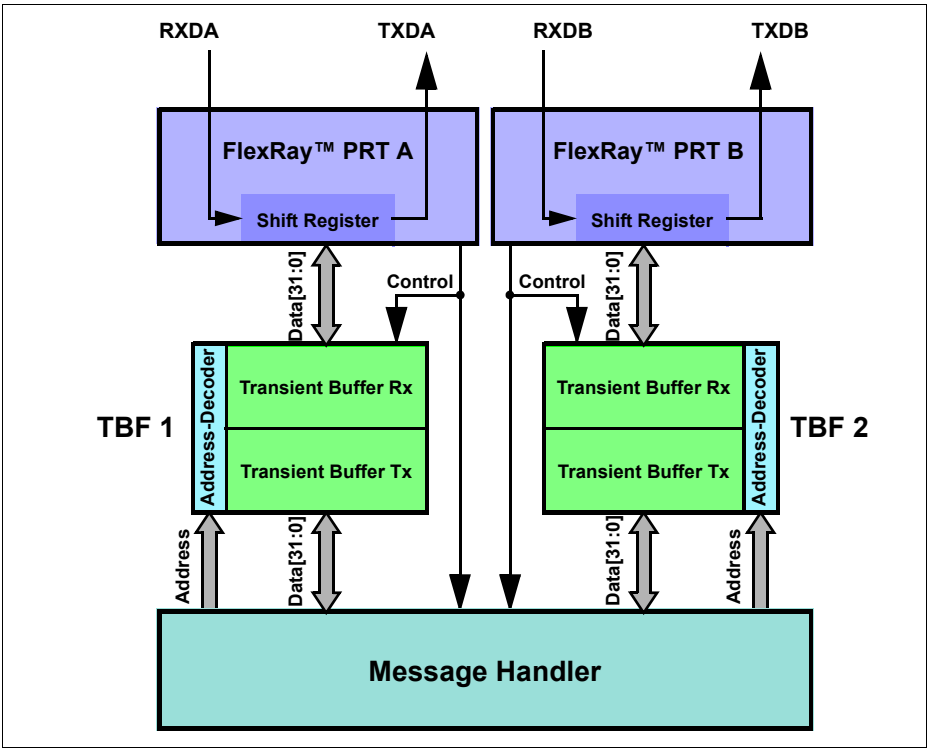

Figure 26-24 Access to Transient Buffer RAMs

26.6.12 Message RAM

To avoid conflicts between Host access to the Message RAM and FlexRay™ message reception / transmission, the Host cannot directly access the Message Buffers in the Message RAM. These accesses are handled via the Input and Output Buffers. The Message RAM is able to store up to 128 Message Buffers depending on the configured payload length.

The Message RAM is organized 2048 x 32. To achieve the required flexibility with respect to different numbers of data byte per FlexRay™ Frame (0 to 254), the Message RAM has a structure as shown in **Figure 26-25**.

The Data Partition is allowed to start at Message RAM word number: (MRC.LCB + 1) • 4

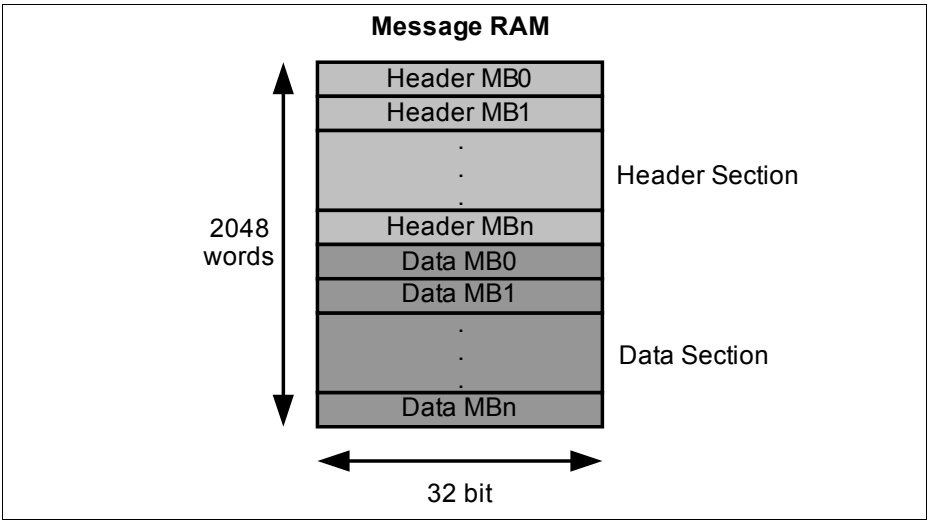

Figure 26-25 Structure of Message RAM

Header Partition

Stores Header Segments of FlexRay™ Frames:

- Supports a maximum of 128 Message Buffers
- Each Message Buffer has a Header of four 32 bit words
- Header 3 of each Message Buffer holds the11 bit pointer to the respective Data Section in the Data Partition

Data Partition

Flexible storage of Data Sections with different length. Some maximum values are:

- 30 Message Buffers with 254 byte Data Section each
- Or 56 Message Buffers with 128 byte Data Section each
- Or 128 Message Buffers with 48 byte Data Section each

Restriction: Header Partition + Data Partition may not occupy more than 2048 32-bit words.

26.6.12.1 Header Partition

The Header of each Message Buffer occupies four 32-bit words in the Header Partition of the Message RAM. The Header of Message Buffer 0 starts with the first word in the Message RAM.

For transmit buffers the Header CRC has to be calculated by the Host.

Payload Length Received **PLR**, Receive Cycle Count **RCC**, Received on Channel Indication **RCI**, Startup Frame Indication bit **SFI**, Sync bit **SYN**, NULL Frame Indication bit **NFI**, Payload Preamble Indication bit **PPI**, and Reserved bit **RES** are only updated from received valid Frames (including valid NULL Frames).

Header word 4 of each configured Message Buffer holds the respective Message Buffer Status **MBS** information.

Table 26-24 Header Section of a Message Buffer in the Message RAM

Bit Word	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1			MBI	TXM	NME	CFG	CHB	CHA		Cycle Code												Frame ID										
2		Payload Length Received								Payload Length Configured												Tx Buffer: Header CRC Configured Rx Buffer: Header CRC Received										
3			RES	PPI	NFI	SYN	SFI	RCI		Receive Cycle Count												Data Pointer										
4			RESS	PPIS	NFIS	SYNS	SFIS	RCIS		Cycle Count Status							TFB	FTY		MLST	ESB	ESA	TCIB	TCIA	SVOB	SVOA	CEOB	CEOA	SEOB	SEOA	VFRB	VFRA

- Frame Configuration
- Filter Configuration
- Message Buffer Control
- Message RAM Configuration
- Updated from received Frame
- Message Buffer Status
- unused

Header 1 (word 0)

Write access via **WRHS1**, read access via **RDHS1**:

- Frame ID: Slot counter filtering configuration
- Cycle Code: Cycle counter filtering configuration
- CHA, CHB: Channel filtering configuration
- CFG: Message Buffer configuration: receive / transmit
- PPIT: Payload Preamble Indicator Transmit
- XMI: Transmit mode configuration: single-shot / continuous
- MBI: Message Buffer receive / transmit service request enable

Header 2 (word 1)

Write access via **WRHS2**, read access via **RDHS2**:

- Header CRC
  - Transmit Buffer: Configured by the Host (calculated from Frame Header Segment)
  - Receive Buffer: Updated from received Frame
- Payload Length Configured
  - Length of Data Section (2-byte words) as configured by the Host
- Payload Length Received
  - Length of Payload Segment (2-byte words) stored from received Frame

Header 3

Write access via **WRHS3**, read access via **RDHS3**:

- Data Pointer
  - Pointer to the beginning of the corresponding Data Section in the Data Partition

Read access via **RDHS3**, valid for receive buffers only, updated from received Frames:

- Receive Cycle Count: Cycle count from received Frame
- RCI: Received on Channel Indicator
- SFI: Startup Frame Indicator
- SYN: SYNC Frame Indicator
- NFI: NULL Frame Indicator
- PPI: Payload Preamble Indicator
- RES: Reserved bit

Message Buffer Status MBS (word 3)

Read access via MBS, updated by the Communication Controller at the end of the configured slot.

- VFRA: Valid Frame Received on channel A
- VFRB: Valid Frame Received on channel B
- SEOA: Syntax Error Observed on channel A
- SEOB: Syntax Error Observed on channel B
- CEOA: Content Error Observed on channel A
- CEOB: Content Error Observed on channel B
- SVOA: Slot boundary Violation Observed on channel A
- SVOB: Slot boundary Violation Observed on channel B
- TCIA: Transmission Conflict Indication channel A
- TCIB: Transmission Conflict Indication channel B
- ESA: Empty Slot Channel A
- ESB: Empty Slot Channel B
- MLST: Message LoST
- FTA: Frame Transmitted on Channel A
- FTA: Frame Transmitted on Channel B
- Cycle Count Status: Actual cycle count when status was updated
- RCIS: Received on CHannel Indicator Status
- SFIS: Startup Frame Indicator Status
- SYNS: SYNC Frame Indicator Status
- NFIS: NULL Frame Indicator Status
- PPIS: Payload Preamble Indicator Status
- RESS: Reserved Bit Status

26.6.12.2 Data Partition

The Data Partition of the Message RAM stores the Data Sections of the Message Buffers configured for reception / transmission as defined in the Header Partition. The number of data bytes for each Message Buffer can vary from 0 to 254. To optimize the data transfer between the shift registers of the two FlexRay™ Protocol Controllers and the Message RAM as well as between the Host interface and the Message RAM, the physical width of the Message RAM is set to 4 bytes.

The Data Partition starts after the last word of the Header Partition. When configuring the Message Buffers in the Message RAM the programmer has to assure that the data pointers point to addresses within the Data Partition. **Table 26-25** below shows an example how the Data Sections of the configured Message Buffers can be stored in the Data Partition of the Message RAM.

The beginning and the end of a Message Buffer's Data Section is determined by the data pointer and the payload length configured in the Message Buffer's Header Section,

respectively. This enables a flexible usage of the available RAM space for storage of Message Buffers with different data length.

If the size of the Data Section is an odd number of 2-byte words, the remaining 16 bits in the last 32-bit word are unused (see **Table 26-25** below)

Table 26-25 Example for Structure of the Data Section in the Message RAM

Bit Word	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

26.6.12.3 ECC Check

There is an ECC checking mechanism implemented in the E-Ray module to assure the integrity of the data stored in the seven RAM blocks of the module. The RAM blocks have an ECC generator / checker attached as shown in **Figure 26-26**. When data is written to a RAM block, the local ECC generator generates the ECC data. The ECC data is stored together with the respective data word. The ECC data is checked each time a data word is read from any of the RAM blocks.

If an ECC error is detected, the respective error flag is set. The ECC error flags **MHDS.EIBF**, **MHDS.EOBF**, **MHDS.EMR**, **MHDS.ETBF1**, **MHDS.ETBF2**, and the faulty Message Buffer indicators **MHDS.FMBD**, **MHDS.MFMB**, **MHDS.FMB** are located in the Message Handler Status register. These error flags control the error interrupt flag **EIR.EERR**.

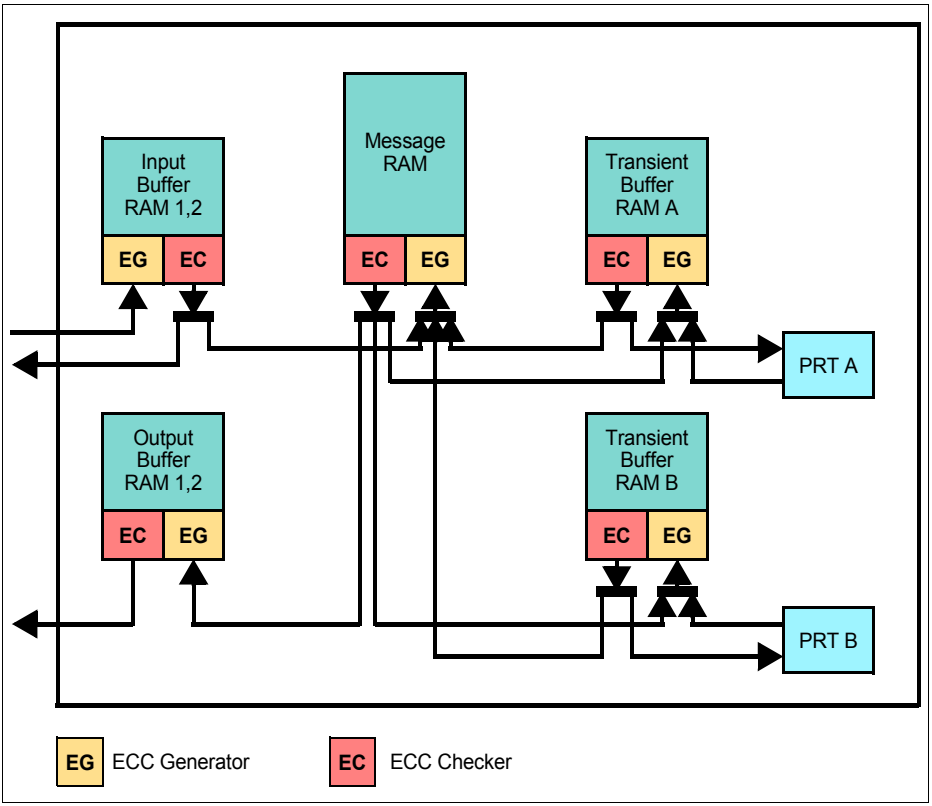

Figure 26-26 ECC Generation and Check

When an ECC error has been detected the following actions will be performed:

In all cases

- The respective ECC error flag in the Message Handler Status **MHDS** register is set
- The ECC error flag **EIR.EERR** in the Error Service Request Register is set, and if enabled, a module service request to the Host will be generated.

Additionally in specific cases

1. ECC error in data transfer from Input Buffer RAM 1,2 ⇒ Message RAM (Transfer of Header and Data Section)
   a) **MHDS.EIBF** bit is set
   b) **MHDS.FMBD** bit is set to indicate that **MHDS.FMB** has been updated
   c) **MHDS.FMB** indicates the number of the faulty Message Buffer
   d) Transmit buffer: Transmission request for the respective Message Buffer is not set
2. ECC error in data transfer from Input Buffer RAM 1,2 ⇒ Message RAM (Transfer of Data Section only)
   a) **MHDS.EMR** bit is set
   b) **MHDS.FMBD** bit is set to indicate that **MHDS.FMB** points to a faulty Message Buffer
   c) **MHDS.FMB** indicates the number of the faulty Message Buffer
   d) The Data Section of the respective Message Buffer is not updated
   e) Transmit buffer: Transmission request for the respective Message Buffer is not set
3. ECC error during host reading Input Buffer RAM
   a) • **MHDS.EIBF** bit is set
4. ECC error during scan of Header Sections in Message RAM
   a) **MHDS.EMR** bit is set
   b) **MHDS.FMBD** bit is set to indicate that **MHDS.FMB** points to a faulty Message Buffer
   c) **MHDS.FMB** indicates the number of the faulty Message Buffer
   d) Ignore Message Buffer (Message Buffer is skipped)
5. ECC error during data transfer from Message RAM ⇒ Transient Buffer RAM A, B
   a) **MHDS.EMR** bit is set
   b) **MHDS.FMBD** bit is set to indicate that **MHDS.FMB** points to a faulty Message Buffer
   c) **MHDS.FMB** indicates the number of the faulty Message Buffer
   d) Frame not transmitted, Frames already in transmission are invalidated by setting the Frame CRC to zero
6. ECC error during data transfer from Transient Buffer RAM A, B ⇒ Protocol Controller 1, 2
   a) **MHDS.ETBF1**, **MHDS.ETBF2** bit is set
7. ECC error in data transfer from Transient Buffer RAM A, B ⇒ Message RAM (ECC error when reading Header Section of respective Message Buffer from Message RAM)
   a) **MHDS.EMR** bit is set
   b) **MHDS.FMBD** bit is set to indicate that **MHDS.FMB** points to a faulty Message Buffer
   c) **MHDS.FMB** indicates the number of the faulty Message Buffer
   d) The Data Section of the respective Message Buffer is not updated

8. ECC error in data transfer from Transient Buffer RAM A, B ⇒ Message RAM (ECC error when reading Transient Buffer RAM A, B)
   a) **MHDS.ETBF1**, **MHDS.ETBF2** bit is set
   b) **MHDS.FMBD** bit is set to indicate that **MHDS.FMB** points to a faulty Message Buffer
   c) **MHDS.FMB** indicates the number of the faulty Message Buffer
9. ECC error during data transfer from Message RAM ⇒ Output Buffer RAM
   a) **MHDS.EMR** bit is set
   b) **MHDS.FMBD** bit is set to indicate that **MHDS.FMB** points to a faulty Message Buffer
   c) **MHDS.FMB** indicates the number of the faulty Message Buffer
10. ECC error during Host reading Output Buffer RAM
   a) • **MHDS.EOBF** bit is set
11. ECC error during data read of Transient Buffer RAM A, B

If an ECC error occurs while the Message Handler reads a Frame with Network Management information (PPI = 1) from the Transient Buffer RAM A, B the corresponding Network Management vector registers NMV1 to NMV3 are not updated from that Frame.

26.6.13 Host Handling of Errors

An ECC error caused by transient bit flips can be fixed by:

26.6.13.1 Self-Healing

ECC errors located in

- Input Buffer RAM 1,2
- Output Buffer RAM 1,2
- Data Section of Message RAM
- Transient Buffer RAM A
- Transient Buffer RAM B

are overwritten with the next write access to the disturbed bit(s) caused by Host access or by FlexRay communication.

26.6.13.2 CLEAR_RAMS Command

When called in DEFAULT_CONFIG or CONFIG state POC command CLEAR_RAMS initializes all module-internal RAMs to zero.

26.6.13.3 Temporary Unlocking of Header Section

An ECC error in the header section of a locked message buffer can be fixed by a transfer from the Input Buffer to the locked buffer Header Section. For this transfer, the write-

access to the IBCR (specifying the message buffer number) must be immediately preceded by the unlock sequence normally used to leave CONFIG state (see **“Lock Register (LCK)” on Page 26-39**).

For that single transfer the respective message buffer header is unlocked, regardless whether it belongs to the FIFO or whether its locking is controlled by MRC.SEC[1:0], and will be updated with new data.

26.7 Module Service Request

In general, service requests provide a close link to the protocol timing as they are triggered almost immediately when an error or status change is detected by the controller, a Frame is received or transmitted, a configured timer service request is activated, or a stop watch event occurred. This enables the Host to react very quickly on specific error conditions, status changes, or timer events. On the other hand too many service requests can cause the Host to miss deadlines required for the application. Therefore the Communication Controller supports disable / enable controls for each individual service request source separately.

An service request may be triggered when

- An error was detected
- A status flag is set
- A timer reaches a preconfigured value
- A message transfer from Input Buffer to Message RAM or from Message RAM to Output Buffer has completed
- A stop watch event occurred

Tracking status and generating service requests when a status change or an error occurs are two independent tasks. Regardless of whether an service request is enabled or not, the corresponding status is tracked and indicated by the Communication Controller. The Host has access to the actual status and error information by reading the Error Service Request Register **EIR** and the Status Service Request **SIR** Register.

Table 26-26 Module Service Request Flags and Service Request Line Enable

Register	Bit	Function
SIR	WST	Wakeup Status
	CAS	Collision Avoidance Symbol
	CYCS	Cycle Start Service Request
	TXI	Transmit Service Request
	RXI	Receive Service Request
	RFNE	Receive FIFO not Empty
	RFF	Receive FIFO Full
	NMVC	Network Management Vector Changed
	TI0	Timer Service Request 0
	TI1	Timer Service Request 1
	TIBC	Transfer Input Buffer Completed
	TOBC	Transfer Output Buffer Completed
	SWE	Stop Watch Event
	SUCS	Startup Completed Successfully
	MBSI	Message Buffer Status Interrupt
	SDS	Start of Dynamic Segment
	WUPA	Wakeup Pattern Channel A
	MTSA	MTS Received on Channel A
	WUPB	Wakeup Pattern Channel B
	MTSB	MTS Received on Channel B
ILE	EINT0	Enable Service Request Line 0
	EINT1	Enable Service Request Line 1
EIR	PEMC	Protocol Error Mode Changed
	CNA	Command Not Valid
	SFBM	SYNC Frames Below Minimum
	SFO	SYNC Frame Overflow
	CCF	Clock Correction Failure
	CCL	CHI Command Locked
	EERR	ECC Error
	RFO	Receive FIFO Overrun

Table 26-26 Module Service Request Flags and Service Request Line Enable

Register	Bit	Function
EIR	EFA	Empty FIFO Access
	IIBA	Illegal Input Buffer Access
	IOBA	Illegal Output Buffer Access
	MHF	Message Handler Constraints Flag
	EDA	Error Detected on Channel A
	LTVA	Latest Transmit Violation Channel A
	TABA	Transmission Across Boundary Channel A
	EDB	Error Detected on Channel B
	LTVB	Latest Transmit Violation Channel B
	TABB	Transmission Across Boundary Channel B

The interrupt lines to the Host TINT0SR and TINT1SR are controlled by the enabled interrupts. In addition each of the two interrupt lines can be enabled / disabled separately by programming bit ILE.EINT0/INT0SRC.SRE and ILE.EINT1/ INT1SRC.SRE.

The interrupt lines to the Host NDAT0SR and NDAT1SR are controlled by the enabled new data interrupts (**NDIC1** to **NDIC4**). In addition each of the two interrupt lines can be enabled / disabled separately by programming bit NDAT0SRC.SRE and NDAT1SRC.SRE.

The interrupt lines to the Host MBSC0SR and MBSC1SR are controlled by the enabled new data interrupts (**MSIC1** to **MSIC4**). In addition each of the two interrupt lines can be enabled / disabled separately by programming bit MBSC0SRC.SRE and MBSC1SRC.SRE.

The two timer service requests generated by service request timer 0 and 1 are available on pins TINT0SR and TINT1SR. They can be configured via the Timer 0 and Timer 1 Configuration register. In addition each of the two interrupt lines can be enabled / disabled separately by programming bit TINT0SRC.SRE and TINT1SRC.SRE.

A stop watch event may be triggered via input pin STPWn.

The status of the data transfer between IBF / OBF and the Message RAM is signalled on signals IBUSY and OBUSY. When a transfer has completed bit **SIR.TIBC** or **SIR.TOBC** is set.

26.8 Restrictions

The following restrictions have to be considered when programming the E-Ray IP-module. A violation of these restrictions may lead to an erroneous behavior of the E-Ray IP-module.

26.8.1 Message Buffers with the same Frame ID

If two or more Message Buffers are configured with the same Frame ID, and if they have a matching cycle counter filter value for the same slot, then the Message Buffer with the lowest Message Buffer number is used.

Sharing of a static time slot via cycle counter filtering between different nodes of a FlexRay™ network is **not** allowed.

26.8.2 Data Transfers between IBF / OBF and Message RAM

The time required to transfer the contents of a Message Buffer between IBF / OBF and Message RAM depends on the setup time to start the first transfer, the number of 4-byte words to be transferred, and the number of concurrent tasks to be managed by the Message Handler. The number of 4-byte words varies from 4 (Header Section only) to 68 (Header + maximum Data Section) while the number of concurrent task varies from one to three.

The following concurrent tasks are executed under control of the Message Handler:

- Data transfer between IBF or OBF and Message RAM
- Data transfer between TBF1 and Message RAM, search next TX / RX Message Buffer CHA
- Data transfer between TBF2 and Message RAM, search next TX / RX Message Buffer CHB

Transfers between IBF and Message RAM respectively Message RAM and OBF can only be handled one after another. In case that e.g. a transfer between IBF and Message RAM has been started shortly before a transfer between Message RAM and OBF is requested, the OBF transfer has to wait until the IBF transfer has completed.

The relative time is measured in f_{CLC_ERAY} cycles. Absolute time depends on the actual f_{CLC_ERAY} cycle period.

cyclestrans = (remaining cycles of transfer running) + (cycles of requested transfer)

cyclestrans = cyclesrem + cyclesreq

cyclesrem = (number of concurrent tasks) * (setup time + (number of 4-byte words)rem)

cyclesreq = (number of concurrent tasks) * (setup time + (number of 4-byte words)req)

setup time = 2 f_{CLC_ERAY} cycles

Under worst case conditions a transfer is requested directly after the previous transfer started:

Max. number of f_{CLC_ERAY} cycles: cyclestrans = (3 * (2 + 68)) + (3 * (2 + 68)) = 420

Worst case timing: timetrans(40MHz) = 420 * 25ns = 10.5 ms

26.9 E-Ray Module Implementation

This section describes the E-Ray interfaces as implemented in TC1798 with the clock control, port and DMA connections, interrupt control, and address decoding.

Figure 26-27 shows a detailed view of the E-Ray interface.

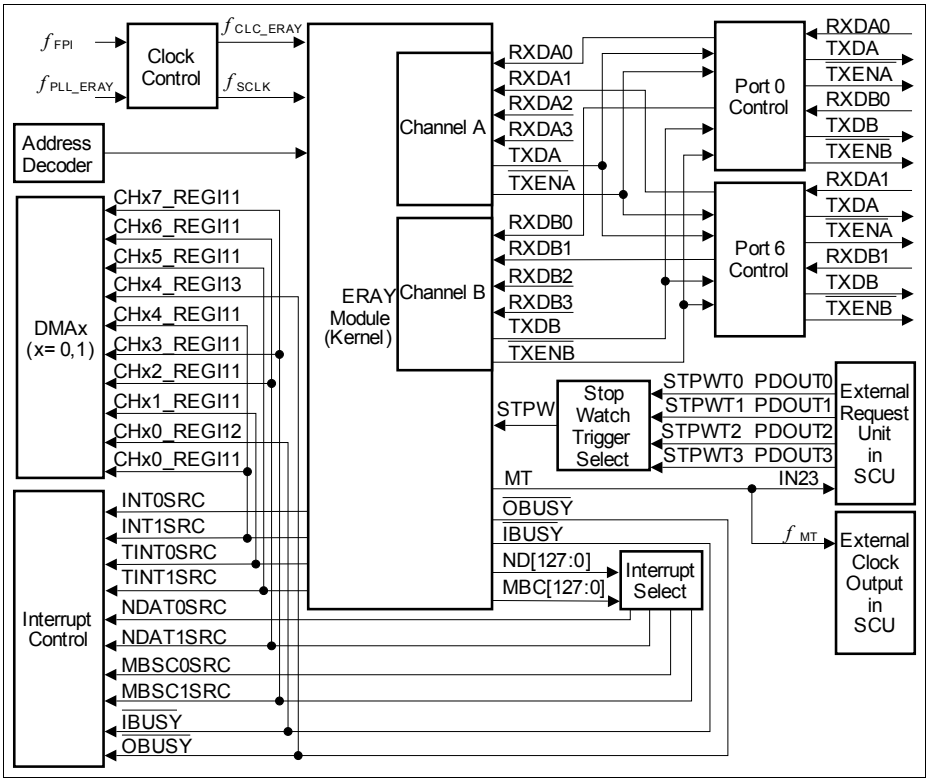

Figure 26-27 Detailed Block Diagram of the E-Ray Interface

26.9.1 Interconnections of the E-Ray Module

The E-Ray module has 2 FlexRay™ communication channels, channel A and channel B. Each channel provides a set of signals to drive a bus driver. The E-Ray module requires two different clocks, a sampling clock of the FlexRay™ bus f_{SCLK}. f_{SCLK} has to be 8 times the baud rate of the FlexRay™ communication. A second clock f_{CLC_ERAY} is

used for the main protocol controller state machine and the customer interface logic. To enable deactivation of the E-Ray Module, f_{CLC_ERAY} and f_{SCLK} may be disabled (clock gated) by the **CLC.DISR** Enable E-Ray (Clock Gating) bit.The following items are described in this section:

- E-Ray module (kernel) external registers
- Port control and connections
  - I/O port line assignment
  - I/O function selection
  - Pad driver characteristics selection
- On-chip connections
  - SCU Connections
  - DMA connections
- Module clock generation
- Interrupt registers
- E-Ray address map

26.9.2 Port Control and Connections

This section describes the I/O connections of the E-Ray module.

26.9.2.1 Input/Output Function Selection

Table 26-27 shows how bits and bit fields must be programmed for the required I/O functionality of the E-Ray I/O lines. This table also shows the values of the peripheral input select registers.

Table 26-27 E-Ray I/O Control Selection and Setup

FlexRay™ Channel	Port Lines	Input Select Register	Input/Output Control Register Bits	I/O
A	RXDA0/ P0.9	ERAY_**CUST1.RISA** = 00_B	P0_IOCR8.PC9 = $0XXX_B$	Input
	RXDA1/ P6.12	ERAY_**CUST1.RISA** = 01_B	P6_IOCR12.PC12 = $0XXX_B$	Input
	RXDA2	ERAY_**CUST1.RISA** = 10_B		Input
	RXDA3	ERAY_**CUST1.RISA** = 11_B		Input
	TXDA/ P0.14	not applicable	P0_IOCR12.PC14 = $1X01_B$	Output
	TXDA/ P6.13	not applicable	P6_IOCR12.PC13 = $1X10_B$	Output
	$\overline{\text{TXENA}}$/ P0.10	not applicable	P0_IOCR8.PC10 = $1X01_B$	Output
	$\overline{\text{TXENA}}$/ P6.10	not applicable	P6_IOCR8.PC10 = $1X11_B$	Output
B	RXDB0/ P0.13	ERAY_**CUST1.RISB** = 00_B	P0_IOCR12.PC13 = $0XXX_B$	Input
	RXDB1/ P6.14	ERAY_**CUST1.RISB** = 01_B	P6_IOCR12.PC14 = $0XXX_B$	Input
	RXDB2	ERAY_**CUST1.RISB** = 10_B		Input
	RXDB3	ERAY_**CUST1.RISB** = 11_B		Input
	TXDB/ P0.12	not applicable	P0_IOCR12.PC12 = $1X01_B$	Output
	TXDB/ P6.15	not applicable	P6_IOCR12.PC15 = $1X10_B$	Output
	$\overline{\text{TXENB}}$/ P0.11	not applicable	P0_IOCR8.PC11 = $1X01_B$	Output
	$\overline{\text{TXENB}}$/ P6.11	not applicable	P6_IOCR8.PC11 = $1X11_B$	Output

26.9.3 On-Chip Connections

This section describes all on-chip interconnections of the E-Ray modules except the connections to I/O ports (see **Section 26.9.2**).

26.9.3.1 E-Ray Connections with DMA

The E-Ray module of the TC1798 has several on-chip interconnections to the DMA modules. **Table 26-28** shows these interconnections. These enable the DMA to handle different service request of E-Ray module via the DMA.

Table 26-28 DMA Request Assignment for DMA Sub-Block 0 and DMA Sub-Block 1

DMA Channel	ERAY Output Signal	DMA Request Input Line	Selected by
00	INT1SRC	CH00_REGI11	CHCR00.PRSEL = 1011_B
00	IBUSY	CH00_REGI12	CHCR00.PRSEL = 1100_B
01	TINT0SRC	CH01_REGI11	CHCR01.PRSEL = 1011_B
02	NDAT1SRC	CH02_REGI11	CHCR02.PRSEL = 1011_B
03	MBSC1SRC	CH03_REGI11	CHCR03.PRSEL = 1011_B
04	INT1SRC	CH04_REGI11	CHCR04.PRSEL = 1011_B
04	OBUSY	CH04_REGI13	CHCR04.PRSEL = 1101_B
05	TINT1SRC	CH05_REGI11	CHCR05.PRSEL = 1011_B
06	NDAT1SRC	CH06_REGI11	CHCR06.PRSEL = 1011_B
07	MBSC1SRC	CH07_REGI11	CHCR07.PRSEL = 1011_B
10	INT1SRC	CH10_REGI11	CHCR10.PRSEL = 1011_B
10	IBUSY	CH10_REGI12	CHCR10.PRSEL = 1100_B
11	TINT0SRC	CH11_REGI11	CHCR11.PRSEL = 1011_B
12	NDAT1SRC	CH12_REGI11	CHCR12.PRSEL = 1011_B
13	MBSC1SRC	CH13_REGI11	CHCR13.PRSEL = 1011_B
14	INT1SRC	CH14_REGI11	CHCR14.PRSEL = 1011_B
14	OBUSY	CH14_REGI13	CHCR14.PRSEL = 1101_B
15	TINT1SRC	CH15_REGI11	CHCR15.PRSEL = 1011_B
16	NDAT1SRC	CH16_REGI11	CHCR16.PRSEL = 1011_B
17	MBSC1SRC	CH17_REGI11	CHCR17.PRSEL = 1011_B

26.9.3.2 E-Ray Connections with the External Request Unit of SCU

The E-Ray module of the TC1798 has several on-chip interconnections to the External Request Unit (ERU) in the SCU to externally trigger stop watch events and to provide a global time e.g. to the on chip timers. **Table 26-29** and **Table 26-30** show these interconnections.

Table 26-29 External Stop Watch Request Assignment

ERAY Input Signal	ERU Request Output Line	Selected by
STPWT0	ERU_PDOUT0	**CUST1.STPWTS** = 00_B
STPWT1	ERU_PDOUT1	**CUST1.STPWTS** = 01_B
STPWT2	ERU_PDOUT2	**CUST1.STPWTS** = 10_B
STPWT3	ERU_PDOUT3	**CUST1.STPWTS** = 11_B

Table 26-30 Global Macrotick Connection to ERU

ERAY Output Signal	ERU Request Input Line	Selected by
MT	ERU_IN23	ERU_EICR1.EXIS2 = 11_B

26.9.3.3 E-Ray Connections with the ECC Error Handling Unit of SCU

The E-Ray module of the TC1798 has one on-chip interconnection to the ECC Error Handling Unit in the SCU to trigger an ECC Error Trap. **Table 26-31** shows this interconnection.

Table 26-31 ECC Error Signalling to SCU

ERAY Output Signal	SCU Line	Selected by
EERR	ECCT	TRAPDIS.ECCT = 0_B

26.9.3.4 E-Ray Connections with the External Clock Output of SCU

The E-Ray module of the TC1798 has one on-chip interconnections to the External Clock Output Unit in the SCU to distribute externally as also internally the Macro Tick as time base for distributed system control e.g. to the GPTA® as global system timer or external devices. **Table 26-32** shows this interconnection.

Table 26-32 Global Macrotick Connection to External Clock Output

ERAY Output Signal	External Clock Output	Selected by
MT	f_{MT}	SCU_EXCTCON.SEL0 = 1111_B

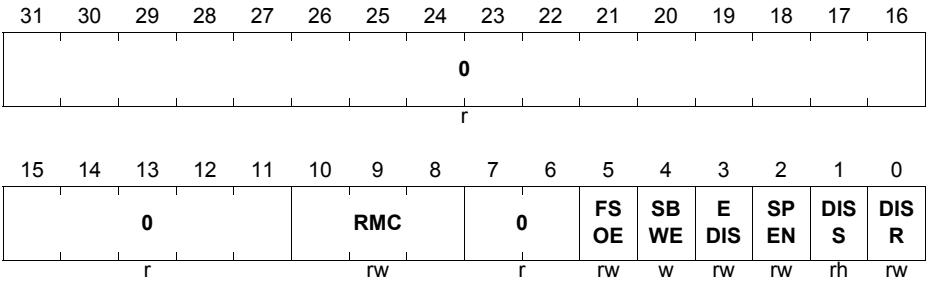
26.9.4 Clock Control Register

The clock control register makes it possible to control (enable/disable) the E-Ray module control clock f_{CLC_ERAY}. The clock signal f_{CLC_ERAY} is used by the E-Ray as a clock for internal control operations but not for FlexRay™ Bus Signal Sampling.

After an application reset, by default, the startup software (SSW) will disable the module by setting CLC.DISR and thereby requesting the HW to set bit CLC.DISS. In consequence, the initial value readable by the application is $0x0000\ 0003_H$

Note: The application SW must make sure that the Transceiver Enable ($\overline{TXENA}$, $\overline{TXENB}$) pins are forced to their inactive state first, before the module clock is switched off.

ERAY_CLC
ERAY Clock Control Register (0000_H) Reset Value: $0000\ 0100_H$



Field	Bits	Type	Description
DISR	0	rw	**E-Ray Module Disable Request Bit** Used for enable/disable control of the E-Ray module. *Note: This bit disables the kernel clocks f_{CLC_ERAY} and the sampling clock f_{SCLK}.*
DISS	1	rh	**E-Ray Module Disable Status Bit** Bit indicates the current status of the E-Ray module.
SPEN	2	rw	**E-Ray Module Suspend Enable for OCDS** Used to enable the suspend mode.
EDIS	3	rw	**External Request Disable** Used to control the external clock disable request.
SBWE	4	w	**E-Ray Module Suspend Bit Write Enable for OCDS** Determines whether SPEN and FSOE are write-protected.

Field	Bits	Type	Description
FSOE	5	rw	**Fast Switch Off Enable** Used for fast clock switch off in suspend mode.
RMC	[10:8]	rw	**Clock Divider in Run Mode** 000_B No clock signal f_{CLC_ERAY} generated (default after reset) 001_B Clock $f_{CLC\_ERAY} = f_{FPI}$ selected 010_B Clock $f_{CLC\_ERAY} = f_{FPI}$ /2 selected 011_B Clock $f_{CLC\_ERAY} = f_{FPI}$ /3 selected 100_B Clock $f_{CLC\_ERAY} = f_{FPI}$ /4 selected 101_B Clock $f_{CLC\_ERAY} = f_{FPI}$ /5 selected 110_B Clock $f_{CLC\_ERAY} = f_{FPI}$ /6 selected 111_B Clock $f_{CLC\_ERAY} = f_{FPI}$ /7 selected *Note: This bit field is not affected by an application reset.* *Note: This bit field only controls the kernel clock f_{CLC_ERAY} and not the sampling clock f_{SCLK}.*
0	[7:6], [31:11]	r	**Reserved** Read as 0; should be written with 0.

Note: After an application reset, the f_{CLC_ERAY} clock is disabled (DISS set). Therefore, the E-Ray modules clock generation is completely disabled.

26.9.5 Interrupt Registers

Two different type of Interrupt Registers are described within this chapter.
The Interrupt Control register enable the selection of the Service Request used to signal an event. The Interrupt Control registers **NDIC1** to **NDIC4** select the service request node used for New Data Events.The Interrupt Control registers **MSIC1** to **MSIC4** select the service request node used for Message Buffer Status Changed Events.
The Interrupt Service Request Control Registers control the eight service request nodes.

New Data Interrupt Control 1 (NDIC1)

This New Data Interrupt Control register controls the interrupt that becomes active (NDAT0SRC or NDAT1SRC) on a ND flag turning active of all configured Message Buffers 0 to Message Buffers 31.

NDIC1
New Data Interrupt Control 1 **($03A8_H$)** **Reset Value: $0000\ 0000_H$**

Service Request Control Registers

Each of the service request outputs of the E-Ray module kernels is able to generate an interrupt and is controlled by an interrupt service request control register INT0SRC, INT1SRC, TINT0SRC, TINT1SRC, NDAT0SRC, NDAT1SRC, MBSC0SRC, MBSC1SRC, OBUSYSRC, and IBUSYSRC.The service request OBUSYSRC, and IBUSYSRC is generated, when the Output Buffer or Input Buffer switches from busy state to the state being accessible by the host.

Note: Additional details on service request nodes and the service request control registers are described in Chapter “Interrupt System” of the TC1798 User´s Manual System Units part (Volume 1).

27 Micro Link Interface (MLI)

This chapter describes the Micro Link Interface module and the MLI protocol. It contains the following sections:

- Functional description of the MLI (see **Page 27-2**)
- Module kernel description (see **Page 27-27**)
- Operation the MLI module (see **Page 27-69**)
- MLI kernel register descriptions (see **Page 27-77**)
- Device implementation-specific descriptions and details (see **Page 27-127**)

*Note: The MLI kernel register names described in **Section 27.3** are referenced in the TC1798 User´s Manual by the module name prefix “MLI0_” for the MLI0 interface and “MLI1_” for the MLI1 interface.*

27.1 Functional Description

This chapter describes the functionality of the MLI interface.

- A general introduction to the interface (see **Page 27-2**)
- The MLI frame structure for data exchange (see **Page 27-10**)

27.1.1 General Introduction

The introduction comprises:

- An overview about the MLI (see **Page 27-2**)
- Naming conventions (see **Page 27-4**)
- A description of the MLI communication principles (see **Page 27-6**)

27.1.1.1 MLI Overview

The Micro Link Interface (MLI) is a fast synchronous serial interface to exchange data between microcontrollers or other devices, such as stand-alone peripheral components. **Figure 27-1** shows how two microcontrollers are typically connected together via their MLI interfaces.

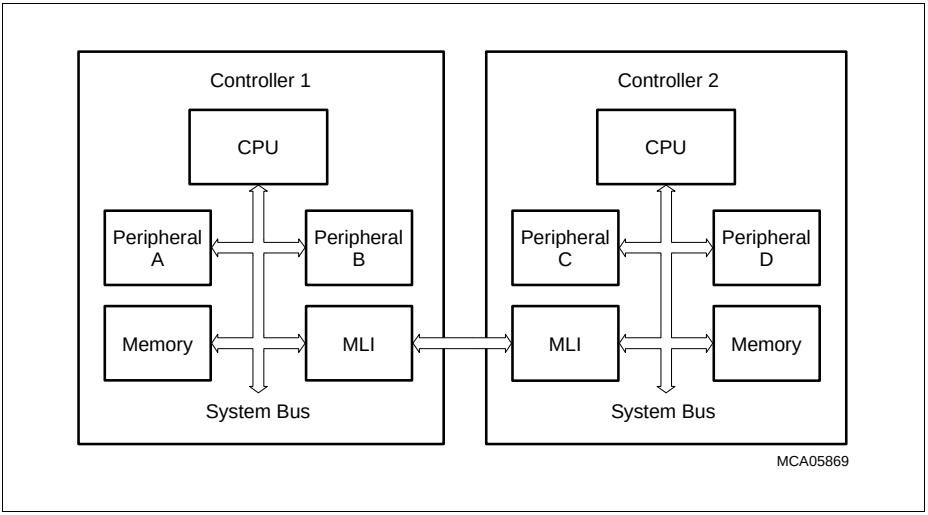

Figure 27-1 Typical Micro Link Interface Connection

Features

- Synchronous serial communication between an MLI transmitter and an MLI receiver
- Different system clock speeds supported in MLI transmitter and MLI receiver due to full handshake protocol (4 lines between a transmitter and a receiver)
- Fully transparent read/write access supported (= remote programming)
- Complete address range of target device available
- Specific frame protocol to transfer commands, addresses and data
- Error detection by parity bit
- 32-bit, 16-bit, or 8-bit data transfers supported
- Programmable baud rates
  - MLI transmitter baud rate: max. $f_{MLI}/2$
  - MLI receiver baud rate: max. f_{MLI}
- Address range protection scheme to block unauthorized accesses
- Multiple receiving devices supported

27.1.1.2 Naming Conventions

Local and Remote Controller

The terms “Local” and “Remote” Controller are assigned to the two partners (microcontrollers or other devices with MLI modules) of a serial MLI connection. The controller with an MLI module initiating a data exchange or a control task is defined as Local Controller. Each data exchange and control task starts with a frame transmission of the Local Controller. The controller with an MLI module reacting on received data exchange requests or executing control tasks is defined as Remote Controller. The terms “Local” and “Remote” are independent of the direction of the information flow (transmission or reception), except for Read Frames (always transmitted by the Local Controller) and Answer Frames (always transmitted by the Remote Controller). A Triggered Command Frame is transferred from the Local to the Remote Controller.

Due to the full duplex operation capability of an MLI module (independent transmitter and receiver), each microcontroller with an MLI module is able to operate as a Local Controller (e.g. for data transmission) as well as a Remote Controller (e.g. for data reception) at the same time.

Transmitting and Receiving Controller

The terms “transmitting” and “receiving” controller are referring to the direction of the information flow. These terms are independent from the terms “Local” and “Remote”. For example, the initialization of a bidirectional MLI connection between two controllers (or between a controller and a stand-alone device) is always controlled and initiated by one controller (named Local), although during this phase, both MLI participants can transmit and receive frames.

Due to the full duplex operation capability of the MLI module (independent transmitter and receiver), each microcontroller with an MLI module is able to operate as a transmitting controller as well as a receiving controller at the same time.

Transfer Window

A Transfer Window is an address space in the address map of the transmitting controller. Transfer Windows are typically assigned to a fixed address space (base address and size). The Transfer Windows are the logical data inputs for the MLI transmitter. Data write actions via MLI are initiated by a write access to a Transfer Window, whereas data read actions are started by a read access from a Transfer Window.

Each MLI module supports up to four independent Transfer Windows, one for each pipe. In the implementation of a specific device, a Transfer Window can appear at several locations in the address map. Here, each Transfer Window can be accessed at two different address ranges with two different window sizes (one 64 Kbyte and one 8 Kbyte area for each Transfer Window), leading to:

- Four Small Transfer Windows STW with 8 Kbyte address range each and

- Four Large Transfer Windows LTW with 64 Kbyte address range each

Remote Window

A Remote Window is an area in the address space of the receiving controller. Remote Window parameters (base address and size) of the receiving controller are programmable by the transmitting microcontroller by MLI transfers, independently for each pipe. Each Remote Window of a receiving controller is related to specific Transfer Window of the transmitting controller.

The Remote Windows are the logical data outputs of the MLI receiver. If enabled, the MLI module can automatically execute the requested data transfer to/from the defined address location in the Remote Window. If the automatic data handling is disabled, the offset and the data are available in the MLI receiver registers and have to be handled by software. Remote windows can not be accessed by read or write accesses by software of the Remote Controller (either the data is automatically transferred or it is located in receiver registers).

Pipe

A pipe defines the logical connection between a Transfer Window in the transmitting controller and the associated Remote Window in the receiving controller. The MLI protocol supports four independent pipes.

Frame

A frame is a contiguous set of bits forming a message sent by an MLI transmitter to an MLI receiver.

A **Normal Frame** is a frame used for data exchange between a transmitting and a receiving controller (read request and write data from a Local Controller to a Remote Controller, as well as the answer to a read request back to the Local Controller). Base address copy frames are also considered as Normal Frames.

A **Command Frame** contains information about the receiver setting or triggers actions in the MLI receiver.

A **Triggered Command Frame** is generated under hardware control and can be used to transfer interrupt or service requests between the MLI participants.

Offset

The offset is an address distance relative to the base address of the Transfer Window in the transmitting controller and the base address of the Remote Window in the receiving controller. For example, a write access to the 10th byte of the Transfer Window is transferred to a write to the 10th byte of the Remote Window.

The offset of a write access to a Transfer Window is also called write offset, whereas a read offset is related to a read access from a Transfer Window.

27.1.1.3 MLI Communication Principles

The communication principle of the MLI modules allows data to be transferred between a Local and a Remote Controller without intervention of a CPU in the Remote Controller. Data transfers are always triggered in the Local Controller by read or write operations to an address location in a Transfer Window. All control tasks, address and data transmissions that are required for the data transfer/request between Local and Remote Controller can be handled autonomously by the two connected MLI modules.

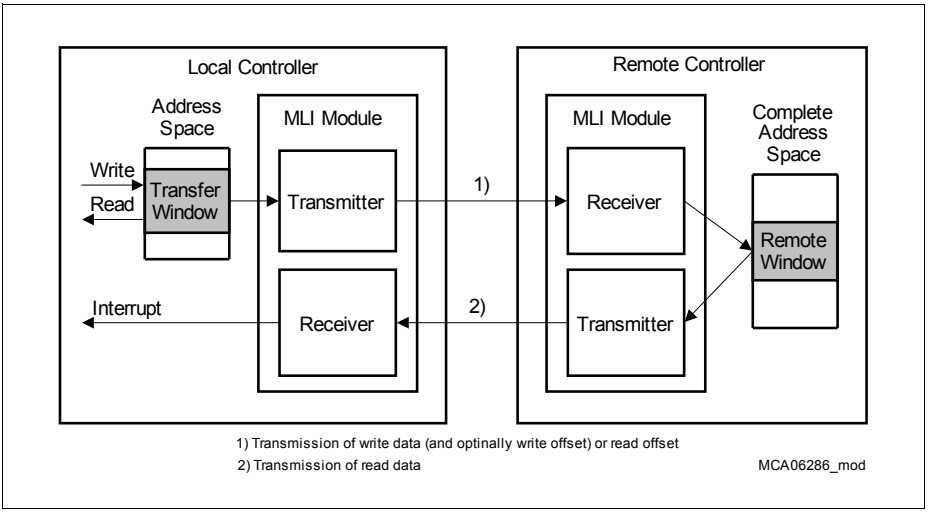

Figure 27-2 MLI Communication Principles

Write Access to a Transfer Window

A write access to a location within a Transfer Window of the transmitting (Local) controller is detected by the MLI transmitter. This detection initiates a transfer of the data that has been written to the Transfer Window together with the write offset to the MLI of the receiving controller. The receiving controller stores the data internally and can also automatically place the data in the Remote Window of the receiving controller (at the address location defined by the write offset plus the base address).

Read Access from a Transfer Window

A read access from a location of a Transfer Window in the Local Controller is detected by the MLI transmitter and delivers dummy data. This detection initiates a transfer of the read offset from the Local microcontroller to the MLI receiver to request data from the Remote Controller. This data can be automatically read or prepared by a CPU in the Remote Controller. When the requested data is available in the Remote Controller, it is

introduced into the data stream back to the Local Controller (Answer Frame). Then, the CPU in the Local Controller is informed by an MLI event that the requested data is now available and can be read.

Transfer Window Organization

Figure 27-3 shows an example of the organization of Transfer Windows and Remote Windows with a possible assignment in Local and Remote Controller. Each of the four pipes assigns one Transfer Window to one Remote Window with its base address and window size. For reasons of simplicity, a pipe to a Remote Window is only shown either from a LTW or from a STW, although each Transfer Window can be accessed at both address locations, its LTW and its STW.

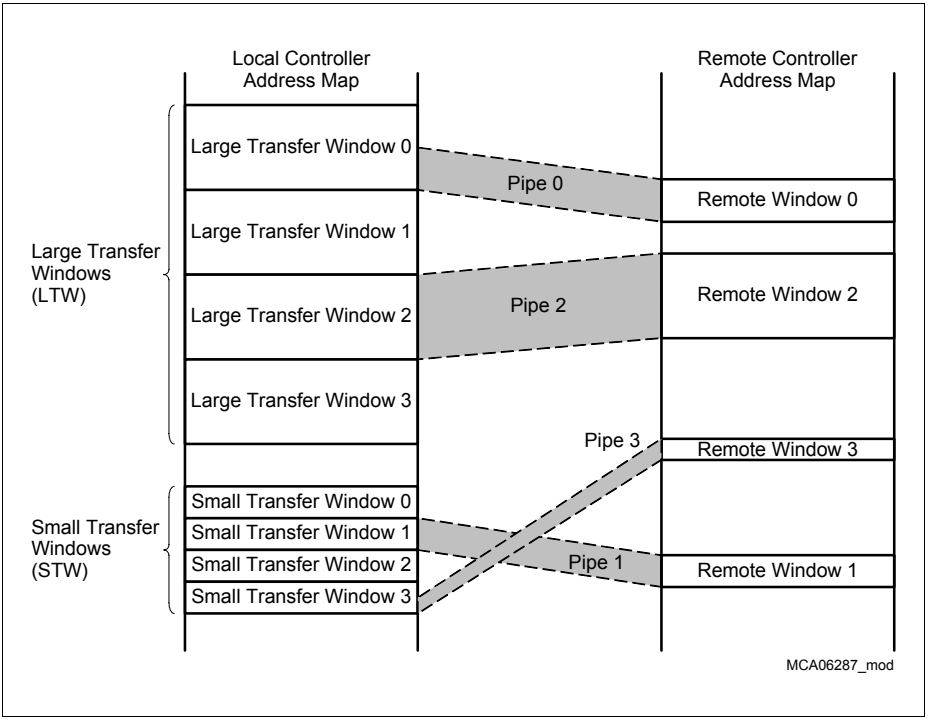

Figure 27-3 Transfer/Remote Window Assignment Example

During initialization of the pipes, base addresses and sizes of the Remote Windows are transmitted from the Local Controller to the Remote Controller. In the example of **Figure 27-3**, pipe 1 and pipe 2 cover the full range of their Transfer and Remote

Windows. The ranges of the Remote Windows of pipe 0 and pipe 3 are sub-ranges of the related Transfer Windows.

The location of a Transfer Window (base address and size) in the Local Controller is always fixed in a specific product device. Remote windows can be freely moved and located within the address space of the receiving controller. They are used to overlay address ranges of peripheral modules or internal memories.

Remote Window Address Generation

Figure 27-4 shows the generation of the Remote Window address ranges, with fixed base address part and additional variable address part. The variable address part is determined by the available address area for each Remote Window (also named buffer size, value of BSx = buffer size for Remote Window x indicates how many address bits are variable, defining the available address range).

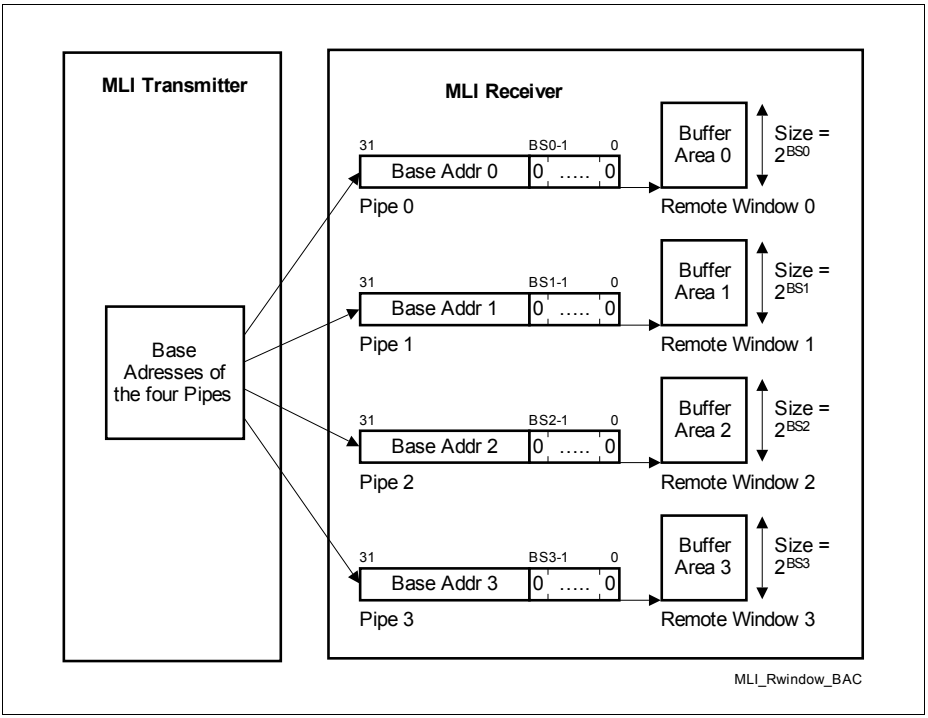

Figure 27-4 Base Address Definition of Remote Windows

Figure 27-5 shows the generation of the complete Remote Window address without address prediction. The variable address part can be transferred as offset by a write or a Read Frame, or it can be predicted in case of regular address modifications, whereas the fixed part of the address is defined by the upper bits of the base address.
In case of address prediction, the variable address part is internally calculated and taken as lower address bits of the target address (the upper address bits are given by the Remote Window's base address).

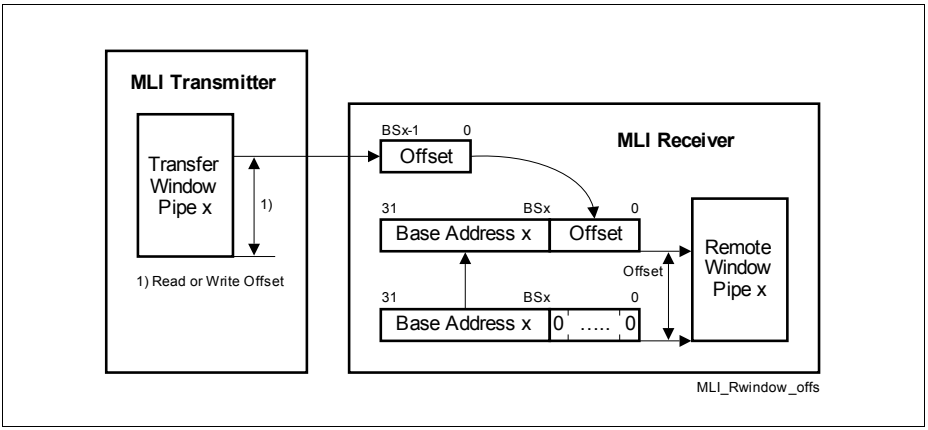

Figure 27-5 Remote Window Address Generation without Address Prediction

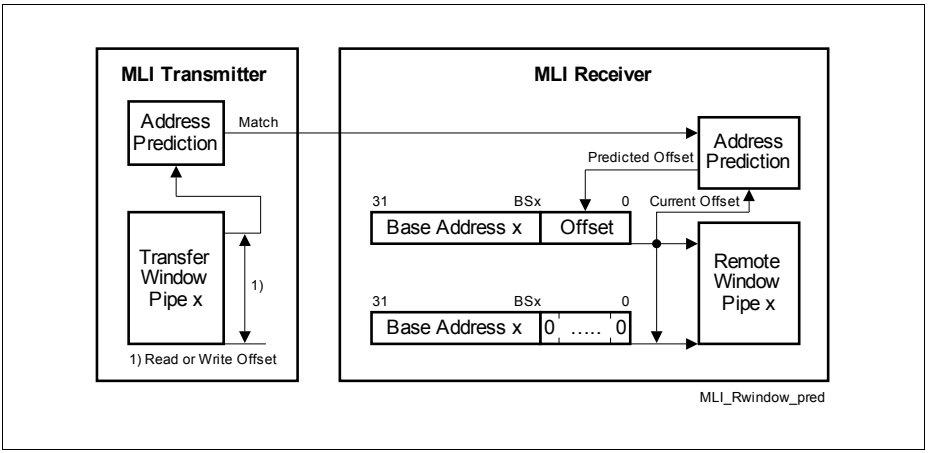

Figure 27-6 Remote Window Address Generation with Address Prediction

27.1.2 MLI Frame Structure

A frame is a message sent by an MLI transmitter to an MLI receiver. Depending on the desired behavior, different frame types exist:

- Copy Base Address Frame to define location and size of a Remote Window (see **Page 27-12**)
- Write Offset and Data Frame to transmit the write offset and the write data (see **Page 27-13**)
- Optimized Write Frame to transmit write data without write offset in case of an address prediction match (see **Page 27-14**)
- Discrete Read Frame to transmit read request with the read offset (see **Page 27-15**)
- Optimized Read Frame to transmit the read request without read offset in case of an address prediction match (see **Page 27-16**)
- Command Frame to transmit a command, e.g. setup information or MLI service request generation (see **Page 27-17**)
- Answer Frame to transmit the data previously requested by a Read Frame (see **Page 27-18**)

The local/remote structure of an MLI connection between two microcontrollers requires a transmitter unit and a receiver unit in both MLI modules (local and remote) for communication.

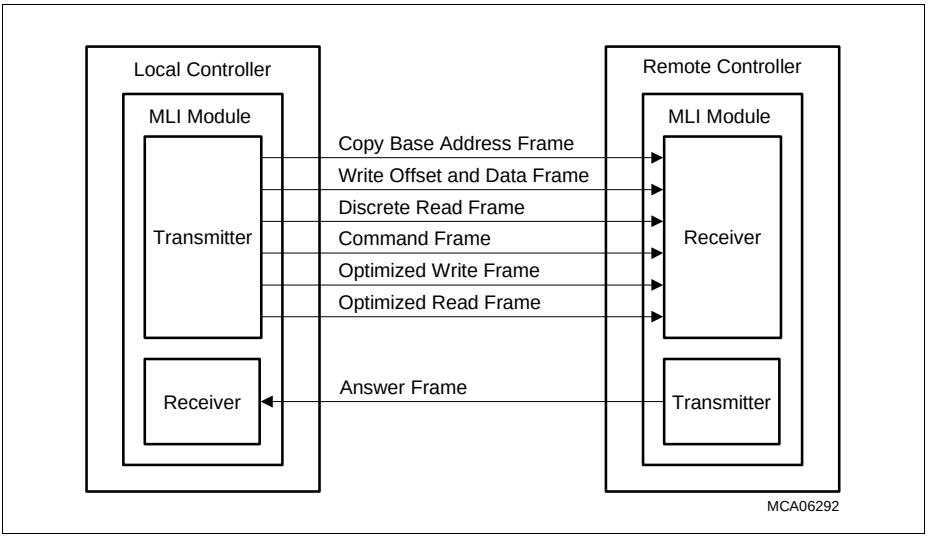

Figure 27-7 Logic Frame Assignment to Local/Remote Controller

27.1.2.1 General Frame Layout

The general layout of a frame is shown in **Figure 27-8**. It contains the following parts:

- A frame starts with a 4-bit header field that contains a 2-bit frame code (FC) and a 2-bit pipe number (PN).
- The data field can contain address, data, or control information. The width of the data field depends on the frame type.
- The frame is terminated by a parity bit (P) with even parity (see **Page 27-26**), calculated over header and data field bits.

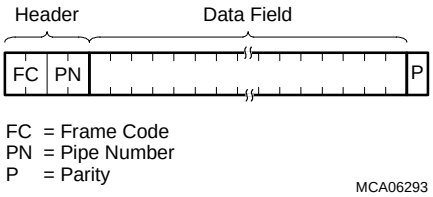

Figure 27-8 General Frame Layout

The frame code (FC) determines the frame type of the transmitted frame. The pipe number (PN) indicates the pipe that is related to the frame content (the value of PN is defined as 00_B for pipe 0, 01_B for pipe 1, 10_B for pipe 2, and 11_B for pipe 3).

The FC parameter is coded according to **Table 27-1**. If more than one frame type is defined with the same frame code value (see FC = 01_H, 10_H or 11_H), the width of the received frame defines the type. The value given by m in the table below represents the number of address bits transferred as offset (defined by the buffer size BSx of the Remote Window x).

Table 27-1 Frame Code Definition

Frame Code FC	Frame Type	Data Field Width [bits]	Description see
00_B	Copy Base Address Frame	32	**Page 27-12**
01_B	Write Offset and Data Frame	8+m, 16+m, or 32+m	**Page 27-13**
	Discrete Read Frame	2+m	**Page 27-15**
10_B	Command Frame	4	**Page 27-17**
	Answer Frame	8, 16, or 32	**Page 27-18**
11_B	Optimized Write Frame	8, 16, or 32	**Page 27-14**
	Optimized Read Frame	2	**Page 27-16**

27.1.2.2 Copy Base Address Frame

With a Copy Base Address Frame, the two parameters of a Remote Window are transferred from the transmitting controller to the receiving controller to initialize or to redirect the Remote Window.

The Copy Base Address Frame contains the following parts:

- Header:
  The header starts with frame code FC = 00_B followed by the pipe number PN of the pipe targeted by the transmitted base address bits and the size code.
- Remote Window address location:
  The 28 most significant bits of the 32-bit base address bits can be programmed by the transmitting controller (the 4 LSBs are considered as 0). The base address of a Remote Window has to be aligned to its size, e.g. a window of 1 Kbyte has to start at 1Kbyte address boundaries.
- Remote Window size:
  The size is defined by the 4-bit coded buffer size BS. The maximum size is 64 Kbytes.
- Parity bit P

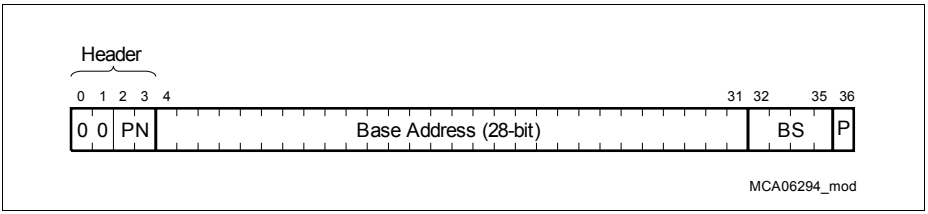

Figure 27-9 Copy Base Address Frame

Table 27-2 BS Coding

Buffer Size Code BS	Remote Window Size (also named Buffer Size)	Number m of Offset Bits
0000_B	2 bytes	m = 1
0001_B	4 bytes	m = 2
...	...	...
1110_B	32 Kbytes	m = 15
1111_B	64 Kbytes	m = 16

More details about the Copy Base Address Frame handling of the MLI module are described on **Page 27-28**.

27.1.2.3 Write Offset and Data Frame

A Write Offset and Data Frame is used by the transmitting controller to send an address offset and data to the receiving controller. This frame is initiated by a write operation to one of the Transfer Windows in the transmitting controller.

The Write Offset and Data Frame contains the following parts:

- Header:
  The header starts with frame code FC = 01_B followed by the pipe number PN of the Transfer Window that has been the target of the write operation.
- m-Bits of write offset:
  These bits define the write offset. The value of m depends on the size of the Remote Window, defined by the Copy Base Address Frame (m = 1-16).
- Write data field:
  The write data field can be 8-bit, 16-bit, or 32-bit wide, depending on the data width of the write access to the Transfer Window.
- Parity bit P

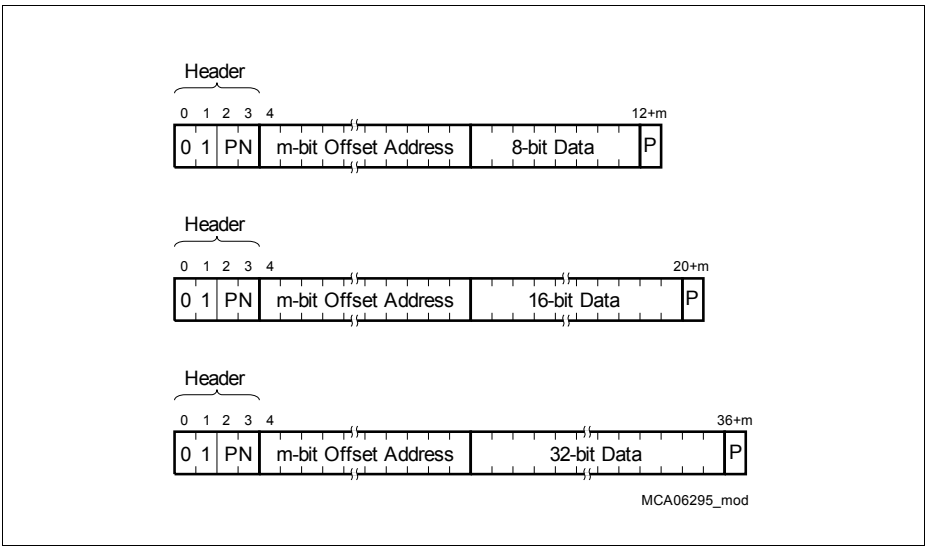

Figure 27-10 Write Offset and Data Frame

More details about the Write Offset and Data Frame handling of the MLI module are provided on **Page 27-30**.

27.1.2.4 Optimized Write Frame

An Optimized Write Frame is used by the transmitting controller to send 8-bit, 16-bit, or 32-bit wide data to the receiving controller. This frame is initiated by a write operation to one of the Transfer Windows in the transmitting controller. In contrast to a Write Offset and Data Frame, no write offset is transmitted because the offset address for the write data can be predicted and calculated by the receiving controller. An Optimized Write Frame allows a higher data bandwidth than Write Offset and Data Frames, because they are shorter. An optimized frame is only possible if the predicted address matches with the actually written one.

The Optimized Write Frame contains the following parts:

- Header:
  The header starts with frame code FC = 11_B followed by the pipe number PN of the Transfer Window that has been the target of the write operation.
- Write data field:
  The write data field can be 8-bit, 16-bit, or 32-bit wide, depending on the data width of the write access to the Transfer Window.
- Parity bit P

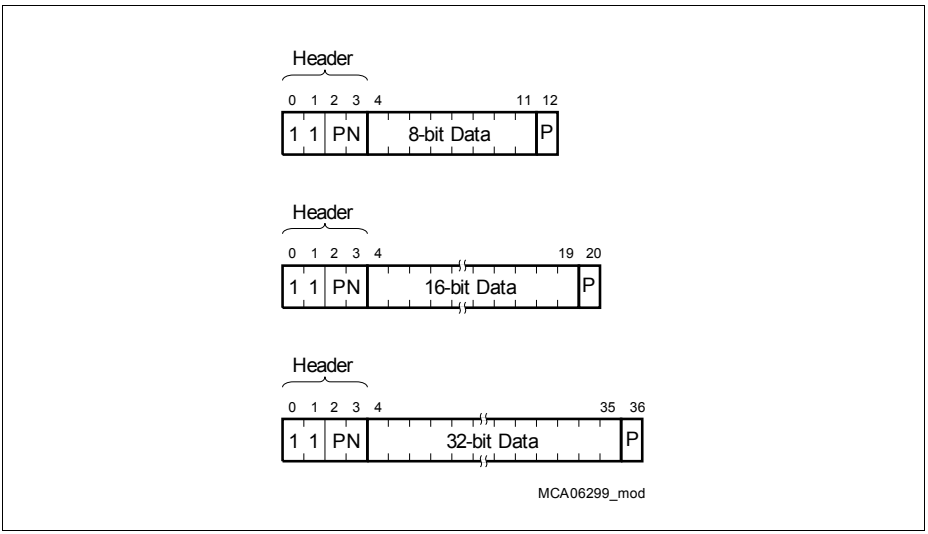

Figure 27-11 Optimized Write Frame

More details about the Optimized Write Frame handling of the MLI module are provided on **Page 27-30**.

27.1.2.5 Discrete Read Frame

A Discrete Read Frame is used by the Local Controller to request data to be read from the Remote Window in the Remote Controller. If the data is available, the Remote Controller typically responds to this request by sending an Answer Frame with the requested read data back to the Local Controller.

The Discrete Read Frame contains the following parts:

- Header:
  The header starts with frame code FC = 01_B followed by the pipe number PN of the Transfer Window that has been the target of the read operation.
- m-Bits of write offset:
  These bits define the read offset. The value of m depends on the size of the Remote Window, defined by the Copy Base Address Frame (m = 1-16).
- Data Width DW:
  The data width DW indicates if the read from the Transfer Window was a 8-bit, 16-bit, or 32-bit read action. It defines how many bytes have to be delivered to the Local Controller by the Answer Frame.
- Parity bit P

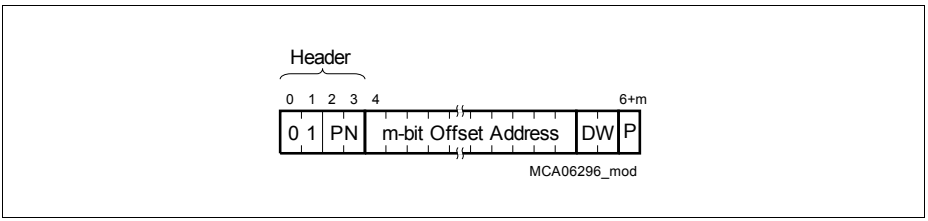

Figure 27-12 Discrete Read Frame

Table 27-3 Data Width DW Coding

Data Width DW	Number of Data Bits to be transferred
00_B	8-bit read access
01_B	16-bit read access
10_B	32-bit read access
11_B	reserved for future use

More details about the Discrete Read Frame handling of the MLI module are provided on **Page 27-34**.

27.1.2.6 Optimized Read Frame

An Optimized Read Frame is used by the Local Controller to request 8-bit, 16-bit, or 32-bit wide data from the Remote Controller without sending any offset address. The address for the requested data can be predicted and calculated by the MLI receiver of the Remote Controller.

The Optimized Read Frame contains the following parts:

- Header:
  The header starts with frame code FC = 11_B followed by the pipe number PN of the Transfer Window that has been the target of the read operation.
- Data Width DW:
  The data width DW indicates if the read from the Transfer Window was a 8-bit, 16-bit, or 32-bit read action. It defines how many bytes have to be delivered to the Local Controller by the Answer Frame. Same coding as for the Discrete Read Frame.
- Parity bit P

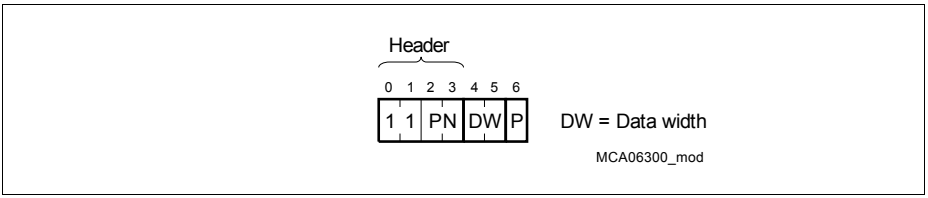

Figure 27-13 Optimized Read Frame

More details about the Optimized Read Frame handling of the MLI module are provided on **Page 27-30**.

27.1.2.7 Command Frame

The transmitting controller is able to initiate control actions to be executed by the receiving controller by sending a Command Frame.

The Command Frame contains the following parts:

- Header:
  The header starts with frame code FC = 10_B followed by the pipe number PN. The pipe number defines the type of command to be executed.
- Command Code CMD:
  Pipe number PN and a 4-bit CMD field are used for command coding. The command coding of some control actions is fixed, but free programmable software commands can also be defined (with PN = 11_B). The coding of the command bit field is pipe-specific and depends on the transmitted pipe number x.
- Parity bit P

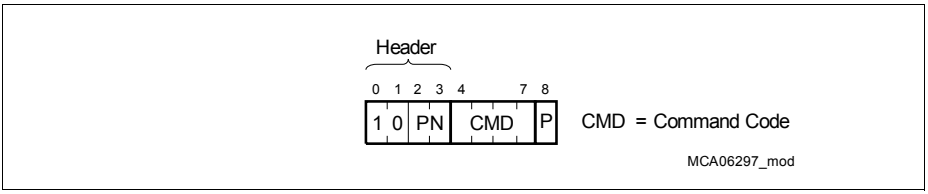

Figure 27-14 Command Frame

Table 27-4 PN for Command Coding

Pipe Number PN	Command Type
00_B	Activate MLI service request or other control signal(s) of the receiving controller. The definition which signal becomes activated is defined by CMD. The usage of these lines depends on the implementation.
01_B	Define delay for parity error indication in the receiving controller. The delay in RCLK cycles is defined by the value of CMD.
10_B	Control of internal functions of the receiving controller. The value of CMD indicates which function is controlled. The coding of CMD and the control mechanisms depend on the implementation.
11_B	Freely programmable software command.

More details about the Command Frame handling of the MLI module are provided on **Page 27-41**.

27.1.2.8 Answer Frame

An Answer Frame is used by the Remote Controller to send 8-bit, 16-bit, or 32-bit wide data to the Local Controller. The Answer Frame is the only frame that is transmitted within a logic Local/Remote Controller assignment from the Remote Controller to the Local Controller. It is the answer to a Discrete Read Frame or an Optimized Read Frame that has been sent by the Local Controller to request data from the Remote Controller.

The Answer Frame contains the following parts:

- Header:
  The header starts with frame code FC = 10_B followed by the pipe number PN. The value of PN is taken from the Read Frame that has triggered the Answer Frame.
- Read data field:
  The read data field can be 8-bit, 16-bit, or 32-bit wide, depending on the data width requested by the Read Frame that triggered the Answer Frame.
- Parity bit P

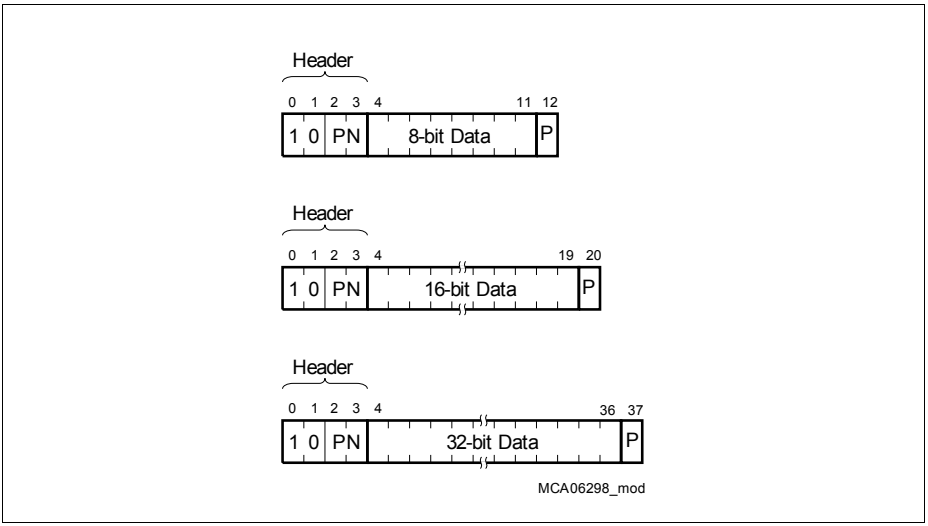

Figure 27-15 Answer Frame

More details about the Answer Frame handling of the MLI module are provided on **Page 27-39**.

27.1.3 Handshake Description

The description of the transmitter/receiver signal handshaking refers to an MLI connection between an MLI transmitter and an MLI receiver. MLI module transmitter I/O signals are indicated with prefix “T” and MLI receiver I/O signals are indicated with the prefix “R”. The 4-line MLI bus between a transmitter and a receiver outside the controllers uses signal names without any prefix.
In order to lay emphasis where a signal is generated or sampled, actions taken by the transmitter are described referring to signals with the prefix “T”, whereas receiver actions are referring to signals with the prefix “R”.

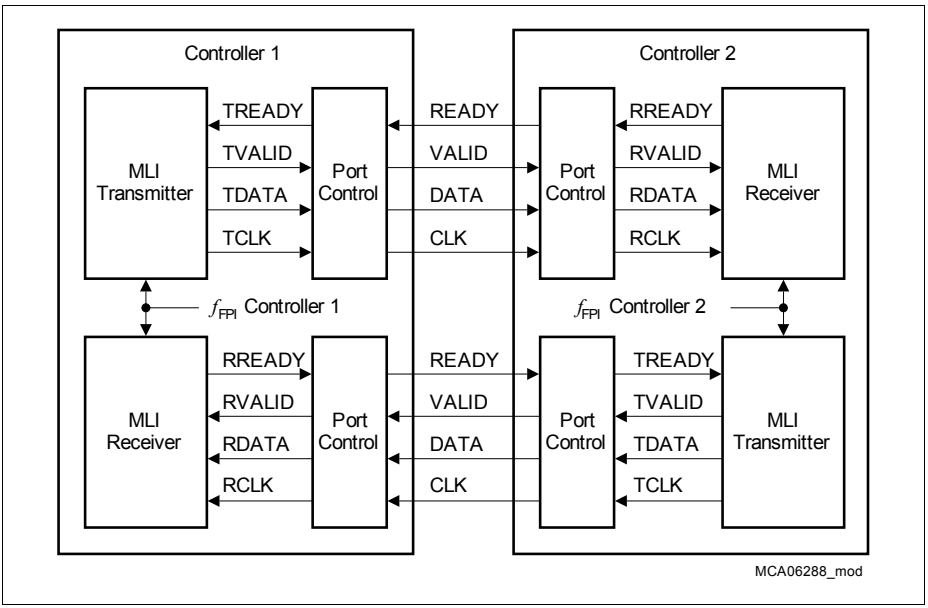

Figure 27-16 Transmitter/Receiver Signal Definitions

The MLI connection allows high data rates and, at the same time, supports significant signal propagation delays between the transmitter and the receiver. As shown in **Figure 27-16**, each output signal passes through the port stage, reaches the physical interface line between the MLI modules, enters via an input stage and can be finally evaluated. All these steps introduce an accumulating propagation delay. In standard synchronous serial connections (such as SPI), this delay limits the reachable baud rate to a few Mbit/s (closed-loop delay problem). In order to support higher baud rates than a standard SPI, the MLI protocol is based on a full handshake (READY-VALID) to deal with propagation delays in the range of some shift clock cycles and to avoid the closed-loop delay limitations of an SPI connection.

In a full handshake, each edge of the handshake signals has a defined meaning and the sequence of edges is clearly specified.
As a result, the propagation delays do not directly limit the MLI baud rate. Therefore, the points in time when a signal is generated, when it is visible on the physical interface line, or when it is evaluated have to be considered independently. This is done by defining 3 different names for a signal, referring to the 3 significant locations:

- The place where it is generated, also in relation to the generation clock edge
- The physical interface line where it can be observed
- The place where it is evaluated, also in relation to the evaluation clock edge

If a Local Controller should be connected to more than one Remote Controller, the transmitter signals CLK and DATA can be used as broadcast signals (parallel connection to the Remote Controllers), whereas the handshake signals VALID and READY have to be established as independent signal pairs for each device. As a result, a Local Controller only needs one CLK and one DATA output, but an individual set of READY and VALID handshake signals for each Remote Controller. Please note that Read Frames and Answer Frames are based on an established connection between a Local and a Remote Controller (because the Answer Frame is the only frame sent back to the Local Controller). Therefore, switching between several Remote Controllers can only be done while no read request is pending in the Local Controller. If no Read Frames are used by the Local Controller, frames can be sent out in parallel to all Remote Controllers if their READY signals are all respected.
If a Remote Controller should be connected to several Local Controllers, it may have several DATA and CLK inputs in addition to the READY-VALID signal sets. Please note that an active switching of a Remote Controller between several Local Controllers requires that all Local Controllers have the information which connection is active.
In any case, switching between Local and Remote Controllers is not allowed while frame transmission is in progress.

27.1.3.1 Handshake Signals

The synchronous serial frame transfer from an MLI transmitter to an MLI receiver is based on the following 4 signals (the MLI protocol only defines the signal transitions, but neither the signaling level nor the driver characteristics):

- Shift clock CLK:
  This signal is used as serial shift clock that is generated by the transmitter during the complete frame transfer (TVALID is active) and until the end of ready delay time. Signal TCLK can also be generated while no frame is transferred. In this case, the receiving controller can use the incoming RCLK receiver signal as base for its internal clock generation.
  The transmitter signals are always referring to the rising edge of TCLK, so TREADY is sampled and the output signals TDATA and TVALID are changing with the rising edge of TCLK.
  The MLI receiver actions refer to the falling edges of its RCLK input. The receiver samples the RVALID and RDATA signals and outputs its RREADY line with the falling edges of RCLK.
- Shift data DATA:
  This signal represents the transmit data TDATA transferred from the MLI transmitter to the MLI receiver input RDATA. Changes on transmitter side take place with rising edges of TCLK, whereas sampling on the receiver side takes place with falling edges of RCLK.
- Transmitter valid handshake VALID:
  This signal indicates the start and the end of each frame. It is active (1-level) during a frame transmission and passive (0-level) while no frame is transferred. Changes of TVALID on transmitter side take place with rising edges of TCLK, whereas sampling of RVALID on the receiver side takes place with falling edges of RCLK.
  An activation of TVALID to start a new frame can only take place if TREADY is 1.
- Receiver ready handshake READY:
  This signal indicates that the receiver is ready for a data transfer. Additionally, this line is used to indicate reception errors (parity error indication). Changes of RREADY on receiver side take place with falling edges of RCLK, whereas sampling of TREADY on the transmitter side takes place with rising edges of TCLK.

27.1.3.2 Error-free Handshake

A transmission can be started by an MLI transmitter when the MLI receiver is ready to receive data indicated by RREADY = 1 by the receiver. When the MLI transmitter detects TREADY = 1 and starts its transmission, TVALID is asserted to 1 level while a frame transfer is in progress. When the MLI receiver has detected the 0-to-1 transition of the RVALID signal it will de-assert RREADY back to 0 (transmission start acknowledged by receiver). At the end of the frame transmission, the MLI transmitter also de-asserts signal TVALID back to 0 and checks if the TREADY signal is at 0 level,

too. This check is used as life-sign of the receiver and the MLI transmitter can detect whether the receiver is able to react in-time to the transmitter actions (see also Page 27-23).

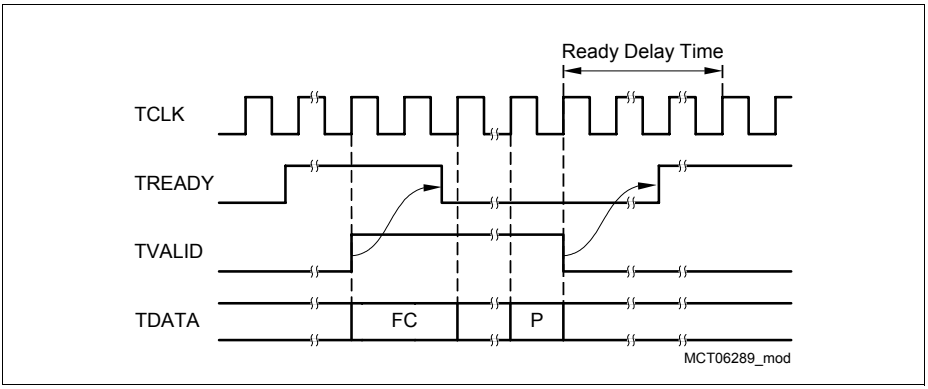

Figure 27-17 MLI Handshake without Error Indication

27.1.3.3 Ready Delay Time

In order to support significant propagation delays, the handshake signal TREADY is evaluated with respect to TVALID and TCLK in an time interval called Ready Delay Time after the end of the frame (see **Figure 27-17**). The length of the Ready Delay Time is programmable, defining the size of the time interval.

When a transmission is finished (RVALID becomes 0), the MLI receiver checks the received frame for correct reception (parity error). If no parity error has been detected, the MLI receiver asserts its RREADY signal again to 1 to indicate the correct reception with the next falling edge of RCLK. The MLI transmitter checks its TREADY input with each rising edge of TCLK after TVALID has become 0 and increments a counter. This counter is started from 0 at the end of a frame transmission (TVALID becomes 0) and counts TCLK periods (Ready Delay Time Counter). If the condition TREADY = 1 is detected before the programmed Ready Delay Time has elapsed, the MLI receiver has indicated a frame reception without parity error to the MLI transmitter. In this case, a new frame transmission can be started. The transfer handshake signalling without a parity error indication is shown in **Figure 27-17**.

Figure 27-18 shows the transfer handshake if a parity error condition has been detected by the MLI receiver and indicated to the MLI transmitter. In this case, the receiver waits a programmable number of RCLK clock cycles before setting RREADY to 1. If the TREADY = 1 condition is detected by the transmitter after the ready delay has elapsed, a parity error has been indicated by the MLI receiver. In this case, it is assumed that the MLI receiver has detected a frame with a parity error and has discarded the frame. The

transmitter automatically sends the last frame again after a parity error indication. Optionally, this MLI event can activate a service request output.

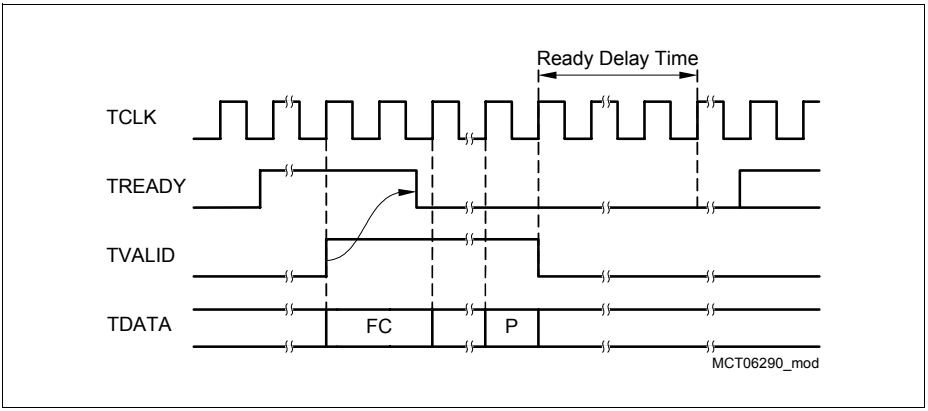

Figure 27-18 MLI Handshake with Parity Error Indication

27.1.3.4 Non-Acknowledge Error

A transmitter of an MLI module is able to detect an inoperable receiver by analyzing the handshake signal TREADY. After TVALID has been asserted to 1, the transmitter checks the receiver's acknowledge (TREADY becoming 0). A Non-Acknowledge error condition is detected by the transmitter when at the end of a frame transmission the TREADY signal is still at high level (TREADY = 1 when TVALID becomes 0). **Figure 27-19** shows the Non-Acknowledge error case. In this case, the transmitter automatically sends the last frame again. Optionally, this MLI event can activate a service request output.

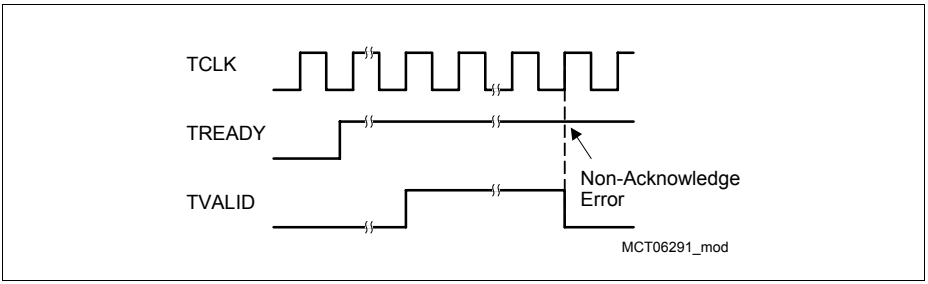

Figure 27-19 Non-Acknowledge Error

27.1.3.5 Signal Timing

Figure 27-20 shows the MLI timing requirements.

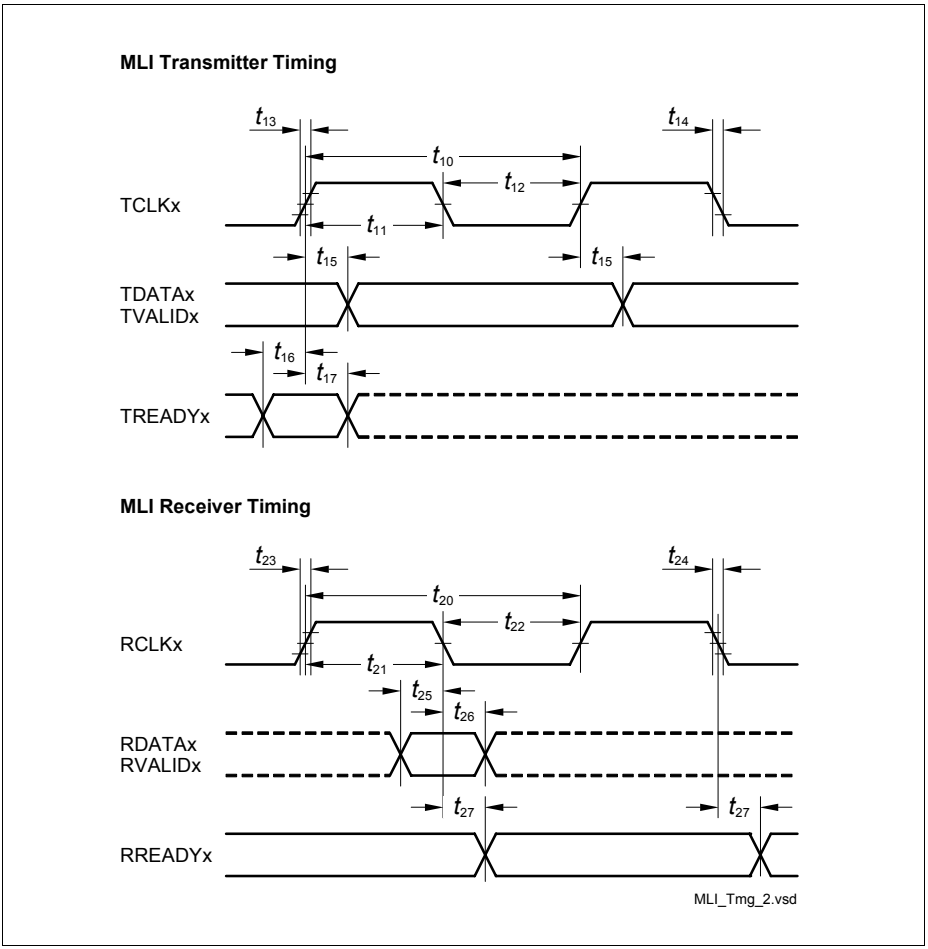

Figure 27-20 Signal Timing

The transmitter output signals TDATA and TVALIDx might have a certain delay to the transmitter clock output TCLK due to on-chip variation of the driver stages and differences in the propagation delays. The transmitter TREADY input can change at any point in time compared to TCLK. In order to ensure stability, it is internally synchronized to f_{MLI} of the transmitter before being evaluated with the rising TCLK edge when TVALID becomes 0. For the calculation of the signal propagation time, these 2 clock cycles have to be taken into account.

The transmitter input TREADYx has to be stable a certain time before TVALID becomes low, referring to the rising edge of TCLK when TVALID becomes low. If at this point in time, TREADYx is detected at a high level, a Non-Acknowledge error is signaled. The same timing relation has to be considered at the end of the ready delay time for the parity error detection.

The receiver input signals are handled asynchronously based on the RCLK signal. The synchronization to the receiver's system clock f_{FPI} is done in the receiver logic. The input signals RDATA and RVALID have to respect a certain setup and hold time at the falling edge of RCLK.

27.1.4 Parity Generation

For parity generation, the number of transmitted bits with the value of 1 is counted over the header and the complete data field of a frame. For even parity, the parity bit is set if the result of a modulo-2 division of the elaborated number is 1. For error-free MLI traffic, even parity generation and checking is defined.

More details about the parity handling of the MLI module are provided on **Page 27-44**.

27.1.5 Address Prediction

An address prediction method can be enabled to support communication between MLI transmitter and MLI receiver without sending address offset information in the frames. This feature reduces the required bandwidth for MLI communication. Both of the communication partners, MLI transmitter and receiver are able to detect regular offset differences of consecutive window accesses to the same window. The address prediction mechanism working independently for each pipe, different prediction values can be handled in parallel for the different pipes.

The MLI transmitter can compare the offset of each Transfer Window read or write access with the offset of the previous access to the same Transfer Window. Between the accesses to a specific window, other windows can be accessed without disturbing the prediction. Bigger offset differences than 512 bytes are not supported by the address prediction.

If the offset differences are identical in at least two accesses to the same Transfer Window, an address prediction is possible and Optimized Write Frames or Optimized Read Frames can be sent to the receiving controller for this pipe. If the offset difference of a next access to this Transfer Window does not match the former ones (predicted offset), address prediction is not possible. In this case, a Normal Frame for writing or reading (Write Offset and Data Frame or Discrete Read Frame) is started.
The identical address prediction mechanism is built in the receiver. As a result, the receiver can elaborate the original offset value in the transmitter when receiving an optimized frame for any pipe.

More details about the address prediction mechanism of the MLI module are provided on **Page 27-47**.

27.2 Module Kernel Description

This chapter describes how the MLI protocol is implemented in the MLI module and how frame handling can be done by software, comprising:

- The frame handling (see **Page 27-27**)
- The general MLI features (see **Page 27-44**)
- The interface signals (see **Page 27-51**)
- The general MLI service request structure (see **Page 27-57**)
- The MLI transmitter events (see **Page 27-59**)
- The MLI receiver events (see **Page 27-62**)
- The baud rate generation (see **Page 27-67**)

27.2.1 Frame Handling

The frame handling is based on receiver and transmitter registers and the Transfer Windows. Depending on the type of access to the Transfer Windows, different actions take place inside the MLI module. Please refer to the following pages for the handling of:

- Copy Base Address Frame (see **Page 27-28**)
- Data Frames (see **Page 27-30**)
- Read Frames (see **Page 27-34**)
- Answer Frame (see **Page 27-39**)
- Command Frame (see **Page 27-41**)

27.2.1.1 Copy Base Address Frame

A Copy Base Address Frame defines the location and the size of a Remote Window.

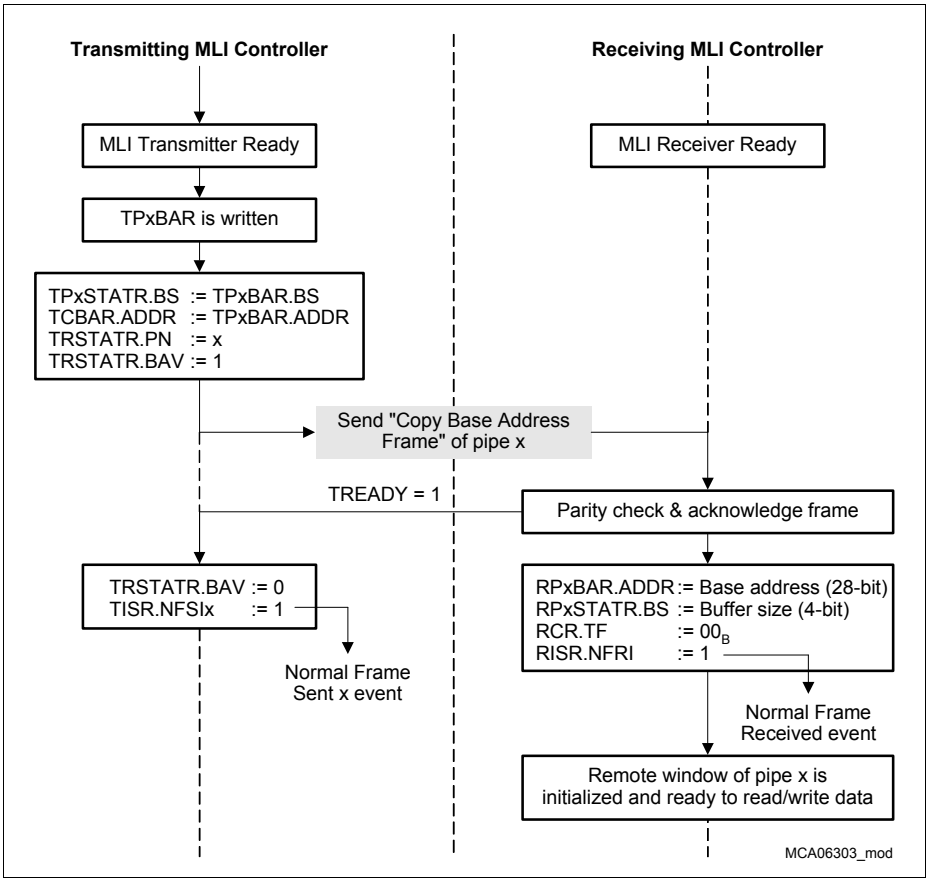

Figure 27-21 Copy Base Address Frame Flow

Transmitting Controller

The transmission of a Copy Base Address Frame is started after a transmitter pipe x base address registers TPxBAR has been written, triggering the following actions for pipe x.

- Bit field TPxBAR.BS (4-bit coded buffer size) is loaded into bit field TPxSTATR.BS
- Bit field TPxBAR.ADDR (28 most significant base address bits) is loaded into bit field TCBAR.ADDR.

- Status bit field TRSTATR.PN is updated with the pipe number x (for example x = 2 when TP2BAR has been written).
- Status flag TRSTATR.BAV (base address valid) becomes set.
- The transmission of a Copy Base Address Frame with the two buffered parameters TCBAR.ADDR and TPxSTATR.BS is started for pipe x (if the corresponding pipe is idle and TREADY = 1).
- Status flag TRSTATR.BAV (in the transmitting controller) is cleared after the Copy Base Address Frame has been finished and correctly acknowledged by the MLI receiver of the receiving controller.
- MLI event status flag TISR.NFSIx (Normal Frame Sent event in pipe x) is set and a service request output is activated if enabled by TIER.NFSIEx = 1.

Note: After the transfer of a Copy Base Address Frame the optimized mode will be suppressed automatically by hardware for the next two data frames. This ensures a correct offset prediction afterwards.

Receiving Controller

When a Copy Base Address Frame for pipe x has been received correctly and acknowledged, the following actions are executed in the MLI receiver.

- The received 28 most significant address bits are written into the receiver pipe x base address register bit field RPxBAR.ADDR. This bit field determines the base address of the pipe x Remote Window.
- The received 4-bit coded buffer size is stored in the receiver pipe x status register bit field RPxSTATR.BS. This bit field determines the number of variable address bits for the offset (determining the size) of the pipe x Remote Window.
- The information about the received frame type (= 00_B for Copy Base Address Frame) is written into the receiver control register bit field RCR.TF.
- MLI event status flag RISR.NFRI (Normal Frame Received event) is set and a service request output is activated if enabled by RIER.NFRIE = 01_B or 10_B.

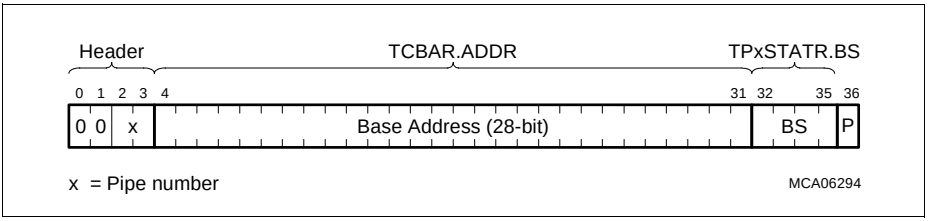

Figure 27-22 Copy Base Address Frame

27.2.1.2 Write/Data Frames

Write Frames (also named Data Frames) transmit the write data and optionally the write offset.

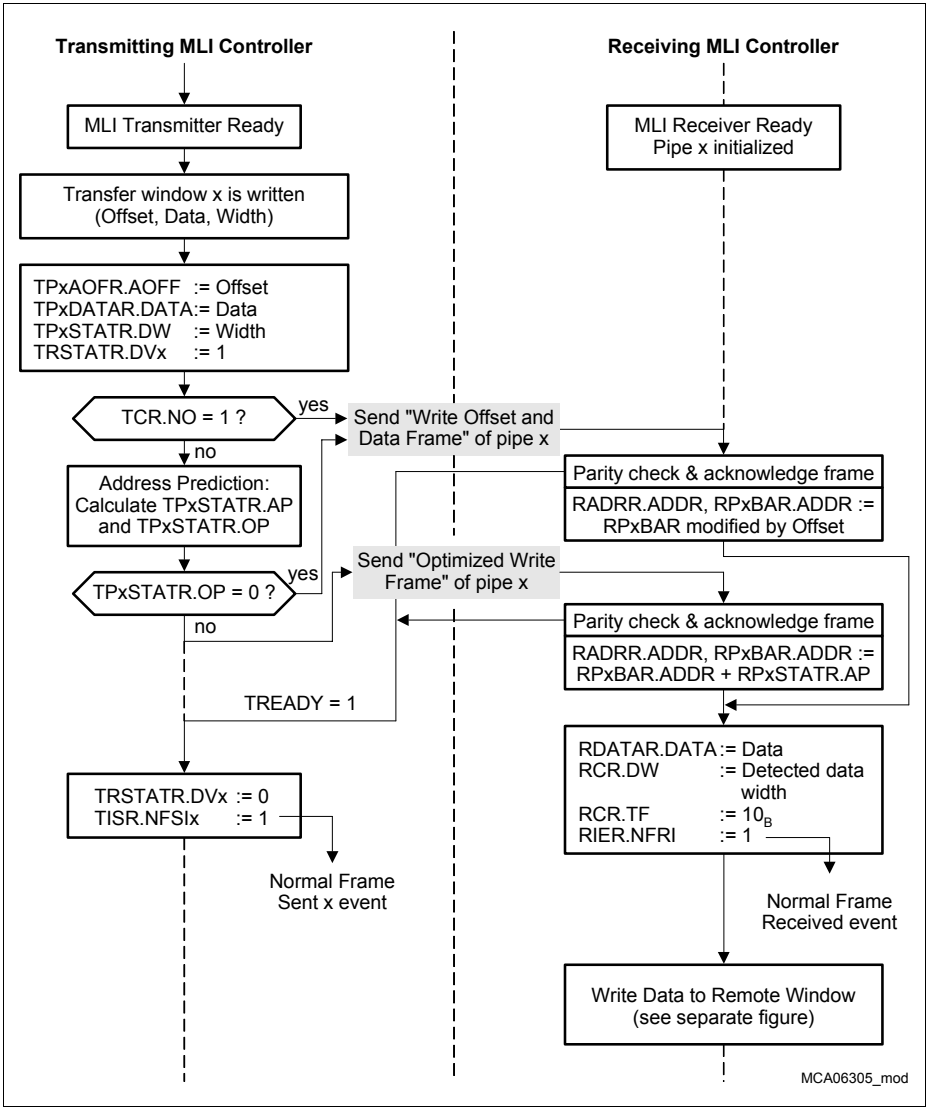

Figure 27-23 Write Frame Flow

Transmitting Controller

In the transmitting controller, a write operation to a location within a Transfer Window delivers the address, the data, and the data size to the transmitter and triggers the following actions in the MLI transmitter.

- The 16 least significant address bits of the Transfer Window write access are stored in TPxAOFR.AOFF as write offset address. In case of a an access to a Small Transfer Window, also 16 bits are stored, but the higher bits are not taken into account assuming the buffer size is configured correctly (see **Page 27-105**).
- The data of the write access to the Transfer Window is stored in TPxDATAR.DATA.
- The data width of the write access to the Transfer Window (8-bit, 16-bit, or 32-bit) is stored in bit field TPxSTATR.DW.
- Status flag TRSTATR.DVx (data valid) is set, indicating that the pipe contains valid data for transmission.
- If the address prediction method is disabled (TCR.NO = 1), the transmission of a Write Offset and Data Frame is started as soon as the MLI transmitter is idle, no higher priority frames are pending, and TREADY = 1.
  If the address prediction method is enabled (TCR.NO = 0), a Write Offset and Data Frame is started only if an address prediction is not possible (indicated by TPxSTATR.OP = 0). If TPxSTATR.OP = 1, an address prediction is possible in the MLI transmitter (and the MLI receiver) and an Optimized Write Frame can be started. The address prediction method used is described on **Page 27-47**.
- Status flag TRSTATR.DVx is cleared by hardware and MLI event status flag TISR.NFSIx (Normal Frame Sent event in pipe x) is set (and a service request output is activated if enabled by TIER.NFSIEx = 1) after the Write Frame has been finished and correctly acknowledged by the MLI receiver.

The number m of offset address bits that are transmitted at a Write Offset and Data Frame is determined by the size of the Remote Window in the receiving controller that has been previously initialized by the transmission of a Copy Base Address Frame. Parameter m is referring to bit field TPxSTATR.BS (and RPxSTATR.BS) and can be in the range of 1 to 16 bits.

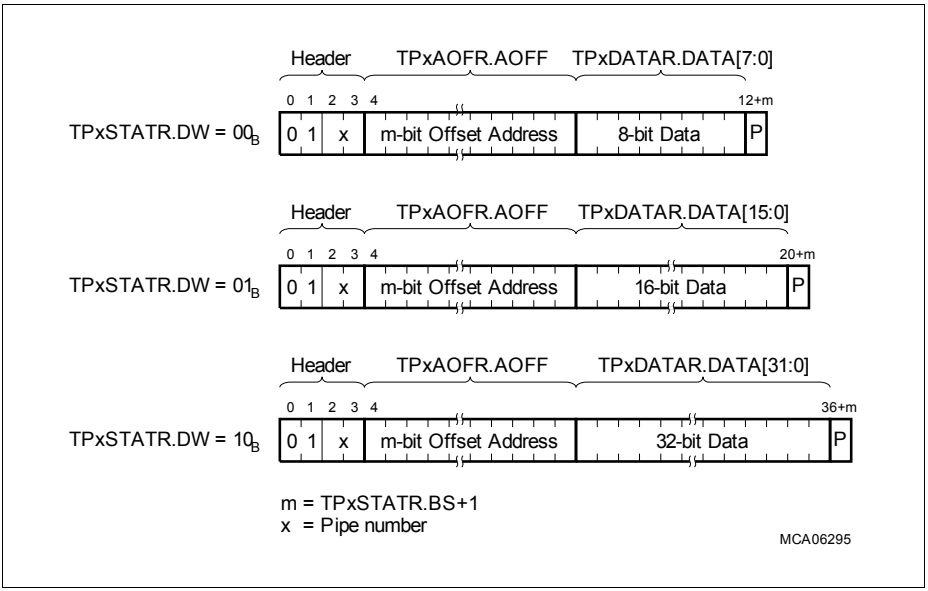

Figure 27-24 Write Offset and Data Frame

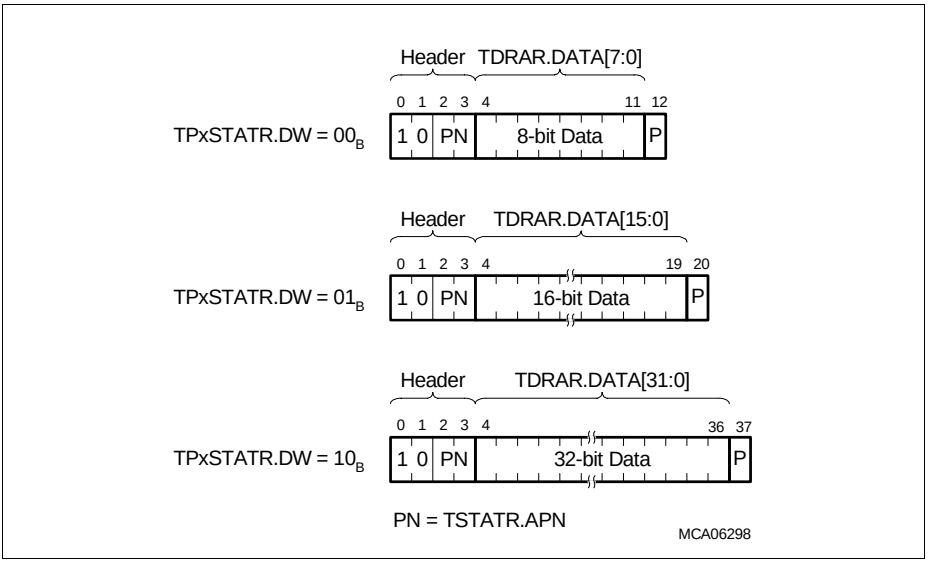

Figure 27-25 Optimized Write Frame

Receiving Controller

After a Write Frame has been received correctly and acknowledged, the following actions are automatically executed in the MLI receiver:

- In the case of a Write Offset and Data Frame:
  The result of the internal address prediction is not taken into account. The received offset address is added to the base address of the pipe x Remote Window and the result is stored in RPxBAR.ADDR. It is also stored in RADDR.ADDR and represents the destination address in the receiving controller where data should be written to.
  In the case of an Optimized Write Frame:
  The result of the internal address prediction is taken into account. The next address in the receiving controller where data should be written to is calculated by adding the detected receiver address prediction value RPxSTATR.AP to the actual address stored in RPxBAR.ADDR and the result is stored in RPxBAR.ADDR and in RADDR.ADDR.
- The received data is written into the receiver data register RDATAR (right aligned, unused bits are 0).
- The detected data width of the received data is written into bit field RCR.DW.
- The information about the received frame type (= 10_B for a Write Frame) is written into bit field RCR.TF.
- MLI event status flag RISR.NFRI (Normal Frame Received event) is set and an SR output line is activated if enabled by RIER.NFRIE = 01_B or 10_B.

After these actions related to the reception of a Write Frame by the receiving controller, the data that has been received from the transmitting controller is ready to be written into the Remote Window related to the receiving pipe.
This write operation can be executed in two ways:

- RCR.MOD = 0: Automatic Data Mode is disabled.
  In this mode, a bus master of the receiving controller, typically a CPU, is informed by a Normal Frame received event RISR.NFRI (a service request output is activated if RIER.NFRIE = 10_B) to transfer the received write data from the MLI receiver to the Remote Window. Therefore, it must read the data from RDATAR, together with width RCR.DW and the address stored in RADRR and write it to the indicated address location.
- RCR.MOD = 1: Automatic Data Mode is enabled.
  In this mode, the MLI module automatically writes the received write data to the Remote Window. This automatic action is controlled by a move engine block in the MLI receiver. It also sets event status flag RISR.MEI (move engine event when the access is terminated). A service request output is activated if enabled by RIER.MEIE = 1.
  The write operation to the Remote Window is executed only if the write address is within an enabled access protection range. If the address range is disabled for the write address, the automatic write action does not take place and event status flag RISR.MPEI (memory protection error) is set and a service request output is activated

if enabled by RIER.MPEIE = 1. In this case, the receiving controller software can analyze the values in RDATAR, together with width RCR.DW and the address stored in RADRR.

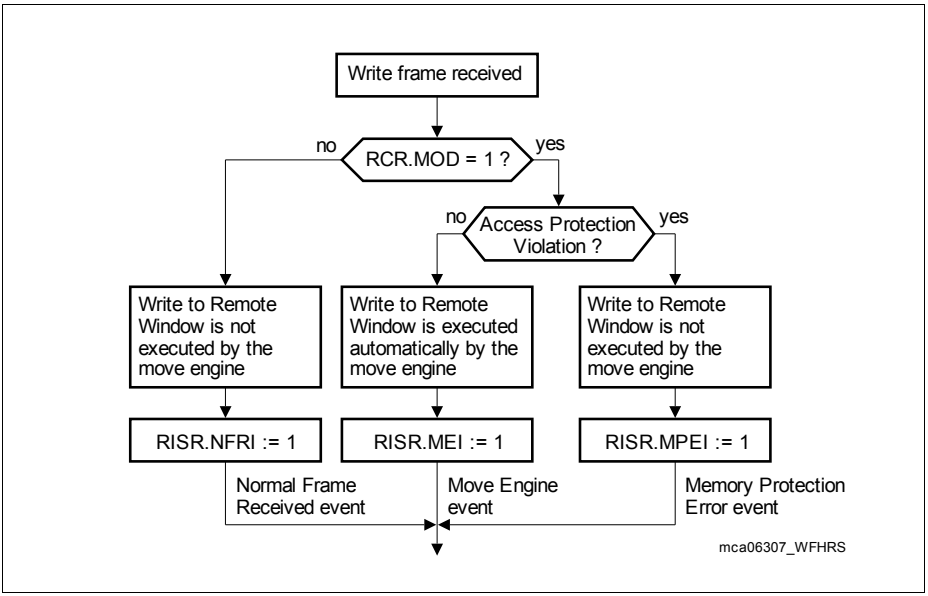

Figure 27-26 Write Frame Handling on Receiving Side

Note: In Automatic Data Mode, Write Frames are leading to a write action executed by the MLI move engine. During the move engine operation, only one more MLI frame can be received (stored in a waiting position to be executed). Then the reception of more frames is blocked by Non-Acknowledge handshake. If the move engine operation is finished, frame execution and reception continue normally.
If Automatic Data Mode is disabled, no blocking mechanism has been implemented. The receiving controller software has to take care to deal with the received data before it is overwritten by new incoming frames.

27.2.1.3 Read Frames

Read Frames transmit read request and optionally the read offset from the Local Controller to the Remote Controller.

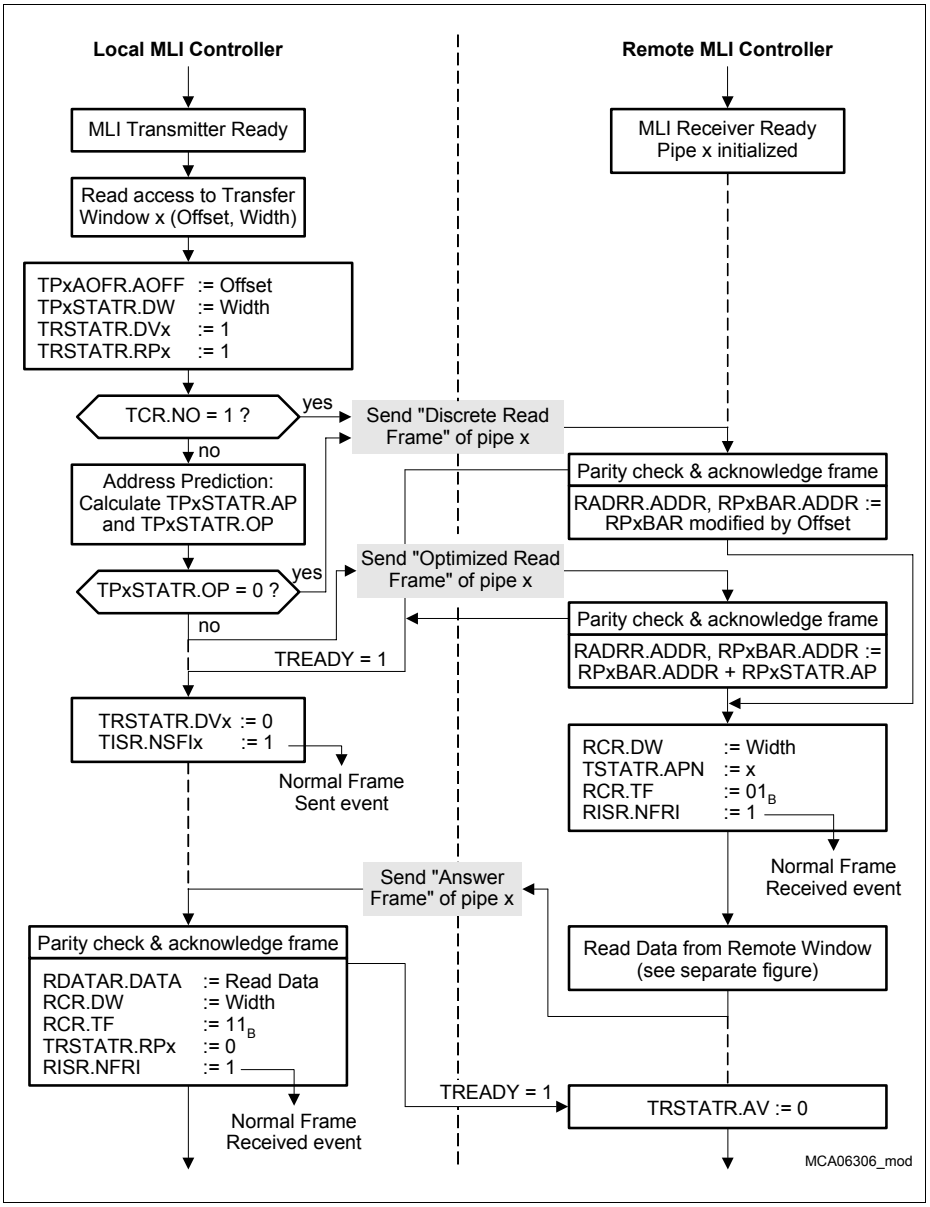

Figure 27-27 Read Frame and Answer Frame Flow

Local Controller

A read operation from a location within a Transfer Window x of the Local Controller delivers a dummy value as result of the read action and triggers the transmission of a Read Frame. The dummy value of the initial read action should be ignored and the software has to wait for the reception of the Answer Frame to get the desired data.

- The 16 least significant address bits of the Transfer Window read access are stored in TPxAOFR.AOFF as read offset address. In case of a an access to a Small Transfer Window, also 16 bits are stored, but the higher bits are not taken into account assuming the buffer size is configured correctly (see **Page 27-105**).
- The data width of the Transfer Window read access (8-bit, 16-bit, or 32-bit) is stored in bit field TPxSTATR.DW.
- Status flag TRSTATR.DVx (data valid) is set.
- Status flag TRSTATR.RPx (read pending) is set. This bit is cleared by hardware when an Answer Frame has been received correctly.
- If the address prediction method is not enabled (TCR.NO = 1), transmission of a Discrete Read Frame is started. If the address prediction method is enabled (TCR.NO = 0), a Discrete Read Frame is started only if an address prediction is not possible (indicated by TPxSTATR.OP = 0). If TPxSTATR.OP = 1, an address prediction is possible and an Optimized Read Frame is started.
- Status flag TRSTATR.DVx is cleared by hardware and MLI event status flag TISR.NFSIx (Normal Frame Sent event in pipe x) is set (and a service request output is activated if enabled by TIER.NFSIEx = 1) after the Read Frame has been finished and correctly acknowledged by the MLI receiver of the Remote Controller.

The number m of offset address bits that are transmitted at a Discrete Read Frame is determined by the (coded) size of the Remote Window in the Remote Controller that has been previously initialized by the transmission of a Copy Base Address Frame. Parameter m is stored in bit field TPxSTATR.BS (and RPxSTATR.BS) and can be in the range of 1 to 16 bits.

After a completed transmission of a Read Frame, the Local Controller expects the reception of an Answer Frame. The Answer Frame is introduced with the highest priority into the data flow of the transmitter of the Remote Controller.

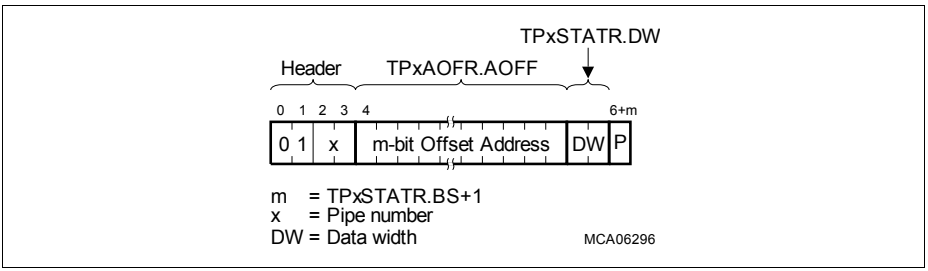

Figure 27-28 Discrete Read Frame

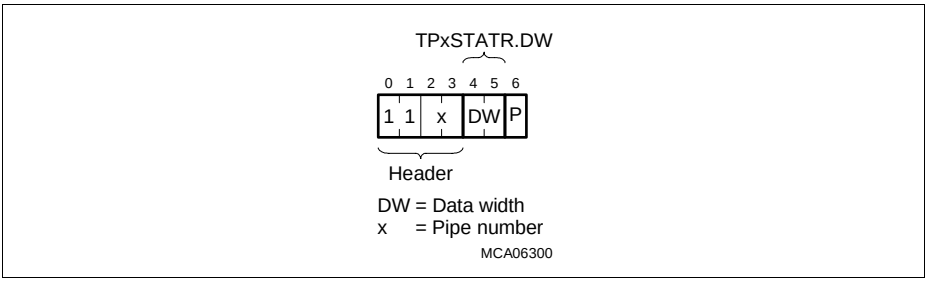

Figure 27-29 Optimized Read Frame

Remote Controller

After a Read Frame has been correctly received and acknowledged, the following actions are executed in the MLI receiver of the Remote Controller:

- In the case of a Discrete Read Frame:
  The result of the address prediction is not taken into account. The received offset address is added to the base address of the pipe x Transfer Window (stored in RPxBAR.ADDR). The result of this addition is stored in RADRR.ADDR and also in RPxBAR.ADDR and represents the destination address in the Remote Controller from where data should be read.
  In the case of an Optimized Read Frame:
  The result of the address prediction is taken into account. The next address in the Remote Controller where data should be read is calculated by adding the detected receiver address prediction value RPxSTATR.AP to the actual address stored in RPxBAR.ADDR. The result of this addition is stored in RADRR.ADDR and also in RPxBAR.ADDR and represents the destination address in the Remote Controller from where data should be read.
- The transmitted data width DW is written into bit field RCR.DW.
- The information about the received frame type (= 01_B for a Read Frame) is written into bit field RCR.TF.
- MLI event status flag RISR.NFRI (Normal Frame Received event) is set and a service request output is activated if enabled by RIER.NFRIE = 01_B or 10_B.

After correct reception of a Read Frame by the Remote Controller, the data requested by the Local Controller can be read by the Remote Controller and sent back to the Local Controller in form of an Answer Frame.

This read operation can be executed in two ways:

- RCR.MOD = 0:
  Automatic Data Mode is disabled. In this mode, a bus master of the Remote Controller, typically a CPU, is informed by a Normal Frame received event to read the requested read data and transfer it to the MLI receiver. Therefore, it must read data

with width RCR.DW from the address stored in RADRR and write the data into TDRAR.DATA.

- RCR.MOD = 1:
  Automatic Data Mode is enabled. In this mode, the move engine of the MLI automatically reads data from the Remote Window and sets event status flag RISR.MEI (move engine access terminated). A service request output is activated if enabled by RIER.MEIE = 1.
  The read operation from the Remote Window is executed only if the read address is within an enabled access protection range. If no address range is enabled for the actual read address, the automatic read action is not executed by the move engine, event status flag RISR.MPEI (memory protection error) is set and a service request output is activated if enabled by RIER.MPEIE = 1. In the interrupt handler routine, a bus master (e.g. CPU or PCP) must then take care of the remote window read operation and the data transfer to TDRAR.
- After TDRAR.DATA has been updated, status flag TRSTATR.AV of the Remote Controller is set and the transmission of an Answer Frame is started.

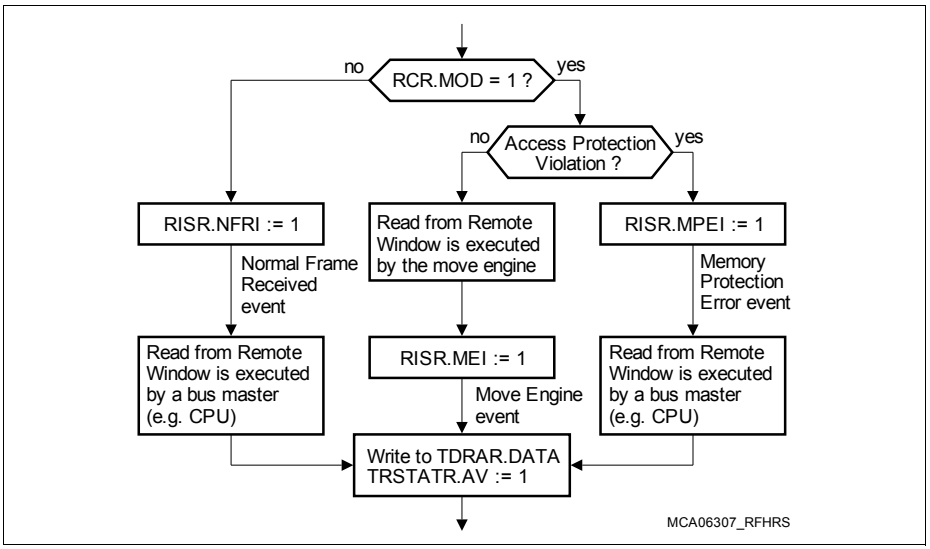

Figure 27-30 Read Frame Handling on Remote Side

Note: In Automatic Data Mode, Read Frames are leading to a read action executed by the MLI move engine. During the move engine operation, only one more MLI frame can be received (stored in a waiting position to be executed). Then the reception of more frames is blocked by a Non-Acknowledge handshake. If the move engine operation is finished, frame execution and reception can continue normally. If Automatic Data Mode is disabled, no blocking mechanism has been

implemented. The Remote Controller software has to take care to read the received data.

27.2.1.4 Answer Frame

Please note that only one Answer Frame can be handled by the system at a time (no Read Frame request while any TRSTATR.RPx is set). Make sure that not more than one Read Frame is pending at a time. If a Read Frame is not answered by an Answer Frame during a certain time interval, a time-out criterion should be handled in software. The Remote Controller has to take care that no Answer Frame is delivered after the time-out criterion has been detected (e.g. by a software-triggered Command Frame). Do not start a new Read Frame while waiting for an Answer Frame if the time-out criterion has not yet been detected and the Answer Frame has not yet been received. The length of the time-out interval depends on the application and has to be defined accordingly on a case by case base (e.g. the transfer rates between MLI modules, bus architecture, etc. have to be considered). In the case a time-out has been detected, the Local Controller software has to clear the TRSTATR.RPx bit by writing 1 to SCR.CDVx and can start a new Read Frame.

Remote Controller (Receiving the read request)

The Answer Frame is the only frame sent from the Remote Controller back to the Local Controller. The transmitter registers of the Remote Controller are used to generate the Answer Frame.

Every time the transmitter data read answer register TDRAR is written in the Remote Controller, the transmission of an Answer Frame is started and the following actions are triggered.

- Status flag TRSTATR.AV is set to trigger the transmission of an Answer Frame.

The following parameter is transmitted in the data field of the Answer Frame:

- Read data: stored in TDRAR.DATA; data width is determined by TRSTATR.DW.
- Status flag TRSTATR.AV is cleared after the Answer Frame has been finished and correctly acknowledged by the MLI receiver of the Local Controller.

An Answer Frame should be sent through the pipe that has received a read request but there must be only one MLI Transfer Window read access pending on any side of a MLI connection at any time, because the answer mechanism does not contain buffers for multiple Answer Frames.

Local Controller (Transmitting the read request)

If an Answer Frame has been received correctly and acknowledged, the following actions are executed in the MLI receiver of the Local Controller:

- The TRSTATR.RPx flags are cleared.

- The received data is written into the receiver data register RDATAR.
  If 8 data bits are received, they are duplicated to all 4 bytes in RDATAR.
  If 16 data bits are received, they are duplicated to both half-words in RDATAR.
- The detected data width of the received data is written into bit field RCR.DW.
- The received Pipe Number x represents the answer Pipe Number and is written into bit field TSTATR.APN.
- The information about the received frame type (= 11_B for an Answer Frame) is written into bit field RCR.TF.
- MLI event status flag RISR.NFRI (Normal Frame Received event) is set and a service request output is activated if enabled by RIER.NFRIE = 01_B or 10_B.
- The content of RADRR becomes invalid.
- The data that has been previously requested from the Remote Controller by a Read Frame is now available in RDATAR and can be read by a bus master (e.g. the CPU) of the Local Controller.
- If an Answer Frame is received while the corresponding TRSTATR.RPx bit is 0, the reception is declared as unintended and a Discarded Read Answer event is generated (see **Page 27-62**).

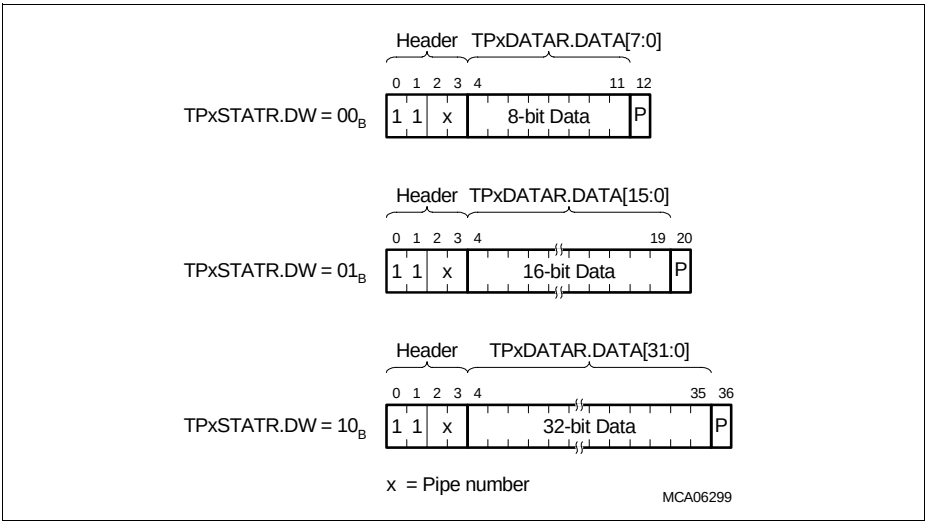

Figure 27-31 Answer Frame

Note: If an Answer Frame has been correctly received in the Local Controller, the Local Controller's software has to read it. As long as at least one byte of this data has not yet been read out, only one more MLI frame can be received (stored in a waiting position to be executed). Then the reception of more frames is blocked by Non-Acknowledge handshake. If the received data has been read out, frame execution and reception continue normally.

27.2.1.5 Command Frame

Command Frames transmit a command (e.g. setup information or service request) from a transmitting controller to a receiving controller.

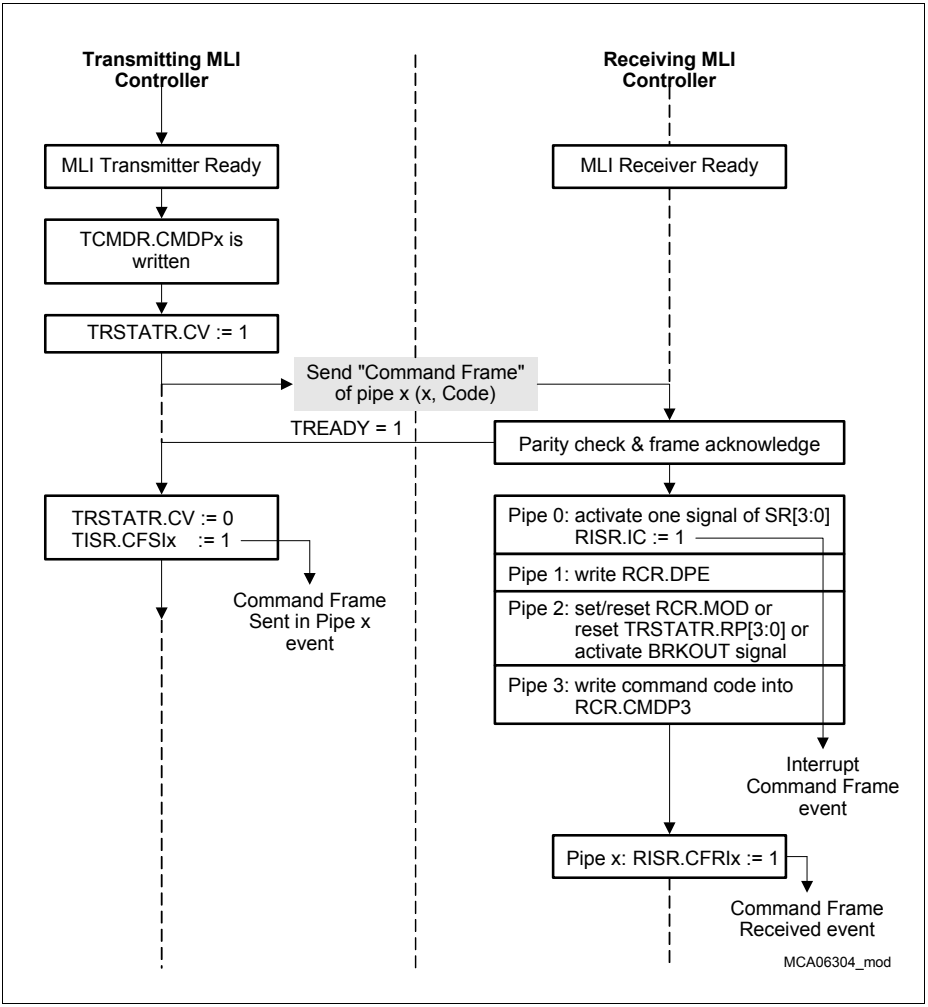

Figure 27-32 Command Frame Transaction Flow

Transmitting Controller

The transmission of a Command Frame is initiated by writing one of the four pipe x related command code bit fields in register TCMDR.CMDPx, triggering the following actions:

- Status flag TPxSTATR.CVx (command valid) is set and the Command Frame transmission is started using x as pipe number PN and the command code stored in TCMDR.CMDPx as parameters.
- TRSTATR.CVx is cleared after the Command Frame has been finished and correctly acknowledged by the MLI receiver of the Remote Controller.
- MLI event status flag TISR.CFSIx (Command Frame Sent event in pipe x) is set and a service request output is activated if enabled by TIER.CFSIEx = 1.

Receiving Controller

Depending on the pipe x related command code that is transmitted by a Command Frame, different actions are triggered in the receiving controller. **Table 27-5** describes the actions that are transmitted by a Command Frame and that cause a specific control task in the MLI receiver.

- The received PN value is checked and the corresponding control actions are executed according to **Table 27-5**.
- Independent of the received Pipe Number, event status flag RISR.CFRIx (Command Frame Received event in pipe x) is set and a service request output is activated if enabled by RIER.CFRIEx = 1.

If a Command Frame is received for pipe 2 with command code 1111_B, the $\overline{\text{BRKOUT}}$ output signal of the MLI module becomes activated if it is enabled by bit RCR.BEN = 1. If disabled by RCR.BEN = 0, signal $\overline{\text{BRKOUT}}$ will not be activated. The usage of $\overline{\text{BRKOUT}}$ is implementation-specific and can be used, for example, to generate a break condition in the on-chip debug support logic or trigger other functions.

Table 27-5 Command Frame Encoding

PN	CMD	Command Description
00_B	0001_B	Activate service request output SR0 of receiving MLI module
	0010_B	Activate service request output SR1 of receiving MLI module
	0011_B	Activate service request output SR2 of receiving MLI module
	0100_B	Activate service request output SR3 of receiving MLI module
	Others	no effect, reserved for future use

Table 27-5 Command Frame Encoding (cont'd)

PN	CMD	Command Description
01_B	0000_B	Set RCR.DPE (delay for parity error indication) in receiving MLI to 0000_B
	0001_B	Set RCR.DPE in receiving MLI to 0001_B
	0010_B	Set RCR.DPE in receiving MLI to 0010_B
	...	...
	1111_B	Set RCR.DPE in receiving MLI to 1111_B
10_B	0001_B	Enable Automatic Data Mode in receiving MLI (set RCR.MOD = 1)
	0010_B	Disable Automatic Data Mode in receiving MLI (set RCR.MOD = 0)
	0100_B	Clear bit TRSTATR.RP0 in receiving MLI
	0101_B	Clear bit TRSTATR.RP1 in receiving MLI
	0110_B	Clear bit TRSTATR.RP2 in receiving MLI
	0111_B	Clear bit TRSTATR.RP3 in receiving MLI
	1111_B	Generate break output signal $\overline{\text{BRKOUT}}$ in receiving MLI (if enabled by RCR.BEN = 1)
	others	no effect, reserved for future use
11_B	Any	Free programmable software command, written into bit field RCR.CMDP3 of receiving MLI

27.2.2 General MLI Features

The general MLI features comprise the:

- Parity generation and checking (see **Page 27-44**)
- Non-Acknowledge error (see **Page 27-47**)
- Address prediction (see **Page 27-47**)
- Automatic data transfers (see **Page 27-48**)
- Access protection (see **Page 27-49**)
- Triggered Command Frames (see **Page 27-49**)
- Transmit priority (see **Page 27-50**)
- Transmission delay (see **Page 27-50**)

27.2.2.1 Parity Check and Parity Error Indication

For parity generation, the number of transmitted bits with the value of 1 is counted over the header and the complete data field of a frame. For even parity, the parity bit is set if the result of a modulo-2 division of the elaborated number is 1. For odd parity, the parity bit is set if the result of a modulo-2 division of the elaborated number is 0.

For a parity error-free MLI connection, even parity must be selected in the transmitter because the receiver operates only with even parity detection. The capability to select odd parity can be used by the transmitter to force a parity error reply from the receiver during the startup procedure of the MLI connection. This can be used to measure the propagation delay and to optimize the ready delay time (see **Page 27-73**).

Note: There is no protection against frames where more than one bit is corrupted (e.g. shortened frames). In such a case, an unpredictable behavior of the MLI module may occur.

Transmitting Controller

The MLI transmitter counts the detected parity error conditions and generates a parity error event if a programmable number (max. 16) of parity error conditions has occurred. A parity error condition is indicated to the transmitter by the receiver after the transmission of a frame (see **Page 27-23**). The transmitter parity error condition is detected when the TREADY signal is sampled at low level within a programmable number (TCR.MDP = maximum delay for parity errors) of TCLK clock cycles after TVALID has been de-asserted to low.

If a transmitter parity error condition is detected, the MLI transmitter sets the parity error flag TSTATR.PE and also decreases the maximum parity error counter TCR.MPE by 1. The maximum parity error counter of the transmitter TCR.MPE determines the number of transmit parity error conditions that can be still detected until a transmitter parity error event is generated. If a transmitter parity error condition is detected and TCR.MPE is becoming 0 or while it is 0, a transmitter parity error event is generated by setting bit TISR.PEI (see **Figure 27-40** on **Page 27-60**) and an SRx output line is activated if

enabled by TIER.PEIE = 1. After a transmitter parity error event occurred, TCR.MPE can be set again by software to a value greater 0001_B. Otherwise, each additional transmitter parity error condition will generate a parity error event.

The transmitter parity error flag TSTATR.PE is cleared by hardware when a correct frame transmission and TREADY has been sampled with 1 within the ready delay time. It can be cleared by software by writing a 1 to bit SCR.CTPE. If for example, each transmitter parity error condition should generate a transmitter parity error event, TCR.MPE should be set to 0000_B. The software can check for accumulated parity error conditions by reading TCR.MPE or TISR.PEI, for the status of the latest received frame, it can check TSTATR.PE.

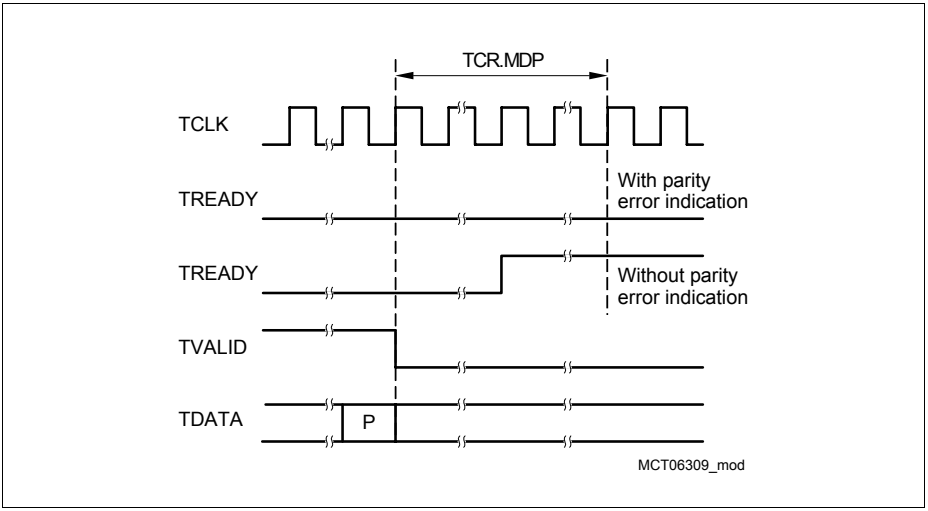

Figure 27-33 Parity Error Indication for the Transmitter

Receiving Controller

The receiver always checks the parity bit of a received frame for even parity. A receiver parity error condition is detected if the received parity bit does not match with the internally calculated one. If no receiver parity error condition is found after the reception of a frame, RREADY is immediately set to 1, otherwise RREADY is kept at 0 until a defined number of RCLK cycles (determined by bit field RCR.DPE = delay for parity error) has been elapsed. Then, RREADY is asserted high.

If a receiver parity error condition is found, the MLI receiver sets the parity error flag RCR.PE and additionally decreases the maximum parity error counter of the receiver RCR.MPE by 1. The maximum parity error counter RCR.MPE determines the number of receiver parity error conditions that can be still detected until a receiver parity error event is generated. If a receiver parity error condition is detected and RCR.MPE is becoming

0 or while it is already 0, a receiver parity error event is generated by setting bit RISR.PEI (see **Figure 27-44** on **Page 27-63**) and a service request output is activated if enabled by RIER.PEIE = 1. After a receiver parity error event has occurred, RCR.MPE can set again by software to a value greater 0001_B. If, for example, each receiver parity error condition should generate a receiver parity error event, RCR.MPE can be programmed to 0000_B or 0001_B.

The receiver parity error flag RCR.PE is cleared by hardware if a correct frame transmission has occurred. RCR.PE can be cleared by software by writing a 1 to bit SCR.CRPE.

The receiver parity error flag RCR.PE is cleared by hardware after a correct frame reception. It can be cleared by software by writing a 1 to bit SCR.CRPE. The software can check for accumulated parity error conditions by reading RCR.MPE or RISR.PEI, for the status of the latest received frame, it can check RCR.PE.

The delay for parity error bit field RCR.DPE is a read-only bit field in the receiver that updated by hardware if a Command Frame for pipe 1 is received. With this frame type, the transmitting controller transfers a value for RCR.DPE to the receiving controller during the setup phase of the MLI connection.

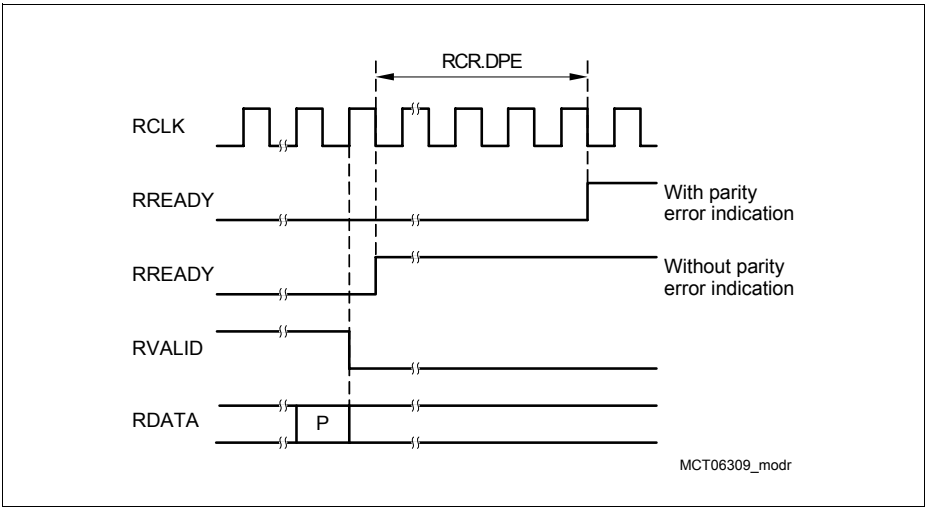

Figure 27-34 Parity Error Indication by the Receiver

27.2.2.2 Non-Acknowledge Error

A Non-Acknowledge error condition is detected by the transmitter when at the end of a frame transmission, the TREADY signal is still at high level (TREADY = 1 when TVALID becomes 0). In this case, the error flag TSTATR.NAE is set and the maximum Non-Acknowledge error counter TCR.MNAE is decremented by 1. If a Non-Acknowledge error condition is detected and TCR.MNAE is becoming 0 or while it is already 0, a time-out event is generated by setting bit TISR.TEI (see **Figure 27-40** on **Page 27-60**) and an MLI service request is generated if enabled by TIER.TEIE = 1. The Non-Acknowledge error flag TSTATR.NAE is cleared by hardware when a frame transmission has been acknowledged correctly. It can also be cleared by software when writing a 1 to bit SCR.CNAE.

The Non-Acknowledge error counter TCR.MNAE is automatically set to 11_B when a frame has been acknowledged correctly. It can be read and written by software, allowing a limited number of consecutive Non-Acknowledge errors to be defined that can be detected until a time-out error event is generated. If, for example, the first occurrence of a Non-Acknowledge error should lead to a time-out event, bit TCR.MNAE has to be written by software with 00_B or 01_B after each correctly received frame.

27.2.2.3 Address Prediction

An address prediction method can be enabled to support communication between MLI transmitter and MLI receiver without sending address offset information in the frames to optimize the required MLI bandwidth. This feature reduces the required bandwidth for MLI communication. Both communication partners, MLI transmitter and the MLI receiver are able to detect regular offset differences of consecutive window accesses to the same window. The address prediction mechanism working independently for each pipe, different prediction values can be handled in parallel for the different pipes.

Transmitting Controller

If the address prediction method is enabled (TCR.NO = 0), the MLI transmitter compares the offset of each Transfer Window read or write access with the offset of the previous access to the same Transfer Window (stored in TPxAOFR.AOFF). The result of this comparison is stored in two's complement representation in TPxSTATR.AP (limited to 9 bits, otherwise prediction is not possible). Between the accesses to a specific window, other windows can be accessed without disturbing the prediction.

If the offset differences are identical in at least two consecutive accesses to the same Transfer Window, an address prediction is possible (flag TPxSTATR.OP becomes set) and optimized frames can be sent to the receiving controller for this pipe. If the offset difference of a next access to the same Transfer Window does not match the calculated value in TPxSTATR.AP, flag TPxSTATR.OP is cleared and address prediction is not possible. In this case, a Normal Frame for writing or reading (Write Offset and Data Frame or Discrete Read Frame) is started.

Receiving Controller

The MLI receiver operates with an address prediction method equivalent to the MLI transmitter. This means that after receiving at least two consecutive Write Offset and Data Frames and/or Discrete Read Frames that include address information, the MLI receiver is able to follow the address prediction method used by the MLI transmitter.
Each received offset is compared in the MLI receiver with the offset of the previously received frame of the same pipe. The result of this comparison is stored in two's complement representation in RPxSTATR.AP (limited 9 bits).

If an optimized frame is received by the MLI receiver, it calculates the next address by adding the value stored in RPxSTATR.AP to the contents of the receiver address register RADRR.

In case of a Write Offset and Data Frame or a Discrete Read Frame (m offset bits), the receiver address registers RADRR and RPxBAR are always loaded with an updated address. This address is calculated by replacing the lowest m bit positions in RPxBAR with the received offset value. In this case, the address delta value stored in RPxSTATR.AP is not taken into account. The programmed size of the Remote Window and the number m of offset bits are given by RPxSTATR.BS. The bit positions RPxBAR[31:m] are kept constant, whereas the bit positions RPxBAR[m-1:0] are replaced.

27.2.2.4 Automatic Data Mode

The MLI module supports automatic data transfers for read or Write Frames without any CPU load in the receiving controller. This features is based on a move engine block providing the data, the complete address and the data width to an associated bus master on the system bus (see **Figure 27-1**). Depending on the implementation, this bus master can be capable of executing the requested data move operations autonomously. The Automatic Data Mode in the receiving controller can be enabled (RCR.MOD = 1) or disabled (RCR.MOD = 0) by software on receiving side or a Command Frame sent by the transmitting controller.
If the Automatic Data Mode is disabled, the receiving controller software has to execute the requested data transfers.
Additionally to the global enable/disable of the automatic mode by **RCR**.MOD, it is possible to individually exclude address ranges from automatic data transfer by an access protection scheme. The definition of the address ranges depend on the product and has been introduced to support the protection of critical data or modules.

Note: If a device contains the MLI move engine block as the only bus master, automatic mode has to be selected to allow transfers. This could be the case for external peripheral devices without own CPU.

27.2.2.5 Memory Access Protection

The MLI receiver provides a memory access protection logic allowing to exclude read and write accesses of the MLI move engine to specific parts of the memory map from automatic mode. Each address of a data move (read or write) is always checked if it targets an address range that is enabled for read/write access. If a requested data move is targeting an excluded address range, a memory access protection error event is generated and the receiving controller's software can take care of the service request.

The memory access protection logic handles two levels of address range definitions:

- Fixed address ranges (for complete modules or memory areas)
- Programmable address sub-ranges (to limit accesses to specific parts of bigger memory areas)

There is a maximum of 2 x 32 fixed address ranges available that can be individually enabled/disabled by the address range enable bits AER0.AENx and AER1.AENx (x = 0-31). If bit AERy.AENx is set, read/write accesses to the associated address range x are supported in automatic mode. If bit AENx is cleared, read/write accesses to the associated address range x are not automatically executed, a memory protection error event is generated, and SRx output line is activated if enabled by RISR.MPEI.

The MLI module supports a definition of up to two times four programmable address sub-ranges (with index n) within fixed address ranges. The parameters for the sub-ranges are stored in the access range registers ARR0 and ARR1, comprising:

- The size of an address slice defined as sub-range (ARRy.SIZEn)
- The location of an address slice defined as sub-range (ARRy.SLICEn)

Note: The definition of the fixed address ranges and the sub-ranges is product-specific. Detailed values are given in the module implementation chapter.

27.2.2.6 Triggered Command Transfers

The MLI module supports the transmission of Command Frames triggered by hardware signals (up to 4 trigger inputs TR[3:0]). If a rising edge at a TRx input is detected, a corresponding bit TRSTATR.CIVx is set. The MLI transmitter sends out a Command Frame with PN = 00_B and CMD = x + 1 if bit CIVx = 1. This Command Frame can then trigger the activation of the corresponding SRx service request output of the Remote Controller. A Triggered Command Frame can be used monitor service request signals in the Local Controller and to transfer the requests to the Remote Controller, without intervention of any CPU.

Bit CIVx is automatically cleared after successful transmission of the related Command Frame or by writing 1 to SCR.CCIVx.

Note: The connection of the TR[3:0] input lines is product-specific. Detailed information is given in the module implementation chapter (see ***Page 27-137****).*

27.2.2.7 Transmit Priority

In the case that several requests for frame transmission are pending at the same time in a MLI transmitter, the following priority scheme is applied, starting with the highest priority.

For the Answer Frame, only one frame can be pending at a time in the transmitter. So the user has to take care that an older Answer Frame is completely handled before requesting a new one. The same applies for the base address copy frame.

For the Triggered Command Frames, the software driven Command Frames and the read or Write Frames, one frame of each type can be pending per pipe at a time.

Note: The MLI has 4 inputs for Triggered Command Frames. They are not necessarily connected in all devices. Please refer to the device specific implementation chapter for details (see ***Page 27-137****).*

- Answer Frame (only one frame pending allowed at a time)
- Triggered Command Transfer (CIV0 before CIV1 before CIV2 before CIV3)
- Software driven Command Frames (CV0 before CV1 before CV2 before CV3)
- Read or Write Frames (DV0 before DV1 before DV2 before DV3)
- Base Address Copy Frame (only one frame pending allowed at a time)

27.2.2.8 Transmission Delay

A transmission delay can be introduced in the transmitter between the detection of the rising edge of the RREADY input signal and the next possible frame start. This delay represents the minimum time between the acknowledge of a former frame by RREADY and a new frame (if a request is pending). The delay is defined by bit field TCR.TDEL in cycles of the transmitter system clock f_{FPI}.

The purpose of the transmission delay is to compensate for the time required for data to be transferred from the receiver frequency domain into the microcontroller frequency domain.

27.2.3 Interface Description

The MLI transmitter and MLI receiver communicate with other MLI receivers and MLI transmitters via a four-line serial connection each. Several I/O lines of these connections are available outside the MLI module kernel as a four-line output or input vector with index numbering A, B, C and D. The MLI module internal I/O control blocks define which signal of a vector is actually taken into account and also allow polarity inversions (to adapt to different physical interconnection means).

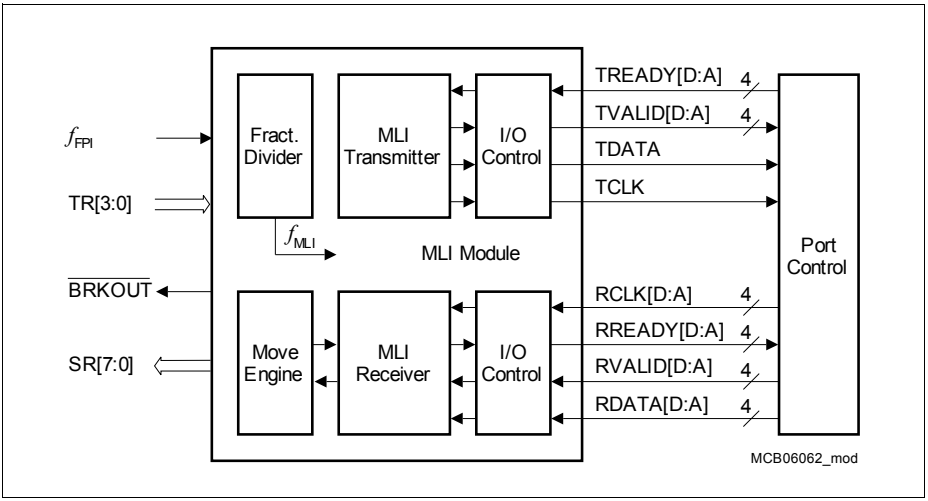

Figure 27-35 General Block Diagram of the MLI Module

Each input/output signal used for MLI communication between a transmitter and a receiver can be disabled and inverted in its polarity. Please note that all waveform diagrams in the MLI chapter refer to non-inverted signals. If polarity inversions are programmed, the waveform diagrams have to be interpreted accordingly. In order to avoid naming mismatches, the signals keep their names, although a polarity inversion might have been programmed. If desired, polarity inversions for the same signal have to be programmed in the transmitter and in the receiver to guaranty signal consistency (there has always to be an even number of inversions between an MLI transmitter and receiver). After reset, the following setting is applied, allowing MLI communication without modification of register OICR[1)]:

- The signal with the index A is selected from each input/output vector.
- TCLK generation is enabled and RCLK reception is enabled.

1) Other services (e.g. an automatic boot sequence or a boot routine) can change the OICR setting. Differing values are then indicated in the corresponding implementation chapter.

- Polarity inversion is disabled for all signals (no inversion).
- Not selected output signals are at low level.

The usage of signal BRKOUT is implementation-specific and can be used, for example, to generate a break condition in the on-chip debug support logic or trigger other functions. This signal is activated (as a pulse) by a Command Frame.

The service request outputs SR[7:0] of the MLI module can be activated (as a pulse) by transmitter or receiver events (for all SRx), as well as by Command Frames (only for SR[3:0]).

The MLI module also supports 4 trigger inputs TR[3:0]. A rising edge at input TRx sets bit TRSTATR.CIVx and requests the transfer of a Triggered Command Frame in pipe 0, with a CMD = x + 1.

27.2.3.1 Transmitter I/O Line Control

Figure 27-36 shows the MLI transmitter I/O control logic.

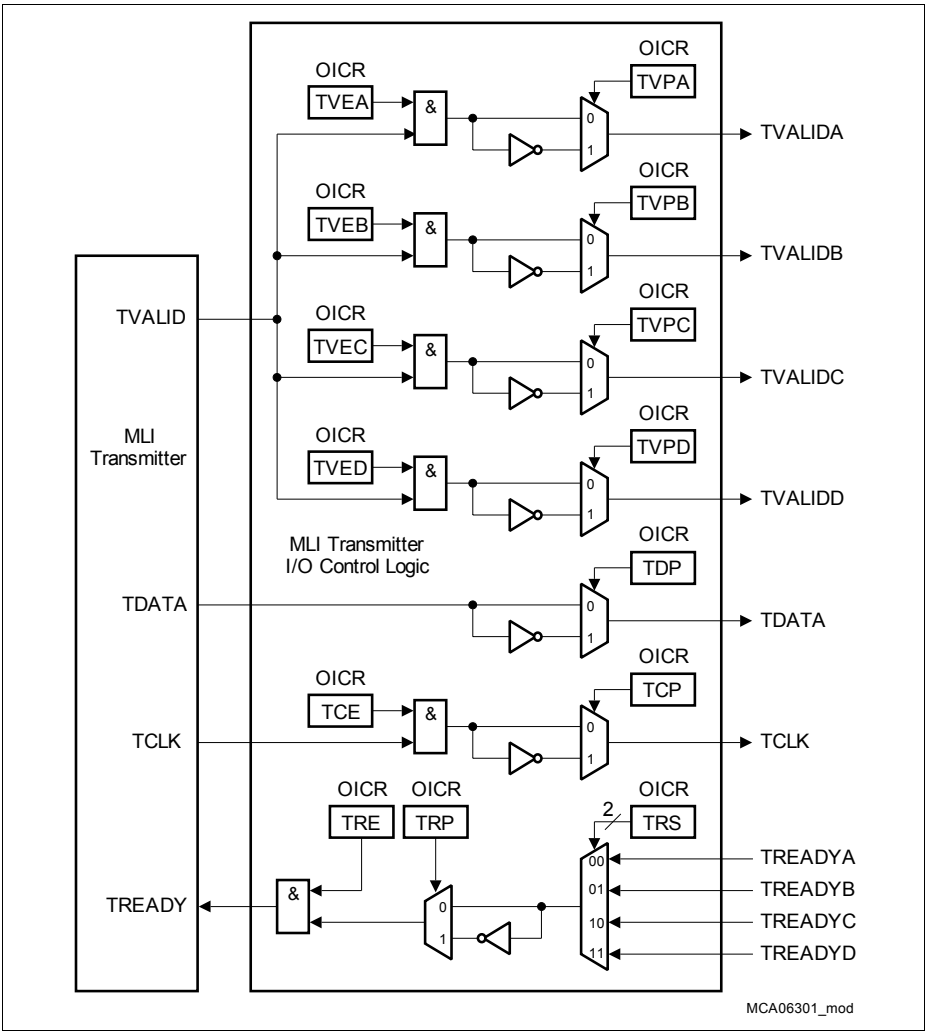

Figure 27-36 Transmitter Input/Output Control Logic

27.2.3.2 Receiver I/O Line Control

Figure 27-37 shows the MLI receiver I/O control logic.

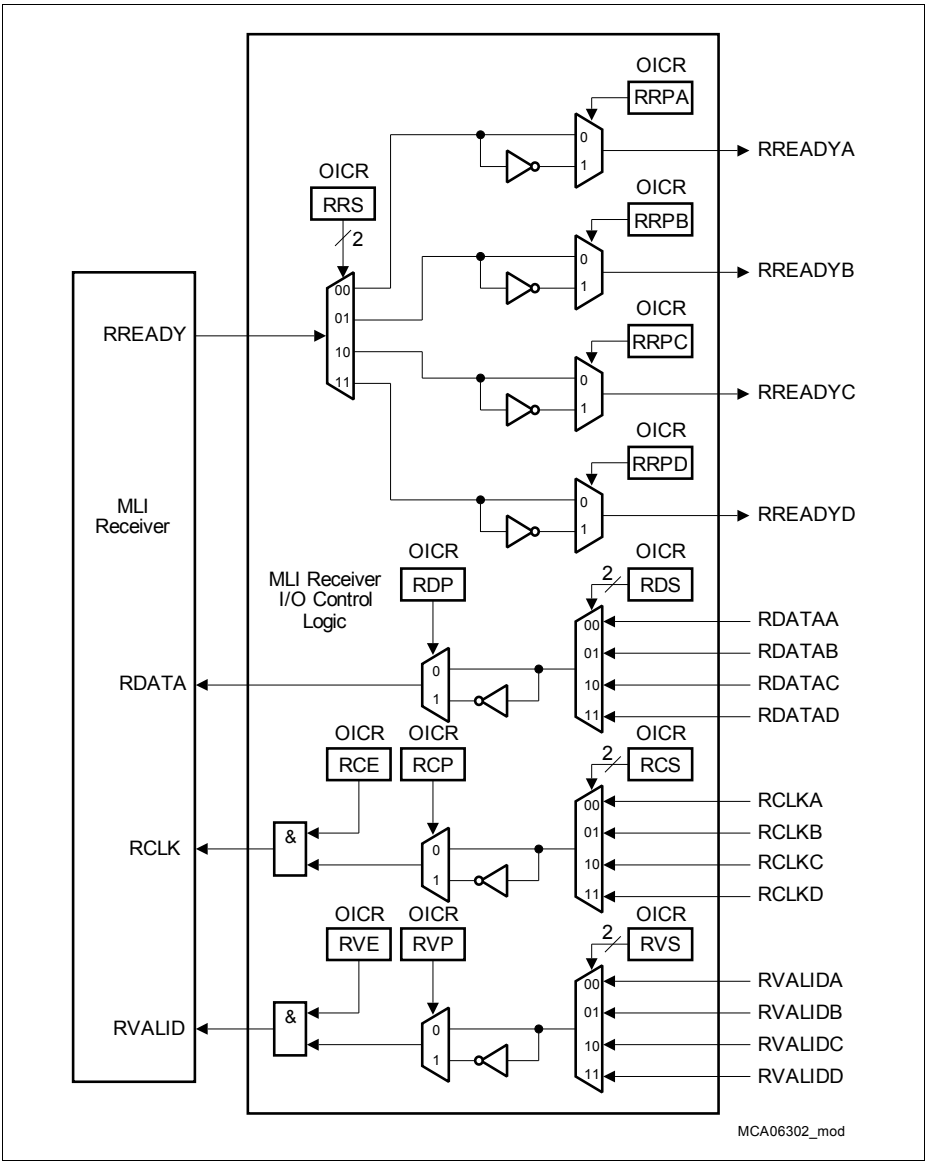

Figure 27-37 Receiver Input/Output Control Logic

27.2.3.3 Connecting Several MLI Modules

The MLI structure also allows to connect several MLI modules together, e.g. two Remote Controllers (X and Y) to one Local Controller. In this case, the Local Controller can send data to either one or the other or to both Remote Controllers in parallel. Each Remote Controller is connected via an own set of READY/VALID signals to the Local Controller, whereas the transmitter DATA and CLK are broadcast signals. The status of the VALID lines defines, which Remote Controller is accessed.

Only one receiver being available in the Local Controller, the reception of data can be handled only either from one or the other Remote Controller. The software has to ensure that only one Remote Controller sends data back to the Local Controller, e.g. by using Read Frames or by enabling/disabling the generation of Write Frames in the Remote Controllers.

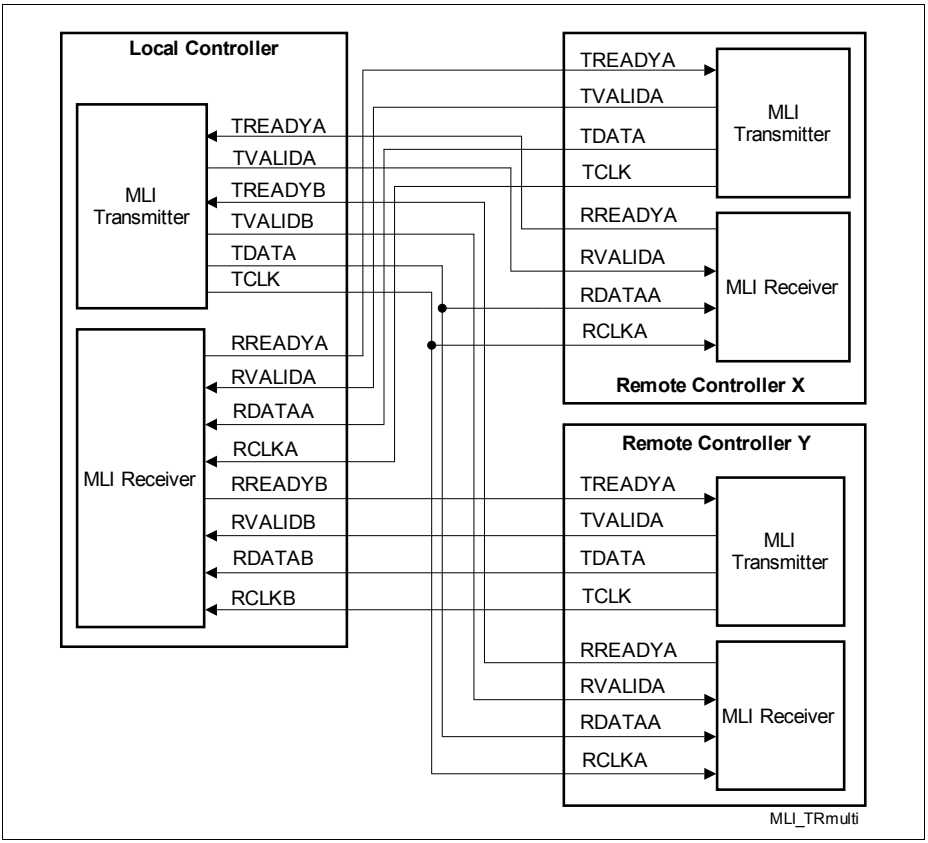

Figure 27-38 Connecting Two Remote Controllers

Another possibility to connect several MLI modules is a ring structure, with (at least) one dedicated pipe per device. This leads to a structure where the Local Controller's transmitter is connected to the receiver of Remote Controller X, the transmitter of Remote Controller X to the receiver of Remote Controller Y, and the transmitter of Remote Controller Y to the Local Controller's receiver.

This structure supports autonomous data generation and transfer in both Remote Controllers, for example to transfer data generated in a Remote Controller to the Local Controller without using Read Frames. In a ring structure, the Read Frame handling should be avoided. It is possible for the Local Controller to access both Remote Controllers independently. For example, the Remote Window of pipe x covers the address range of Remote Controller X, whereas pipe y targets the Transfer Window y of Remote Controller X. In Remote Controller Y, the pipe y targets the available address range. If the Local Controller issues a Write Frame on pipe x, the Remote Controller X is addressed. In case of a Write Frame on pipe y, the Remote Controller Y is targeted, passing through a Transfer Window of Remote Controller X. The two remaining pipes could be used for Write Frames issued by Remote Controller X (passing through a Transfer Window of Remote Controller Y) and by Remote Controller Y.

27.2.4 MLI Service Request Generation

The MLI module's service request outputs SRx are used to indicate module internal MLI events to other modules or devices outside the MLI module, depending on the device implementation. They can trigger interrupts of a CPU (if available), can be used as DMA request lines (if available), or for other trigger purposes. The MLI events being able to trigger interrupts or other service requests, names of some flags and control registers refer to interrupt generation.

MLI module events are generated by event sources in the transmitter and in the receiver. Each event source provides a status flag and an enable bit with software clear capability. In some cases, several event sources are combined to a common event. An MLI event, internally generated by an event source, is stored in a status flag that is located in the interrupt status registers TISR (for transmitter events) or RISR (for receiver events). All event flags can be cleared individually by software write actions to bits located in the interrupt enable registers TIER (for transmitter events) or RIER (for receiver events). These two registers also contain the enable control bits that allow each event source to be enabled/disabled individually for service request activation. Each event can be connected to exactly one of the eight service request outputs SR[7:0] by a 3-bit interrupt node pointer.

One additional register, the Global Interrupt Set Register GINTR, allows each service request output to be activated separately without setting the status flags of the event sources (see **Page 27-58**). This feature is sometimes helpful for software test purposes or to trigger MLI external actions.

Interrupt Registers

The MLI event sources are controlled by several registers (see **Table 27-6** and **Page 27-107**). The register name prefixes "T" and "R" indicate if a register is assigned to the MLI transmitter or to the MLI receiver.

Table 27-6 Interrupt Registers

Unit	Registers with		
	Request Flags	**Enable Bits/ Req. Flag Clear Bits**	**Node Pointer**
MLI Transmitter	TISR	TIER	TINPR
MLI Receiver	RISR	RIER	RINPR

Service Request Compressor

The MLI event logic uses a compressing scheme for flexible service request processing. Eleven MLI events (six transmitter events and four of the five receiver events) are directed via a 3-bit interrupt node pointer to one of the eight service request outputs

SR[7:0]. Each demultiplexer output selected by its Node Pointer = x (x = 0-7) is connected to one input of the SRx OR-Gate. This wiring scheme also supports the connection of more than one event source to an service request output SRx. One receiver event, the interrupt Command Frame event, has a special characteristic: its node pointer is controlled by the received CMD value directly and only SR[3:0] OR-Gates are selectable.

Figure 27-39 shows the service request compressing logic. For reasons of simplicity, not all MLI events, connections, and OR-Gates are explicitly shown. The OR-Gate inputs are connected to the demultiplexers of the MLI event specific lines. Furthermore, a service request output SRx can be triggered by software if the corresponding interrupt set bit in register GINTR is written with a 1.

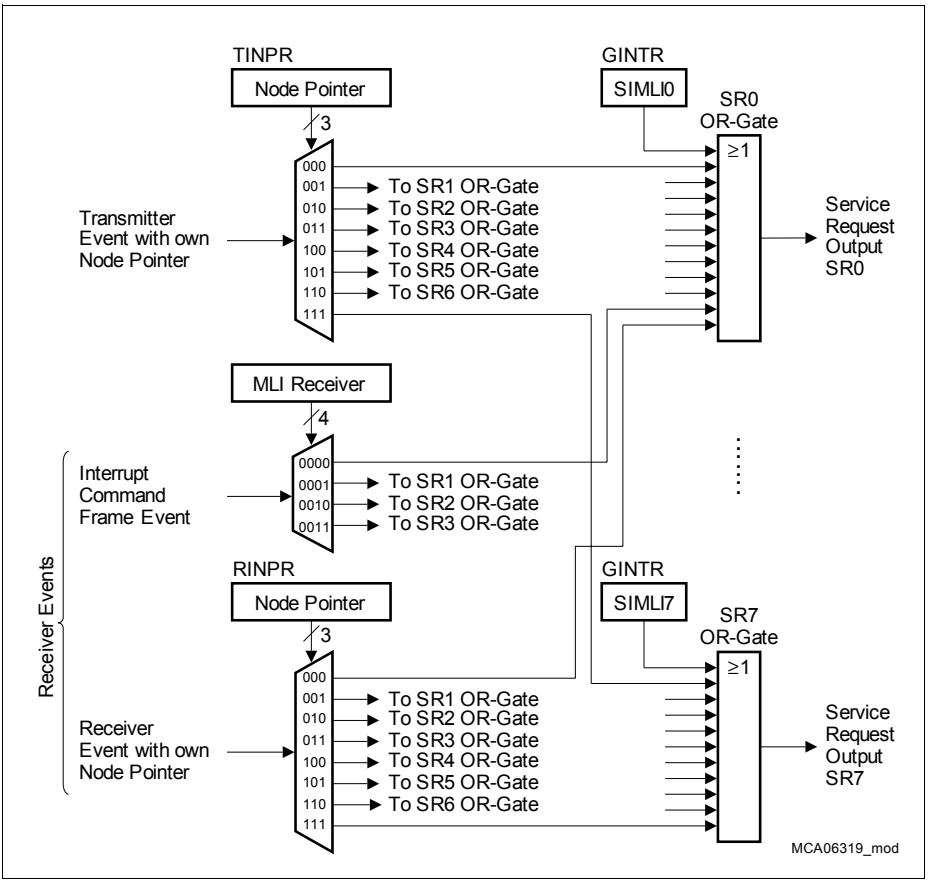

Figure 27-39 Service Request Compressor

Note: The number of SRx outputs of an MLI module and their connection to other modules depends on the implementation of the MLI module in the specific product.

27.2.5 Transmitter Events

The MLI transmitter can generate the following MLI events:

Table 27-7 MLI Transmitter Events

Events	Events combined to	See
Parity Error	Parity/Time-out Error	Page 27-60
Time-out Error		
Normal Frame Sent in Pipe 0	Normal Frame Sent in Pipe 0	Page 27-60
Normal Frame Sent in Pipe 1	Normal Frame Sent in Pipe 1	
Normal Frame Sent in Pipe 2	Normal Frame Sent in Pipe 2	
Normal Frame Sent in Pipe 3	Normal Frame Sent in Pipe 3	
Command Frame Sent in Pipe 0	Command Frame Sent	Page 27-61
Command Frame Sent in Pipe 1		
Command Frame Sent in Pipe 2		
Command Frame Sent in Pipe 3		

27.2.5.1 Parity/Time-out Error Event

A parity/time-out error event is generated when a programmable maximum number of parity errors or a programmable maximum number of Non-Acknowledge errors have been reached. Both events have separate status/control bits but are concatenated to one common error event.

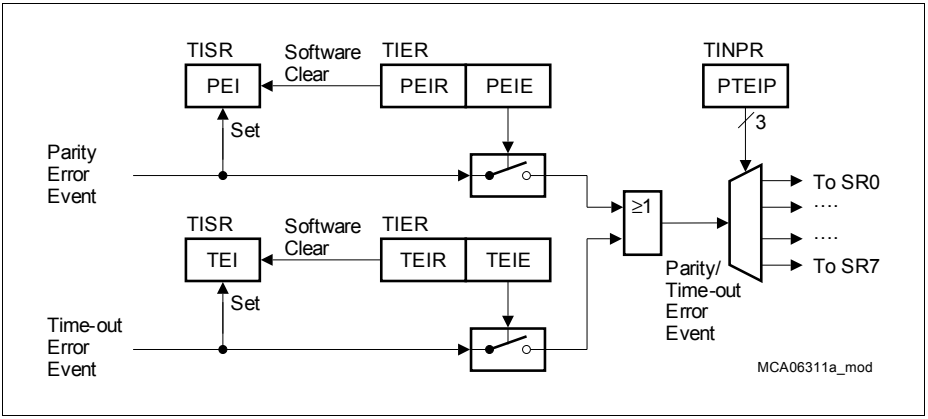

Figure 27-40 Parity/Time-out Error Event Logic

27.2.5.2 Normal Frame Sent x Event

A Normal Frame sent x (x = 0-3) event is generated when a Normal Frame has been sent and correctly received in pipe x.

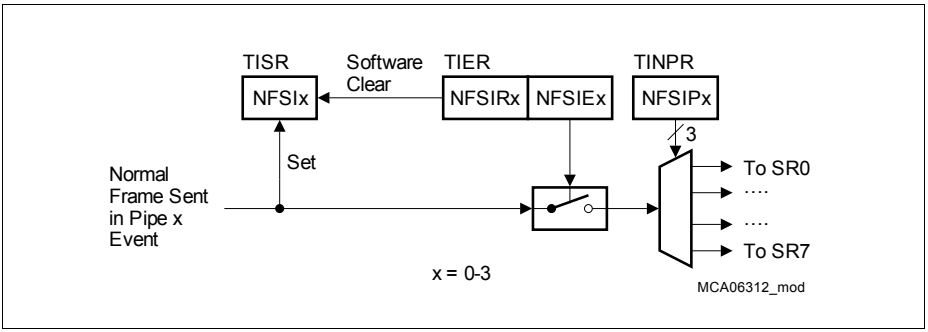

Figure 27-41 Normal Frame Sent x Event Logic

27.2.5.3 Command Frame Sent Events

A Command Frame sent event is generated when the MLI transmitter has sent a Command Frame through pipe x (x = 0-3) that has been correctly received. Separate status/control bits are assigned to each pipe. All four pipe related Command Frame sent events are concatenated to one common Command Frame sent event.

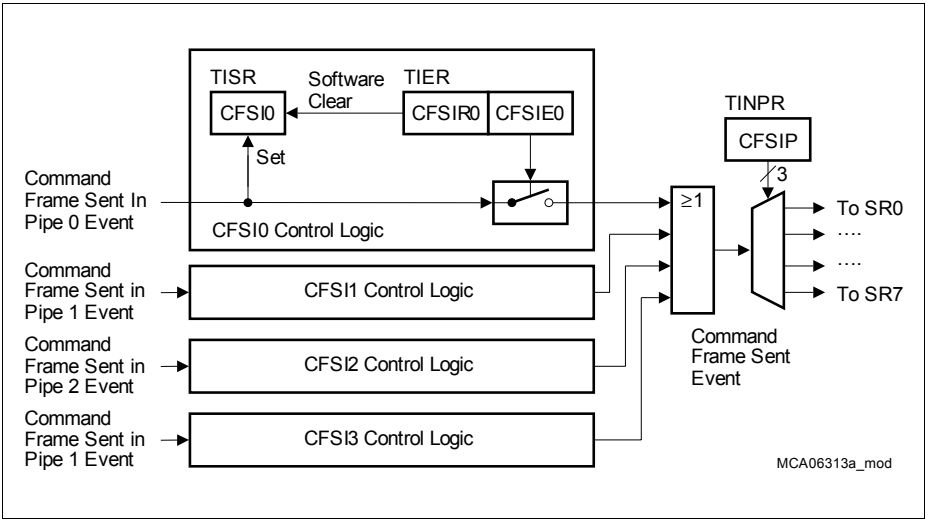

Figure 27-42 Command Frame Sent Event Logic

27.2.6 Receiver Events

The MLI receiver can generate the following MLI events:

Table 27-8 MLI Receiver Interrupts

Events	Events combined to	See
Discarded Read Answer	Discarded Read Answer	Page 27-62
Memory Access Protection Error	Memory Access Protection/ Parity Error	Page 27-63
Parity Error		
Normal Frame Correctly Received	Normal Frame Received	Page 27-64
Move Engine Access Terminated		
Interrupt Command Frame	Interrupt Command Frame	Page 27-65
Command Frame Received on Pipe 0	Command Frame Received	Page 27-66
Command Frame Received on Pipe 1		
Command Frame Received on Pipe 2		
Command Frame Received on Pipe 3		

27.2.6.1 Discarded Read Answer Event

A discarded read answer received event is generated if an Answer Frame has been received and the read pending flag TRSTATR.RPx of its correspondent pipe is 0. Although named “discarded”, the received data is available in the receiver data register until it is overwritten by the next incoming data.

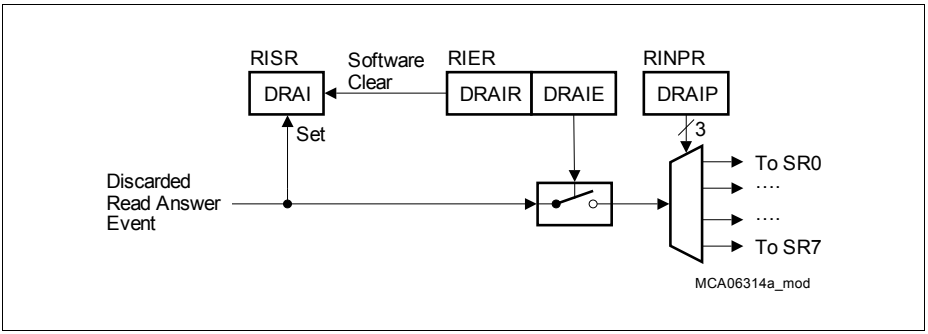

Figure 27-43 Discarded Read Answer Event Logic

27.2.6.2 Memory Access Protection/Parity Error Event

A memory access protection/parity error event is detected if a non allowed read or write access has been detected or if a programmable maximum number of receiver parity errors is reached. Both MLI events have separate status/control bits but are concatenated to one common error event.

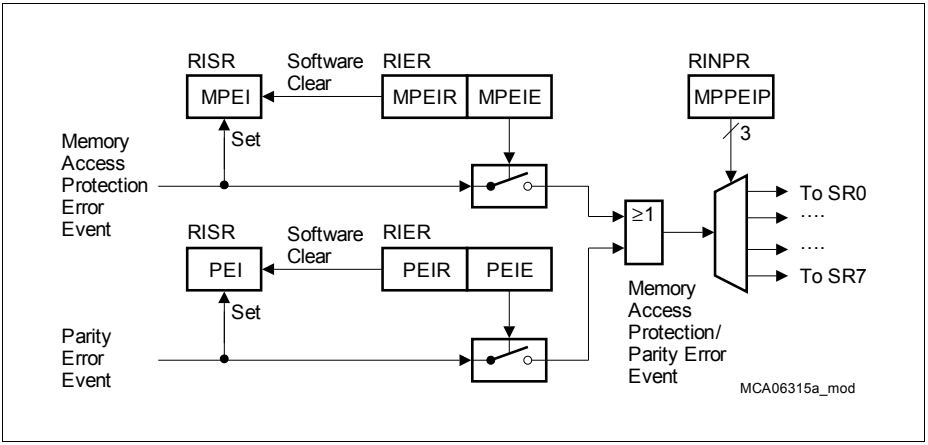

Figure 27-44 Memory Access Protection/Parity Error Event Logic

27.2.6.3 Normal Frame Received/Move Engine Terminated Event

A Normal Frame received event is generated if the MLI receiver has correctly received a Normal Frame (a Copy Base Address Frame, a Read or a Write Frame, an Answer Frame, but not a Command Frame) or if the move engine has terminated its read or write access. Both event sources have separate status/control bits but are concatenated to one common Normal Frame received event.

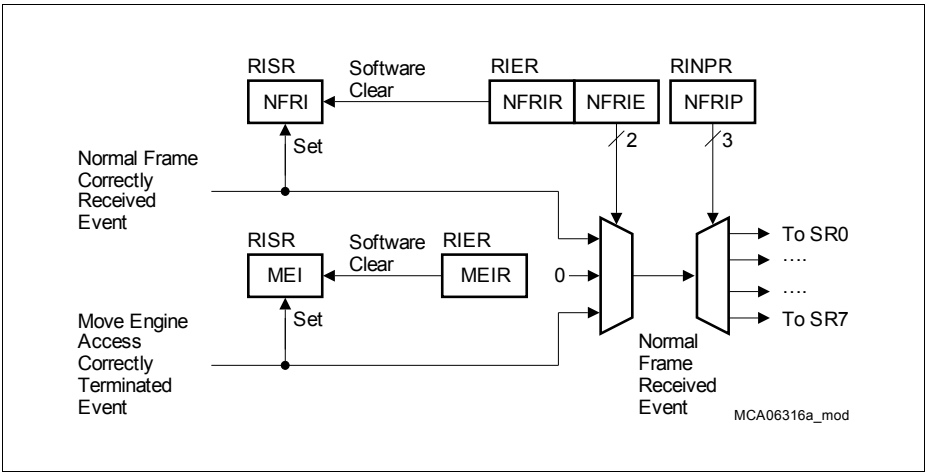

Figure 27-45 Normal Frame Received Event Logic

27.2.6.4 Interrupt Command Frame Event

An interrupt Command Frame event is generated if a Command Frame is received correctly on pipe 0 with a valid command code for service request output activation (CMD = 0000_B to 0011_B). The received command code determines which of the service request outputs SR[3:0] should be activated.

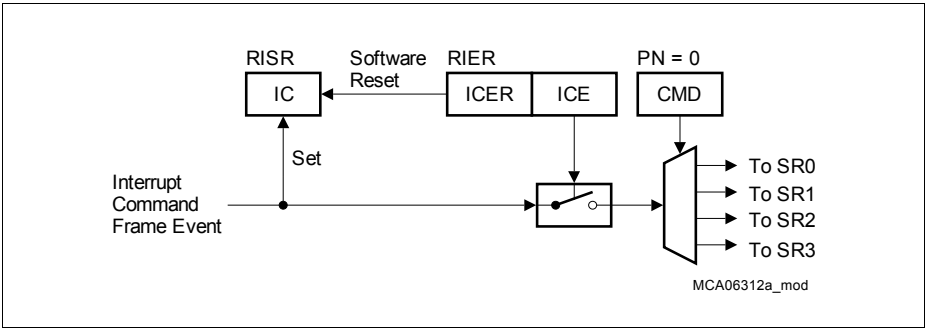

Figure 27-46 Interrupt Command Frame Event Logic

27.2.6.5 Command Frame Received Event

A Command Frame received event is generated if the MLI receiver has correctly received a Command Frame through Pipe Number x (x = 0-3). Separate status/control bits are assigned to each pipe. All four pipe related Command Frame received in pipe x events are concatenated to one common Command Frame received event.

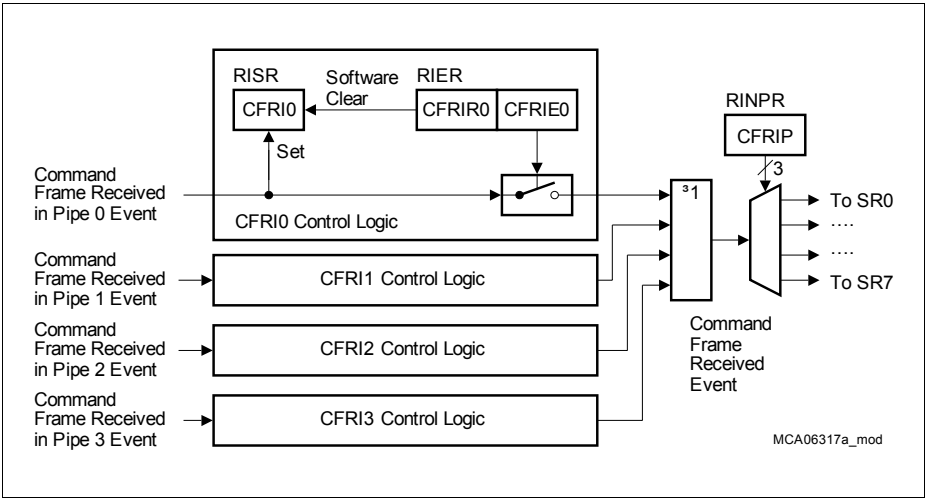

Figure 27-47 Command Frame Received Event Logic

27.2.7 Baud Rate Generation

The MLI transmitter baud rate is given by $f_{MLI}/2$. The MLI shift clock output signal TCLK of the transmitter toggles with each clock cycle of f_{MLI} in order to obtain a 50% duty cycle (the 50% duty cycle can vary up to one clock cycle of f_{FPI} in fractional divider mode). The MLI receiver automatically adapts to the incoming receive shift clock signal RCLK. The received baud rate is determined by the connected transmitter and has no direct relation to f_{FPI} except that it should not exceed f_{FPI}.
The frequency f_{MLI} is generated by the fractional divider FDIV.

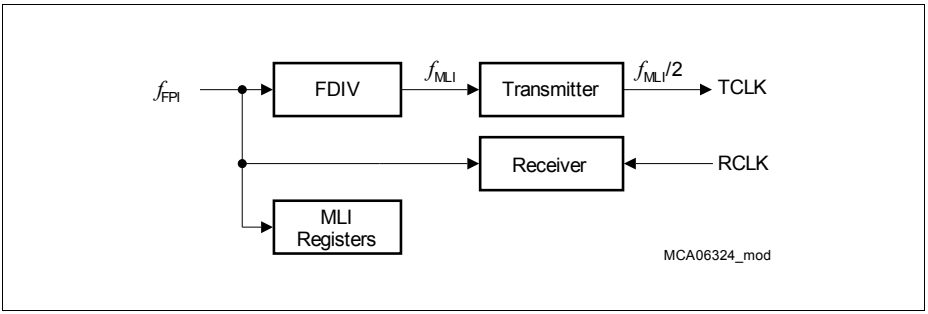

Figure 27-48 MLI Baud Rate Generation

Normal Divider Mode

In normal divider mode (FDR.DM = 01_B) the fractional divider behaves like a reload counter (addition of +1) that generates a clock f_{MLI} on the transition from $3FF_H$ to 000_H. FDR.RESULT represents the counter value and FDR.STEP defines the reload value. In order to achieve $f_{MLI} = f_{FPI}$, FDR.STEP must be programmed with $3FF_H$. The output frequency in normal divider mode is defined according the following equation:

$$f_{MLI} = f_{FPI} \times \frac{1}{1024 - FDR.STEP} \quad (27.1)$$

Fractional Divider Mode

If the fractional divider mode is selected (FDR.DM = 10_B), the clock f_{MLI} is derived from the input clock f_{FPI} by division of a fraction of STEP/1024 for any value of STEP from 0 to 1023. In general, the fractional divider mode allows to program the average clock frequency with a higher accuracy than in normal divider mode. In fractional divider mode a clock pulse f_{MLI} is generated depending on the result of the addition FDR.RESULT + FDR.STEP. The frequency f_{MLI} corresponds to the overflows over $3FF_H$. Note that in fractional divider mode the clock f_{MLI} can have a maximum period jitter of one f_{FPI} clock period. This jitter is not accumulated over several cycles and does not

exceed one cycle of f_{FPI}.
The frequency in fractional divider mode is defined according the following equation:

$$f_{MLI} = f_{FPI} \times \frac{STEP}{1024} \quad (27.2)$$

The baud rate of MLI transmissions equals f_{TCLK}, that is defined by the frequency of clock signal f_{MLI} divided by 2 to create the 50% duty cycle of the shift clock signal TCLK. The signal TCLK toggling with each period of f_{MLI}, a jitter due to fractional dividing is propagated to TCLK.

$$f_{TCLK} = \frac{f_{MLI}}{2} \quad (27.3)$$

27.2.8 Automatic Register Overwrite

The value of register OICR and bit RCR.RCVRST is overwritten by hardware in the next two clock cycles after a reset (first OICR, followed by RCR). The value applied during reset is given in the register description. This automatic overwrite allows adapting the module to different application requirements without changing the module itself. For example, during reset the receiver is set to a defined state and can be used afterwards for reception without the need to modify it by a write action (if the bit RCVRST is modified to 0).

The values applied after the overwrite can be identical to the indicated reset values. Please refer to the implementation chapter for the modified values (see).

27.3 Operating the MLI

Data transfer via MLI between a Local Controller and a Remote Controller is only possible if both are initialized correctly by following sequence of 4 steps. Steps 3 and 4 are necessary if the initialization sequence is exclusively controlled by the Local Controller. If both communication partners are able to run initialization software, steps 1 and 2 can be executed separately by both controllers to initialize both transmitters and both receivers.

1. The transmitter of the Local Controller has to be initialized by write actions to the transmitter registers.
2. The pipes from the Local Controller's transmitter to the Remote Controller's receiver and the Remote Controller's receiver have to be initialized.
3. The Remote Controller's transmitter has to be initialized by data write actions from the Local Controller via the Remote Controller's receiver to the Remote Controller's transmitter registers.
4. The pipes from the Remote Controller's transmitter back to the Local Controller's receiver and the Local Controller's receiver have to be initialized. This is done by frames from the Remote Controller's transmitter. These frames are the result of data write actions of the Local Controller to the Remote Controller's transmitter registers.

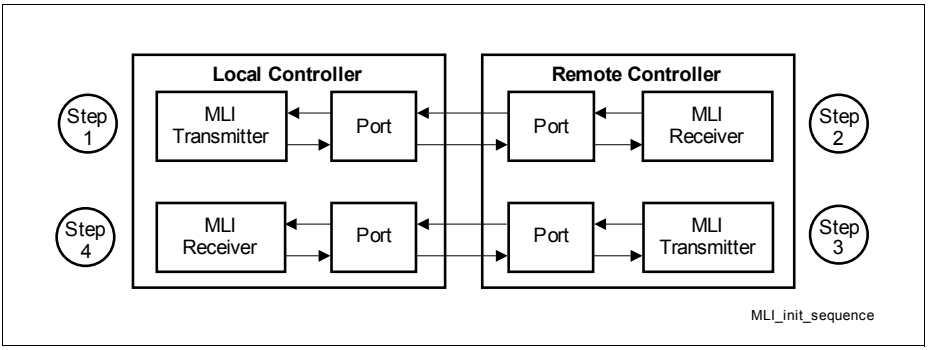

Figure 27-49 Initialization Sequence for an MLI Connection

To initialize and to operate the MLI, the following items should be taken into account:

- Connection setup (see **Page 27-70**)
- Local Controller transmitter and pipe setup (see **Page 27-71**)
- Remote Controller receiver setup (see **Page 27-71**)
- Remote Controller transmitter and Local Controller receiver setup (see **Page 27-72**)
- Delay adjustment (see **Page 27-73**)
- Connection to DMA mechanism (see **Page 27-75**)
- Connection of MLI to SPI (see **Page 27-75**)

27.3.1 Connection Setup

For the general setup of an MLI connection, several steps have to be respected.

- There is the possibility to change the signal routing to adapt to different applications. If another connection than the default one from an input/output vector of the MLI signals is desired, register OICR has to be programmed (see also **Section 27.2.8**).
- In some devices (mainly stand-alone peripheral devices without CPU, where the MLI module is a possible communication channel), the setting “A” can be modified by hardware to another setting (e.g. to setting “B”) during the boot phase. In this case, the initial setting “A” can correspond to an inactive setting (MLI not used for communication), whereas the setting “B” is used for MLI communication.
- In the case a memory access protection is implemented in the receiver and automatic handling of data is desired, the user has to enable the corresponding address range in registers AER and ARR. After a reset, in most microcontrollers, the access protection is generally disabled to avoid access to safety-critical data. Depending on the device, some specific address ranges can already be enabled for automatic access by default.
- In devices with explicit port control (such as microcontrollers), the port pins are generally set to input after a reset. In order to allow MLI communication, the MLI-related port pins have to be configured to make the MLI signals externally available and to adapt the driver setting (refer to port chapter).
  The MLI module should not be enabled for reception (RCR.RCVRST = 1) before programming the desired port setting, because changing the port setting can lead to unintended edges at the module inputs due to setting changes. If the MLI module is already enabled for reception, unintended edges are interpreted as communication signals, so the receiver might deliver wrong results. If this has happened unintentionally, the receiver can be reset by RCR.RCVRST=1.

27.3.2 Local Transmitter and Pipe Setup

The initialization of the transmitter of the Local Controller is done by writing to the transmitter registers. The Remote Controller's MLI receiver can then be initialized by the Local Controller's transmitter.

- After a hardware reset operation, the MLI transmitter is disabled (TCR.MOD = 0). In disabled mode, no frame transmission can take place. After writing TCR.MOD = 1, the transmitter is enabled to send frames.
- The desired transmitter baud rate can be adjusted by the fractional divider FDIV. It has to be ensured that the fractional divider is set to a value that is supported by the port structures of the Local and the Remote Controllers (rise/fall times) and the physical layer. For example, if a division by 1,5 is selected, the fractional divider will deliver count pulses for f_{MLI} with a sequence of 1-2-1-2-1-2- clock cycles of f_{FPI}. The shortest interval between two count pulses in a sequence (given by the truncated divider factor, so 1 cycle of in this example) has to be handled by the communicating devices.f_{FPI}
- Depending on the application requirements, a desired service request output SRx can be activated if a transmitter event is detected.
- The maximum delay for parity error detection in the transmitter has to be programmed. There are two possibilities to get the MLI communication started.
  First (easier) possibility is to write TCR.MDP to 14 and to set RCR.DPE to 15.
  The second possibility could be used to optimize the bandwidth of the MLI connection. It is described in **Section 27.3.5** on **Page 27-73**.

27.3.3 Remote Receiver Setup

The initialization of the Remote Controller's receiver is done by frames sent by the Local transmitter. Therefore, the Remote Controller's receiver has to be able to receive frames.

- In order to allow communication, the Remote Controller's MLI signals have to be connected to the Local Controller's transmitter signals (see register OICR and port settings).
- The Remote Controller's bit RCR.RCVRST has to be 0 to enable frame reception.
- The buffer area size and the base address of the Remote Window for pipe x are defined by the data written to registers TPxBAR. Bit TRSTATR.BAV has to be 0 before each write action to one of these registers. With this information, the buffer area sizes (defining the number of address bits in data frames or Read Frames) are known in the transmitter and in the receiver for each pipe.
  The base addresses for the Remote Windows have to be selected to cover the target address ranges in the Remote Controller. It is recommended to use the minimum buffer size required by the application in order to minimize the bandwidth taken by the transfer of the address bits. The base address of a Remote Window has to be set to a value aligned to its size, e.g. a Remote Window of 8 Kbytes must start at an 8 Kbyte address boundary.

- In devices with access protection mechanism against unauthorized accesses via MLI, the Remote Controller has to enable the desired address range(s) to support automatic mode. If automatic mode is not desired, the Remote Controller has to handle the complete data traffic by software.
- A possibility to test the setup in devices with the capability to run own test software is the local loop back (the transmitter is connected locally to the receiver of the same MLI module). In devices without this capability, the module loop back can be hardly used (or it is even not implemented, refer the connection table in the implementation chapter).
  If implemented, for local loop back, the signal connections have to be programmed to setting “D”, leading to the local receiver being connected directly to the local transmitter (without using a port structure). In this case, the local receiver seems to be the remote receiver. Data written to a local Transfer Window are received and handled by the local receiver. Test software in the Local Controller can check for correct setup, data consistency, MLI event handling, and correct address handling in the Local Controller.
- If automatic data handling is desired (necessary for devices without the capability to handle data traffic by its CPU), the Automatic Data Mode has to be enabled by sending a Command Frame in pipe 2 with CM = 0001_B to set RCR.MOD = 1 in the Remote Controller.

27.3.4 Remote Transmitter and Local Receiver Setup

The initialization of the Remote Controller’s transmitter and the Local Controller’s receiver can be done by data frames sent by the local transmitter. Therefore, the Remote Controller’s receiver has to be able to receive frames (the port structure has to be set up accordingly).

- The Remote Window of pipe x (x can be freely chosen) has to be set to the MLI register address range in the Remote Controller. The initialization by data frames is then done via pipe x.
- The automatic mode has to be enabled in the Remote Controller (Command Frame in pipe 2 with CM = 0001_B).
- The connections between the remote transmitter and the local receiver have to be established (if not already done by the default setting), similar to **Section 27.3.2**.
- The remote transmitter has to be enabled, similar procedure as for the local transmitter. The data word to be written to the Remote Controller’s MLI registers have to be written to the corresponding address in the local Transfer Window of pipe x.
- The local receiver can then be configured by writing the appropriate data (similar scenario as for the remote receiver) to the local Transfer Window of pipe x.
- A possibility to test the complete setup is the remote loop back. In this case another Remote Window is overlaid directly to a Transfer Window in the Remote Controller. Writing data to the corresponding Transfer Window in the Local Controller leads to a data frame sent to the Remote Controller. There, the received data is written to the

Transfer Window and a new data frame is sent back to the Local Controller. The MLI move engine in the Local Controller's receiver can be used to write the received data to a defined location, e.g. to a memory location. Test software in the Local Controller can check for correct setup, data consistency, MLI event handling, and correct address handling in the Local and the Remote Controllers.

27.3.5 Delay Adjustment

The local MLI transmitter is measuring the number of TCLK clock cycles between TVALID becoming 0 after a transmission and TREADY becoming 1 again. This time represents the overall loop delay of the MLI connection. The loop delay is the time used for signal propagation, input/output driver delay and remote receiver reaction. For example, with slow drivers and a high load (due to long wires, etc.), the signals take a longer time to propagate from the local transmitter to the remote receiver and back again (READY-VALID control handshake). This delay (also visible when TVALID becomes 1 at the beginning of a frame) limits the maximum baud rate of an MLI connection, because the answer of the receiver has to be detected by the transmitter with TREADY = 0 at the end of the frame. The value measured after the end of the frame is indicated in bit field TSTATR.RDC.

The receiver participates in the control handshake by changing its RREADY output as a reaction to an incoming RVALID signal. For the transmitter, the TREADY input delivers the information that a receiver is connected and that it is ready for reception (transfer only starts if TREADY = 1). If a receiver is not able to handle the data or is not connected, the TREADY line will not become low after TVALID becomes 1 (Non-Acknowledge).

In addition to this information, the MLI protocol offers the possibility to use the control handshake also to indicate that the receiver has detected a parity error in the received frame. If a correct frame has been received, the receiver immediately asserts RREADY = 1 after the reception of a frame when detecting RVALID = 0. If the receiver has detected a parity error, it waits for a programmable number of RCLK cycles before setting RREADY = 1 again. This additional delay is defined by bit field RCR.DPE.

The transmitter measuring the delay and comparing it to a programmed value, it can detect that the receiver has signaled a parity error by introducing the additional delay. The compare value for the transmitter is programmed by bit field TCR.MDP. A measured value of TSTATR.RDC above TCR.MDP is interpreted as parity error by the transmitter (for parity error handling refer to **Page 27-44**).

In the receiver, frames with parity error are ignored for data transfers and don't lead to internal move actions.

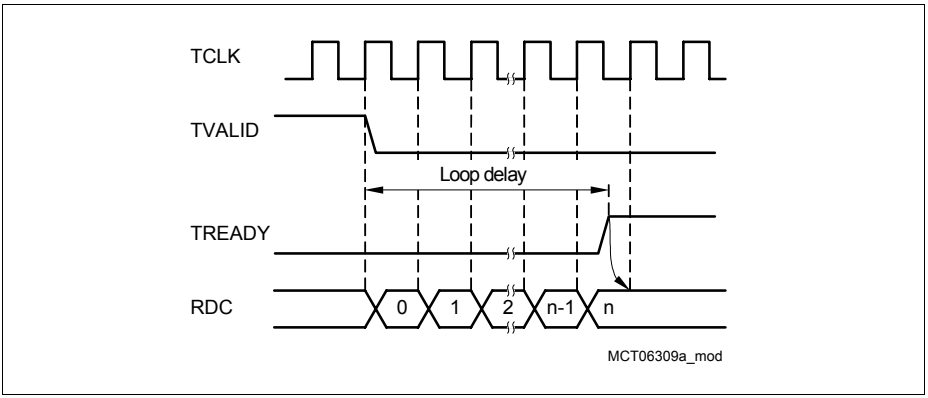

Figure 27-50 Loop Delay Measurement

To adjust the generated parity delay in the local transmitter and in the remote receiver, the following steps are necessary:

- Send a dummy frame to the receiver for measuring the loop delay. This frame should not lead to internal data move actions in the receiver, so a parity error can be simulated in the transmitter. The receiver has a fixed even parity scheme, whereas the transmitter can be programmed either for even or for odd parity. Programming odd parity before sending a frame will generate a (dummy) frame that will be discarded by the receiver (assuming a correct transfer). For a dummy frame, it is recommended to use a data frame with disabled Automatic Data Mode in the receiver (RCR.MOD = 0).
- The receiver delay RCR.DPE being 0 after a module reset, the transmitter can measure the loop delay and the receiver discards the frame (without modification of DPE, there is no difference in time between a frame with or without a parity error having been detected). The value given by TSTATR.RDC indicates how many TCLK cycles are necessary for a control handshake. This value should be incremented by a value DELTA (value see below) and written to TCR.MDP.
- The transmitter parity has to be programmed to even parity to be able to generate frames that are not discarded by the receiver.
- Programming the receiver delay for parity error (RCR.DPE) to a value bigger than DELTA will lead to a value of TSTATR.RDC bigger than TCR.MDP if the receiver detects a parity error. The value of DPE in the remote receiver is modified by the local transmitter by sending a Command Frame in pipe 1 with the desired value. The difference between TSTATR.RDC and TCR.MDP allows a certain timing tolerance between local transmitter and remote receiver.
- The value of DELTA depends on the possible variations of the propagation characteristics of the MLI connection. If the environment does not significantly change, DELTA can be 1. For systems with variations, DELTA could be bigger. The

user can check about changing propagation characteristics by reading TSTATR.RDC from time to time and to check if it is constant for correct transfers. If it changes, either a bigger DELTA value can be applied, or the delay adjustment can be repeated, adapting to the new circumstances.

27.3.6 Connection to DMA Mechanism

The MLI module supports the connection to a DMA (direct memory access) mechanism. This mechanism allows the transfer of blocks of data of programmable size via an MLI connection without CPU intervention. Therefore, a DMA mechanism can be used in the Local Controller to write the desired number of data words one after the other to the corresponding MLI Transfer Window. The address ranges of the data blocks and their length has to be handled by the DMA module.

An MLI pipe supporting only one pending Write Frame request at a time, the DMA has to wait until the pipe is capable to handle new data before writing another data word to the Transfer Window. Therefore, the Normal Frame sent events of the pipes can trigger DMA data transfers. Depending on the connection of the MLI module's service request outputs SRx to the DMA trigger inputs, the Normal Frame sent events have to be enabled for service request activation and directed to the desired SRx outputs. It is recommended to use only one type of MLI event per SRx output to trigger a data transfer by DMA. If the DMA mechanism needs a start trigger for the first data word transfer, register GINTR can be written with the appropriate pattern to activate an SRx output.

27.3.7 Connection of MLI to SPI

The handshake signals between a transmitter and a receiver are based on a synchronous transfer protocol. In the SPI protocol, the shift clock and the data signal are equivalent to CLK and DATA. In case of an 4-wire SPI, the slave select signal represents the VALID signal (the leading and the trailing delay have to be set up accordingly).

Contrary to the MLI, in the SPI protocol, a complete control handshake is not defined, so the READY signal does not exist in SPI modules. As a result, the SPI communication does not check by hardware for correct data transfer, but has to handle this on an upper software layer. If using an SPI module for communication with an MLI transmitter or an MLI receiver, the READY signal has to be handled by software or the handshake has to be given up. This can be done by connecting the TVALID signal of an MLI transmitter to one of its own TREADY inputs with polarity inversion. Like this, the TREADY input directly following the inverted TVALID signal, the parity error indication and the Non-Acknowledge error detection are not possible.

Furthermore, in the MLI protocol, the frames may have a different width, depending on their type and selected buffer size. The different numbers of data bits per frame have also to be handled by the SPI module. In order to minimize the number of different frames, it is recommended to restrict the possibility to program different buffer sizes, the use of Read Frames or Command Frames. In order to simplify the data handling by an

SPI module, the parity generation could be skipped for frames received by the SPI module and an error detection mechanism on an upper software layer could be implemented. For frames sent by an SPI module, the parity bit has to be calculated and sent correctly. Otherwise, the MLI receiver will discard the received frame.

27.4 MLI Kernel Registers

This section describes the kernel registers of the MLI module. All registers can be accessed with 8-bit, 16-bit or 32-bit write or read operations. Accesses to address locations inside the MLI address range not targeting the indicated registers are not allowed. The complete and detailed address map of the of the MLI module and its registers is described in **Table 27-14** on **Page 27-139**.

All registers in the MLI address spaces are reset with the application reset.

Module Base Address (Table 27-9) + Offset Address (shown in this column)

27.4.1 General Module Registers

Fractional Divider Register

The fractional divider register allows to program the frequency f_{MLI} to generate the baud rate of the of the 50% duty cycle transmitter shift clock TCLK.

FDR
Fractional Divider Register **($0C_H$)** **Reset Value: $03FF\ 43FF_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DISCLK	ENHW	SUSREQ	SUSACK	0		RESULT									
rwh	rw	rh	rh	r		rh									

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DM		SC		SM	0	STEP									
rw		rw		rw	r	rw									

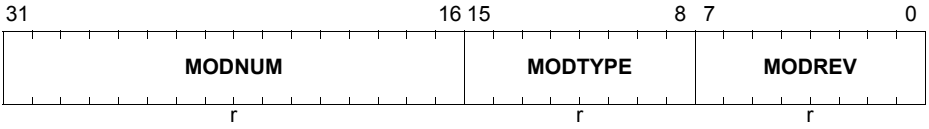
Field	Bits	Type	Description
STEP	[9:0]	rw	**Step Value** In normal divider mode STEP contains the reload value for RESULT. In fractional divider mode this bit field defines the 10-bit value that is added to the RESULT with each input clock cycle.
SM	11	rw	**Suspend Mode** SM selects between granted or immediate suspend mode. This bit is only taken into account in devices supporting suspend mode. 0_B Granted suspend mode selected 1_B Immediate suspend mode selected
SC	[13:12]	rw	**Suspend Control** This bit field defines the behavior of the fractional divider in suspend mode (bit SUSREQ and SUSACK set). This bit field is only taken into account in devices supporting suspend mode. 01_B Clock generation is stopped and the clock output signals are not generated. RESULT is not changed except when writing bit field DM with 01_B or 10_B. 00_B Clock generation continues. 10_B Clock generation is stopped and the clock output signals are not generated. RESULT is loaded with $3FF_H$. 11_B Same as SC = 10_B but RST_EXT_DIV is 1 (independently of bit field DM).
DM	[15:14]	rw	**Divider Mode** This bit fields defines the functionality of the fractional divider block. 00_B Fractional divider is switched off; no output clock is generated. RST_EXT_DIV is 1. RESULT is not updated (default after reset). 01_B Normal divider mode selected. 10_B Fractional divider mode selected. 11_B Fractional divider is switched off; no output clock is generated. RESULT is not updated.

Field	Bits	Type	Description
RESULT	[25:16]	rh	**Result Value** In normal divider mode RESULT acts as reload counter (addition +1). In fractional divider mode this bit field contains the result of the addition RESULT+STEP. If DM is written with 01_B or 10_B, RESULT is loaded with $3FF_H$.
SUSACK	28	rh	**Suspend Mode Acknowledge** 0_B Suspend mode is not acknowledged. 1_B Suspend mode is acknowledged. Suspend mode is entered when SUSACK and SUSREQ are set.
SUSREQ	29	rh	**Suspend Mode Request** 0_B Suspend mode is not requested. 1_B Suspend mode is requested. Suspend mode is entered when SUSACK and SUSREQ are set.
ENHW	30	rw	**Enable Hardware Clock Control** 0_B Bit DISCLK cannot be cleared by hardware by a high level at input signal ECEN. 1_B Bit DISCLK is cleared by hardware while input signal ECEN is at high level.
DISCLK	31	rwh	**Disable Clock** 0_B Clock generation of $f_{OUT} = f_{MLI}$ is enabled according to the setting of bit field DM. 1_B Fractional divider is stopped. Signal $f_{OUT} = f_{MLI}$ becomes inactive. No change except when writing bit field DM. In case of a conflict between hardware reset and software set of DISCLK, the software set wins. Any write or read-modify-write action leads to the described behavior. As a result read-modify-write operations should be avoided.
0	10, [27:26]	r	**Reserved** Read as 0; should be written with 0.

Module Identification Register

The MLI Module Identification Register ID contains read-only information about the module version.

ID
Module Identification Register **(08_H)** **Reset Value: 0025 C0XX$_H$**



Field	Bits	Type	Description
MODREV	[7:0]	r	**Module Revision Number** This bit field defines the module revision number. The value of a module revision starts with 01_H (first revision).
MODTYPE	[15:8]	r	**Module Type** This bit field defines the module as a 32-bit module: $C0_H$
MODNUM	[31:16]	r	**Module Number Value** This bit field defines the module identification number for the MLI: 0025_H

27.4.2 General Status/Control Registers

Global Interrupt Set Register

The Global Interrupt Set Register GINTR is a write only register (always reads 0) that allows each of the service request outputs SRx to be activated under software control (see **Page 27-58**).

GINTR
Global Interrupt Set Register **($B0_H$)** **Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0								SI MLI7	SI MLI6	SI MLI5	SI MLI4	SI MLI3	SI MLI2	SI MLI1	SI MLI0
r								w	w	w	w	w	w	w	w

Field	Bits	Type	Description
SIMLIx (x = 0-7)	x	w	**Set MLI Service Request Output Line x** 0_B No action 1_B Service request output SRx is activated (pulse).
0	[31:8]	r	**Reserved** Read as 0; should be written with 0.

Set Clear Register

The Set Clear Register SCR is a write only register that makes it possible to set or clear by software several status flags located in registers TSTATR, TRSTATR and RCR. Reading register SCR always returns zeros at all bit locations. Bits that are not written with a 1 have no effect.

SCR
Set Clear Register **(94_H)** **Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Bits	Type	Description
SCV0, **SCV1,** **SCV2,** **SCV3**	0, 1, 2, 3	w	**Set Command Valid** 0_B No effect 1_B Bit TRSTATR.CVx is set.
SMOD	4	w	**Set MOD Flag** 0_B No effect 1_B If CMOD = 0, RCR is set. If CMOD = 1, RCR.MOD is cleared.
CDV0, **CDV1,** **CDV2,** **CDV3**	8, 9, 10, 11	w	**Clear Data Valid x Flag** 0_B No effect 1_B Bits TRSTATR.DVx and TRSTATR.RPx are cleared.
CCV0, **CCV1,** **CCV2,** **CCV3**	12, 13, 14, 15	w	**Clear Command Valid x Flag** 0_B No effect. 1_B If SCVx = 0, bit TRSTATR.CVx is cleared. If SCVx = 1, bit TRSTATR.CVx is set.
CMOD	16	w	**Clear MOD Flag** 0_B No effect. 1_B Bit RCR.MOD is cleared.

Field	Bits	Type	Description
CBAV	17	w	**Clear BAV Flag** 0_B No effect. 1_B Bit TRSTATR.BAV is cleared.
CAV	24	w	**Clear AV Flag** 0_B No effect. 1_B Bit TRSTATR.AV is cleared.
CRPE	25	w	**Clear Receiver PE Flag** 0_B No effect. 1_B Bit RCR.PE is cleared.
CTPE	26	w	**Clear Transmitter PE Flag** 0_B No effect. 1_B Bit TSTATR.PE is cleared.
CNAE	27	w	**Clear NAE Flag** 0_B No effect. 1_B Bit TSTATR.NAE is cleared.
CCIV0, **CCIV1,** **CCIV2,** **CCIV3**	28, 29, 30, 31	w	**Clear Command Interrupt Valid x Flag** 0_B No effect. 1_B Bit TSTATR.CIVx is cleared.
0	[7:5], [23:18]	w	**Reserved** Read as 0; should be written with 0.

Output Input Control Register

The Output Input Control Register OICR determines the functionality of the MLI transmitter and MLI receiver I/O control logic. The bits in this register are automatically overwritten after a reset with a value given in the implementation chapter (see). Furthermore, the connection table of the MLI module signals is given there.

Note: The value of register OICR should not be modified while a data transfer (reception or transmission) is ongoing (bits in OICR directly control the I/O signal paths).

OICR
Output Input Control Register ($B4_H$) Reset Value: 1000 8000$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Bits	Type	Description
TVEA, TVEB, TVEC, TVED	0, 1, 2, 3	rw	**Transmitter Valid Enable** These bits enable the module kernel output signals TVALIDx (x = A, B, C, D) to be driven by MLI transmitter output signal TVALID. 0_B TVALIDx is disabled and remains at passive level (as selected by TVPx). 1_B Transmitter output signal TVALIDx is enabled and driven by TVALID.
TVPA, TVPB, TVPC, TVPD	4, 5, 6, 7	rw	**Transmitter Valid Polarity** These bits determine the polarity of the module kernel transmitter output signals TVALIDx (x = A, B, C, D). 0_B Non-inverted polarity for TVALIDx selected: TVALIDx is passive when driving a 0. TVALIDx is active when driving a 1. 1_B Inverted polarity for TVALIDx selected: TVALIDx is passive when driving a 1. TVALIDx is active when driving a 0.

Field	Bits	Type	Description
TRS	[9:8]	rw	**Transmitter Ready Selection** This bit field determines the module kernel input signal TREADYx (x = A, B, C, D) that is used as MLI transmitter input signal TREADY. 00_B TREADYA is selected. 01_B TREADYB is selected. 10_B TREADYC is selected. 11_B TREADYD is selected.
TRP	10	rw	**Transmitter Ready Polarity** This bit determines the polarity of TREADYx. 0_B Non-inverted polarity for TREADYx selected: TREADYx is passive if 0. TREADYx is active if 1. 1_B Inverted polarity for TREADYx selected: TREADYx is passive if 1. TREADY is active if 0.
TRE	11	rw	**Transmitter Ready Enable** This bit enables the MLI transmitter input signal TREADY. 0_B TREADY signal is disabled (always at 0 level). 1_B TREADY signal is enabled and driven by TREADYx according to the settings of TRS and TRP.
TCE	12	rw	**Transmitter Clock Enable** This bit enables the module kernel output signal TCLK. 0_B TCLK is disabled and remains at passive level (as selected by TCP). 1_B TCLK is enabled and driven according to the setting of TCP.
TCP	13	rw	**Transmitter Clock Polarity** This bit determines the polarity of the module kernel output clock signal TCLK. 0_B Non-inverted polarity for TCLK selected: TCLK is driving a 0 when it is passive. 1_B Inverted polarity for TCLK selected: TCLK is driving a 1 when it is passive.

Field	Bits	Type	Description
TDP	14	rw	**Transmitter Data Polarity** This bit determines the polarity of the module kernel output clock signal TDATA. 0_B TDATA is directly driven by MLI transmitter output signal TDATA (non-inverted). 1_B TDATA is directly driven by the inverted MLI transmitter output signal TDATA.
RVE	15	rw	**Receiver Valid Enable** This bit enables the MLI receiver input signal RVALID. 0_B RVALID signal is disabled (always at 0 level). 1_B RVALID signal is enabled and driven by RVALIDx according to the settings of RVS and RVP (default after reset).
RRS	[17:16]	rw	**Receiver Ready Selector** This bit field determines the module kernel output signal RREADYx (x = A, B, C, D) that is driven by the MLI receiver output signal RREADY. The RREADYx output signals that are not selected drives a passive level according to the setting of RRPx. 00_B RREADYA is selected. 01_B RREADYB is selected. 10_B RREADYC is selected. 11_B RREADYD is selected.
RRPA, RRPB, RRPC, RRPD	18, 19, 20, 21	rw	**Receiver Ready Polarity** These bits determine the polarity of the module kernel receiver output signals RREADYx (x = A, B, C, D). 0_B Non-inverted polarity for RREADYx selected: RREADYx is passive if 0. RREADYx is active if 1. 1_B Inverted polarity for RREADYx selected: RREADYx is passive if 1. RREADYx is active if 0.
RVS	[23:22]	rw	**Receiver Valid Selector** This bit field determines the module kernel input signal RVALIDx (x = A, B, C, D) that is used as MLI receiver input signal RVALID. 00_B RVALIDA is selected. 01_B RVALIDB is selected. 10_B RVALIDC is selected. 11_B RVALIDD is selected.

Field	Bits	Type	Description
RVP	24	rw	**Receiver Valid Polarity** This bit determines the polarity of RVALIDx. 0_B Non-inverted polarity for RVALIDx selected: RVALIDx is passive if 0. RVALIDx is active if 1. 1_B Inverted polarity for RVALIDx selected: RVALIDx is passive if 1. RVALIDx is active if 0.
RCS	[26:25]	rw	**Receiver Clock Selector** This bit field determines the module kernel input signal RCLKx (x = A, B, C, D) that is used as MLI receiver input clock CLK. 00_B RCLKA is selected. 01_B RCLKB is selected. 10_B RCLKC is selected. 11_B RCLKD is selected.
RCP	27	rw	**Receiver Clock Polarity** This bit determines the polarity of RCLKx. 0_B Non-inverted polarity for RCLKx selected: RCLKx is at 0 level in passive state. 1_B Inverted polarity for TCLK selected: RCLKx is at 1 level in passive state.
RCE	28	rw	**Receiver Clock Enable** This bit enables the MLI receiver input clock RCLK. 0_B RCLK signal is disabled (always at 0 level). 1_B RCLK signal is enabled and driven by RCLKx according to the settings of RCS and RCP.
RDS	[30:29]	rw	**Receiver Data Selector** This bit field determines the module kernel input signal RDATAx (x = A, B, C, D) that is used as MLI receiver data input line RDATA. 00_B RDATAA is selected. 01_B RDATAB is selected. 10_B RDATAC is selected. 11_B RDATAD is selected.
RDP	31	rw	**Receiver Data Polarity** This bit determines the polarity of RDATAx. 0_B Non-inverted polarity for RDATAx selected: RDATAx is passive if 0. RDATAx is active if 1. 1_B Inverted polarity for RDATAx selected: RDATAx is passive if 1. RDATAx is active if 0.

27.4.3 Access Protection Registers

Access Enable Register

The Access Enable Register AER enables write and read operations in the corresponding address ranges (x = 0 to 31) in addition to the global move engine enable RCR.MOD. Each address range can be individually enabled or excluded from automatic mode.

Note: Please refer to the implementation chapter for the device specific access protection (see ***Page 27-137****).*

AER0
Access Enable Register 0 **($B8_H$)** **Reset Value: 0000 0000$_H$**
AER1
Access Enable Register 1 **($C0_H$)** **Reset Value: 0000 0000$_H$**

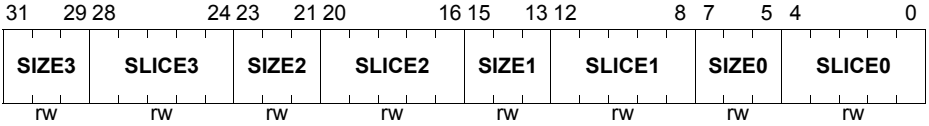
Field	Bits	Type	Description
AENx (x = 0-31)	x	rw	**Address Range x Enable** This bit enables the read and write capability of the MLI move engine for address range x (x = 0-31). 0_B Automatic MLI read and write moves to address range x are disabled. Read/write moves to address range x are not executed automatically and an MLI service request can be generated. The receiving controller's software has to take care about the move. 1_B Automatic MLI read and write moves to address range x are enabled if RCR.MOD = 1.

Access Range Register

The Access Range Register ARR determines size and number of the address sub-range n (n = 0-3).

ARR0
Access Range Register 0 **(BC_H)** **Reset Value: 0000 0000$_H$**
ARR1
Access Range Register 1 **($C4_H$)** **Reset Value: 0000 0000$_H$**



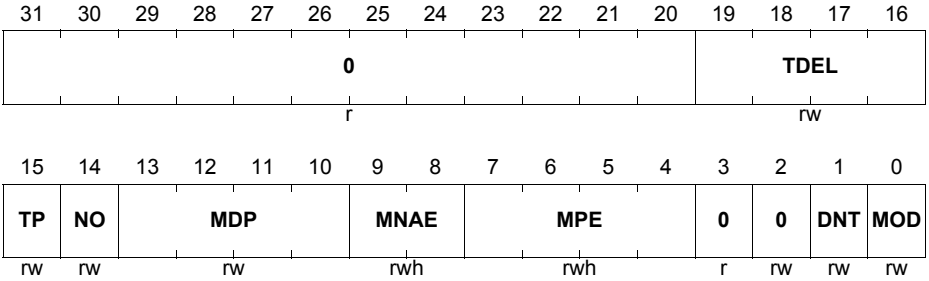
Field	Bits	Type	Description
SLICE0	[4:0]	rw	**Address Slice 0** SLICE0 selects a specific sub-range within address sub-range 0.
SIZE0	[7:5]	rw	**Address Size 0** SIZE0 determines the sub-range size within address sub-range 0.
SLICE1	[12:8]	rw	**Address Slice 1** SLICE1 selects a specific sub-range within address sub-range 1.
SIZE1	[15:13]	rw	**Address Size 1** SIZE1 determines the sub-range size within address sub-range 1.
SLICE2	[20:16]	rw	**Address Slice 2** SLICE2 selects a specific sub-range within address sub-range 2.
SIZE2	[23:21]	rw	**Address Size 2** SIZE2 determines the sub-range size within address sub-range 2.
SLICE3	[28:24]	rw	**Address Slice 3** SLICE3 selects a specific sub-range within address sub-range 3.
SIZE3	[31:29]	rw	**Address Size 3** SIZE3 determines the sub-range size within address sub-range 3.

27.4.4 Transmitter Control/Status Registers

Transmitter Control Register

The Transmitter Control Register TCR includes transmitter related control bits and bit fields that are used for parity/acknowledge, address optimization, TDATA idle polarity, retry, and transmitter enable/disable control.

TCR
Transmitter Control Register (10$_H$) Reset Value: 0000 0110$_H$



Field	Bits	Type	Description
MOD	0	rw	**Mode of Operation** This bit enables the MLI transmitter. 0_B The MLI transmitter is disabled. 1_B The MLI transmitter is enabled.
DNT	1	rw	**Data in Not Transmission** This bit determines the level of the transmitter data line TDATA when no transmission is in progress. 0_B TDATA is at low level if no transmission is running. 1_B TDATA is at high level if no transmission is running.
0	2	rw	**Reserved** Read as 0; should be written with 0.

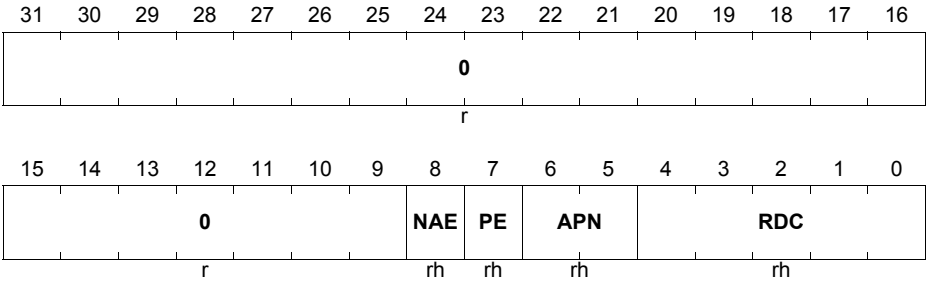
Field	Bits	Type	Description
MPE	[7:4]	rwh	**Maximum Parity Errors** This bit field determines the maximum number of transmitter parity error conditions that can be still detected until a transmitter parity error event is generated (see **Page 27-44**). With each condition detected, MPE is decremented down to 0. 0000_B A parity error event is generated if a transmitter parity error condition is detected. 0001_B A parity error event is generated if a transmitter parity error condition is detected. 0010_B A parity error event is generated if 2 transmitter parity error conditions are detected. 0011_B A parity error event is generated if 3 transmitter parity error conditions are detected. $\ldots_B$ … 1110_B A parity error event is generated if 14 transmitter parity error conditions are detected. 1111_B A parity error event is generated if 15 transmitter parity error conditions are detected.
MNAE	[9:8]	rwh	**Maximum Non Acknowledge Errors** This bit field determines the maximum number of consecutive Non-Acknowledge error conditions that can be still detected in the transmitter until a time-out event is generated. MNAE is decremented down to 0 at each Non-Acknowledge error condition. When MNAE = 0 or becoming 0, a time-out event is generated. MNAE is automatically set to 11_B after a successful frame transmission (see **Page 27-47**). 00_B A time-out event is generated if a non-ack condition is detected. 01_B A time-out event is generated if a non-ack condition is detected. 10_B A time-out event is generated if 2 consecutive non-ack conditions are detected. 11_B A time-out event is generated if 3 consecutive non-ack conditions are detected.

Field	Bits	Type	Description
MDP	[13:10]	rw	**Maximum Delay for Parity Error** This bit field determines a window for the transmitter in number of TCLK clock periods where a TREADY low-to-high signal transition signal is considered as “correctly received” condition (see **Page 27-22**). 0000_B Zero clock periods selected (not useful) 0001_B 1 clock period selected $\cdots_B$ … 1110_B 14 clock periods selected 1111_B 15 clock periods selected
NO	14	rw	**No Optimized Method** This bit field enables/disables the address prediction for read or Write Frames (see **Page 27-47**). 0_B Optimized method (address prediction) enabled. 1_B Optimized method (address prediction) disabled.
TP	15	rw	**Type of Parity** This bit will determines the type of parity used in frame transmissions. For correct data transfers, TP = 0 has to be programmed. The value TP = 1 can be selected to force parity errors to analyze the propagation delay (see **Page 27-26**). 0_B Even parity is selected. 1_B Odd parity selected.
TDEL	[19:16]	rw	**Transmission Delay** This bit field defines a delay in cycles of f_{FPI} of the transmitter between the reception of the rising edge of RREADY and the next possible frame start (see **Page 27-50**). 0000_B No transmission delay selected 0001_B One f_{FPI} cycle delay selected $\cdots_B$ ... 1110_B Fourteen f_{FPI} cycles delay selected 1111_B Fifteen f_{FPI} cycles delay selected
0	3, [31:20]	r	**Reserved** Read as 0; should be written with 0.

Transmitter Status Register

The Transmitter Status Register TSTATR contains transmitter specific status information.

TSTATR
Transmitter Status Register **(14_H)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
RDC	[4:0]	rh	**Ready Delay Counter** This bit field counts TCLK periods after the end of a frame transmission. When the TVALID signal goes to low level, RDC is cleared to zero and starts counting up the TCLK clock periods until a TREADY high level is detected (see **Page 27-22**).
APN	[6:5]	rh	**Answer Pipe Number** This bit field is written by the MLI receiver with the Pipe Number of a received Read Frame. APN is used by an Answer Frame that is transmitted as response to the Read Frame. 00_B Pipe 0 is used in Answer Frame. 01_B Pipe 1 is used in Answer Frame. 10_B Pipe 2 is used in Answer Frame. 11_B Pipe 3 is used in Answer Frame.
PE	7	rh	**Parity Error Flag** This bit is set if a transmitter parity error condition is detected by the transmitter after a frame transmission. PE is cleared by hardware when a frame has been transmitted without a parity error (see **Page 27-44**). Bit PE can be cleared by software via bit SCR.CTPE.

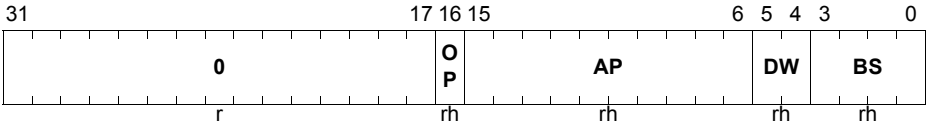
Field	Bits	Type	Description
NAE	8	rh	**Non Acknowledge Error Flag** This bit is set when a Non-Acknowledge error condition is detected by the MLI transmitter after a frame transmission (see **Page 27-47**). NAE is cleared by hardware if a transmitted frame has been acknowledged correctly. Bit NAE can be cleared by software via bit SCR.CNAE.
0	[31:9]	r	**Reserved** Read as 0; should be written with 0.

Transmitter Pipe x Status Registers

The Transmitter Pipe x Status Registers TPxSTATR contain pipe-specific status information related to address optimization and prediction, data width for transmit data, and Remote Window size.

TPxSTATR (x = 0-3)
Transmitter Pipe x Status Register

(18_H+4_H*x) **Reset Value: 0000 0000_H**



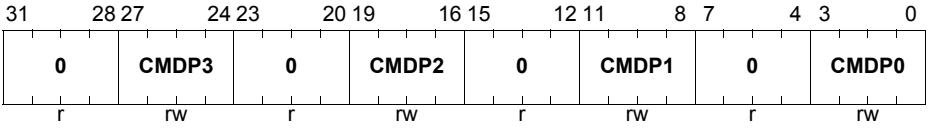
Field	Bits	Type	Description
BS	[3:0]	rh	**Buffer Size** This bit field indicates the coded buffer size of the pipe x Remote Window in the receiving controller. BS further determines how many address offset bits are transmitted in a Write Offset and Data Frame or in a Discrete Read Frame. When register TPxBAR is written for generation of a Copy Base Address Frame, BS is updated by the Copy Base Address Frame (see Page 27-28). 0000_B 1-bit offset address of Remote Window 0001_B 2-bit offset address of Remote Window 0010_B 3-bit offset address of Remote Window $\cdots_B$ ... 1110_B 15-bit offset address of Remote Window 1111_B 16-bit offset address of Remote Window
DW	[5:4]	rh	**Data Width** This bit field indicates the data width that has been detected for a read or write access of a bus master to a Transfer Window of pipe x (see Page 27-30 and Page 27-34). 00_B 8-bit data width detected 01_B 16-bit data width detected 10_B 32-bit data width detected 11_B Reserved

Field	Bits	Type	Description
AP	[15:6]	rh	**Address Prediction Factor** This bit field indicates the delta value (positive or negative number) of offset address used by the MLI transmitter for the next address prediction. AP is a signed 9-bit number (10th bit is the sign bit) that is written with each transmitter address prediction calculation (see **Page 27-26** and **Page 27-47**).
OP	16	rh	**Use Optimized Frame** When address optimization is enabled with TCR.NO = 0, this bit indicates if address prediction is possible in the transmitter. OP is written with each transmitter address prediction calculation (see **Page 27-26** and **Page 27-47**). 0_B No address prediction is possible. A Write Offset and Data Frame or a Discrete Read Frame are used for transmission. 1_B Address prediction is possible. An Optimized Write Frame or an Optimized Read Frame are used for transmission.
0	[31:17]	r	**Reserved** Read as 0; should be written with 0.

Transmitter Command Register

The Transmitter Command Register TCMDR contains the command codes that are used during Command Frame transmission (see **Page 27-41**). Each time one of the CMDPx bit fields is written, a Command Frame transmission is triggered. Independent of the transferred command code value, a Command Frame transmitted event can be generated in the transmitter for each pipe and a Command Frame received event for each pipe in the receiver, respectively.

TCMDR
Transmitter Command Register (28$_H$) Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
CMDP0	[3:0]	rw	**Command Code for Pipe 0** This bit field contains the command code related to pipe 0. The pipe 0 command codes allow an activation (pulse) of one of the service request outputs SR[3:0] in the receiving controller. 0001_B Activate SR0 0010_B Activate SR1 0011_B Activate SR2 0100_B Activate SR3 Other bit combinations are reserved for future use; no further action in the receiver.
CMDP1	[11:8]	rw	**Command Code for Pipe 1** This bit field contains the command code related to pipe 1. The pipe 1 command codes allow to adjust the receiver delay for the parity error condition (see RCR.DPE) in the MLI receiver of the receiving controller. 0000_B Set RCR.DPE = 0000_B 0001_B Set RCR.DPE = 0001_B $\cdots_B$ ... 1110_B Set RCR.DPE = 1110_B 1111_B Set RCR.DPE = 1111_B

Field	Bits	Type	Description
CMDP2	[19:16]	rw	**Command Code for Pipe 2** This bit field contains the command code related to pipe 2. The pipe 2 command codes allow to control the MLI receiver in the receiving controller. 0001_B Enable Automatic Data Mode (RCR.MOD = 1) 0010_B Disable Automatic Data Mode (RCR.MOD = 0) 0100_B Clear bit TRSTATR.RP0 0101_B Clear bit TRSTATR.RP1 0110_B Clear bit TRSTATR.RP2 0111_B Clear bit TRSTATR.RP3 1111_B Activate a pulse at $\overline{\text{BRKOUT}}$ Other bit combinations are reserved for future use; no further action in the receiver.
CMDP3	[27:24]	rw	**Command Code for Pipe 3** This bit field contains the command code related to pipe 3. The command codes for pipe 3 are free programmable by software.
0	[7:4], [15:12], [23:20], [31:28]	r	**Reserved** Read as 0; should be written with 0.

Transmitter-Receiver Status Register

The Transmitter Receiver Status Register TRSTATR contains read-only flags that indicate the status of MLI operations.

TRSTATR
Transmitter Receiver Status Register

($2C_H$) **Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0						PN		RP3	RP2	RP1	RP0	DV3	DV2	DV1	DV0

0						BAV	AV	CV3	CV2	CV1	CV0	CIV3	CIV2	CIV1	CIV0
r						rh	rh	rh	rh	rh	rh	rh	rh	rh	rh

Field	Bits	Type	Description
CIV0, **CIV1,** **CIV2,** **CIV3**	0, 1, 2, 3	rh	**Command Interrupt Valid** Bit is set to 1 by the MLI transmitter whenever it detects a rising edge at the corresponding TRx input line (for Triggered Command Frames in pipe 0). It is cleared by hardware when the Command Frame has been correctly transmitted. CIVx can be cleared by software via bit SCR.CCIVx.
CV0, **CV1,** **CV2,** **CV3**	4, 5, 6, 7	rh	**Command Valid** Bit is set by hardware when a TCMDR.CMDPx bit field is written. It is cleared by hardware when the Command Frame has been correctly transmitted. CVx can be set or cleared by software via bits SCR.SCVx or SCR.CCVx.
AV	8	rh	**Answer Valid** Bit is set by hardware when the TDRAR register in the the MLI transmitter (in the Remote Controller) is written. AV is cleared by hardware when the Answer Frame has been correctly sent. AV can be cleared by software via bit SCR.CAV.

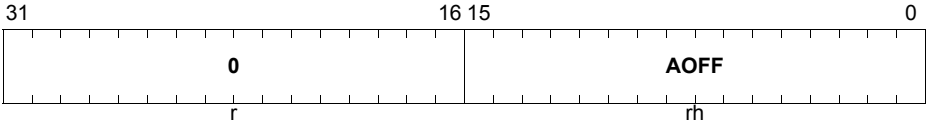
Field	Bits	Type	Description
BAV	9	rh	**Base Address Valid** Bit is set by hardware when the TCBAR register in the MLI transmitter is written. BAV is cleared by hardware when the Copy Base Address Frame has been correctly sent. BAV can be cleared by software via bit SCR.CBAV.
DV0, **DV1,** **DV2,** **DV3**	16, 17, 18, 19	rh	**Data Valid** Bit is set by hardware when the TPxDATAR and/or the TPxAOFR registers of the MLI transmitter are updated after a read or write access to a Transfer Window of pipe x. DVx is cleared again by hardware when the read or Write Frame has been correctly sent. DVx can be cleared by software via bit SCR.CDVx.
RP0, **RP1,** **RP2,** **RP3**	20, 21, 22, 23	rh	**Read Pending** Bit is set by hardware when the TPxAOFR register of the MLI transmitter is updated after a read access to a Transfer Window of pipe x. RPx is cleared by hardware when the MLI receiver in the Local Controller receives an Answer Frame for pipe x from the Remote Controller. RPx can be cleared by software via bit SCR.CDVx.
PN	[25:24]	rh	**Pipe Number** This bit field indicates the Pipe Number x of the base address that has been written into register TPxBAR. 00_B TP0BAR has been last written. 01_B TP1BAR has been last written. 10_B TP2BAR has been last written. 11_B TP3BAR has been last written.
0	[15:10], [31:26]	r	**Reserved** Read as 0; should be written with 0.

27.4.5 Transmitter Pipe x Address Offset Register

Transmitter Pipe x Address Offset Register

The Transmitter Pipe x Address Offset Register TPxAOFR is a read-only register that stores the offset address that has been used by the last read or write access to a Transfer Window of pipe x.

TPxAOFR (x = 0-3)
Transmitter Pipe x Address Offset Register
(30_H+4_H*x) **Reset Value: 0000 0000_H**

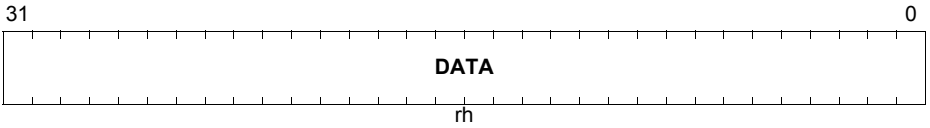


Field	Bits	Type	Description
AOFF	[15:0]	rh	**Address Offset** Whenever a location within a Transfer Window is accessed (read or written) AOFF is loaded with the lowest 16 address bits of the access. Also in the case of a small Transfer Window access, all AOFF bits are loaded, but AOFF[15:13] are not taken into account for further actions assuming the buffer size is configured correctly (see **Page 27-105**).
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

Transmitter Pipe x Data Register

The Transmitter Pipe x Data Register TPxDATAR is a read-only register that stores the data that has been written during the last write access to a Transfer Window of pipe x.

TPxDATAR (x = 0-3)
Transmitter Pipe x Data Register (40_H+4_H*x) Reset Value: 0000 0000$_H$

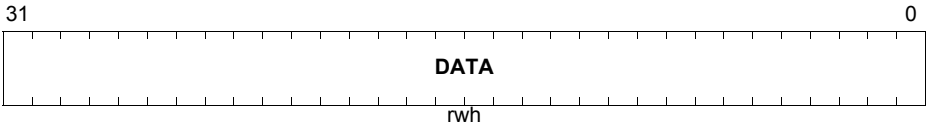


Field	Bits	Type	Description
DATA	[31:0]	rh	**Data** Whenever a location within a Transfer Window is written, the data is loaded in this bit field.

Transmitter Data Read Answer Register

The Transmitter Data Read Answer Register TDRAR contains the read data for the transmission of an Answer Frame.

TDRAR
Transmitter Data Read Answer Register
(50_H) Reset Value: 0000 0000$_H$

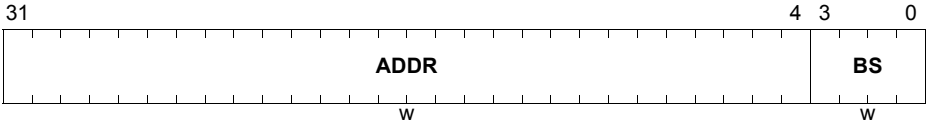


Field	Bits	Type	Description
DATA	[31:0]	rwh	**Data** This bit field is loaded with data that is read from the address requested by a Read Frame. An update of this bit field triggers the start of an Answer Frame with DATA used as content of the Answer Frame. This bit field can be updated either automatically by the move engine (if Automatic Data Mode is enabled) or by the CPU (if Automatic Data Mode is disabled).

Transmitter Pipe x Base Address Register

The write-only Transmitter Pipe x Base Address Register TPxBAR represents the 28-bit pipe x Remote Window base address and the Remote Window size that is transmitted to the receiving controller via a Copy Base Address Frame.

TPxBAR (x = 0-3)
Transmitter Pipe x Base Address Register
(54_H+4_H*x) **Reset Value: 0000 0000_H**

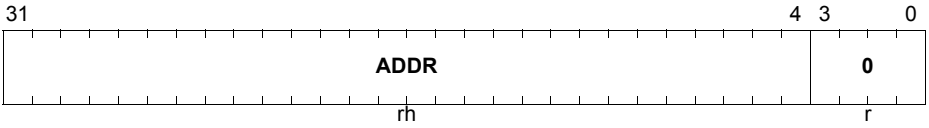


Field	Bits	Type	Description
BS	[3:0]	w	**Buffer Size** This bit field determines the coded buffer size of the pipe x Remote Window in the receiving controller. When writing TPxBAR, BS is copied into bit field TPxSTATR.BS. 0000_B 1-bit offset address of Remote Window 0001_B 2-bit offset address of Remote Window 0010_B 3-bit offset address of Remote Window $...{}_B$ ... 1101_B 14-bit offset address of Remote Window 1110_B 15-bit offset address of Remote Window 1111_B 16-bit offset address of Remote Window Do not use the coding values 1101_B, 1110_B, and 1111_B as buffer size for Small Transfer Windows.
ADDR	[31:4]	w	**Address** This bit field determines the most significant 28 bits of the pipe x Remote Window base address. When writing TPxBAR, ADDR is copied into bit field TCBAR.ADDR[31:4].

Transmitter Copy Base Address Register

The Transmitter Copy Base Address Register TCBAR contains the 28-bit pipe x Remote Window base address of the latest write access to TPxBAR.ADDR.

TCBAR
Transmitter Copy Base Address Register
(64_H) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
ADDR	[31:4]	rh	**Address** This bit field contains the 28 address bits written to TPxBAR.ADDR. This value will be transferred to the receiving controller to define the base address of the Remote Window for pipe x.
0	[3:0]	r	**Reserved** Read as 0; should be written with 0.

27.4.6 Transmitter Interrupt Registers

Transmitter Interrupt Enable Register

The Transmitter Interrupt Enable Register TIER contains the interrupt enable bits and the clear bits for all transmitter events. The bits marked w always read as 0.

TIER
Transmitter Interrupt Enable Register (98_H) **Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r						rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
NFSIE0, **NFSIE1,** **NFSIE2,** **NFSIE3**	0, 1, 2, 3	rw	**Normal Frame Sent in Pipe x Interrupt Enable** 0_B Normal frame sent in pipe x event is disabled for activation of an SRx line. 1_B Normal frame sent in pipe x event is enabled for activation of an SRx line.
CFSIE0, **CFSIE1,** **CFSIE2,** **CFSIE3**	4, 5, 6, 7	rw	**Command Frame Sent in Pipe x Interrupt Enable** 0_B Command frame sent in pipe x event is disabled for activation of an SRx line. 1_B Command frame sent in pipe x event is enabled for activation of an SRx line.
PEIE	8	rw	**Parity Error Interrupt Enable** 0_B Parity error event is disabled for activation of an SRx line. 1_B Parity error event is enabled for activation of an SRx line.

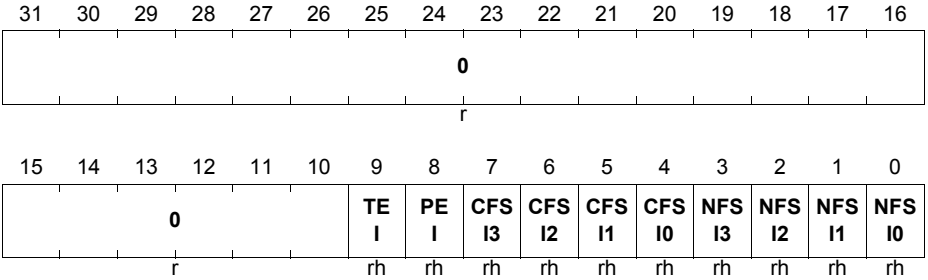
Field	Bits	Type	Description
TEIE	9	rw	**Time-Out Error Interrupt Enable** 0_B Time-out error event is disabled for activation of an SRx line. 1_B Time-out error event is enabled for activation of an SRx line.
NFSIR0, NFSIR1, NFSIR2, NFSIR3	16, 17, 18, 19	w	**Normal Frame Sent in Pipe x Flag Clear** 0_B No action. 1_B Clear TISR.NFSIx.
CFSIR0, CFSIR1, CFSIR2, CFSIR3	20, 21, 22, 23	w	**Command Frame Sent in Pipe x Flag Clear** 0_B No action. 1_B Clear TISR.CFSIx.
PEIR	24	w	**Parity Error Flag Clear** 0_B No action. 1_B Clear TISR.PEIx.
TEIR	25	w	**Time Out Error Flag Clear** 0_B No action. 1_B Clear TISR.TEIx.
0	[15:10], [31:26]	r	**Reserved** Read as 0; should be written with 0.

Transmitter Interrupt Register

The Transmitter Interrupt Status Register TISR contains all MLI event (or interrupt) flags of the MLI transmitter. These flags can be cleared by software when writing the appropriate bits in the TIER register; they are not cleared by hardware.

TISR

Transmitter Interrupt Status Register ($9C_H$) **Reset Value: $0000\ 0000_H$**



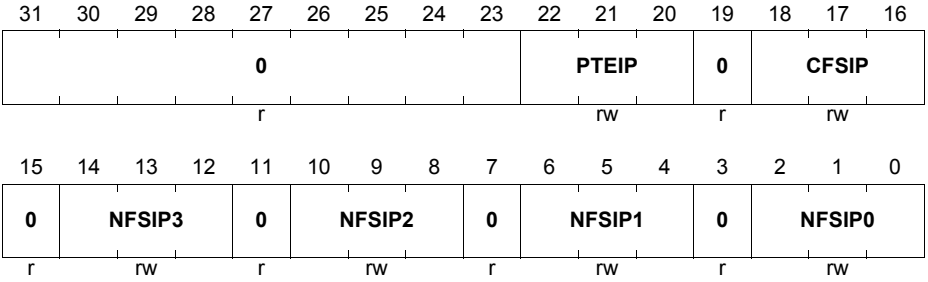
Field	Bits	Type	Description
NFSI0, **NFSI1,** **NFSI2,** **NFSI3**	0, 1, 2, 3	rh	**Normal Frame Sent in Pipe x Flag** The service request output that can be activated is defined by TINPR.NFSIPx. 0_B A Normal Frame has not yet been sent. 1_B A Write or Read Frame has been correctly sent and acknowledged for pipe x.
CFSI0, **CFSI1,** **CFSI2,** **CFSI3**	4, 5, 6, 7	rh	**Command Frame Sent in Pipe x Flag** The service request output that can be activated is defined by TINPR.CFSIP. 0_B A Command Frame has not yet been sent. 1_B A Command Frame has been correctly sent and acknowledged for pipe x.
PEI	8	rh	**Parity Error Flag** The service request output that can be activated is defined by TINPR.PTEIPx. 0_B A parity error event has not yet been detected. 1_B A parity error event has been detected.

Field	Bits	Type	Description
TEI	9	rh	**Time-Out Error Flag** The service request output that can be activated is defined by TINPR.PTEIPx. 0_B A time-out error event has not yet been detected. 1_B A time-out error event has been detected.
0	[31:10]	r	**Reserved** Read as 0; should be written with 0.

Transmitter Interrupt Node Pointer Register

The Transmitter Interrupt Node Pointer Register TINPR contains the node pointers for the MLI transmitter events.

TINPR
Transmitter Interrupt Node Pointer Register
($A0_H$) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
NFSIP0	[2:0]	rw	**Normal Frame Sent in Pipe 0 Interrupt Pointer** This bit field determines which service request output SRx becomes active when a Normal Frame sent in pipe 0 event occurs (if enabled). 000_B The service request output SR0 is selected. 001_B The service request output SR1 is selected. $\cdots_B$ … 110_B The service request output SR6 is selected. 111_B The service request output SR7 is selected.
NFSIP1	[6:4]	rw	**Normal Frame Sent in Pipe 1 Interrupt Pointer** This bit field determines which service request output SRx becomes active when a Normal Frame sent in pipe 1 event occurs (if enabled). Coding see NFSIP0.
NFSIP2	[10:8]	rw	**Normal Frame Sent in Pipe 2 Interrupt Pointer** This bit field determines which service request output SRx becomes active when a Normal Frame sent in pipe 2 event occurs (if enabled). Coding see NFSIP0.
NFSIP3	[14:12]	rw	**Normal Frame Sent in Pipe 3 Interrupt Pointer** This bit field determines which service request output SRx becomes active when a Normal Frame sent in pipe 3 event occurs (if enabled). Coding see NFSIP0.

Field	Bits	Type	Description
CFSIP	[18:16]	rw	**Command Frame Sent Interrupt Pointer** This bit field determines which service request output SRx becomes active when a Command Frame sent event occurs (if enabled). Coding see NFSIP0.
PTEIP	[22:20]	rw	**Parity or Time Out Interrupt Pointer** This bit field determines which service request output SRx becomes active when a parity/time-out event occurs (if enabled). Coding see NFSIP0.
0	3, 7, 11, 15, 19, [31:23]	r	**Reserved** Read as 0; should be written with 0.

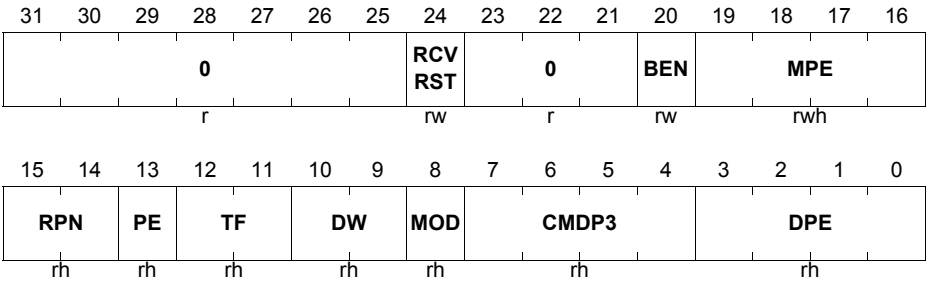
27.4.7 Receiver Control/Status Registers

Receiver Control Register

The Receiver Control Register RCR contains control and status bits/bit fields that are related to the MLI receiver operation.

Bit RCVRST is automatically overwritten after a reset (see **Page 27-68**) with a value given in the implementation chapter (see **Page 27-130**).

RCR
Receiver Control Register **(68_H)** **Reset Value: $0100\ 0000_H$**



Field	Bits	Type	Description
DPE	[3:0]	rh	**Delay for Parity Error** DPE determines the number of RCLK clock periods that the MLI receiver waits before the RREADY signal is raised again when it has detected a parity error (see **Page 27-22**). When a pipe 1 Command Frame is received by the MLI receiver, the command code is stored in this bit field (see **Page 27-41**). 0000_B Zero RCLK clock period delay is selected. 0001_B One RCLK clock period delay is selected. 0010_B Two RCLK clock periods delay is selected. $...B$ ... 1110_B Fourteen RCLK clock periods delay is selected. 1111_B Fifteen RCLK clock periods delay is selected.
CMDP3	[7:4]	rh	**Command From Pipe 3** When a pipe 3 Command Frame is received by the MLI receiver, the command code is stored in this bit field. Pipe 3 commands are free for software use.

Field	Bits	Type	Description
MOD	8	rh	**Mode of Operation** This bit determines the data transfer operation mode of the MLI receiver. Bit MOD can be set by hardware with the reception of a pipe 2 Command Frame (see Page 27-100). It can be set or cleared by software via bits SCR.SMOD or SCR.CMOD. 0_B Automatic Data Mode is disabled. Data read/write operations from/to a Remote Window must be executed by a bus master (e.g. the CPU). 1_B Automatic Data Mode is enabled. Data read/write operations from/to a Remote Window are executed by the MLI's move engine.
DW	[10:9]	rh	**Data Width** This bit field is updated by the MLI receiver whenever new data is received in the RDATAR register. It indicates the relevant data width. 00_B 8-bit relevant data width in RDATAR 01_B 16-bit relevant data width in RDATAR 10_B 32-bit relevant data width in RDATAR 11_B Reserved
TF	[12:11]	rh	**Type of Frame** This bit field determines the frame type that has most recently been received by the MLI receiver. It is updated whenever the MLI receiver updates RDATAR, RADDR, or RPxBAR. The most recently received frame was a: 00_B Copy Base Address Frame 01_B Discrete Read Frame or Optimized Read Frame 10_B Write Offset and Data Frame or Optimized Write Frame 11_B Answer frame Note that the coding of TF is different from the frame coding as defined in Table 27-1 on Page 27-11.
PE	13	rh	**Parity Error** PE is set when a parity error is detected in a received frame (see Page 27-44). PE is cleared by hardware when a frame has been received without parity error. PE can be cleared by software via bit SCR.CRPE.

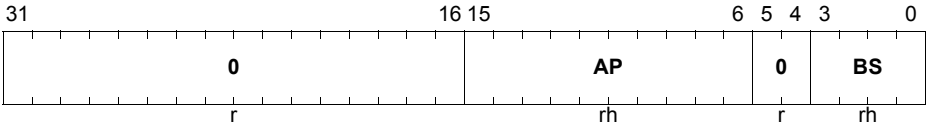
Field	Bits	Type	Description
RPN	[15:14]	rh	**Received Pipe Number** This bit field contains the Pipe Number that was indicated by the Pipe Number bit field of the latest received frame. It is updated by any received frame.
MPE	[19:16]	rwh	**Maximum Parity Errors** This bit field indicates the number of receive parity error conditions after which a receiver parity error event will be generated. It is set to a desired value by software and it is decremented down to 0 automatically by the MLI each time it detects a receiver parity error condition. If a receiver parity error condition is detected and MPE becomes 0 or is already 0, a receiver parity error event is generated (see **Page 27-44**). 0000_B A receiver parity event is generated if a receiver error condition is detected. 0001_B A receiver parity event is generated if a receiver error condition is detected. 0010_B A receiver parity event is generated if 2 receiver error conditions are detected. $\ldots_B$ … 1110_B A receiver parity event is generated if 14 receiver error conditions are detected. 1111_B A receiver parity event is generated if 15 receiver error conditions are detected.
BEN	20	rw	**Break Out Enable** When setting BEN = 1, the MLI receiver generates a pulse on its break output signal BRKOUT when a pipe 2 Command Frame with command code CMD = 1111_B is received. 0_B Break output signal generation is disabled. 1_B Break output signal is enabled.
RCVRST	24	rw	**Receiver Reset** This bit forces the receiver to be reset in order to be able to change OICR settings without affecting the receiver registers. 0_B The MLI receiver is in operating mode. 1_B The MLI receiver is held in reset state and OICR can be modified without unintentional actions in the receiver.

Field	Bits	Type	Description
0	[23:21], [31:25]	r	**Reserved** Read as 0; should be written with 0.

Receiver Pipe x Status Register

The Receiver Pipe x Status Register RPxSTATR indicates the coded buffer size which represents the Remote Window Size of 2 Bytes to 64 Kbytes and the address prediction factor that has been calculated for pipe x in the receiving controller.

RPxSTATR (x = 0-3)
Receiver Pipe x Status Register **($7C_H$+4_H*x)** **Reset Value: 0000 0000_H**



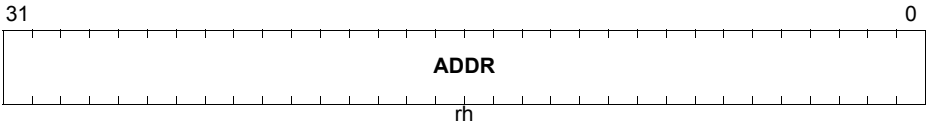
Field	Bits	Type	Description
BS	[3:0]	rh	**Buffer Size** This bit field indicates the size of pipe x Remote Window in the receiving controller. It is updated by hardware when a Copy Base Address Frame has been received (see **Page 27-28**). 0000_B 1-bit offset address of Remote Window 0001_B 2-bit offset address of Remote Window 0010_B 3-bit offset address of Remote Window $...{}_B$ ... 1110_B 15-bit offset address of Remote Window 1111_B 16-bit offset address of Remote Window
AP	[15:6]	rh	**Address Prediction Factor** AP contains the address prediction factor that has been calculated for pipe x in the receiving controller. It is a signed 9-bit number with the sign in its most significant bit (see **Page 27-47**).
0	[5:4], [31:16]	r	**Reserved** Read as 0; should be written with 0.

27.4.8 Receiver Address/Data Registers

Receiver Pipe x Base Address Register

The Receiver Pipe x Base Address Register RPxBAR is a read-only register that contains the complete target address in the Remote Window of pipe x.

RPxBAR (x = 0-3)
Receiver Pipe x Base Address Register
($6C_H$+4_H*x) **Reset Value: 0000 0000_H**

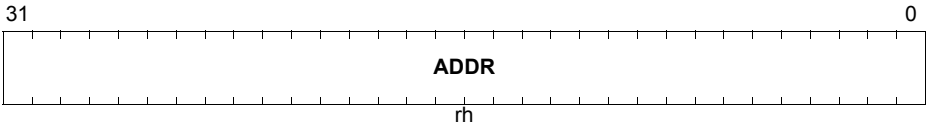


Field	Bits	Type	Description
ADDR	[31:0]	rh	**Address** ADDR indicates the complete target address for the pipe x Remote Window. If a pipe x Copy Base Address Frame is received, ADDR[31:4] becomes loaded with the transmitted 28-bit address and bits [3:0] are cleared. If a write or Read Frame with m bits of address offset is received, bits ADDR[31:m] are held constant and bits ADDR[m-1:0] are replaced by the received offset. If an optimized read or data frame is received, the address prediction mechanism adds the predicted address offset RPxSTATR.AP to ADDR and stores the result in ADDR. If an Answer Frame is received, ADDR is not changed.

Receiver Address Register

The Receiver Address Register RADRR is a read-only register storing the complete address of the most recently (or currently) targeted Remote Window.

RADRR
Receiver Address Register **($8C_H$)** **Reset Value: $0000\ 0000_H$**

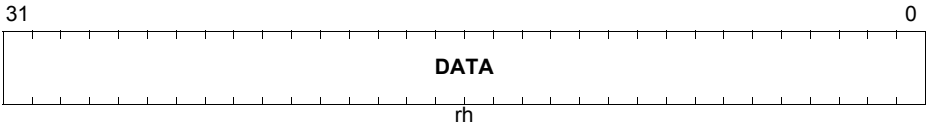


Field	Bits	Type	Description
ADDR	[31:0]	rh	**Address** ADDR indicates the complete target address for the most recently (or currently) targeted Remote Window (pipe x). If a Copy Base Address Frame is received, ADDR is unchanged. If a write or Read Frame with m bits of address offset is received, bits ADDR[31:m] replaced by the bits RPxBAR.ADDR[31:m] and bits ADDR[m-1:0] are replaced by the received offset. If an optimized read or data frame is received, the address prediction mechanism adds the predicted address offset RPxSTATR.AP to RPxBAR.ADDR and stores the result in ADDR. If an Answer Frame is received, ADDR becomes invalid.

Receiver Data Register

The Receiver Data Register RDATAR is a read-only register that stores data received by a Write Frame or an Answer Frame.

RDATAR
Receiver Data Register **(90_H)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
DATA	[31:0]	rh	**Data** In the receiving controller, DATA contains the data received by a Write Frame or an Answer Frame. Bit field RCR.DW determines the width of the relevant data that is stored in RDATAR. RCR.DW = 00_B: RDATAR[7:0] are relevant (8-bit) RCR.DW = 01_B: RDATAR[15:0] are relevant (16-bit) RCR.DW = 10_B: RDATAR[31:0] are relevant (32-bit)

27.4.9 Receiver Interrupt Registers

Receiver Interrupt Enable Register

The Receiver Interrupt Enable Register RIER contains the interrupt enable bits and the clear bits for all receiver events. The bits marked w are always read as 0.

RIER
Receiver Interrupt Enable Register ($A4_H$) **Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0						DRAIR	MPEIR	PEIR	ICER	CFRIR3	CFRIR2	CFRIR1	CFRIR0	MEIR	NFRIR

0						DRAIE	MPEIE	PEIE	ICE	CFRIE3	CFRIE2	CFRIE1	CFRIE0	NFRIE	
r						rw	rw	rw	rw	rw	rw	rw	rw	rw	

Field	Bits	Type	Description
NFRIE	[1:0]	rw	**Normal Frame Received Interrupt Enable** This bit field defines if an SRx output is activated if a Normal Frame is correctly received. 00_B The SRx activation is disabled. 01_B The selected SRx line is activated each time a Normal Frame is correctly received. 10_B The selected SRx line is activated each time a Normal Frame is correctly received that is not handled automatically by the MLI move engine (e.g. an Answer Frame). 11_B Reserved
CFRIE0, CFRIE1, CFRIE2, CFRIE3	2, 3, 4, 5	rw	**Command Received in Pipe x Interrupt Enable** This bit determines if an SRx output is activated if a Command Frame for pipe x has been received correctly. 0_B Command received in pipe x event is disabled for activation of an SRx line. 1_B Command received in pipe x event is enabled for activation of an SRx line.

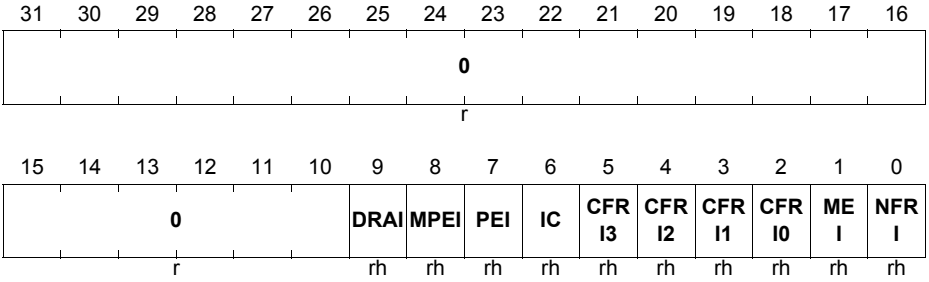
Field	Bits	Type	Description
ICE	6	rw	**Interrupt Command Enable** This bit determines if an SRx output line is activated if a Command Frame is received in pipe 0. 0_B Command frame received in pipe 0 event is disabled for activation of an SRx line. 1_B Command frame received in pipe 0 event is enabled for activation of an SRx line.
PEIE	7	rw	**Parity Error Interrupt Enable** This bit determines if an SRx output line is activated if receiver a parity error event is detected. 0_B Parity error event is disabled for activation of an SRx line. 1_B Parity error event is enabled for activation of an SRx line.
MPEIE	8	rw	**Memory Access Protection Interrupt Enable** This bit determines if an SRx output line is activated if a memory access protection error is detected. 0_B Memory access protection error event is disabled for activation of an SRx line. 1_B Memory access protection error event is enabled for activation of an SRx line.
DRAIE	9	rw	**Discarded Read Answer Interrupt Enable** This bit determines if an SRx output line is activated if a discarded read Answer Frame condition is detected. 0_B Discarded read answer event is disabled for activation of an SRx line. 1_B Discarded read answer event is enabled for activation of an SRx line.
NFRIR	16	w	**Normal Frame Received Interrupt Flag Clear** 0_B No action. 1_B Clear RISR.NFRI.
MEIR	17	w	**MLI Move Engine Interrupt Flag Clear** 0_B No action. 1_B Clear RISR.MEI.
CFRIR0, CFRIR1, CFRIR2, CFRIR3	18, 19, 20, 21	w	**Command Frame Received in Pipe x Interrupt Flag Clear** 0_B No action. 1_B Clear RISR.CFRIx.

Field	Bits	Type	Description
ICER	22	w	**Interrupt Command Flag Clear** 0_B No action. 1_B Clear RISR.ICE.
PEIR	23	w	**Parity Error Interrupt Flag Clear** 0_B No action. 1_B Clear RISR.PEI.
MPEIR	24	w	**Memory Protection Error Interrupt Flag Clear** 0_B No action. 1_B Clear RISR.MPEI.
DRAIR	25	w	**Discarded Read Answer Interrupt Flag Clear** 0_B No action. 1_B Clear RISR.DRAI.
0	[15:10], [31:26]	r	**Reserved** Read as 0; should be written with 0.

Receiver Interrupt Status Register

The Receiver Interrupt Status Register RISR contains all event (interrupt) flags of the MLI receiver. These flags can be cleared by software when writing the appropriate bits in the RIER register; they are not cleared by hardware.

RISR
Receiver Interrupt Status Register (A8$_H$) Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
NFRI	0	rh	**Normal Frame Received Interrupt Flag** This flag is set when a write or a Read Frame has been received. The service request output that is activated is defined by RINPR.NFRIP.
MEI	1	rh	**MLI Move Engine Interrupt Flag** This flag is set when the move engine has finished an operation (read or write, depending on received frame). The service request output that is activated is defined by RINPR.MPPEIP.
CFRI0, CFRI1, CFRI2, CFRI3	2, 3, 4, 5	rh	**Command Frame Received in Pipe x Interrupt Flag** This flag is set when a Command Frame has been received in pipe x. The service request output that is activated is defined by RINPR.CFRIP.
IC	6	rh	**Interrupt Command Flag** This flag is set when a Command Frame has been received in pipe 0 leading to an activation of one of the service request outputs SR[3:0]. The service request output that is activated is defined by the received command CMD.

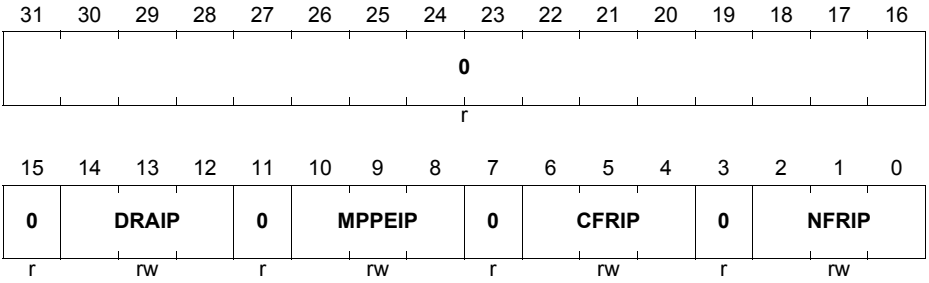
Field	Bits	Type	Description
PEI	7	rh	**Parity Error Interrupt Flag** This flag is set when a parity error event has occurred. The service request output that is activated is defined by RINPR.MPPEIP.
MPEI	8	rh	**Memory Protection Error Interrupt Flag** This flag is set when a memory protection event has occurred. The service request output that is activated is defined by RINPR.MPPEIP.
DRAI	9	rh	**Discarded Read Answer Interrupt Flag** This flag is set when the discarded read answer event has occurred. This condition occurs if an Answer Frame is received while none of the TRSTATR.RPx bits is set (the Answer Frame was not expected). The service request output that is activated is defined by RINPR.DRAIP.
0	[31:10]	r	**Reserved** Read as 0; should be written with 0.

Receiver Interrupt Node Pointer Register

The Receiver Interrupt Node Pointer Register RINPR contains the node pointers for the MLI receiver events.

RINPR
Receiver Interrupt Node Pointer Register

(AC_H) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
NFRIP	[2:0]	rw	**Normal Frame Received Interrupt Pointer** This bit field determines which service request output SRx becomes active when a Normal Frame received event occurs. 000_B The service request output SR0 is selected. 001_B The service request output SR1 is selected. $\ldots_B$ … 110_B The service request output SR6 is selected. 111_B The service request output SR7 is selected.
CFRIP	[6:4]	rw	**Command Frame Received Interrupt Pointer** This bit field determines which service request output SRx becomes active when a Command Frame received event occurs. Coding see NFRIP.
MPPEIP	[10:8]	rw	**Memory Protection or Parity Error Interrupt Pointer** This bit field determines which service request output SRx becomes active when a memory protection/parity error event occurs. Coding see NFRIP.
DRAIP	[14:12]	rw	**Discarded Read Answer Interrupt Pointer** This bit field determines which service request output SRx becomes active when a discarded read answer event occurs. Coding see NFRIP.

Field	Bits	Type	Description
0	3, 7, 11, [31:15]	r	**Reserved** Read as 0; should be written with 0.

27.5 Implementation of the MLI0/MLI1 in TC1798

This section describes the MLI0/MLI1 module related external functions such as port connections, interrupt and service request control, connections to other on-chip modules, clock control, and the address map.

27.5.1 Interfaces of the MLI Modules

Each MLI module is supplied with separate clock control, address decoding, and interrupt control logic. Four (for MLI0) and two (for MLI1) of the eight module service request outputs are connected to service request nodes. Four service request outputs of each MLI module are connected as DMA request to with the DMA controller.

The data, clock, and control lines of each MLI receiver and transmitter are connected to GPIO lines. Alternate functions of Port 1 and Port 5 lines are assigned to the MLI0 module I/O lines while alternate functions of Port 8 lines are assigned to the MLI0 module I/O lines. Additionally, within one MLI module transmitter and receiver signals can be dynamically connected among each other without using pins; this is useful for test purposes.

Figure 27-52 and **Figure 27-53** show how the MLI0 and MLI1 modules are interconnected to port lines and other on-chip functional blocks.

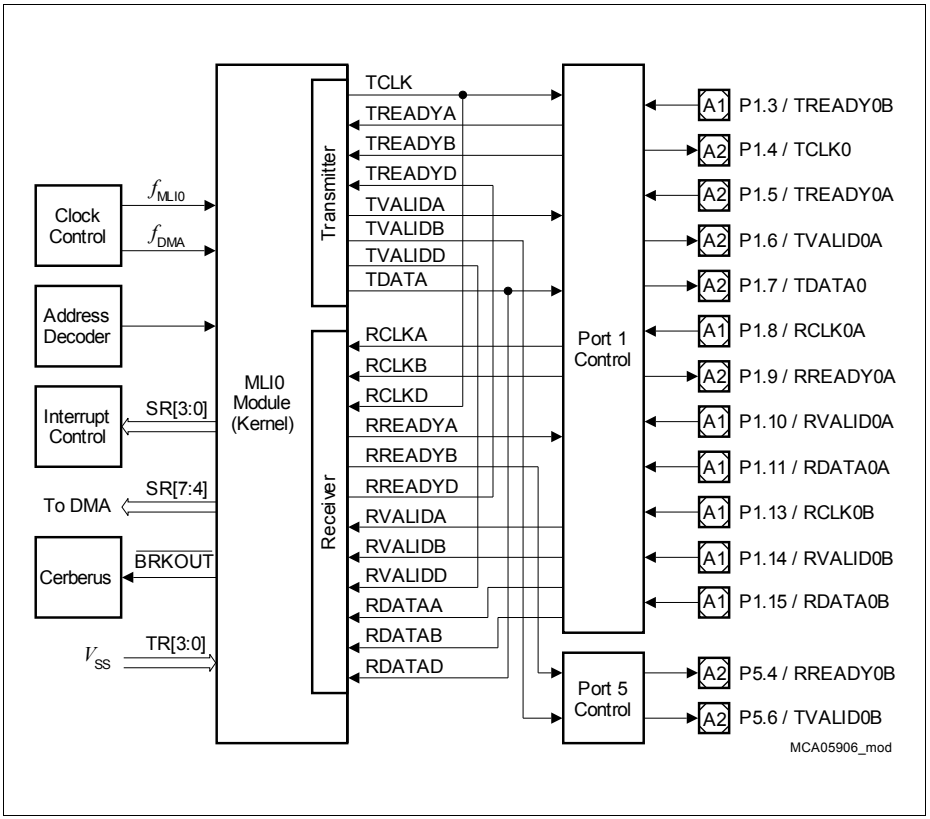


Figure 27-52 MLI0 Module Implementation and Interconnections

When programming the MLI0_OICR register, the following additional items must be considered:

- Unused transmitter/receiver output lines with index “C” (TVALIDC and RREADYC) are not connected.
- Unused transmitter/receiver input lines with index “C” (TREADYC, RCLKC, RVALIDC, and RDATAC) are connected to low level.

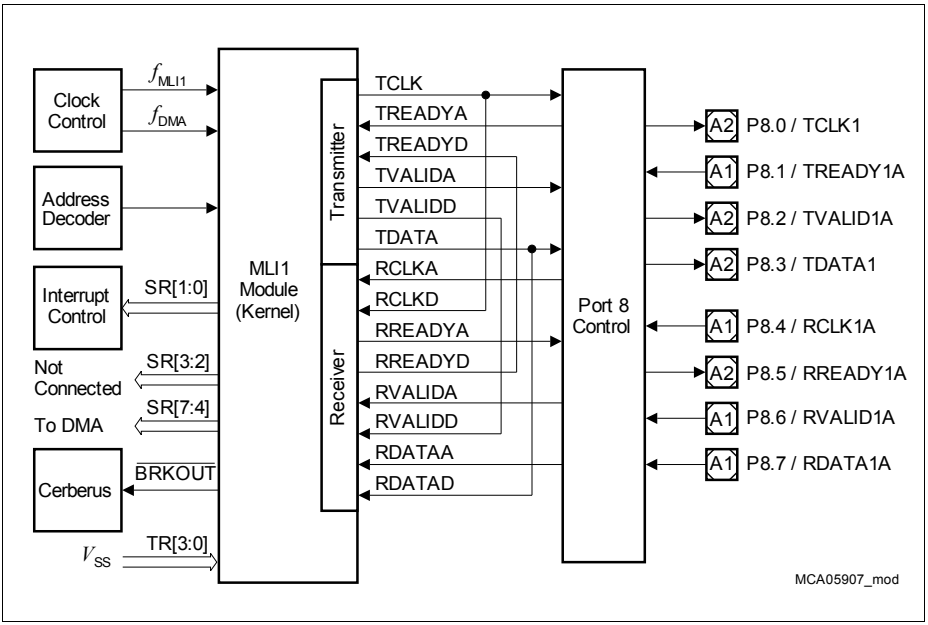

Figure 27-53 MLI1 Module Implementation and Interconnections

When programming the MLI1_OICR register, the following additional items must be considered:

- Lines with index “B” (not shown in the figure above)
  - Unused transmitter/receiver output lines TVALIDB and RREADYB are not connected.
  - Unused transmitter/receiver input lines TREADYB, RCLKB, RVALIDB, and RDATAB are connected to low level.
- Lines with index “C” (not shown in the figure above)
  - Unused transmitter/receiver output lines TVALIDC and RREADYC are reserved for emulation purposes.
  - Unused transmitter/receiver input lines TREADYC, RCLKC, RVALIDC, and RDATAC are reserved for emulation purposes and should not be selected during normal operation of the TC1798.

See also **Page 27-133** for additional details on I/O line control and function.

27.5.2 MLI Module External Registers

Figure 27-54 summarizes the module related external registers that are required for MLI0/MLI1 programming. Details on MLI0/MLI1 related register settings are shown in the following sections.

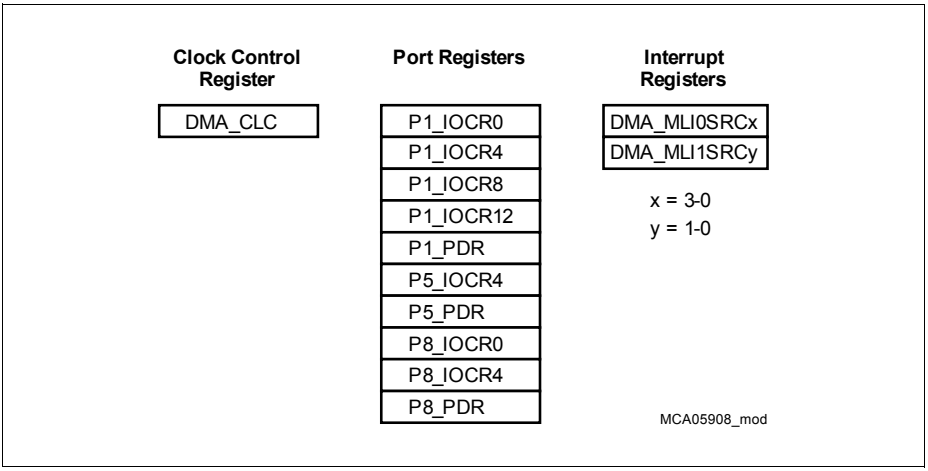

Figure 27-54 MLI0/MLI1 Implementation-Specific Special Function Registers

27.5.2.1 Automatic Register Overwrite

The following values are applied after reset (see **Page 27-68**).

- OICR = 1000 8000_H; Setting “A” is selected
- RCR.RCVRST = 0: the receiver is enabled for reception.

27.5.3 Module Clock Generation

The module clock generation configuration for the two MLI modules is shown in **Figure 27-55**.

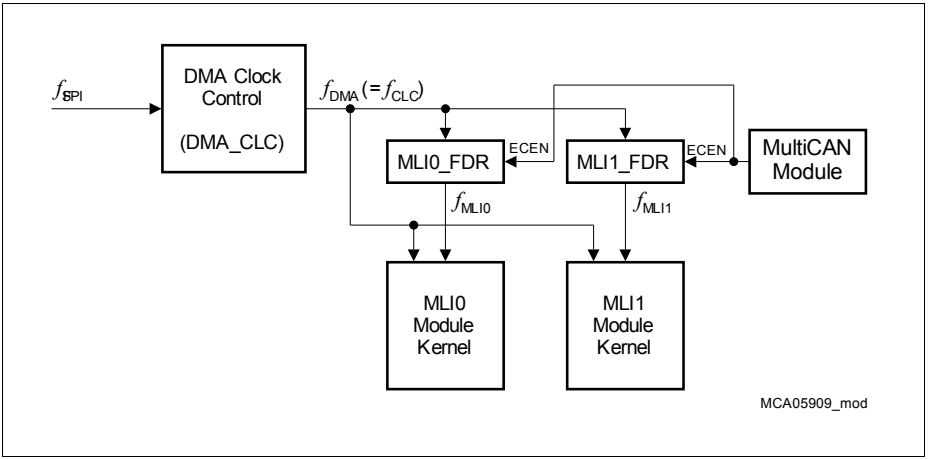

Figure 27-55 Clock Configuration of the MLI Modules

The DMA controller and the two MLI modules (MLI0 and MLI1) are supplied from a common module clock f_{DMA}, that has the frequency of the system clock f_{FPI}) and is controlled via the DMA_CLC clock control register. The MLI modules do not have its own clock control registers. Its module clocks f_{MLI0} and f_{MLI1} are derived from f_{DMA} by two separate fractional divider registers, MLI0_FDR and MLI1_FDR (description see **Page 27-79**).

Output signal CAN_INT_O15 of the MultiCAN module can be used for external clock enable control of the fractional divider.

- f_{DMA}
  This is the module clock used inside the MLI kernels for control purposes such as for clocking of control logic and register operations. The clock control register DMA_CLC makes it possible to enable/disable f_{DMA} under certain conditions. DMA_CLC is described in the DMA chapter of this document.
- f_{MLI0} and f_{MLI1}
  This clock is the module clock used in the MLI kernels as base for the shift clock and therefore determines the baud rate of the synchronous serial data transmission. The fractional divider registers MLI0_FDR and MLI1_FDR control the frequencies of f_{MLI0} and f_{MLI1}. This configuration makes it possible to enable/disable the module clocks f_{MLI0} and f_{MLI1} independently of f_{DMA}.

Combined with the baud rate as derived in the MLI module (see **Equation (27.1)** on **Page 27-67**) and the MLIx_FDR fractional divider setup, the resulting MLI baud rate is defined by:

$$\text{Baud rate}_{MLIx} = \frac{f_{DMA}}{2} \times \frac{1}{n} \quad \text{with n = 1024 - FDR.STEP} \tag{27.4}$$

$$\text{Baud rate}_{MLIx} = \frac{f_{DMA}}{2} \times \frac{n}{1024} \quad \text{with n = 0-1023} \tag{27.5}$$

Equation (27.4) applies to normal divider mode of the fractional divider (FDR.DM = 01_B). **Equation (27.5)** applies to fractional divider mode (FDR.DM = 10_B).

After a reset operation, both MLI modules are enabled in normal divider mode. According the MLIx_FDR register's reset value of 03FF $43FF_H$, the selected baud rate is $f_{DMA}/2$. Note that the DMA controller is also enabled after a reset operation with clock $f_{DMA} = f_{FPI}$.

27.5.4 Port Control and Connections

MLI0 and MLI1 clock and data output lines are connected to GPIO ports and are, therefore, controlled in the port logics (see also **Page 27-128** and **Page 27-129**). The following port control operations selections must be executed for these I/O lines:

- Input/output function selection (IOCR registers)
- Pad driver characteristics selection for the outputs (PDR registers)

27.5.4.1 Input/Output Function Selection

The port input/output control registers contain the bit fields that select the digital output and input driver characteristics such as port direction (input/output) with alternate output selection, pull-up/down devices, and open-drain selections. The I/O lines for the MLI modules are controlled by the Port 1, Port 5 and Port 8 input/output control registers. When the MLI modules are connected to the GPIO port lines, the correct settings of the enable/polarity control bits and bit fields in the output input control registers MLI0_IOCR and MLI1_IOCR must also be regarded (transmitter I/O line control see **Page 27-53**, receiver I/O line control see **Page 27-54**). Note that after a reset operation the MLI0 and MLI1 modules (although enabled) have no direct connections to the GPIO lines.

Table 27-11 shows how OICR register bits and bit fields must be programmed for the required GPIO functionality of the MLI I/O lines.

Table 27-11 MLI0 and MLI1 I/O Line Selection and Setup

Module	Port Lines	Input/Output Control Register Bits	I/O

27.5.5 On-Chip Connections

27.5.5.1 Service Request Output Connections

Each MLI module provides eight service request outputs SR[7:0] that can be used to generate interrupts or DMA requests. In the TC1798, four service request outputs SR[3:0] of the MLI0 module and two service request outputs SR[1:0] of the MLI1 module are connected to an interrupt node. Service request outputs SR[3:2] of the MLI1 module are not connected. Four service request outputs (SR[7:4]) of each MLI module are connected to DMA request inputs of the TC1798 DMA controller.

Each of the service request outputs used as interrupt requests are controlled by a service request control register. The service request control registers of the MLI modules are located inside the DMA address area. Therefore, all MLI0/MLI1 service request control registers are named as DMA_MLIxSRCy and described in the DMA chapter implementation part of the TC1798 User´s Manual.

All MLI service request output connections are listed in **Table 27-12**.

Table 27-12 Service Request Lines and Interconnections of MLI0/MLI1

Module	Service Req. Output Line	Connected to Node or DMA Request Input	Description
MLI0	SR0	DMA_MLI0SRC0	MLI0 Service Request Node 0 (in DMA)
	SR1	DMA_MLI0SRC1	MLI0 Service Request Node 1 (in DMA)
	SR2	DMA_MLI0SRC2	MLI0 Service Request Node 2 (in DMA)
	SR3	DMA_MLI0SRC3	MLI0 Service Request Node 3 (in DMA)
	SR4	CH00_REQI7	DMA Channel 00 Request Input 7
		CH04_REQI7	DMA Channel 04 Request Input 7
	SR5	CH01_REQI7	DMA Channel 01 Request Input 7
		CH05_REQI7	DMA Channel 05 Request Input 7
	SR6	CH02_REQI7	DMA Channel 02 Request Input 7
		CH06_REQI7	DMA Channel 06 Request Input 7
	SR7	CH03_REQI7	DMA Channel 03 Request Input 7
		CH07_REQI7	DMA Channel 07 Request Input 7

Table 27-12 Service Request Lines and Interconnections of MLI0/MLI1 (cont'd)

Module	Service Req. Output Line	Connected to Node or DMA Request Input	Description
MLI1	SR0	DMA_MLI1SRC0	MLI1 Service Request Node 0 (in DMA)
	SR1	DMA_MLI1SRC1	MLI1 Service Request Node 1 (in DMA)
	SR2	–	Not connected
	SR3	–	Not connected
	SR4	CH10_REQI15	DMA Channel 10 Request Input 15
		CH14_REQI15	DMA Channel 14 Request Input 15
	SR5	CH11_REQI15	DMA Channel 11 Request Input 15
		CH15_REQI15	DMA Channel 15 Request Input 15
	SR6	CH12_REQI15	DMA Channel 12 Request Input 15
		CH16_REQI15	DMA Channel 16 Request Input 15
	SR7	CH13_REQI15	DMA Channel 13 Request Input 15
		CH17_REQI15	DMA Channel 17 Request Input 15

27.5.5.2 Break Signals

The $\overline{\text{BRKOUT}}$ output signals of MLI0 and MLI1 are connected as break input signals to the Multi Core Break Switch (MCBS) that is a part of the Cerberus on-chip debug control module. These connections allow MLI0/MLI1 initiated break conditions to be generated in the Cerberus.

27.5.5.3 Trigger Input Signals

The five Trigger Input Signals TR[4:0] are connected to V_{SS}.

27.5.6 Access Protection

The access protection parameters for the MLI module in the TC1798 are identical with access protection parameters of the DMA Controller. Details of the access protection parameters are defined in the DMA chapter at "DMA Module Implementation" - "Access Protection Assignment".

The Table "DMA Access Protection Address Ranges" in the DMA chapter is also valid for MLI register bits AER0.AENRx and AER1.AENRx (x = 0-31).

The Tables "... Address Protection Sub-Range Definition" for PMI, OVRAM, DMI, and PCP PRAM in the DMA chapter are also valid for MLI register bits ARR0,1.SLICEn and ARR0,1.SIZEn (n = 0-3).

27.5.7 MLI0/MLI1 Transfer Window Address Maps

In the TC1798, the transfer windows for the MLI0 and MLI1 modules are located in the address ranges as identified in **Table 27-13**.

Table 27-13 MLI0/MLI1 Transfer Windows

Module	Window Type	Pipe	Address Range
MLI0	Small Transfer Window (STW)	Pipe 0	F01E 0000$_H$ to F01E 1FFF$_H$
		Pipe 1	F01E 2000$_H$ to F01E 3FFF$_H$
		Pipe 2	F01E 4000$_H$ to F01E 5FFF$_H$
		Pipe 3	F01E 6000$_H$ to F01E 7FFF$_H$
	Large Transfer Window (LTW)	Pipe 0	F020 0000$_H$ to F020 FFFF$_H$
		Pipe 1	F021 0000$_H$ to F021 FFFF$_H$
		Pipe 2	F022 0000$_H$ to F022 FFFF$_H$
		Pipe 3	F023 0000$_H$ to F023 FFFF$_H$
MLI1	Small Transfer Window (STW)	Pipe 0	F01E 8000$_H$ to F01E 9FFF$_H$
		Pipe 1	F01E A000$_H$ to F01E BFFF$_H$
		Pipe 2	F01E C000$_H$ to F01E DFFF$_H$
		Pipe 3	F01E E000$_H$ to F01E FFFF$_H$
	Large Transfer Window (LTW)	Pipe 0	F024 0000$_H$ to F024 FFFF$_H$
		Pipe 1	F025 0000$_H$ to F025 FFFF$_H$

27.5.8 MLI0/MLI1 Address Map

An absolute register address is given by the offset address of the register (given in Table 27-10) plus the module base address (given in Table 27-9).

Table 27-14 Address Map of MLI0/MLI1

Short Name	Description	Address	Access Mode		Reset Value
			Read	Write	
Multi Link Interface 0 (MLI0)

28 General Purpose Timer Array (GPTA®v5)

This chapter describes the General Purpose Timer Array of the TC1798. The GPTA[1] consists of the following units: GPTA0 and GPTA1 with identical functionality; LTCA2 with reduced GPTA0 functionality.

This chapter contains the following sections:

- A summary on the structure and basic functionalities (see **Page 28-4**)
- Functional description of the GPTA®v5 kernel, applicable for GPTA0 and GPTA1 (see **Page 28-8**)
- Register descriptions of all GPTA®v5 kernel specific registers, applicable for GPTA0 and GPTA1 (see **Page 28-160**)
- Functional description of the LTCA2 kernel (see **Page 28-234**)
- Register descriptions of all LTCA2 kernel specific registers (see **Page 28-250**)
- TC1798 implementation-specific details and registers of the GPTA®v5 module, including port connections and control, interrupt control, address decoding, and clock control (see **Page 28-274**).

*Note: The GPTA®v5 kernel register names described in **Section 28.4**, **Section 28.6**, and **Section 28.7.2** will be referenced in the TC1798 User´s Manual by the unit name prefix "GPTA0_" for the GPTA0 unit, by "GPTA1_" for the GPTA1 unit, and by "LTCA2_" for the LTCA2 unit.*

28.1 What is new?

The major updates from GPTAv4 to GPTAv5 are:

- The flexibility to generate on-chip trigger and gating signals have been increased. The GPTAv5 provides 16 such signals. Each of the signals may be mapped to any output signal of a Local or Global Timer Cell. Therefore it is not limited as before to a single group of Global or Local Timer Cells (25% of the GTC or LTC). Limitation now is, that no more than 4 different on-chip trigger and gating signals may be mapped to one group of LTC or GTC. Details concerning this new on-chip trigger and gating signal multiplexer are described in **Section 28.3.4.3** (see **Page 28-108**). This new features is not fully upwards compatible to the GPTAv4. Additional output multiplexer registers have to be configured to achieve the same functionality (see **"Multiplexer Register Array Programming" on Page 28-121**). Some very minor issue may occur due to a minor reduction of on-chip signal and trigger signals compared to GPTAv4, but on the other hand the increased flexibility should nearly always compensated this. The following list summarizes the principle of mapping former GPTAv4 signals to the new GPTAv5 signals:
  - GPTAv4 Signal GPTA0_OUT0 is replaced by GPTAv5 Signal GPTA0_TRIG01
  - GPTAv4 Signal GPTA0_OUT1 is replaced by GPTAv5 Signal GPTA0_TRIG11

1) *TriCore®, C166®, Infineon®, Infineon Technologies®, and GPTA® are trademarks of Infineon Technologies AG.*

- GPTAv4 Signal GPTA0_OUT2 is replaced by GPTAv5 Signal GPTA0_TRIG00
- GPTAv4 Signal GPTA0_OUT3 is replaced by GPTAv5 Signal GPTA0_TRIG10
- GPTAv4 Signal GPTA0_OUT8 is replaced by GPTAv5 Signal GPTA0_TRIG03
- GPTAv4 Signal GPTA0_OUT9 is replaced by GPTAv5 Signal GPTA0_TRIG13
- GPTAv4 Signal GPTA0_OUT10 is replaced by GPTAv5 Signal GPTA0_TRIG02
- GPTAv4 Signal GPTA0_OUT11 is replaced by GPTAv5 Signal GPTA0_TRIG12
- GPTAv4 Signal GPTA0_OUT16 is replaced by GPTAv5 Signal GPTA0_TRIG05
- GPTAv4 Signal GPTA0_OUT18 is replaced by GPTAv5 Signal GPTA0_TRIG15
- GPTAv4 Signal GPTA0_OUT19 is replaced by GPTAv5 Signal GPTA0_TRIG04
- GPTAv4 Signal GPTA0_OUT24 is replaced by GPTAv5 Signal GPTA0_TRIG07
- GPTAv4 Signal GPTA0_OUT26 is replaced by GPTAv5 Signal GPTA0_TRIG17
- GPTAv4 Signal GPTA0_OUT27 is replaced by GPTAv5 Signal GPTA0_TRIG06
- GPTAv4 Signal GPTA0_OUT28 is replaced by GPTAv5 Signal GPTA0_TRIG07
- GPTAv4 Signal GPTA0_OUT4 is no longer available in GPTAv5. This signal was routed to the ERU (TC1766 only) to cover 75% of the GTC and LTC cells as input to Input channel 1. But Signal GPTA0_TRIG12 may be routed to all (100%) GTC and LTC cells due to the on-chip trigger and gating multiplexer and therefore fulfills this requirement already.
- GPTAv4 Signal GPTA0_OUT7 is no longer available in GPTAv5. This signal was routed to the ERU (TC1766 only) to cover 75% of the GTC and LTC cells as input to Input channel 2. But Signal GPTA0_TRIG14 may be routed to all (100%) GTC and LTC cells due to the on-chip trigger and gating multiplexer and therefore fulfills this requirement already.
- To be consistent to TC1797, the double connected input group of IOG3 is renamed to IOG6 and the Output Group OG1-7 are renamed to OG0-OG6 and the OG0 is renamed to IOG7.
- GPTAv4 Signal GPTA0_OUT17 is no longer available in GPTAv5. This signal was routed to the ERU to cover 50% of the GTC and LTC cells as input to Input channel 2. But Signal GPTA0_TRIG14 may be routed to all (100%) GTC and LTC cells due to the on-chip trigger and gating multiplexer and therefore fulfills this requirement already.
- GPTAv4 Signal GPTA0_OUT22 is no longer available in GPTAv5. This signal was routed to the ERU (TC1766 only) to cover 75% of the GTC and LTC cells as input to Input channel 3. But Signal GPTA0_TRIG16 may be routed to all (100%) GTC and LTC cells due to the on-chip trigger and gating multiplexer and therefore fulfills this requirement already.
- GPTAv4 Signal GPTA0_OUT25 is no longer available in GPTAv5. This signal was routed to the ERU to cover 50% of the GTC and LTC cells as input to Input channel 3. But Signal GPTA0_TRIG16 may be routed to all (100%) GTC and LTC cells due to the on-chip trigger and gating multiplexer and therefore fulfills this requirement already.
- GPTAv4 Signal GPTA0_OUT5 is no longer required (Time Trigger CAN) but GPTAv5 Signal GPTA0_TRIG05 is reserved for it.

- To improve effective usage of the Local Timer Cells, a new cell bypassing, so called global bypass, is introduced. This bypassing enables more flexible cell allocation and also reduces the number of LTC required for coherent update. Details on the two different Local Timer Cell Bypass mechanism may be found in the section **"Data Output Line Control" on Page 28-73**. Two different application examples using the global and local bypass may be found in **Section 28.3.3.5**(see **Page 28-85**). This new features is upwards compatible to the GPTAv4.
- Due to the new bypassing mechanism, a new coherent update mechanism has been introduced, the Local Coherent update described within **Section 28.3.3.5** (see **Page 28-85**). This new local coherent update or double action principle, is very useful to update single Local Timer Cells or a couple of Local Timer Cells within a Group sequentially (not simultaneously) without signal distortion (no other signal output beside the previously configured and the new configured). The new update principle allows to update a local timer cell within a group of local timer cells independent of other local timer cells and therefore also not synchronous/coherent to other local timer cells. This new mechanism upgrades the older mechanism of global coherent update. This older principle of global coherent is very useful to update a number of Local Timer Cells simultaneously. This new features is upwards compatible to the GPTAv4.
- The GPTA0/GPTA1, and LTCA2 OUTs are additionally assigned to new ports. Eight new outputs on Port 0, eight new outputs on Port 1, one new output on Port 2, two new outputs on Port 3, fourteen new outputs on Port 5, four new outputs on Port 14, sixteen new outputs on Port 13, and twelve new outputs on Port 14.
- To enable a family concept between TC1797 and TC1767, the GPTA to MSC Interconnection Assignment of MSC0 and MSC1 has been changed. Details can be found in **Section 28.7.4.2** (see **Page 28-287**).
- To fix a design bug for TC1797 and TC1767, the input line IN1 of the GPTA1 now switches the common input of GPTA0/GPTA1/LTCA2 units for connecting to the output of a 4-to-1 multiplexer. This multiplexer is controlled by bit field SCU_SYSCON.GPTAIS and allows the GPTA0/GPTA1/LTCA2 input IN1 to be connected to one out of four port input lines.
- GPTA1 provided the clock base for LTCA2 within the GPTAv4 version. This disables a family concept of products only having a GPTA0 and an LTCA2 (e.g. TC1767). Therefore GPTA0 is now used as clock source for the LTCA2 and GPTA1 is used as clock source for LTCA3.
- The common IN0 of GPTA0/GPTA1/LTCA2 is multiplexed within the SCU to connect either to a port pin or the EXTCLK0 (see **Page 28-296**).

28.2 GPTA®v5 Overview

The TC1798 contains the two General Purpose Timer Arrays (GPTA0 and GPTA1) with identical functionality, plus the additional Local Timer Cell Array (LTCA2). **Figure 28-1** shows a global view of the GPTA®v5 units.

The GPTA®v5 provides a set of timer, compare, and capture functionalities that can be flexibly combined to form signal measurement and signal generation cells. They are optimized for tasks typical of engine, gearbox, and electrical motor control applications, but can also be used to generate simple and complex signal waveforms required for other industrial applications.

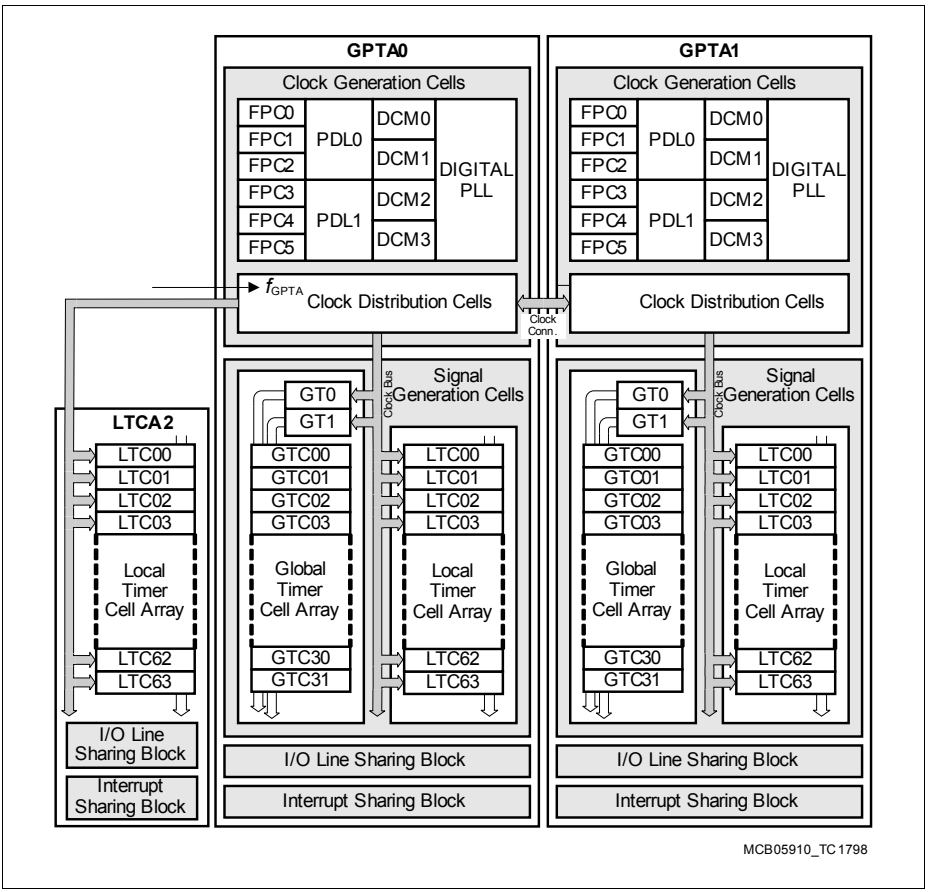

Figure 28-1 General Block Diagram of the GPTA®v5 units in the TC1798

28.2.1 Functionality of GPTA0 and GPTA1

The General Purpose Timer Arrays (GPTA0 and GPTA1) each provides a set of hardware cells required for high-speed digital signal processing:

- Filter and Prescaler Cells (FPC) support input noise filtering and prescaler operation.
- Phase Discrimination Logic cells (PDL) decode the direction information output by a rotation tracking system.
- Duty Cycle Measurement Cells (DCM) provide pulse-width measurement capabilities.
- A Digital Phase Locked Loop cell (PLL) generates a programmable number of GPTA®v5 unit ticks during an input signal's period.
- Global Timer cells (GT) driven by various clock sources are implemented to operate as a time base for the associated Global Timer Cells.
- Global Timer Cells (GTC) can be programmed to capture the contents of a Global Timer on an external or internal event. A GTC may also be used to control an external port pin depending on the result of an internal compare operation. GTCs can be logically concatenated to provide a common external port pin with a complex signal waveform.
- Local Timer Cells (LTC) operating in Timer, Capture, or Compare Mode may also be logically tied together to drive a common external port pin with a complex signal waveform. LTCs – enabled in Timer Mode or Capture Mode – can be clocked or triggered by various external or internal events.
- On-chip Trigger and Gating Signals (OTGS) can be configured to provide trigger or gating signals to integrated peripherals (GPTA0 only).

Input lines can be shared by an LTC and a GTC to trigger their programmed operation simultaneously.

The following list summarizes the specific features of the GPTA®v5 cells.

Clock Generation Cells

- Filter and Prescaler Cell (FPC)
  - Six independent cells
  - Three basic operating modes:
    Prescaler, Delayed Debounce Filter, Immediate Debounce Filter
  - Selectable input sources:
    Port lines, GPTA®v5 unit clock, FPC output of preceding FPC cell
  - Selectable input clocks:
    GPTA®v5 unit clock, prescaled GPTA®v5 unit clock, DCM clock, compensated or uncompensated PLL clock.
  - $f_{GPTA}/2$ maximum input signal frequency in Filter Modes
- Phase Discriminator Logic (PDL)
  - Two independent cells
  - Two operating modes (2- and 3- sensor signals)

  - f_{GPTA}/4 maximum input signal frequency in 2-sensor Mode, f_{GPTA}/6 maximum input signal frequency in 3-sensor Mode
- Duty Cycle Measurement (DCM)
  - Four independent cells
  - 0 - 100% margin and time-out handling
  - f_{GPTA} maximum resolution
  - f_{GPTA}/2 maximum input signal frequency
- Digital Phase Locked Loop (PLL)
  - One cell
  - Arbitrary multiplication factor between 1 and 65535
  - f_{GPTA} maximum resolution
  - f_{GPTA}/2 maximum input signal frequency
- Clock Distribution Cells (CDC)
  - One unit
  - Provides nine clock output signals:
    f_{GPTA}, divided f_{GPTA} clocks, FPC1/FPC4 outputs, DCM clock, LTC prescaler clock

Signal Generation Cells

- Global Timers (GT)
  - Two independent cells
  - Two operating modes (Free-Running Timer and Reload Timer)
  - 24-bit data width
  - f_{GPTA} maximum resolution
  - f_{GPTA}/2 maximum input signal frequency
- Global Timer Cell (GTC)
  - 32 cells related to the Global Timers
  - Two operating modes (Capture, Compare and Capture after Compare)
  - 24-bit data width
  - f_{GPTA} maximum resolution
  - f_{GPTA}/2 maximum input signal frequency
- Local Timer Cell (LTC)
  - 64 independent cells
  - Three basic operating modes (Timer, Capture and Compare) for 63 cells
  - Special compare modes for one cell
  - 16-bit data width
  - f_{GPTA} maximum resolution
  - f_{GPTA}/2 maximum input signal frequency

Interrupt Sharing Block

- 318 interrupt sources, generating up to 108 service requests

On-chip Trigger Block

- 16 on-chip trigger signals

I/O Sharing Block

- Interconnecting inputs and outputs from internal clocks, FPC, GTC, LTC, ports, and MSC interface

28.2.2 Functionality of LTCA2

The Local Timer Cell Array (LTCA2) provide a set of hardware cells required for high-speed digital signal processing:

- Local Timer Cells (LTC) operating in Timer, Capture, or Compare Mode may also be logically tied together to drive a common external port pin with a complex signal waveform. LTCs – enabled in Timer Mode or Capture Mode – can be clocked or triggered by various external or internal events.

The following list summarizes the specific features of the LTCA cells.

Signal Generation Cells

- Local Timer Cell (LTC)
  - 64 independent cells
  - Three basic operating modes (Timer, Capture and Compare) for 63 cells
  - Special compare modes for one cell
  - 16-bit data width
  - f_{GPTA} maximum resolution
  - f_{GPTA}/2 maximum input signal frequency

I/O Sharing Block

- Interconnecting inputs and outputs from internal clocks, LTC, ports, and MSC interface

28.3 GPTA0/GPTA1 Kernel Description

The functionality of the General Purpose Timer Arrays GPTA0/GPTA1 kernel is described in this section. Clock control, address decoding, and service (interrupt) request control are managed outside the GPTA0/GPTA1 unit kernel.

Figure 28-2 shows a global unit diagram of the GPTA®v5 unit kernel.

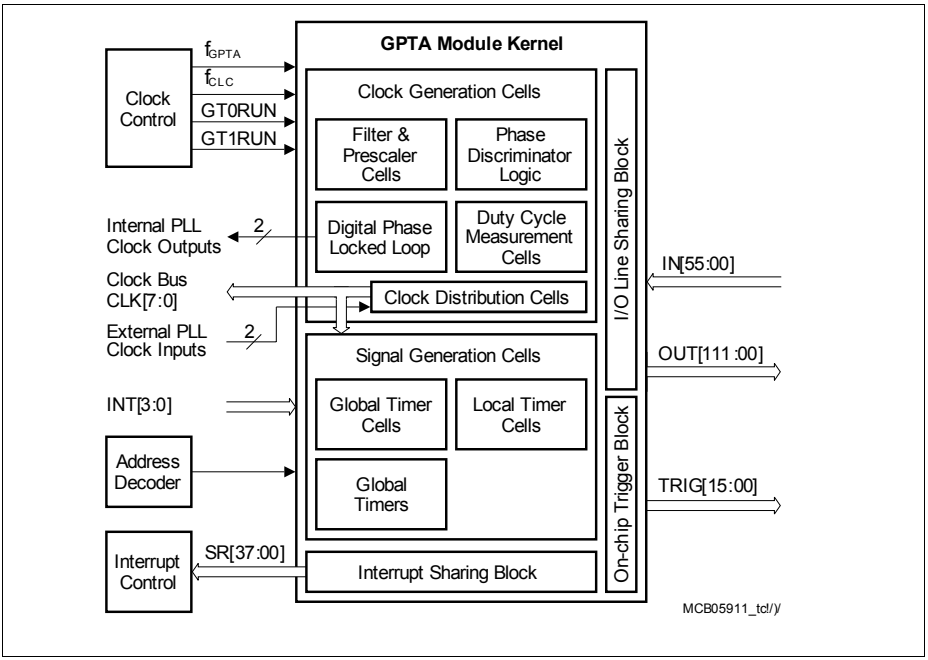

Figure 28-2 Block Diagram of GPTA®v5 Kernel

Each GPTA0/1 kernel has 56 input signals, 112 output signals, and four input signals, that can be connected to port pins or other on-chip logic modules (see **"GPTA®v5 Module Implementation" on Page 28-274** for the TC1798 specific interconnections). Further, several clock input and output signals are provided.

28.3.1 GTPA Units

Each of the General Purpose Timer Arrays GPTA0 and GPTA1 (**Figure 28-2**) is split into Clock Generation Cells (CGC) and a Signal Generation Cells (SGC):

- The **Clock Generation Cells** (see **Page 28-10**) allow a preprocessing of the input signals using filter, timer, capture, compare and enhanced digital PLL cells:
  - The **Filter and Prescaler Cells** (FPC) provide input noise filtering (Immediate Debounce and Delayed Debounce) and may also work as prescalers for the GPTA®v5 module clock and external signals.
  - The **Phase Discrimination Logic** (PDL) may take the outputs of the FPCs to decode phase encoded signals from a position and rotation direction sensor system.
  - The **Duty Cycle Measurement Cells** (DCM) provide signal measurement capabilities (timer plus capture register, single and double capture on rising and falling edges or both) as well as missing pulse detection/reconstruction functions.
  - The **Digital Phase Locked Loop** (Digital PLL) generates a clock with higher clock resolution (harmonic) out of the signal measured by DCM cells. Any arbitrary multiplication factor between 1 and 65535 is supported and may be changed each PLL clock period.
  - The **Clock Distribution Cells** (CDC) provide all LTCs and GTs with a variety of different clock signals. It is equipped with GPTA®v5 module clock prescalers and multiplexers supporting alternate clock sources.

The original signals and all outputs of the preprocessing cells are distributed to the Global Timers and LTCs via the clock bus.

- The **Signal Generation Cells** (see **Page 28-38**) provide a set of timers, capture and compare cells:
  - The two 24-bit **Global Timers** (GT) can be individually configured as free-running counters or as reload counters starting at a programmable value from 0_H to $FFFFFF_H$. Each GT is equipped with a scalable greater-or-equal comparator; the number of bits to be compared is selectable.
  - The **Global Timer Cell** registers (GTC) are 24-bit wide. GTCs may be used as comparators (modifying the logical state of a related output port pin), or as capture cells, storing the current GT0 or GT1 value on rising, falling or both signal edges detected on a related input port pin. Several adjacent GTCs may be connected to logical cells operating on the same pin, allowing complex functions to be implemented.
  - The **Local Timer Cell** registers (LTC) are 16-bit wide. 63 LTCs can be configured to operate in one of four different modes: free-running or resetable counter, capture or compare cell. Adjacent cells can be combined to operate on the same pin, thus generating complex waveforms. One LTC (LTC63) can be used for special compare modes.

28.3.2 Clock Generation Cells

As described in detail in the following sections, the Clock Generation Cells (CGC) provides the following signal pre-processing cells:

- Filter and Prescaler Cell (FPC)
- Phase Discrimination Logic (PDL)
- Duty Cycle Measurement cell (DCM)
- Digital Phase Locked Loop Cell (PLL)
- Clock Distribution Cells (CDC)

The **Filter and Prescaler Cells** (FPC) provide input noise filtering using a debounce filter. FPCs are also able to operate as a prescaler for the GPTA®v5 module clock and external signals. Each FPC can select among different data and clock input signals.

The **Phase Discrimination Logic** (PDL) is able to decode FPC debounce filtered and phase encoded signals coming from a position and rotation direction sensor system. In the PDL, phase encoding can be bypassed.

The **Duty Cycle Measurement Cells** (DCM) provide signal measurement capabilities (timer plus capture register, single and double capture on rising and falling edges or both) as well as missing pulse detection/reconstruction functions.

The **Digital Phase Locked Loop** (PLL) is intended to generate a higher resolution clock out of the values measured by DCM cells. Any arbitrary multiplication factor between 1 and 65535 is supported and may be changed from input clock period to input clock period.

The **Clock Distribution Cells** (CDC) provide all Local and Global Timer Cells with a variety of different clock signals. It is equipped with GPTA®v5 module clock prescalers and multiplexers supporting alternate clock sources.

Figure 28-3 shows how the cells of the CGC are interconnected. The external interface signals of the CGC are:

- GPTA®v5 module clock f_{GPTA}
- GPTA®v5 module input signals (connected to the FPCs)
- Clock bus outputs (generated by the CDC)
- PDL bus outputs
- External PLL clock inputs (fed into CDC)

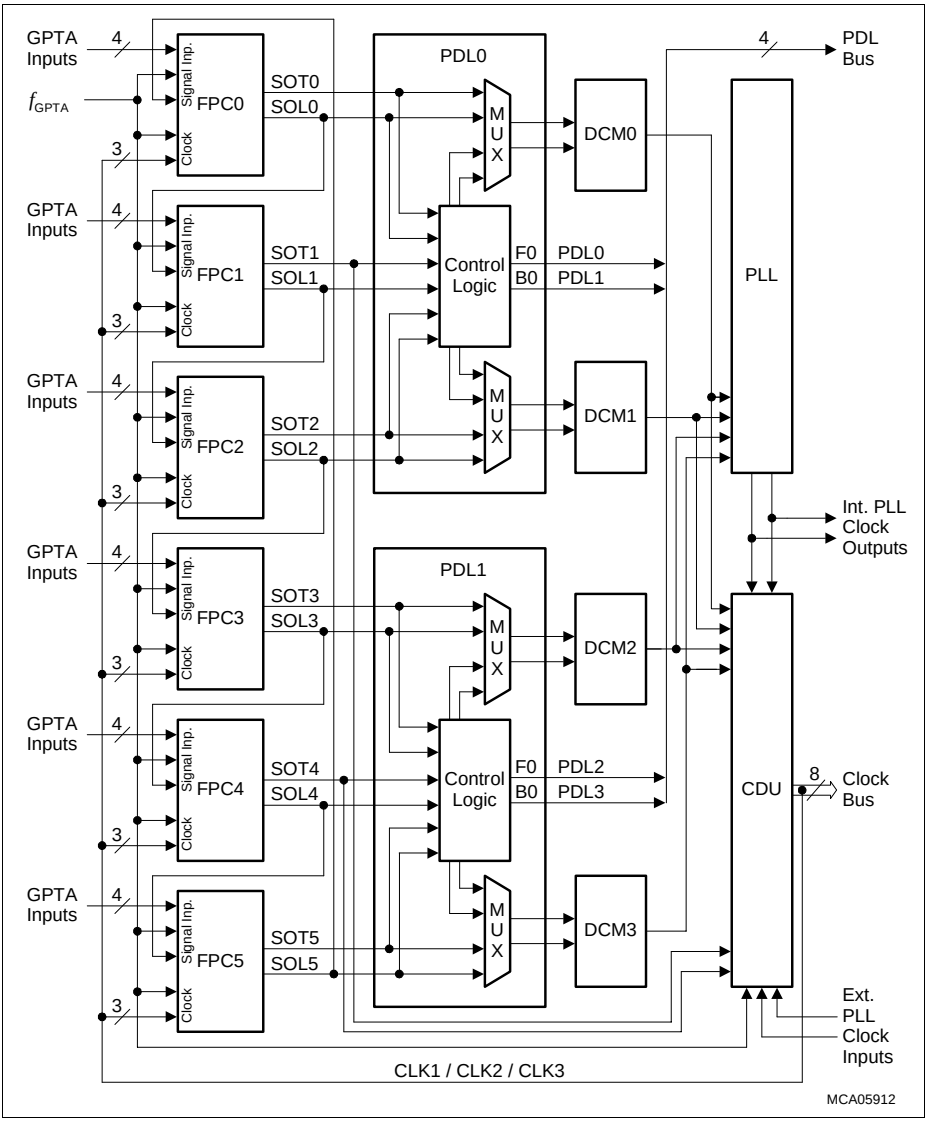

Figure 28-3 Interconnections in the Clock Generation Cells

28.3.2.1 Filter and Prescaler Cell (FPC)

Each GPTA®v5 contains six filter and prescaler cells, FPC0 to FPC5. As shown in **Figure 28-4**, each FPC is equipped with an signal input multiplexer, a clock multiplexer, an edge detection circuitry, a 16-bit timer, a 16-bit compare register, a 16-bit comparator, and a FPC control circuitry (see also **Page 28-126** for the FPC functional algorithm description). The edge detection circuitry detects respective edges for the prescaler modes and detects glitches in all other modes.

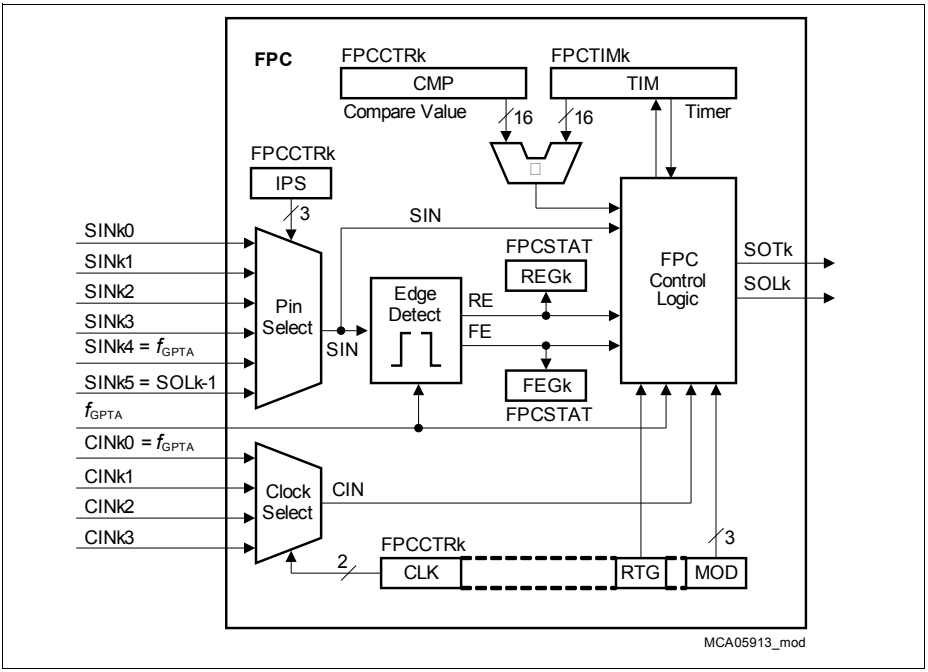

Figure 28-4 Filter and Prescaler Cell Architecture

FPC Registers

The following registers are assigned to the filter and prescaler cells FPCk (k = 0-5):

- FPCSTAT = Filter and Prescaler Cell Status Register (see **Page 28-167**)
- FPCCTRk = Filter and Prescaler Cell Control Register k (see **Page 28-168**)
- FPCTIMk = Filter and Prescaler Cell Timer Register k (see **Page 28-170**)

FPC Operating Modes

Each filter and prescaler cell can be individually configured to operate in one of the following operating modes:

- Delayed Debounce Filter Mode on both edges
- Immediate Debounce Filter Mode on both edges
- Rising edge: Immediate Debounce Filter Mode, falling edge: No filtering
- Rising edge: No filtering, falling edge: Immediate Debounce Filter Mode
- Rising edge: Delayed Debounce Filter Mode, falling edge: Immediate Debounce Filter Mode
- Rising edge: Immediate Debounce Filter Mode, falling edge: Delayed Debounce Filter Mode
- Prescaler Mode (triggered by edge detection circuitry on rising edge)
- Prescaler Mode (triggered by edge detection circuitry on falling edge)

The operation mode is selected by bit field FPCCTRk.MOD (**Page 28-168**).

FPC Input Signals

Bit field FPCCTRk.IPS (see **Page 28-168**) selects one of the following inputs for FPCk:

- Signal input 0 (SINk0)
- Signal input 1(SINk1)
- Signal input 2 (SINk2)
- Signal input 3 (SINk3)
- GPTA®v5 module clock f_{GPTA} (SINk4)
- Preceding FPC level output signal SOLk-1 (SIN05 is connected to SOL5)

When the preceding FPC level output signal is selected as input, two or more FPCs may be concatenated; for example, to combine a delayed debounce filter and an immediate debounce filter.

The maximum FPC input signal frequency must be less than or equal to the sampling rate ($f_{GPTA}/2$). The assignment of GPTA®v5 I/O line and FPC signal inputs SINk is defined in **“FPC Input Line Selection” on Page 28-102**.

FPC Filter Clocks

Bit field FPCCTRk.CLK (see **Page 28-169**) selects one of four filter clocks for FPCk:

- Clock input line 0 (CINk0) = GPTA®v5 module clock f_{GPTA}
- Clock input line 1 (CINk1) = local PLL clock,
- Clock input line 2 (CINk2) = (prescaled) GPTA®v5 module clock f_{GPTA} or PLL clock from other unit or DCM 3 clock
- Clock input line 3 (CINk3) = DCM 2 clock or PLL clock of other unit or uncompensated PLL clock or uncompensated PLL clock of other unit

When using a PLL clock for the FPC, no software is needed to adapt the FPC filter to changing speed for angle-based input signals. The standard PLL clock can be either the

compensated or uncompensated PLL clock or can be the PLL clock of the other GPTA®v5 units. The uncompensated PLL clock is useful in applications in which bursts (due to acceleration) might disturb the filter function.

With a prescaled GPTA®v5 module clock, very long time filter time periods can be achieved.

Note: All filter operation are always synchronously to f_{GPTA}. Therefore the further signal analysis (e.g. glitch detection) is not processed on the rising edge of the selected filter clock CIN, but on the next rising edge of f_{GPTA} following the rising edge of selected CIN (gated clock principle). Therefore CIN clock rates above f_{GPTA} will lead to non deterministic behavior.

Output Signal Splitting

Two output lines are provided by each FPC cell as follows:

- An trigger output signal SOTk, reporting a falling or rising signal edge on the FPC input by a single f_{GPTA} clock pulse,
- A level output signal SOLk, indicating the direction of the detected signal transition.

This signal-splitting scheme (pair of trigger and level output) provides subsequent PDL and DCM cells with the information about an input signal transition in the same f_{GPTA} clock cycle. This feature avoids cascading a one clock delay per edge detection circuitry implemented at the input of each subsequent cell. **Figure 28-5** shows the FPC output signal splitting scheme.

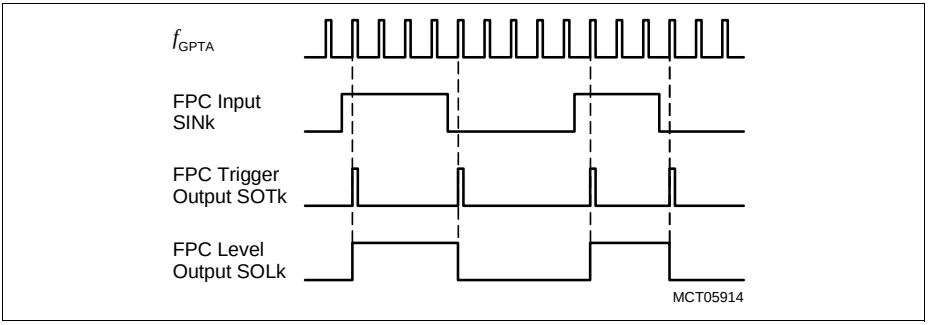

Figure 28-5 FPC Output Splitting into Trigger and Level Information

Delayed Debounce Filter Mode

In Delayed Debounce Filter Mode, the signal input SIN is filtered from all signal transitions and glitches with a width smaller than the selected clock period length multiplied by the compare register value.

The input signal SIN (sampled with f_{GPTA}) is analyzed at the selected filter clock rate of CIN. If the state of the input sample differs from the current output signal value, the 16-bit timer is incremented by one. When the timer register FPCTIMk is not in its idle state (0000_H) **and** the state of the input sample matches the current output signal value, the 16-bit timer is decremented by one (see **Figure 28-6**); if bit FPCCTRk.RTG is set, the timer will be set to idle state again (see **Figure 28-7**). A rising or falling edge, occurring on the signal input line SIN when the timer is greater than zero but less than the compare value, sets the corresponding glitch flag FPCSTAT.REG (on rising edge glitch) or FPCSTAT.FEG (on falling edge glitch). When the timer matches the 16-bit compare value stored in FPCCTRk.CMP (timer threshold), the level output signal line SOLk is inverted, a GPTA®v5 module clock pulse is generated at the trigger output signal SOTk, and the timer is reset to 0000_H. The rising/falling edge glitch flags must be reset by software.

The filter is by-passed if the compare value FPCCTRk.CMP is programmed to zero (0000_H). In this case, the input signal is directly copied to the output signal.

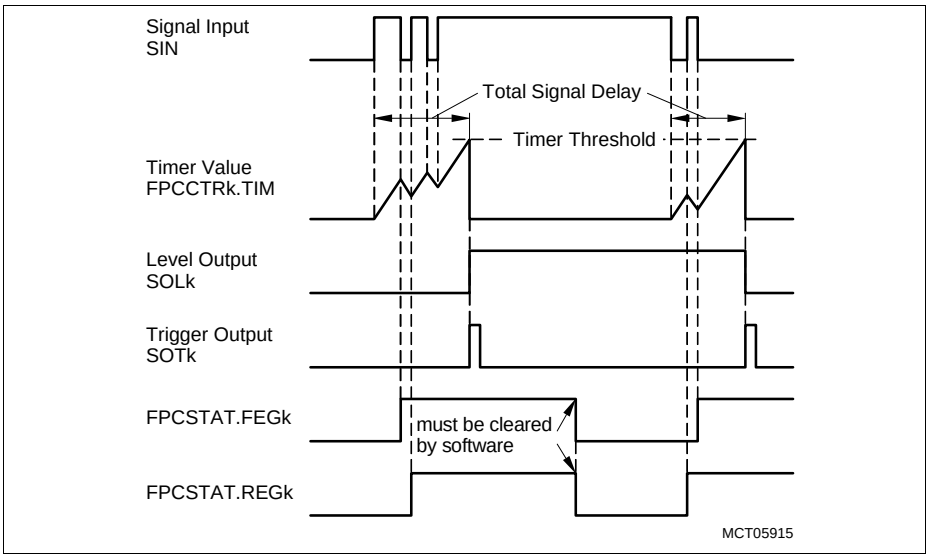

Figure 28-6 FPC Delayed Debounce Filter Algorithm with Timer Decrement

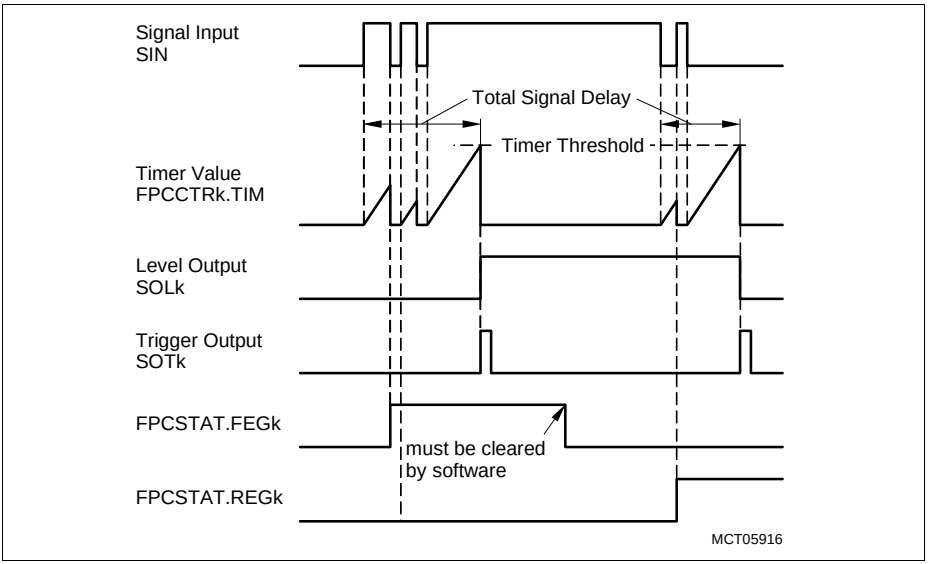

Figure 28-7 FPC Delayed Debounce Filter Algorithm with Timer Reset

The total signal delay from input to output depends on the programmed compare register value, the number of high-frequency pulses (glitches) during the filter operating time, and the timer behavior in case of a glitch (decrement or reset).

The FPC Delayed Debounce Filter Mode is selected by:

- FPCCTRk.MOD = 000_B

Immediate Debounce Filter Mode

In Immediate Debounce Filter Mode, the input signal is filtered from signal transitions and glitches arriving a programmable time after an input signal edge detection (see **Figure 28-8**).

The input signal SIN is sampled with f_{GPTA} and the input signal SIN edge detection is also performed with f_{GPTA}. The further analysis (e.g. filter timer increment, glitch detection) is done at the selected filter clock rate of CIN.

As long as the timer is reset, the FPC control circuitry copies the sampled input value directly to the level output signal line SOLk. When a rising or falling edge occurs on the signal input line SIN and the 16-bit compare value FPCCTRk.CMP is not zero, the timer is enabled to be incremented by the selected clock and the copy mechanism is disabled. When the timer value FPCTIMk.TIM matches the compare value FPCCTRk.CMP, the timer is reset and the copy mechanism is enabled again. A rising or falling edge, occurring on SIN while the timer is greater than zero but less than the compare value, sets the corresponding glitch flag FPCSTAT.REG (on rising edge glitch) or FPCSTAT.FEG (on falling edge glitch). The rising/falling edge glitch flags must be reset by software.

The filter is by-passed if the compare value FPCCTRk.CMP is programmed to zero (0000_H). In this case, the input signal is directly copied to the output signal without any disable periods.

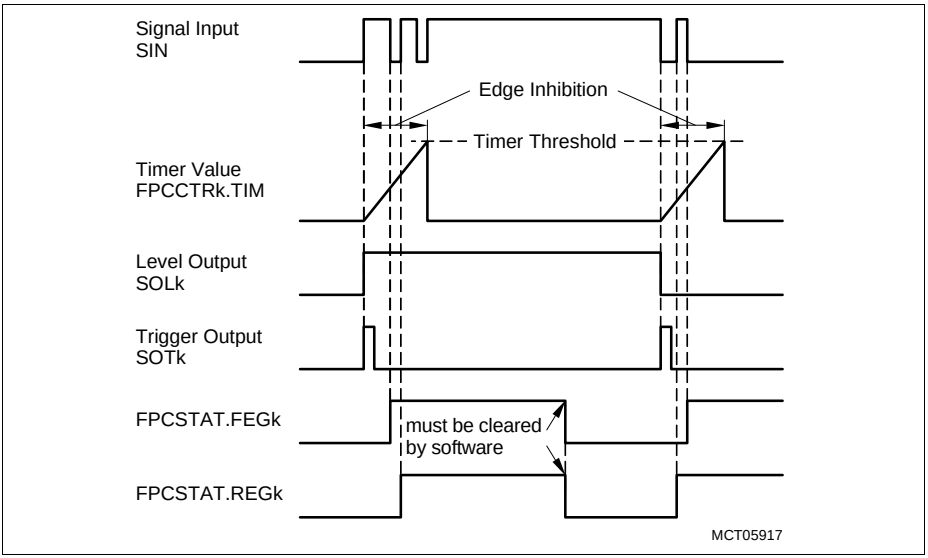

Figure 28-8 FPC Immediate Debounce Filter Algorithm on Both Edges

Note: During the last clock cycle of edge inhibition time (where timer value is equal to the compare value) an input signal glitch will be filtered but the corresponding glitch status flag in register FPCSTAT is not set.

The Immediate Debounce Filter can be enabled only for one edge, either rising or falling. In this case, the signal output follows the signal input value immediately after the timer threshold of the filtered edge is reached, without re-starting the timer (see **Figure 28-9**).

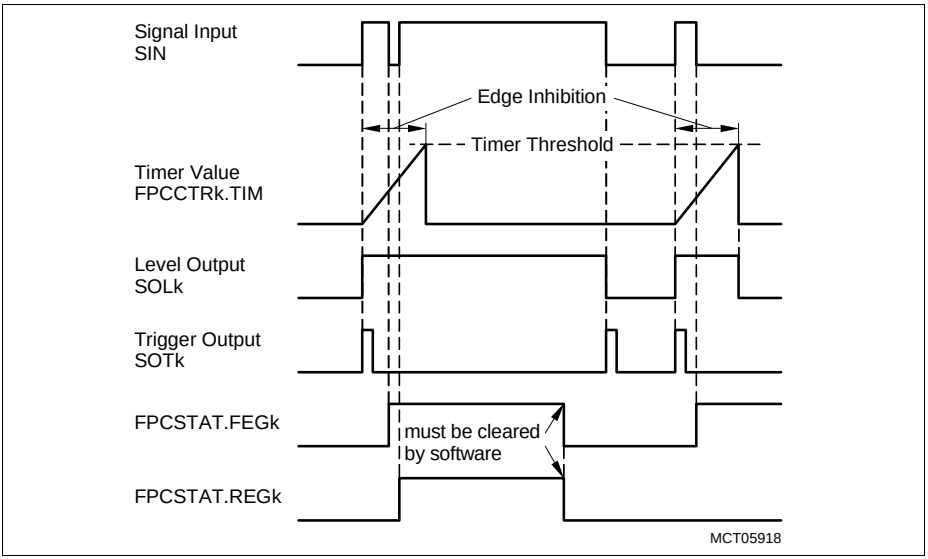

Figure 28-9 FPC Immediate Debounce Filter Algorithm on Rising Edge only

The FPC Immediate Debounce Filter Modes are selected by:

- FPCCTRk.MOD = 001_B: Immediate Debounce Filter Mode on both edges
- FPCCTRk.MOD = 010_B: Immediate Debounce Filter Mode on rising edge only, no filtering on falling edge.
- FPCCTRk.MOD = 011_B: Immediate Debounce Filter Mode on falling edge only, no filtering on rising edge.

Mixed Filter Modes

In the Mixed Filter Modes, one edge of a signal is filtered in the Delayed Debounce Mode, and the other edge is filtered in the Immediate Debounce Mode. The Debounce Mode is switched when the timer threshold is reached. Note that both filter modes use the same timer threshold in this case (see **Figure 28-10**, demonstrating Delayed Debounce Mode with Timer Decrement on Rising Edge and Immediate Debounce of on Falling Edge).

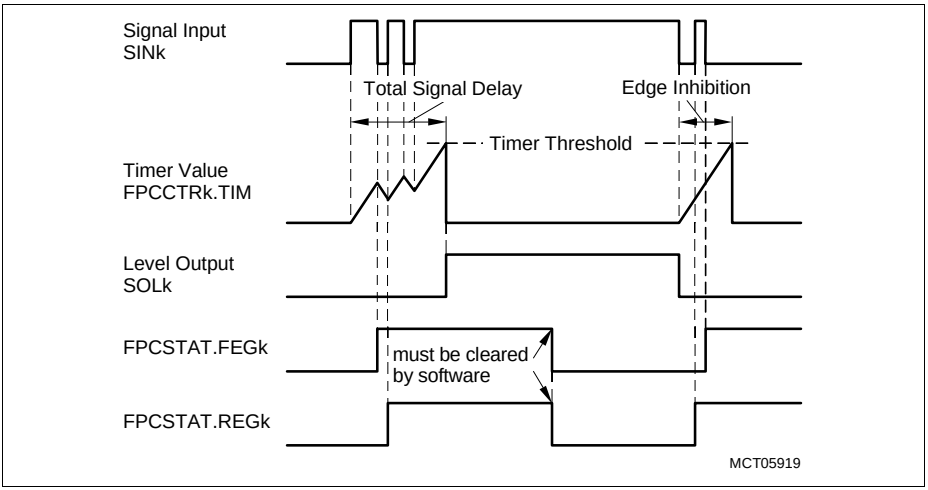

Figure 28-10 FPC Mixed Filter Algorithm

The FPC Mixed Filter Modes are selected by:

- FPCCTRk.MOD = 100_B: Delayed Debounce Filter Mode on rising edge
  Immediate Debounce Filter Mode on falling edge
- FPCCTRk.MOD = 101_B: Immediate Debounce Filter Mode on rising edge
  Delayed Debounce Filter Mode on falling edge

Prescaler Mode

In Prescaler Mode, the input signal is sampled and analyzed with f_{GPTA}. The FPC control circuitry counts each rising (or falling) edge of the input signal. When the timer value matches the compare value:

- one GPTA®v5 module clock pulse is generated at the trigger output signal SOTk and level output signal SOLk
- the timer FPCTIMk.TIM is reset to 0000_H

Figure 28-11 shows a divide-by-6 operation using the FPC in Prescaler Mode with trigger on rising edge selected.

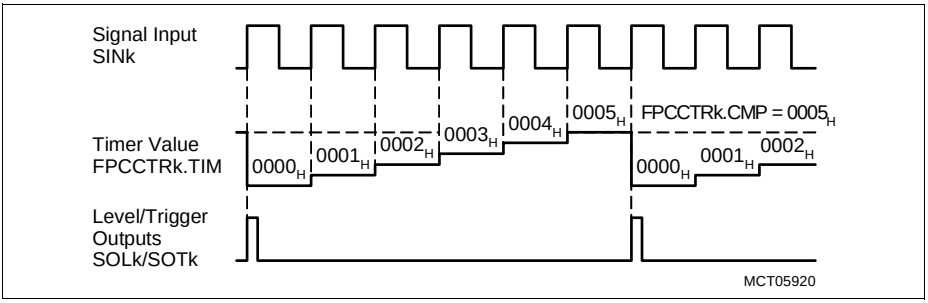

Figure 28-11 FPC Prescaler Mode

For a divide-by-n operation, the compare value FPCCTRk.CMP must be set to n - 1.

The FPC Prescaler Modes are selected by:

- FPCCTRk.MOD = 110_B: Prescaler Mode triggered by edge detection circuitry on rising edge
- FPCCTRk.MOD = 111_B: Prescaler Mode triggered by edge detection circuitry on falling edge

28.3.2.2 Phase Discrimination Logic (PDL)

The GPTA®v5 provides two Phase Discrimination Logic cells (PDL0, PDL1) driven by two signal lines coming from an FPC cell (for description, see Page 28-14):

- An event input signal
- A level input signal

Both Phase Discrimination Logic cells are controlled by the Phase Discrimination Logic Control Register PDLCTR (see Page 28-171).

Each PDL is equipped with an edge detection circuitry, a phase detection circuitry, a PDL control circuitry, and an output multiplexer. Six output lines are provided by each PDL Cell:

- A forward output signal (F0, F1) is driven by one f_{GPTA} clock pulse if an input signal edge is recognized as forward rotation. These signals can be connected to any Local Timer Cell via the PDL bus.
- A backward output signal (B0, B1) is driven by one f_{GPTA} clock pulse if an input signal edge is recognized as backward rotation. This signal can be connected to any Local Timer Cell via the PDL bus.
- Two pairs of output signals, carrying the bypassed input level and event information from the driving FPC cells or the angular velocity and error information provided by the PDL function. These output lines are directly connected to the adjacent Duty Cycle Measurement Cells, DCM0/DCM1(for PDL0) and DCM2/DCM3 (for PDL1).

The PDL processes the output signal of a 2-sensor or 3-sensor positioning system. With bit PDLCTR.TSEx = 1, a 3-sensor system execution is selected providing the DCM1 and/or DCM3 cell with information concerning erroneous states in the signal input. When PDLCTR.TSEx = 0, a 2-sensor system is selected and DCM1 and/or DCM3 are supplied with the input event and level information from the driving FPC2 and/or FPC5.

The rotation direction, monitored by the connected sensors, is automatically derived from the sequence in which the input signals change. Each edge detected on an input signal line generates a pulse on the F0, F1 forward output lines or on the B0, B1 backward output lines. Input jitter, which might occur if a sensor rests near to one of its switching points, is compensated.

If bit PDLCTR.MUXx = 1, the trigger output signal to DCM0/DCM2 (angular velocity information) is driven by a boolean ‘OR’ operation of the corresponding forward trigger and backward trigger signal while the level output signal at DCM0/DCM2 is at fixed high level. In this case, every pulse at F0/B0 and F1/B1 generates a rising edge at the DCM0/DCM trigger signal.

If bit PDLCTR.MUXx = 0, the associated DCM0/DCM2 signals are directly connected with the input event and level signals from the driving FPC0/FPC3.

To calculate the sensor’s current position, the associated LTCs should be clocked with the PDL forward and backward output pulses. A software operation, subtracting the backward counter contents from the forward counter contents, provides the absolute

position. Dynamic information (speed, acceleration, deceleration) may be obtained by analyzing the angular velocity signal periods with the associated DCM cell.

The maximum input frequency is $f_{GPTA}/4$ for a 2-sensor positioning system and $f_{GPTA}/6$ for a 3-sensor positioning system. To ensure that a transition of any input signal is correctly recognized, its level should be held high or low for at least two f_{GPTA} cycles before it changes (three f_{GPTA} cycles for a 3-sensor positioning system).

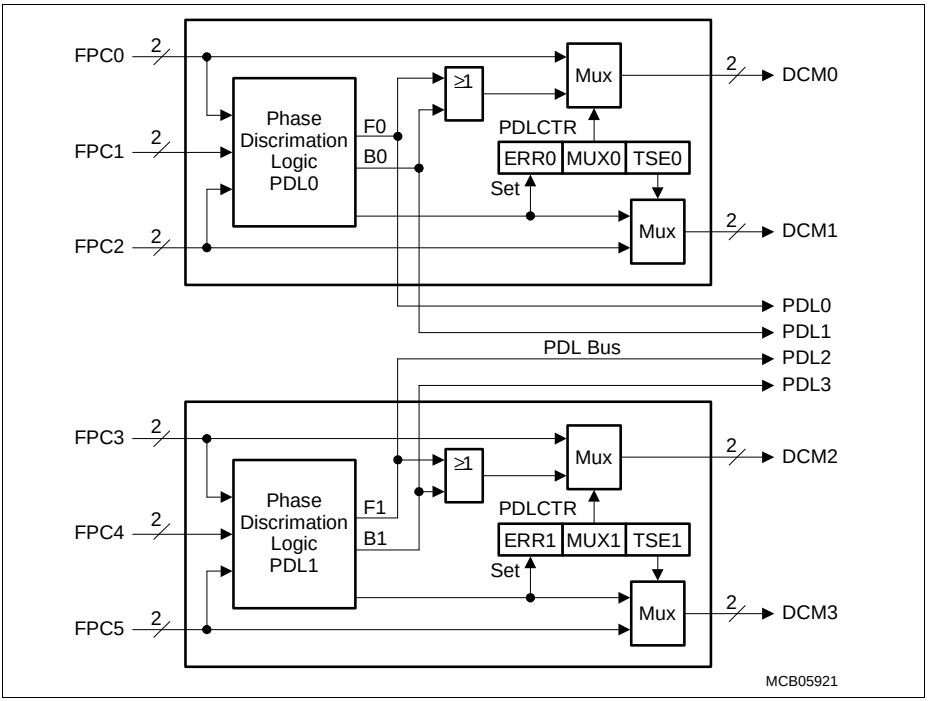

Figure 28-12 Block Diagram of Phase Discrimination Logic Cells

Positioning System With Two Sensors

The 2-sensor Mode is enabled when bit PDLCTR.TSEx is reset. The sensors are mounted at a 90° angle to each other (see **Figure 28-13**). The third sensor input of the PDL cell is internally disabled and DCM1/DCM3 cell inputs are driven by fed-through FPC2/FPC5 output lines.

This configuration can measure an absolute position with a resolution of 90°. No error conditions can be detected.

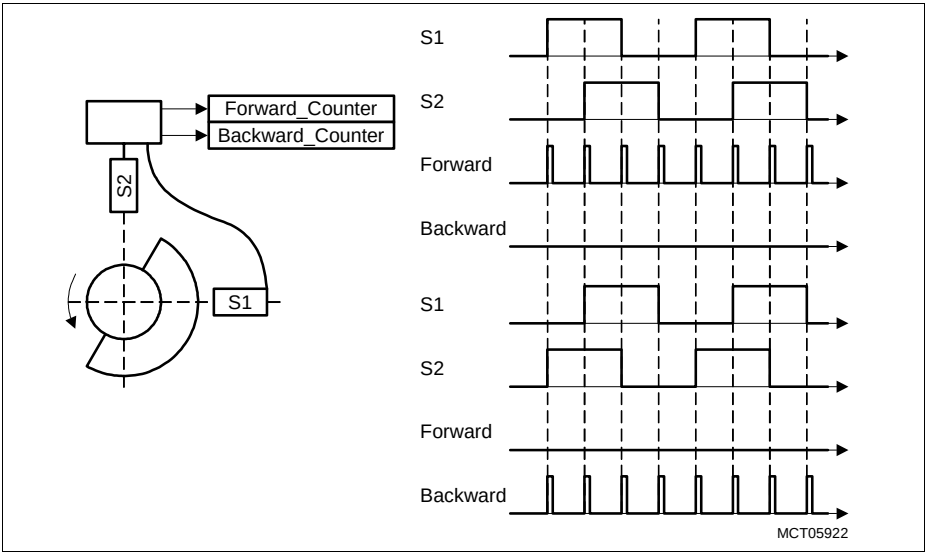

Figure 28-13 Interface Signals of a PDL in a 2-Sensor Positioning System

Figure 28-14 illustrates how the output signals of a 2-sensor system superimposed with noise are processed by the PDL cell. Jitter pulses are completely compensated if they do not occur on both signal lines simultaneously.

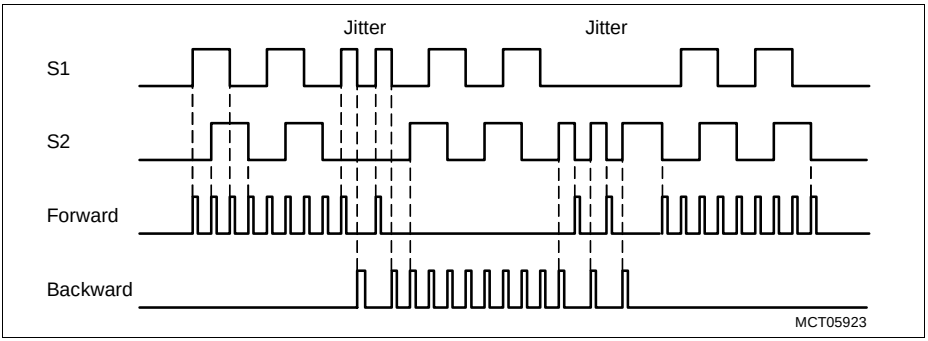

Figure 28-14 Compensation of Input Jitter

Positioning System with Three Sensors

The 3-sensor Mode is enabled when bit PDLCTR.TSEx is set to 1. The sensors are mounted at an 120° angle to each other (see **Figure 28-15**). This configuration can measure an absolute position with a resolution of 60°.

Input signal combinations that are not allowed in a properly-working positioning system (all inputs low or all inputs high) cause the following to occur:

- An error signal is generated, driving the Duty Cycle Measurement cells DCM1 and/or DCM3,
- The error flag PDLCTR.ERRx is set,
- No forward or backward pulses are generated.

When the error disappears, the error signal will be cleared. The error flag PDLCTR.ERRx must be reset by software.

Jitter pulses are completely compensated as illustrated in **Figure 28-14**.

28.3.2.3 Duty Cycle Measurement Cell (DCM)

The GPTA®v5 contains four DCM cells (DCM0 to DCM3). The input signal to be analyzed is delivered as a 2-line signal input (see **Figure 28-5** for the event/level input signal splitting scheme). It is build by:

- An event input, and
- A signal level input.

Each DCM cell has four outputs:

- An event output line,
- An interrupt output that can become active at a signal input rising edge,
- An interrupt output that can become active at a signal input falling edge,
- An interrupt output that can become active at a compare event.

Each DCM cell is equipped with a 24-bit timer, a 24-bit capture register, a 24-bit capture/compare register, a 24-bit comparator and a DCM control circuitry (**Figure 28-16**).

The following registers are assigned to the DCM cells:

- DCMCTRk = Duty Cycle Measurement Control Register k (see **Page 28-173**)
- DCMTIMk = Duty Cycle Measurement Timer Register k (see **Page 28-175**)
- DCMCAVk = Duty Cycle Measurement Capture Register k (see **Page 28-175**)
- DCMCOVk = Duty Cycle Measurement Capture/Compare Register k (also referred as “CAPCOM”, see **Page 28-176**)
- SRSC0 = Service Request State Clear Register 0 (see **Page 28-223**)
- SRSS0 = Service Request State Set Register 0 (see **Page 28-225**)

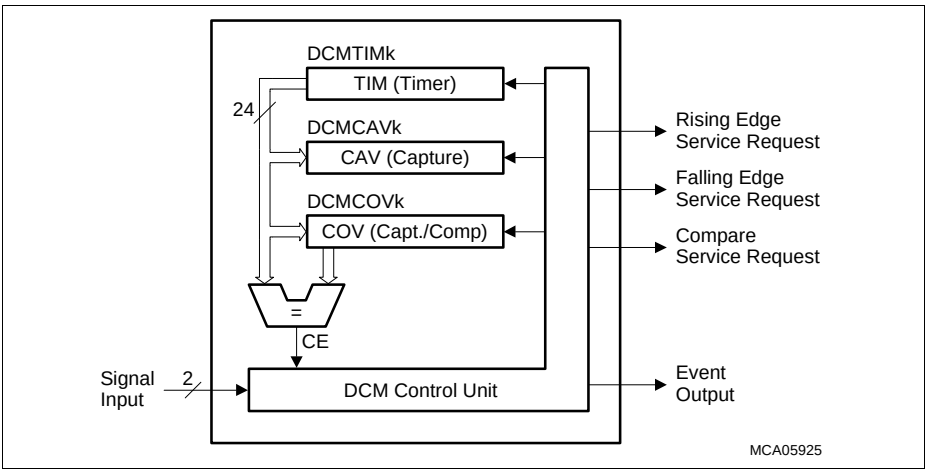

Figure 28-16 Block Diagram of a Duty Cycle Measurement Cell

The DCM cell inputs are connected to the PDL outputs. Depending on the configuration of the associated PDL cell, the DCM cells can also be driven by a FPC directly (as shown in **Figure 28-12**):

- DCM0 is driven by FPC0 or PDL0 angular velocity signal,
- DCM1 is driven by FPC2 or PDL0 error signal,
- DCM2 is driven by FPC3 or PDL1 angular velocity signal,
- DCM3 is driven by FPC5 or PDL1 error signal.

When the driving FPCs and PDL cells are programmed in feed-through mode, an external port pin signal as selected by the FPC input multiplexer can be directly processed by a DCM cell.

The duty cycle of the DCM cell signal input can be determined by measuring its period length and the width of its low or high state. For this purpose, several operations can be started on an signal input edge:

- **Reset Timer**
  The local timer can be reset on rising, falling, or both edges of the signal input line as selected via control bits DCMCTRk.RZE (for rising edge) and DCMCTRk.FZE (for falling edge). After a reset timer event, the timer is continuously incremented by the GPTA®v5 module clock f_{GPTA} until the next reset condition occurs. If no reset timer event is enabled, the timer operates in Free-Running Timer Mode, repeatedly counting from its lower limit (000000_H) to its upper limit ($FFFFFF_H$).
- **Capture**
  The current timer value is stored in the capture register DCMCAV on the rising edge (DCMCTR.RCA = 1) or falling edge (DCMCTRk.RCA = 0) of the signal input line.
  The current timer value is stored in the capture/compare register DCMCOV on the opposite signal edge as selected by DCMCTRk.RCA and if enabled by bit DCMCTRk.OCA = 1. With DCMCTRk.OCA = 0 the capture/compare register DCMCOV is not affected.
- **Edge Service Request and Interrupt Request**
  On a rising input signal edge of the DCMk cell (k = 0-3) the service request flag SRS0.DCM0kR is set. Additionally, a service request signal is triggered if bit DCMCTRk.RRE = 1. A falling input signal edge sets the service request flag SRS0.DCM0kF. An interrupt request generation on this edge is triggered if bit DCMCTRk.FRE = 1. Both edges of the signal input line initiate an interrupt request when both bits, DCMCTRk.FRE and DCMCTRk.RRE, are set. The interrupt on signal input edges is disabled if both bits are cleared.
- **Hardware Generated Output Pulse**
  A single f_{GPTA} clock pulse is generated on the DCM output line if enabled by control register bit DCMCTRk.RCK (rising edge at signal line) and/or DCMCTRk.FCK (falling edge at signal line) and an appropriate edge is detected at the input.
  The 0% or 100% duty cycle exception (no edge or only one edge detected) can be handled by a **limit checking** option. The expected input signal's maximum period length (measured in f_{GPTA} clock ticks) can be loaded into the capture/compare

register DCMCOV that is continuously compared with the timer value. When the timer is incremented up to the limit stored in capture/compare register, the service request flag SRS0.DCM0xC is set. If the compare service request is enabled (control register bit DCMCTRk.CRE = 1), an interrupt request is generated.

- **Software Generated Output Pulse**
  If the **software** intends to compensate an input pulse backlog, bit DCMCTRk.QCK should be set to 1. This immediately triggers a single **clock pulse generation** on the DCM output signal line.

DCM Interrupt Control

Each DCM cell is able to generate three service request output signals. The service request outputs of a DCMk cell are controlled as shown in **Figure 28-17**. When a service request condition occurs, the corresponding service request flag is always set. The service request output is activated only if it is enabled by the corresponding enable bit. Further details on service request and interrupt handling are provided in section **"Interrupt Sharing Block (IS)" on Page 28-123**.

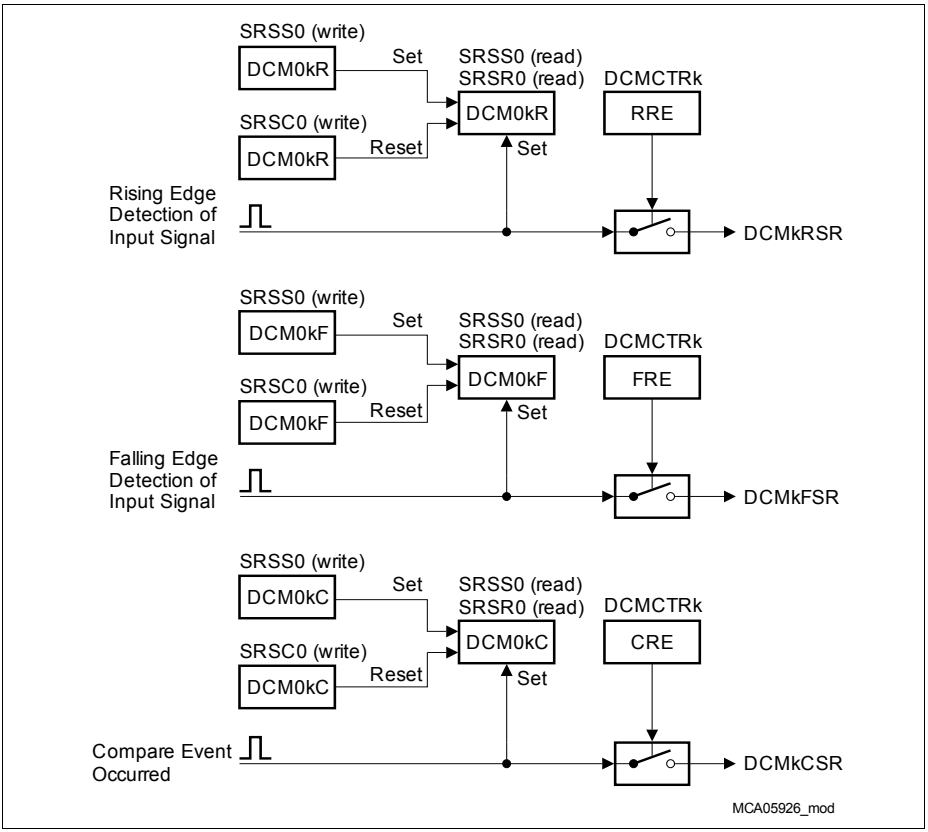

Figure 28-17 DCMk Service Request Generation

28.3.2.4 Digital Phase Locked Loop Cell (PLL)

The GPTA®v5 provides a digital Phase Locked Loop cell (PLL) with a frequency multiplier function. An input signal edge is used as a trigger to generate a programmable number of GPTA®v5 module clocks f_{GPTA} on the output signal line. The four signal output lines of the DCM cells can be used as PLL trigger input. The PLL control circuitry distributes the desired number of GPTA®v5 clocks in regular time intervals over the input signal period length. The PLL can automatically follow an acceleration or deceleration of the input signal. Alternatively, an external software routine may handle the input signal's period length variation.

The PLL includes a 4-channel input multiplexer, a 16-bit timer, a 16-bit step register, a 24-bit reload register, a 24-bit adder, a 24-bit multiplexer, a 25-bit delta register extended by one sign bit and a PLL control circuitry (see **Figure 28-18**).

The following registers are assigned to the Phase Locked Loop cell:

- PLLCTR = Phase Locked Loop Control Register (see **Page 28-177**)
- PLLMTI = Phase Locked Loop Microtick Register (see **Page 28-178**)
- PLLCNT = Phase Locked Loop Counter Register (see **Page 28-179**)
- PLLSTP = Phase Locked Loop Step Register (see **Page 28-179**)
- PLLREV = Phase Locked Loop Reload Register (see **Page 28-180**)
- PLLDTR = Phase Locked Loop Delta Register (see **Page 28-181**)
- SRSC0 = Service Request State Clear Register 0 (see **Page 28-223**)
- SRSS0 = Service Request State Set Register 0 (see **Page 28-225**)

Three output signals are available on the PLL cell:

- PLL signal output line
- Uncompensated PLL signal output line
- Service request line

The desired input signal is selected by programming bit field PLLCTR.MUX. The number of output pulses to be generated within one input signal period must be stored in the microtick register PLLMTI and (coded in 2-complement data format) in the step register PLLSTP. The PLLREV reload register must be programmed with a reload value. This reload value is calculated by subtracting the number of output pulses to be generated within one input signal period from the input signal's period length (measured in number of f_{GPTA} clocks). An automatic compensation of an input signal acceleration or deceleration is enabled by setting bit PLLCTR.AEN to 1 (Automatic End Mode). After disabling the Automatic End Mode, the PLL continuously generates output pulses without synchronization to an input signal edge.

When the counter for the number of remaining output signal pulses PLLCNT decrements to zero, the PLL service request flag is set. Additionally, a service request signal PLLSR will be generated if the control register bit PLLCTR.REN is set.

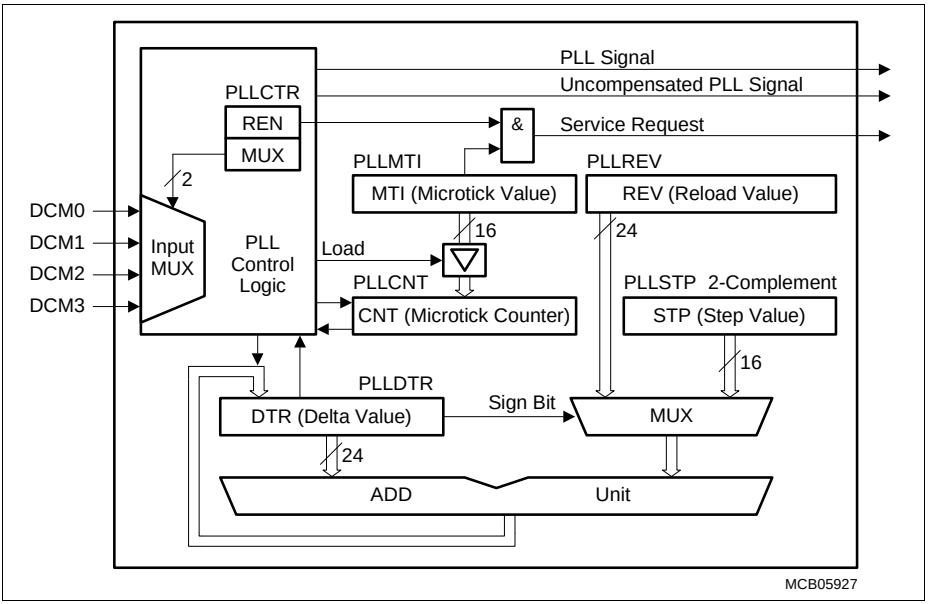

Figure 28-18 Block Diagram of Digital PLL Cell

PLL Interrupt Control

The PLL cell is able to generate a service request output signal PLLSR. This signal is controlled as shown in **Figure 28-19**. When the service request condition PLLCNT = 0 occurs, the service request flag is always set. The service request output PLLSR is activated only if it is enabled by the enable bit PLLCTR.REN. Additional information about service request and interrupt handling are given in section **“Interrupt Sharing Block (IS)” on Page 28-123**.

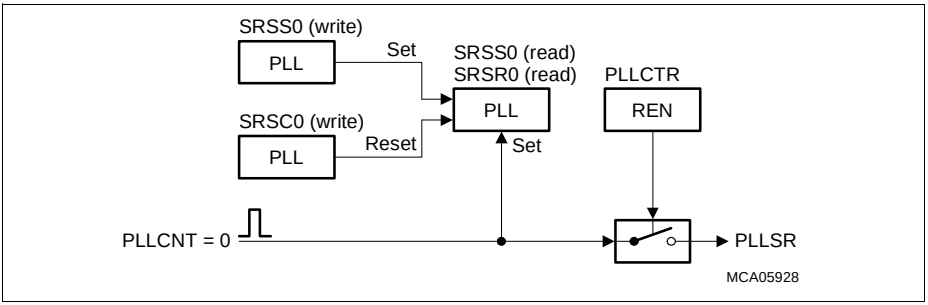

Figure 28-19 PLL Service Request Generation

Steady Input Signal Example

In the following example, the input signal's period length is 13 f_{GPTA} clock periods, which should be subdivided into three equally spaced sections. The reload value to be stored in PLLREV.REV register is calculated to $0A_H$ (10 = 13 - 3). PLLMTI.MTI is loaded with 03_H (number of output pulses) and its 2-complement representation ($FFFD_H$) is written into PLLSTP.STP.

After a reset, a state machine driven by the GPTA®v5 module clock, updates the delta register PLLDTR with the reload value. Afterwards, the PLLSTP register's contents are continuously added to the delta register value (**Figure 28-20**). In fact, the difference between both values is computed and stored in the PLLDTR register again, because the PLLSTP register has been loaded with a negative value (2-complement data format). When the PLLDTR register has been decremented to a negative value, the reload register contents are added to Delta register's current contents.

A rising edge detected on the selected input signal triggers the counter register PLLCNT to load the number of requested output pulses from PLLMTI. When a negative content of the PLLDTR register is detected, the microtick counter is decremented by one. In Automatic Mode (AEN = 1), the output pulse generation is stopped when the microtick counter reaches zero.

The period length of a single output pulse varies between four and five f_{GPTA} clocks; the maximum period length variation of output pulses is restricted to one f_{GPTA} clock. The total period length of all three output pulses, generated by one PLL loop corresponds to the input signal period width (5 + 4 + 4 = 13 f_{GPTA} clocks).

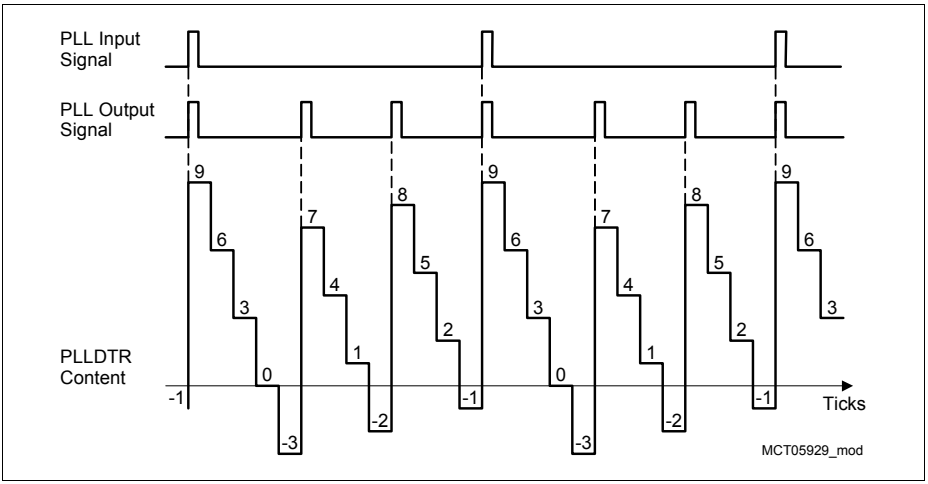

Figure 28-20 Digital PLL Steady State Simulation

This type of PLL implementation presents a valuable advantage compared to classic PLL implementation. Indeed, the generated microticks are equally distributed. The division reminder is distributed to several clocks instead of adding this reminder to the last pulse clock of the period.

Figure 28-21 illustrates this advantage. Considering a period of 15 clock pulses to be divided by a factor of 4, it gives a result of 3 with a reminder equal to 3. The reload value is calculated to $0B_H$ (11 = 15 - 4). The number of output pulses is equal to 4 and its 2-complement representation ($FFFC_H$) is written into the step register.

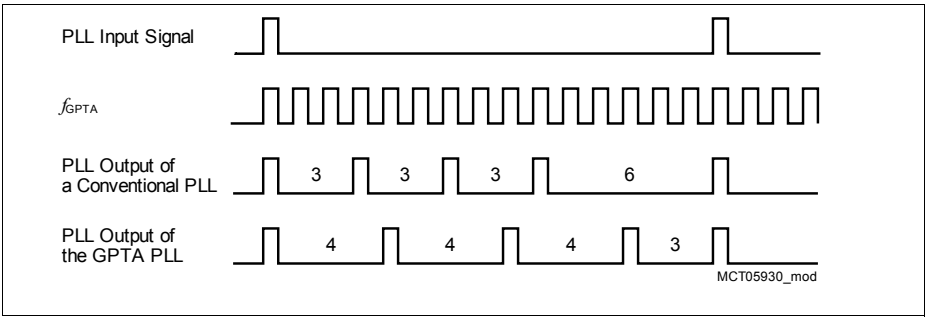

Figure 28-21 Advantage of the GPTA®v5 PLL

Input Signal Acceleration and Deceleration

The consequence of an input signal acceleration or deceleration can be compensated either automatically or by an external software routine. It detects an input signal's period length variation by comparing the current period length (measured in the associated DCM cell) with the expected period length used as calculation base for the PLLREV register contents.

- Compensation of input signal deceleration
  - Compensation by PLL Automatic End Mode
    If Automatic End Mode is enabled (PLLCTR.AEN = 1), the PLL stops at the calculated end of the current input signal period. Due to the deceleration, the rising edge of the following input signal period is delayed, starting the next PLL operation later than expected. A gap occurs between the last output pulse of the current input signal period and the first pulse of the following one (see **Figure 28-22**).
  - Compensation by Software
    After disabling the Automatic End Mode (PLLCTR.AEN = 0), the PLL generates output pulses without synchronization to an input signal edge. In case of a deceleration, more output pulses than calculated are generated during one input signal period. Several algorithms can be implemented to compensate the surplus of generated output pulses:
    The length of the current input signal period has been underestimated by a certain

number of f_{GPTA} clock periods. This deficit could be added to the calculated length of the next input signal period.
The PLL can continue to operate with the old input signal period length estimation, but the number of output pulses to be generated during the next input clock period may be decreased by the surplus of output pulses initiated during the last signal period.

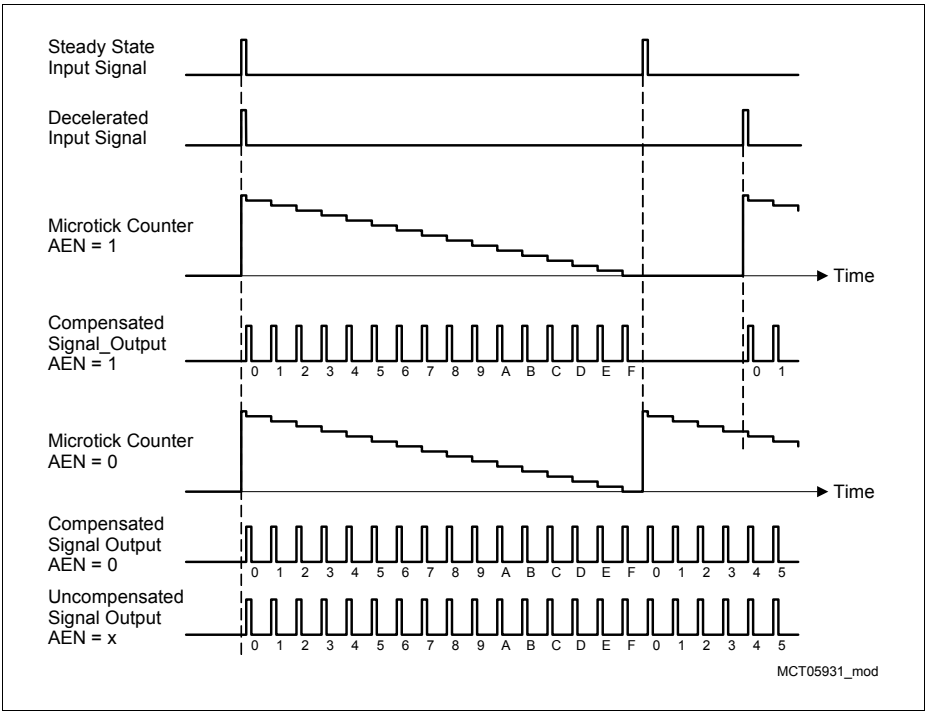

Figure 28-22 Compensation of Input Signal Deceleration

- Compensation of input signal acceleration
  - Compensation by PLL Automatic End Mode
    The next rising edge of the input signal arrives while the counter has not been decremented to zero. The PLL performs all remaining output signal pulses at full speed (f_{GPTA}), when control register bit AEN is set to 1. Afterwards, counter and Delta register are reloaded with their calculated values and the PLL operates at normal speed (see **Figure 28-23**).
  - Compensation by Software
    After disabling the Automatic End Mode, the PLL generates fewer output pulses than calculated during one input signal period. Several algorithm can be

implemented to compensate for the lack of generated output pulses:
The length of the current input signal period has been overestimated by a certain number of f_{GPTA} clock periods. This deficit should be subtracted from the calculated length of the next input signal period.
The PLL can continue to operate with the old input signal period length estimation, but the number of output pulses to be generated during the next input clock period may be increased by the lack of output pulses initiated during the last signal period.

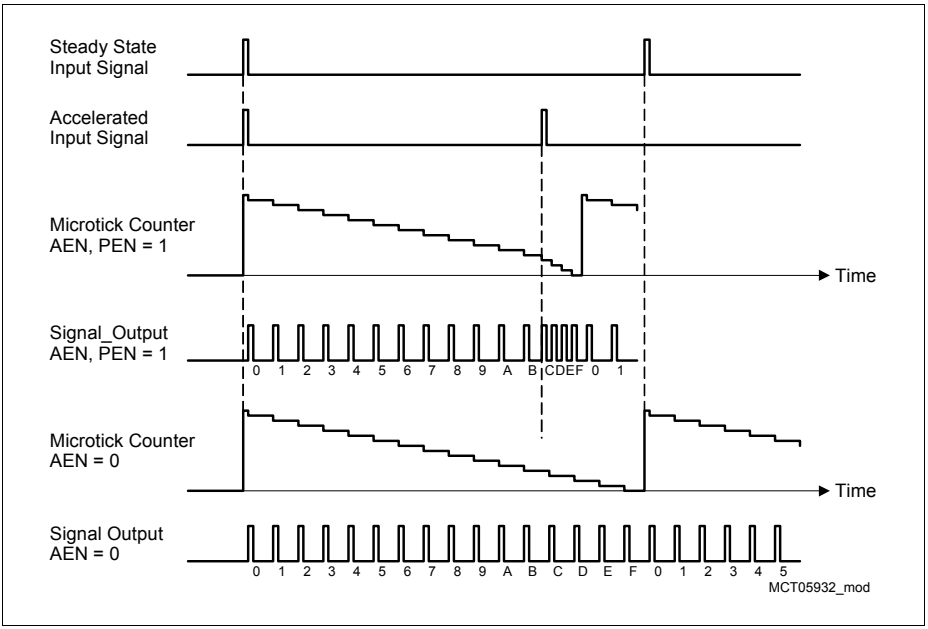

Figure 28-23 Compensation of Input Signal Acceleration

Additionally to the normal output signal, the PLL provides an uncompensated output signal. This signal has no gaps or acceleration bursts. However, the number of microticks during one signal period may be incorrect.

28.3.2.5 Clock Distribution Cell (CDC)

The Clock Distribution Cells (CDC) provides all Local and Global Timer Cells with a clock bus containing eight different clock output signals CLK[7:0] and a special LTC prescaler clock LTCPRE. These nine clock signals are generated out of eleven clock input signals coming from different clock sources (see **Figure 28-24**).

The prescalers divide the GPTA®v5 module clock f_{GPTA} by a programmable 2^n factor. Factor n is defined by bit fields DFA02, DFA04, DFA06 and DFA07 of control register

CKBCTR. A bit field value of 15 disables the related prescaler and selects alternate sources for clock bus lines 2, 4, 6 and 7. For clock bus line CLK2, a bit field value of 14 selects an alternate source.

For clock bus line CLK3, the 2-bit wide bit field DFA03 of control register CKBCTR selects one of the four available clocks.

The LTC prescaler clock LTCPRE is generated by dividing the f_{GPTA} module clock by a factor defined by the 3-bit wide bit field DFALTC of control register CKBCTR. Note that the LTCPRE clock is not a part of the clock bus but a clock signal that is distributed directly from the CDC to each LTC except LTC63.

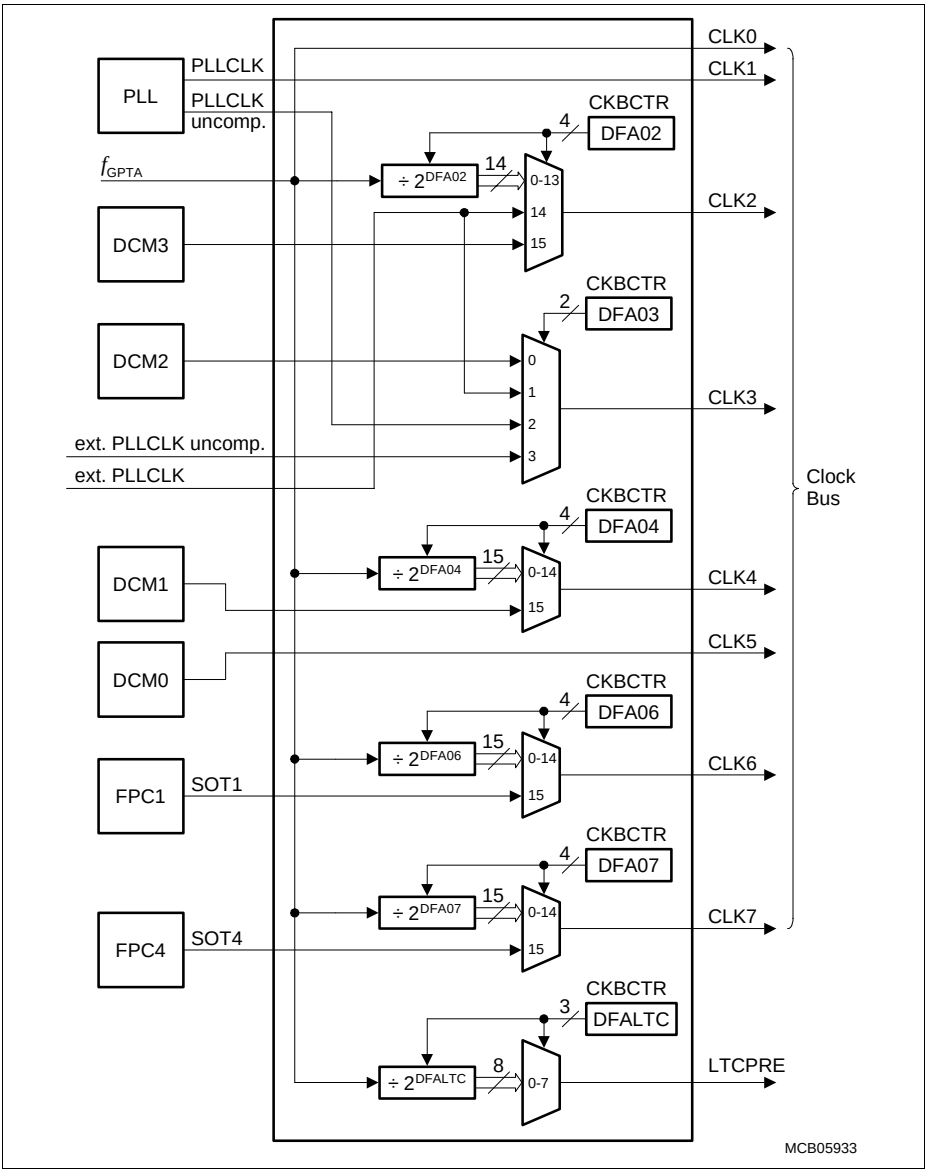

Figure 28-24 Block Diagram of Clock Distribution Cells

28.3.3 Signal Generation Cells

As described in detail in the following sections, the Signal Generation Cells contains the following types of cells:

- Global Timer (GT)
- Global Timer Cell (GTC)
- Local Timer Cell (LTC)

28.3.3.1 Global Timers (GT)

The GPTA®v5 provides two global 24-bit timers (GT) that are connected to the clock bus with its eight clock lines. Each GT is locally equipped with a clock source multiplexer, a 24-bit up-counter, a 24-bit reload register, and a 24-bit greater/equal comparator (see **Figure 28-25**).

Note: Index variable k (= 0, 1) determines the number of the Global Timer.

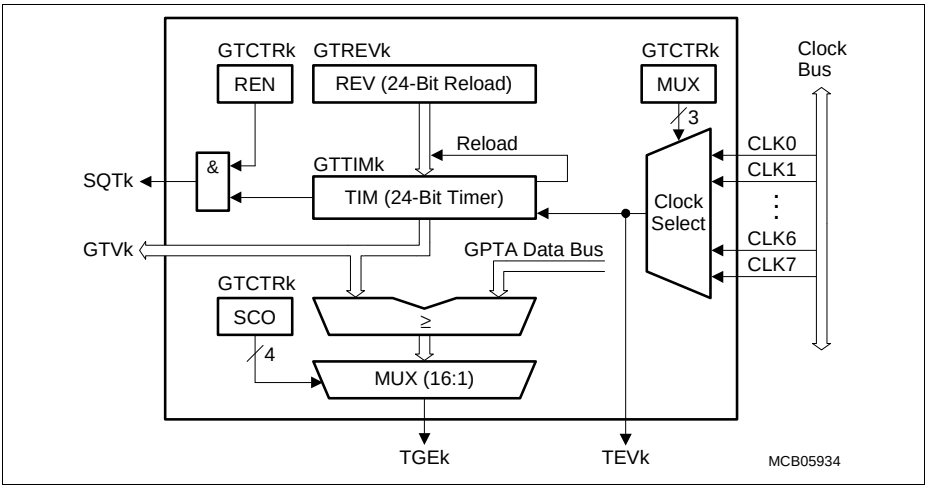

Figure 28-25 Block Diagram of Global Timer (GT)

The following registers are assigned to the Global Timers GTk (k = 0, 1):

- GTCTRk = Global Timer Control Register k (see **Page 28-182**)
- GTREVk = Global Timer Reload Value Register k (see **Page 28-184**)
- GTTIMk = Global Timer Register k (see **Page 28-183**)
- SRSC0 = Service Request State Clear Register 0 (see **Page 28-223**)
- SRSS0 = Service Request State Set Register 0 (see **Page 28-225**)

Each of the two GT cells provides the following input/output signals:

- Eight clock inputs, connected to the clock bus from the clock distribution cells (CDC)
- Global timer value bus GTVk (outputs), carrying the 24-bit GTk counter value
- TEVk output, indicating a GT counter update
- TGEk output, indicating the result of a compare operation
- SQTk service request output, triggered at a timer overflow.

The Global Timer output signals GTVk, TEVk, and TGEk are available as input signals at each GTC (see also **Page 28-56**).

Global timer k can be initialized with a start value, that is written by software into the GTTIMk register. The 24-bit Global Timer value GTTIMk.TIM is incremented by each rising edge of clock input signal TEVk that is selected from the 8-bit clock bus via bit field GTCTRk.MUX. On a Global Timer overflow (transition of $FFFFFF_H$ to 000000_H), the following events occur:

- The 24-bit reload value GTREVk.REV is copied into GTTIMk.TIM
- Bit SRSC0.GT0k is set
- The service request output SQTk is activated (if enabled by bit GTCTRk.REN)

A free-running timer is configured by programming GTREVk.REV with 000000_H.

The “Timer Event” (TEVk) output is activated if the GTk value changes because of a clock edge, a timer reload operation, or a software write access to GTCTRk. The TEVk output is connected to all GTCs. TEVk is used in the GTCs to trigger a compare operation, re-checking the equality of their compare register contents and the updated Global Timer value.

GT Interrupt Control

Each of the GTs is able to generate a service request output signal SQTk. This signal is controlled as shown in **Figure 28-26**. On a GTk timer overflow, the service request flag GT0k is always set. The service request output SQTk is activated only if it is enabled by the enable bit GTCTRk.REN. Additional information about service request and interrupt handling is given in section **"Interrupt Sharing Block (IS)" on Page 28-123**.

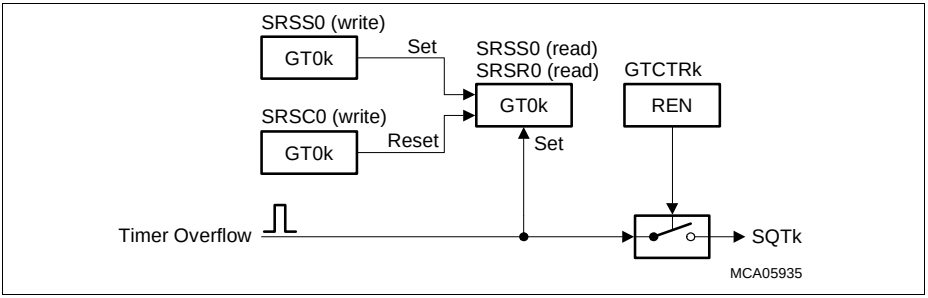

Figure 28-26 GTk Service Request Generation

Synchronization of Global Timers

Both Global Timers, GT0 and GT1, can be enabled and disabled individually. Each GT has its own run signal GTkRUN that is generated outside the GPTA®v5 kernel (see also **Page 28-8**). Signal GTkRUN is generated in a GPTA®v5 clock control circuitry. This external control capability allows the run signals GTkRUN to be controlled in a way that all Global Timers of one ore more GPTA®v5 units can be enabled/disabled synchronously.

The two Global Timers will run synchronously only if all of the following conditions are true:

- Timers use the same input signal
- Timers are started (and stopped, if required) synchronously
- Timers use identical start and reload values
- Timers are not written while they are running

Scalable Signed Greater or Equal Compare

This section (up to **Page 28-54**) explains the **classical timer update problem**, and the solutions supported by the GPTA®v5.

The two Global Timers embedded into the GPTA®v5 include a 24-bit greater/equal comparator. This comparator cell performs compare operations between the GT timer contents and the data value found on the GPTA®v5-internal data bus (coming from a GTC compare register update). The goal of this comparator is to be able to perform an action immediately if the compare cell is updated with a new threshold but the timer has already passed this value. **Figure 28-27** gives an example on this greater/equal concept.

Assumption: a timer is running and a new threshold (value T) is set.

The different points Px represent different cases of present time. When at P1 or P2, the moment represented by T lies in the future and no action is yet required. When at P3 or P4, the moment represented by T lies in the past, and an action is required immediately.

So, the problem is to determine if the threshold T has been passed or not.

Considering an **infinite counter**, the situation is simple. The evaluation consists in determining if point P is before or after T.

Considering a **reloaded counter**, as the timer rolls over at its maximum value, the situation is more complex.

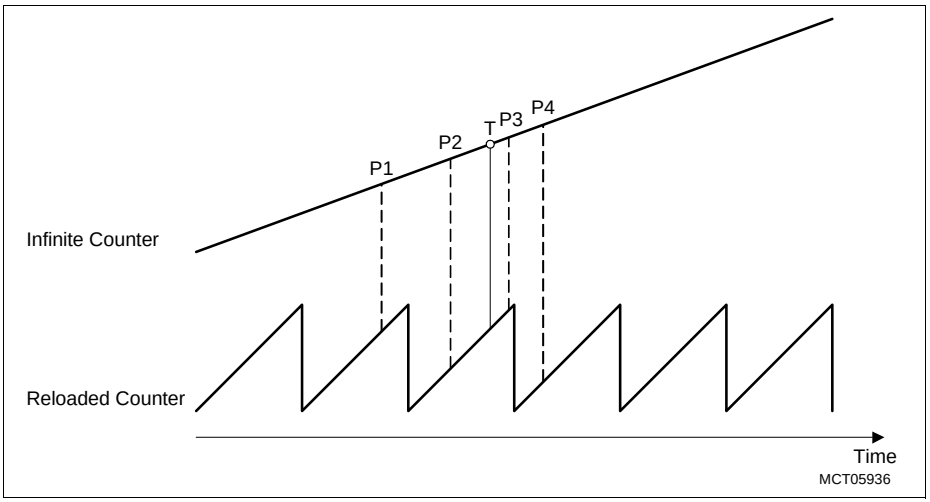

Figure 28-27 Greater/Equal Concept

The **observation window** determines the space in time where writing the value T to the comparator will lead to correct observation (meaning, there is an event if “After”; there is no event if “Before”). Considering an observation window, an event (threshold T) is

programmed and then the window is split into two windows, the “After” window and the “Before” window (**Figure 28-28**). If the timer lies in the “After” window at the time of programming the threshold, the event is performed immediately. If it lies in the “Before” window, the event will happen later when the timer reaches the threshold T. The “Before” window refers to a “prediction range”, and the “After” window refers to the “history buffer”.

From a practical point of view, once the value T is determined, it is necessary to calculate the observation window (position and width). Before updating the value T, the application must assure that the observation window was entered but has not yet been left.

The width of the **observation window** cannot exceed the timer period. To support reloaded counters where the overflow can occur within the observation window, a **signed** comparison is performed.

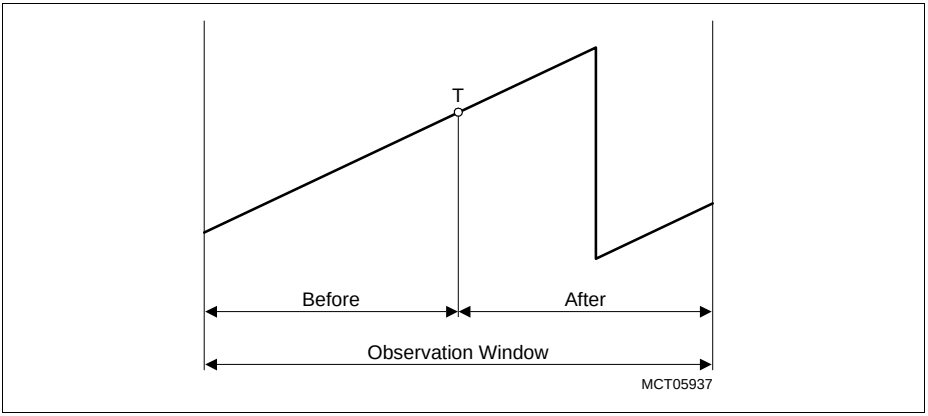

Figure 28-28 Before and After Windows

Comparison Between Unsigned and Signed Compare

To be able to support different timer periods and to support correct observation even beyond timer overflow, the GPTA®v5 embeds the **scalable** and **signed** greater/equal comparator. Using a signed comparison allows one overflow of the timer to occur within the observation window. This is illustrated in **Figure 28-29**.

Using a signed compare in order to take into account the timer overflow, the comparator window is introduced. The comparator window is centered to the point T and its width can be selected by the user.

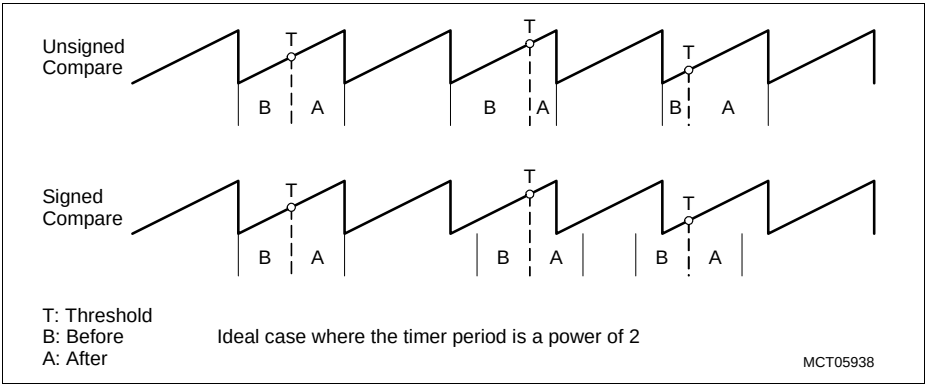

Figure 28-29 Unsigned Versus Signed Compare

When the timer range is a multiple of 2 and because the comparator is scalable, the observation window and the comparator window are identical. See **Figure 28-30**.

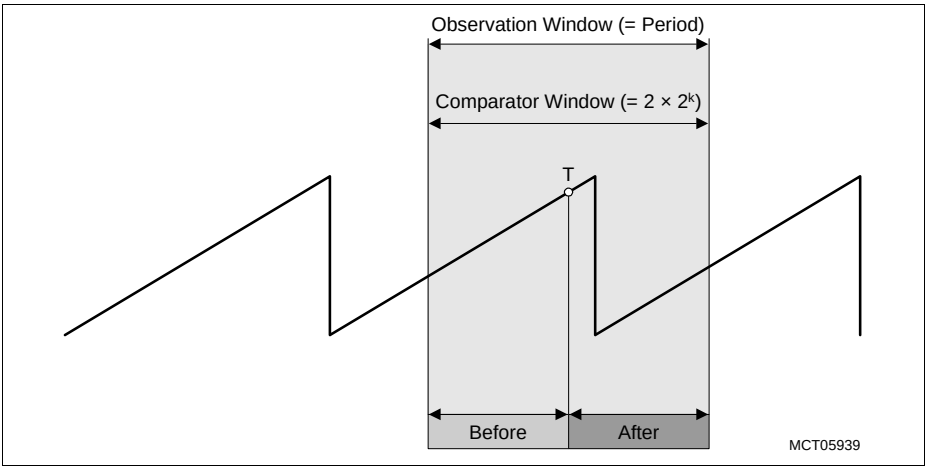

Figure 28-30 Observation and Comparator Windows (timer is a power of 2)

The scalable and signed greater/equal comparator scheme leads to a limitation that must be considered when programming the GPTA®v5 Module. If the timer range is not a power of 2, the comparator window (always a power of 2) will no longer match the timer period. This will impact the observation window as described in the following paragraph.

Observation window for reloaded timers (period is not a power of 2)

In that case, the comparator window must exceed the timer period. The user must find the comparator window (by selecting the scale factor k) which fits best the timer period.

The following equation must apply:

$$2^k < \text{Period} \leq 2 \times 2^k \quad (28.1)$$

Figure 28-31 and **Figure 28-32** show that one part of the comparator window must be discarded in order to avoid inconsistency, resulting in the observation window.

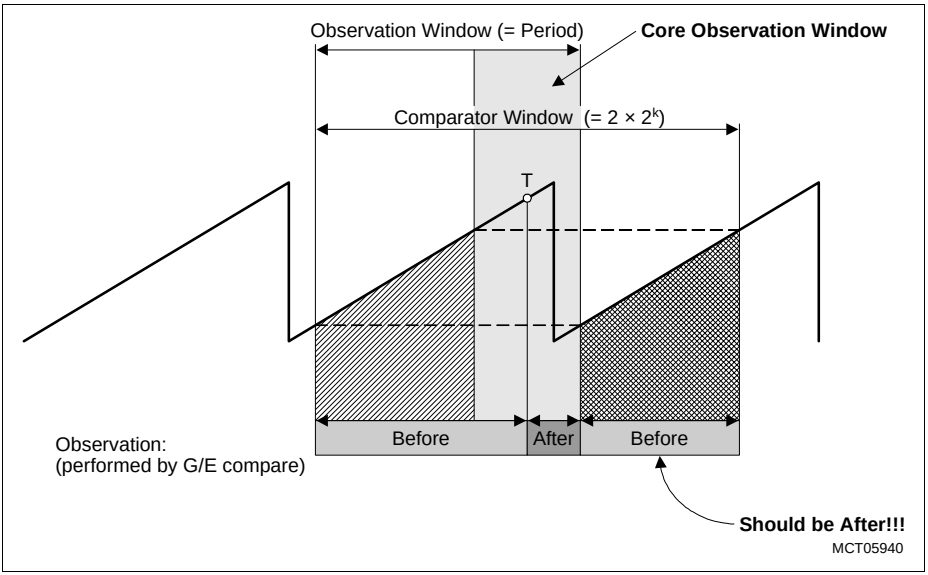

Figure 28-31 Observation Window when Threshold T is High

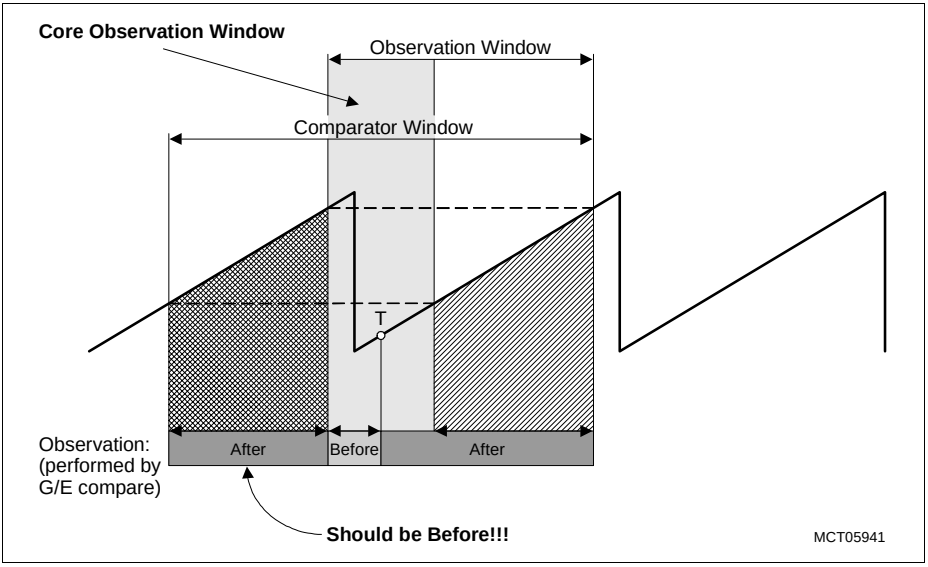

Figure 28-32 Observation Window when Threshold T is Low

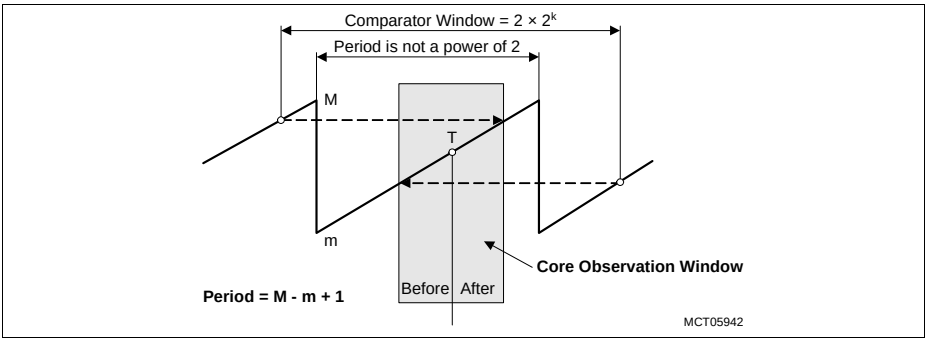

Figure 28-33 The Core Observation Window

A comparison of the previous figures shows that the position of the observation window with respect to T is dependent on the value of T itself. That means the user, before updating the comparator with T, needs to calculate the observation window as a function of T. To avoid this calculation, a **core observation window** can be defined that is independent of T. It will always be centered on T, whatever its value. However, one particularity exists when using the core observation window: the size of the core observation window varies depending on two static values: the timer period and the comparator window's sizes. In particular, the core observation window reduces as the value of the timer period is just after a power of 2. This is shown in **Figure 28-34**.

For any timer period (whatever the range) and any threshold position, a symmetrical core observation window of a statically defined size can be determined.

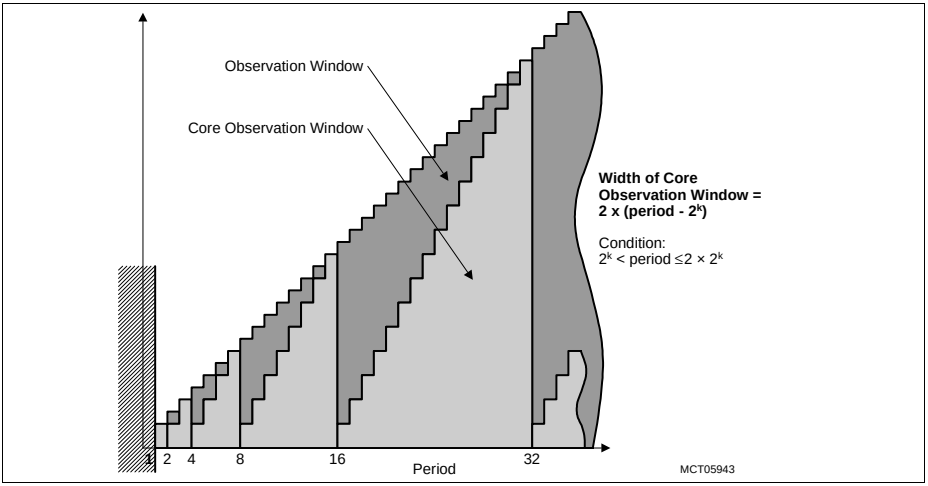

Figure 28-34 Core Observation Window Sizes Versus Period Sizes

Implementation

The hardware implementation of the **scalable and Signed/Unsigned** Greater/Equal compare is illustrated in **Figure 28-35**. The function consists of subtracting the threshold T from the GT timer value. The result is in 2s complement format. The result's sign bit and the 15 most significant bits are at available for observation. One of those bits is selected according to the mode of operation (Unsigned or Signed) and the period length (bit field GTCTRk.SCO). This bit drives the TGE (Timer Greater Equal) flag.

Unsigned compare: Select Sign bit (SCO = $0F_H$)

Signed compare: Select one of the 15 most significant result bits (SCO = 00_H to $0E_H$)

Note: How to choose one of the 15 bits is explained later.

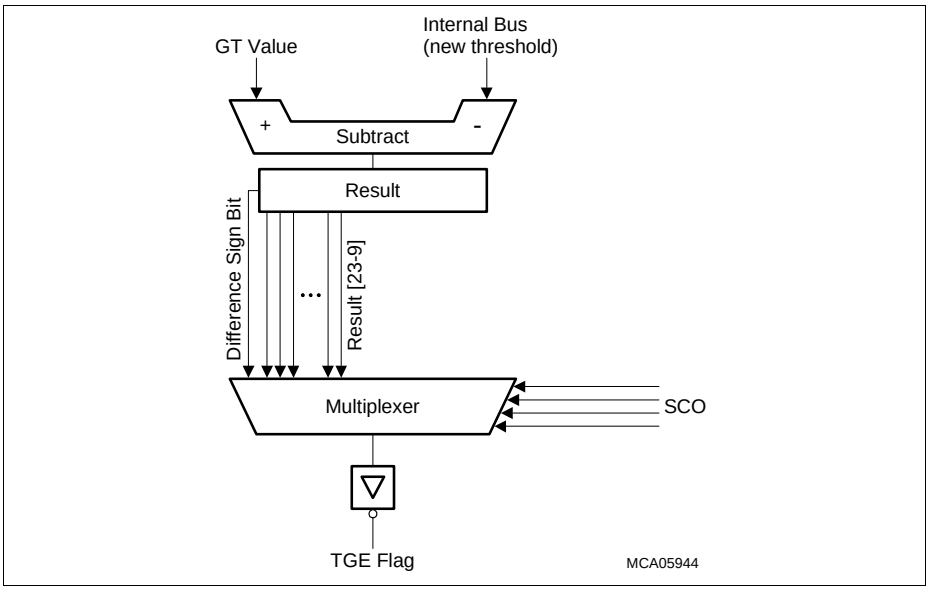

Figure 28-35 Comparator Implemented by a Subtraction Circuitry

The interpretation of the selected result bit is provided in the following simple example: For a 4-bit timer, the subtraction of the threshold T from the timer value, leads to a 4-bit signed result, as illustrated in **Figure 28-36**. This example is selected for simplicity although 4-bit periods are not covered by the implementation.

When using Unsigned compare, the sign bit S is selected. If it equals 0, the result is positive, indicating that the timer is greater or equal the threshold, and hence **After**. If it equals 1, the result is negative, and the observation indicates **Before**.

When using Signed compare, the result bit R_3 can be selected and interpreted, provided that the timer period is at least 9. Here, the range of the result can be split into four sub-

ranges. Because the result is in 2s complement format, a value of 0 for R_3 is interpreted as **After**, and a value of 1 is interpreted as **Before**. A comparison of **Figure 28-36** and **Figure 28-37** shows why this proceeding leads to correct interpretation within the observation window. **Figure 28-37** shows the case of a period equal a multiple of 2.

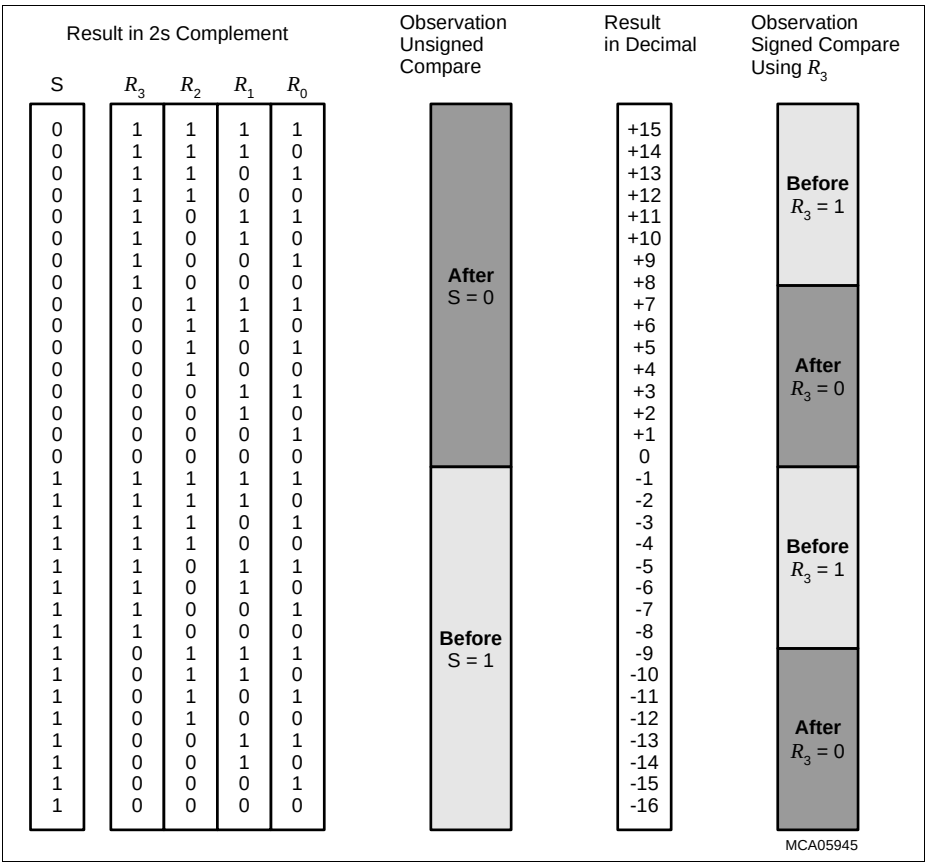

Figure 28-36 Result and Observation for a 4-Bit Timer

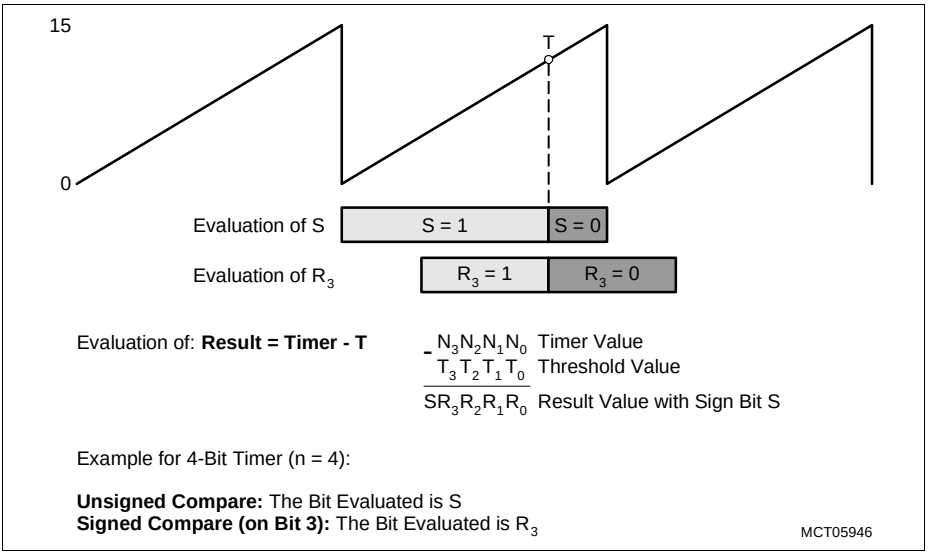

Figure 28-37 Result and Observation (Period = 16)

Figure 28-38 shows the case of a period of 12 which is not a power of 2. Here again, the Table in **Figure 28-36** applies.

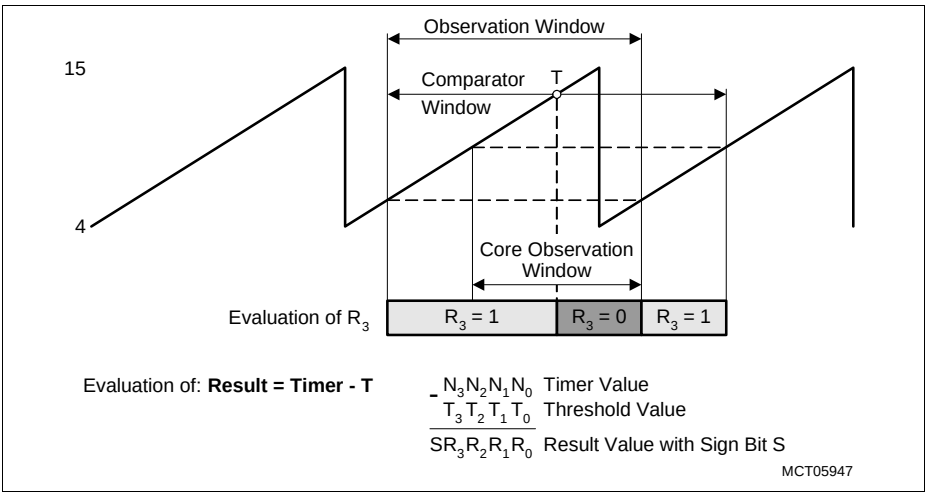

Figure 28-38 Result and Observation (Period = 12)

The previous examples show that the result bit to select for observation (R_3) corresponds to the comparator window's size (k = 3).

Considering the case in which the period is not a multiple of 2, choose a comparator window whose width is between 1 and 2 times the timer period:

$$2^k < \text{Period} \leq 2 \times 2^k \quad (28.2)$$

In no case may the comparator window be equal to or greater than twice the period.

k represents the Result bit to select.

How to Proceed

- Unsigned greater/equal compare:

SCO bit field = $0F_H$ (15_d)

Thereby, the sign bit of the result is selected to drive TGE flag.

This setting is valid for all possible periods. The observation window always matches the period.

- Signed greater/equal compare:

Depending on the period, the appropriate k is selected, so that:

$$\text{Period} = M - m + 1 \; (= \text{Max} - \text{Min} + 1) \quad (28.3)$$

$$2^k < \text{Period} \leq 2 \times 2^k \quad (28.4)$$

SCO bit field = 0 to $0E_H$ (0 to 14_d)

Thereby, the result bit R_k is selected to drive TGE flag.

This setting is possible for periods greater than 512.

Table 28-1 Period Range Depending on Selected k

$2^k < Period \leq 2 \times 2^k$	k	SCO Bit Field (decimal)
0 < period ≤ 512	Not covered by implementation	
512 < period ≤ 1024	9	0
1024 < period ≤ 2048	10	1
2048 < period ≤ 4096	11	2
4096 < period ≤ 8192	12	3
8192 < period ≤ 16384	13	4
16384 < period ≤ 32768	14	5
32768 < period ≤ 65536	15	6
65536 < period ≤ 131072	16	7
131072 < period ≤ 262144	17	8
262144 < period ≤ 524288	18	9
524288 < period ≤ 1048576	19	10
1048576 < period ≤ 2097152	20	11
2097152 < period ≤ 4194304	21	12
4194304 < period ≤ 8388608	22	13
8388608 < period ≤ 16777216	23	14

The width of the core observation window is defined by:

$$2 \times (period - 2^k) \quad (28.5)$$

As a consequence, the width of the “Before” window within the core observation window is (period - 2^k) and the width of the “After” window within the core observation window is (period - 2^k), including the value T.

Additional Information: Illustration on the General Case

The previous section illustrated the greater/equal compare for the particular case of a 4-bit timer. The purpose of this section is to describe the implementation from a general point of view, that is, for a timer period equal to M - m + 1.

In the following figures, the X axis indicates the timer value (elapsing time) and the Y axis indicates the threshold value T. The 45° line starting at (m, m) represents the position in time of T. The graphic shows the observation performed by the hardware for all cases of T (m ≤ T ≤ M).

Figure 28-39 illustrates the Unsigned compare. A particular case is shown in which, for a higher value of T, the observation indicates “Before” at the beginning of the period, and until the timer reaches the value T. Thereafter, the observation switches to “After” and remains there until the timer exits the period.

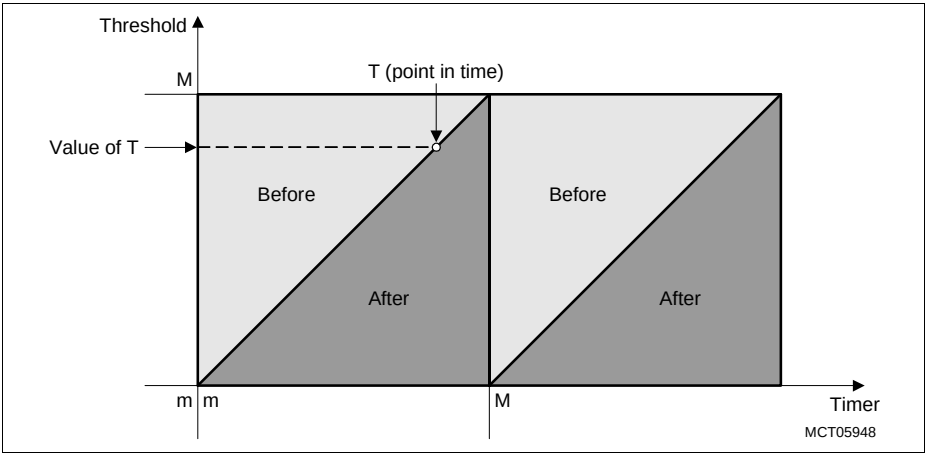

Figure 28-39 Graphical Representation of Unsigned Compare

Figure 28-40 illustrates the Signed compare where the period equals a multiple of 2 (that means $M - m + 1 = 2 \times 2^k$). In this case, for a higher value of T, the observation indicates “After” at the beginning of the period (not yet inside the observation window). When entering the observation window, “Before” is indicated until the timer reaches the value T. Thereafter, the observation switches to “After” and remains there until the timer exits the observation window. This graphic can be related to Table 28-37 where the comparator window equals the period, and the observation window is always centered on the threshold T.

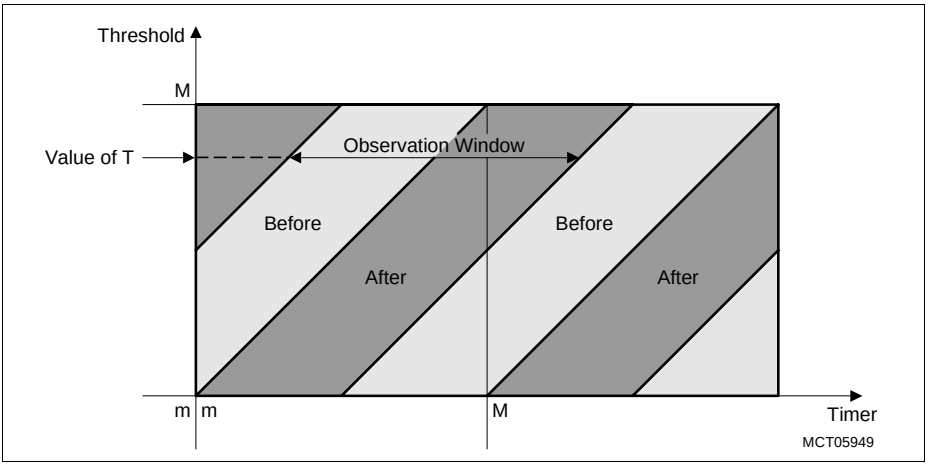

Figure 28-40 Graphical Representation of Signed Compare (Period = 2×2^k)

The **Figure 28-41** illustrates the Signed compare where the period may also be unequal a multiple of 2. The graphical representation of this general case is analogous to the one described in **Figure 28-31**.

If the period is not a multiple of 2, the graphical representation of the Signed compare shows a discontinuity in the “Before” and “After” ranges. Indeed, the widths of the “Before” and “After” windows are not constant, as they depend on the value T. As a consequence, the observation window is not centered on T. The result is that the position of the observation window would have to be re-evaluated for each value T (i.e. determining the widths of the “After” and the “Before” window). For this calculation, the principal characteristic is shown in **Table 28-41** (2×2^k - period = comparator window - period).

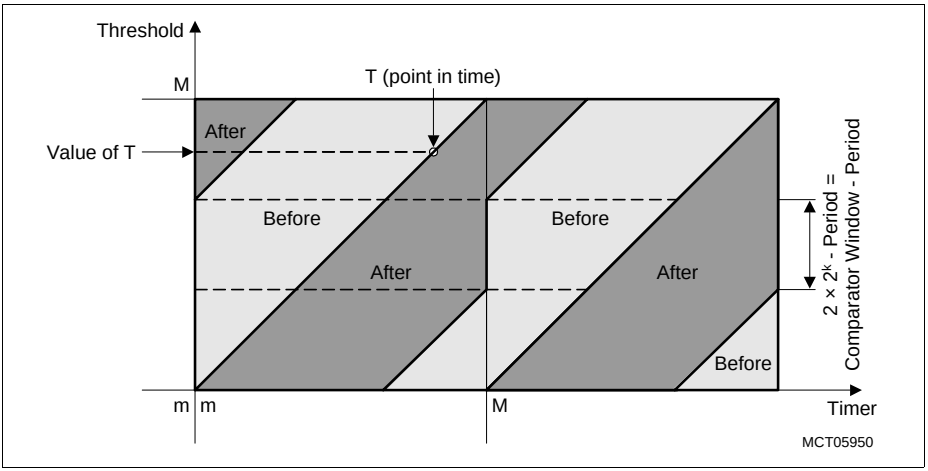

Figure 28-41 Graphical Representation of Signed Compare (2^k < Period ≤ 2 × 2^k)

Figure 28-42 shows how the observation window is positioned with respect to T. It also shows the **core observation window** that is always centered on T and which has a constant width.

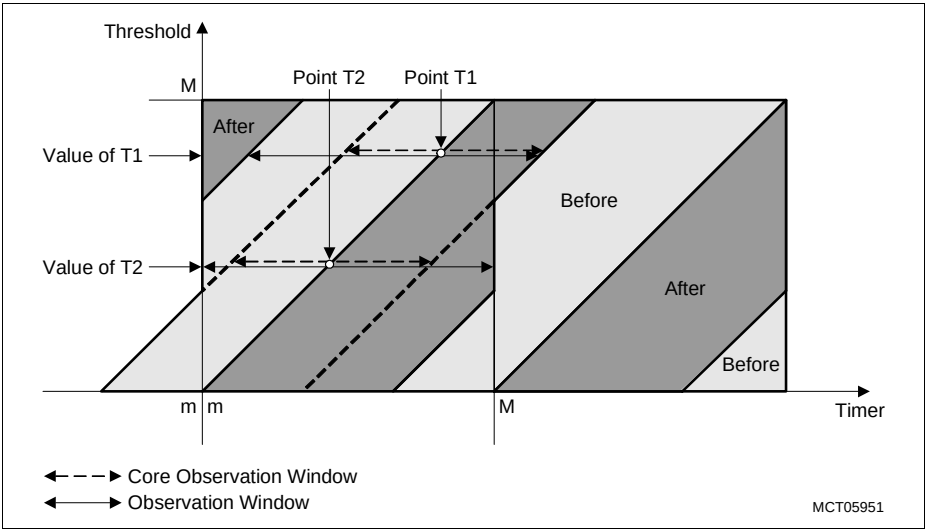

Figure 28-42 Core Observation Window in the Graphic

28.3.3.2 Global Timer Cell (GTC)

The GPTA®v5 provides 32 Global Timer Cells (GTC00 to GTC31) used for capture/compare operations.

Registers

The following registers are assigned to a GTCk (k = 00-31):

- GTCCTRk = Global Timer Cell Control Register k (see **Page 28-187**)
- GTCXRk = Global Timer Cell X Register k (see **Page 28-191**)
- SRSC1 = Service Request State Clear Register 1 (see **Page 28-226**)
- SRSS1 = Service Request State Set Register 1 (see **Page 28-227**)

Features

- **24-bit based timer cells** related to two Global Timers GT0 and GT1.
- **Capture Mode** on rising, falling or both edges with following actions:
  - Service request generation
  - Output signal transition generation (set, reset, toggle the output signal)
- **Compare Mode** on equal compare, or greater than, or equal to compare with following actions:
  - Service request generation
  - Output signal transition generation (set, reset, toggle the output signal)
  - Capture (after compare match) the value of the selected Global Timer or the opposite Global Timer
- **One Shot Mode** allows the selected (capture or compare) mode to be stopped after the first event.
- **Flexible mechanism** to link pin actions and allow complex combination of cells. (A cell has the ability to propagate actions over adjacent cells with higher number, in order to perform complex waveforms such as PWMs).

Architecture

The architecture of a GTC is shown in **Figure 28-43**. Each GTC has a multiplexer that allows selection of the GT0 or GT1 Global Timer value bus as data source, a 24-bit capture/compare register GTCXRk, and a 24-bit equal comparator.

The 32 Global Timer Cells (GTC00 to GTC31) have the following inputs:

- Two Global Timer value buses, GTV0 and GTV1, coming from the two Global Timers and carrying the GT0 and GT1 timer values
- Two inputs, TEV0 and TEV1, reporting GT0 and GT1 timer value updates
- Two inputs, TGE0 and TGE1, reporting the result of the GT0 and GT1 compare operations
- A trigger input (GTCkIN) that is connected via the GTC input multiplexer to one of the following signal sources:

  - External port lines
  - Local Timer Cell outputs
  - Filter and Prescaler Cell outputs
  - Internal input signals INTx
- Two action mode inputs (M0I, M1I) coming from the adjacent GTC with lower order number (M1I and M0I of GTC00 are 0)

Each GTC provides the following outputs:

- One data output (GTCkOUT) that can be connected to:
  - External port lines
  - Inputs of an MSC module
  - Outputs and/or inputs of Local Timer Cell inputs
- Two action mode outputs (M0O, M1O) going to the adjacent GTC with higher order number
- One service request line (SQSk) triggered by a capture/compare event.

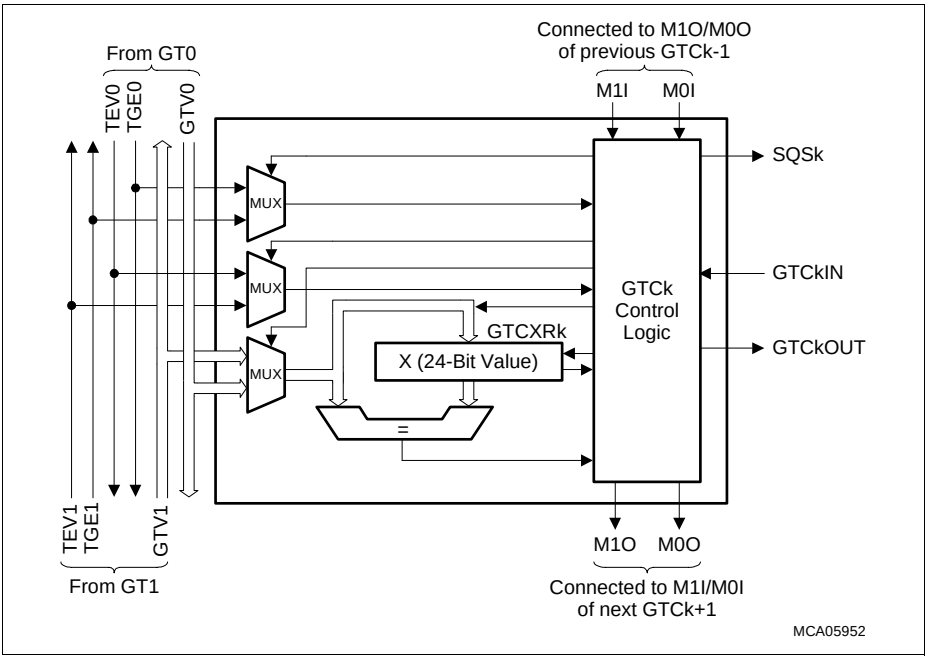

Figure 28-43 Architecture of Global Timer Cells

Figure 28-44 shows how the GTCs are arranged and connected to the adjacent GTCs and with the Global Timers GT0 and GT1.

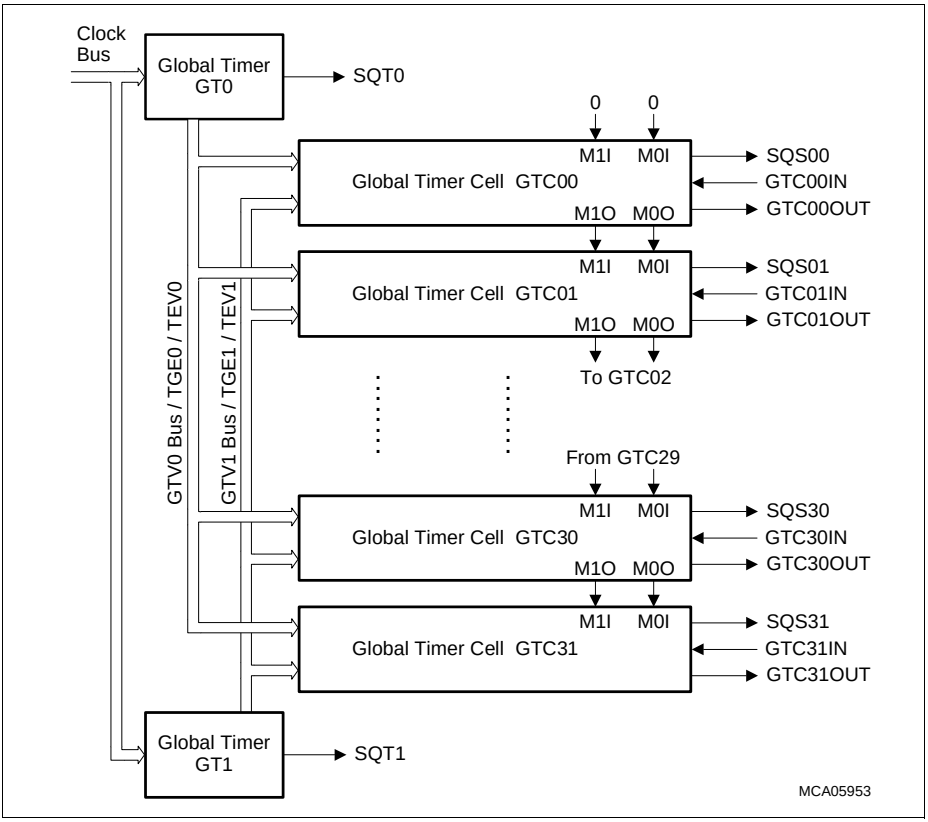

Figure 28-44 GTC Interconnections

Note: Cascading of GTCs is limited. TC1798 specific details are given on Page 28-306.

Capture Mode

The capture function of a GTCk cell is performed on a rising edge (GTCCTRk.RED = 1), a falling edge (GTCCTRk.FED = 1) or both edges of the selected GTCkIN input signal. On the requested event, the GTC:

- Copies the 24-bit value of the selected Global Timer into the 24-bit capture/compare register GTCXRk.X,
- Sets the GTCk service request flag in register SRSS1/SRSC1,
- Activates the service request output SQSk if control register bit GTCCTRk.REN = 1,
- Performs an GTCkOUT output signal line manipulation (set, reset, toggle, unchanged) as defined by bit field GTCCTRk.OCM,
- Transfers an action request, generated by an internal event or received on the M1I, M0I input lines, to the M1O, M0O output lines.

Compare Mode

In the Compare Code of a GTCk cell, several functions can be performed when the value of the selected Global Timer matches and/or exceeds the value stored in register GTCXR. With GTCCTRk.GES = 0 an “Equal Compare” match is selected while GTCCTRk.GES = 1 selects a “Greater Equal Compare” match. On the requested event, the GTC:

- Sets the GTCk service request flag in register SRSS1/SRSC1,
- Activates service request output SQSk if control register bit GTCCTRk.REN = 1,
- Performs an GTCkOUT output signal line manipulation (set, reset, toggle, unchanged) as defined by bit field GTCCTRk.OCM,
- Transfers an action request, generated by an internal event or received on the M1I, M0I input lines, to the M1O, M0O output lines.

If a greater or equal compare is selected, the condition is evaluated only when the compare value is written to the GTCXRk register. The user should then assure that the GTC is already enabled so that the evaluation can take place.

Capture after Compare Mode

When bit GTCCTRk.CAC = 1 and a compare event has occurred, register GTCXR is loaded with:

- The Global Timer value as selected by bit field GTCCTRk.MOD (GTCCTRk.CAT = 0),
- The alternate Global Timer value (GTCCTRk.CAT = 1). If a greater or equal compare match has been detected, the GTCk should be set into One Shot Mode in order to prevent double capturing.

One Shot Mode

In One Shot Mode (GTCCTRk.OSM = 1), a self-disable of GTCk is executed after each GTC event (GTCCTRk.CEN = 0). The current state of a GTCk can be evaluated by reading the control register flag bit GTCCTRk.CEN.

Note: The contents of the GTCk capture/compare register GTCXRk are write-protected for Capture_After_Compare in Single Shot Mode. Write protection is activated when the compare value is reached and released after a read access of register GTCXRk occurred.

Data Output Line Control

The data output GTCkOUT can be controlled by the GTCk itself and by adjacent GTCs with a lower order number. For this purpose, two communication signals between GTCs are available connecting all GTCs via their M1I/M0I inputs and their M1O/ M0O outputs respectively (see **Figure 28-45**).

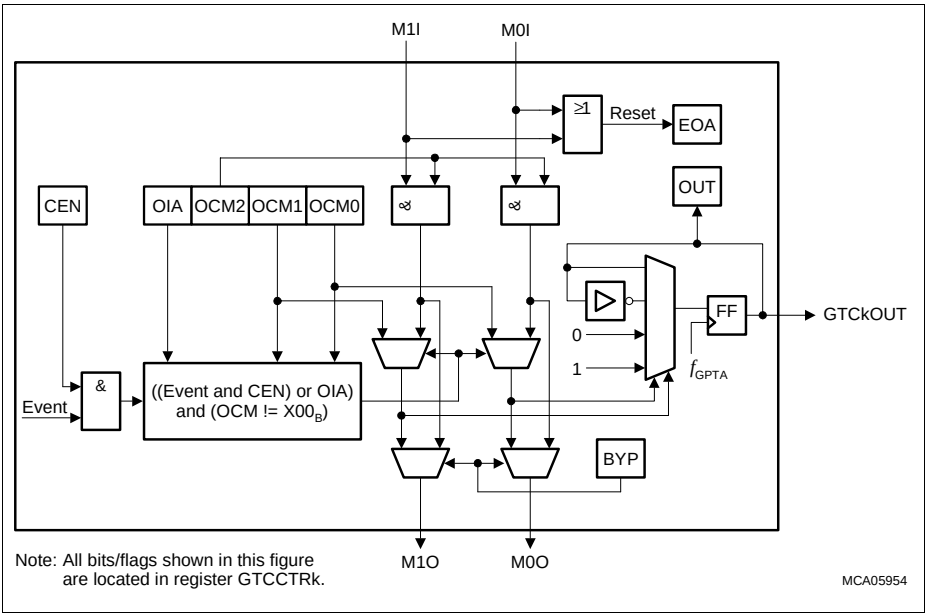

Figure 28-45 GTC Output Operation and Action Transfer

When bit GTCCTRk.OCM2 is reset, the data output GTCkOUT is only controlled by the local GTCk. A set, reset, toggle, or hold operation can be performed as selected by bits GTCCTRk.OCM1 and GTCCTRk.OCM0 (Table 28-2).

When bit GTCCTRk.OCM2 is set, the data output GTCkOUT is affected either by the local GTCCTRk.OCM1 and GTCCTRk.OCM0 bits or by the M1I/M0I input lines, which are connected to the adjacent GTCk-1 Global Timer output lines M1O/M0O. An enabled GTCk event superimposes an action request generated simultaneously by the M1I/M0I inputs.

When the bypass bit GTCCTRk.BYP is cleared, the M1O/M0O output lines logically OR together the local GTCk events and, if enabled by bit GTCCTRk.OCM2, the action requests received via the M1I/M0I input lines.

When bit GTCCTRk.BYP is set to 1, a local GTCk event will not modify the M1O/M0O output lines.

Table 28-2 Selection of GTC Output Operations and Action Transfer Modes

Bit Field OCM[2:0]	Local Capture or Compare Event	M1O/M0O BYP = 0		M1O/M0O BYP = 1		State of Local Data Output Line
0 0 0	not occurred	0	0	0	0	not modified
	occurred	0	0	0	0	not modified
0 0 1	not occurred	0	0	0	0	not modified
	occurred	0	1	0	0	inverted
0 1 0	not occurred	0	0	0	0	not modified
	occurred	1	0	0	0	0
0 1 1	not occurred	0	0	0	0	not modified
	occurred	1	1	0	0	1
1 0 0	not occurred	M1I	M0I	M1I	M0I	modified according M1I/M0I
	occurred	M1I	M0I	M1I	M0I	modified according M1I/M0I
1 0 1	not occurred	M1I	M0I	M1I	M0I	modified according M1I/M0I
	occurred	0	1	M1I	M0I	inverted
1 1 0	not occurred	M1I	M0I	M1I	M0I	modified according M1I/M0I
	occurred	1	0	M1I	M0I	0
1 1 1	not occurred	M1I	M0I	M1I	M0I	modified according M1I/M0I
	occurred	1	1	M1I	M0I	1

The GTCkOUT output line can be connected to output ports, on-chip peripheral inputs, and/or LTC inputs via the I/O Line Sharing Block (see Page 28-98). GTCkOUT can be updated directly by software (setting bit GTCCTRk.OIA = 1) or upon a timer, capture or compare event within the local GTCk or a preceding GTC. The current state of the data output line can be evaluated by reading status flag GTCCTRk.OUT.

Cell Enabling

After reset all GTCs are disabled. A GTC may be enabled by resetting GTCTRk.**EOA** (Enable-Of-Action) to 0 in Capture Mode or Compare Mode using a standard write assembler operation[1]. Because bit **EOA** is hardware protected, intrinsic read-modify-write assembler operations[2] only enable the GTC if bit **EOA** is modified from 1 to 0.

Cell Deactivation

By programming a GTC to Capture Mode with no edge selected (GTCCTRk.FED = GTCCTRk.RED = 0), an enabled cell becomes inactive and performs no action, but continues passing action commands via the communication link from M1I/M0I to M1O/M0O.

Cell Enabling on Event

A GTC can be enabled by an event in a GTC with lower index number. For this purpose, the local event function of an GTC must be temporary disabled by setting GTCCTRk.EOA (Enable-Of-Action) to 1. Because bit EOA is hardware protected, intrinsic read-modify-write assembler operations[2] only disable the GTC if bit EOA is modified from 0 to 1. Both operations will clear GTCCTRk.CEN and now a local event cannot affect the GTC. When a preceding GTC generates and communicates an event (or OIA) via its communication link M1O/M0O, at least one of the M1I/ M0I input lines changes its state to 1. This condition clears bit GTCCTRk.EOA of the disabled GTC via the OR gate as shown in **Figure 28-45**. Now GTCCTRk.CEN is set and the cell is enabled for local events.

It is also possible to enable the following GTC via the communication link for local events. For this purpose, the GTCCTRk.EOA bit of the following GTC must be set, too. If bit GTCCTRk.OCM2 of the preceding GTC is 1, the enable action will take place at the same time as in the preceding GTC. Otherwise, the GTC will be enabled later on a capture/compare event in the preceding GTC, provided OCM0 or OCM1 of this GTC is different from 0.

In this way, several GTCs can be enabled at the same time or one after the other. Normally, the cells will be used in One Shot Mode, and an interrupt will be generated after the last event to evaluate the data and to prepare the next enable sequence.

A disabled GTC (GTCCTRk.CEN = 0) behaves as an inactive cell.

1) Standard TriCore® write operations: ST.A, ST.B, ST.D, ST.DA, ST.DD, ST.HST.Q, ST.W
Standard PCP write operations: ST.F, ST.IF,BCOPY, COPY

2) Intrinsic TriCore® read-modify-write Operations: LDMST, ST.T, SWAP
Intrinsic PCP read-modify-write Operations: SET.F, XCH.F, CLR.F

Logical Operating Cells

The inter-cell communication architecture allows implementation of a complex waveform generation to be distributed over several GTCs, controlling a common port pin.

For example, one GTC may be configured in Capture Mode triggered by a rising edge detected on the associated input pin line. The related interrupt service routine can increment the captured timer value by a delay offset and store the result in the GTCXR register of the adjacent GTC configured in Compare Mode. Upon a compare event in the second GTC, the output port line of a third GTC can be set via M1O, M0O interface lines. When the GTCXR register of the third cell is loaded with another compare value by the interrupt service routine related to the second GTC, the output port line may be reset by the next compare event within GTC3.

This logical operating cell provides an output signal with programmable pulse width and configurable delay with minimal software overhead.

GTC Service Request

The service request output SQSk of a Global Timer Cell GTCk is controlled as shown in **Figure 28-46**. When the GTCk service request condition becomes active, the service request flag always becomes set. The service request output SQSk is only activated if it is enabled by the enable bit GTCCTRk.REN. Additional information about service request and interrupt handling is given on **Page 28-123**.

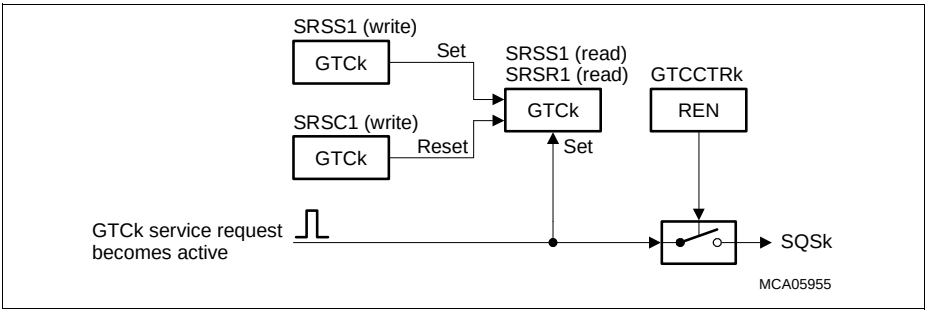

Figure 28-46 GTCk Service Request Generation

GTC Application Examples

The Global Timers together with GTCs can typically be used for input signal timing analysis of very complex input signals as well as for generation of complex output signals. **Figure 28-47** shows a configuration with Global Timer 0 and four GTCs, which is used in the following two examples:

- Example 1: Complex input signal capturing and analyzing
- Example 2: Complex periodical output signal generation

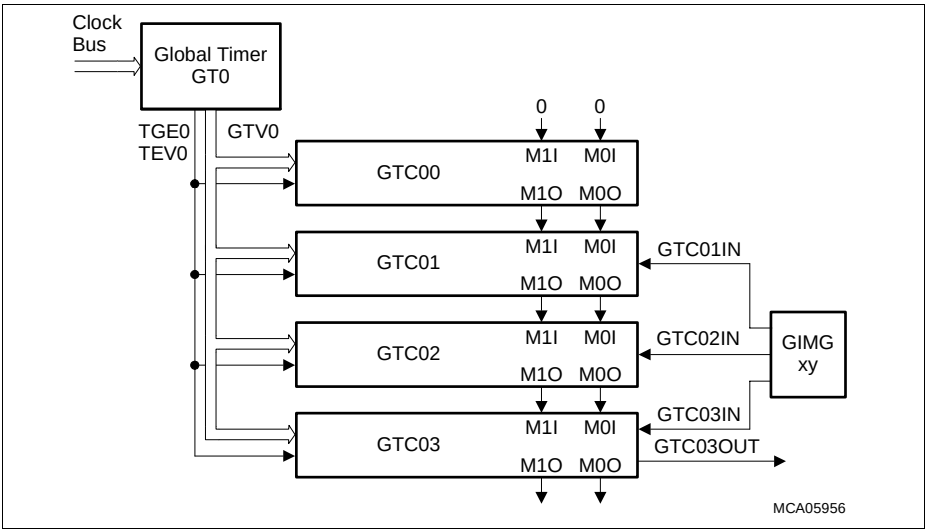

Figure 28-47 Complex Input/Output Signal Capturing/Generation with GTs and GTCs

Complex Input Signal Capturing and Analyzing

In this application example, one input signal from a GTC input multiplexer group becomes analyzed from a timing reference point for three consecutive signal transitions. This common input signal (e.g. a port line) is selected by a GTC input multiplexer group (GIMG) common for GTC01, GTC02, and GTC03 (see also **Page 28-111**). The GTCs are configured in the following way:

- GT0 operates as free-running up-counting 24-bit timer with reload to GTREV0.REV on overflow. It is clocked by one clock signal from the clock bus.
- GTC00 operates in Compare Mode with timer GT0. The compare match event is reported on the M0O/M1O output lines to the GTC01.
- GTC01 operates in Capture Mode at **rising** edge with enable-on-action set (EOA set) and One Shot Mode enabled (OSM set).

- GTC02 operates in Capture Mode at **falling** edge with enable-on-action set (EOA set) and One Shot Mode enabled (OSM set).
- GTC03 operates in Capture Mode at **rising** edge with enable-on-action set (EOA set) and One Shot Mode enabled (OSM set).

With the compare event of GTC00 (time stamp), GTC01 becomes active and waits for the next rising edge at its data input GTC01IN. While GTC01 is active, GTC02 and GTC03 are inactive.

When GTC01 detects a rising edge at its data input, it captures the current GT0 value into its GTCXR01 register, enables GTC02, and becomes disabled afterwards because it was operating in One Shot Mode. When GTC02 detects a falling edge at its data input, it captures the current GT0 value into its GTCXR02 register, enables GTC03, and becomes disabled afterwards because it was operating in One Shot Mode. When GTC03 detects a rising edge at its data input, it captures the current GT0 value into its GTCXR03 register and becomes disabled afterwards because it was operating in One Shot Mode. Optionally, the capture event at GTC03 may generate a service request to indicate that the three capture events have occurred and the captured values can be checked by software. Note that all of these capture events are executed by the GPTA®v5 hardware without any software interactions and with a resolution of the GT0 clock rate.

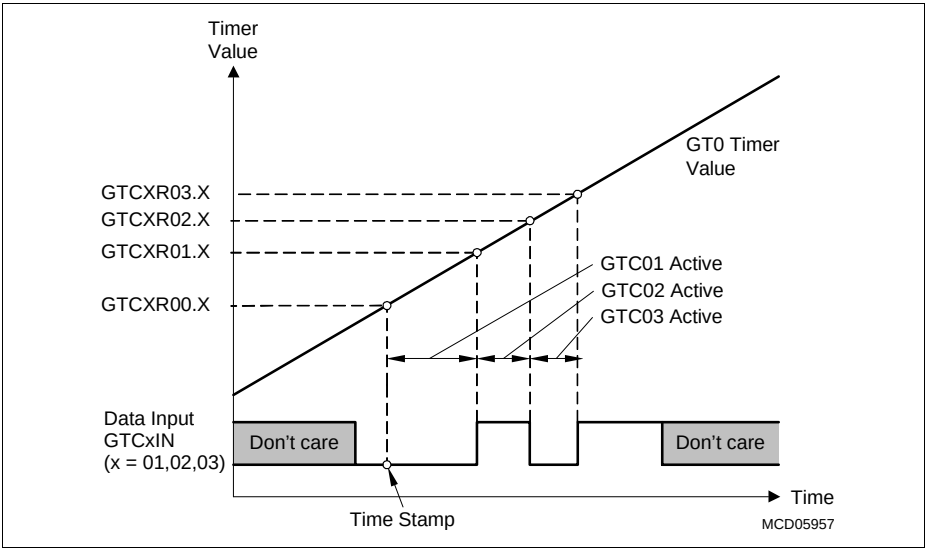

Figure 28-48 Complex Input Signal Analysis/Capturing with GTCs

Complex Periodic Output Signal Generation

This application example uses the GT/GTC configuration as shown in **Figure 28-47**. The generated output signal is available at GTC03OUT. The GTC input signals of the GT/GTC configuration are not used in this example.

- GT0 operates as free-running up-counting 24-bit timer with reload to GTREV0.REV on overflow. It is clocked by a clock signal from the clock bus. Its reload period determines the period of the generated PWM output signal.
- GTC00 operates in Compare Mode with timer GT0 with enable-on-action set (EOA set) and One Shot Mode enabled (OSM set). Furthermore, the output GTC03OUT becomes **set** on a local event (OCM = $X11_B$).
- GTC01 operates in Compare Mode with timer GT0 with enable-on-action set (EOA set) and One Shot Mode enabled (OSM set). Furthermore, the output GTC03OUT becomes **reset** on a local event (OCM = 110_B).
- GTC02 operates in Compare Mode with timer GT0 with enable-on-action set (EOA set) and One Shot Mode enabled (OSM set). Furthermore, the output GTC03OUT becomes **set** on a local event (OCM = 111_B).
- GTC03 operates in Compare Mode with timer GT0 with enable-on-action set (EOA set) and One Shot Mode enabled (OSM set). Furthermore, the output GTC03OUT becomes **reset** on a local event (OCM = 110_B).

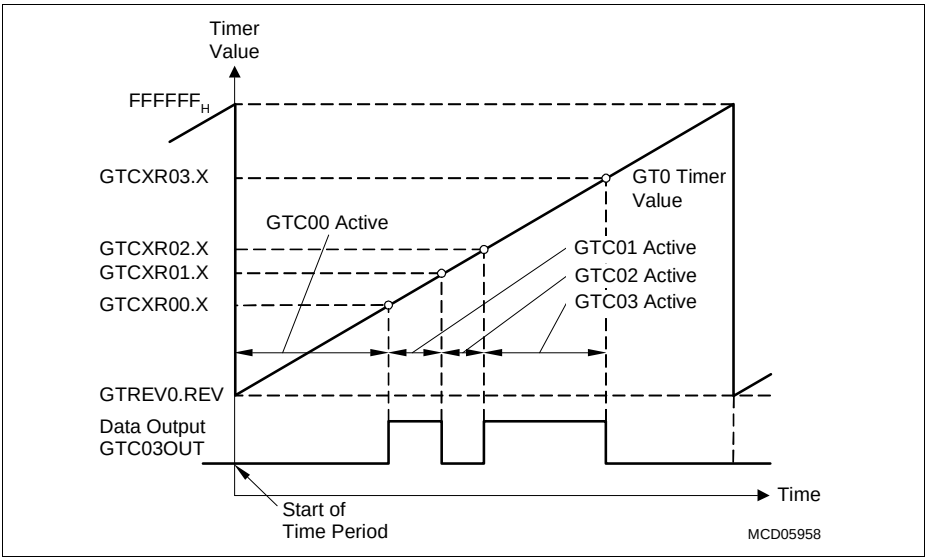

Figure 28-49 Complex Output Signal Generation with GTCs

At the start of the time period (reload of GT0), GTC00 becomes active and waits for the compare event. At this event, it sets the output signal GTC03OUT, enables GTC01 for

compare operation, and becomes disabled afterwards because it was operating in One Shot Mode. When the GTC01 compare event occurs, the output signal GTC03OUT is reset, GTC02 becomes enabled, and GTC01becomes disabled because it was operating in One Shot Mode. When the GTC02 compare event occurs, the output signal GTC03OUT is set, GTC03 becomes enabled, and GTC02 becomes disabled because it was operating in One Shot Mode. When the GTC03 compare event occurs, the output signal GTC03OUT is reset, and GTC02 becomes disabled because it was operating in One Shot Mode.

The capture event at GTC03 should generate a service request to indicate that the three compare events have occurred and that GTC01 can be enabled again (setting EOA and OSM). Note that all of the compare events are executed by the GPTA®v5 hardware without any software interactions and with a resolution of the GT0 clock rate.

28.3.3.3 Local Timer Cell (LTC00 to LTC62)

LTC00 to LTC62 are functionally identical. The functionality of LTC63 is different to LTC00 to LTC62 and therefore described separately at **Page 28-79**.

Registers

The following registers are assigned to a Local Timer Cell LTCk (k = 00-62):

- LTCCTRk = Local Timer Cell Control Register k (see **Page 28-192**)
- LTCXRk = Local Timer Cell X Register k (see **Page 28-205**)
- SRSC2 = Service Request State Clear Register 2 (see **Page 28-228**)
- SRSC3 = Service Request State Clear Register 3 (see **Page 28-230**)
- SRSS2 = Service Request State Set Register 2 (see **Page 28-229**)
- SRSS3 = Service Request State Set Register 3 (see **Page 28-231**)

Features

- **16-bit based timer cells** providing capture, compare, and timer functions.
- **Capture Mode** on rising, falling or both edges with following actions:
  - Service request generation
  - Output signal transition generation (set, reset, toggle the output signal).
- **Compare Mode** on equal compare of the corresponding (Reset-)Timer LTC with following actions:
  - Service request generation
  - Output signal transition generation (set, reset, toggle the output signal).
- **Timer Mode** incremented on hardware signal with following actions:
  - Event generation at overflow
  - Service request generation
  - Output signal transition generation (set, reset, toggle the output signal).
- **Reset Timer Mode** allows the selected LTC to be reset by an adjacent cell. Coherent update capability of adjacent LTCs for PWM management is provided.
- **One Shot Mode** allows the selected (capture, compare, timer or reset timer) mode to be stopped after the first event.
- **Flexible mechanism** to link pin actions and allow complex combination of cells. (A cell has the ability to propagate actions over adjacent cells with higher number, in order to perform complex waveforms such as multi channel PWMs).

Architecture

The architecture of an LTC is shown in **Figure 28-50**. Each LTC has a 16-bit capture/compare register and a 16-bit equal to comparator.

The first 63 Local Timer Cells (LTC00 to LTC62) have the following inputs:

- A local input data bus (YI) carrying the local timer value of the adjacent LTC with lower order number (YI of LTC00 is always 0000_H)

- A TI input reporting the occurrence of a local timer value update of the adjacent LTC with lower order number (TI of LTC00 is 0)
- A SI input used by the LTC in Compare Mode as enable line (SI of LTC00 is 0)
- Four action mode inputs (M3I, M2I, M1I, M0I) coming from the adjacent LTC cell with lower order number (M3I, M2I, M1I, and M0I of LTC00 are 0)
- An EI input reporting an event coming from the adjacent LTC with higher order number
- A trigger/clock/enable input LTCkIN hooked to one of the following signals sources:
  - External port lines
  - GTC00 to GTC31 outputs
  - Clock bus signals
  - PDL0 or PDL1 outputs
  - Internal GPTA®v5 kernel input signals INTx (x = 0-3)

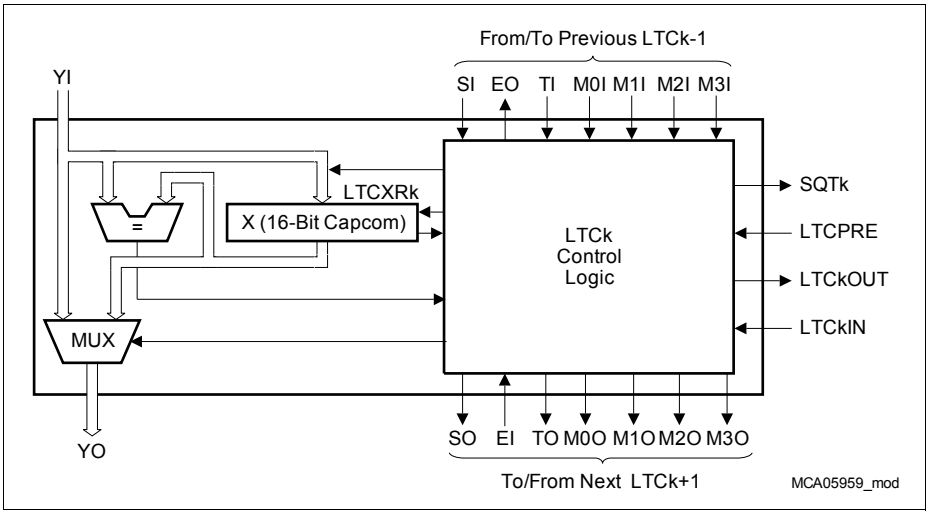

Figure 28-50 Architecture of Local Timer Cells

Each LTC provides the following input / output signals:

- One data output line (LTCkOUT) that can be connected to:
  - External port lines
  - Inputs of an MSC module
  - Outputs and/or inputs of Global Timer Cell inputs
- One LTC prescaler clock input (LTCPRE) for Timer Mode
- One service request line (SQT) triggered by a capture/compare event
- A local output data bus (YO) carrying the local timer value to the adjacent LTC with higher order number or the value on YI

- A TO output reporting the occurrence of a local timer value update to the adjacent LTC with higher order number
- An SO output used by the adjacent LTC with higher order number as enable signal for a compare function
- An EO output reporting the occurrence of a local event to the adjacent LTC with lower order number
- Four mode lines (M3O, M2O, M1O, M0O) going to the adjacent LTC with higher order number.

Figure 28-51 shows the arrangement of the LTCs and the connections with adjacent LTCs. LTC63 is a Local Timer Cell that differs from all other LTCs (LTC00 to LTC62). LTC63 is described in detail on **Page 28-79**.

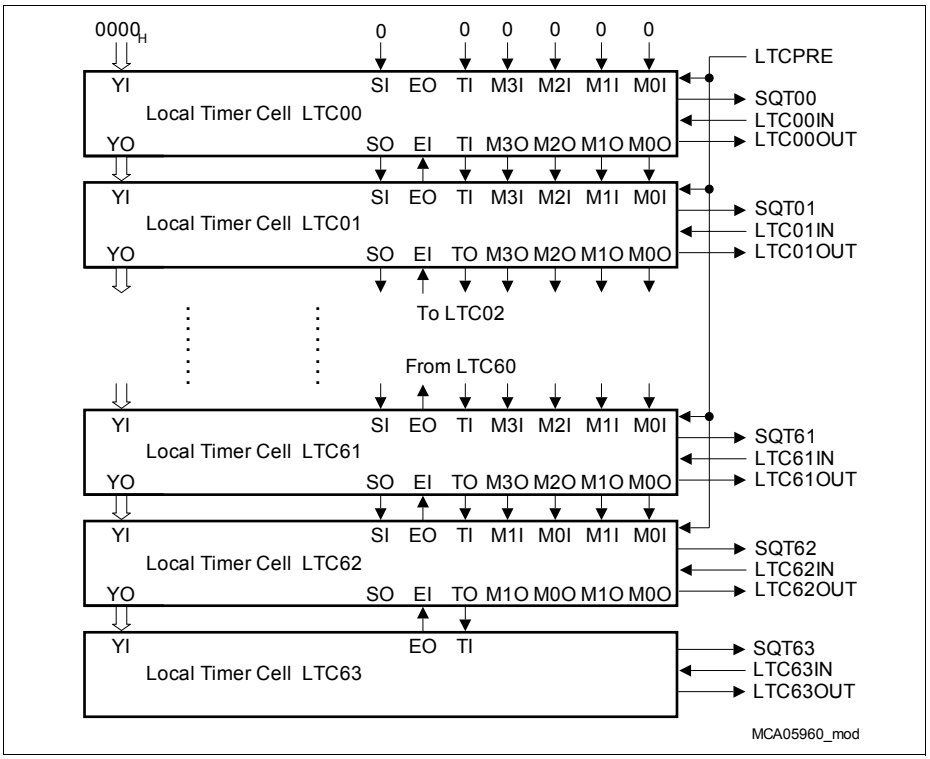

Figure 28-51 Interconnections between the LTCs

*Note: Cascading of LTCs is limited. TC1798 specific details are given on **Page 28-306**.*

Operating Mode Selection

The operating mode of an LTC – Free-Running Timer, Reset Timer, Capture, or Compare Mode – is defined by bit field LTCCTRk.MOD.

Free-Running Timer Mode

The content of the Local Timer Cell Register LTCXRk is initialized by a software write operation. LTCXRk is incremented by the selected LTCkIN input signal. Level or Edge Sensitive Mode can be selected for LTCkIN (see **Page 28-72**). In Level Sensitive Mode prescaler clock from the CDC (LTCPRE) can be used to reduce the timer frequency. Every change of the Local Timer Cell Register LTCXRk (increment, reset, or write access) is indicated by output signal TO = 1. When the timer reaches its overflow value ($FFFF_H$),

- the LTCk service request flag is set,
- the service request output SQTk is activated if control register bit LTCCTRk.REN = 1,
- the LTCk output line LTCkOUT can be altered (set, reset, toggle, unchanged),
- the LTCkOUT output line can be altered (set, reset, toggle, unchanged), depending on bit field LTCCTRk.OCM,
- an action request, generated by an LTCk internal event or received on the M1I/M0I input lines, is transferred via the M1O/M0O output lines to the LTC with higher order number (LTCk+1).

The event output line EO is also activated (set to high) by a software reset when writing $FFFF_H$ to register LTCXRk.

Reset Timer Mode

An LTC that is configured in Reset Timer Mode provides the same functionality as in Free-Running Timer Mode, but is extended by two additional features:

- The Local Timer Cell Register LTCXRk can be reset to $FFFF_H$ via the EI line, which can be activated by an event that occurred in the adjacent LTC with higher order number.
- If bit LTCCTRk.CUD is set to 1, the EI line reset event also toggles the logic state of the SO output line before it clears register bit LTCCTRk.CUD automatically. By accessing register bit LTCCTRk.SLO, the state of the timer's output line SO can be read or explicitly written.

Capture Mode

In Capture Mode, the LTCkIN input signal is used for capture function. Level or edge Sensitive Modes can be selected (see **Page 28-72**). On a capture event, the LTCk:

- copies the state of the local input data bus (YI) to the LTCXRk register (LTC00 always copies 0000_H),
- sets the LTCk service request flag,

- activates the service request line SQTk, if LTCCTRk.REN is set to 1,
- changes the LTCkOUT output line state (set, reset, toggle, unchanged), depending on bit field LTCCTRk.OCM and the M1I/ M0I input line state,
- generates and/or passes an action request via the M1O/M0O output lines to the LTC with higher order number (LTCk+1),
- sets the event output EO to high level for one f_{GPTA} clock cycle.

Compare Mode

The Compare Mode can be enabled on a low, high, or both levels of the select input line SI (LTCCTRk.SOL = 1, LTCCTRk.SOH = 1). The current state of SI is indicated by bit field LTCCTRk.SLL and can be read. When the value of the local input data bus (YI) matches the LTCXRk contents,

- The LTCk service request flag is set,
- The service request line SQTk is activated if LTCCTRk.REN is set to 1,
- The LTCkOUT output line state is changed (set, reset, toggle, unchanged), depending on bit field LTCCTRk.OCM,
- An action request is generated and/or passed via the M1O/M0O output lines to the LTC with higher order number (LTCk+1),
- The event output EO is set to high level for one f_{GPTA} clock cycle.

Note: To enable the compare function in all cases (on every timer or compare register update caused by a software write access, a reset event or a compare match), bits LTCCTRk.SOL and LTCCTRk.SOH must be set to 1.

An inactive cell (LTCCTRk.SOL = LTCCTRk.SOH = 0, or SI does not match the programmed value) will transfer the state of the event input line EI to the event output line EO.

One Shot Operation

When bit LTCCTRk.OSM is set to 1, a self-disable is executed after each LTC event. The current state of LTCk can be checked by reading the control register flag bit LTCCTRk.CEN.

Data Input Line Control

The data input line LTCkIN can operate in two modes (selected by bit LTCCTRk.ILM):

- Level Sensitive or
- Edge Sensitive.

In Edge Sensitive Mode, the active edges are selected by bits LTCCTRk.FED and LTCCTRk.RED. For the Level Sensitive Mode, the active level of the input signal can be selected by bit FED/AIL of register LTCCTRk.

Depending on which source is selected for the input line by the input multiplexer, different clocking modes of the LTC cell are possible (**Table 28-3**).

Table 28-3 LTC Data Input Line Operation (in Timer Mode)

Input Source	Level Sensitive Input Line LTCCTRk.ILM = 1	Edge Sensitive Input Line LTCCTRk.ILM = 0
External Signal (Port line)	The external signal operates as gating signal for the cell. The active input level can be selected with control register bit AIL. Additionally, the LTC prescaler mode can be enabled with LTCCTRk.PEN to reduce the timer frequency. The programmed function of the LTC is performed with the GPTA®v5 module clock frequency, or with the programmed prescaler clock LTCPRE (see **Page 28-37**).	The programmed function of the LTC cell is performed on selected edge(s).
Internal Clock Bus Line or PDL output or INT input	The programmed function is performed with the internal clock or PDL/INT signal. Note that all internal clock bus lines and PDL signals are active high pulses. The LTC Prescaler Mode and the input signal inversion must not be used.	The programmed function of the LTC cell is performed on selected edge(s). In case of full speed GPTA®v5 module clock selection as input clock, the Level Sensitive Mode must be selected. The Edge Sensitive Mode will not produce an event in this special case.

Table 28-3 LTC Data Input Line Operation (in Timer Mode) (cont'd)

Input Source	Level Sensitive Input Line LTCCTRk.ILM = 1	Edge Sensitive Input Line LTCCTRk.ILM = 0
GTC output	The GTC output signal operates as gating signal for the cell. The active input level can be selected with bit LTCCTRk.AIL. Additionally, the LTC prescaler clock LTCPRE can be enabled with bit LTCCTRk.PEN to reduce the timer frequency.	The programmed function of the LTC cell is performed on selected edge(s).

Note: If Capture Mode and level sensitive input is selected for an LTCk (bit LTCCTRk.ILM = 1), a capture event occurs on every LTC timer clock event if the corresponding LTC input signal is a high level.

Data Output Line Control

The data output LTCkOUT can be controlled by the LTCk itself and by adjacent LTCs with a lower order number. For this purpose, two communication signals between LTCs are available that make it possible to connect all LTCs via their M1I/M0I inputs and their M1O/ M0O outputs respectively (**Figure 28-52**).

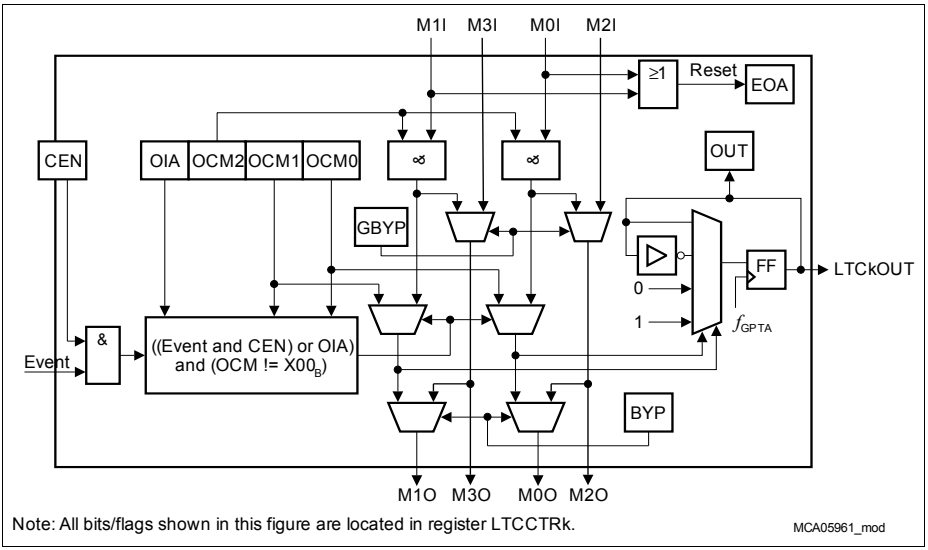

Figure 28-52 LTC Output Operation and Action Transfer

When bit LTCCTRk.OCM2 is reset, the data output LTCkOUT is controlled only by the local LTCk. A set, reset, toggle, or hold operation can be performed as selected by bits LTCCTRk.OCM1 and LTCCTRk.OCM0 (see **Table 28-4**).

When bit LTCCTRk.OCM2 is set, the data output LTCkOUT is affected either by the local LTCCTRk.OCM1 and LTCCTRk.OCM0 bits or by the M1I/M0I input lines, which are connected to the adjacent LTCk-1 Global Timer output lines M1O/M0O. An enabled LTCk event superimposes an action request generated simultaneously by the M1I/M0I inputs.

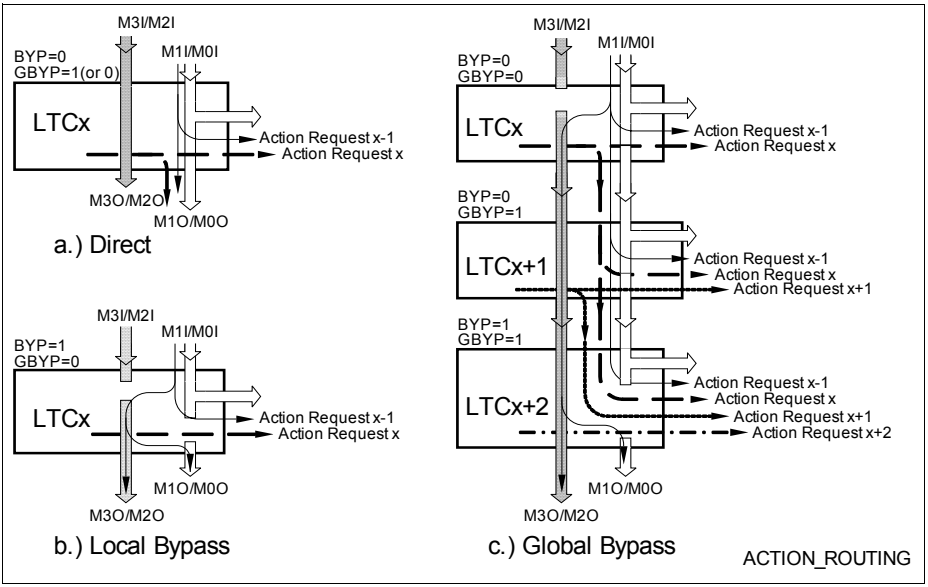

Figure 28-53 Direct, Local Bypass, and Global Bypass Action Request Routing

When the bypass bit LTCCTRk.BYP is cleared, the M1O/M0O output lines logically OR together the local LTCk events and, if enabled by bit LTCCTRk.OCM2, the action requests received via the M1I/M0I input lines.

When the bypass bit LTCCTRk.GBYP is cleared, the action requests received via M1I/M0I input lines, if enabled by bit LTCCTRk.OCM2, are forwarded to the subsequent LTCk+1 via the M3O/M2O output lines. If LTCCTRk.GBYP is set to 1, the action requests received via M3I/M2I input lines are forwarded to the subsequent LTCk+1 via the M3O/M2O output lines. Therefore the M3I/M2I may be used to pass the action requests of a reseted timer cross a group of LTC generating a complex signal or providing coherent update.

The two bypass bit LTCCTRk.BYP and LTCCTRk.GBYP enable three different types of action request routing, a direct routing, a local bypass routing and a global bypass

routing. These three different types of action request routing is sketched in **Figure 28-53**. The direct routing uses only the action request lines M1I/M0I. All action request run done the same path. The M3I/M2I are forwarded unchanged to M3O/M2O (next cells).

The local bypass copies all action request coming into a cell (M1I/M0I) to the outputs of the cell (M1O/M0O and M3O/M2O. The following cells do not see any action request generated within this locally bypassed cell.

The global bypass routing copies all action request coming into a group of sequential cells (M1I/M0I) to the outputs of this group of sequential cells (M1O/M0O and M3O/M2O. The following cells do not see any action request generated within this group of cells. Typically for edge aligned signals, the one action request for the edge is globally or locally bypassed, an all non edge aligned action request then locally generated within the group or local bypassed cell. Within a group complex signals may be generated or two cells used for local coherent update (double action principle).

Table 28-4 Selection of LTC Output Operations and Action Transfer Modes

Bit Field OCM [2:0]	Local Event	M1O/M0O								State of Local Data Output Line
		BYP = 0				BYP = 1				
		GBYP =0		GBYP=1		GBYP = 0		GBYP = 1		
0 0 0	No	0	0	0	0	0	0	M3I	M2I	not modified
	Yes	0	0	0	0	0	0	M3I	M2I	not modified
0 0 1	No	0	0	0	0	0	0	M3I	M2I	not modified

If OCM2 = 1: M3O/M2O = M1I/M0I

The LTCkOUT output line can be connected to output ports, on-chip peripheral inputs (OTGS) and/or LTC inputs via the I/O Line Sharing Block (see **Page 28-98**). LTCkOUT can be updated directly by software (setting bit LTCCTRk.OIA = 1) or upon a timer, capture, or compare event within the local LTCk or a preceding LTC. The current state of the data output line can be evaluated by reading status flag LTCCTRk.OUT.

Global bypass may also be used to move a group of Local Timer Cells (Consecutive Local Timer Cells using the same Local Timer) into the previous group of Local Timer to e.g. hit a specific output pin. The previous Local Timer Group will therefore have some Local Timer before and some after the to be moved Local Timer Group. Because the Local Time Bus YI and YO is driven by every LTC configured as timer regardless of the chosen bypass mechanism, special care has to be taken. An example is sketched in **Figure 28-54**. Three Local Timer for an edge aligned PWM, using the same time base as the local Timer Cell Group1 but different offsets (not edge aligned), is inserted into another group of Local Timer Cells implementing an independent other signal.

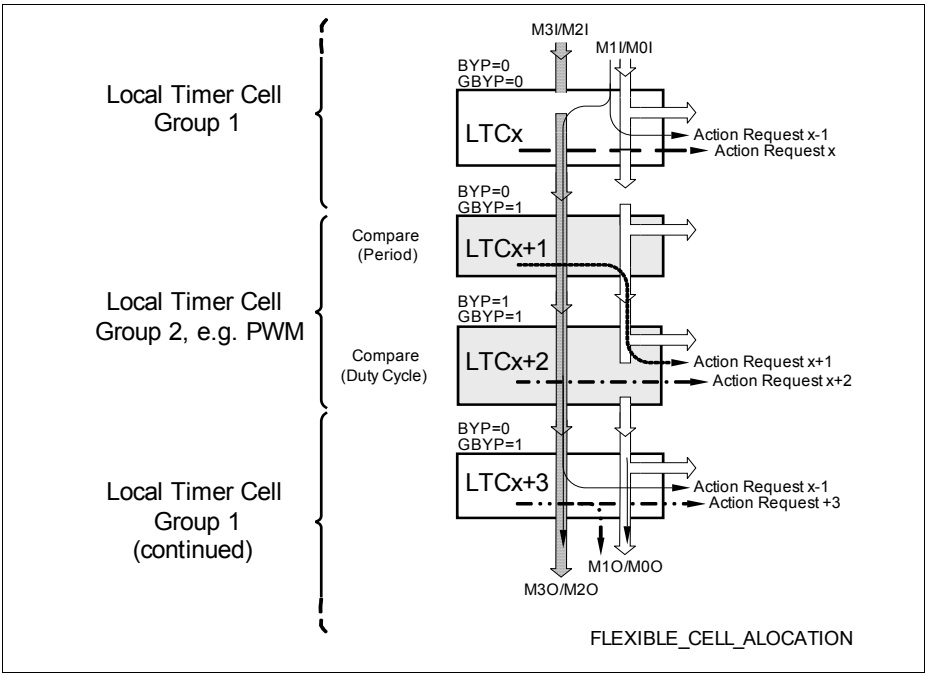

Figure 28-54 Global Bypass Action Request Routing for Flexible Cell Allocation

Cell Enabling

After reset all LTCs are disabled. An LTC may be enabled by resetting LTCCTRk.**EOA** (Enable-Of-Action) to 0 in Capture Mode or Compare Mode using a standard write assembler operation[1]. Because bit **EOA** is hardware protected, intrinsic read-modify-write assembler operations[2] only enable the LTC in Capture Mode or Compare Mode if bit **EOA** is modified from 1 to 0. If switching to Timer Mode, the LTC cell is enabled. In Timer Mode every write operation to bit 0…7 of LTCCTRk will enable the LTC.

Cell Deactivation

By programming an LTC to Capture Mode with no edge selected (LTCCTRk.ILM = LTCCTRk.FED = LTCCTRk.RED = 0), an enabled cell becomes inactive and performs no action, but continues passing action commands via the communication link from M1I/M0I to M1O/M0O. Output EO is inactive.

Alternatively, the LTC can be deactivated by setting it into Compare Mode with no active select line level (LTCCTRk.SOL = LTCCTRk.SOH = 0) but the communication link remains active. In this mode configuration, EI will be passed to EO.

Cell Enabling on Event

An LTC can be enabled in Capture Mode or Compare Mode by an event in an LTC with lower index number. For this purpose, the local event function of an LTC must be temporary disabled by setting LTCCTRk.EOA (Enable-Of-Action) to 1. Because bit EOA is hardware protected, intrinsic read-modify-write assembler operations[2] only disables the LTC if bit EOA is modified from 0 to 1. Both operations will clear LTCCTRk.CEN and now a local event cannot affect the LTC. When a preceding LTC generates and communicates an event (or OIA) via the communication link M1O/M0O, at least one of the M1I/M0I input lines changes its state to 1. This condition clears bit LTCCTRk.EOA of the disabled LTC via the OR gate as shown in **Figure 28-52**. Now LTCCTRk.CEN is set and the LTC is enabled for local events.

It is also possible to enable the following LTC via the communication link for local events. For this purpose, the bit LTCCTRk.EOA of this cell must be set, too. If bit LTCCTRk.OCM2 of the preceding cell is 1, the enable action will take place at the same time as in the preceding cell. Otherwise, the LTC will be enabled later on a capture/compare event in the preceding LTC, provided LTCCTRk.OCM0 or LTCCTRk.OCM1 of this cell is different from 0.

In this way, several LTCs can be enabled at the same time or one after the other. Normally, the LTCs will be used in One Shot Mode, and a service request will be

1) Standard TriCore® write operations: ST.A, ST.B, ST.D, ST.DA, ST.DD, ST.HST.Q, ST.W
Standard PCP write operations: ST.F, ST.IF,BCOPY, COPY

2) Intrinsic TriCore® read-modify-write Operations: LDMST, ST.T, SWAP
Intrinsic PCP read-modify-write Operations: SET.F, XCH.F, CLR.F

generated after the last event to evaluate the data and to prepare the next enable sequence. A disabled LTC (LTCCTRk.CEN = 0) behaves as an inactive capture LTC.

Logical Operating Cells

The inter-cell communication architecture allows concatenation of several LTCs to a logical cell. A logical cell contains any number of LTCs communicating via M1 and M0 lines and ends at an LTC disabled for action input or transfer (such as an LTC configured as timer, reset timer or LTC initiated with LTCCTRk.OCM2 = 0).

Therefore, the LTC with the lowest order number should be configured in Reset Timer Mode, thus providing all other LTCs of the logical cell with a time base (YO) and a compare enable signal (SO). Another LTC of the same logical cell can be initiated in Compare Mode to reset the LTC via its event output line EO, when a programmed threshold value is reached (register LTCXR) and the current state of its select line input SI matches the condition selected by the LTCCTRk bits SOH/SOL. Additional LTCs of the same logical cell can operate in Capture Mode triggered by a rising edge, falling edge, or both edges of a GPTA®v5 input line or a clock line of the clock bus. On the generated event, these LTCs capture the current contents of the timer cell, can generate a service request, can perform a manipulation of a GPTA®v5 output line (set, reset or toggle), and can also reset the LTC via the event output line EO.

LTC Service Request

The service request output SQTk of a Local Timer Cell LTCk is controlled as shown in **Figure 28-55**. When the LTCk service request condition becomes active, the service request flag becomes always set. The service request output SQTk is only activated if it is enabled by the enable bit LTCCTRk.REN. Additional information about service request and interrupt handling is given on **Page 28-123**.

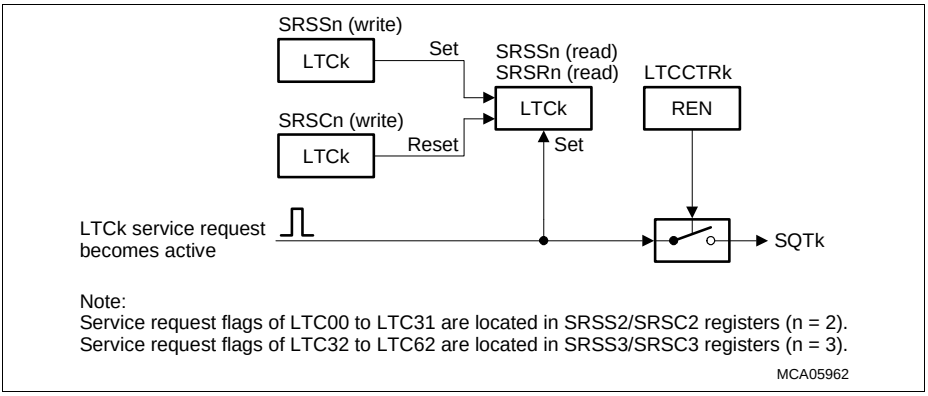

Figure 28-55 LTCk Service Request Generation

28.3.3.4 Local Timer Cell LTC63

The functionality of LTC63 is different to LTC00 to LTC62 and therefore described below.

Registers

The following registers are assigned to Local Timer Cell LTC63:

- LTCCTR63 = Local Timer Cell Control Register 63 (see **Page 28-204**)
- LTCXR63 = Local Timer Cell X Register 63 (see **Page 28-206**)
- SRSC3 = Service Request State Clear Register 3 (see **Page 28-230**)
- SRSS3 = Service Request State Set Register 3 (see **Page 28-231**)

Features

The GPTA®v5 Local Timer Cell array has one special cell, LTC63, which provides the following special features:

- **Compare Mode** on greater equal compare of the last timer, 16-bit based with following actions:
  - Service request generation
  - Output signal transition generation (set, reset, toggle the output signal).
- **Bit Reversal Mode:**
  - Timer can be selected to enable a special PWM Mode, called pulse count modulation (PCM)
- **Compare Value Switching** can be triggered by a hardware signal. This function can generate a service request. One Shot Mode makes it possible to stop the function after the first event.

Architecture

LTC63 is locally equipped with a 16-bit compare register, a 16-bit shadow register and a 16-bit greater comparator (**Figure 28-56**).

The LTC63 has the following inputs:

- A local input data bus (YI) carrying the local timer value of the adjacent LTC with lower order number
- A TI input reporting the occurrence of a local timer value update of the adjacent LTC with lower order number
- A trigger/enable input LTCkIN for compare value switching hooked to one of the following signals sources:
  - External port lines
  - GTC00 to GTC31 outputs
  - Clock bus signals
  - PDL0 or PDL1 outputs
  - Internal GPTA®v5 kernel input signals INTx (x = 0-3)

The LTC63 provides the following output signals:

- One data output line (LTCkOUT) that can be connected to:
  - External port lines
  - Inputs of an MSC module
  - Outputs and/or inputs of Global Timer Cell inputs
- One service request line (SQT) triggered by a compare or copy event
- An EO output reporting the occurrence of a local event to the adjacent LTC with lower order number

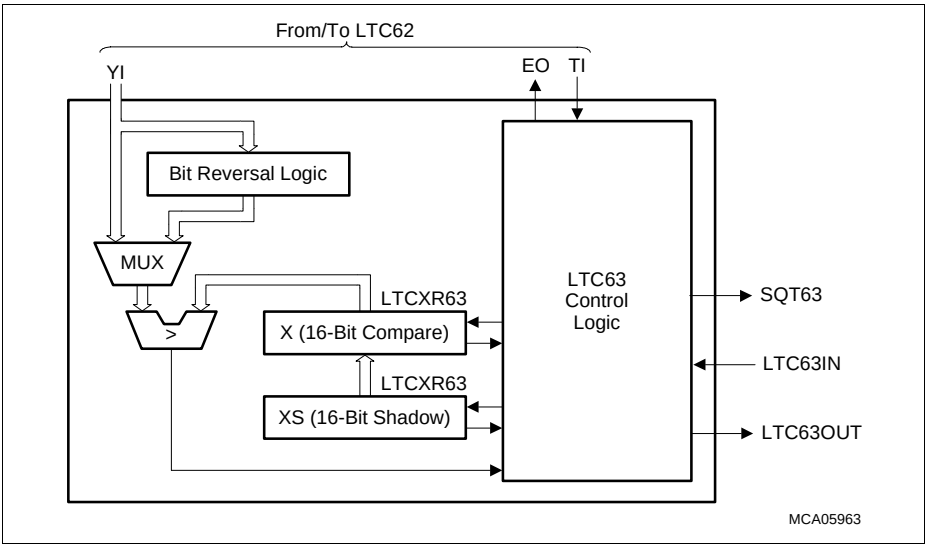

Figure 28-56 Architecture of Local Timer Cell 63

Compare

The compare function is always enabled. As long as the 16-bit compare value LTCXR63.X is greater than the timer value provided at YI, the comparator output signal is 1. The timer value at YI comes from the LTC62 either in original or in reversed order (Bit0 <-> Bit15, Bit1 <-> Bit14, etc.). The greater comparator output is connected directly to the output line LTC63OUT.

The 16-bit compare value LTCXR63.X is never greater than the LTC timer value ($FFFF_H$) coming from YI and which is used on LTC timer reset. Without special measures, a duty cycle of 100% cannot be achieved. There is always one LTC timer clock missing. Therefore, additional logic generates a permanent high signal whenever the 16-bit compare value LTCXR63.X is $FFFF_H$.

When the comparator output signal changes from 1 to 0,

- the service request flag LTC63 is set,
- an interrupt request will be activated if enabled by bit field LTCCTR63.REN,
- the event output line EO is set to high level for one f_{GPTA} clock cycle.

As well as the16-bit compare register LTCXR63.X, the LTC63 also contains a 16-bit shadow register LTCXR63.XS. Both 16-bit registers are combined in the 32-bit register LTCXR. On an LTC input signal selected via the LTC input multiplexer, the contents of the shadow register are copied to the compare register.

Standard PWM Mode

The LTC63 can be used for standard PWM duty cycle generation with enhanced update features. For this purpose, a pair of LTCs with lower index is configured as reset timer/period compare register. The user must set the period compare register to the desired period - 2 and LTC63 to the desired duty cycle. With LTCCTR63.BRM = 0 (Bit Reversal Mode), timer bit reversal is disabled. LTC63 is used for standard PWM Mode but with enhanced update features due to the “greater” comparator. The compare register LTCXR63.X can be written on-the-fly. If the duty cycle is changed at an arbitrary time, the actual duty cycle for the current period will reflect the old duty cycle, the new one, or a mixture of both. A duty cycle of 100% will be generated if the compare register is set to $FFFF_H$.

Pulse Count Modulation Mode (PCM)

With a period of 100 clocks and a duty cycle of 64%, standard PWM will produce an output signal that is ON for 64 clock cycles and OFF for the remaining 36 clock cycles. In contrast, pulse count modulation will generate 64 ON pulses and 36 OFF pulses distributed over the whole period as evenly as possible. PCM offers higher output frequency than standard PWM. This allows faster settling time e.g. when building a D/A converter in conjunction with an external low-pass filter. Only for very short or very long duty cycles does the method show no advantage or just little advantage compared to standard PWM.

As with standard PWM, a pair of LTCs with lower index is configured as reset timer/period compare register and LTC63 is used as duty cycle compare register. But now, Bit BRM (Bit Reversal Mode) in the LTCCTR63 register is set to 1 which enables the timer bit reversal to activate PCM.

The algorithm will also work if fewer than 16 timer bits are effectively used, even if the period is not a power of two. In any case, the user must write the duty cycle in unsigned 16-bit fractional format to the compare register.

Figure 28-57 shows an PCM example for an effective period of 6 clocks.

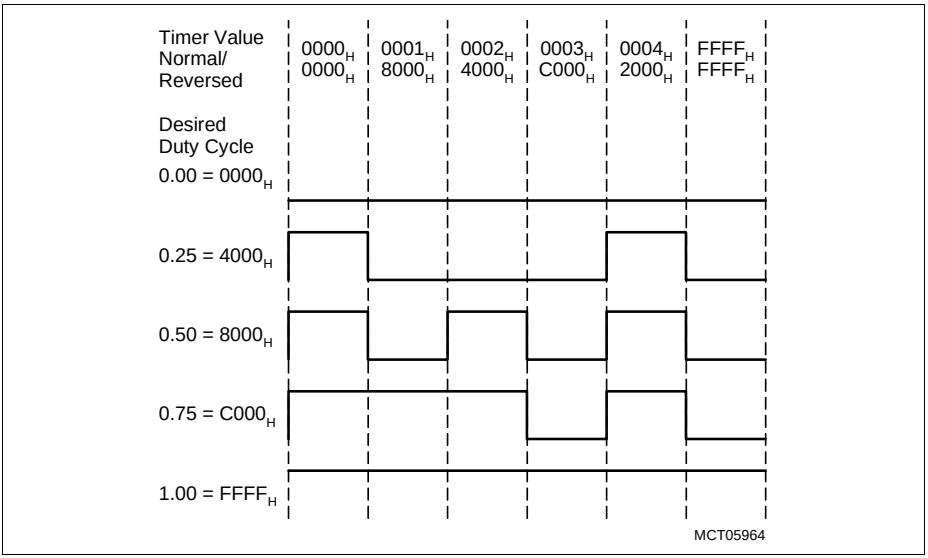

Figure 28-57 Pulse Count Modulation Example 1

Table 28-5 shows the rounding behavior for a period of 100 clocks.

Table 28-5 Implicit PCM Rounding

Desired Duty Cycle	Expected ON Pulses	Actual ON Pulses
0.000 = 0000	0	0
0.100 = $199A_H$	10	11
0.500 = 8000_H	50	50
0.800 = $CCCD_H$	80	82
0.900 = $E666_H$	90	90
0.999 = $FFBE_H$	100	99
1.000 = $FFFF_H$	100	100

The output is OFF for the remaining cycles of the period. The worst case error is approximately +2/-1 ON pulses. A subtraction performed via software may be used to reduce the worst case error.

If the duty cycle is changed at an arbitrary time, the actual duty cycle for the entire current period will reflect the old duty cycle, the new one, or a mixture of both.

Figure 28-58 shows another PCM example that demonstrates the difference between a standard PWM signal and the derived PCM signal. During one PWM period (128 clock cycles), the standard PWM signal is ON for 8 clock cycles and OFF for the remaining 120 clock cycles (duty cycle of 6.25%). The PCM signal operates with a PCM duty cycle of 1/8 = 0.125 resulting in 8 ON pulses of 1 clock cycle width within 1 PWM period.

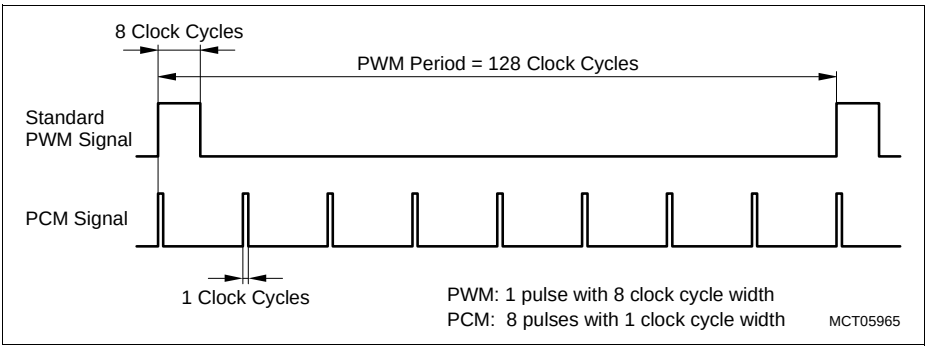

Figure 28-58 Pulse Count Modulation Example 2

Compare Value Switching

In both pulse modulation modes, it is possible to change the duty cycle either by software or on an LTC input signal. LTC63 contains two registers, the compare register and a shadow register. For software access, the compare register LTCXR63.X (= 16-bit low part of LTCXR63) is written directly.

For compare value switching triggered by hardware, the shadow register LTCXR63.XS (= 16-bit high part of LTCXR63) is pre-loaded with the desired duty cycle. On an LTC input signal selected via the LTC input multiplexer,

- The shadow register content LTCXR63.XS is copied to the compare register LTCXR63.X,
- The LTC63 service request flag is set,
- An interrupt request will be activated if enabled by bit field LTCCTR63.REN.

The data input line LTC63IN can operate in two modes (selected by bit LTCCTR63.ILM):

- Level Sensitive Mode or
- Edge Sensitive Mode

In Edge Sensitive Mode, the active edges are selected by bits LTCCTR63.FED and LTCCTR63.RED. In Level Sensitive Mode, the data input line LTCkIN is sensitive on a high level.

Various clocking modes of the LTC63 copy function are possible, depending on the source selected for the input line by the input multiplexer (see Table 28-6).

Table 28-6 LTC63 Data Input Line Operation

Input Source	Level Sensitive Input Line	Edge Sensitive Input Line
External Signal (Port line)	The external signal operates as gating signal for the cell. If the input is high the copy function of the LTC cell is performed with each rising edge of the GPTA®v5 module clock f_{GPTA}.	The copy function of the LTC cell is performed on selected edge(s).
Internal Clock Bus Line or PDL output or INT input	The copy function is performed with the internal clock or PDL/INT signal.	The copy function of the LTC cell is performed on selected edge(s). In case of full speed GPTA®v5 module clock selection, the Level Sensitive Mode must be selected. The Edge Sensitive Mode will not produce an event in this special case.
GTC output	The GTC output signal operates as gating signal for the cell. If the input is high the copy function of the LTC cell is performed with each rising edge of the GPTA®v5 module clock f_{GPTA}.	The copy function of the LTC cell is performed on selected edge(s).

When bit LTCCTR63.OSM is set to 1, a self-disable is executed after each copy event (PWM is not affected). The current state of the LTC copy enable may be evaluated by reading the control register flag bit LTCCTR63.CEN.

The output can be switched immediately to 0 or 1 in any pulse modulation mode by writing 0000_H or $FFFF_H$ to the duty cycle compare register LTCXR63.X.

LTC63 Service Request

The service request SQT63 can be generated by one of the following events:

- Comparator output changes from 1 to 0 (this makes sense mainly for standard PWM),
- Copy event.

Bit combinations 01_B and 10_B of bit field LTCCTR63.REN selects one of the two service request sources and enables it. Output SQT63 becomes active in these two cases. With the other two bit combinations of bit field LTCCTR63.REN (00_B, 11_B), the SQT63 output will not be activated. The LTC63 service request flag SRSS3.LTC63 will be set on a service request independently of LTCCTR63.REN. Additional information on service request and interrupt handling is provided on **Page 28-123**.

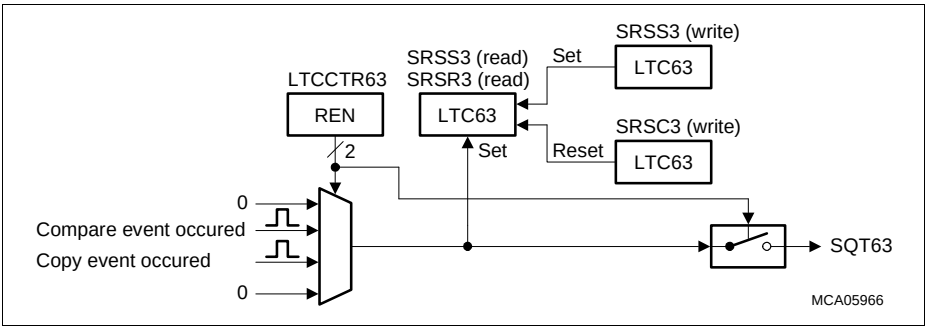

Figure 28-59 LTC63 Service Request Generation

28.3.3.5 Coherent Update

This section describes the two different mechanism to update signal features (e.g. period, duty cycle) if using Local Timer Cells. Both mechanism grant a coherent update only if a single update within a group of Local Timer Cells using a common Local Timer is performed within a timer period. So coherent update can only be granted if between coherent updating routine exit and coherent updating routine entry a time period of more then a period is maintained. If updating more frequently, software has to take care of coherency.

Global Coherent Update

The first mechanism, the so called global coherent update, is very useful to update a number of Local Timer Cells simultaneously. Furthermore this is the only way to grant a coherent update of a Local Timer Cell used as the period cell for a Reseted Timer. This global coherent update uses a common signal line (SI/SO) within a group of Local Timer Cells (all Local Timer Cells following an LTC configured as Timer). A pair of Local Timer Cells are configured so one cell being active on a high level of this SI/SO

(LTCCTRk.SOH = 1, LTCCTRk.SOL = 0) signal and the other cell being active on a low level of this SI/SO (LTCCTRk.SOH = 0, LTCCTRk.SOL = 1) signal. This pair of Local Timer Cells are configured to generate both action request for a single output signal (e.g. pin). If the global SI/SO is in a low state, all Local Timer Cells to be active on a high level of SI/SO can be configured (programmed with new values) without distortion of the output signal, because of being inactive. By setting the LTCCTRk.CUD bit within the Local TImer Cell used as Local Timer, the SI/SO bit will be toggled at the start of the next timer period, so all pair of Local Timer Cells simultaneously switch from active to passive (LTCCTRk.SOH = 0, LTCCTRk.SOL = 1) or passive to active state. Now the Local Timer Cells being inactive (LTCCTRk.SOH = 0, LTCCTRk.SOL = 1) may be configured (programmed) for the next update. No Local Timer Cell may be configured (programmed) while respective timer bit LTCCTRk.CUD =1, else wise a coherent update is no longer granted. Either the LTCCTRk.CUD has to be reset to 0 by software or a update of the Local Timer Registers have to be delayed to the next start of the period (LTCCTRk.CUD is reset by hardware to 0). The following example shows a PWM using global coherent update.

Fully Programmable PWM Signal Generation with 5 LTCs (global coherent update)

As shown in **Figure 28-59**, a logical cell of five LTCs can be used to generate a PWM signal with a programmable duty cycle, period length, and fully global coherent update of the period and duty cycle. In this example, LTC00 up to LTC04 are used to generate a PWM signal at the output of LTC04. To reduce complexity of this example, only a single duty cycle pair is described in the following text. More duty cycle cells may follow using the same reseted timer and pair of period cells. So if requiring a second duty cycle LTC pair, the first pair would be located to LTC2 and LTC6, the next pair on LTC 3 and LTC7 and the period cells would be assigned to LTC1 and LTC4.

LTC00 is configured in Reset Timer Mode thus providing all subsequent cells with a time base. LTC00 is clocked by a clock signal at the LTC00IN which has been selected by the LTC input multiplexer. LTC00 counts after reseted by LTC01 or LTC02 from $FFFF_H$, 0000_H, 0001_H … LTCXR01.X or LTCXR01.X. The period of the generated PWM is therefore LTCXR01.X +2 or LTCXR02.X + 2.

LTC01 and LTC02 are configured in Compare Mode. They are enabled if its SI inputs are at low level and responsible for the LTC04OUT signal generation in Phase 1. With the programmed values from **Table 28-7**, the LTC04OUT signal of Phase 1 has a period of 1000_D (= $3E8_H$) clocks of the LTC00IN clock signal and a duty cycle of 20% (= 200_D or $C8_H$).

LTC01 is configured in such a way (LTCCTR01.OCM = 011_B) that its output LTC01OUT is set to 1 whenever the LTC00 timer value LTCXR00.X is equal to the LTC01 compare value LTCXR01.X.

LTC02 is configured in such a way (LTCCTR02.OCM = 110_B) that its output LTC02OUT is reset whenever the LTC00 timer value LTCXR00.X is equal to the LTC02 compare value LTCXR02.X or it copies the action from the previous LTC01.

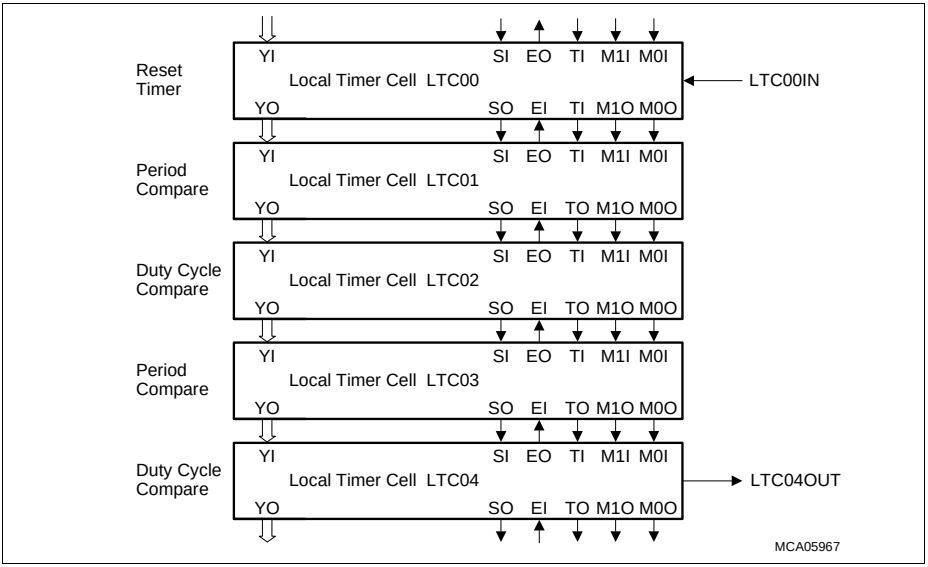

Figure 28-60 PWM Signal Generation with LTCs (Global Coherent Update)

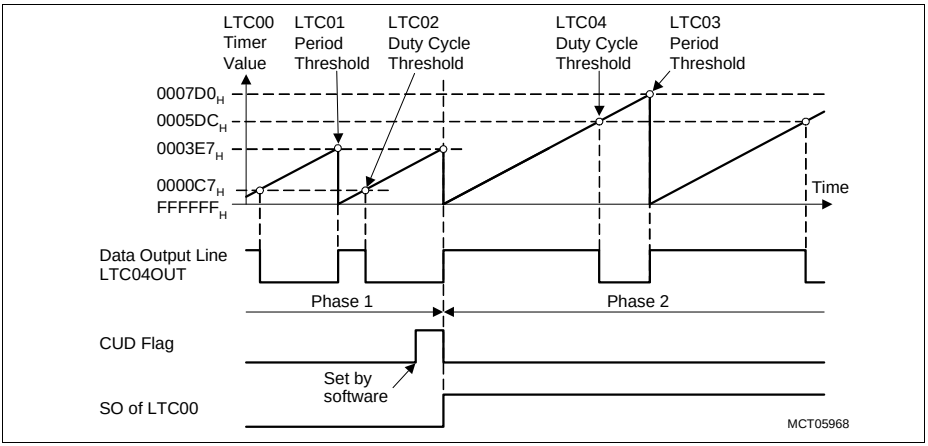

Figure 28-61 Internal Signal States of the PWM Signal Generation with 5 LTCs

LTC03 and LTC04 are configured in Compare Mode. They are enabled if its SI inputs are at high level and are responsible for the LTC04OUT signal generation in Phase 2. With the programmed values from **Table 28-7**, the LTC04OUT signal of Phase 2 has a period of 2000_D (= $7D0_H$) clocks of the LTC00IN clock signal and a duty cycle of 75% (= 1500_D or $5DC_H$).

LTC00 to LTC04 for the PWM example must be configured as defined in **Table 28-7**.

Note: Special care has to be taken not to reprogrammed the group of local timer cells (LTC) CAPCOM register before the previous global or local coherent update has been completed (end of current local timer period). Therefore maximum only one global coherent update within a timer period is possible! No Local coherent updates may be activated while a global coherent update modifying the period has not been completed.

Note: If several sequential coherent updates within a group of Local Timer Cells (LTC) is required, instead of using the global coherent update feature, the local coherent update mechanism (double action principle) is preferable. Mixing both principle, so updating the period using the coherent update and updating one or more duty cycle using local coherent update (double action principle) may result under specific condition in distorted signals (new duty cycle, old period or old duty cycle and new period). Therefore within a period either a global coherent update or multiple local coherent updates may be scheduled.

Note: To generate an output signal having 0% duty cycle (continuously low), the duty compare of the active cells must be set to $FFFF_H$. The timer sets the data output line by generating a respective signal on MO0 and MO1, but this signal is overruled by the dominating duty compare cell resetting the same data output line and therefore not passing the MI0 and MI1 signal from the timer to the data output line. This result in a data output line remaining continuously low.

Note: To generate an output signal having 100% duty cycle (continuously high), the duty cycle threshold must be set above the period threshold value. Therefore no reset event for the data line is generated and periodically the timer generates a set event. This result in a data output line remaining continuously high.

Table 28-7 Programming Values for PWM Signal Generation with 5 LTCs

Register	Value	Function
LTC00 Configuration Setup

Local Coherent Update

The second mechanism, the so called local coherent update or double action principle, is very useful to update single Local Timer Cells without signal distortion (no other signal output beside the previously configured and the new configured). This coherent update may not be used for Local Timer Cells generating toggle action requests (LTCCTRk.OCM = OCM = $x01_B$). The local coherent update is useful to configure (programme) several Local Timer Cells within a group of Local Timer Cells (all using the same Local Timer Cell as time base) sequentially (not simultaneously), e.g. within different routines of the application software. The only restriction to grant non distorted output signals by hardware is to update (configure or programme) every single pair of Local Timer Cells no often than once within a timer period (time measured from previous routine exit and current routine entry), else wise software has to take care of coherency (non distorted signals). A pair of Local Timer Cells are configured one cell being active (LTCCTRk.SOH = 1, LTCCTRk.SOL = 1) and the other being inactive (LTCCTRk.SOH = 0, LTCCTRk.SOL = 0, LTCCTRk.CEN = 0). This pair of Local Timer Cells are configured to generate both action requests for a single output signal (e.g. pin). A Local Timer Cell being inactive may be configured (programmed with a new value) without distortion of the output signal, because of being inactive. By activating the newly configured Local Timer Cell (LTCCTRk.SOH = 1, LTCCTRk.SOL = 1, LTCCTRk.OSM = 0), now two Local Timer Cells generate the same type of action request. The one being earlier within the period will now drive the output signal (either the newly configured or the previously configured one). Now the Local Timer Cell being active before configuration is coherently deactivated (LTCCTRk.OSM = 1) on its next action. So one period later this cell will be inactive (LTCCTRk.CEN = 0) and may be used for the next local coherent update. Local and coherent update may be used simultaneously within a group of Local Timer Cells. The following example shows a PWM using local coherent update. To reduce complexity of this example, only a single duty cycle pair is described in the following text. More duty cycle cells may follow using the same reseted timer and pair of period cells. So if requiring a second duty cycle LTC pair, the first pair would remain on LTC2 and LTC3 and the next pair on LTC 4and LTC5 using LTC05 as output.

Programmable PWM Signal Generation with 4 LTCs (local coherent update)

As shown in **Figure 28-62**, a logical cell of four LTCs can be used to generate a PWM signal with a programmable duty cycle and local coherent update of this duty cycle. In this example, LTC00 up to LTC03 are used to generate a PWM signal at the output of LTC03.

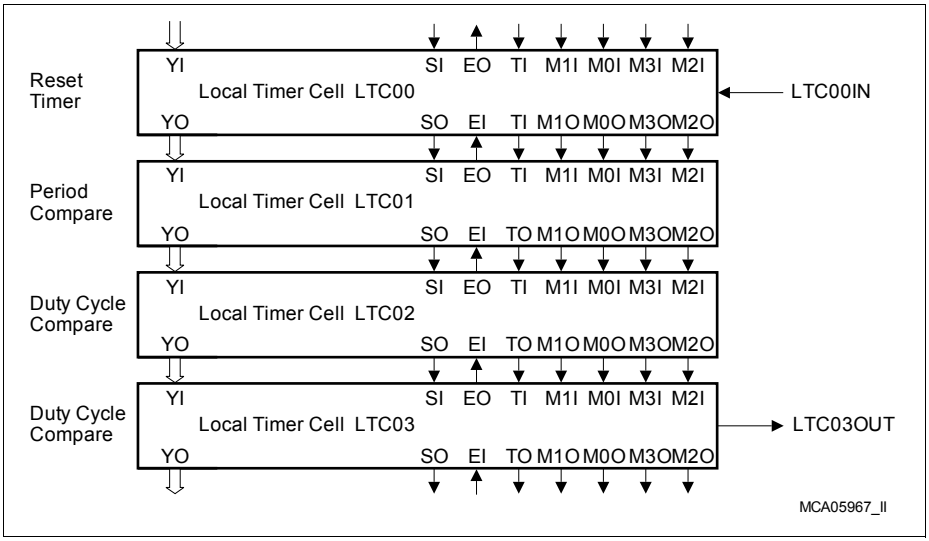

Figure 28-62 PWM Signal Generation with LTCs (Local Coherent Update)

LTC00 is configured in Reset Timer Mode thus providing all subsequent cells with a time base. LTC00 is clocked by a clock signal at the LTC00IN which has been selected by the LTC input multiplexer. LTC00 counts after reseted by LTC01 or LTC02 from $FFFF_H$, 0000_H, 0001_H … LTCXR01.X or LTCXR01.X. The period of the generated PWM is therefore LTCXR01.X +2 or LTCXR02.X + 2.

LTC01 is configured in Compare Mode. It is always active and responsible for the LTC03OUT signal generation in Phase 1. With the programmed value from **Table 28-8**, the LTC03OUT signal of Phase 1 has a period of 1000_D (= $3E8_H$) clocks of the LTC00IN clock signal and a duty cycle of 20% (= 200_D or $C8_H$).

LTC01 is configured in such a way (LTCCTR01.OCM = 011_B) that its output LTC01OUT is set to 1 whenever the LTC00 timer value LTCXR00.X is equal to the LTC01 compare value LTCXR01.X.

LTC02 and LTC03 are configured in Compare Mode. They are responsible for the LTC03OUT signal generation in Phase 2. With the programmed values from **Table 28-8**, the LTC03OUT signal of Phase 2 has a duty cycle of 77% (= 770_D or 302_H).

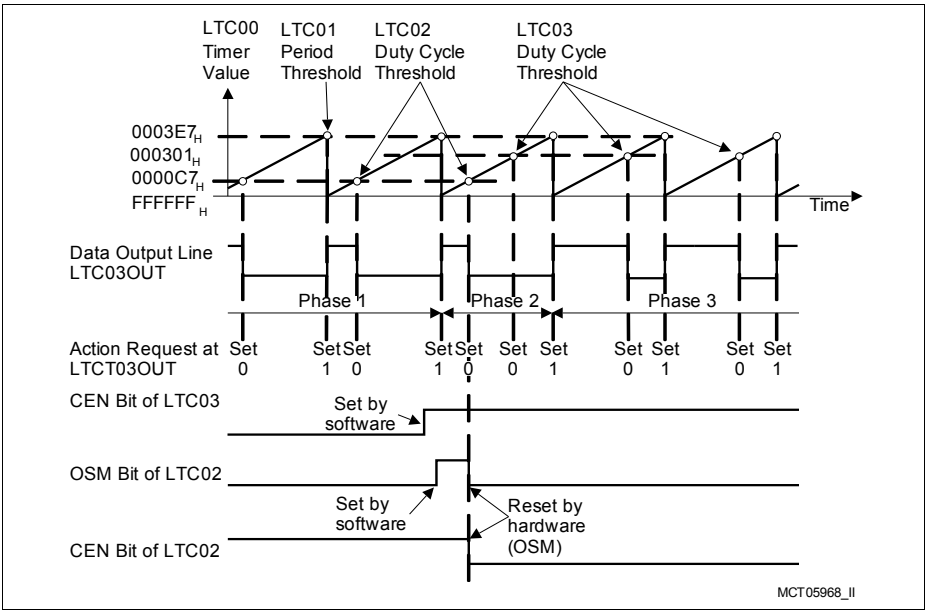

Figure 28-63 Internal Signal States of the PWM Signal Generation with 4 LTCs

LTC00 to LTC03 for the PWM example must be configured as defined in **Table 28-8**.

Note: Special care has to be taken not to reprogram LTCXR02.X or LTCXR03.X before the previous local coherent update has been completed (LTCXR02.CEN = 0 or LTCXR03.CEN = 0). Therefore maximum one coherent update within a timer period is possible (measured from previous routine exit to current routine entry)!

Note: If simultaneous coherent updates of several Local Timer Cells within a group of Local Timer Cells (LTC) is required, instead of using the local coherent update (double action principle), the global coherent update mechanism must be used.

Note: If coherent updating the period of a Timer in Reset Timer Mode is required, the global coherent update mechanism must be used.

Note: Global bypass may be used to route e.g. period action request (edge aligned PWM) around the pair of locally coherent updated Local Timer Cells to following Local Timer Cells. But special care has to be taken, because the timer bus is not routed over a LTC configured as timer.

Note: This scheme activates for one period two cells in parallel. Therefore, if enabled, also two interrupts for this one signal are generated, one for the old (previous) edge, one for the new (updated) edge.

Note: To generate an output signal having 0% duty cycle (continuously low), the duty compare of the active cells must be set to $FFFF_H$. The timer sets the data output line by generating a respective signal on MO0 and MO1, but this signal is overruled by the dominating duty compare cell resetting the same data output line and therefore not passing the MI0 and MI1 signal from the timer to the data output line. This result in a data output line remaining continuously low.

Note: To generate an output signal having 100% duty cycle (continuously high), the duty cycle threshold must be set above the period threshold value. Therefore no reset event for the data line is generated and periodically the timer generates a set event. This result in a data output line remaining continuously high.

Table 28-8 Programming Values for PWM Signal Generation with 4 LTCs

Register	Value	Function
LTC00 Configuration Setup		
GPTA0_LTCXR00	0000 0000_H	LTC00 data register value = 0
GPTA0_LTCCTR00	0000 0413_H	MOD = 11_B: Reset Timer Mode selected OSM = 0: LTC00 continuously enabled ILM = 0, RED = 1, FED = 0: Input LTC00IN operates in Edge Sensitive Mode with rising edge; one clock bus signal is selected via the LTC input multiplexer SLO = 0: state of select line output SO is 0 CEN = 0: enable LTC00 for local events OCM = 000_B: hold LTC00OUT state
LTC01 Configuration Setup		
GPTA0_LTCXR01	0000 $03E7_H$	Load compare value = $3E7_H$ = 999_D
GPTA0_LTCCTR01	0000 $5C11_H$	MOD = 01_B: Compare Mode with LTC00 selected OSM = 0: LTC01 continuously enabled SOH = 1, SOL = 1: enabled by both level at SI BYP = 0: bypass in LTC02 is disabled GBYP = 0: global bypass in LTC02 is disabled EOA = 0: LTC02 enabled for local events OCM = 011_B: set LTC01OUT by a local event only OIA = 1: output action defined by OCM must be performed immediately

Table 28-8 Programming Values for PWM Signal Generation with 4 LTCs (cont'd)

Register	Value	Function
LTC02 Configuration Setup		
GPTA0_LTCXR02	0000 00C7$_H$	Load compare value = C7$_H$ = 199$_D$
GPTA0_LTCCTR02	0000 3431$_H$	MOD = 01$_B$: Compare Mode with LTC00 selected OSM = 0: LTC02 continuously enabled SOH = 1, SOL = 1: compare enabled by low and high level at SI BYP = 0: local bypass in LTC02 is disabled GBYP = 0: begin of global bypass in LTC02 EOA = 0: LTC02 enabled for local events OCM = 110$_B$: reset LTC02OUT by a local event or copy the previous cell action OIA = 0: no immediate output action required
LTC03 Configuration Setup		
GPTA0_LTCXR03	0000 0301$_H$	Load compare value = 301$_H$ = 769$_D$
GPTA0_LTCCTR03	0001 3401$_H$	MOD = 01$_B$: Compare Mode with LTC00 selected OSM = 0: LTC03 continuously enabled SOH = 0, SOL = 0: compare disabled by low and high level at SI BYP = 1: local bypass in LTC03 is disabled GBYP = 1: end of global bypass in LTC03 EOA = 0: LTC04 enabled for local events OCM = 110$_B$: reset LTC03OUT by a local event or copy the previous cell action OIA = 0: no immediate output action required

The following code exemplifies the scheme to update the duty cycle of the PWM signal generation with 4 LTCs

```
Read LTCCTR02
If ( LTCCTR02.SOL=1 and LTCCTR02.SOH=1 and LTCCTR02.CEN=1 and
    LTCCTR02.OSM=0) Then
   Write New_Value into LTCXR03 of LTC03
   Set LTCCTR03.OSM=0 and LTCCTR03.SOL=LTCCTR03.SOH=1 for LTC03
    (Do not use LOAD/MODIFY/STORE, SWAP, or CLEAR_BIT assembler instructions)
   Set LTCCTR02.OSM=1 of LTC02
     (Use LOAD/MODIFY/STORE, SWAP, or CLEAR_BIT assembler instructions)
   Read LTCXR02
   Read LTCXR00
   If LTCXR00>Read_LTCXR02 then
      Clear LTCCTR02.SOL=LTCCTR02.SOH=0 of LTC02
   End If
Else
   Write New_Value into LTCXR02 of LTC02
   Set LTCCTR02.OSM=0 and LTCCTR02.SOL=LTCCTR02.SOH=1 for LTC02
    (Do not use LOAD/MODIFY/STORE, SWAP, or CLEAR_BIT assembler instructions)
   Set LTCCTR03.OSM=1 of LTC03
     (Use LOAD/MODIFY/STORE, SWAP, or CLEAR_BIT assembler instructions)
   Read LTCXR03
   Read LTCXR00
   If LTCXR00>Read_LTCXR03 then
      Clear LTCCTR03.SOL=LTCCTR03.SOH=0 of LTC03
   End If
End If
```

28.3.4 Input/Output Line Sharing Block (IOLS)

The I/O Line Sharing Block allows the 56 inputs and 112 outputs of the GPTA®v5 units to be routed with high flexibility between I/O lines, output lines, clock inputs, other on-chip peripherals and other GPTA®v5 cells. The GPTA®v5 module provides a total of 56 input lines and 112 output lines, assigned to seven I/O groups IOG[6:0], two on-chip trigger and gating signal groups OTG[1:0], and seven output groups OG[6:0].

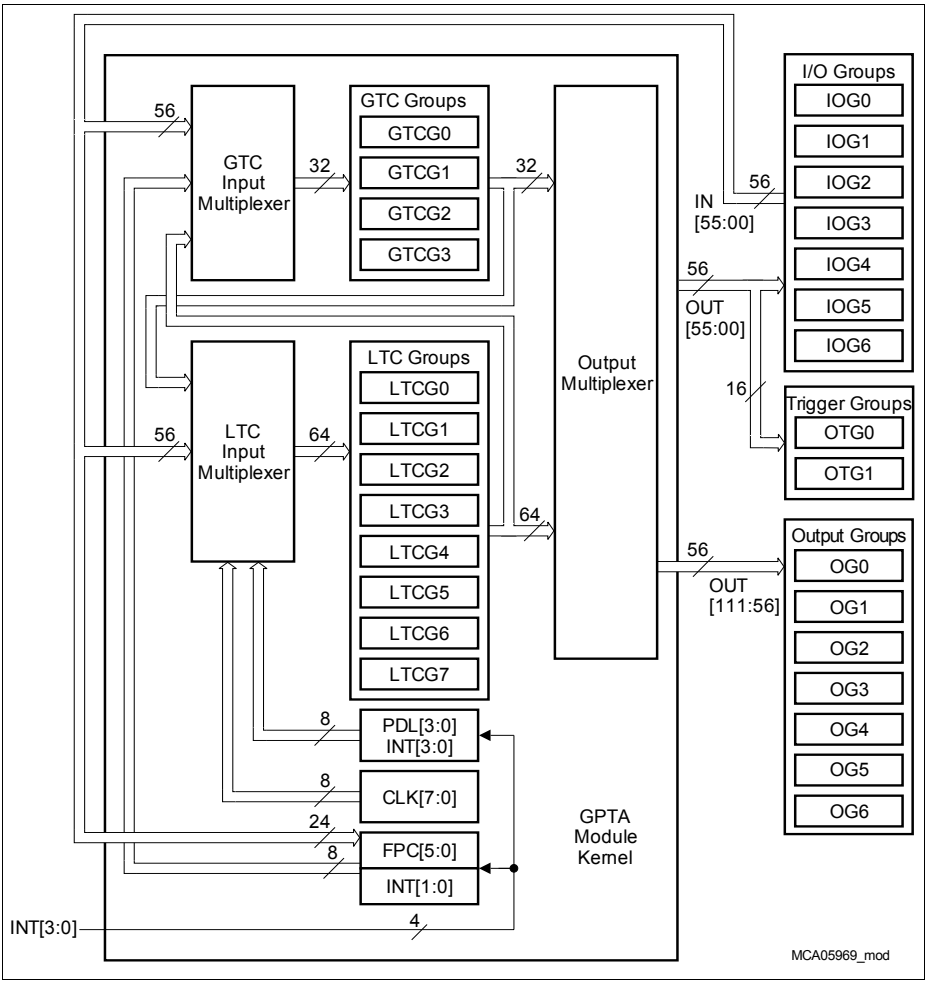

Figure 28-64 Input/Output Line Sharing Block Overview

The I/O Line Sharing Block does the following selections:

- FPC input line selection
- GTC and LTC output multiplexer selection
- On-chip trigger and gating signal selection
- GTC input multiplexer selection
- LTC input multiplexer selection

For choosing these selection, the input and output lines of the related cells are integrated into groups with eight parts each. Seven I/O groups, two on-chip and gating signal groups, seven output groups, four GTC groups, eight LTC groups, one clock group, one FPC/INT group, and one PDL/INT group are defined.

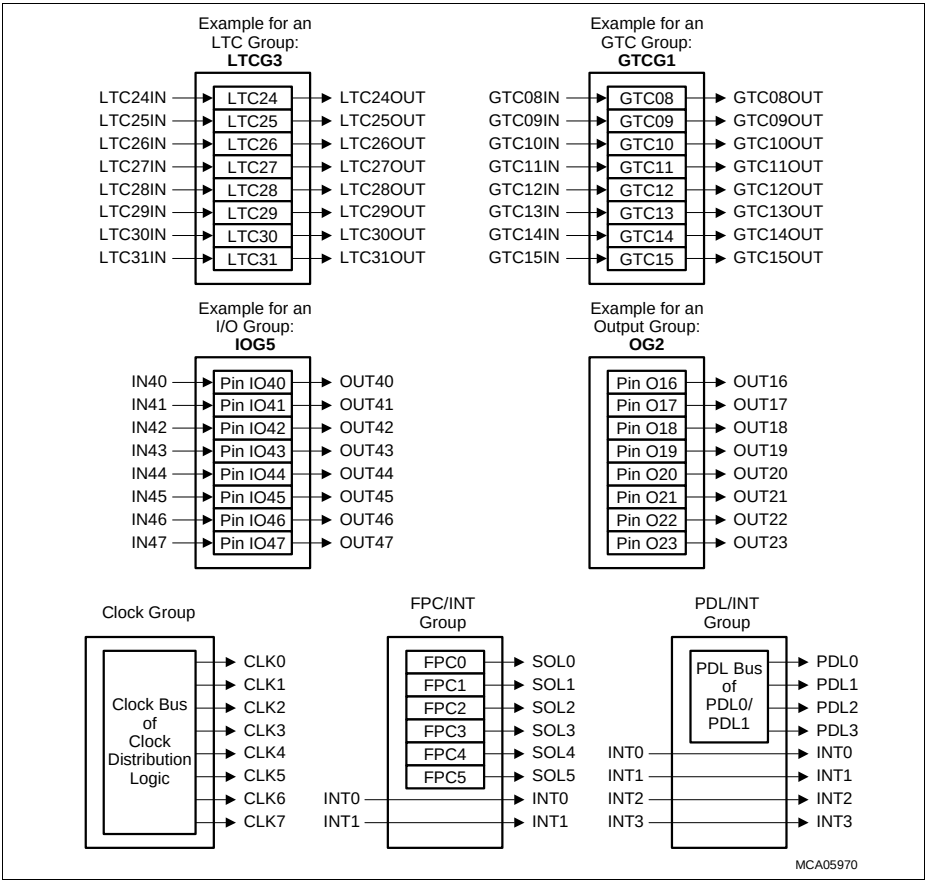

Figure 28-65 Groups Definitions for I/O Line Sharing Block

An **LTC group** combines eight LTC cells with its input and output lines. This results in eight LTC groups, LTCG0 to LTCG7.

A **GTC group** combines eight GTC cells with its input and output lines. This results in four GTC groups, GTCG0 to GTCG3.

An **I/O group** combines eight GPTA®v5 I/O lines connected to bi-directional device pins with its input and output lines. This results in seven I/O groups, IOG0 to IOG6, supporting 56 I/O lines.

An **Output group** combines eight GPTA®v5 output lines connected to device pins as an output. This results in seven output groups, OG0 to OG6, supporting 56 output lines.

The **Clock group** is a group that combines the eight clock bus output signals CLK[7:0] generated by the clock distribution cells.

The **FPC/INT group** is a group that combines the six level output signals SOL[5:0] of the FPCs with two external input lines INT[1:0] of the GPTA®v5 unit.

The **PDL/INT group** is a group that combines the four PDL output lines of the PDL bus with four external input lines INT[3:0] of the GPTA®v5 unit.

An **On-chip trigger and gating signal group** combines eight GPTA®v5 output lines connected to on-chip peripherals. This results in two on-chip trigger and gating signal groups, OTG0 to OG1, supporting 16 on-chip trigger and gating lines.

28.3.4.1 FPC Input Line Selection

As shown on **Page 28-12**, each FPC cell can be connected to one out of four input lines SINk[3:0], to the GPTA®v5 module clock f_{GPTA}, or to the output of the preceding FPC. In total, 24 input lines out of the 56 input lines IN[55:00] from the I/O groups are connected (not programmable) with the FPCk inputs. The FPCk input line selection is controlled by the FPCCTRk.IPS bit fields. **Table 28-10** shows the FPC input line connections.

Table 28-10 FPC Input Line Assignments

FPC Control Register	Bit Field IPS	Selected Input Signal
FPCCTR0	000_B	IN0
	001_B	IN12

28.3.4.2 GTC and LTC Output Multiplexer Selection

The output multiplexer shown in **Figure 28-64** and **Figure 28-66** below connects the 32 GTC output lines and the 64 LTC output lines with the I/O groups (7 × 8 = 56 output lines) and the output groups (7 × 8 = 56 output lines).

In case of low pin count packages, not all I/O groups may be routed to a pin.

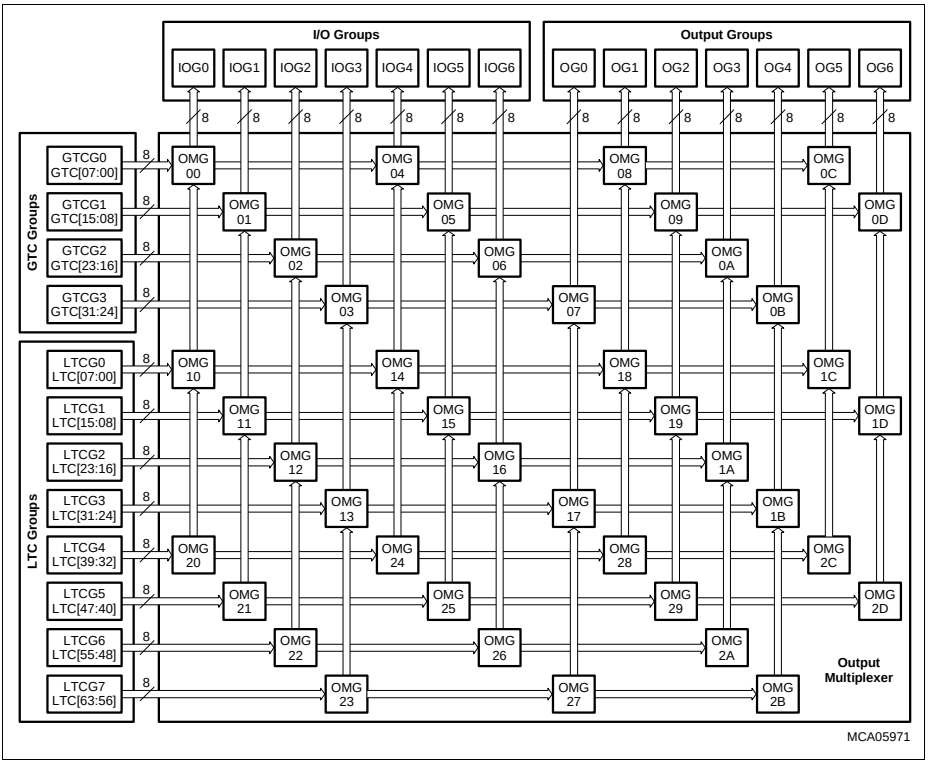

Figure 28-66 Output Multiplexer

The output multiplexer contains Output Multiplexer Groups (OMGs) that connect the Global Timer Cells or Local Timer Cells with the input lines of the I/O groups and output groups. GTCs and LTCs are grouped into four GTC groups (GTCG[3:0]) and eight LTC groups (LTCG[7:0]) with 8 cells each. In the same way, I/O groups and output groups are grouped into 14 groups (seven I/O groups and seven output groups) with 8 lines each.

Figure 28-67 shows the logical structure of an OMG.

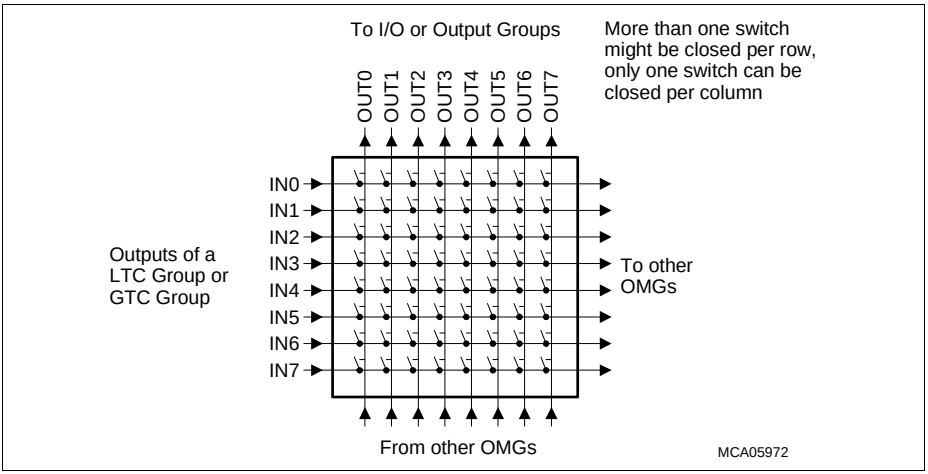

Figure 28-67 Output Multiplexer Group (OMG) Structure

Rules for connections to Output Multiplexer Group OMG:

- Within a GTC or LTC group, the output of the cell with the lowest index number is connected to OMG input line IN0. The remaining cells of a cell group are connected to OMG input lines IN1 to IN7 with ascending cell index numbers.
  Example: for OMG13 (see Figure 28-66), the cells LTC24 up to LTC31 are wired to the OMG13 input lines IN0 to line IN7.
- OMG output line OUT0 is always connected to the input of an I/O or output group with the lowest index. The remaining output lines OUT1 to OUT7 are connected to the I/O or Output lines with ascending index.
  Example: for OMG13 (see Figure 28-66), the outputs OUT0 to OUT7 are wired (via OMG03) to input lines 0 to 7 of I/O group 3 (IOG3).
- One input of an I/O or output group can be connected to the output of only one timer cell. This is guaranteed by the OMG control register layout. Otherwise, short circuits and unpredictable behavior would occur. On the other hand, it is permissible for the output of a GTC or LTC to be connected to more than one input of an I/O or output group.

The output multiplexer group configuration is based on the following principles:

- Each OMG is referenced with two index variables: n and g (OMGng)
- Index n is a group number. Global timer cell groups GTCG[3:0] have the group number 0, Local Timer Cell Groups LTCG[3:0] have the group number 1, and Local Timer Cell Groups LTCG[7:4] have the group number 2.

- Index g indicates the number of an I/O or output group g (g = 0-13$_D$) to which the outputs of the output multiplexer group OMGng are connected. I/O groups IOG0 to IOG6 are assigned to index variable g = 0 to 6 and output groups OG0 to OG6 are assigned to index variable g = 7 to 13.

The output multiplexer logic as seen for programming is shown in **Figure 28-68**. With this logic, always three GTC or LTC group signals are combined to one output line that leads to the input of an I/O or output group. For example, when looking at **Figure 28-66**, each of the eight output multiplexer output lines to I/O group IOG5 is connected via three OMGn5 (n = 0, 1, 2) with the eight outputs of one GTC group (GTCG1) and two LTC groups (LTCG1 and LTCG5).

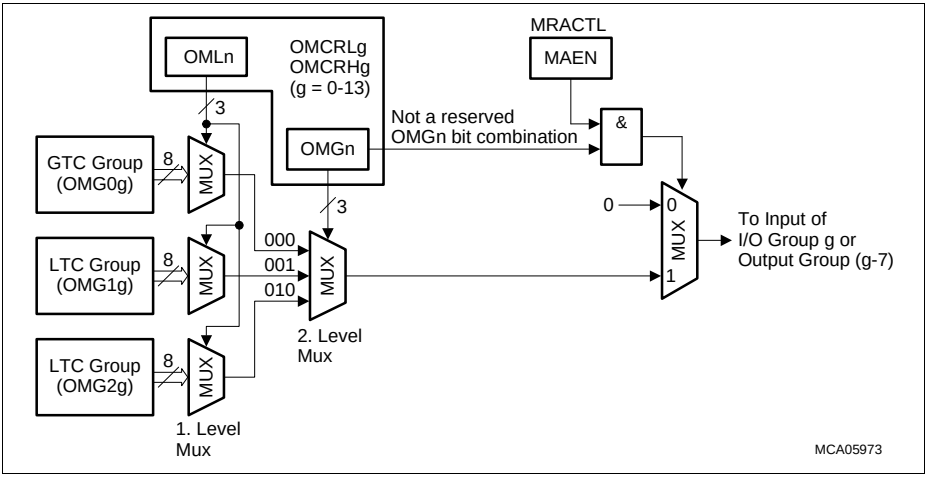

Figure 28-68 Output Multiplexer Group (Programmer's View)

The 1. level multiplexer is built up by three 8:1 multiplexers that are controlled in parallel by bit field OMLn. Bit field OMGn controls the 2. level multiplexer and connects one of the 1. level multiplexer outputs to output n. The output of the 2. level multiplexer is connected only to the input of an I/O group or output group if bit MRACTL.MAEN is set (multiplexer array enabled) and no reserved bit combination of OMGn is selected. If one of these conditions is not true, the corresponding OMG output will be held at a low level.

Two Output GPTA®v5, OMCRL and OMCRH (see also **Page 28-121**), are assigned to each of the I/O or output groups. Therefore, a total of 28 registers control the connections within the output multiplexer of the GPTA®v5 module.

The OMCRL registers control the OMG output lines 0 to 3. The OMCRH registers control the OMG output lines 4 to 7. **Table 28-11** lists all Output Multiplexer Control Registers with its control functions. Please note that the Output Multiplexer Control Registers are

not directly accessible but must be written or read using a FIFO array structure as described on Page 28-121.

Table 28-11 Output Multiplexer Control Register Assignments

I/O Group or Output Group		Controlled by Multiplexer Control Register	Selectable Groups via OMGng

28.3.4.3 On-chip Trigger and Gating Output Multiplexer Selection

The On-chip Trigger and Gating Signal (OTGS) multiplexer shown in **Figure 28-64** and **Figure 28-69** below connects the 32 GTC output lines and the 64 LTC output lines with the on-chip trigger and gating signal groups ($2 \times 8 = 16$ output lines).

In case of low pin count packages, not all I/O groups may be routed to a pin.

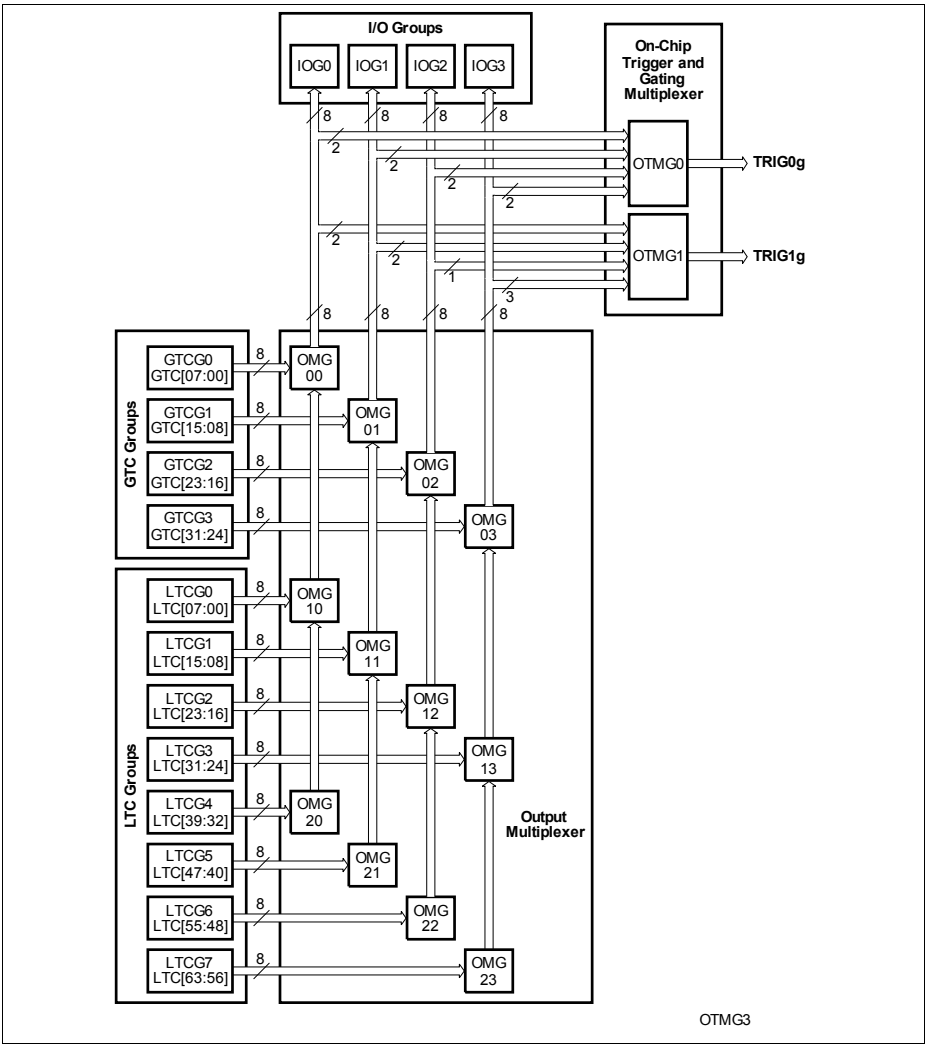

Figure 28-69 On-Chip Trigger and Gating Signal Multiplexer

The On-chip Trigger and Gating Signal multiplexer contains Output Multiplexer Groups (OMGs) that connect the Outputs of the I/O groups with the On-Chip Trigger Signals. These On-Chip Trigger Signals are grouped into two On-Chip Trigger groups (OTMG[1:0]) with 8 cells each.

Figure 28-67 shows the logical structure of an OTMG.

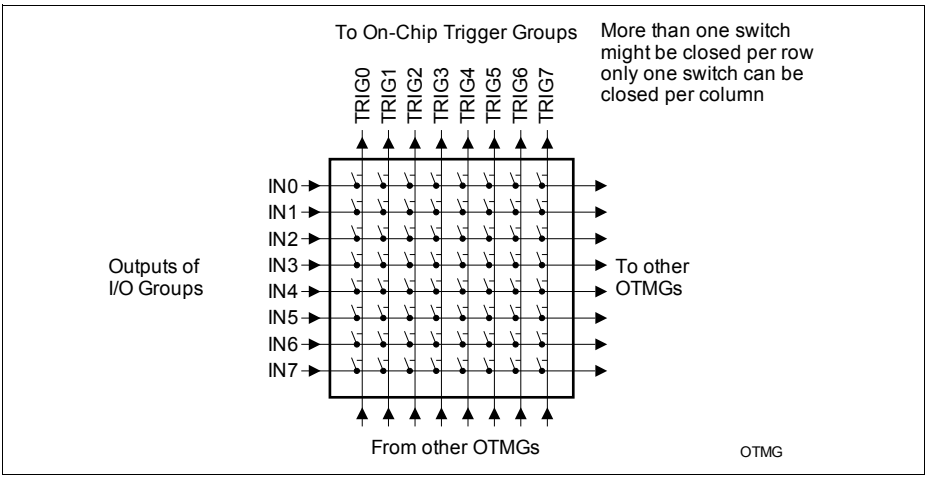

Figure 28-70 On-Chip Trigger and Gating Multiplexer Group (OTMG) Structure

Rules for connections to Output Multiplexer Group OTMG:

- Only one input of an On-chip Trigger and Gating Signal group can be connected to a On-chip Trigger and Gating Signal (TRIG). This is guaranteed by the OTMG control register layout. Otherwise, short circuits and unpredictable behavior would occur. On the other hand, it is permissible for the output of a I/O Group to be connected to more than one on-chip trigger and gating signal (TRIG).

The on-chip trigger and gating multiplexer group configuration is based on the following principles:

- Each OTMG is referenced with a single index variables: g (OTMGg)
- Index g indicates the number of an On-Chip Trigger and Gating Signal multiplexer group g (g = 0-1_D) to which the outputs of the On-Chip Trigger and Gating Signal multiplexer group OTMGg are connected. TRIG00 to TRIG07 are assigned to OTMG0 and TRIG10 to TRIG17 are assigned to OTMG1.

The on-chip trigger and gating signal multiplexer logic as seen for programming is shown in **Figure 28-71**.

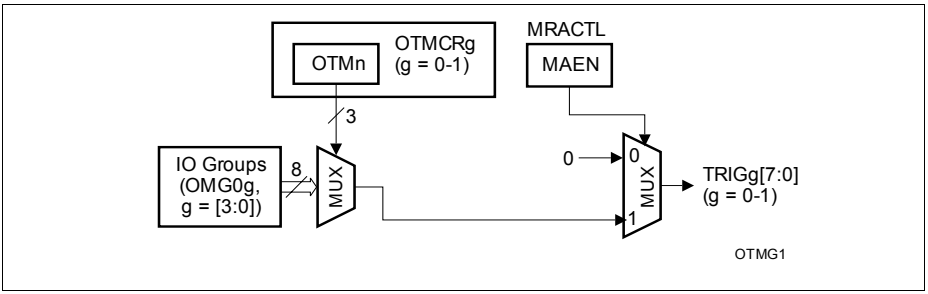

Figure 28-71 On-Chip Trigger and Gating Multiplexer Group (Programmer's View)

The multiplexer is built up by three 8:1 multiplexer that is controlled by bit field OTMn. Bit field The output of the multiplexer is connected only to the on-chip trigger and gating signal TRIGn if bit MRACTL.MAEN is set (multiplexer array enabled). If this condition is not true, the corresponding OTMG output will be held at a low level.

Sixteen on-chip trigger and gating signals are assigned to the GPTA0. Therefore, a total of 2 registers control the connections within the on-chip gating and trigger signal multiplexer of the GPTA0 unit.

Further sixteen on-chip trigger and gating signals are assigned to the GPTA1. Therefore, a total of 2 registers control the connections within the on-chip gating and trigger signal multiplexer of the GPTA1 unit.

The OTMCR0 register control the OTMG output lines TRIG00 to TRIG07. The OTMCR1 register control the OTMG output lines TRIG10 to TRIG17. **Table 28-12** lists all On-Chip Trigger and Gating Signal Multiplexer Control Registers with its control functions. Please note that the On-Chip Trigger and Gating Signal Multiplexer Control Registers are not directly accessible but must be written or read using a FIFO array structure as described on **Page 28-121**.

Table 28-12 On-Chip Trigger/Gating Multiplexer Control Register Assignments

I/O Group Signal		OTMG Input Signal	Controlled by Multiplexer Control Register	Trigger/Gating Signal (x=0-7)	Selectable Groups via OMGng
IOG0	OUT00	IN00	OTMCR0	TRIG0x	GTCG0, LTCG0, LTCG4

28.3.4.4 GTC Input Multiplexer Selection

The GTC input multiplexer as shown in **Figure 28-64** and **Figure 28-72** connects the 56 (= 7 × 8) input lines of the I/O groups, the 64 LTC output lines of the eight LTC groups, the six FPC output lines, and two internal input lines INT[1:0] with the 32 (= 4 × 8) LTC input lines, organized into eight LTC groups.

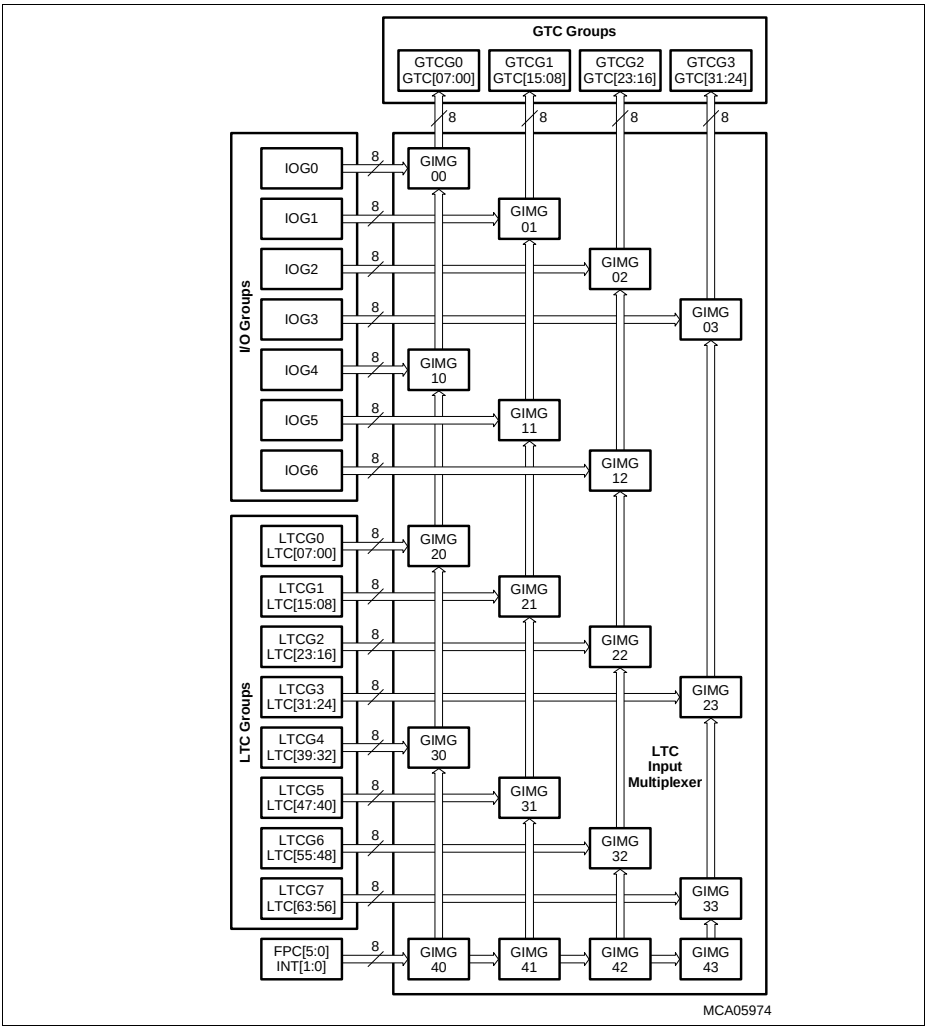

Figure 28-72 GTC Input Multiplexer

The GTC input multiplexer contains GTC input Multiplexer Groups (GIMGs) that connect the I/O groups or Local Timer Cells with the input lines of the GTC input lines, organized into four GTC groups with 8 cells each. GTC input Multiplexer Group are grouped into seven IOGs (IOG[6:0]) with eight lines each and eight LTC groups (LTCG[7:0]) with 8 cells each. One special FPC/INT group with eight outputs is established that combines the six FPC outputs and two internal input lines INT[1:0] as a group of GIMGs inputs.

Figure 28-73 shows the logical structure of a GIMG.

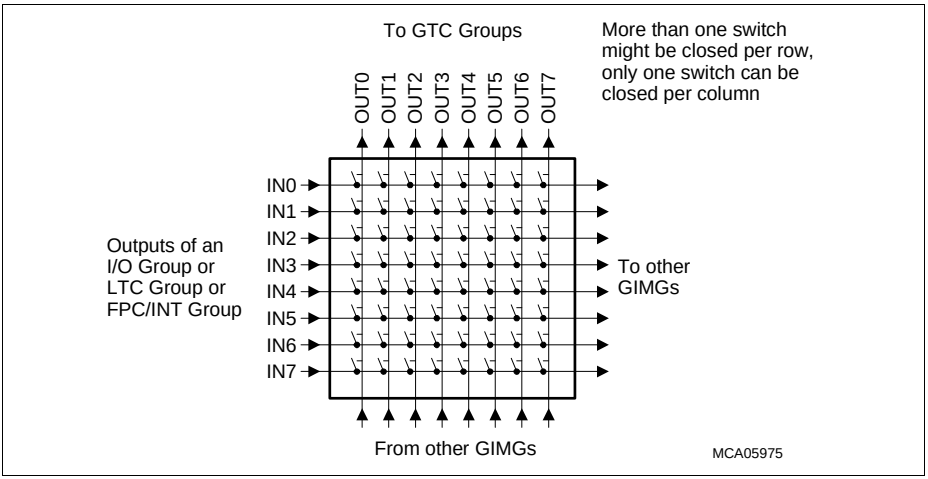

Figure 28-73 GTC Input Multiplexer Group (GIMG) Structure

Rules for connections to GTC Input Multiplexer Group GIMG:

- Within a I/O group or LTC group, the line or the output of the cell with the lowest index number is connected to GIMG input line IN0. The remaining lines, cells or lines of a group are connected to GIMG input lines IN1 to IN7 with ascending index numbers. At the FPC/INT group, FPC[5:0] is connected to IN[5:0] and INT[1:0] is connected to IN[7:6].
  Example: for GIMG23 (see Figure 28-72), the cells LTC24 up to LTC31 are wired to the GIMG23 input lines IN0 to line IN7.
- Multiplexer output OUT0 is always connected to the input of a GTC group with the lowest index. The remaining output lines OUT1 to OUT7 are connected to the GTC inputs with ascending index.
  Example: for GIMG23 (see Figure 28-72), the outputs OUT0 to OUT7 are wired to the inputs of GTC16 to GTC23.
- A GTC input can be connected either to an I/O group output, or to an LTC output, or to an FPC/INT output. This is guaranteed by the GIMG control register layout. Otherwise, short circuits and unpredictable behavior would occur. In contrast, it is permissible for an I/O group output, or an LTC output, or an FPC/INT output to be connected to more than one GTC input.

The GTC input multiplexer group configuration is based on the following principles:

- Each GIMG is referenced with two index variables: n and g (GIMGng)
- Index n is a group number. I/O groups IOG[3:0] have group number 0, I/O groups IOG[6:4] have group number 1, Local Timer Cell Groups LTCG[3:0] have group

number 2, Local Timer Cell Groups LTCG[7:4] have group number 3, and the FPC/INT group has group number 4.

- Index g indicates the number of the GTC group g (g = 0-3) to which the outputs of the input multiplexer group GIMGng are connected.

The GTC input multiplexer logic as seen for programming is shown in **Figure 28-74**. With this logic, five group signals (from an I/O group, LTC group, or FPC/INT group) are always combined to one output line that leads to the input of a GTC of GTC group g. For example, when looking at **Figure 28-73**, each of the eight GTC input multiplexer output lines to GTC group GTCG2 is connected via five OMGn2 (n = 0-4) with the eight outputs of two I/O group (IOG2 and IOG6), two LTC groups (LTCG2 and LTCG6), and the FPC/INT group.

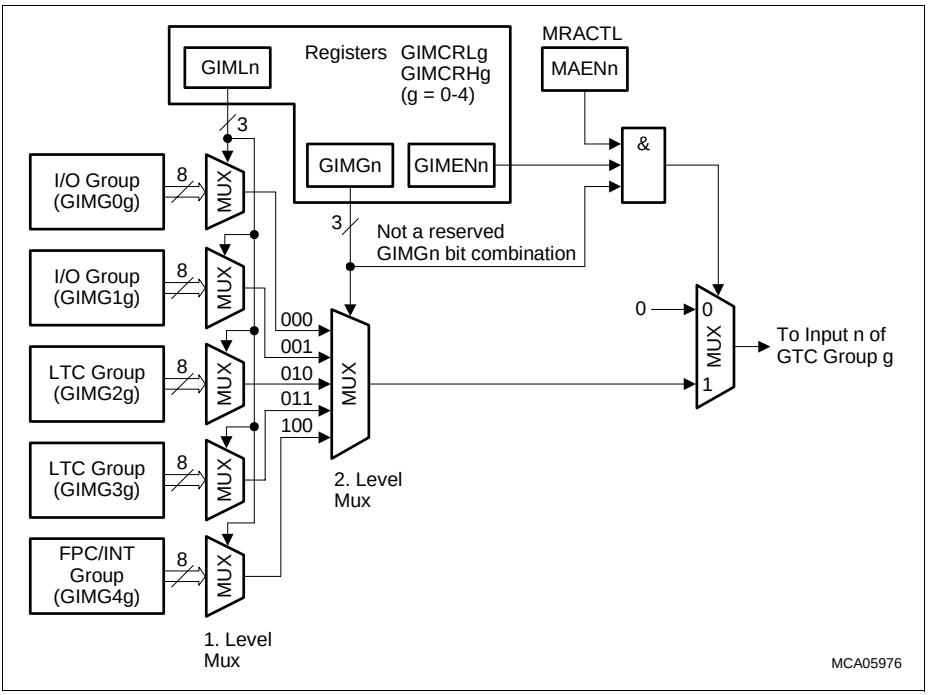

Figure 28-74 GTC Input Multiplexer Group (Programmer's View)

The 1. level multiplexer is built up by five 8:1 multiplexers that are controlled in parallel by bit field GIMLn. Bit field GIMGn controls the 2. level multiplexer and connects one of the 1. level multiplexer outputs to one of the GIMGng outputs. The output of the 2. level multiplexer is only connected to the input of an GTC if bit GIMENn (enable multiplexer connection) is set, and bit MRACTL.AEN is set (multiplexer array enabled), and no

reserved bit combination of GIMGn is selected. If one of these conditions is not true, the corresponding GIMG output will be held at a low level.

If one of these bit is not set, the corresponding GTC input will be held at a low level.

Two GTC Input Multiplexer Control Registers, GIMCRL and GIMCRH (see also Page 28-215), are assigned to each of the GTC groups. Therefore, a total of eight registers control the connections within the GTC input multiplexer of the GPTA®v5 module.

The GIMCRL registers control the GIMG output lines 0 to 3 and the GIMCRH registers control the GIMG output lines 4 to 7. **Table 28-13** lists all of the GTC Input Multiplexer Control Registers with its control functions. Please note that all GTC Input Multiplexer Control Registers are not directly accessible but must be written or read using a FIFO array structure as described on Page 28-121.

Table 28-13 GTC Input Multiplexer Control Register Assignments

GTC Group and GTCs		Controlled by Multiplexer Control Register	Selectable Groups via GIMGng
GTCG0	GTC[03:00]	GIMCRL0	IOG0, IOG4, LTCG0, LTCG4, FPC/INT
	GTC[07:04]	GIMCRH0	
GTCG1	GTC[11:08]	GIMCRL1	IOG1, IOG5, LTCG1, LTCG5, FPC/INT
	GTC[15:12]	GIMCRH1	
GTCG2	GTC[19:16]	GIMCRL2	IOG2, IOG6, LTCG2, LTCG6, FPC/INT
	GTC[23:20]	GIMCRH2	
GTCG3	GTC[27:24]	GIMCRL3	IOG3, LTCG3, LTCG7, FPC/INT
	GTC[31:28]	GIMCRH3	

28.3.4.5 LTC Input Multiplexer Selection

The LTC input multiplexer as shown in **Figure 28-64** and **Figure 28-75** connects the 56 (= 7 × 8) input lines of the I/O groups, the 32 (= 4 × 8) GTC output lines of the GTC groups, the eight clock bus lines, or the four PDL output lines with four internal input lines INT[3:0] with the 64 (= 8 × 8) LTC input lines, organized into eight LTC groups.

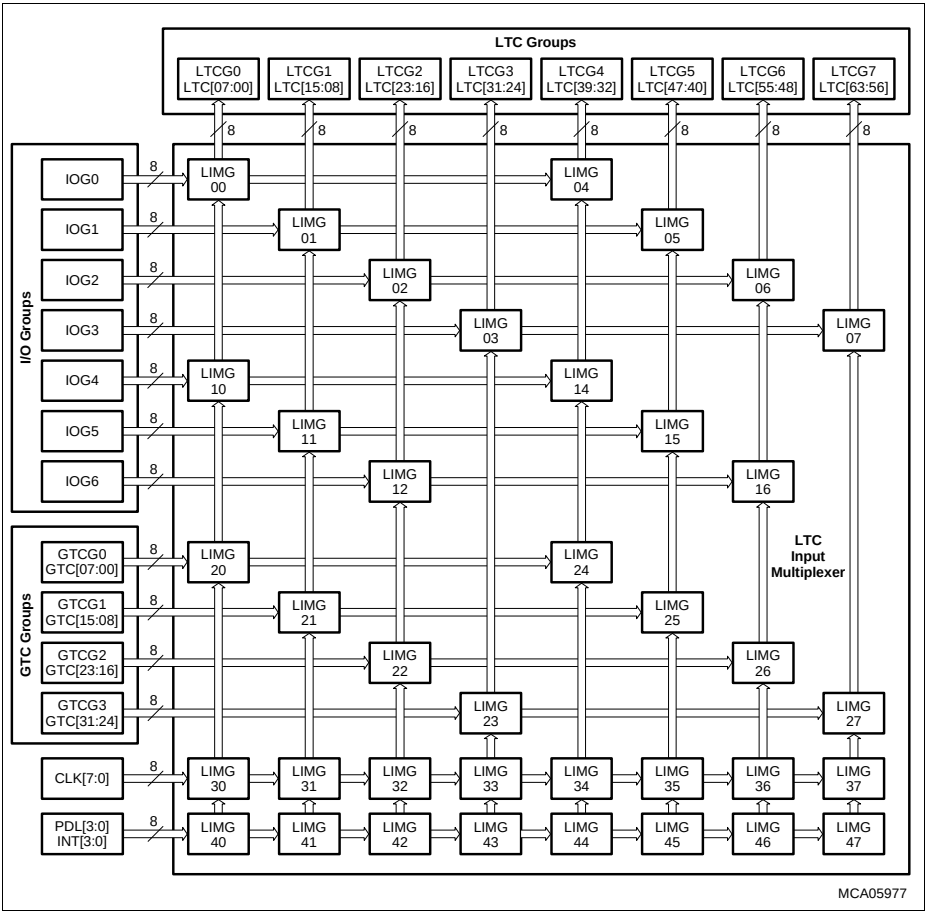

Figure 28-75 LTC Input Multiplexer

The LTC input multiplexer contains LTC input Multiplexer Groups (LIMGs) that connect the I/O groups or Global Timer Cells with the input lines of the LTCs, organized into eight LTC groups with 8 cells each. IOGs and GTCs are grouped into seven IOGs (IOG[6:0]) with eight lines each and four GTC groups (GTCG[3:0]) with 8 cells each. Two special groups are available: a clock group with eight lines representing the clock bus lines CLK[7:0] of the clock distribution cells and a PDL/INT group with eight outputs that combines the four PDL outputs and four internal input lines INT[3:0] as a group of LIMGs inputs.

Note: GPTA0 generates the clock bus lines CLK[7:0] and the four PDL outputs.

Figure 28-76 shows the logical structure of a LIMG.

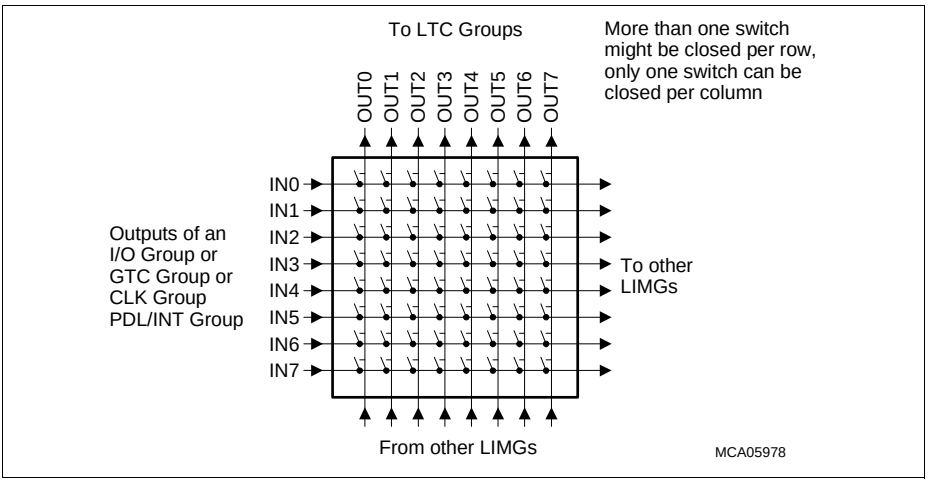

Figure 28-76 LTC Input Multiplexer Group (LIMG) Structure

Rules for connections to LTC Input Multiplexer Group LIMG:

- Within a I/O group or GTC group, the line or the output of the cell with the lowest index number is connected to LIMG input line IN0. The remaining lines, cells or lines of a group are connected to LIMG input lines IN1 to IN7 with ascending index numbers. At the clock group, CLK0 is connected to IN0 and the remaining clock lines are connected to LIMG input lines IN1 to IN7 with ascending index numbers. At the PDL/INT group, PDL[3:0] (see **Page 28-22**) is connected to IN[3:0] and INT[3:0] is connected to IN[7:4].
  Example: for LIMG23 (see **Figure 28-75**), the cells GTC24 up to GTC31 are wired to the LIMG23 input lines IN0 to line IN7.
- Multiplexer output OUT0 is always connected to the input of an LTC group with the lowest index. The remaining output lines OUT1 to OUT7 are connected to the LTC inputs with ascending index.

Example: for LIMG23 (see **Figure 28-75**), the outputs OUT0 to OUT7 are wired to the inputs of LTC24 to GTC31.

- An LTC input can be connected either to an I/O group output, or to an GTC output, or to a clock bus output, or to an PDL/INT output. This is guaranteed by the LIMG control register layout. Otherwise, short circuits and unpredictable behavior would occur. In contrast, it is permitted that an I/O group output, or an GTC output, or an PDL/INT output is connected to more than one LTC input.

The LTC input multiplexer group configuration is based on the following principles:

- Each LIMG is referenced with two index variables: n and g (LIMGng)
- Index n is a group number. I/O groups IOG[3:0] have group number 0, I/O groups IOG[6:4] have group number 1, Global Timer Cell Groups GTCG[3:0] have group number 2, clock bus lines CLK[7:0] have group number 3, and the PDL/INT group has group number 4.
- Index g indicates the number of the LTC group g (g = 0-7) to which the outputs of the input multiplexer group LIMGng are connected.

The LTC input multiplexer logic as seen for programming is shown in **Figure 28-77**. With this logic, five group signals (from an I/O group, GTC group, clock group, or PDL/INT group) are always combined to one output line that leads to the input of an LTC of LTC group g. For example, when looking at **Figure 28-75**, each of the eight LTC input multiplexer output lines to LTC group LTCG2 is connected via five LIMGn2 (n = 0-4) with the eight outputs of two I/O group (IOG2 and IOG6), one GTC group (GTCG2), the clock group, and the PDL/INT group.

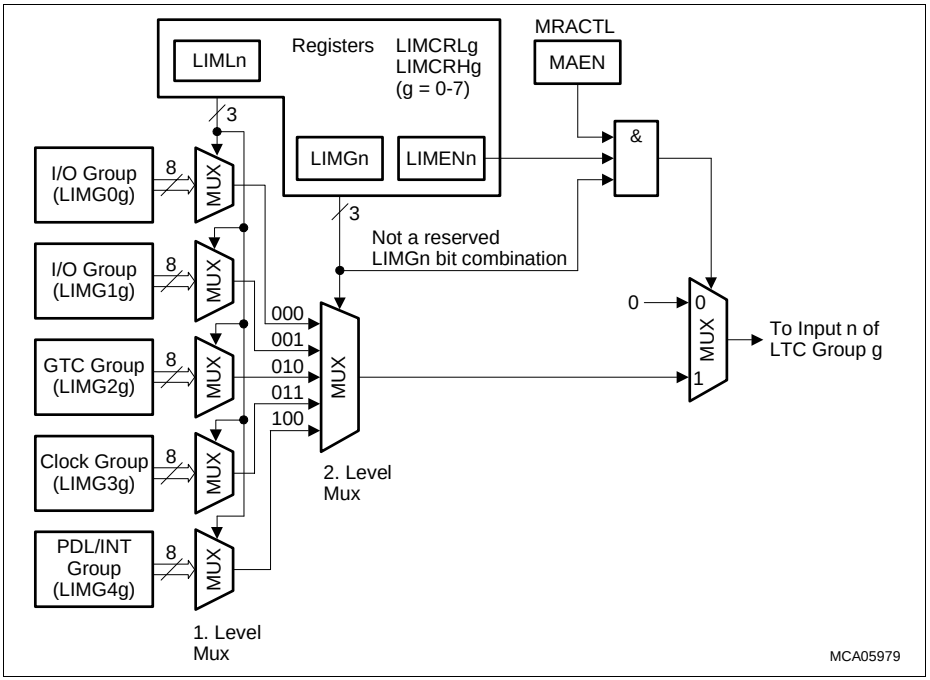

Figure 28-77 LTC Input Multiplexer Group (Programmer's View)

The 1. level multiplexer is built up by five 8:1 multiplexers that are controlled in parallel by bit field LIMLn. Bit field LIMGn controls the 2. level multiplexer and connects one of the 1. level multiplexer outputs to one of the LIMGng outputs. The output of the 2. level multiplexer is connected only to the input of an LTC if bit LIMENn is set (enable multiplexer connection), and bit MRACTL.AEN is set (multiplexer array enabled), and no reserved bit combination of LIMGn is selected. If one of these conditions is not true, the corresponding LTC input will be held at a low level.

Two LTC Input Multiplexer Control Registers, LIMCRL and LIMCRH (see also **Page 28-219**), are assigned to each of the LTC groups. Therefore, in total sixteen registers control the connections within the LTC input multiplexer of the GPTA®v5 module.

The LIMCRL registers control the LIMG output lines 0 to 3 and the GIMCRH registers control the LIMG output lines 4 to 7. **Table 28-14** lists all LTC Input Multiplexer Control Registers with its control functions. Please note that all LTC Input Multiplexer Control Registers are not directly accessible but must be written or read using a FIFO array structure as described on **Page 28-121**.

Table 28-14 LTC Input Multiplexer Control Register Assignments

LTC Group and LTCs		Controlled by Register	Selectable Groups via LIMGng
LTCG0	LTC[03:00]	LIMCRL0	IOG0, IOG4, GTCG0, CLOCK, PDL/INT

	LTC[55:52]	LIMCRH6	
LTCG7	LTC[59:56]	LIMCRL7	IOG3, GTCG3, CLOCK, PDL/INT
	LTC[63:60]	LIMCRH7	

28.3.4.6 Multiplexer Register Array Programming

A total of 54 control registers are required to program the configuration of the output multiplexer, the On-chip trigger and gating multiplexer, and the two input multiplexers of the Input/Output Line Sharing Block. These IOLS control registers are combined into a Multiplexer Register Array FIFO that can only be read or written sequentially. Therefore, the control registers values cannot be accessed directly but must be accessed in a specific sequential order.

Three registers are available for controlling the Multiplexer Register Array:

- Multiplexer Register Array Control Register MRACTL
- Multiplexer Register Array Data In Register MRADIN
- Multiplexer Register Array Data Out Register MRADOUT

Figure 28-78 shows the structure of the multiplexer array FIFO with the arrangement of the multiplexer control registers.

For programming of the multiplexer array FIFO, the following steps must be executed:

1. Disable interconnections of the multiplexer array by writing MRACTL.MAEN = 0 (default after reset). The multiplexer array is disabled, all cell input lines are driven with 0, and device pins assigned to GPTA®v5 I/O lines or output lines are disconnected.
2. Reset the write cycle counter to 0 by writing MRACTL.WCRES = 1.
3. Write sequentially the multiplexer control register contents one after the other (54 values) into MRADIN, starting with the register values for OTMCR1, OTMCR0, … up to GIMCRH0, GIMCRL0 (see **Figure 28-78**). After the first MRADIN write operation, the contents for OTMCR1 is at FIFO position 1. With each following MRADIN write operation, it becomes shifted one FIFO position upwards. After the 54. MRADIN write operation, the OTMCR1 value is at its final position. The contents of FIFO position 54 can be read via register MRADOUT. With each MRADIN write operation the write cycle counter MRACTL.FIFOFILLCNT is incremented by 1. After all FIFO entries have been written, the FIFO is locked, bit MRACTL.FIFOFULL is set, and further MRADIN write operations are discarded until bit MRACTL.WCRES is written again with a 0.
4. Enable the multiplexer array by writing MRACTL.MAEN = 1. This establishes and enables all programmed interconnections.

To check the FIFO contents, the FIFO can be written a second time. At this check MRADIN is written before MRADOUT is read. This will return the FIFO contents of the first write sequence in the order of OTMCR1, OTMCR0, …, GIMCRH0, GIMCRL0.

Before disabling the multiplexer array FIFO, GPTA®v5 output pins that are already enabled as GPTA®v5 output should be switched to GPIO function to avoid output spikes. After enabling the multiplexer array FIFO again, the GPTA®v5 output can be switched again back to GPTA®v5 output function.

Shifting the write data through the FIFO requires a few clock cycles. When new data becomes written before the FIFO is ready to accept them, wait states will be inserted into the write access.

If the OMCRLg register bit field OMGn of the multiplexer array is programmed with an invalid (reserved) value, the related outputs will be forced to 0. When the array is disabled (MRACTL.MAEN = 0), all cell inputs and outputs are disconnected from the GPIO lines and are driven with 0.

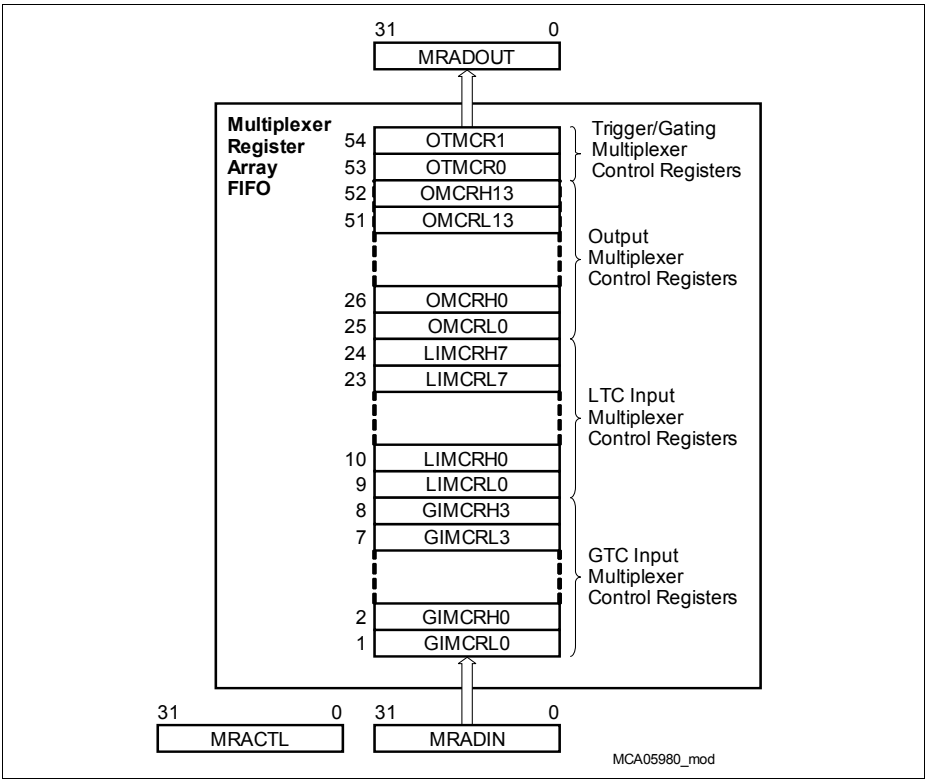

Figure 28-78 GPTA®v5 Multiplexer Array Control Register FIFO Structure

28.3.5 Interrupt Sharing Block (IS)

The GPTA®v5 provides 111 service request sources. These service request sources are generated by different cell types, as shown in **Table 28-15**.

Table 28-15 GPTA®v5 Number of Service Request Sources

Cell Type	Number of Cells	Number of Service Request Sources/Cell	Total Number of Request Sources
DCM	4	3	12
PLL	1	1	1
GT	2	1	2
GTC	32	1	32
LTC	64	1	64
			Sum: 111

To reduce hardware and software overhead, at maximum five request sources are combined together in service request groups. A service request group has up to five service request inputs and one service request output SRy which is typically connected outside the GPTA®v5 kernel with a standard interrupt node y and controlled by its SRCy register.

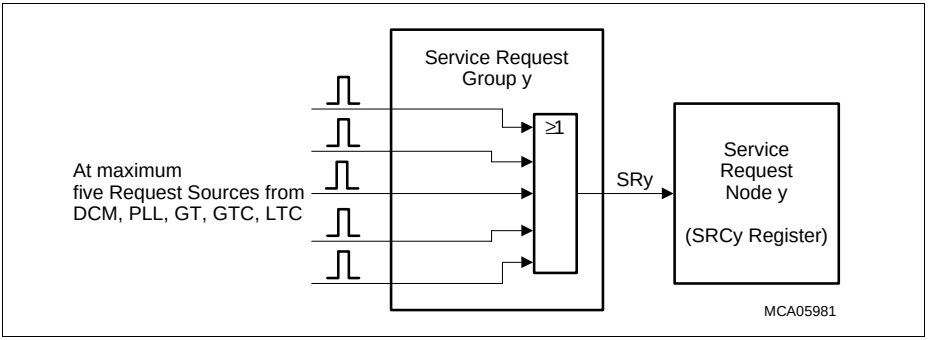

Figure 28-79 Service Request Groups

The bits in the Service Request State Registers (SRSSx and SRSCx) are service request status flags that are set by hardware (type “h”) when the related event occurs. Each GPTA®v5 service request source has its own service request flag. This flag is normally set by hardware but can be set and reset by software. Each service request status flag can be read twice, at the same bit location in the SRSCx register and in the SRSSx register, and cleared or set by software when writing to the corresponding request bit in SRSCx or SRSSx. When writing to SRSCx or SRSSx, several request flags

can be cleared at once by one write operation. Request flags of bit positions that are written with 0 are not changed. This feature allows fast, simple clearing or setting of request flags without affecting other bits in the same service request state register.

Note that service request flag is always set independently of whether it is enabled or disabled by the related cell; but the service request line to the corresponding service request group becomes only active if the corresponding service request is enabled by the related cell. Finally, each service request group y must be enabled by the enable flag that is located in SRC register y.

Table 28-16 lists all of the service requests groups with its request sources. Note that service requests of GTCs with an odd index number k can be individually redirected via register SRNR to a service request group that is assigned mainly to four LTCs.

Table 28-16 GPTA®v5 Service Request Groups

Service Request Group Number y	Request Source 1	Request Source 2	Request Source 3	Request Source 4	Request Source 5

LTCk.Timer_Event_In	*TIk	I	Signal for timer change from preceding cell
LTCk.Event_In	*EIk	I	Signal for event from following cell
LTCk.Select_In	*SI	I	Select signal from preceding cell
LTCk.X_Write_Access	*XWA	L	Indicates that LTCk.X was modified
LTCk.Select_Line_Value	*SLV	L	Internal value for select line reset value: 0
LTCk.Signal_Input	*INS	L	Qualified input signal for Timer Mode and Capture Mode
LTCk.Reset_Timer_Bit	*RTM	L	Flip-flop to reset timer on next clock
LTCk.Event	*EVE	L	Local event
LTCk.Data_Out	*DOUk	O	Data output for output multiplexer
LTCk.Service_Request_Trigger	*SQTk	O	Service request line
LTCk.Y_Out	*YOk	O	Timer going to following cell
LTCk.Output_Mode_Out	*M1Ok *M0Ok	O	Link signals to following cell
LTCk.Output_Mode_Alternate_Out	*M3Ok *M2Ok	O	Link signals to following cell
LTCk.Timer_Event_Out	*TOk	O	Event output to following cell
LTCk.Select_Out	*SO	O	Select output to following cell
LTCk.Event_Out	*EOk	O	Event output to preceding cell

Global variables

Name k = [0 to 62] for LTC	Short Name (*)LTC	Size (bits)	Comment
LTCk.Mode	*MODk	2	Operation mode: TIMER, TIMER_RESET, CAPTURE, COMPARE
LTCk.One_Shot_Mode	*OSMk	1	One shot mode
LTCk.Request_Enable	*RENk	1	Allows a request on event
LTCk.Input_Rising_Edge_Select (Timer Mode, Capture Mode) LTCk.Select_On_Low_Level (Compare Mode)	*REDk *SOLk	1 1	Selects rising edge of input pin Enables compare on low level of select line
LTCk.Input_Falling_Edge_Select (Timer Mode, Capture Mode) LTCk.Select_On_High_Level (Compare Mode)	*FEDk *SOHk	1 1	Selects falling edge of input pin Enables compare on high level of select line
LTCk.Bypass (Capture Mode, Compare Mode)	*BYPk	1	Local events bypassed for output link
LTCk.GlobalBypass	*GBYPk	1	Alternative output links forwarded to alternative output link
LTCk.Enable_Of_Action (Capture Mode, Compare Mode)	*EOAk	1	Enables cell on action communicated via link
LTCk.Input_Line_Mode	*ILMk	1	Selects edge input line mode
LTCk.Coherent_Update_Enable (Timer Mode) LTCk.Select_Line_Level (Capture Mode, Compare Mode)	*CUDk *SLLk	1 1	Selects coherent update Select line level
LTCk.Cell_Enable	*CENk	1	Cell enable state
LTCk.Output_Control_Mode	*OCMk	3	Output control mode
LTCk.Output_Immediate_Action	*OIAk	1	Forces immediate action
LTCk.Output_State	*OUTk	1	Read value of Data_Out
LTCk.X	*Xk	16	Timer/Capture/Compare value

28.3.6.8 LTC Algorithm for Cell 63

Variables

Input, Local, Output variables of the cell (I, L, O)

Name	Short Name (*)LTC	Used (ILO)	Comment
LTC63.Data_In	*DIN63	I	Data input from input multiplexer
LTC63.Y_In	*YI63	I	Timer coming from preceding cell
LTC63.Timer_Event_In	*TI63	I	Signal for timer change from preceding cell
LTC63.Y_Rev	*YR	L	Timer coming from preceding cell, bit reversed
LTC63.Y_Comp	*YC	L	Timer actually used for compare
LTC63.X_Write_Access	*XWA	L	Indicates that LTC63.X was modified
LTC63.Signal_Input	*INS	L	Qualified input signal
LTC63.Data_Out	*DOU63	O	Data output for output multiplexer
LTC63.Service_Request_Trigger	*SQT63	O	Service request line
LTC63.Event_Out	*EO63	O	Event output to preceding cell

Global variables

Name	Short Name (*)LTC	Size (bits)	Comment
LTC63.Bit_Rev_Mode	*BRM63	1	Bit reverse mode
LTC63.One_Shot_Mode	*OSM63	1	One shot mode for copy
LTC63.Request_Enable	*REN63	2	Allows a request on compare or copy
LTC63.Input_Rising_Edge_Select	*RED63	1	Selects rising edge of input pin
LTC63.Input_Falling_Edge_Select	*FED63	1	Selects falling edge of input pin
LTC63.Input_Line_Mode	*ILM63	1	Selects edge input line mode
LTC63.Cell_Enable	*CEN63	1	Cell enable state for copy
LTC63.Output_State	*OUT63	1	Read value of Data_Out
LTC63.X	*X63	16	Compare value
LTC63.X_Shadow	*XS63	16	Shadow compare value

28.3.7 Programming of a GPTA®v5 Unit

A hierarchical top-down design approach may be used to implement a complex signal processing circuitry as follows:

- Partitioning the complex signal processing circuitry into simple function cells.
- Implementing each simple function cell by configuring the LTC and/or GTC cells which can be tied together for realizing a common signal operation.
- Implementing necessary signal pre-processing tasks by configuring the FPC, PDL, DCM and PLL cells accordingly.
- Defining and configuring all input/output port pins required as clock source, trigger input or signal output.

Table 28-17 summarizes all of the software tasks to be implemented for getting a GPTA®v5 unit into operation.

Table 28-17 Software Tasks Controlling a GPTA®v5 Unit

GPTA®v5 Shell Initialization	
GPTA®v5 Module Clock Enable	
Fractional Divider Setting	
Unit Enable	
Configuration of Interrupt Handling	
GPTA®v5 Kernel Initialization	
FPC:	**PDL:**
Selection of Operating Mode (Prescaler, Filter or Feed-Through)	Selection of Operating Mode (Phase Discriminator or Feed-Through)
Input Channel Selection	2- or 3-Sensor Mode Selection
Clock Selection	**PLL:**
Configuration of Prescaler Factor or Debounce Mode	Selection of Input Channel
DCM:	Estimation of Input Signal Period Width
Selection of Reset Event for Timer	Configuration of Output Signal Frequency
Selection of Trigger Source for Capture Event	Handling of Input Signal Period Length Variation
Selection of Trigger Source for Capture Compare Register Update	Interrupt Request Enable on End of Output Pulse Generation
Interrupt Request Enable on Input Edge or Compare Event	

Table 28-17 Software Tasks Controlling a GPTA®v5 Unit (cont'd)

Clock Bus Setup	
Selection and Configuration of 8 Clock Sources for GT, GTC and LTC Cells	
GT:	**GTC:**
Selection of Timer Clock Source	Selection of Operating Mode (Capture or Compare) and Time Base (GT0 or GT1)
Configuration of Timer Width (Reload Value, TGE Flag)	Configuration of Trigger Events for Capture Mode or Selection of a Relational Operator for Compare Mode
Interrupt Request Enable on Timer Overflow	Interrupt Request Enable on Capture or Compare Event
Start Global Timer(s)	Configuration of Data Output triggered by a GTC Event
LTC:	**IOLS:**
Selection of Operating Mode (Timer, Capture or Compare)	Configuration of the Multiplexer Array to link GTC and LTC data outputs/inputs to external Port Pins or other cells by writing the Multiplexer Register Array FIFO Configuration of the On-chip Trigger and Gating Signal Multiplexer Array to link GTC and LTC data outputs to on-chip modules by writing the Multiplexer Register Array FIFO
Selection of Trigger Source for Timer, Capture or Compare Mode	Configuration of Port Output Source
Configuration of Trigger Event for Timer, Capture or Compare Mode	
Interrupt Request Enable on Timer, Capture or Compare Event	
Configuration of Data Output triggered by an LTC Event	
Port Initialization	
Definition of Electrical Port Characteristic	
Configuration of Port Pin Direction (Input or Output)	

28.4 GPTA0/1 Kernel Registers

This section describes the kernel registers of the GPTA0 and GPTA1 unit.

GPTA0/1 Kernel Register Overview

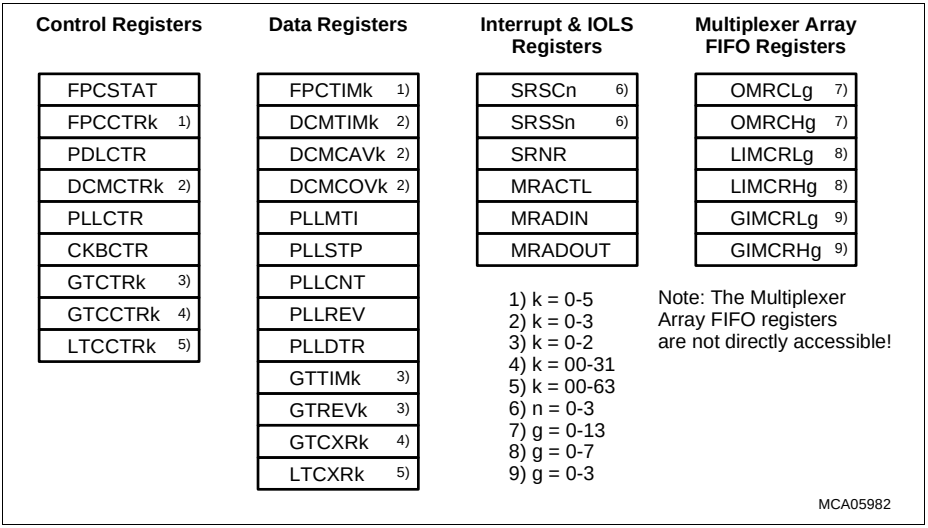

Figure 28-80 GPTA0 and GPTA1 Kernel Registers

In the TC1798, the registers of the GPTA®v5 units are located in the following address ranges.

Table 28-18 Registers Address Space

Module	Base Address	End Address	Note
GPTA0	F000 1800_H	F000 $1FFF_H$	-
GPTA1	F000 2000_H	F000 $27FF_H$	-
LTCA2	F000 2800_H	F000 $2FFF_H$	-

Table 28-19 Registers Overview - GPTA0 and GPTA1 Kernel Registers

Register Short Name	Register Long Name	Offset Addr.[1]	Access Mode		Reset Class	Description see
			Read	Write		
GPTA0_CLC[2]	GPTA Clock Control Register	0000_H	U, SV	SV, E	3	Page 28-300

LIMCRLg	Input Multiplexer Control Register for Upper Half of LTC Group g (g = 0-7)		n.a.	n.a.	3	Page 28-221

1) The absolute register address is calculated as follows:
Unit Base Address + Offset Address (shown in this column)

2) Only implemented in GPTA0 kernel.

Bit Protection

Bits with bit protection (this is valid, for example, for all bits in the Service Request State Registers) are not changed during a read-modify-write instruction, for example when

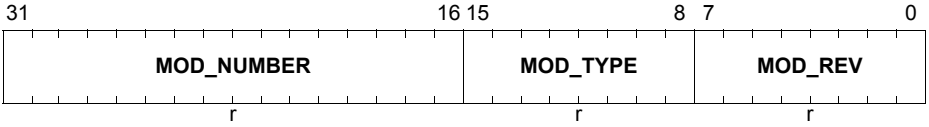
hardware sets a request state bit between the read and the write of the read-modify-write sequence. For bit protected bits it is guaranteed that a hardware setting operation always has priority. Thus, no hardware triggered events are lost.

Bits with bit protection are marked in the corresponding bit descriptions.

28.4.1 GPTA®v5 Identification Register

The GPTA®v5 Identification Register ID contains read-only information about the module version.

GPTA0_ID
GPTA0 Identification Register **(08_H)** **Reset Value: 0029 C0XX$_H$**
GPTA1_ID
GPTA1 Identification Register **(08_H)** **Reset Value: 0029 C0XX$_H$**
LTCA2_ID
LTCA2 Identification Register **(08_H)** **Reset Value: 002A C0XX$_H$**



Field	Bits	Type	Description
MOD_REV	[7:0]	r	**Module Revision Number** MOD_REV defines the Module revision number. The value of a module revision starts with 01_H (first revision). GPTAv5 will start with module revision 05_H.
MOD_TYPE	[15:8]	r	**Module Number Value** This bit field defines the module as a 32 bit module: $C0_H$
MOD_NUM	[31:16]	r	**Module Number Value** This bit field defines the identification number for the GPTA: 0029_H and LTCA: $002A_H$

28.4.2 FPC Registers

GPTA0_FPCSTAT
GPTA0 Filter and Prescaler Cell Status Register
(044_H) **Reset Value: 0000 0000$_H$**

GPTA1_FPCSTAT
GPTA1 Filter and Prescaler Cell Status Register
(044_H) **Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

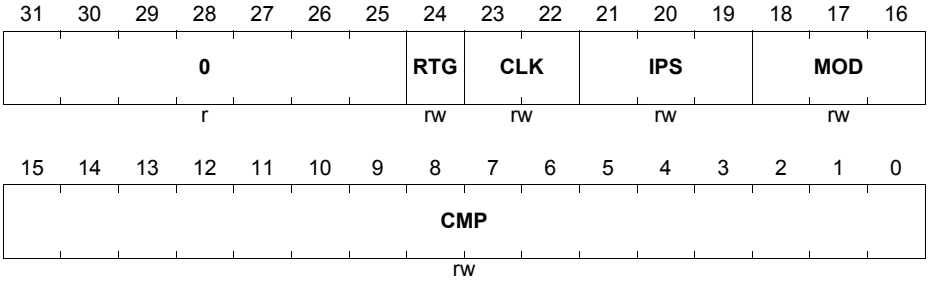
Field	Bits	Type	Description
REGk (k = 0-5)	k	rwh	**Rising Edge Glitch Flag for FPCk** 0_B No rising edge of glitch detected during filtering 1_B Rising edge of glitch detected during filtering Bits REGk are bit protected (see **Section 28.4.2**).
FEGk (k = 0-5)	k+8	rwh	**Falling Edge Glitch Flag for FPCk** 0_B No falling edge of glitch detected during filtering 1_B Falling edge of glitch detected during filtering Bits FEGk are bit protected (see **Section 28.4.2**).
0	[7:6], [31:14]	r	**Reserved** Read as 0; should be written with 0.

GPTA0_FPCCTRk (k = 0-5)
GPTA0 Filter and Prescaler Cell Control Register k
(048_H+k*8_H) **Reset Value: 0000 0000_H**

GPTA1_FPCCTRk (k = 0-5)
GPTA1 Filter and Prescaler Cell Control Register k
(048_H+k*8_H) **Reset Value: 0000 0000_H**

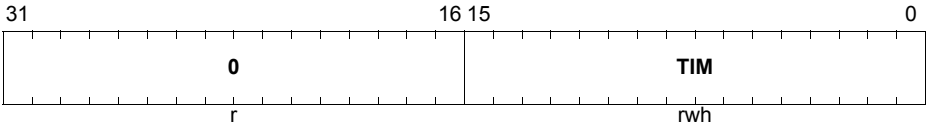


Field	Bits	Type	Description
CMP	[15:0]	rw	**Threshold Value of Filter and Prescaler Cell k** CMP is the 16-bit threshold value that is compared with the 16-bit timer value FPCTIMk.TIM.
MOD	[18:16]	rw	**Operation Mode Selection for FPCk** 000_B Delayed Debounce Filter Mode on both edges 001_B Immediate Debounce Filter Mode on both edges 010_B Rising edge: Immediate Debounce Filter Mode, falling edge: no filtering 011_B Rising edge: no filtering, falling edge: Immediate Debounce Filter Mode 100_B Rising edge: Delayed Debounce Filter Mode, falling edge: Immediate Debounce Filter Mode 101_B Rising edge: Immediate Debounce Filter Mode, falling edge: Delayed Debounce Filter Mode 110_B Prescaler Mode (triggered on rising edge) 111_B Prescaler Mode (triggered on falling edge)

Field	Bits	Type	Description
IPS	[21:19]	rw	**Input Line Selection for FPCk** IPS determines the signal input used for edge detection. 000_B Signal input SINk0 selected 001_B Signal input SINk1 selected 010_B Signal input SINk2 selected 011_B Signal input SINk3 selected 100_B Signal input SINk4 = GPTA®v5 module clock f_{GPTA} selected 101_B Signal input SINk5 = preceding FPC output SOLk-1 selected; SIN05 is connected to SOL5 $11X_B$ Reserved
CLK	[23:22]	rw	**Clock Selection for FPCk** CLK selects the clock signal used for edge detection. 00_B Clock input line 0 selected (GPTA®v5 module clock f_{GPTA}) 01_B Clock bus line 1 selected (local PLL clock) 10_B Clock bus line 2 selected (prescaled) GPTA®v5 module clock f_{GPTA} or PLL clock from other unit or DCM 3 clock 11_B Clock bus line 3 selected DCM 2 clock or PLL clock of other unit or uncompensated PLL clock or uncompensated PLL clock of other unit
RTG	24	rw	**Reset Timer for FPCk on Glitch** 0_B Timer for FPCk is decremented on glitch 1_B Timer for FPCk is cleared on glitch This bit is effective in Delayed Debounce Filter Mode only.
0	[31:25]	r	**Reserved** Read as 0; should be written with 0.

GPTA0_FPCTIMk (k = 0-5)
GPTA0 Filter and Prescaler Cell Timer Register k
(048_H+k*8_H+4_H) **Reset Value: 0000 0000_H**

GPTA1_FPCTIMk (k = 0-5)
GPTA1 Filter and Prescaler Cell Timer Register k
(048_H+k*8_H+4_H) **Reset Value: 0000 0000_H**

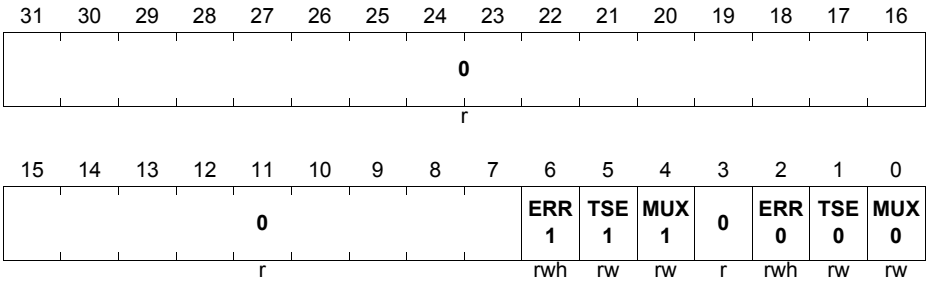


Field	Bits	Type	Description
TIM	[15:0]	rwh	**Timer Value of Filter and Prescaler Cell k**
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

28.4.3 Phase Discriminator Registers

GPTA0_PDLCTR
GPTA0 Phase Discrimination Logic Control Register
(078$_H$) **Reset Value: 0000 0000$_H$**

GPTA1_PDLCTR
GPTA1 Phase Discrimination Logic Control Register
(078$_H$) **Reset Value: 0000 0000$_H$**



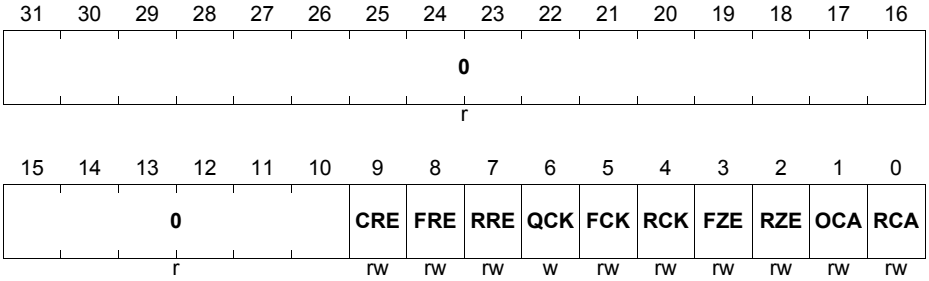
Field	Bits	Type	Description
MUX0	0	rw	**Output Signal Source Selection for PDL0** 0_B DCM0 cell input is driven by fed-through FPC0 output lines 1_B DCM0 cell input is provided with PDL0 “Forward” and “Backward” pulses
TSE0	1	rw	**3-Sensor Mode Enable for PDL0** 0_B PDL0 operates in “2-Sensor Mode” and DCM1 cell input is driven by fed-through FPC2 output lines 1_B PDL0 operates in “3-Sensor Mode” and DCM1 cell input is provided with PDL0 error information
ERR0	2	rwh	**Error Flag for PDL0** 0_B No error has occurred 1_B Error detected in “3-Sensor Mode”: all PDL0 input signals are simultaneously provided with high or low level Bit ERR0 is bit protected (see **Page 28-167**).
MUX1	4	rw	**Output Signal Source Selection for PDL1** 0_B DCM2 cell input is driven by fed-through FPC3 output lines 1_B DCM2 cell input is provided with PDL1 “Forward” and “Backward” pulses

Field	Bits	Type	Description
TSE1	5	rw	**3-Sensor Mode Enable for PDL1** 0_B PDL1 operates in “2-Sensor Mode” and DCM3 cell input is driven by fed-through FPC5 output lines 1_B PDL1 operates in “3-Sensor Mode” and DCM3 cell input is provided with PDL1 error information
ERR1	6	rwh	**Error Flag for PDL1** 0_B No error has occurred 1_B Error detected in “3-Sensor Mode”: all PDL1 input signals are simultaneously provided with high or low level Bit ERR1 is bit protected (see **Page 28-167**).
0	3, [31:7]	r	**Reserved** Read as 0; should be written with 0.

28.4.4 Duty Cycle Measurement Registers

GPTA0_DCMCTRk (k = 0-3)
GPTA0 Duty Cycle Measurement Control Register k
(080_H+k*10_H) **Reset Value: 0000 0000_H**

GPTA1_DCMCTRk (k = 0-3)
GPTA1 Duty Cycle Measurement Control Register k
(080_H+k*10_H) **Reset Value: 0000 0000_H**

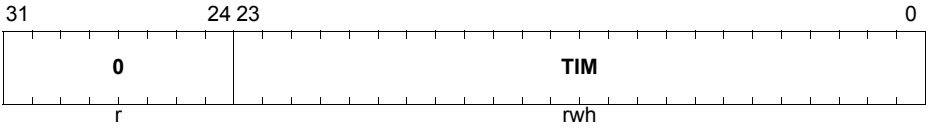


Field	Bits	Type	Description
RCA	0	rw	**Trigger Source Selection for Capture Event** 0_B Timer contents are copied to DCMCAVk capture register on a falling input signal edge 1_B Timer contents are copied to capture register on a rising input signal edge
OCA	1	rw	**Trigger Source for Capture/Compare Register Update** 0_B Capture/Compare register DCMCOVk is not affected. 1_B Timer contents are copied to DCMCOVk capture/compare register on the opposite edge selected by RCAk.
RZE	2	rw	**Timer Reset on Rising Edge** 0_B Timer is not affected 1_B Timer is reset on a rising input signal edge
FZE	3	rw	**Timer Reset on Falling Edge** 0_B Timer is not affected 1_B Timer is reset on a falling input signal edge
RCK	4	rw	**Output Pulse on Rising Edge** 0_B DCM output line is not affected 1_B DCM output line is provided with a single clock pulse generated on a rising input signal edge

Field	Bits	Type	Description
FCK	5	rw	**Output Pulse on Falling Edge** 0_B DCM output line is not affected 1_B DCM output line is provided with a single clock pulse generated on a falling input signal edge
QCK	6	w	**Additional Output Pulse Generation** 0_B DCM output line is not affected 1_B DCM output line is immediately provided with a single clock pulse QCK is always read as 0.
RRE	7	rw	**Interrupt Request on Rising Edge** 0_B Interrupt request is not affected 1_B Interrupt request is set on rising input signal edge
FRE	8	rw	**Interrupt Request on Falling Edge** 0_B Interrupt request is not affected 1_B Interrupt request is set on falling input signal edge
CRE	9	rw	**Interrupt Request on Compare Event** 0_B Interrupt request is not affected 1_B Interrupt request is set when the timer matches capture/compare register DCMCOVk
0	[31:10]	r	**Reserved** Read as 0; should be written with 0.

GPTA0_DCMTIMk (k = 0-3)
GPTA0 Duty Cycle Measurement Timer Register k
(080_H+k*10_H+4_H) **Reset Value: 0000 0000_H**

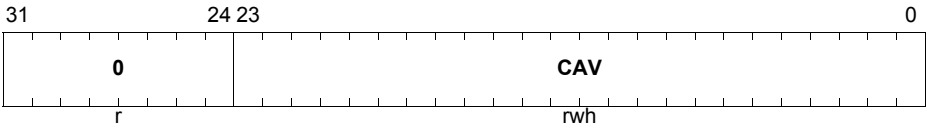
GPTA1_DCMTIMk (k = 0-3)
GPTA1 Duty Cycle Measurement Timer Register k
(080_H+k*10_H+4_H) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
TIM	[23:0]	rwh	**Timer Value of DCMk**
0	[31:24]	r	**Reserved** Read as 0; should be written with 0.

GPTA0_DCMCAVk (k = 0-3)
GPTA0 Duty Cycle Measurement Capture Register k
(088_H+k*10_H) **Reset Value: 0000 0000_H**

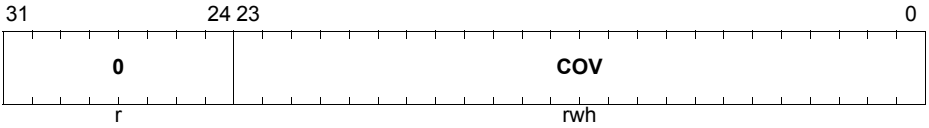
GPTA1_DCMCAVk (k = 0-3)
GPTA1 Duty Cycle Measurement Capture Register k
(088_H+k*10_H) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
CAV	[23:0]	rwh	**Capture Value of DCMk**
0	[31:24]	r	**Reserved** Read as 0; should be written with 0.

GPTA0_DCMCOVk (k = 0-3)
GPTA0 Duty Cycle Measurement Capture/Compare Register k
($08C_H$+k*10_H) **Reset Value: 0000 0000_H**

GPTA1_DCMCOVk (k = 0-3)
GPTA1 Duty Cycle Measurement Capture/Compare Register k
($08C_H$+k*10_H) **Reset Value: 0000 0000_H**

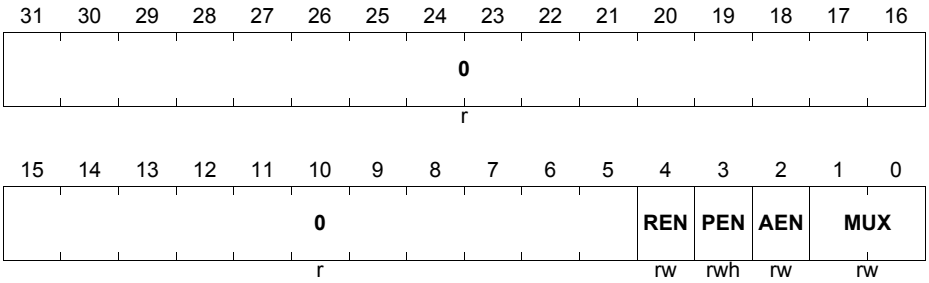


Field	Bits	Type	Description
COV	[23:0]	rwh	**Capture/Compare Register Value of DCMk**
0	[31:24]	r	**Reserved** Read as 0; should be written with 0.

28.4.5 Digital Phase Locked Loop Registers

GPTA0_PLLCTR
GPTA0 Phase Locked Loop Control Register
($0C0_H$) **Reset Value: $0000\ 0000_H$**

GPTA1_PLLCTR
GPTA1 Phase Locked Loop Control Register
($0C0_H$) **Reset Value: $0000\ 0000_H$**

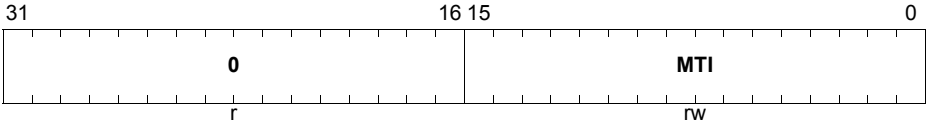


Field	Bits	Type	Description
MUX	[1:0]	rw	**Trigger Input Channel Selection** 00_B DCM0 output is selected as PLL input 01_B DCM1 output is selected as PLL input 10_B DCM2 output is selected as PLL input 11_B DCM3 output is selected as PLL input
AEN	2	rw	**Automatic End Mode Enable** With the Automatic End Mode compensation of input signal's period length variation (acceleration, deceleration) is requested 0_B Automatic End Mode is disabled 1_B Automatic End Mode is enabled
PEN	3	rwh	**Unexpected Period End Behavior** 0_B Counter decrements with constant frequency 1_B Counter is allowed to decrement with f_{GPTA} frequency in case of an input signal period length' reduction Programming PEN to 1 immediately changes the microtick counter to decrement with f_{GPTA} frequency. This bit is protected during read-modify-write operations (hardware will win).

Field	Bits	Type	Description
REN	4	rw	**Interrupt Service Request Enable** 0_B Interrupt request is disabled 1_B An interrupt request is set when the number of remaining output pulses to be generated reaches zero
0	[31:5]	r	**Reserved** Read as 0; should be written with 0.

GPTA0_PLLMTI
GPTA0 Phase Locked Loop Microtick Register
($0C4_H$) **Reset Value: $0000\ 0000_H$**

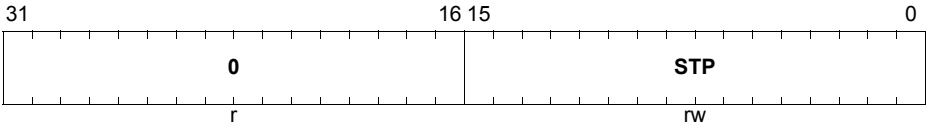
GPTA1_PLLMTI
GPTA1 Phase Locked Loop Microtick Register
($0C4_H$) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
MTI	[15:0]	rw	**Microtick Value** Number of output pulses to be generated within one input signal period.
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

GPTA0_PLLSTP
GPTA0 Phase Locked Loop Step Register
($0CC_H$) **Reset Value: 0000 0000$_H$**

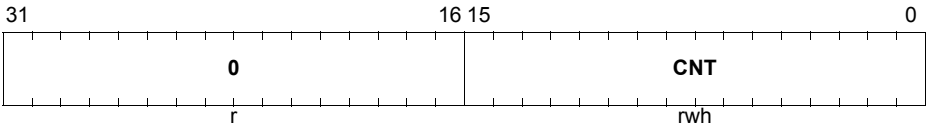
GPTA1_PLLSTP
GPTA1 Phase Locked Loop Step Register
($0CC_H$) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
STP	[15:0]	rw	**Step Value** Number of output pulses to be generated within one input signal period (2-complement data format).
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

GPTA0_PLLCNT
GPTA0 Phase Locked Loop Counter Register
($0C8_H$) **Reset Value: 0000 0000$_H$**

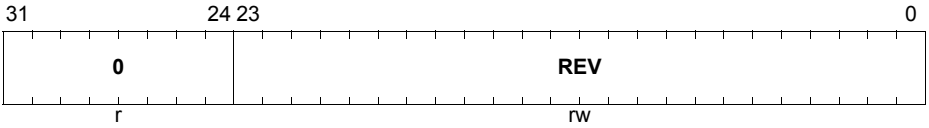
GPTA1_PLLCNT
GPTA1 Phase Locked Loop Counter Register
($0C8_H$) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
CNT	[15:0]	rwh	**Pulse Counter** Counter for the number of remaining output pulses to be generated.
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

GPTA0_PLLREV
GPTA0 Phase Locked Loop Reload Register
($0D0_H$) **Reset Value: $0000\ 0000_H$**

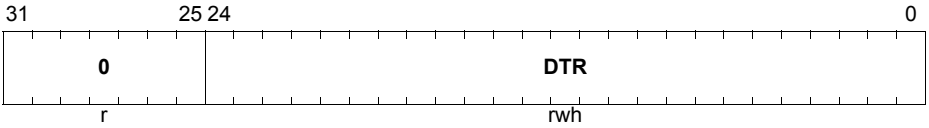
GPTA1_PLLREV
GPTA1 Phase Locked Loop Reload Register
($0D0_H$) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
REV	[23:0]	rw	**Reload Value** Reload value calculated by a subtraction of the number of output pulses to be generated within one input signal period from the input signal's period length (measured in number of GPTA®v5 module clocks).
0	[31:24]	r	**Reserved** Read as 0; should be written with 0.

GPTA0_PLLDTR
GPTA0 Phase Locked Loop Delta Register
($0D4_H$) **Reset Value: $0000\ 0000_H$**

GPTA1_PLLDTR
GPTA1 Phase Locked Loop Delta Register
($0D4_H$) **Reset Value: $0000\ 0000_H$**

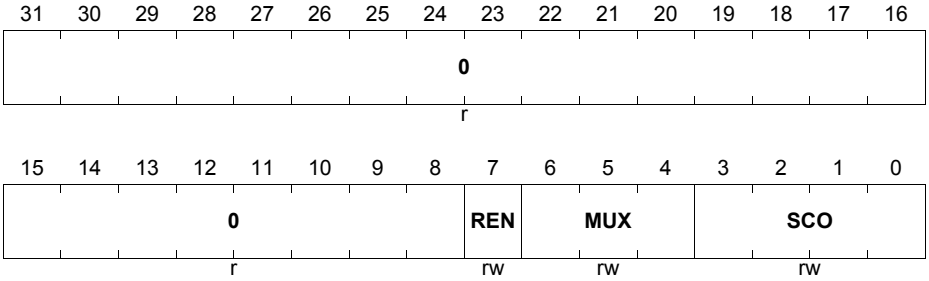


Field	Bits	Type	Description
DTR	[24:0]	rwh	**Delta Register Value** Internal register used to store intermediate results for output pulse generation. **Do not write to this register while PLL is running!**
0	[31:25]	r	**Reserved** Read as 0; should be written with 0.

28.4.6 Global Timer Registers

GPTA0_GTCTRk (k = 0-1)
GPTA0 Global Timer Control Register k
($0E0_H$+k*10_H) **Reset Value: 0000 0000_H**

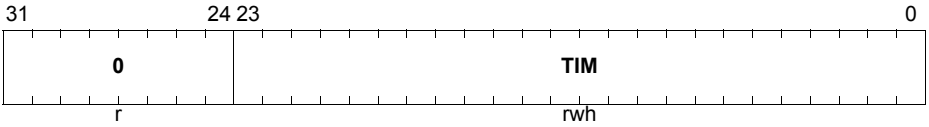
GPTA1_GTCTRk (k = 0-1)
GPTA1 Global Timer Control Register k
($0E0_H$+k*10_H) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
SCO	[3:0]	rw	**TGE Flag Source Selection** This bit field determines the bit of the operation result “GTk timer value - data bus value” which is used as TGE flag. 0000_B 10^{th} bit is used as TGE flag. 0001_B 11^{th} bit is used as TGE flag. …B … 1110_B 24^{th} bit is used as TGE flag. 1111_B 25^{th} bit is used as TGE flag.
MUX	[6:4]	rw	**Timer Clock Selection** One of eight available clock bus lines is selected as the timer GTk clock. 000_B Clock bus line CLK0 selected 001_B Clock bus line CLK1 selected 010_B Clock bus line CLK2 selected 011_B Clock bus line CLK3 selected 100_B Clock bus line CLK4 selected 101_B Clock bus line CLK5 selected 110_B Clock bus line CLK6 selected 111_B Clock bus line CLK7 selected

Field	Bits	Type	Description
REN	7	rw	**Interrupt Request Enable** 0_B The interrupt request is disabled 1_B An interrupt request is generated when timer GTk overflows
0	[31:8]	r	**Reserved** Read as 0; should be written with 0.

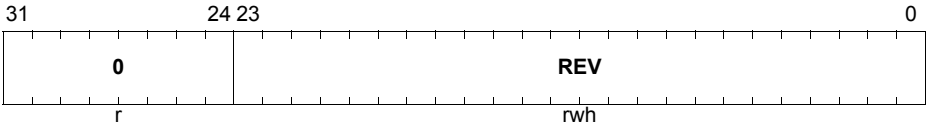
GPTA0_GTTIMk (k = 0-1)
GPTA0 Global Timer Register k **($0E8_H$+k*10_H)** **Reset Value: 0000 0000_H**
GPTA1_GTTIMk (k = 0-1)
GPTA1 Global Timer Register k **($0E8_H$+k*10_H)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
TIM	[23:0]	rwh	**Timer Value of Global Timer k**
0	[31:24]	r	**Reserved** Read as 0; should be written with 0.

GPTA0_GTREVk (k = 0-1)
GPTA0 Global Timer Reload Value Register k
($0E4_H$+k*10_H) **Reset Value: 0000 0000_H**

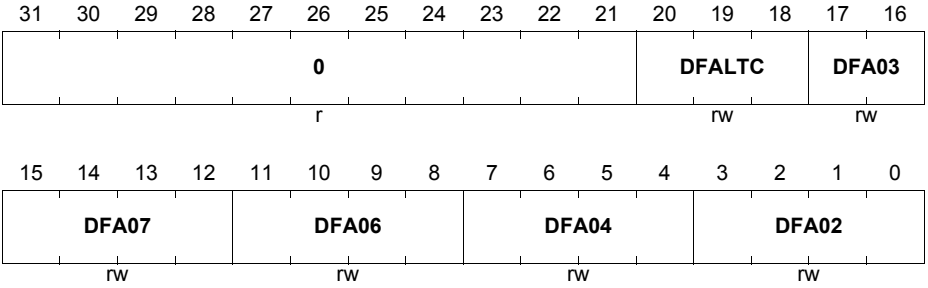
GPTA1_GTREVk (k = 0-1)
GPTA1 Global Timer Reload Value Register k
($0E4_H$+k*10_H) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
REV	[23:0]	rw	**Reload Value of Global Timer k** Reload value for timer GTk after an overflow
0	[31:24]	r	**Reserved** Read as 0; should be written with 0.

28.4.7 Clock Bus Register

GPTA0_CKBCTR
GPTA0 Clock Bus Control Register ($0D8_H$) Reset Value: 0000 FFFF$_H$
GPTA1_CKBCTR
GPTA1 Clock Bus Control Register ($0D8_H$) Reset Value: 0000 FFFF$_H$



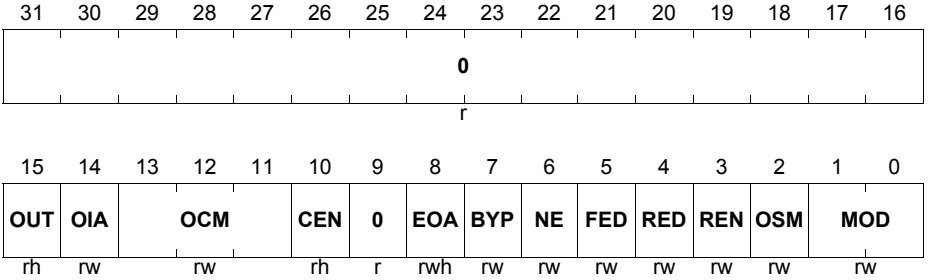
Field	Bits	Type	Description
DFA02	[3:0]	rw	**Clock Line 2 Driving Source Selection** 0_D CLK2 is provided with the GPTA®v5 module clock f_{GPTA} divided by 2^{DFA02} 1_D CLK2 is provided with the GPTA®v5 module clock f_{GPTA} divided by 2^{DFA02} ... 13_D CLK2 is provided with the GPTA®v5 module clock f_{GPTA} divided by 2^{DFA02} 14_D CLK2 is driven by PLL clock of other GPTA®v5 unit 15_D CLK2 is driven by DCM3 output
DFA04	[7:4]	rw	**Clock Line 4 Driving Source Selection** 0_D CLK4 is provided with the GPTA®v5 module clock f_{GPTA} divided by 2^{DFA04} 1_D CLK4 is provided with the GPTA®v5 module clock f_{GPTA} divided by 2^{DFA04} ... 14_D CLK4 is provided with the GPTA®v5 module clock f_{GPTA} divided by 2^{DFA04} 15_D CLK4 is driven by DCM1 output

Field	Bits	Type	Description
DFA06	[11:8]	rw	**Clock Line 6 Driving Source Selection** 0_D CLK6 is provided with the GPTA®v5 module clock f_{GPTA} divided by 2^{DFA06} 1_D CLK6 is provided with the GPTA®v5 module clock f_{GPTA} divided by 2^{DFA06} ... 14_D CLK6 is provided with the GPTA®v5 module clock f_{GPTA} divided by 2^{DFA06} 15_D CLK6 is driven by FPC1 output
DFA07	[15:12]	rw	**Clock Line 7 Driving Source Selection** 0_D CLK7 is provided with the GPTA®v5 module clock f_{GPTA} divided by 2^{DFA07} 1_D CLK7 is provided with the GPTA®v5 module clock f_{GPTA} divided by 2^{DFA07} ... 14_D CLK7 is provided with the GPTA®v5 module clock f_{GPTA} divided by 2^{DFA07} 15_D CLK7 is driven by FPC4 output
DFA03	[17:16]	rw	**Clock Line 3 Driving Source Selection** 0_D CLK3 is driven by DCM2 output 1_D CLK3 is driven by PLL clock of other GPTA®v5 unit 2_D CLK3 is driven by uncompensated PLL clock 3_D CLK3 is driven by uncompensated PLL clock of other GPTA®v5 unit
DFALTC	[20:18]	rw	**Dividing Factor for LTC Prescaler Clock Selection** 0_D The LTCPRE clock is provided with the GPTA®v5 module clock f_{GPTA} divided by 2^{DFALTC}. 1_D The LTCPRE clock is provided with the GPTA®v5 module clock f_{GPTA} divided by 2^{DFALTC}. ... 7_D The LTCPRE clock is provided with the GPTA®v5 module clock f_{GPTA} divided by 2^{DFALTC}.
0	[31:21]	r	**Reserved** Read as 0; should be written with 0.

28.4.8 Global Timer Cell Registers

GPTA0_GTCCTRk (k = 00-31)
GPTA0 Global Timer Cell Control Register k [Capture Mode]
(100_H+k*8_H) **Reset Value: 0000 0000_H**

GPTA1_GTCCTRk (k = 00-31)
GPTA1 Global Timer Cell Control Register k [Capture Mode]
(100_H+k*8_H) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
MOD	[1:0]	rw	**Mode Control Bits** 00_B GTCk operates in Capture Mode hooked to GT0. 01_B GTCk operates in Capture Mode hooked to GT1. 10_B GTCk operates in Compare Mode hooked to GT0. 11_B GTCk operates in Compare Mode hooked to GT1.
OSM	2	rw	**One Shot Mode Enable** 0_B GTCk is continuously enabled. 1_B GTCk is enabled for one event only.
REN	3	rw	**Interrupt Request Enable** 0_B Service request is disabled. 1_B Service request line SQSk is activated when a capture or compare event has occurred.
RED	4	rw	**Input Rising Edge Select** 0_B Capture event is not triggered by a rising edge. 1_B Capture event is triggered by a rising edge on the GTCkIN input line.
FED	5	rw	**Input Falling Edge Select** 0_B Capture event is not triggered by a falling edge. 1_B Capture event is triggered by a falling edge on the GTCkIN input line.

Field	Bits	Type	Description
NE	6	rw	**Not Effective** Reserved
BYP	7	rw	**Bypass** 0_B M0O/M1O lines are affected either by M0I/M1I lines or by OCM0/OCM1 bits. 1_B M0O/M1O lines are affected only by M0I/M1I lines. *Note: OCM2 must be set in any case to enable reaction on M0I/M1I changes.*
EOA	8	rwh	**Enable On Action** 0_B GTCk is enabled for local events. 1_B GTCk is disabled for local events. On an event on the communication link via M0I/M1I lines, EOA will be cleared and local events will be enabled. EOA is bit protected (see **Section 28.4.2**). EOA is cleared if mode is switched to Timer Mode.
CEN	10	rh	**Cell Enable** 0_B GTCk is currently disabled for local events. 1_B GTCk is currently enabled for local events.
OCM	[13:11]	rw	**Output Control Mode Select** 000_B Current state of GTCkOUT output line is hold 001_B Current state of GTCkOUT output line is toggled by an internal GTCk event otherwise hold 010_B GTCkOUT output line is forced to 0 by an internal GTCk event otherwise hold 011_B GTCkOUT output line is forced to 1 by an internal GTCk event otherwise hold $1XX_B$ GTCkOUT output line state is affected by an internal GTCk event and/or by an operation occurred in an adjacent GTCn (n = less or equal k) and reported by the M1I, M0I interface lines.
OIA	14	rw	**Output Immediate Action** 0_B No immediate action required. 1_B Action defined by OCM must be performed immediately. Reading bit OIA always returns 0.
OUT	15	rh	**Output State** 0_B GTCkOUT output line is 0. 1_B GTCkOUT output line is 1.

Field	Bits	Type	Description
0	9, [31:16]	r	**Reserved** Read as 0; should be written with 0.

GPTA0_GTCCTRk (k = 00-31)
GPTA0 Global Timer Cell Control Register k [Compare Mode]
(100_H+k*8_H) **Reset Value: 0000 0000_H**

GPTA1_GTCCTRk (k = 00-31)
GPTA1 Global Timer Cell Control Register k [Compare Mode]
(100_H+k*8_H) **Reset Value: 0000 0000_H**

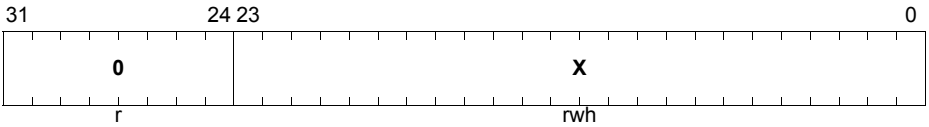
0	9, [31:16]	r	**Reserved** Read as 0; should be written with 0.

GPTA0_GTCXRk (k = 00-31)
GPTA0 Global Timer Cell X Register k
(104_H+k*8_H) **Reset Value: 0000 0000_H**

GPTA1_GTCXRk (k = 00-31)
GPTA1 Global Timer Cell X Register k
(104_H+k*8_H) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
X	[23:0]	rwh	**Capture/Compare Register Contents of GTCk**
0	[31:24]	r	**Reserved** Read as 0; should be written with 0.

Note: GTCXRk is write-protected when control bits CAC and OSM are set to 1 (“capture after compare” in Single Shot Mode). Write protection is activated, when the value of the selected GT timer matches and/or exceeds the capture/compare register contents. Write protection is released after a software access to register GTCXRk.

28.4.9 Local Timer Cell Registers

GPTA0_LTCCTRk (k = 00-62)
GPTA0 Local Timer Cell Control Register k [Timer Mode ILM=0]
(200_H+k*8_H) Reset Value: 0000 0000_H

GPTA1_LTCCTRk (k = 00-62)
GPTA1 Local Timer Cell Control Register k [Timer Mode ILM=0]
(200_H+k*8_H) Reset Value: 0000 0000_H

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															GBYP
r															rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OUT	OIA	OCM			CEN	CUD	ILM	CUD CLR	SLO	FED	RED	REN	OSM	MOD	
rh	rw	rw			rh	rwh	rw	w	rwh	rw	rw	rw	rw	rw	

Field	Bits	Type	Description
MOD	[1:0]	rw	**Mode Control Bits** 00_B LTCk operates in Capture Mode. 01_B LTCk operates in Compare Mode. 10_B LTCk operates in Free-Running Timer Mode. 11_B LTCk operates in reset Timer Mode.
OSM	2	rw	**One Shot Mode Enable** 0_B LTCk is continuously enabled. 1_B LTCk is enabled for one event only.
REN	3	rw	**Request Enable** 0_B Service request is disabled. 1_B Service request SQSk is activated when a - capture event has occurred - compare event has occurred - timer overflow has happened depending on the operation mode selected by bit field MOD.
RED	4	rw	**Input Rising Edge Select** 0_B Timer is not updated by a rising edge. 1_B Timer is updated by a rising edge on the LTCkIN input line.

Field	Bits	Type	Description
FED	5	rw	**Input Falling Edge Select** 0_B Timer is not updated by a falling edge. 1_B Timer is updated by a falling edge on the LTCkIN input line.
SLO	6	rwh	**Select Line Output** 0_B State of select line output SO is 0. 1_B State of select line output SO is 1. SLO is bit protected (see **Page 28-167**).
CUDCLR	7	w	**Coherent Update Disable** 0_B No effect. 1_B Coherent update disabled (bit CUD is cleared). If bits CUD and CUDCLR are both written with 1, bit CUD will be set. CUDCLR is always read as 0.
ILM	8	rw	**Input Line Mode** 0_B Input line is operating in Edge Sensitive Mode. 1_B Input line is operating in Level Sensitive Mode. In case of full speed GPTA®v5 module clock selection as input clock, Level Sensitive Mode must be selected. In this case the Edge Sensitive Mode will not produce any event.
CUD	9	rwh	**Coherent Update Enable** 0_B Select output SO is not toggled on timer reset overflow. 1_B Select output SO is toggled on next timer reset overflow. When CUD is set by software, it remains set until the next timer reset overflow (LTCk reset event) occurs and is cleared by hardware afterwards. CUD can be reset by software by writing bit CUDCLR with 1 and CUD with 0. CUD is automatically cleared after LTCk reset event and when mode is switched to another mode than Reset Timer Mode. This bit can only be set in Reset Timer Mode. If bits CUD and CUDCLR are both written with 1, bit CUD will be set. CUDCLR is always read as 0.
CEN	10	rh	**Cell Enable** 0_B LTCk is currently disabled for local events. 1_B LTCk is currently enabled for local events.

Field	Bits	Type	Description
AIL	5	rw	**Active Input Level Select** 0_B Input signal is active high. 1_B Input signal is active low.
SLO	6	rwh	**Select Line Output** 0_B State of select line output SO is 0. 1_B State of select line output SO is 1. SLO is bit protected (see **Page 28-167**).
CUDCLR	7	w	**Coherent Update Disable** 0_B No effect. 1_B Coherent update disabled (bit CUD is cleared). If bits CUD and CUDCLR are both written with 1, bit CUD will be set. CUDCLR is always read as 0.
ILM	8	rw	**Input Line Mode** 0_B Input line is operating in Edge Sensitive Mode. 1_B Input line is operating in Level Sensitive Mode. In case of full speed GPTA®v5 module clock selection as input clock, Level Sensitive Mode must be selected. In this case the Edge Sensitive Mode will not produce any event.
CUD	9	rwh	**Coherent Update Enable** 0_B Select output SO is not toggled on timer reset overflow. 1_B Select output SO is toggled on next timer reset overflow. When CUD is set by software, it remains set until the next timer reset overflow (LTCk reset event) occurs and is cleared by hardware afterwards. CUD can be reset by software by writing bit CUDCLR with 1 and CUD with 0. CUD is automatically cleared after LTCk reset event and when mode is switched to another mode than Reset Timer Mode. This bit can only be set in Reset Timer Mode. If bits CUD and CUDCLR are both written with 1, bit CUD will be set. CUDCLR is always read as 0.
CEN	10	rh	**Cell Enable** 0_B LTCk is currently disabled for local events. 1_B LTCk is currently enabled for local events.

X	[15:0]	rwh	**Compare Register Value** Software write operations has priority above a simultaneous hardware update.
XS	[31:16]	rw	**Shadow Register Value**

28.4.10 Multiplexer Control Registers

These registers are not directly accessible and can be written and read only via the multiplexer register array FIFO (see **Page 28-121**).

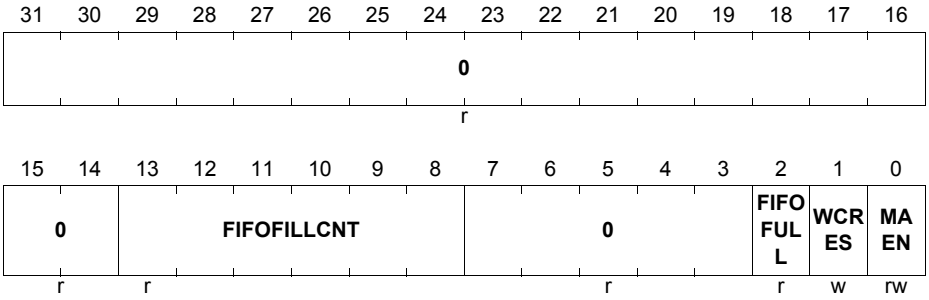
I/O Sharing Block Registers

The three registers MRACTL, MRADIN, and MRADOUT are used to write data to and read data from the GTCA Multiplexer Register Array FIFO. The Multiplexer Register Array FIFO controls the operation of the Input/Output Line Sharing Block (see **"Input/Output Line Sharing Block (IOLS)" on Page 28-235**).

The Multiplexer Register Array Control register controls the operation of the Multiplexer Register Array FIFO.

GPTA0_MRACTL
GPTA0 Multiplexer Register Array Control Register
(038_H) **Reset Value: 0000 0000$_H$**

GPTA1_MRACTL
GPTA1 Multiplexer Register Array Control Register
(038_H) **Reset Value: 0000 0000$_H$**



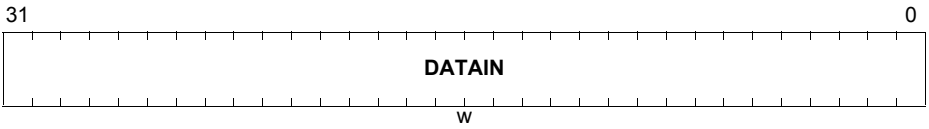
Field	Bits	Type	Description
MAEN	0	rw	**Multiplexer Array Enable** Bit field MAEN enables/disables the programming and the interconnections of the multiplexer array. 0_B Multiplexer array is disabled; all cell inputs are driven with 0, GPTA®v5 I/O lines (pins) are disconnected and FIFO writing is enabled. 1_B Multiplexer array is enabled; all cell and I/O line interconnections are established as previously programmed and FIFO writing is disabled.

Field	Bits	Type	Description
WCRES	1	w	**Write Count Reset** Writing WCRES with 1 while the array is disabled (MAEN = 0), resets the write cycle counter to zero and the FIFO written sequentially (initialized). WCRES is always read as 0.
FIFOFULL	2	r	**FIFO Full Status** 0_B FIFO not completely written (write access to MRADIN allowed). 1_B FIFO completely written (write access to MRADIN ignored). Must be re-enabled via WCRES before array can be re-initialized.
FIFOFILLCNT	[13:8]	r	**FIFO Fill Count** This bit field shows the current contents of the write cycle counter.
0	[7:3], [31:14]	r	**Reserved** Read as 0; should be written with 0.

The Multiplexer Register Array Data In register is used to **write** data to the Multiplexer Register Array FIFO. The Multiplexer Register Array Data Out register is used to **read** data from the Multiplexer Register Array FIFO.

GPTA0_MRADIN
GPTA0 Multiplexer Register Array Data In Register
($03C_H$) **Reset Value: $0000\ 0000_H$**

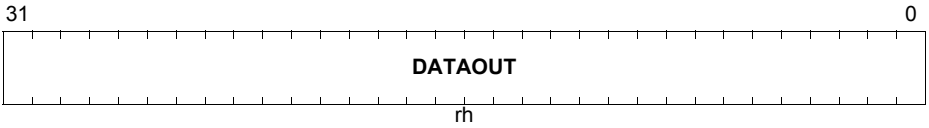
GPTA1_MRADIN
GPTA1 Multiplexer Register Array Data In Register
($03C_H$) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
DATAIN	[31:0]	w	**FIFO Write Data** This register contains the FIFO write data as defined for the Output Multiplexer Control Registers and the Input Multiplexer Control Registers.

GPTA0_MRADOUT
GPTA0 Multiplexer Register Array Data Out Register
(040_H) **Reset Value: 0000 0000_H**

GPTA1_MRADOUT
GPTA1 Multiplexer Register Array Data Out Register
(040_H) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
DATAOUT	[31:0]	rh	**FIFO Read Data** This register contains the FIFO read data as assigned for the Output Multiplexer Control Registers and the Input Multiplexer Control Registers.

Note: For correct operation, the MRADIN and MRADIN registers must be always read or written 32-bit wide. 8-bit and 16-bit accesses are ignored without any bus error!

Output Multiplexer Control Registers

Two registers, OMCRL and OMCRH, are assigned to each I/O Group IOG[6:0] and each Output Group OG[6:0]. OMCRL[6:0]/OMCRH[6:0] are assigned to IOG[6:0] and OMCRL[13:7]/OMCRH[13:7] are assigned to OG[6:0].

OMCRL controls the connections of group pins 0 to 3. OMCRH controls the connections of group pins 4 to 7.

GPTA0_OMCRLg (g = 0-13)
GPTA0 Output Multiplexer Control Register for Lower Half of Group g
Reset Value: 0000 0000$_H$

Field	Bits	Type	Description
GIML4, GIML5, GIML6, GIML7	[2:0], [10:8], [18:16], [26:24]	rw	**Multiplexer Line Selection** This bit field selects the input line of a GIMG that can be selected by bit field GIMGn for GIMG output n. 000_B GIMG input IN0 selected 001_B GIMG input IN1 selected 010_B GIMG input IN2 selected 011_B GIMG input IN3 selected 100_B GIMG input IN4 selected 101_B GIMG input IN5 selected 110_B GIMG input IN6 selected 111_B GIMG input IN7 selected
GIMG4, GIMG5, GIMG6, GIMG7	[6:4], [14:12], [22:20], [30:28]	rw	**Multiplexer Group Selection** This bit field determines the GIMGng which is connected to input n of GTC group g. 000_B GIMG0g selected 001_B GIMG1g selected (reserved for g = 3) 010_B GIMG2g selected 011_B GIMG3g selected 100_B GIMG4g selected All other combinations are reserved.

Field	Bits	Type	Description
GIMEN4, GIMEN5, GIMEN6, GIMEN7	7, 15, 23, 31	rw	**Enable Multiplexer Connection** 0_B Input n is not connected to any line. 1_B Input n is connected to the line defined by GIMLn and GIMGn.
0	3, 11, 19, 27	r	**Reserved** Read as 0; should be written with 0.

LTC Input Multiplexer Control Registers

Two registers, LIMCRL and LIMCRH, are assigned to each LTC group. LIMCRL controls the connections of LTC group cells with index 0 to 3. LIMCRH controls the connections of LTC group cells with index 4 to 7.

*Note: These registers are not directly accessible and can be written and read only via the multiplexer register array FIFO (see **Section 28.3.4.6**).*

GPTA0_LIMCRLg (g = 0-7)
GPTA0 Input Multiplexer Control Register for Lower Half of LTC Group g
Reset Value: 0000 0000$_H$

LIML4, LIML5, LIML6, LIML7	[2:0], [10:8], [18:16], [26:24]	rw	**Multiplexer Line Selection** This bit field selects the input line of a LIMG that can be selected by bit field LIMGn for LIMG output n. 000_B LIMG input IN0 selected 001_B LIMG input IN1 selected 010_B LIMG input IN2 selected 011_B LIMG input IN3 selected 100_B LIMG input IN4 selected 101_B LIMG input IN5 selected 110_B LIMG input IN6 selected 111_B LIMG input IN7 selected
LIMG4, LIMG5, LIMG6, LIMG7	[6:4], [14:12], [22:20], [30:28]	rw	**Multiplexer Group Selection** This bit field determines the LIMGng which is connected to input n of LTC group g. 000_B LIMG0g selected 001_B LIMG1g selected (reserved for g = 3) 010_B LIMG2g selected 011_B LIMG3g selected 100_B LIMG4g selected All other combinations are reserved.

Field	Bits	Type	Description
LIMEN4, **LIMEN5,** **LIMEN6,** **LIMEN7**	7, 15, 23, 31	rw	**Enable Multiplexer Connection** 0_B Input n is not connected to any line. 1_B Input n is connected to the line defined by LIMLn and LIMGn.
0	3, 11, 19, 27	r	**Reserved** Read as 0; should be written with 0.

28.4.11 Service Request Registers

The bits in the Service Request State Registers are service request status flags that are set by hardware (type “h”) when the related event occurs, regardless if a respective Interrupt Request is enabled. Each service request status flag can be read twice (in SRSCx register and in SRSSx register, x = 0-3) and cleared or set by software when writing to the specific request bit in SRSCx or SRSSx. If enabled, a interrupt request is generated regardless of the content of the SRSSx or SRSCx registers.

The service request status flags can be reset (cleared) by software when writing a 1 to the corresponding bit location in the SRSCx registers. Writing a 0 has no effect.

The service request status flags can be set by software when writing a 1 to the corresponding bit location in the SRSSx registers. Writing a 0 has no effect.

Node Redirection Register

The Service Request Node Redirection Register allows that GTC service requests of GTCs with an odd index number k can be individually redirected via register SRNR to a service request group that is assigned mainly to four LTCs. More details are provided on Page 28-124.

28.5 LTCA Kernel Description

The Local Timer Cell Array (LTCA2) is a unit that contains signal generation cells with 64 Local Timer Cells. These LTCs have identical functionality as the LTCs which are available in the signal generation cells of the GPTA®v5 module.

The Local Timer Cells (LTC00 to LTC62) can be configured to operate in different modes: Capture Mode, Compare Mode, Free-Running Timer Mode, Reset Timer Mode, and One Shot Mode. Adjacent cells may be combined to operate on the same pin, thus generating complex waveforms. One LTC (LTC63) can be used for special compare modes.

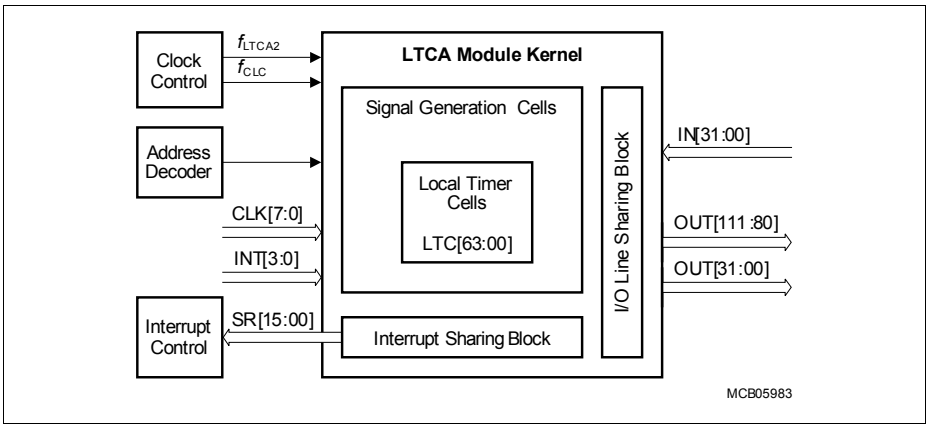

Figure 28-81 Block Diagram of LTCA Unit Kernel

The LTCA Unit Kernel contains Signal Generation Cells that contains all Local Timer Cells including an I/O Line Sharing Block that controls the LTC connections to the I/O lines and output lines. I/O lines are supposed to be connected to I/O port lines while the output lines are typically connected to a MSC interface that is especially able to control external power devices via a serial connection. The LTCs can be further connected to input signals of an external clock bus and input lines coming e.g. from other on-chip peripheral modules.

The clock control cells generates two modules clocks that are required for LTCA operation. An address decoder generates the select signals for the LTC registers. Service requests, coming from the LTCs, are able to generate interrupts via the Interrupt Sharing Block. The interrupts are handled by the external interrupt logic.

28.5.1 Local Timer Cell (LTC00 to LTC63)

LTC00 to LTC62 are fully identical with the Local Timer Cells in the GPTA0 and GPTA1 units. Its functionalities are described in GPTA®v5 section **"Local Timer Cell (LTC00 to LTC62)" on Page 28-67** and LTC63 functionalities are described in GPTA®v5 section **"Local Timer Cell LTC63" on Page 28-79**.

28.5.2 Input/Output Line Sharing Block (IOLS)

The I/O Line Sharing Block allows the inputs and outputs of the LTCA unit to be routed with high flexibility between I/O lines, output lines, clock inputs, and other on-chip peripherals. The LTCA unit provides a total of 32 input lines and 64 output lines, that are connected to four I/O groups IOG[3:0] and four output groups OG[6:3].

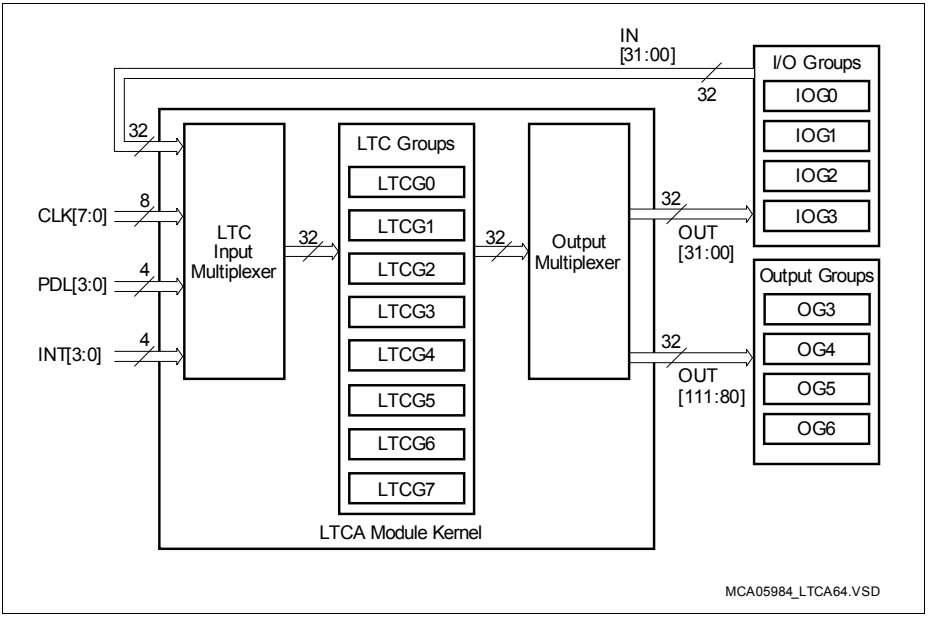

Figure 28-82 Input/Output Line Sharing Block Overview

The LTCA I/O Line Sharing Block makes the following two selections:

- LTC output multiplexer selection
- LTC input multiplexer selection

To choose these selection, the input and output lines of the related cells are integrated into groups with eight parts, each. There are I/O groups, output groups, LTC groups, and a PDL/INT group.

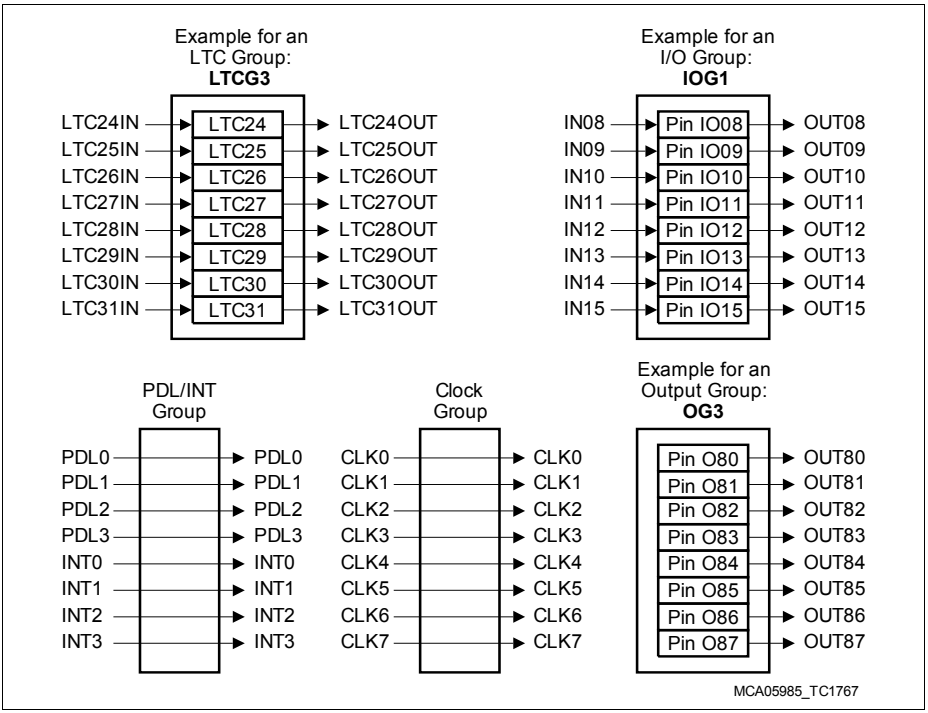

Figure 28-83 Groups Definitions for I/O Line Sharing Block

An **LTC group** combines eight LTC cells with its input and output lines. This results in eight LTC groups, LTCG0 to LTCG7.

An **I/O group** combines eight LTCA I/O lines connected to bi-directional device pins with its input and output lines. This results in four I/O groups, IOG0 to IOG3, supporting 32 I/O lines.

An **output group** combines four LTCA output lines connected to device pins as an output. This results in four output groups, OG3 to OG6, supporting 32 output lines.

The **PDL/INT group** is a logical group that combines the LTCA unit inputs PDL[3:0] together with the inputs INT[3:0].

The **clock group** is a logical group that combines the eight LTCA unit clock inputs CLK[7:0].

28.5.2.1 Output Multiplexer

The output multiplexer shown in **Figure 28-84** and **Figure 28-86** connects the 64 LTC output lines with the I/O groups ($4 \times 8 = 32$ output lines) and the output groups ($4 \times 8 = 32$ output lines).

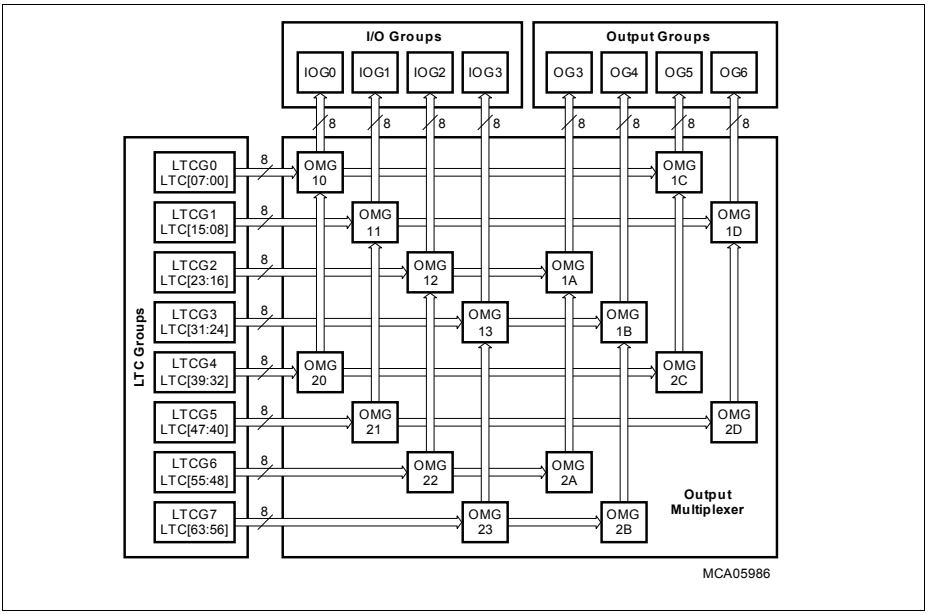

Figure 28-84 Output Multiplexer of LTCA

The output multiplexer contains Output Multiplexer Groups (OMGs) that connect the Local Timer Cells with the input lines of the I/O groups and output groups. The LTCs are grouped into eight LTC groups (LTCG[7:0]) with 8 cells each. In the same way, I/O groups and output groups are grouped into 8 groups (four I/O groups and four output groups) with 8 lines each.

Figure 28-85 shows the logical structure of an OMG.

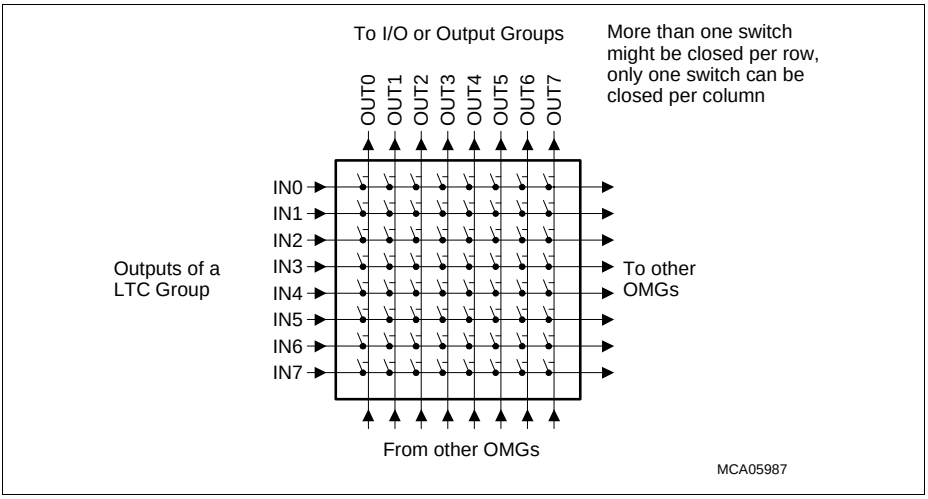

Figure 28-85 Output Multiplexer Group (OMG) Structure

Rules for connections to Output Multiplexer Group OMG:

- OMG output line OUT0 is always connected to the input of an I/O or output group with the lowest index. The remaining output lines OUT1 to OUT7 are connected to the I/O or Output lines with ascending index.
  Example: for OMG13 (see **Figure 28-84**), the outputs OUT0 to OUT7 are wired to input lines 0 to 7 of I/O group 3 (IOG3).
- One input of an I/O or output group can be connected only to the output of one timer cell. This is guaranteed by the OMG control register layout. Otherwise, short circuits and unpredictable behavior would occur. On the other hand, it is permitted that for the output of an LTC cell to be connected to more than one input of an I/O or output group.

The output multiplexer group configuration is based on the following principles:

- Each OMG is referenced with two index variables: n and g (OMGng)
- Index n is a group number. Local Timer Cell Groups LTCG[3:0] have the group number 1, and Local Timer Cell Groups LTCG[7:4] have the group number 2.
- Index g indicates the number of an I/O or output group g ($g = 3\text{-}7_D$) to which the outputs of the output multiplexer group OMGng are connected. I/O groups OG0 to OG3 are assigned to index variable g = 0 to 3 and output groups OG3 to OG6 are assigned to index variable g = 10 to 13. Index g = 4, 5, 6, 7, 8, 9 are not available.

The output multiplexer logic as seen for programming is shown in **Figure 28-86**. With this logic, one LTC group signal is always combined to one output line that leads to the

input of an I/O or output group. For example, when looking at **Figure 28-84**, each of the eight output multiplexer output lines to I/O group IOG0 is connected via two OMGs (OMG10 and OMG20) with the eight outputs of two LTC groups (LTCG0 and LTCG4).

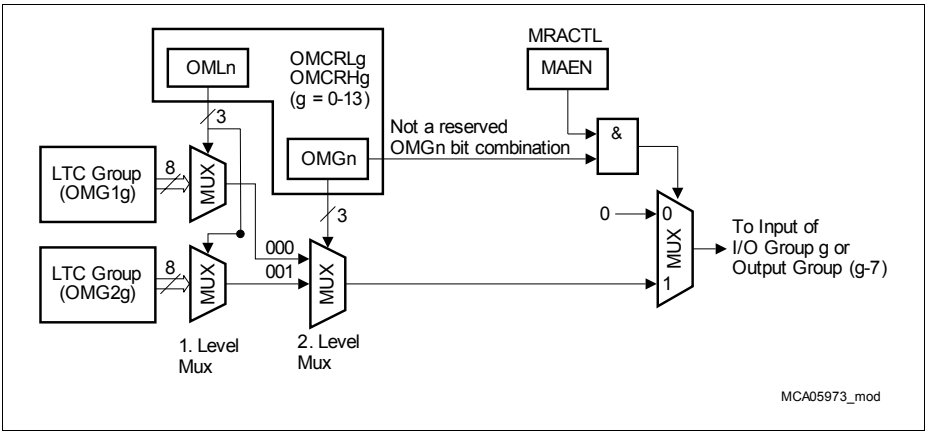

Figure 28-86 OMG Multiplexer (Programmer's View)

The 1. level multiplexer is built up by two 8:1 multiplexers that are controlled in parallel by bit field OMLn. Bit field OMGn controls the 2. level multiplexer and connects one of the 1. level multiplexer outputs to the 2. level inputs.The output of the 2. level multiplexer is connected only to the input of an I/O group or output group if bit MRACTL.MAEN (multiplexer array enabled) is set. If MRACTL.MAEN = 0, the corresponding OMG output will be held at a low level.

Two Output Multiplexer Control Registers, OMCRL and OMCRH (see also **Page 28-210**), are assigned to each of the I/O or output groups. Therefore, in total 16 registers control the connections within the output multiplexer of the LTCA unit.

The OMCRL registers control the OMG output lines 0 to 3 and the OMCRH registers control the OMG output lines 4 to 7. **Table 28-21** lists all Output Multiplexer Control Registers with its control functions. Please note that all Output Multiplexer Control Registers are not directly accessible but must be written or read using the FIFO array structure as described on **Page 28-210**.

Table 28-21 Output Multiplexer Control Register Assignments

I/O Group or Output Group		Controlled by Multiplexer Control Register	Selectable Groups via OMGng
IOG0	IN[03:00]/OUT[03:00]	OMCRL0	LTCG0 / LTCG4

	OUT[111:108]	OMCRH13	

1) OUT[55:32] is not available.

28.5.2.2 LTC Input Multiplexing Scheme

The LTC input multiplexer as shown in **Figure 28-87** and **Figure 28-89** connects the 32 (= 4 × 8) input lines of the I/O groups, the eight clock bus input lines, or the four PDL input lines PDL[3:0] and the four internal input lines INT[3:0] with the 64 (= 8 × 8) LTC inputs, organized in eight LTC groups.

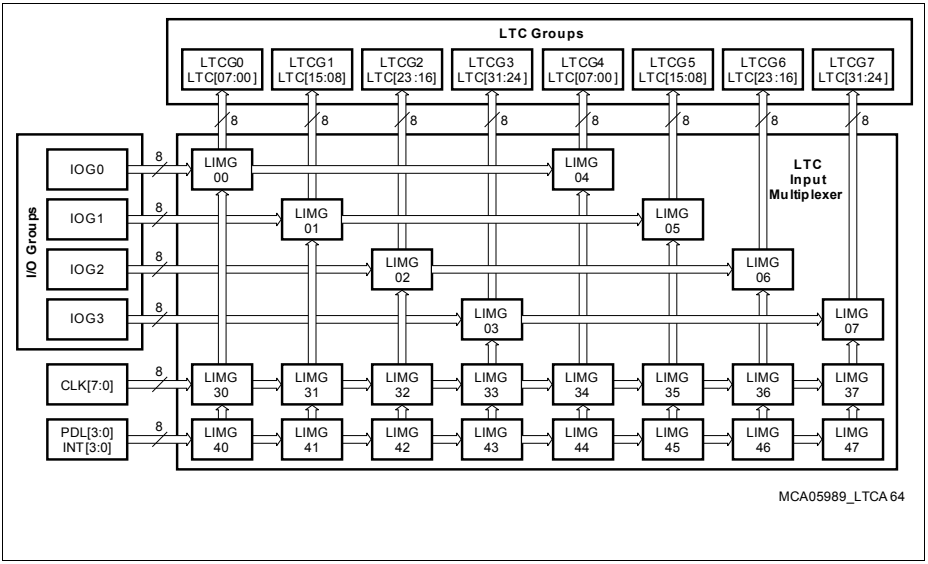

Figure 28-87 LTC Input Multiplexer of LTCA

The LTC input multiplexer contains LTC input Multiplexer Groups (LIMGs) that connect the I/O groups or the clock, PDL, or INT inputs to the input lines of the LTCs, organized in eight LTC groups with 8 cells each. IOGs are grouped into four IOGs (IOG[3:0]) with eight lines each. Two special groups are available, a clock group with eight lines representing the clock bus inputs CLK[7:0] and a PDL/INT group with eight outputs that combines the four PDL inputs and the four inputs INT[3:0] as a group of LIMGs inputs.

Figure 28-88 shows the logical structure of a LIMG.

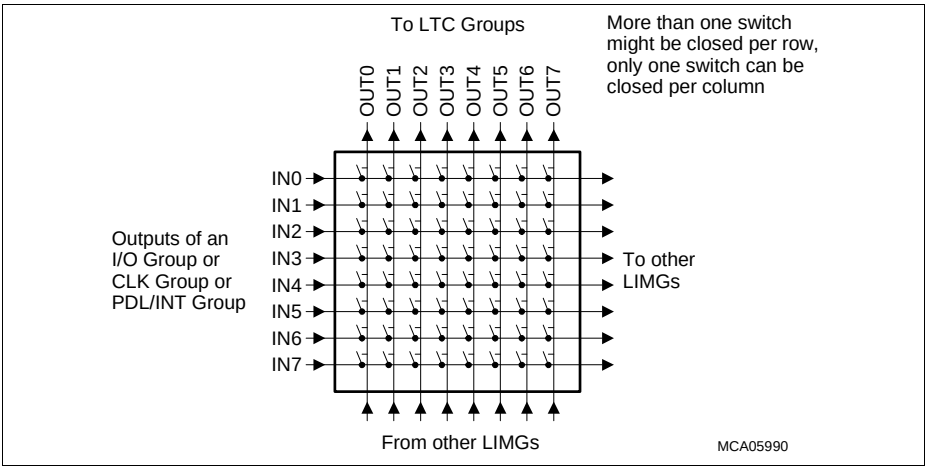

Figure 28-88 LTC Input Multiplexer Group (LIMG) Structure

Rules for connections to LTC Input Multiplexer Group LIMG:

- Within a I/O group, the line or the output of the cell with the lowest index number is connected to LIMG input line IN0. The remaining lines, cells or lines of a group are connected to LIMG input lines IN1 to IN7 with ascending index numbers. At the clock group, CLK0 is connected to IN0 and the remaining clock lines are connected to LIMG input lines IN1 to IN7 with ascending index numbers. At the PDL/INT group, PDL[3:0] (see **Page 28-22**) are connected to IN[3:0] and INT[3:0] are connected to IN[7:4].
  Example: for LIMG04 (see **Figure 28-87**), the I/O lines of IOG0 (IN00 up to IN07) are wired to its input lines IN0 to line IN7.
- Multiplexer output OUT0 of a LIMG is always connected to the input of an LTC group with the lowest index. The remaining output lines OUT1 to OUT7 are connected to the LTC inputs with ascending index.
  Example: for LIMG04 (see **Figure 28-87**), the outputs OUT0 to OUT7 are wired to the inputs of LTC32 to LTC39.
- An LTC input can be connected either to an I/O group output, or to a clock bus output, or to an PDL/INT output. This is guaranteed by the LIMG control register layout.

Otherwise, short circuits and unpredictable behavior would occur. In contrast, it is permitted that an I/O group output, or to a clock bus output, or a PDL/INT output is connected to more than one LTC input.

The LTC input multiplexer group configuration is based on the following principles:

- Each LIMG is referenced with two index variables: n and g (LIMGng)
- Index n is a group number. I/O groups IOG[3:0] have group number 0, I/O group IOG4 is not implemented, clock bus lines CLK[7:0] have group number 3, and the PDL/INT group has group number 4.
- Index g indicates the number of the LTC group g (g = 0-7) to which the outputs of the input multiplexer group LIMGng are connected.

The LTC input multiplexer logic as seen for programming is shown in **Figure 28-89**. With this logic, three group signals (from I/O groups, clock group, or PDL/INT group) are always combined to one output line that leads to an LTC input of LTC group g. For example, when looking at **Figure 28-87**, each of the eight LTC input multiplexer output lines to LTC group LTCG2 is connected via three LIMGn2 (n = 0, 3, 4) to the eight outputs of I/O group IOG2, the clock group, and the PDL/INT group.

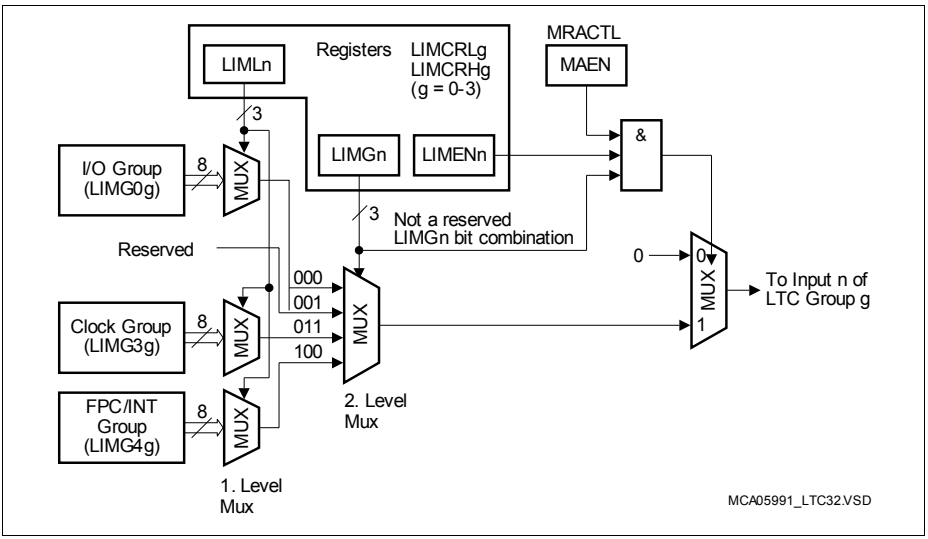

Figure 28-89 LTC Input Multiplexer (Programmer's View)

The 1. level multiplexer is built up by four three 8:1 multiplexers that are controlled in parallel by bit field LIMLn. The output of the multiplexer is connected only to the input of an LTC if bit LIMENn is set (enable multiplexer connection), and bit MRACTL.AEN is set (multiplexer array enabled), and no reserved bit combination is selected. If one of these conditions is not true, the corresponding LTC input will be held at a low level.

Two LTC Input Multiplexer Control Registers, LIMCRL (see also Page 28-271 and Page 28-272), are assigned to each of the LTC groups. Therefore, in total sixteen registers control the connections within the LTC input multiplexer of the LTCA unit.

The LIMCRL registers control the LIMG output lines 0 to 3 and the LIMCRH registers control the LIMG output lines 4 to 7. Table 28-22 lists all LTC Input Multiplexer Control Registers with its control functions. Please note that all LTC Input Multiplexer Control Registers are not directly accessible but must be written or read using a FIFO array structure as described on Page 28-121.

Table 28-22 LTC Input Multiplexer Control Register Assignments

LTC Group and LTCs		Controlled by Register	Selectable Groups via LIMGng
LTCG0	LTC[03:00]	LIMCRL0	IOG0, CLOCK, PDL/INT
	LTC[07:04]	LIMCRH0	
LTCG1	LTC[11:08]	LIMCRL1	IOG1, CLOCK, PDL/INT
	LTC[15:12]	LIMCRH1	
LTCG2	LTC[19:16]	LIMCRL2	IOG2, CLOCK, PDL/INT
	LTC[23:20]	LIMCRH2	
LTCG3	LTC[27:24]	LIMCRL3	IOG3, CLOCK, PDL/INT
	LTC[31:28]	LIMCRH3	
LTCG4	LTC[35:32]	LIMCRL4	IOG0, CLOCK, PDL/INT

	LTC[55:52]	LIMCRH6	
LTCG7	LTC[59:56]	LIMCRL7	IOG3, CLOCK, PDL/INT
	LTC[63:60]	LIMCRH7	

28.5.2.3 Multiplexer Register Array Programming

A total of 38 control registers are required to program the configuration of the output multiplexer and the LTC input multiplexer of the Input/Output Line Sharing Block. These IOLS control registers are combined into a Multiplexer Register Array FIFO that can only be read or written sequentially. Therefore, the control registers values cannot be accessed directly but must be accessed in a specific sequential order.

Three registers are available for controlling the Multiplexer Register Array:

- Multiplexer Register Array Control Register MRACTL

- Multiplexer Register Array Data Out Register MRADOUT
- Multiplexer Register Array Data In Register MRADIN

Figure 28-90 shows the structure of the multiplexer array FIFO with the arrangement of the multiplexer control registers.

For programming of the multiplexer array FIFO, the following steps must be executed:

1. Disable interconnections of the multiplexer array by writing MRACTL.MAEN = 0 (default after reset). The multiplexer array is disabled, all cell input lines are driven with 0, and device pins assigned to LTCA I/O lines or output lines are disconnected.
2. Reset the write cycle counter to 0 by writing MRACTL.WCRES = 1.
3. Write sequentially the multiplexer control register contents one after the other (38 values) into MRADIN, starting with the register values for OMCRH10, OMCRL10, … up to LIMCRH0, LIMCRL0 (see **Figure 28-90**). After the first MRADIN write operation, the contents for OMCRH10 is at FIFO position 1. With each following MRADIN write operation, it becomes shifted one FIFO position upwards. After the 38. MRADIN write operation, the OMCRH10 value is at its final position. The contents of FIFO position 38 can be read via register MRADOUT. With each MRADIN write operation the write cycle counter MRACTL.FIFOFILLCNT is incremented by 1. After all FIFO entries have been written, the FIFO is locked, bit MRACTL.FIFOFULL is set, and further MRADIN write operations are discarded until bit MRACTL.WCRES is written again with a 0.
4. Enable the multiplexer array by writing MRACTL.MAEN = 1. This establishes and enables all programmed interconnections.

To check the FIFO contents, the FIFO can be written a second time. At this check MRADIN is written before MRADOUT is read. This will return the FIFO contents of the first write sequence in the order of OMCRH10, OMCRL10, …, LIMCRL0.

Before disabling the multiplexer array FIFO, LTCA output pins that are already enabled as LTCA output should be switched to GPIO function to avoid output spikes. After enabling the multiplexer array FIFO again, the LTCA output can be switched again back to LTCA output function.

Shifting the write data through the FIFO requires a few clock cycles. When new data becomes written before the FIFO is ready to accept them, wait states will be inserted into the write access.

If the OMCRLg register bit field OMGn of the multiplexer array is programmed with an invalid (reserved) value, the related outputs will be forced to 0. When the array is disabled (MRACTL.MAEN = 0), all cell inputs and outputs are disconnected from the GPIO lines and are driven with 0.

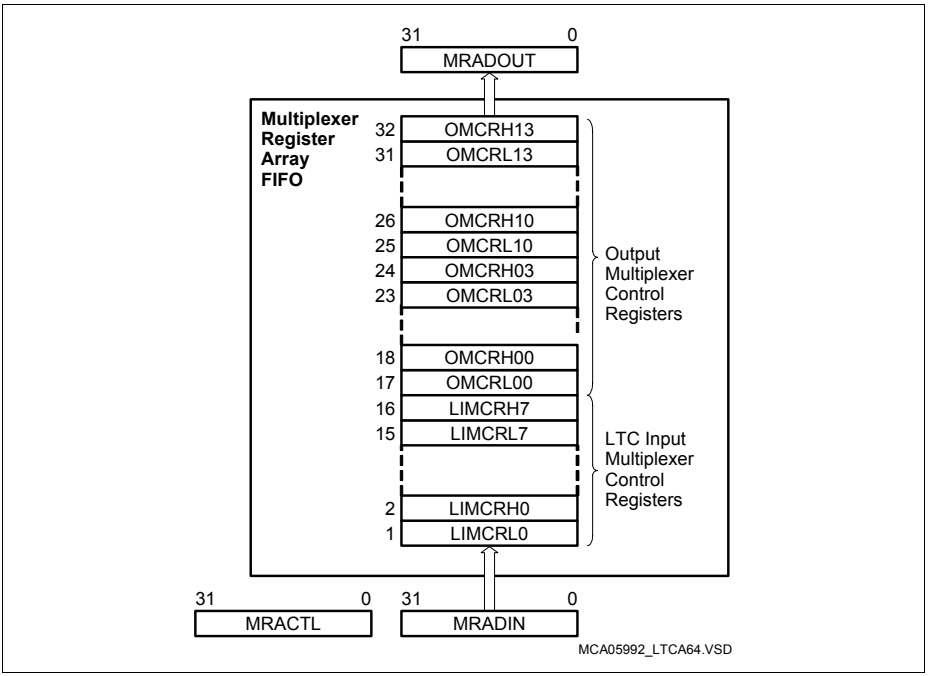

Figure 28-90 LTCA Multiplexer Array Control Register FIFO Structure

28.5.3 Interrupt Sharing Block (IS)

The LTCA provides 16 service request sources. These service request sources are generated by the LTCs.

Table 28-23 LTCA Number of Service Request Sources

Cell Type	Number of Cells	Number of Service Request Sources/Cell	Total Number of Request Sources
LTC	64	1	16

To reduce hardware and software overhead, four request sources are combined together in service request groups. A service request group y (y = 00-15) has four service request inputs and one service request output SRy which is typically connected outside the LTCA kernel to a standard interrupt node y and controlled by its SRCy register.

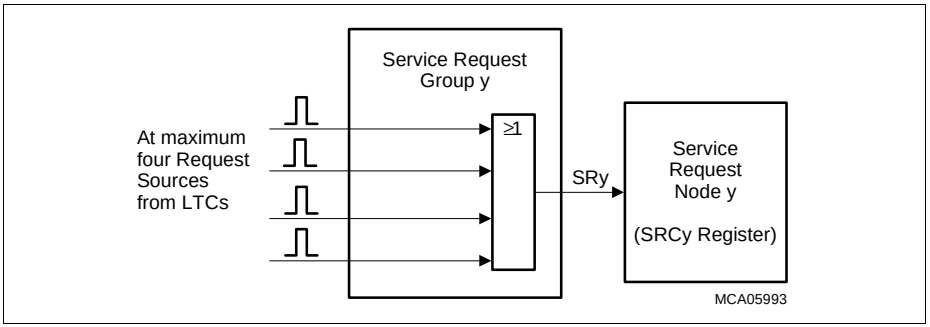

Figure 28-91 Service Request Groups

The bits in the Service Request State Registers (SRSSx and SRSCx, x = 3, 2) are service request status flags that are set by hardware (type “h”) when the related event occurs. Each LTCA service request source has its own service request flag. This flag is normally set by hardware but can be set and reset by software. Each service request status flag can be read twice, at the same bit location in SRSCx register and in SRSSx register, and cleared or set by software when writing to the corresponding request bit in SRSCx or SRSSx. When writing to SRSCx or SRSSx, several flags can be cleared at once by one write operation. Flags written with 0 are not influenced. This feature allows fast, simple clearing or setting of request flags without affecting other bits in the same register.

Note that the service request flag is always set by the service request event even if the corresponding service request is disabled in the interrupt node.

Table 28-24 lists the interrupt requests used by LTCA.

Table 28-24 LTCA Service Request Groups

Service Request Group Number	Source 1	Source 2	Source 3	Source 4
00	LTC00	LTC01	LTC02	LTC03
01	LTC04	LTC05	LTC06	LTC07
02	LTC08	LTC09	LTC10	LTC11

28.6 LTCA Kernel Registers

This section describes the LTCA kernel registers. Some of the kernel registers (SRSCn, SRSSn, LTCCTRk, and LTCXRk) are already described as GPTA®v5 kernel register at the pages as referenced in column “Description see” of **Table 28-25**. The multiplexer array FIFO registers are LTCA specific and therefore defined on the next pages.

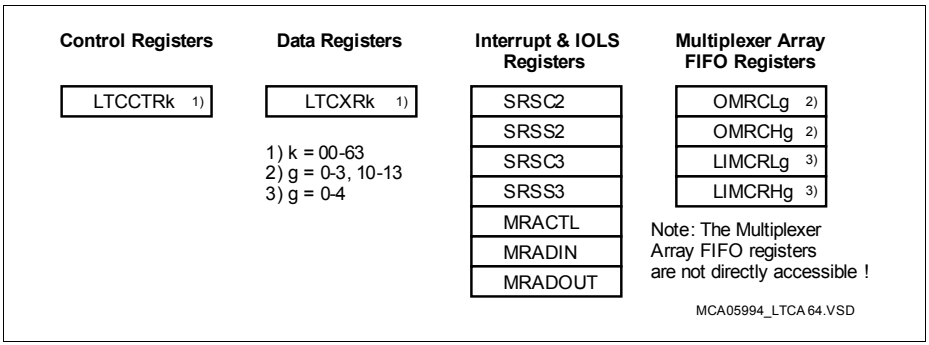

Figure 28-92 LTCA2 Kernel Registers

Table 28-25 LTCA2 Kernel Registers

Register Short Name	Register Long Name	Offset Addr.	Access Mode		Reset Class	Description see
			Read	Write		
ID	LTCA Identification Register	0008_H	U, SV	nBE	1	**Page 28-166**

LIMCRHg	Input Multiplexer Control Register for Upper Half of LTC Group g (g = 0-7)		n.a.	n.a.	3	Page 28-272

28.6.1 Bit Protection

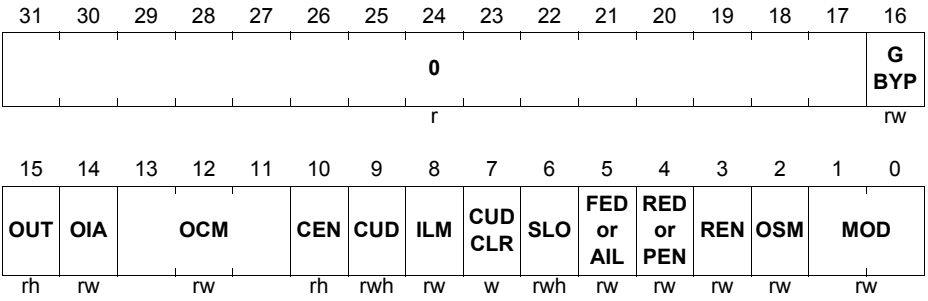
Bits with bit protection (this is valid, for example, for all bits in the Service Request State Registers) are not changed during a read-modify-write instruction, that is when hardware sets a request state bit between the read and the write of the read-modify-write sequence. For bit protected bits it is guaranteed that a hardware setting operation always has priority. Thus, no hardware triggered events are lost.

28.6.2 Service Request Registers

See **"GPTA0_SRSC2" on Page 28-228**.

28.6.3 Local Timer Cell Registers

LTCA2_LTCCTRk (k = 00-62)
Local Timer Cell Control Register k [Timer Mode]
(200_H+k*8_H) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
MOD	[1:0]	rw	**Mode Control Bits** 00_B LTCk operates in Capture Mode 01_B LTCk operates in Compare Mode 10_B LTCk operates in Free-Running Timer Mode 11_B LTCk operates in reset Timer Mode
OSM	2	rw	**One Shot Mode Enable** 0_B LTCk is continuously enabled 1_B LTCk is enabled for one event only
REN	3	rw	**Request Enable** 0_B Service request is disabled. 1_B Service request SQSk is activated when a - capture event has occurred - compare event has occurred - timer overflow has happened depending on the operation mode selected by bit field MOD.

Field	Bits	Type	Description
RED	4	rw	**ILM = 0: Input Rising Edge Select** 0_B Timer is not updated by a rising edge 1_B Timer is updated by a rising edge on the LTCkIN input line
PEN	4	rw	**ILM = 1: LTC Prescaler Enable** 0_B LTC Prescaler Mode is disabled 1_B LTC Prescaler Mode with LTC prescaler clock LTCPRE is enabled
FED	5	rw	**ILM = 0: Input Falling Edge Select** 0_B Timer is not updated by a falling edge 1_B Timer is updated by a falling edge on the LTCkIN input line
AIL	5	rw	**ILM = 1: Active Input Level Select** 0_B Input signal is active high 1_B Input signal is active low
SLO	6	rwh	**Select Line Output** 0_B State of select line output SO is 0 1_B State of select line output SO is 1 SLO is bit protected (see **Page 28-167**).
CUDCLR	7	w	**Coherent Update Disable** 0_B No effect 1_B Coherent update disabled (bit CUD is cleared) If bits CUD and CUDCLR are both written with 1, bit CUD will be set. CUDCLR is always read as 0.
ILM	8	rw	**Input Line Mode** 0_B Input line is operating in Edge Sensitive Mode. 1_B Input line is operating in Level Sensitive Mode. In case of full speed GPTA®v5 module clock selection as input clock, Level Sensitive Mode must be selected. In this case the Edge Sensitive Mode will not produce any event.
CUD	9	rwh	**Coherent Update Enable** 0_B Select output SO is not toggled on timer reset overflow 1_B Select output SO is toggled on next timer reset overflow When CUD is set by software (writing CUD and CUDCLR both with 1), it remains set until the next timer reset overflow (LTCk reset event) occurs and is cleared by hardware afterwards. CUD can be reset by software by writing bit CUDCLR with 1 and CUD with 0.

Field	Bits	Type	Description
CEN	10	rh	**Cell Enable** 0_B LTCk is currently disabled for local events 1_B LTCk is currently enabled for local events
OCM	[13:11]	rw	**Output Control Mode Select** 000_B Current state of LTCkOUT output line is hold 001_B Current state of LTCkOUT output line is toggled by an internal LTCk event otherwise hold 010_B LTCkOUT output line is forced to 0 by an internal LTCk event otherwise hold 011_B LTCkOUT output line is forced to 1 by an internal LTCk event otherwise hold $1XX_B$ LTCkOUT output line state is affected by an internal LTCk event and/or by an operation occurred in an adjacent LTCk cell (reported by M1I/M0I interface lines)
OIA	14	rw	**Output Immediate Action** 0_B No immediate action required 1_B Action defined by bit field OCM must be performed immediately OIA is always read as 0.
OUT	15	rh	**Output State** 0_B LTCkOUT output line is 0 1_B LTCkOUT output line is 1
GBYP	16	rw	**Global Bypass** 0_B M3O/M2O lines are affected by M1I/M0I lines 1_B M3O/M2O lines are affected by M3I/M2I lines
0	[31:17]	r	**Reserved** Read as 0; should be written with 0.

LTCA2_LTCCTRk (k = 00-62)

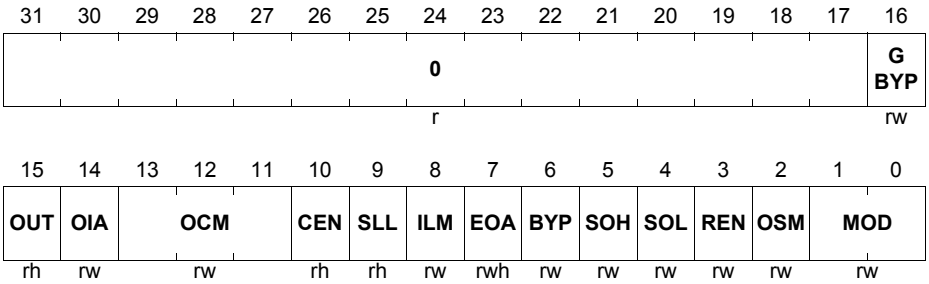
LTCA2_LTCCTRk (k = 00-62)
Local Timer Cell Control Register k [Compare Mode]
(200_H+k*8_H) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
MOD	[1:0]	rw	**Mode Control Bits** 00_B LTCk operates in Capture Mode. 01_B LTCk operates in Compare Mode. 10_B LTCk operates in Free-Running Timer Mode. 11_B LTCk operates in reset Timer Mode.
OSM	2	rw	**One Shot Mode Enable** 0_B LTCk is continuously enabled. 1_B LTCk is enabled for one event only.
REN	3	rw	**Request Enable** 0_B Service request is disabled. 1_B Service request SQSk is activated when a - capture event has occurred - compare event has occurred - timer overflow has happened depending on the operation mode selected by bit field MOD.
SOL	4	rw	**Compare Mode: Select Output Low** 0_B Compare is deactivated or on high level. 1_B Compare operation is enabled by a low level on select input SI[1)].
SOH	5	rw	**Compare Mode: Select Output High** 0_B Compare is deactivated or on high level. 1_B Compare operation is enabled by a high level on select input SI[1)].

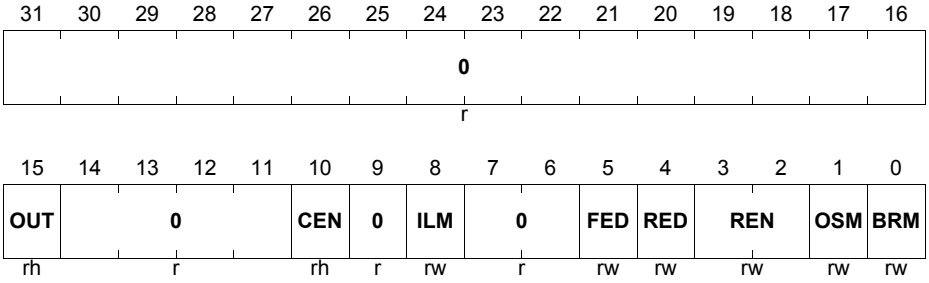
Field	Bits	Type	Description
BYP	6	rw	**Bypass** 0_B M1O/M0O lines are affected either by M1I/M0I lines or by OCM1/OCM0 bits. 1_B M1O/M0O lines are affected only by M1I/M0I lines. This bit is cleared if mode is switched to Timer Mode. OCM2 must be set in any case to enable reaction on M1I/M0I change.
EOA	7	rwh	**Enable On Action** 0_B LTCk is enabled for local events. 1_B LTCk is disabled for local events. On an event on the communication link via M0I/M1I lines, EOA will be cleared and local events will be enabled. EOA is bit protected (see **Section 28.4.2**). EOA is cleared if mode is switched to Timer Mode.
ILM	8	rw	**Input Line Mode** 0_B Input line is operating in Edge Sensitive Mode. 1_B Input line is operating in Level Sensitive Mode. In case of full speed GPTA®v5 module clock selection as input clock, Level Sensitive Mode must be selected. In this case the Edge Sensitive Mode will not produce any event.
SLL	9	rh	**Select Line Level** 0_B Current state of select input SI is 0. 1_B Current state of select input SI is 1.
CEN	10	rh	**Cell Enable** 0_B LTCk is currently disabled for local events. 1_B LTCk is currently enabled for local events.
OCM	[13:11]	rw	**Output Control Mode Select** 000_B Current state of LTCkOUT output line is hold 001_B Current state of LTCkOUT output line is toggled by an internal LTCk event otherwise hold 010_B LTCkOUT output line is forced to 0 by an internal LTCk event otherwise hold 011_B LTCkOUT output line is forced to 1 by an internal LTCk event otherwise hold $1XX_B$ LTCkOUT output line state is affected by an internal LTCk event and/or by an operation occurred in an adjacent LTCk cell (reported by M1I/M0I interface lines).

Field	Bits	Type	Description
OIA	14	rw	**Output Immediate Action** 0_B No immediate action required. 1_B Action defined by bit field OCM must be performed immediately. OIA is always read as 0.
OUT	15	rh	**Output State** 0_B LTCkOUT output line is 0. 1_B LTCkOUT output line is 1.
GBYP	16	rw	**Global Bypass** 0_B M3O/M2O lines are affected by M1I/M0I lines. 1_B M3O/M2O lines are affected by M3I/M2I lines.
0	[31:17]	r	**Reserved** Read as 0; should be written with 0.

1) To enable Compare Mode in all cases, SOL and SOH bits must be set to 1.

LTCA2_LTCCTR63

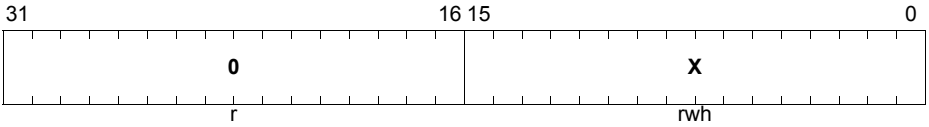
Local Timer Cell Control Register 63 ($3F8_H$) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
BRM	0	rw	**Bit Reversal Mode Control** 0_B Compare uses normal sequence of local input data bus (YI) bits. 1_B Compare uses reversed sequence of local input data bus (YI) bits.
OSM	1	rw	**One Shot Mode Enable for Shadow Register Copy** 0_B Shadow register copy is continuously enabled. 1_B Shadow register copy is enabled for one event only.
REN	[3:2]	rw	**Request Enable** 00_B Service request SQT63 is disabled. 01_B Service request SQT63 is generated when a compare event has occurred. 10_B Service request SQT63 is generated when a shadow register copy event has occurred. 11_B Reserved.
RED	4	rw	**Rising Edge Select for Shadow Register Copy** 0_B Shadow register copy is not triggered by a rising edge on the LTC63IN input line. 1_B Shadow register copy is triggered by a rising edge on the LTC63IN input line.
FED	5	rw	**Falling Edge Select for Shadow Register Copy** 0_B Shadow register copy is not triggered by a falling edge on the LTC63IN input line. 1_B Shadow register copy is triggered by a falling edge on the LTC63IN input line.

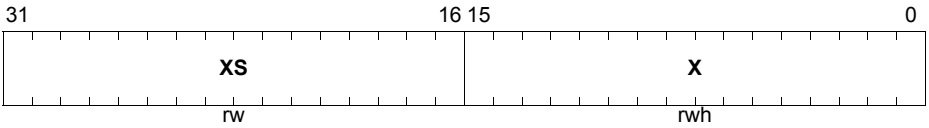
Field	Bits	Type	Description
ILM	8	rw	**Shadow Register Copy Input Line Mode** 0_B LTC63IN is operating in Edge Sensitive Mode. 1_B LTC63IN is operating in Level Sensitive Mode.
CEN	10	rh	**Enable for Shadow Register Copy** 0_B Shadow register copy is currently disabled. 1_B Shadow register copy is currently enabled.
OUT	15	rh	**Output State** 0_B LTC63OUT output line is 0. 1_B LTC63OUT output line is 1.
0	[7:6], 9, [14:11], [31:16]	r	**Reserved** Read as 0; should be written with 0.

LTCA2_LTCXRk (k = 00-62)
Local Timer Cell X Register k **(204_H+k*8_H)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
X	[15:0]	rwh	**Local Timer Data Register Value**
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

LTCA2_LTCXR63
Local Timer Cell X Register 63 **($3FC_H$)** **Reset Value: 0000 0000_H**



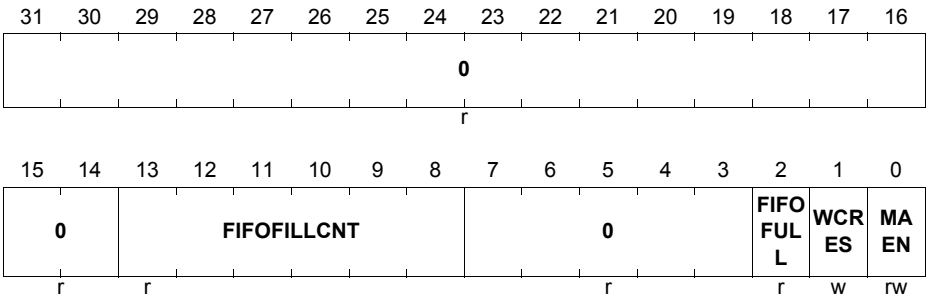
Field	Bits	Type	Description
X	[15:0]	rwh	**Compare Register Value** Software write operations has priority above a simultaneous hardware update.
XS	[31:16]	rw	**Shadow Register Value**

28.6.4 I/O Sharing Block Registers

The three registers MRACTL, MRADIN, and MRADOUT are used to write data to and read data from the LTCA Multiplexer Register Array FIFO. The Multiplexer Register Array FIFO controls the operation of the Input/Output Line Sharing Block (see **“Input/Output Line Sharing Block (IOLS)” on Page 28-98**).

The Multiplexer Register Array Control register controls the operation of the Multiplexer Register Array FIFO.

LTCA2_MRACTL
Multiplexer Register Array Control Register
(038_H) **Reset Value: $0000\ 0000_H$**

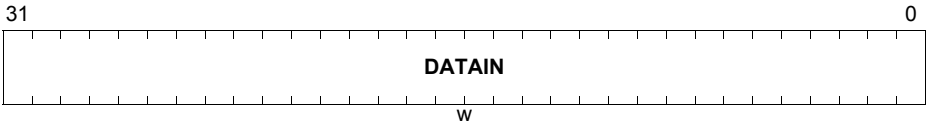


Field	Bits	Type	Description
MAEN	0	rw	**Multiplexer Array Enable** Bit field MAEN enables/disables the programming and the interconnections of the multiplexer array. 0_B Multiplexer array is disabled; all cell inputs are driven with 0, LTCA I/O lines (pins) are disconnected and FIFO writing is enabled. 1_B Multiplexer array is enabled; all cell and I/O line interconnections are established as previously programmed and FIFO writing is disabled.
WCRES	1	w	**Write Count Reset** Writing WCRES with 1 while the array is disabled (MAEN = 0), resets the write cycle counter to zero and the FIFO written sequentially (initialized). WCRES is always read as 0.
FIFOFULL	2	r	**FIFO Full Status** 0_B FIFO not completely written (write access to MRADIN allowed). 1_B FIFO completely written (write access to MRADIN ignored). Must be re-enabled via WCRES before array can be re-initialized.

Field	Bits	Type	Description
FIFOFILLCNT	[13:8]	r	**FIFO Fill Count** This bit field shows the current contents of the write cycle counter.
0	[7:3], [31:14]	r	**Reserved** Read as 0; should be written with 0.

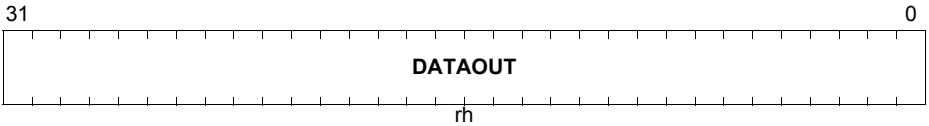
The Multiplexer Register Array Data In register is used to **write** data to the Multiplexer Register Array FIFO. The Multiplexer Register Array Data Out register is used to **read** data from the Multiplexer Register Array FIFO.

LTCA2_MRADIN
Multiplexer Register Array Data In Register
($03C_H$) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
DATAIN	[31:0]	w	**FIFO Write Data** This register contains the FIFO write data as defined for the LTC Output Multiplexer Control Registers and the LTC Input Multiplexer Control Registers.

LTCA2_MRADOUT
Multiplexer Register Array Data Out Register
(040_H) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
DATAOUT	[31:0]	rh	**FIFO Read Data** This register contains the FIFO read data as assigned for the LTC Output Multiplexer Control Registers and the LTC Input Multiplexer Control Registers.

Note: For correct operation, the MRADIN and MRADIN registers must be always read or written 32-bit wide. 8-bit and 16-bit accesses are ignored without any bus error!

28.6.5 Multiplexer Control Registers

These registers are not directly accessible and can be written and read only via the multiplexer register array FIFO (see **Page 28-121**).

28.6.5.1 Output Multiplexer Control Registers

Two registers, OMCRL and OMCRH, are assigned to each I/O Group IOG[3:0] and each Output Group OG[3:0]. OMCRL[3:0]/OMCRH[3:0] are assigned to IOG[3:0] and OMCRL[13:10]/OMCRH[13:10] are assigned to OG[6:3].

OMCRL controls the connections of group pins 0 to 3. OMCRH controls the connections of group pins 4 to 7.

LTCA2_OMCRLg (g = 0-3, 10-13)
Output Multiplexer Control Register for Lower Half of Pin Group g

Reset Value: 0000 0000$_H$

If a reserved combination of LIMGn is selected, or if LIMENn = 0, the corresponding LIMG output is forced to 0 level.

Field	Bits	Type	Description
LIMEN4, **LIMEN5,** **LIMEN6,** **LIMEN7**	7, 15, 23, 31	rw	**Enable Multiplexer Connection** 0_B Input n is not connected to any line. 1_B Input n is connected to the line defined by LIMLn and LIMGn.
0	3, 11, 19, 27	r	**Reserved** Read as 0; should be written with 0.

28.7 GPTA®v5 Module Implementation

This section describes the GPTA®v5 interfaces as implemented in TC1798 with the clock control, port and Micro Second Channel connections, interrupt control, and address decoding.

28.7.1 Interconnections of GPTA0/GPTA1/LTCA2 Units

The following items are described in this section:

- GPTA®v5 module (kernel) external registers
- Port control and connections
  - I/O port line assignment
  - I/O function selection
  - Pad driver characteristics selection
  - Emergency control of GPTA®v5 outputs
- On-chip connections
  - Clock bus connections
  - MSC controller connections
  - FADC connections
  - MultiCAN, SCU, and DMA connections
  - SCU connections (ADC, DMA)
- Module clock generation
- Interrupt registers
- GPTA®v5 address map

Figure 28-93 shows the TC1798 specific implementation details and interconnections of the units GPTA0/GPTA1/LTCA2.The units are supplied by clock control and address decoding logic.

Additional connections are described in the following sections.

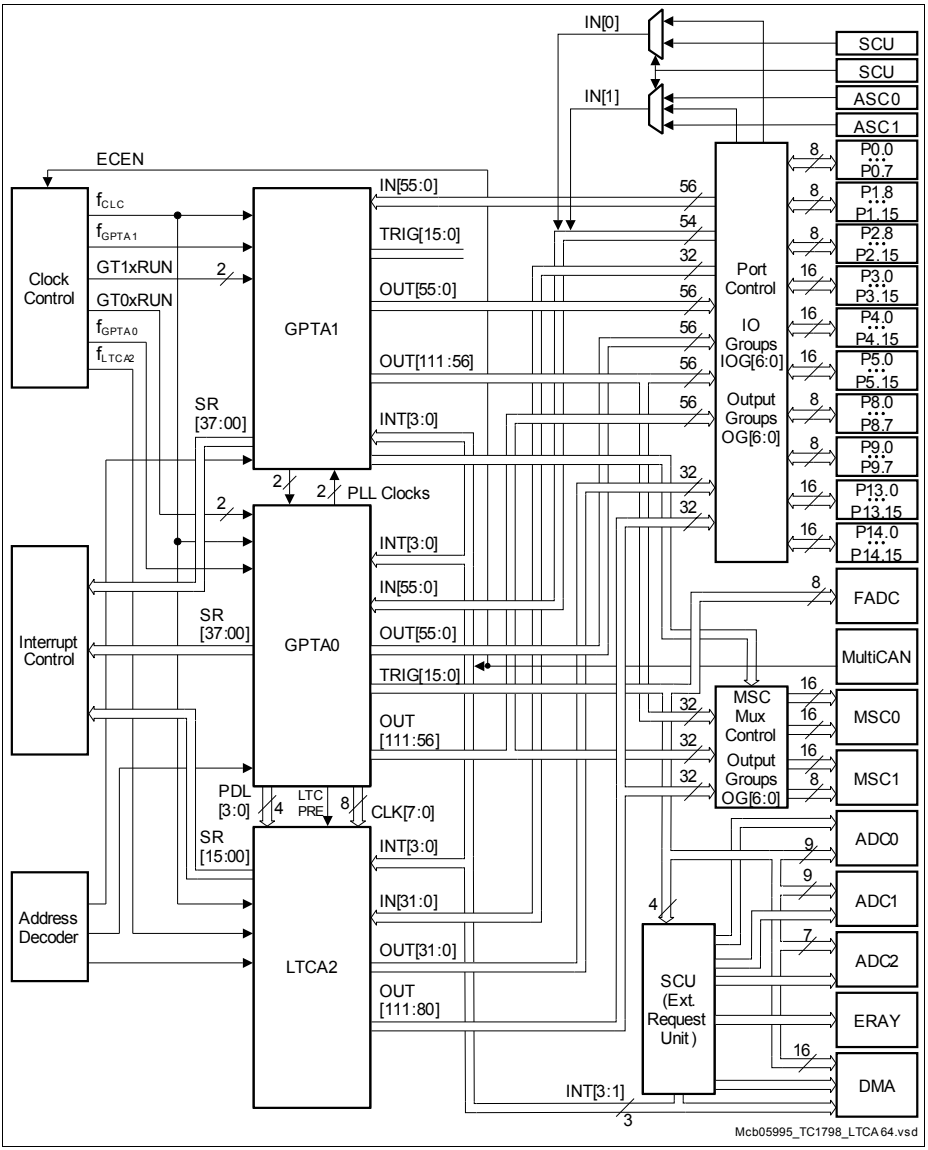

Figure 28-93 Block Diagram of GPTA®v5 Implementation

28.7.2 GPTA®v5 Module External Registers

Figure 28-94 summarizes the GPTA®v5 module related external registers that are required for GPTA0/GPTA1/LTCA2 programming. These registers are referenced and (some of it) described in detail in the following sub-sections.

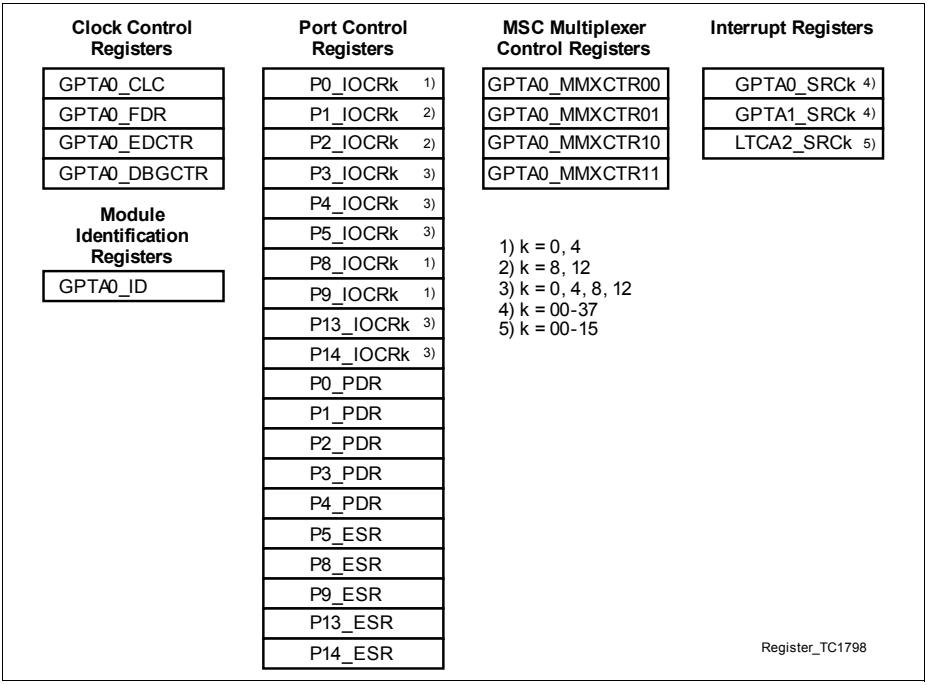

Figure 28-94 GPTA®v5 Implementation-Specific Special Function Registers

28.7.3 Port Control and Connections

This section describes the I/O connections of the GPTA0 unit.

28.7.3.1 I/O Port Line Assignment

In the TC1798, the seven I/O groups and seven output groups of GPTA0 and GPTA1 with their input lines IN[55:0] and output lines OUT[111:0] are assigned to seven 8-bit port groups as shown in Figure 28-95. Within an 8-bit I/O group, the IN/OUT line with lowest index number is assigned to the port line with the lowest index number. The remaining lines are assigned linearly with increasing index numbers. For example, P3.15 is assigned to IN13/OUT13. In the TC1798, the four I/O groups and seven output groups of LTCA2 with their input lines IN[31:0] and output lines OUT[56:0] are assigned to five

8-bit port groups Therefore, the LTCA does not have IOG4, IOG5, and IOG6 and therefore it has no connection to Port 8 or Port 9 pins and only output connections to Port 4, pins 15 down to 8.

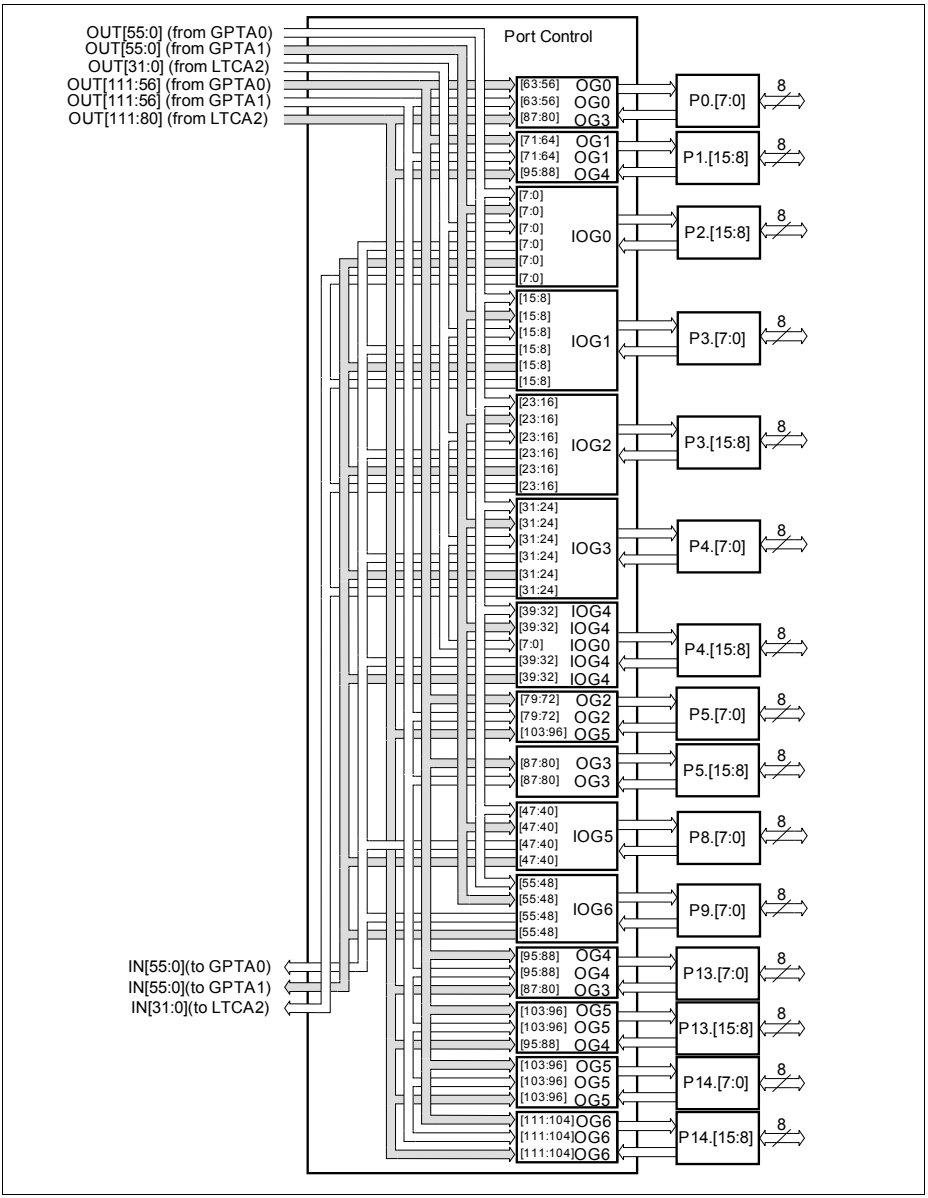

Figure 28-95 I/O Port Line Assignment

The interconnections between the GPTA0 unit and the port I/O lines are controlled in the port logics. The following port control operations selections must be executed:

- Input/output function selection (IOCR registers)
- Pad driver characteristics selection for outputs (PDR registers)

28.7.3.2 Input/Output Function Selection

Table 28-26 shows the GPTA0/GPTA1/LTCA2 I/O lines mapping to the ports. Note that GPTA0/GPTA1/LTCA2 input P2.8/IN0 (see Page 28-296) and GPTA0/GPTA1/LTCA2 input P2.9/IN1 (see Page 28-296) has special connections.

P14.8						OUT[104]

1) There is a special connection provided for GPTA0/GPTA1 input line IN0 (see Page 28-296).
2) There is a special connection provided for GPTA0/GPTA1 input line IN0 (see Page 28-296).
3) OUT[78] is not available as output on a pin.
4) OUT[65], OUT[76], and OUT[78] are only as output of GPTA0 available on a pin.
5) OUT[100], OUT[102] and OUT[103] are not connected to this port.
6) OUT[42] is not available as output on a pin.
7) OUT[52] and OUT[53] are not available as output on a pin.

A port line that is programmed as input can be used by the GPTA0 or other units simultaneously as input.

Port lines selected as GPTA0/GPTA1/LTCA2 output are forced to a 0 level if the related multiplexer array in the I/O Line Sharing Block is disabled or if a reserved combination of an OMGn value is selected. Therefore, no glitches and spikes can occur during the programming of the related multiplexer array.

28.7.3.3 Emergency Control of GPTA®v5 Output Ports Lines

Port lines connected to GPTA0/GPTA1/LTCA2 unit output pins can be selectively switched into an Emergency Mode. In this mode, GPTA0/GPTA1/LTCA2 unit output pins react immediately to an active input signal P10.1 (HWCFG1) and drive a logic level that has been programmed in the port output register. As a result, in Emergency Mode a GPTA0/GPTA1/LTCA2 unit output pin drives a predefined value instead of the corresponding logic level that is provided on the related GPTA0/GPTA1/LTCA2 unit output line.

All GPTA®v5 pins at Port 0, Port 1, Port 2, Port 3, Port 4, Port 8, Port 9, Port 13, and Port 14 are connected to one common emergency stop signal that is generated in the System Control Unit of the TC1798. More details about the generation of this emergency stop signal are described in the "System Control Unit" chapter of the TC1798 System Units User´s Manual.

The emergency stop signal always controls 8-bit groups of port lines. The enable function is controlled for each pin by bits ENy (y = number of port line) which are located in the Px_ESR (x = port number) registers. When the emergency stop signal generated in the SCU becomes active and bit Px_ESR.ENy set, output line Px.y is set to the value

of register Px_OUT.Py (emergency enabled). Output Px.y is not affected by the emergency stop signal when bit Px_OUT.Py is reset (emergency disabled).

When the emergency stop signal is released, Pin x.y is switched back to the previously selected GPTA®v5 output function without reprogramming the related port registers.

Table 28-29 Emergency Control for GPTA®v5 Port Output Lines

Port	ESR Register	ESR Enable Bits	GPTA®v5 Output Lines	LTCA Output Lines
Port 0	P0_ESR	EN[7:0]	OUT[63:56]	OUT[87:80]

28.7.4 On-Chip Connections

This section describes all on-chip interconnections of the GPTA0/GPTA1/LTCA2 units except the connections to I/O ports (see **Section 28.7.3**).

28.7.4.1 Clock Bus Connections

The clock bus signals generated in the GPTA0 and GPTA1 clock distribution cells and PLL clocks are interconnected between the GPTA0/GPTA1/LTCA2 units as shown in **Figure 28-96**.

The GPTA0 clock bus drives Global Timers (GTs), Global Timer Cells (GTCs), and Local Timer Cells (LTCs) of the GPTA0 unit **and** the LTCs of the LTCA2 unit. The GPTA1 clock bus drives its GTs, GTCs, and LTCs.

Each GPTA0 and GPTA1 clock distribution cells has two pairs for PLL clock inputs, an input pair for the local PLL clocks and an input pair for unit-external PLL clocks. The GPTA0 and GPTA1 units are capable to use the PLL clocks from each other.

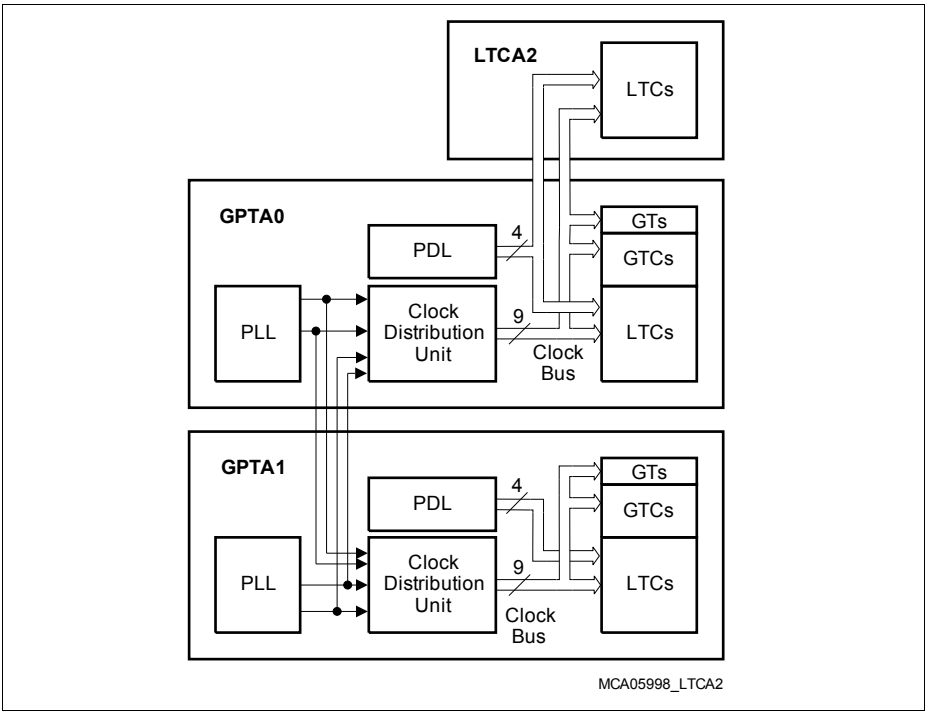

Figure 28-96 Clock Bus Connections of GPTA0/GPTA1/LTCA2

28.7.4.2 MSC Controller Connections

The MSC interfaces (MSC0 and MSC1) provide a serial communication link typically used to connect power switches or other peripheral devices. Each output multiplexers of GPTA0/GPTA1 generate 7 × 8 = 56 output lines OUT[111:56] grouped into seven output groups. Each output multiplexers of LTCA2 generate 4 × 8 = 32 output lines OUT[111:80] grouped into four output groups. All these output lines are wired to 32 MSC0 inputs. Up to 32 MSC0 and 24 MSC1 output extension lines (bits) can be connected to the GPTA®v5. **Figure 28-97** shows the interconnections among the MSC0/1 modules and the GPTA®v5 units. The source for each line of the ALTINL/ALTINH MSC input buses can be selected via a multiplexer connected either to GPTA0 output OUTx(x = 56-111), GPTA1 output OUTx(x = 56-111), LTCA2 output OUTx(x = 80-111).

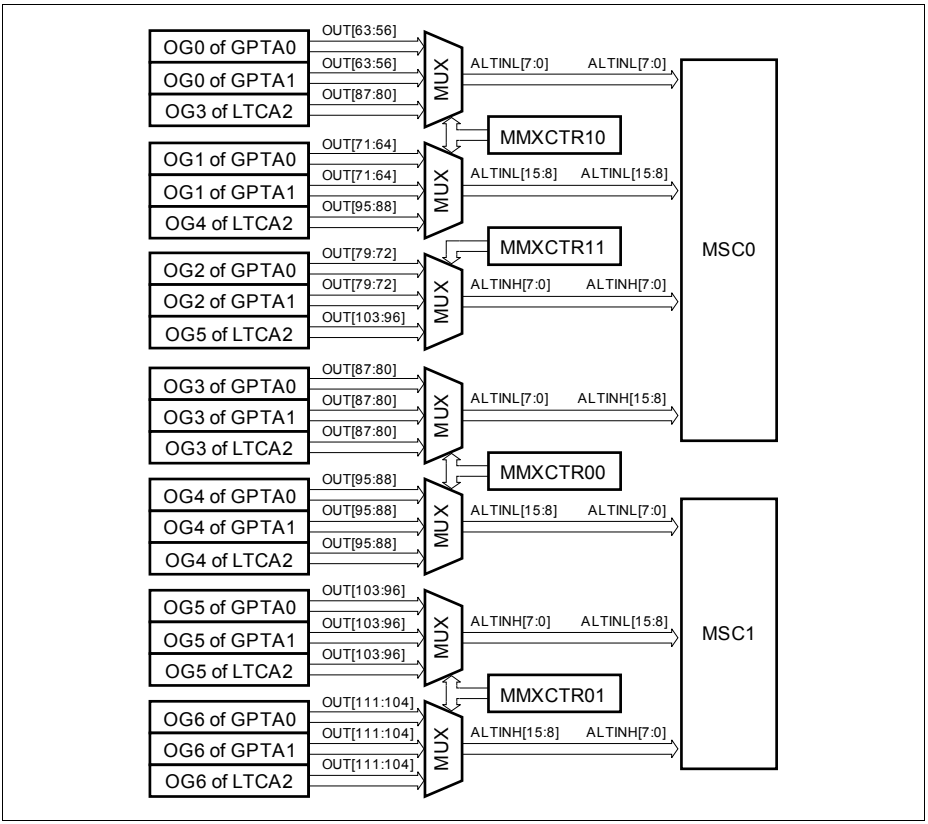

Figure 28-97 GPTA®v5-to-MSC Multiplexer

The multiplexer selection is controlled by four multiplexer control registers that are logically assigned to the GPTA0 unit address range (but described in this section).

Note: Note that eight ALTINH inputs (ALTINH[15:8]) of the MSC1 module are not connected.

Table 28-30 and **Table 28-31** shows the GPTA®v5-to-MSC interconnection assignment.

*Note: **Table 28-30** and **Table 28-31** also shows the assignment of the GPTA0/GPTA1/LTCA2 unit's seven OGx output group lines OGx.y to the output signals OUT[111:56].*

GPTA®v5-to-MSC Multiplexer Control Registers

The following registers are required for GPTA®v5-to-MSC multiplexer control:

- **GPTA0_MMXCTR00** controls the interconnections of GPTA®v5 Units to the MSC0 ALTINH[15:8] and MSC1 ALTINL[7:0] inputs.
- **GPTA0_MMXCTR01** controls the interconnections of GPTA®v5 Units to the MSC0 ALTINH[15:0] inputs. MSC1 ALTINL[15:8] inputs and MSC1 ALTINH[7:0] inputs.
- **GPTA0_MMXCTR10** controls the interconnections of GPTA®v5 Units to the MSC0 ALTINL[15:0] inputs.
- **GPTA0_MMXCTR11** controls the interconnections of GPTA®v5 Units to the MSC0 ALTINH[7:0] inputs.

For each of the ALTINL/ALTINH inputs of the MSC, the 2-bit bit fields in these registers determine which unit output is selected.

28.7.4.3 Connections to SCU, MultiCAN, FADC, DMA, Ports

The GPTA0/GPTA1/LTCA2 units of the TC1798 GPTA®v5 module have several on-chip interconnections with the SCU, MultiCAN, FADC, DMA modules. **Figure 28-98** shows these interconnections.

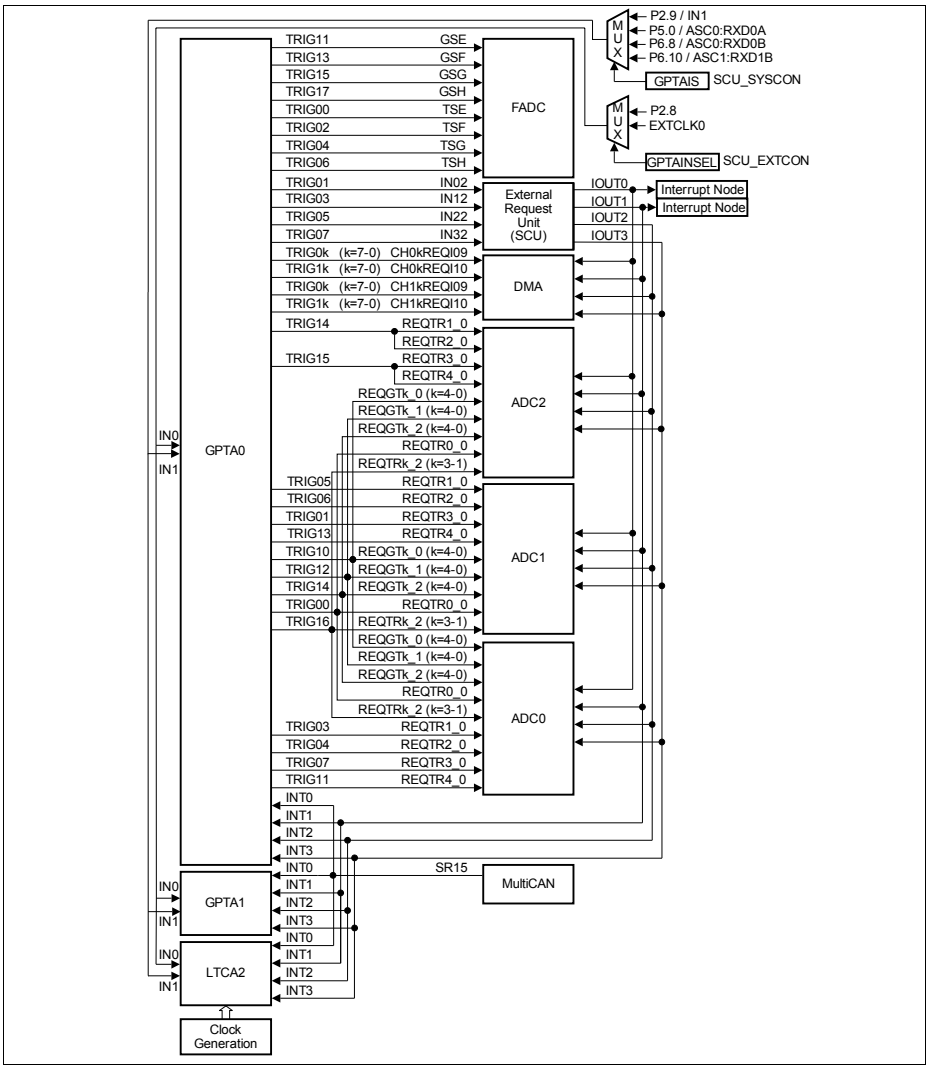

Figure 28-98 Connections of GPTA®v5 with On-Chip Modules

System Control Unit

The SCU contains the external request unit (ERU), which is especially responsible for controlling requests coming from the MSC modules, port pins, or from the GPTA0/GPTA1/LTCA2 unit and passing these request to AD converters, DMA controller, ERAY communication controller or interrupt nodes.

MultiCAN Connections

The MultiCAN controller has the following connections to the GPTA0/GPTA1/LTCA2 unit:

- MultiCAN service request output SR15 is connected to the INT0 input of GPTA0/GPTA1/LTCA2.
- GPTA0 output line OUT5 is connected to the external time trigger input ECTT3 of the MultiCAN module.

DMA Controller

As shown in **Figure 28-98**, eight GPTA0 on-chip trigger and gating output lines are connected as trigger input signals to the DMA request inputs. Furthermore the external request unit generates four DMA request output signals (IOUT[3:0]) that can be activated via port pins, the MSC clock outputs, or the four GPTA®v5 output lines. Three of these four DMA request output signals are connected to the GPTA0/GPTA1/LTCA2 internal inputs INT[3:1]. These connections allow, for example, GTC or LTC events in the GPTA®v5 units to be triggered by a request coming from a port pin or from the MSC clock.

ADC Connections

As shown in **Figure 28-98**, for each ADC nine GPTA0 on-chip trigger and gating output lines are connected as trigger input signals or gating input signals to the channel trigger logic of the ADC. Thus dedicated GPTA0 outputs can generate trigger events or act as gating signals for ADC channels. Furthermore the external request unit generates two ADC conversion trigger signals (IOUT[3:2]) and two ADC conversion gating signals (PDOUT[3:2]) that can be activated each via port pins, the MSC clock outputs, or two GPTA®v5 output lines.

FADC Connections

As shown in **Figure 28-98**, eight GPTA0 on-chip trigger and gating output lines are connected as trigger input signals or gating input signals to the channel trigger logic of the FADC. Thus dedicated GPTA0 outputs can generate trigger events or act as gating signals for FADC channels.

Port Connections of Input IN0

The common input line IN0 of the GPTA0/GPTA1/LTCA2 unit is connected to the output of a 2-to-1 multiplexer. This multiplexer is controlled by bit field SCU_EXTCON.GPTAINSEL and allows the common GPTA0/GPTA1/LTCA2 input IN0 to be connected to one out of two input lines. This feature especially allows the number of clock of the PLL (to determine clock stability) to be measured by GTs (Global Timers) or FPC0 (Filter and Prescaler Cell) of the GPTA0/GPTA1.

Table 28-32 GPTA0 Input Line IN0 Connections

SCU_EXTCON. GPTAINSEL	GPTA0/GPTA1/LTCA2 Input IN0 Connected to
00_B	P2.9 / IN0 (default after reset)
01_B	SCU: EXTCLK0

Port Connections of Input IN1

The common input line IN1 of the GPTA0/GPTA1/LTCA2 unit is connected to the output of a 4-to-1 multiplexer. This multiplexer is controlled by bit field SCU_SYSCON.GPTAIS and allows the common GPTA0/GPTA1/LTCA2 input IN1 to be connected to one out of four port input lines. This feature especially allows the baud rates of an ASC0 or ASC1 receiver input signal to be measured by timers of the GPTA0/GPTA1/LTCA2.

Table 28-33 GPTA0 Input Line IN1 Connections

SCU_SYSCON. GPTAIS	GPTA0/GPTA1/LTCA2 Input IN1 Connected to
00_B	P2.9 / IN1 (default after reset)

10_B	P6.8 ASC0: RXD0B
11_B	P6.10 / ASC1: RXD1B

28.7.5 Module Clock Generation

As shown in **Figure 28-99**, the clock signals for the GPTA0/GPTA1/LTCA2 units are generated and controlled by one clock generation circuitry. This clock generation circuitry is responsible for the enable/disable control, the clock frequency adjustment, and the debug clock control. The circuitry includes the following registers:

- **Clock Control Register GPTA0_CLC** (see **Page 28-300**), responsible for the generation of the control clock f_{CLC} that is used by each of the units.
- **Fractional Divider Register GPTA0_FDR** (see **Page 28-301**), responsible for the frequency control of the module timer clock f_{GPTA}.

- **Clock Enable/Disable Control Register GPTA0_EDCTR** (see **Page 28-303**), responsible for the enable/disable control of the different units as clocks f_{GPTA0},f_{GPTA1}/f_{LTCA2}, and for the run control for the Global Timers in GPTA0 and GPTA1.
- **Debug Clock Control Register GPTA0_DBGCTR** (see **Page 28-305**), responsible for the module timer clock control in Debug Mode.

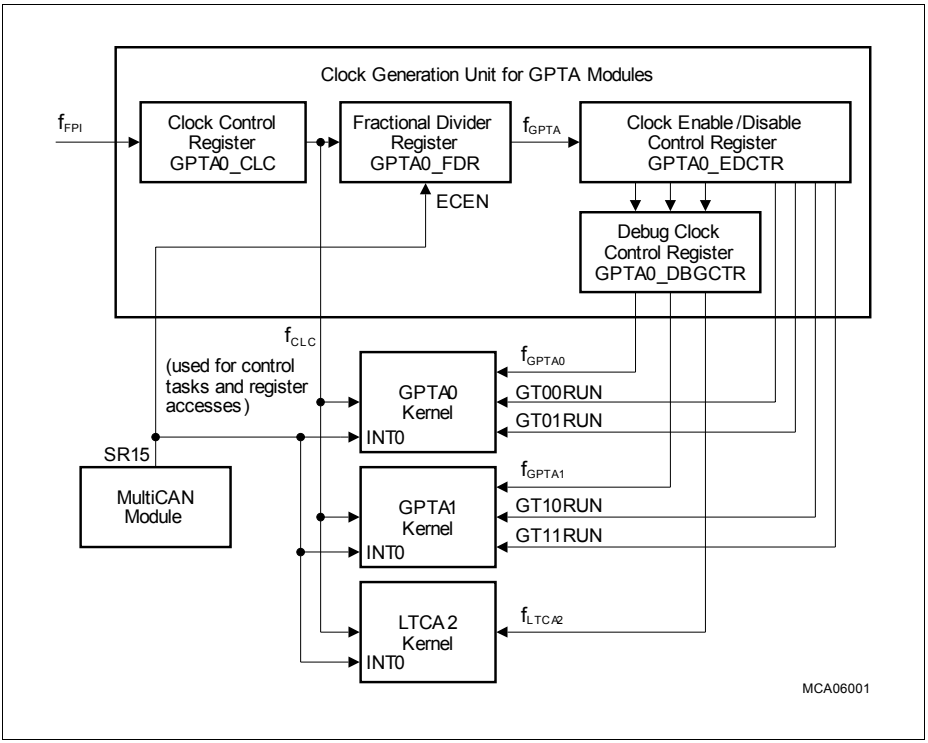

Figure 28-99 GPTA®v5 Clock Generation for the units

Note: Registers GPTA0_CLC, GPTA0_FDR, GPTA0_EDCTR and GPTA0_DBGCTR are located in the address space of GPTA0.

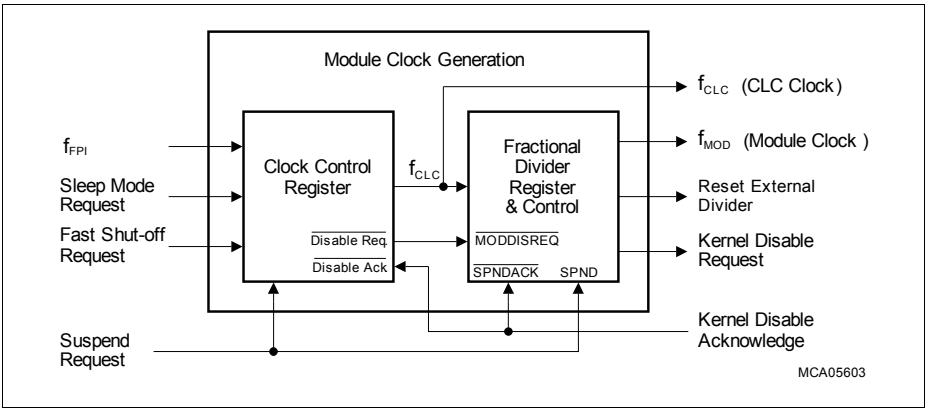

Figure 28-100Details on Module Clock Generation

The GPTA®v5 module control clock f_{CLC} is used inside the GPTA®v5 module kernels for control purposes such as clocking of control logic and register operations. The frequency of f_{CLC} is identical to the clock frequency f_{FPI}. The clock control registers GPTA0_CLC make it possible to enable/disable f_{CLC} under certain conditions.

The separate GPTA®v5 unit clocks f_{GPTA0}, f_{GPTA1}, f_{LTCA2} are used inside the GPTA®v5 units as input clocks for the timers. All unit clocks have the same frequency as f_{GPTA} (as selected through register GPTA0_FDR) and can be enabled/disabled separately each through register GPTA0_ECDTR.

Note: If f_{GPTA0}, f_{GPTA1}, f_{LTCA2} are disabled by the enable bits in register GPTA0_ECDTR, f_{CLC} keeps running. In this case, that means that register accesses to the GPTA®v5 units are possible.

The frequency of f_{GPTA} is defined by:

$$f_{GPTA} = f_{FPI} \times \frac{1}{n} \quad \text{with n = 1024 - FDR.STEP or} \tag{28.6}$$

$$f_{GPTA} = f_{FPI} \times \frac{n}{1024} \quad \text{with n = 0-1023} \tag{28.7}$$

Note: The upper formula applies to normal divider mode of the fractional divider (GPTA0_FDR.DM = 01_B). The lower formula applies to fractional divider mode (GPTA0_FDR.DM = 10_B).

The debug clock control register additionally makes it possible to control the timer clocks f_{GPTA0}, f_{GPTA1}, f_{LTCA2} for debug purposes on basis of a clock counter.

If the debug clock feature is enabled (GPTA0_DBGCTR.DBGCEN = 1) and bit GPTA0_DBGCTR.DBGCST is set, the timer clocks f_{GPTA0}, f_{GPTA1}, f_{LTCA2} will be activated in parallel for as many clock cycles as have been programmed into bit field GPTA0_DBGCTR.CLKCNT. When the debug clock feature becomes enabled, bit field CLKCNT counts down and stops counting at 0000_H. Bit DBGCST is again reset by hardware after the programmed number of clock pulses has been issued. This feature makes it possible to single step the GPTA®v5 units with a programmable timer clock granularity.

Note: The GPTA®v5 module is disabled after reset. In general, after reset, the GPTA®v5 module control clock f_{CLC} must be switched on (writing to register GPTA0_CLC) before the frequency of the GPTA®v5 module timer clock f_{GPTA} is defined (writing to register GPTA0_FDR).

28.7.5.1 Clock Control Registers

The clock control register makes it possible to control (enable/disable) the GPTA®v5 module control clock f_{CLC}. The clock signal f_{CLC} is used by the GPTA0/GPTA1/LTCA2 as a clock for internal control operations but not for timer purposes.

GPTA0_CLC
GPTA Clock Control Register (000_H) Reset Value: 0000 0003$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0										FSOE	SBWE	EDIS	SPEN	DISS	DISR
r										rw	w	rw	rw	r	rw

Field	Bits	Type	Description
DISR	0	rw	**GPTA®v5 Module Disable Request Bit** Used for enable/disable control of the GPTA®v5 module.
DISS	1	r	**GPTA®v5 Module Disable Status Bit** Bit indicates the current status of the GPTA®v5 module.
SPEN	2	rw	**GPTA®v5 Module Suspend Enable for OCDS** Used to enable the suspend mode.
EDIS	3	rw	**External Request Disable** Used to control the external clock disable request.
SBWE	4	w	**GPTA®v5 Module Suspend Bit Write Enable for OCDS** Determines whether SPEN and FSOE are write-protected.
FSOE	5	rw	**Fast Switch Off Enable** Used for fast clock switch off in suspend mode.
0	[31:6]	r	**Reserved** Read as 0; should be written with 0.

Note: After a hardware reset operation, the f_{CLC} clock is disabled (DISS set). Therefore, the GPTA®v5 module clock generation is completely disabled.

Note: In disabled state, no registers of GPTA®v5 module can be read or written except the GPTA_CLC register.

28.7.5.2 Fractional Divider Register

The fractional divider makes it possible to generate a GPTA®v5 module clock from an input clock using a programmable divider. The fractional divider divides the input clock f_{CLC} either by the factor 1/n or by a fraction of n/1024 for any value of n from 0 to 1023, and outputs the clock signal, f_{GPTA}. The fractional divider is controlled by the FDR register.

The fractional divider register controls the clock frequency of the GPTA®v5 module timer clock f_{GPTA}. The clock frequency of f_{GPTA0}, f_{GPTA1}, f_{LTCA2} is identical to the one of f_{GPTA}.

GPTA0_FDR
GPTA Fractional Divider Register (00C$_H$) Reset Value: 0000 0000$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

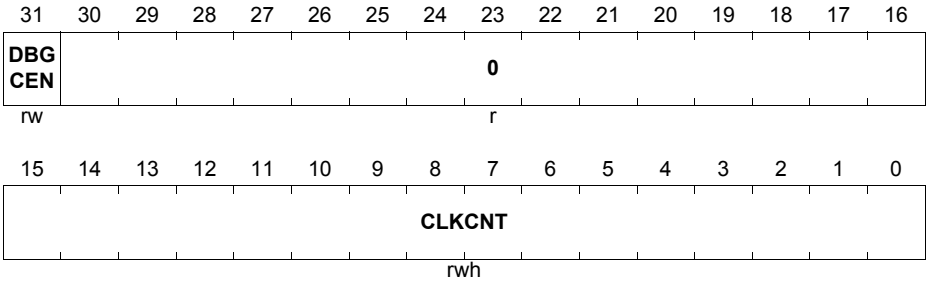
0	[7:4], [31:11]	r	**Reserved** Read as 0; should be written with 0.

The debug clock control register makes it possible to control the GPTA®v5 unit clocks f_{GPTA0}, f_{GPTA1}, f_{LTCA2} for debug purposes on the basis of a clock counter.

GPTA0_DBGCTR
GPTA Debug Clock Control Register (004_H) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
CLKCNT	[15:0]	rwh	**Debug Clock Count** This bit field determines the number of clock pulses to be issued when the debug clock feature is enabled (DBGCEN = 1). CLKCNT counts down to 0000_H and stops when the debug clock feature is enabled.
DBGCEN	31	rw	**Debug Clock Enable** 0_B The debug clock feature is disabled. The GPTA®v5 unit clocks are always enabled. 1_B The debug clock feature is enabled. If a non-zero value is written to bit field CLKCNT the related number of clock pulses is issued at f_{GPTA0}, f_{GPTA1}, f_{LTCA2}.
0	[30:16]	r	**Reserved** Read as 0; should be written with 0.

28.7.6 Limits of Cascading GTCs and LTCs

As shown on **Page 28-57** and **Page 28-69**, a maximum of 32 GTCs and a maximum of 64 LTCs can be cascaded. In the TC1798, however cascading of GTCs and LTCs is limited under certain conditions.

If the LTCs are running with the maximum GPTA®v5 unit clock of $f_{GPTA} = f_{FPI}$ = 90 MHz, a maximum of 16 GTCs and 16 LTCs can be connected together. If the GPTA®v5 unit clock f_{GPTA} is reduced, the number of LTCs that can be cascaded increases accordingly. Only the integer part of the divider ratio as selected by the GPTA0_FDR fractional divider register determines the maximum number of cascaded GTCs and LTCs.

Table 28-34 Limits of Cascading GTCs and LTCs

f_{FPI}	Selected Clock Divider Ratio[1)]	Max. Number of Cascaded GTCs/LTCs
90 MHz	$1 <= f_{FPI}/f_{GPTA} < 2$	16 GTCs, 16 LTCs
	$2 <= f_{FPI}/f_{GPTA} < 3$	no limits for GTCs, 32 LTCs
	$3 <= f_{FPI}/f_{GPTA} < 4$	no limits for GTCs, 48 LTCs
	$4 <= f_{FPI}/f_{GPTA}$	no limits for GTCs and LTCs
45 MHz	$1 <= f_{FPI}/f_{GPTA} < 2$	no limits for GTCs, 32 LTCs
	$2 <= f_{FPI}/f_{GPTA}$	no limits for GTCs and LTCs

1) Selected by the GPTA0_FDR fractional divider register.

28.7.7 Interrupt Registers

Each of the service request outputs of the GPTA0/GPTA1/LTCA2 units is able to generate an interrupt and is controlled by an interrupt service request control register GPTA_SRCk. Therefore, the following interrupt service request control registers are available:

- GPTA0: GPTA0_SRC[37:00]
- GPTA1: GPTA1_SRC[37:00]
- LTCA2: LTCA2_SRC[15:00]

GPTA0_SRCk (k = 00-37)

28.8 Revision History

This chapter gives a summary of recent changes within this specification.

Table 28-35 Revision History

Version Number	Changes to Previous Version
Rev_1.11	Modified the tables “PDR Assignment for GPTA®v5 Port Lines” in TC7197, TC1767, and TC1736 specifications. Included the Pad Classes in PDR assignment table. Included PDx description for A1 and F pad class. Table on On-Chip Trigger/Gating Multiplexer Control Register Assignments modified. For LTCA2 the numbering of the Output Groups was done consistently as OG3-OG6. Further more the Output Multiplexer of LTCA2 has been made consistently to be 0-3/4 and 7/10-13. OUT[65], OUT[76] and OUT[78] are marked as signals not available as output for GPTA1.
Rev_1.12	- Add to What’s new section: To be consistent to TC1797, the double connected input group of IOG3 is renamed to IOG6 and the Output Group OG1-7 are renamed to OG0-OG6 and the OG0 is renamed to IOG7. - Section ’Functionality of LTCA2; remove plural for LTCAs and double centence: The Local Timer Cell Array (LTCA2) provide a set of hardware cells required for high-speed digital signal processing - Add term input to LTC signal overview - Add ILM indication to LTCCTRk register and split register view to different modes - Change for registers SRSC0, SRSC1, SRSC2 and SRSC3 in footnote 1) zero to one - Add LTCA2 outputs for port 5 to IOCR Assigment table for TC1797 - Add footnote 1) and 2) to IOCR Assigment table for TC1797 - changed bit description for bit fileds OCM in order to allow bit extraction
Rev_1.13	- split registers GTCCTRk for timer mode into ILM = 0 and ILM = 1 views - remove some redundant sentense at the beginning of the implementation part - improve tables “IOCR Assignment for GPTA Port Lines” to cover the different packages - remove table for PCx Coding as redundant to port chapter - remove table for PDR Assignmemt for GPTA Port Lines as redundant to port chapter
Rev_1.14	- improve bit field description for GTCCTRk and LTCCTRk register bit fields OCM

29 Capture/Compare Unit 6 (CCU6)

The CCU6 is a high-resolution 16-bit capture and compare unit with application specific modes, mainly for AC drive control. Special operating modes support the control of Brushless DC-motors using Hall sensors or Back-EMF detection. Furthermore, block commutation and control mechanisms for multi-phase machines are supported.
It also supports inputs to start several timers synchronously, an important feature in devices with several CCU6 modules.

This chapter is structured as follows:

- Introduction (see **Section 29.1**)
  including register overview (see **Section 29.1.3**)
- Operating T12 (see **Section 29.2**)
  including T12-related registers (see **Section 29.2.8**)
  and capture/compare control registers (see **Section 29.2.9**)
- Operating T13 (see **Section 29.3**)
  including T13-related registers (see **Section 29.3.6**)
- Synchronous start feature (see **Section 29.4**)
- Trap handling (see **Section 29.5**)
- Multi-Channel mode (see **Section 29.6**)
- Hall sensor mode (see **Section 29.7**)
- Modulation control registers (see **Section 29.8**)
- Interrupt handling (see **Section 29.9**)
  including interrupt registers (see **Section 29.9.2**)
- General module operation (see **Section 29.10**)
  including general registers (see **Section 29.10.4**)
- Module implementation (see **Section 29.11**)

29.1 Introduction

The CCU6 unit is made up of a Timer T12 Block with three capture/compare channels and a Timer T13 Block with one compare channel. The T12 channels can independently generate PWM signals or accept capture triggers, or they can jointly generate control signal patterns to drive AC-motors or inverters.

A rich set of status bits, synchronized updating of parameter values via shadow registers, and flexible generation of interrupt request signals provide means for efficient software-control.

Note: The capture/compare module itself is named CCU6 (capture/compare unit 6).
A capture/compare channel inside this module is named CC6x.

29.1.1 Feature Set Overview

This section gives an overview over the different building blocks and their main features.

Timer 12 Block Features

- Three capture/compare channels, each channel can be used either as capture or as compare channel
- Generation of a three-phase PWM supported (six outputs, individual signals for high-side and low-side switches)
- 16-bit resolution, maximum count frequency = peripheral clock
- Dead-time control for each channel to avoid short-circuits in the power stage
- Concurrent update of T12 registers
- Center-aligned and edge-aligned PWM can be generated
- Single-shot mode supported
- Start can be controlled by external events
- Capability of counting external events
- Many interrupt request sources
- Hysteresis-like control mode

Timer 13 Block Features

- One independent compare channel with one output
- 16-bit resolution, maximum count frequency = peripheral clock
- Concurrent update of T13 registers
- Can be synchronized to T12
- Interrupt generation at period-match and compare-match
- Single-shot mode supported
- Start can be controlled by external events
- Capability of counting external events

Additional Specific Functions

- Block commutation for Brushless DC-drives implemented
- Position detection via Hall-sensor pattern
- Noise filter supported for position input signals
- Automatic rotational speed measurement and commutation control for block commutation
- Integrated error handling
- Fast emergency stop without CPU load via external signal ($\overline{\text{CTRAP}}$)
- Control modes for multi-channel AC-drives
- Output levels can be selected and adapted to the power stage

29.1.2 Block Diagram

The Timer T12 can operate in capture and/or compare mode for its three channels. The modes can also be combined (e.g. a channel operates in compare mode, whereas another channel operates in capture mode). The Timer T13 can operate in compare mode only. The multi-channel control unit generates output patterns which can be modulated by T12 and/or T13. The modulation sources can be selected and combined for the signal modulation.

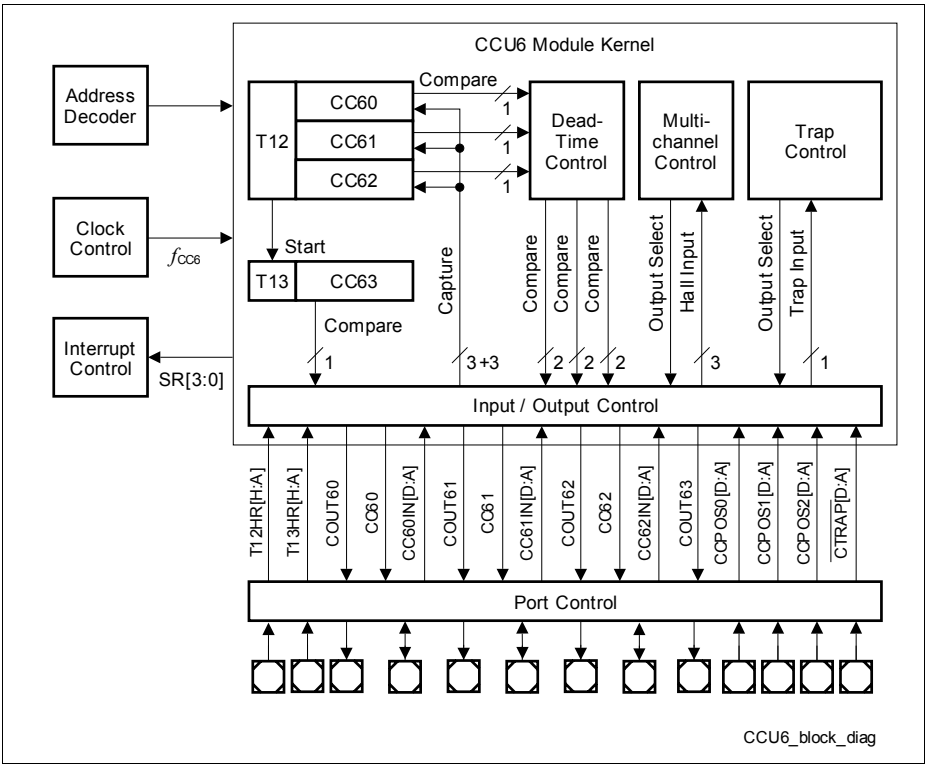

Figure 29-1 CCU6 Block Diagram

29.1.3 CCU6 Kernel Registers

For the generation of the overall register table, the prefix “CCU6x_” has to be added to the register names in this table to identify the registers of different CCU6 modules that are implemented. In this naming convention, x indicates the module number.

Table 29-1 shows all registers required for programming of a CCU6 module. It summarizes the CCU6 kernel registers and defines their offset addresses.

CCU6 Kernel Register Overview

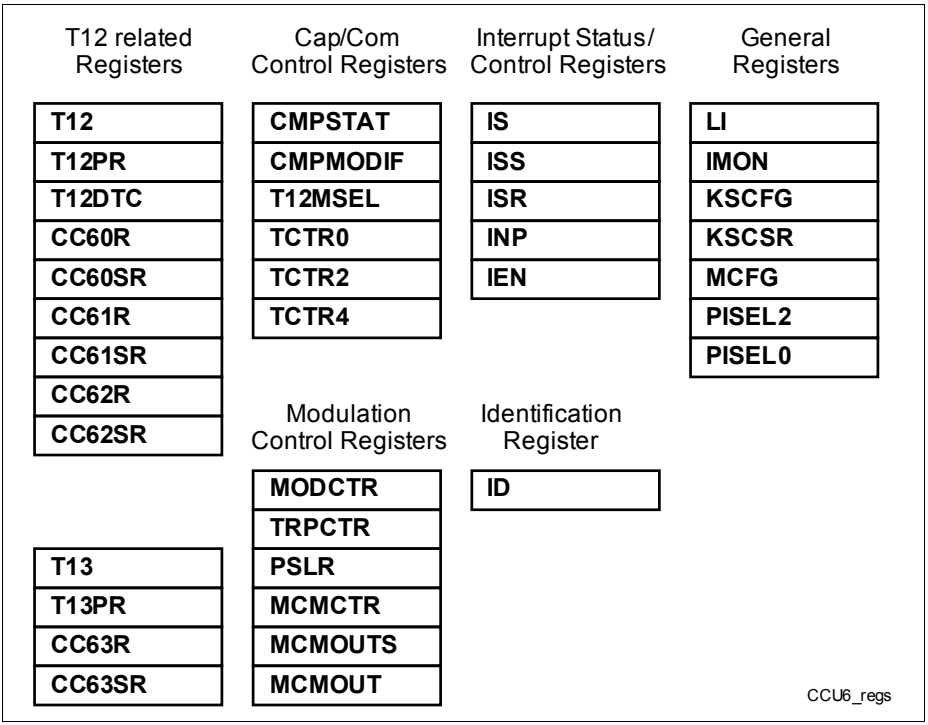

Figure 29-2 CCU6 Registers

Note: In the case of a write access to addresses inside the address range (that is covered by the same chip select signal), but that are not the addresses explicitly mentioned for the module, the write access is not taken into account for the module. The same principle is valid for read accesses. In case of a read access to another address, the module does not react.

*Note: The exact register address is given by the relative address of the register (given in **Table 29-1**) plus the kernel base address (given in **Table 29-14**) of the kernel.*

29.2 Operating Timer T12

The timer T12 block is the main unit to generate the 3-phase PWM signals. A 16-bit counter is connected to 3 channel registers via comparators, that generate a signal when the counter contents match one of the channel register contents. A variety of control functions facilitate the adaptation of the T12 structure to different application needs.
Besides the 3-phase PWM generation, the T12 block offers options for individual compare and capture functions, as well as dead-time control and hysteresis-like compare mode.

This section provides information about:

- T12 overview (see **Section 29.2.1**)
- Counting scheme (see **Section 29.2.2**)
- Compare modes (see **Section 29.2.3**)
- Compare mode output path (see **Section 29.2.4**)
- Capture modes (see **Section 29.2.5**)
- Shadow transfer (see **Section 29.2.6**)
- T12 operating mode selection (see **Section 29.2.7**)
- T12 register description (see **Section 29.2.8**

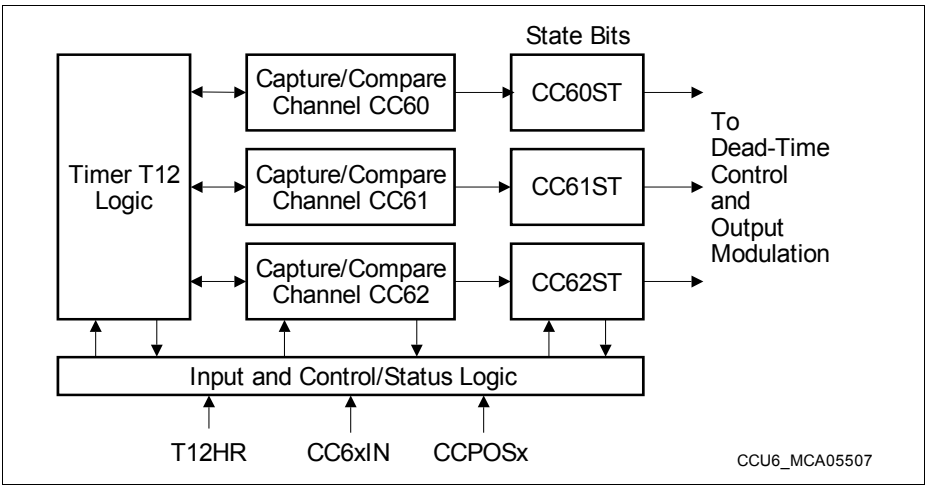

Figure 29-3 Overview Diagram of the Timer T12 Block

29.2.1 T12 Overview

Figure 29-4 shows a detailed block diagram of Timer T12. The functions of the timer T12 block are controlled by bits in registers **TCTR0**, **TCTR2**, and **PISEL0**.

Timer T12 receives its input clock (f_{T12}) from the module clock f_{CC6} via a programmable prescaler and an optional 1/256 divider or from an input signal T12HR. These options are controlled via bit fields T12CLK and T12PRE (see **Table 29-2**). T12 can count up or down, depending on the selected operation mode. A direction flag, CDIR, indicates the current counting direction.

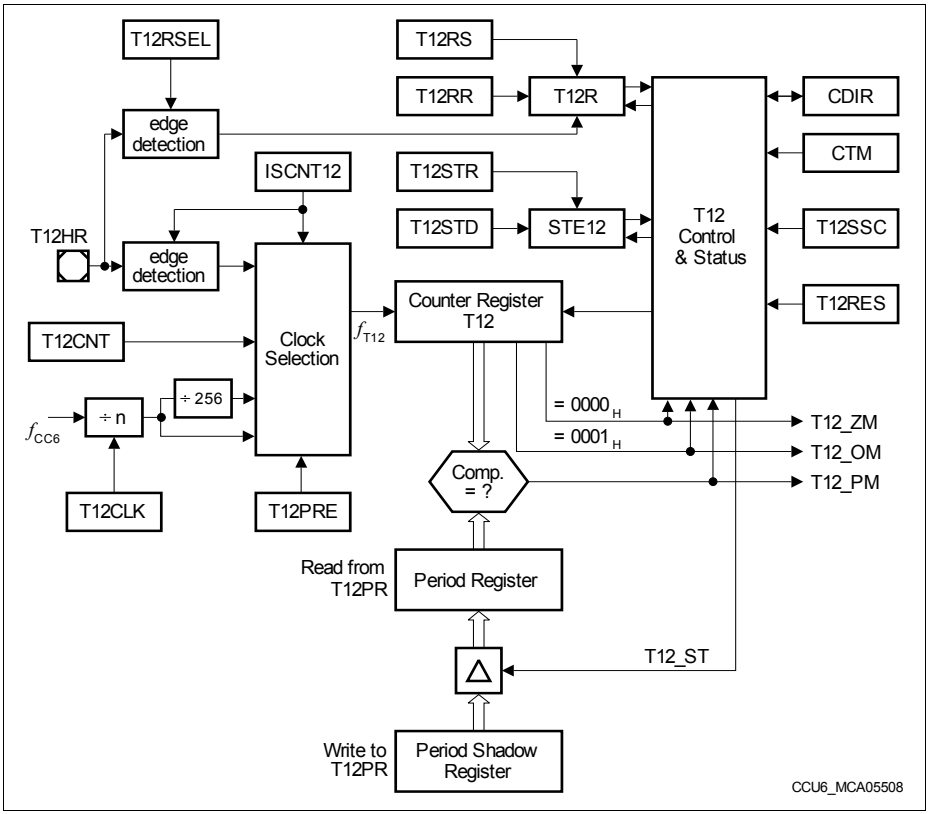

Figure 29-4 Timer T12 Logic and Period Comparators

Via a comparator, the T12 counter register **T12** is connected to a Period Register **T12PR**. This register determines the maximum count value for T12.

In Edge-Aligned mode, T12 is cleared to 0000_H after it has reached the period value defined by T12PR. In Center-Aligned mode, the count direction of T12 is set from ‘up’ to

‘down’ after it has reached the period value (please note that in this mode, T12 exceeds the period value by one before counting down). In both cases, signal T12_PM (T12 Period Match) is generated. The Period Register receives a new period value from its Shadow Period Register.
A read access to T12PR delivers the current period value at the comparator, whereas a write access targets the Shadow Period Register to prepare another period value. The transfer of a new period value from the Shadow Period Register into the Period Register (see **Section 29.2.6**) is controlled via the ‘T12 Shadow Transfer’ control signal, T12_ST. The generation of this signal depends on the operating mode and on the shadow transfer enable bit STE12. Providing a shadow register for the period value as well as for other values related to the generation of the PWM signal allows a concurrent update by software for all relevant parameters.
Two further signals indicate whether the counter contents are equal to 0000_H (T12_ZM = zero match) or 0001_H (T12_OM = one match). These signals control the counting and switching behavior of T12.

The basic operating mode of T12, either Edge-Aligned mode (**Figure 29-5**) or Center-Aligned mode (**Figure 29-6**), is selected via bit CTM. A Single-Shot control bit, T12SSC, enables an automatic stop of the timer when the current counting period is finished (see **Figure 29-7** and **Figure 29-8**).

The start or stop of T12 is controlled by the Run bit T12R that can be modified by bits in register **TCTR4**. The run bit can be set/cleared by software via the associated set/clear bits T12RS or T12RR, it can be set by a selectable edge of the input signal T12HR (**TCTR2**.T12RSEL), or it is cleared by hardware according to preselected conditions.
The timer T12 run bit T12R must not be set while the applied T12 period value is zero.
Timer T12 can be cleared via control bit T12RES. Setting this write-only bit does only clear the timer contents, but has no further effects, for example, it does not stop the timer.

The generation of the T12 shadow transfer control signal, T12_ST, is enabled via bit STE12. This bit can be set or reset by software indirectly through its associated set/clear control bits T12STR and T12STD.
While Timer T12 is running, write accesses to the count register T12 are not taken into account. If T12 is stopped and the Dead-Time counters are 0, write actions to register T12 are immediately taken into account.

29.2.2 T12 Counting Scheme

This section describes the clocking and counting capabilities of T12.

29.2.2.1 Clock Selection

In **Timer Mode** (**PISEL2**.ISCNT12 = 00_B), the input clock f_{T12} of Timer T12 is derived from the internal module clock f_{CC6} through a programmable prescaler and an optional 1/256 divider. The resulting prescaler factors are listed in **Table 29-2**. The prescaler of T12 is cleared while T12 is not running (**TCTR0**.T12R = 0) to ensure reproducible timings and delays.

Table 29-2 Timer T12 Input Frequency Options

T12CLK	Resulting Input Clock f_{T12} Prescaler Off (T12PRE = 0)	Resulting Input Clock f_{T12} Prescaler On (T12PRE = 1)
000_B	f_{CC6}	f_{CC6} / 256
001_B	f_{CC6} / 2	f_{CC6} / 512
010_B	f_{CC6} / 4	f_{CC6} / 1024
011_B	f_{CC6} / 8	f_{CC6} / 2048
100_B	f_{CC6} / 16	f_{CC6} / 4096
101_B	f_{CC6} / 32	f_{CC6} / 8192
110_B	f_{CC6} / 64	f_{CC6} / 16384
111_B	f_{CC6} / 128	f_{CC6} / 32768

In **Counter Mode**, timer T12 counts one step:

- If a 1 is written to **TCTR4**.T12CNT and **PISEL2**.ISCNT12 = 01_B
- If a rising edge of input signal T12HR is detected and **PISEL2**.ISCNT12 = 10_B
- If a falling edge of input signal T12HR is detected and **PISEL2**.ISCNT12 = 11_B

29.2.2.2 Edge-Aligned / Center-Aligned Mode

In **Edge-Aligned Mode** (CTM = 0), timer T12 is always counting upwards (CDIR = 0). When reaching the value given by the period register (period-match T12_PM), the value of T12 is cleared with the next counting step (saw tooth shape).

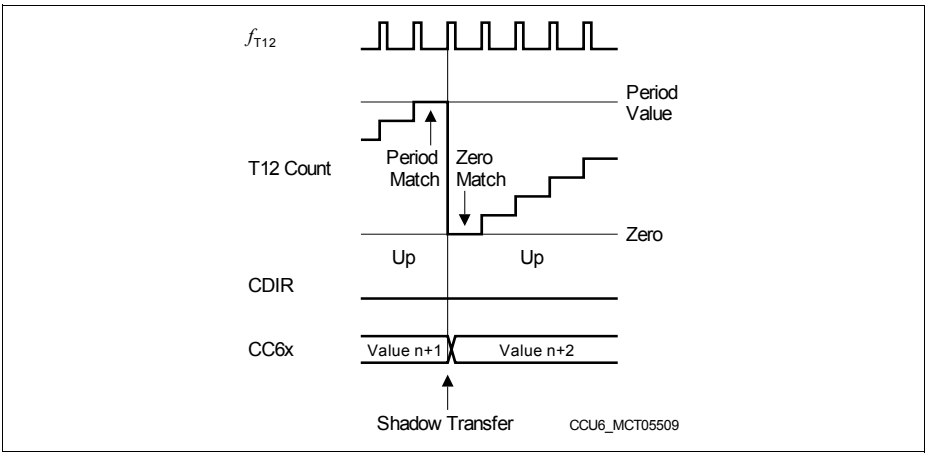

Figure 29-5 T12 Operation in Edge-Aligned Mode

As a result, in Edge-Aligned mode, the timer period is given by:

$$T12_{PER} = \text{<Period-Value>} + 1; \text{ in T12 clocks } (f_{T12}) \quad (29.1)$$

In **Center-Aligned Mode** (CTM = 1), timer T12 is counting upwards or downwards (triangular shape). When reaching the value given by the period register (period-match T12_PM) while counting upwards (CDIR = 0), the counting direction control bit CDIR is changed to downwards (CDIR = 1) with the next counting step.
When reaching the value 0001_H (one-match T12_OM) while counting downwards, the counting direction control bit CDIR is changed to upwards with the next counting step.

As a result, in Center.Aligned mode, the timer period is given by:

$$T12_{PER} = (\text{<Period-Value>} + 1) \times 2; \text{ in T12 clocks } (f_{T12}) \quad (29.2)$$

- With the next clock event of f_{T12} the count direction is set to counting up (CDIR = 0) when the counter reaches 0001_H while counting down.
- With the next clock event of f_{T12} the count direction is set to counting down (CDIR = 1) when the Period-Match is detected while counting up.
- With the next clock event of f_{T12} the counter counts up while CDIR = 0 and it counts down while CDIR = 1.

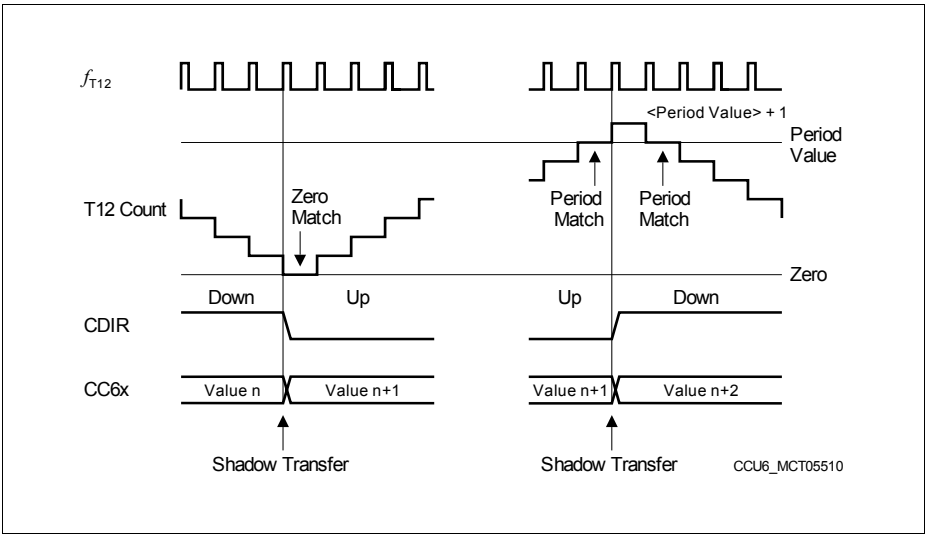

Figure 29-6 T12 Operation in Center-Aligned Mode

*Note: Bit CDIR changes with the next timer clock event after the one-match or the period-match. Therefore, the timer continues counting in the previous direction for one cycle before actually changing its direction (see **Figure 29-6**).*

29.2.2.3 Single-Shot Mode

In Single-Shot Mode, the timer run bit T12R is cleared by hardware. If bit T12SSC = 1, the timer T12 will stop when the current timer period is finished.

In Edge-Aligned mode, T12R is cleared when the timer becomes zero after having reached the period value (see **Figure 29-7**).

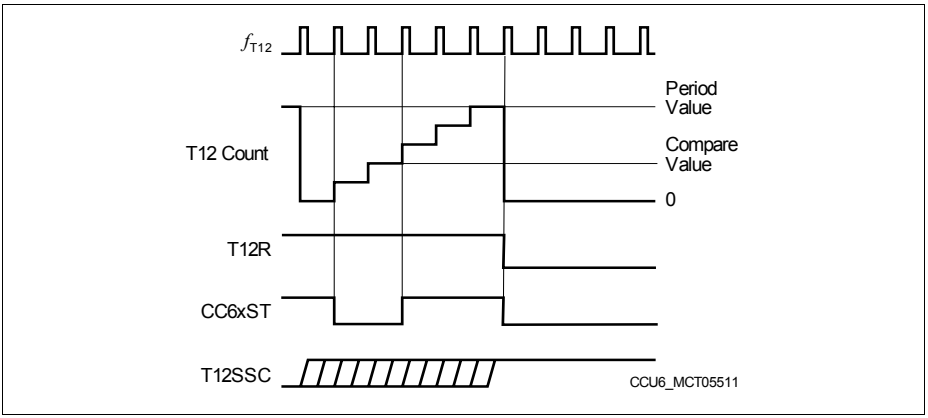

Figure 29-7 Single-Shot Operation in Edge-Aligned Mode

In Center-Aligned mode, the period is finished when the timer has counted down to zero (one clock cycle after the one-match while counting down, see **Figure 29-8**).

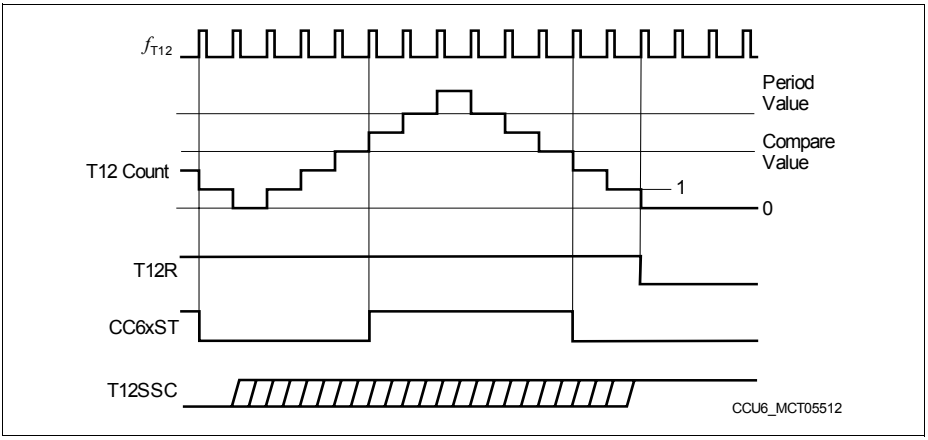

Figure 29-8 Single-Shot Operation in Center-Aligned Mode

29.2.3 T12 Compare Mode

Associated with Timer T12 are three individual capture/compare channels, that can perform compare or capture operations with regard to the contents of the T12 counter. The capture functions are explained in **Section 29.2.5**.

29.2.3.1 Compare Channels

In Compare Mode (see **Figure 29-9**), the three individual compare channels CC60 CC61, and CC62 can generate a three-phase PWM pattern.

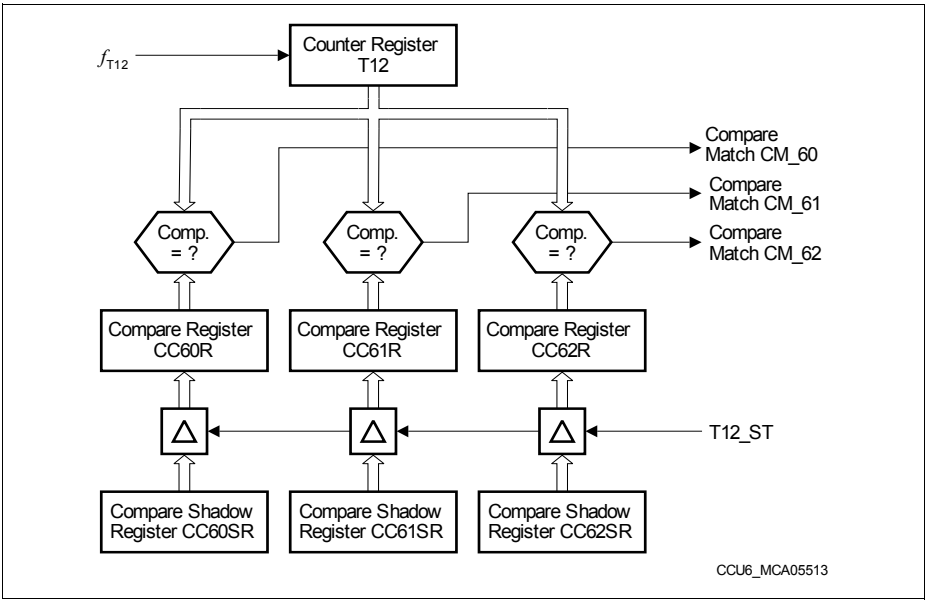

Figure 29-9 T12 Channel Comparators

Each compare channel is connected to the T12 counter register via its individual equal-to comparator, generating a match signal when the contents of the counter matches the contents of the associated compare register. Each channel consists of the comparator and a double register structure - the actual compare register CC6xR, feeding the comparator, and an associated shadow register CC6xSR, that is preloaded by software and transferred into the compare register when signal T12 shadow transfer, T12_ST, gets active. Providing a shadow register for the compare value as well as for other values related to the generation of the PWM signal facilitates a concurrent update by software for all relevant parameters of a three-phase PWM.

29.2.3.2 Channel State Bits

Associated with each (compare) channel is a State Bit, **CMPSTAT**.CC6xST, holding the status of the compare (or capture) operation (see **Figure 29-10**). In compare mode, the State Bits are modified according to a set of switching rules, depending on the current status of timer T12.

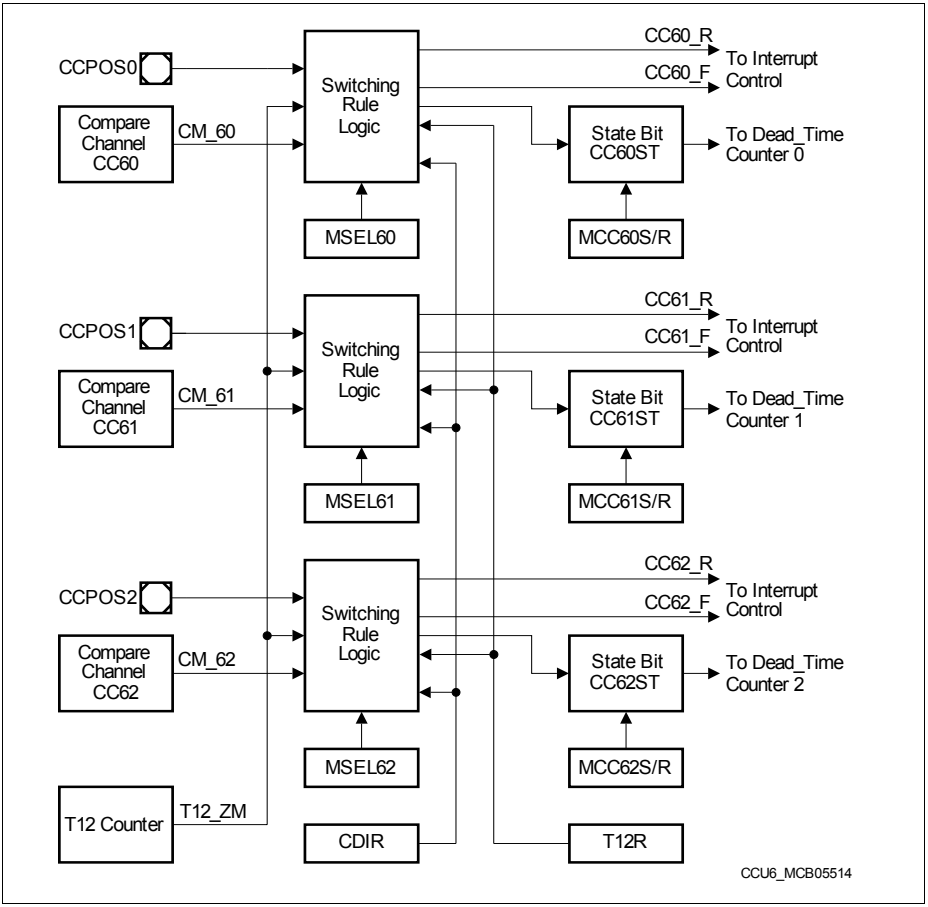

Figure 29-10 Compare State Bits for Compare Mode

The inputs to the switching rule logic for the CC6xST bits are the timer direction (CDIR), the timer run bit (T12R), the timer T12 zero-match signal (T12_ZM), and the actual individual compare-match signals CM_6x as well as the mode control bits, **T12MSEL**.MSEL6x.

In addition, each state bit can be set or cleared by software via the appropriate set and reset bits in register **CMPMODIF**, MCC6xS and MCC6xR. The input signals CCPOSx are used in hysteresis-like compare mode, whereas in normal compare mode, these inputs are ignored.

Note: In Hall Sensor, single shot or capture modes, additional/different rules are taken into account (see related sections).

A compare interrupt event CC6x_R is signaled when a compare match is detected while counting upwards, whereas the compare interrupt event CC6x_F is signaled when a compare match is detected while counting down. The actual setting of a State Bit has no influence on the interrupt generation in compare mode.

A modification of a State Bit CC6xST by the switching rule logic due to a compare action is only possible while Timer T12 is running (T12R = 1). If this is the case, the following switching rules apply for setting and clearing the State Bits in Compare Mode (illustrated in **Figure 29-11** and **Figure 29-12**):

A State Bit **CC6xST is set** to 1:

- with the next T12 clock (f_{T12}) after a compare-match when T12 is counting up (i.e., when the counter is incremented above the compare value);
- with the next T12 clock (f_{T12}) after a zero-match AND a parallel compare-match when T12 is counting up.

A State Bit **CC6xST is cleared** to 0:

- with the next T12 clock (f_{T12}) after a compare-match when T12 is counting down (i.e., when the counter is decremented below the compare value in center-aligned mode);
- with the next T12 clock (f_{T12}) after a zero-match AND NO parallel compare-match when T12 is counting up.

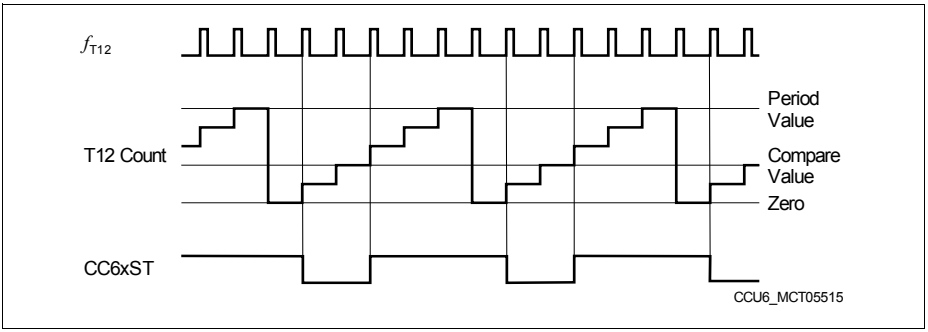

Figure 29-11 Compare Operation, Edge-Aligned Mode

Figure 29-13 illustrates some more examples for compare waveforms. It is important to note that in these examples, it is assumed that some of the compare values are changed

while the timer is running. This change is performed via a software preload of the Shadow Register, CC6xSR. The value is transferred to the actual Compare Register CC6xR with the T12 Shadow Transfer signal, T12_ST, that is assumed to be enabled.

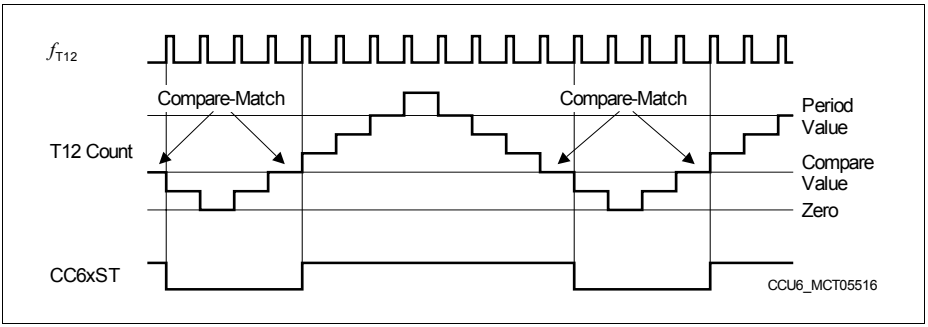

Figure 29-12 Compare Operation, Center-Aligned Mode

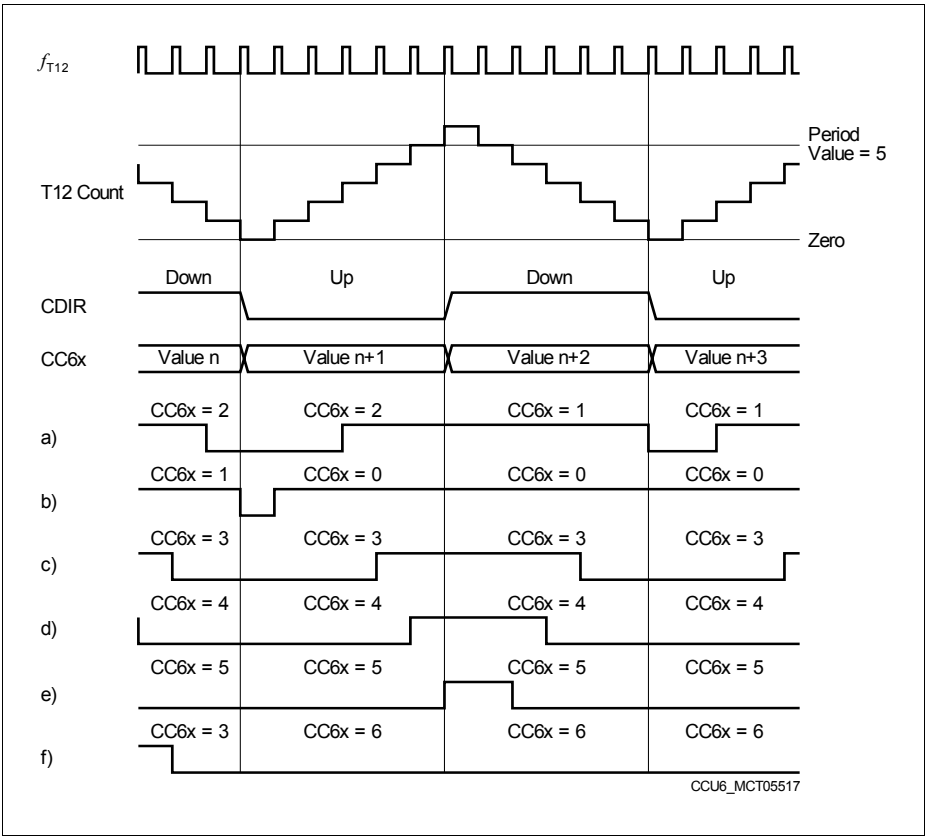

Figure 29-13 Compare Waveform Examples

Example b) illustrates the transition to a duty cycle of 100%. First, a compare value of 0001_H is used, then changed to 0000_H. Please note that a low pulse with the length of one T12 clock is still produced in the cycle where the new value 0000_H is in effect; this pulse originates from the previous value 0001_H. In the following timer cycles, the State Bit CC6xST remains at 1, producing a 100% duty cycle signal. In this case, the compare rule ‘zero-match AND compare-match’ is in effect.

Example f) shows the transition to a duty cycle of 0%. The new compare value is set to <Period-Value> + 1, and the State Bit CC6ST remains cleared.

Figure 29-14 illustrates an example for the waveforms of all three channels. With the appropriate dead-time control and output modulation, a very efficient 3-phase PWM signal can be generated.

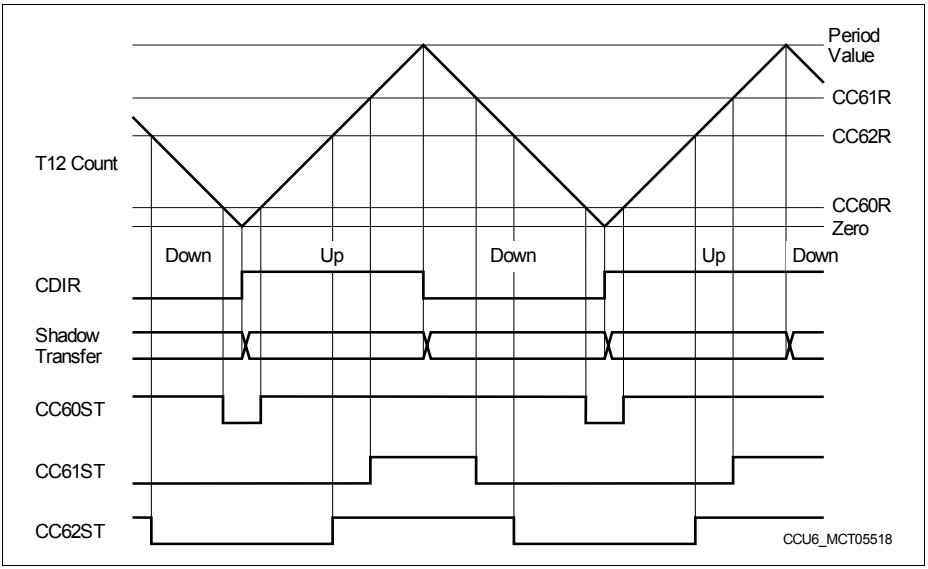

Figure 29-14 Three-Channel Compare Waveforms

29.2.3.3 Hysteresis-Like Control Mode

The hysteresis-like control mode (**T12MSEL**.MSEL6x = 1001_B) offers the possibility to switch off the PWM output if the input CCPOSx becomes 0 by clearing the State Bit CC6xST. This can be used as a simple motor control feature by using a comparator indicating, e.g., overcurrent. While CCPOSx = 0, the PWM outputs of the corresponding channel are driving their passive levels, because the setting of bit CC6xST is only possible while CCPOSx = 1.
As long as input CCPOSx is 0, the corresponding State Bit is held 0. When CCPOSx is at high level, the outputs can be in active state and are determined by bit CC6xST (see **Figure 29-10** for the state bit logic and **Figure 29-15** for the output paths).
The CCPOSx inputs are evaluated with f_{CC6}.

This mode can be used to introduce a timing-related behavior to a hysteresis controller. A standard hysteresis controller detects if a value exceeds a limit and switches its output according to the compare result. Depending on the operating conditions, the switching frequency and the duty cycle are not fixed, but change permanently.

If (outer) time-related control loops based on a hysteresis controller in an inner loop should be implemented, the outer loops show a better behavior if they are synchronized to the inner loops. Therefore, the hysteresis-like mode can be used, that combines timer-related switching with a hysteresis controller behavior. For example, in this mode, an output can be switched on according to a fixed time base, but it is switched off as soon as a falling edge is detected at input CCPOSx.

This mode can also be used for standard PWM with overcurrent protection. As long as there is no low level signal at pin CCPOSx, the output signals are generated in the normal manner as described in the previous sections. Only if input CCPOSx shows a low level, e.g. due to the detection of overcurrent, the outputs are shut off to avoid harmful stress to the system.

29.2.4 Compare Mode Output Path

Figure 29-15 gives an overview on the signal path from a channel State Bit to its output pin in its simplest form. As illustrated, a user has a variety of controls to determine the desired output signal switching behavior in relation to the current state of the State Bit, CC6xST. Please refer to **Section 29.2.4.3** for details on the output modulation.

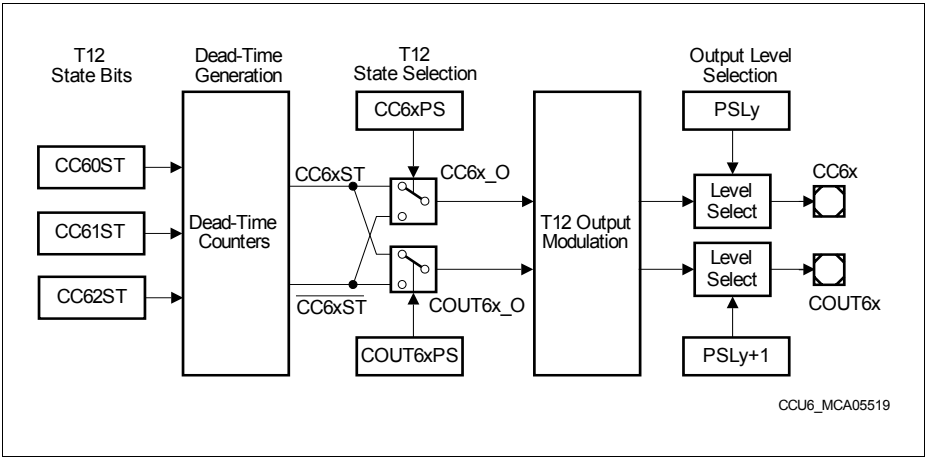

Figure 29-15 Compare Mode Simplified Output Path Diagram

The output path is based on signals that are defined as active or passive. The terms active and passive are not related to output levels, but to internal actions. This mainly applies for the modulation, where T12 and T13 signals are combined with the multi-channel signals and the trap function. The Output level Selection allows the user to define the output level at the output pin for the passive state (inverted level for the active state). It is recommended to configure this block in a way that an external power switch is switched off while the CCU6 delivers an output signal in the passive state.

29.2.4.1 Dead-Time Generation

The generation of (complementary) signals for the high-side and the low-side switches of one power inverter phase is based on the same compare channel. For example, if the high-side switch should be active while the T12 counter value is above the compare value (State Bit = 1), then the low-side switch should be active while the counter value is below the compare value (State Bit = 0).

In most cases, the switching behavior of the connected power switches is not symmetrical concerning the switch-on and switch-off times. A general problem arises if the time for switch-on is smaller than the time for switch-off of the power device. In this case, a short-circuit can occur in the inverter bridge leg, which may damage the complete system. In order to solve this problem by HW, this capture/compare unit

contains a programmable Dead-Time Generation Block, that delays the passive to active edge of the switching signals by a programmable time (the active to passive edge is not delayed).

The Dead-Time Generation Block, illustrated in **Figure 29-16**, is built in a similar way for all three channels of T12. It is controlled by bits in register **T12DTC**. Any change of a CC6xST State Bit activates the corresponding Dead-Time Counter, that is clocked with the same input clock as T12 (f_{T12}). The length of the dead-time can be programmed by bit field DTM. This value is identical for all three channels. Writing **TCTR4**.DTRES = 1 sets all dead-times to passive.

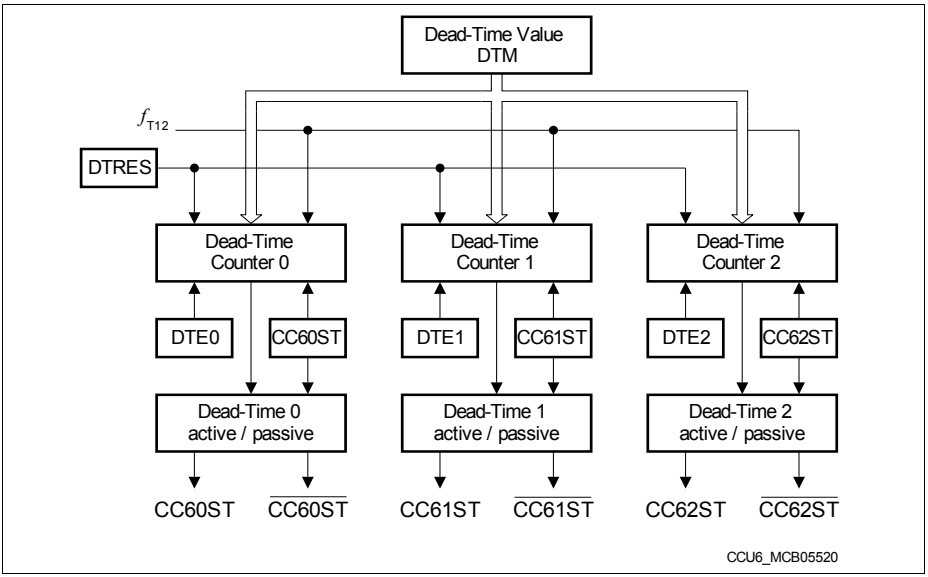

Figure 29-16 Dead-Time Generation Block Diagram

Each of the three dead-time counters has its individual dead-time enable bit, DTEx. An enabled dead-time counter generates a dead-time delaying the passive-to-active edge of the channel output signal. The change in a State Bit CC6xST is not taken into account while the dead-time generation of this channel is currently in progress (active). This avoids an unintentional additional dead-time if a State Bit CC6xST changes too early.
A disabled dead-time counter is always considered as passive and does not delay any edge of CC6xST.
Based on the State Bits CC6xST, the Dead-Time Generation Block outputs a direct signal CC6xST and an inverted signal $\overline{CC6xST}$ for each compare channel, each masked with the effect of the related Dead-Time Counters (waveforms illustrated in **Figure 29-17**).

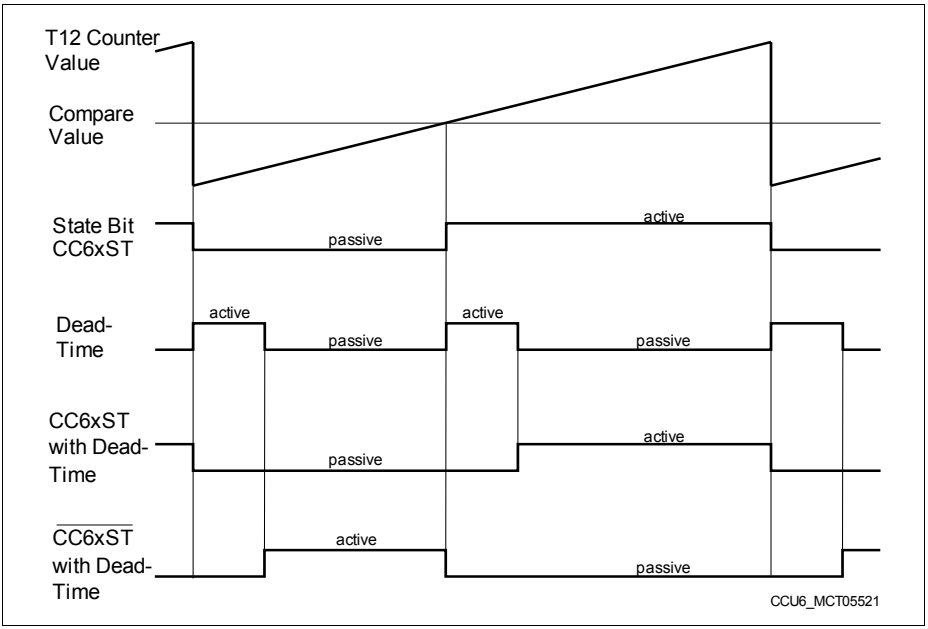

Figure 29-17 Dead-Time Generation Waveforms

29.2.4.2 State Selection

To support a wide range of power switches and drivers, the state selection offers the flexibility to define when an output can be active and can be modulated, especially useful for **complementary or multi-phase PWM** signals.

The state selection is based on the signals CC6xST and $\overline{\text{CC6xST}}$ delivered by the dead-time generator (see **Figure 29-15**). Both signals are never active at the same time, but can be passive at the same time. This happens during the dead-time of each compare channel after a change of the corresponding State Bit CC6xST.

The user can select independently for each output signal CC6xO and COUT6xO if it should be active before or after the compare value has been reached (see register **CMPSTAT**). With this selection, the active (conducting) phases of complementary power switches in a power inverter bridge leg can be positioned with respect to the compare value (e.g. signal CC6xO can be active before, whereas COUT6xO can be active after the compare value is reached). Like this, the output modulation, the trap logic and the output level selection can be programmed independently for each output signal, although two output signals are referring to the same compare channel.

29.2.4.3 Output Modulation and Level Selection

The last block of the data path is the Output Modulation block. Here, all the modulation sources and the trap functionality are combined and control the actual level of the output pins (controlled by the modulation enable bits T1xMODENy and MCMEN in register **MODCTR**). The following signal sources can be combined here **for each T12 output signal** (see **Figure 29-18** for compare channel CC60):

- A **T12 related compare signal** CC6x_O (for outputs CC6x) or COUT6x_O (for outputs COUT6x) delivered by the T12 block (state selection with dead-time) with an individual enable bit T12MODENy per output signal (y = 0, 2, 4 for outputs CC6x and y = 1, 3, 5 for outputs COUT6x)
- The **T13 related compare signal** CC63_O delivered by the T13 state selection with an individual enable bit T13MODENy per output signal (y = 0, 2, 4 for outputs CC6x and y = 1, 3, 5 for outputs COUT6x)
- A **multi-channel output signal** MCMPy (y = 0, 2, 4 for outputs CC6x and y = 1, 3, 5 for outputs COUT6x) with a common enable bit MCMEN
- The **trap state** TRPS with an individual enable bit TRPENy per output signal (y = 0, 2, 4 for outputs CC6x and y = 1, 3, 5 for outputs COUT6x)

If one of the modulation input signals CC6x_O/COUT6x_O, CC63_O, or MCMPy of an output modulation block is enabled and is at passive state, the modulated is also in passive state, regardless of the state of the other signals that are enabled. Only if all enabled signals are in active state the modulated output shows an active state. If no modulation input is enabled, the output is in passive state.
If the Trap State is active (TRPS = 1), then the outputs that are enabled for the trap signal (by TRPENy = 1) are set to the passive state.

The output of each of the modulation control blocks is connected to a level select block that is configured by register **PSLR**. It offers the option to determine the actual output level of a pin, depending on the state of the output line (decoupling of active/passive state and output polarity) as specified by the Passive State Select bit PSLy. If the modulated output signal is in the passive state, the level specified directly by PSLy is output. If it is in the active state, the inverted level of PSLy is output. This allows the user to adapt the polarity of an active output signal to the connected circuitry.

The PSLy bits have shadow registers to allow for updates without undesired pulses on the output lines. The bits related to CC6x and COUT6x (x = 0, 1, 2) are updated with the T12 shadow transfer signal (T12_ST). A read action returns the actually used values, whereas a write action targets the shadow bits. Providing a shadow register for the PSL value as well as for other values related to the generation of the PWM signal facilitates a concurrent update by software for all relevant parameters.

Figure 29-18 shows the output modulation structure for compare channel CC60 (output signals CC60 and COUT60). A similar structure is implemented for the other two compare channels CC61 and CC62.

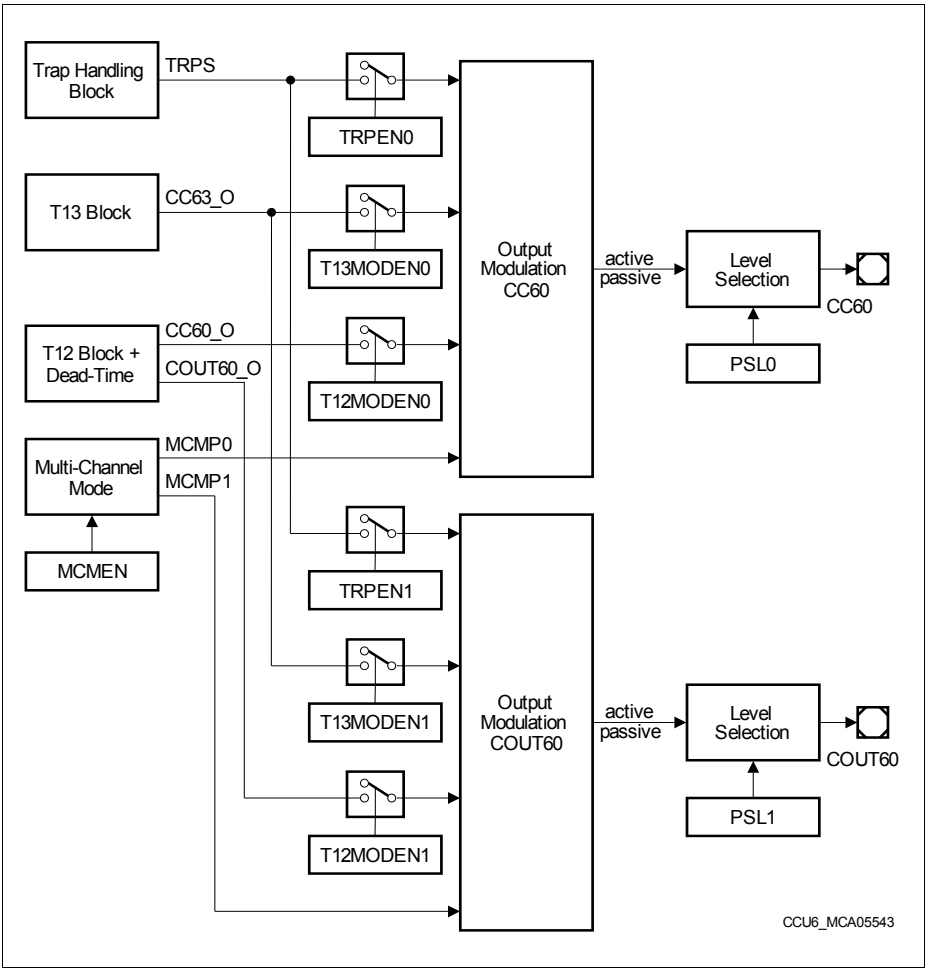

Figure 29-18 Output Modulation for Compare Channel CC60

29.2.5 T12 Capture Modes

Each of the three channels of the T12 Block can also be used to capture T12 time information in response to an external signal CC6xIN.
In capture mode, the interrupt event CC6x_R is detected when a rising edge is detected at the input CC6xIN, whereas the interrupt event CC6x_F is detected when a falling edge is detected.

There are a number of different modes for capture operation. In all modes, both of the registers of a channel are used. The selection of the capture modes is done via the **T12MSEL**.MSEL6x bit fields and can be selected individually for each of the channels.

Table 29-3 Capture Modes Overview

MSEL6x	Mode	Signal	Active Edge	CC6nSR Stored in	T12 Stored in
0100_B	1	CC6xIN	Rising	–	CC6xR
		CC6xIN	Falling	–	CC6xSR
0101_B	2	CC6xIN	Rising	CC6xR	CC6xSR
0110_B	3	CC6xIN	Falling	CC6xR	CC6xSR
0111_B	4	CC6xIN	Any	CC6xR	CC6xSR

Figure 29-19 illustrates **Capture Mode 1**. When a rising edge (0-to-1 transition) is detected at the corresponding input signal CC6xIN, the current contents of Timer T12 are captured into register CC6xR. When a falling edge (1-to-0 transition) is detected at the input signal CC6xIN, the contents of Timer T12 are captured into register CC6xSR.

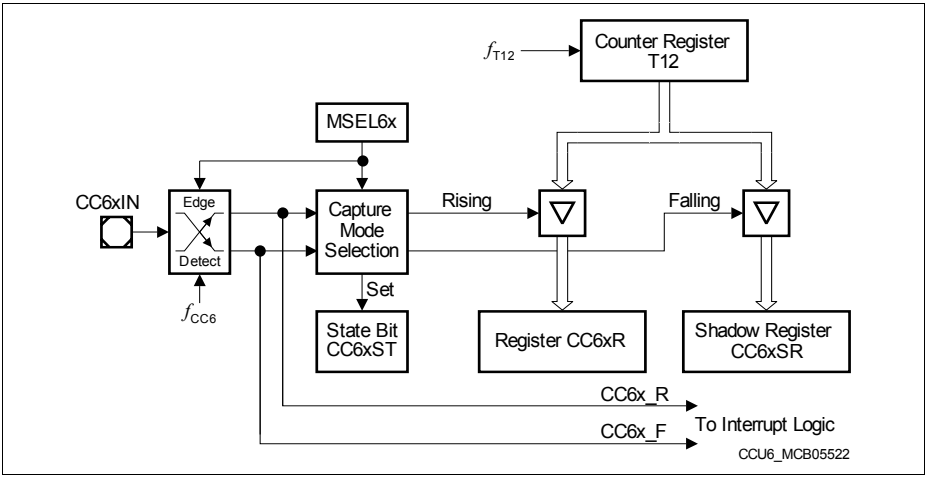

Figure 29-19 Capture Mode 1 Block Diagram

Capture Modes 2, 3 and 4 are shown in **Figure 29-20**. They differ only in the active edge causing the capture operation. In each of the three modes, when the selected edge is detected at the corresponding input signal CC6xIN, the current contents of the shadow register CC6xSR are transferred into register CC6xR, and the current Timer T12 contents are captured in register CC6xSR (simultaneous transfer). The active edge is a rising edge of CC6xIN for Capture Mode 2, a falling edge for Mode 3, and both, a rising or a falling edge for Capture Mode 4, as shown in **Table 29-3**. These capture modes are very useful in cases where there is little time between two consecutive edges of the input signal.

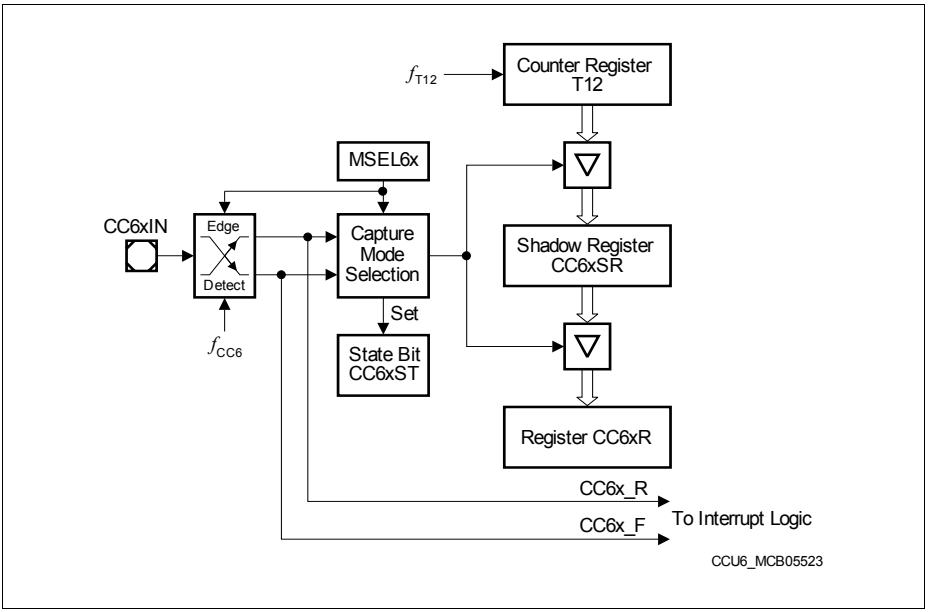

Figure 29-20 Capture Modes 2, 3 and 4 Block Diagram

Five further capture modes are called **Multi-Input Capture Modes**, as they use two different external inputs, signal CC6xIN and signal CCPOSx.

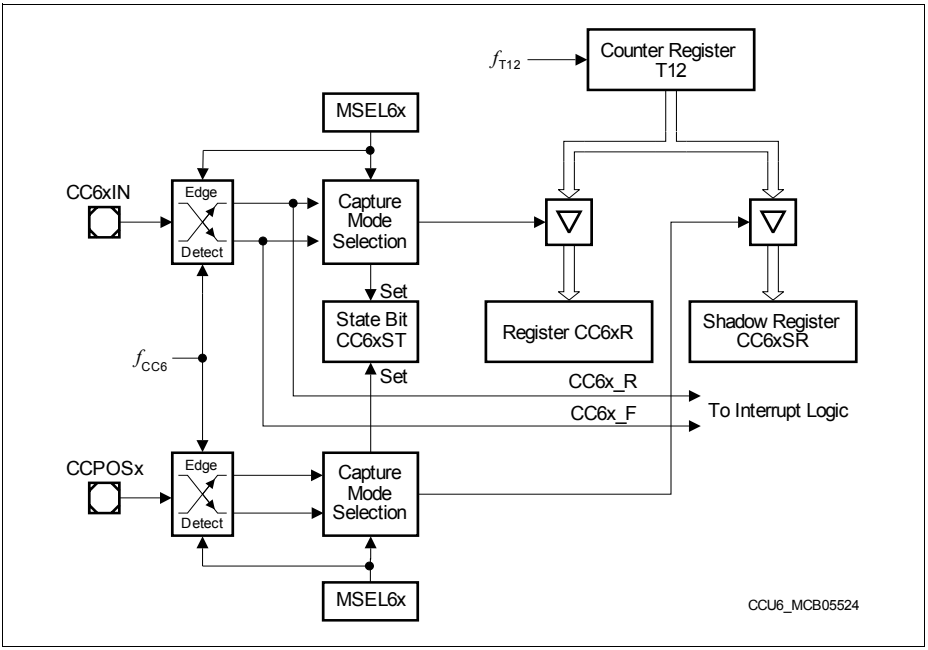

Figure 29-21 Multi-Input Capture Modes Block Diagram

In each of these modes, the current T12 contents are captured in register CC6xR in response to a selected event at signal CC6xIN, and in register CC6xSR in response to a selected event at signal CCPOSx. The possible events can be opposite input transitions, or the same transitions, or any transition at the two inputs. The different options are detailed in **Table 29-4**.

In each of the various capture modes, the Channel State Bit, CC6xST, is set to 1 when the selected capture trigger event at signal CC6xIN or CCPOSx has occurred. The State Bit is not cleared by hardware, but can be cleared by software.

In addition, appropriate signal lines to the interrupt logic are activated, that can generate an interrupt request to the CPU. Regardless of the selected active edge, all edges detected at signal CC6xIN can lead to the activation of the appropriate interrupt request line (see also **Section 29.9**).

Table 29-4 Multi-Input Capture Modes Overview

MSEL6x	Mode	Signal	Active Edge	T12 Stored in
1010_B	5	CC6xIN	Rising	CC6xR
		CCPOSx	Falling	CC6xSR
1011_B	6	CC6xIN	Falling	CC6xR
		CCPOSx	Rising	CC6xSR
1100_B	7	CC6xIN	Rising	CC6xR
		CCPOSx	Rising	CC6xSR
1101_B	8	CC6xIN	Falling	CC6xR
		CCPOSx	Falling	CC6xSR
1110_B	9	CC6xIN	Any	CC6xR
		CCPOSx	Any	CC6xSR
1111_B	–	reserved (no capture or compare action)		

29.2.6 T12 Shadow Register Transfer

A special shadow transfer signal (T12_ST) can be generated to facilitate updating the period and compare values of the compare channels CC60, CC61, and CC62 synchronously to the operation of T12. Providing a shadow register for values defining one PWM period facilitates a concurrent update by software for all relevant parameters. The next PWM period can run with a new set of parameters. The generation of this signal is requested by software via bit **TCTR0**.STE12 (set by writing 1 to the write-only bit **TCTR4**.T12STR, cleared by writing 1 to the write-only bit **TCTR4**.T12STD).

Figure 29-22 shows the shadow register structure and the shadow transfer signals, as well as on the read/write accessibility of the various registers.

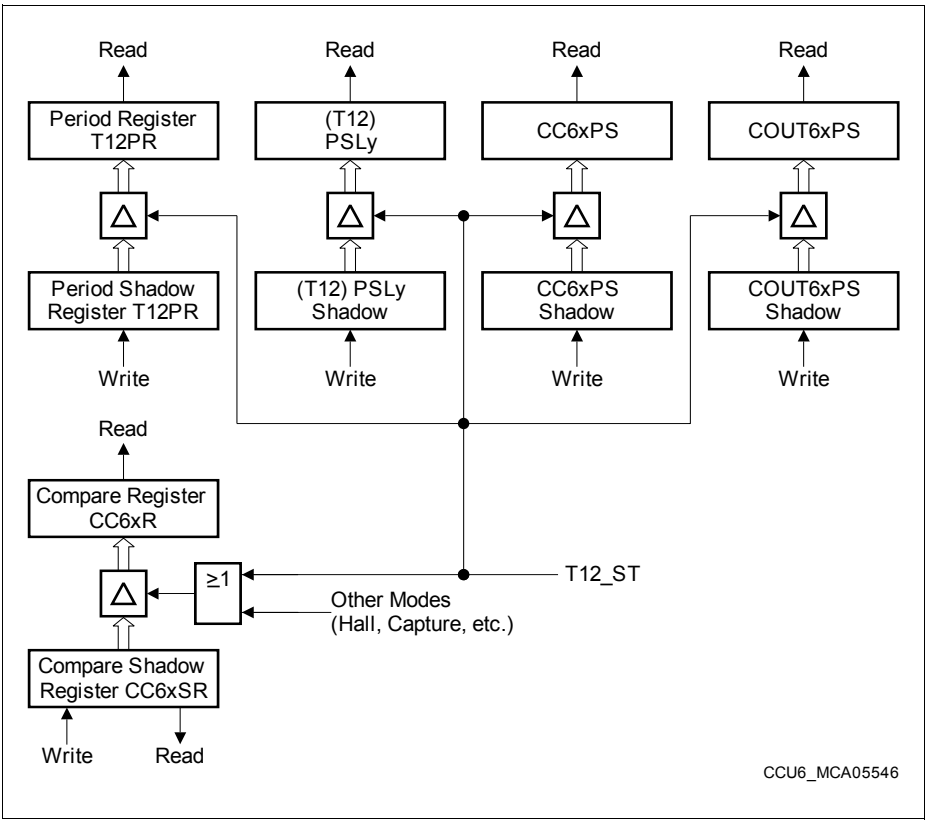

Figure 29-22 T12 Shadow Register Overview

A T12 shadow register transfer takes place (T12_ST active):

- while timer T12 is not running (T12R = 0), or
- STE12 = 1 and a Period-Match is detected while counting up, or
- STE12 = 1 and a One-Match is detected while counting down

When signal T12_ST is active, a shadow register transfer is triggered with the next cycle of the T12 clock. Bit STE12 is automatically cleared with the shadow register transfer.

29.2.7 Timer T12 Operating Mode Selection

The operating mode for the T12 channels are defined by the bit fields **T12MSEL**.MSEL6x.

Table 29-5 T12 Capture/Compare Modes Overview

MSEL6x	Selected Operating Mode
0000_B, 1111_B	Capture/Compare modes switched off
0001_B, 0010_B, 0011_B	Compare mode, see **Section 29.2.3** same behavior for all three codings
$01XX_B$	Double-Register Capture modes, see **Section 29.2.5**
1000_B	Hall Sensor Mode, see **Section 29.7** In order to properly enable this mode, all three MSEL6x fields have to be programmed to Hall Sensor mode.
1001_B	Hysteresis-like compare mode, see **Section 29.2.3.3**
1010_B 1011_B, 1100_B, 1101_B 1110_B	Multi-Input Capture modes, see **Section 29.2.5**

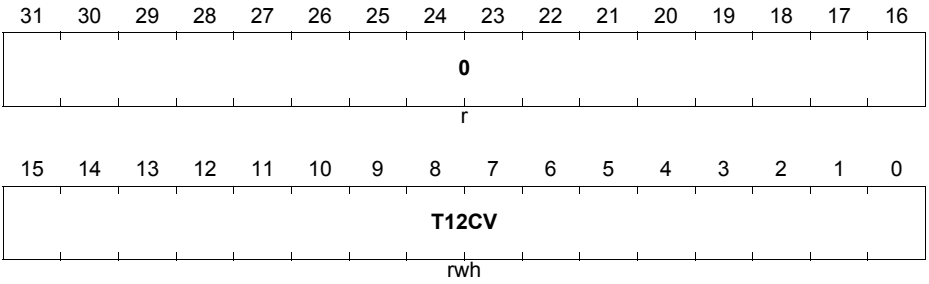
The clocking and counting scheme of the timers are controlled by the timer control registers **TCTR0** and **TCTR2**. Specific actions are triggered by write operations to register **TCTR4**.

29.2.8 T12 related Registers

29.2.8.1 T12 Counter Register

Register T12 represents the counting value of timer T12. It can only be written while the timer T12 is stopped. Write actions while T12 is running are not taken into account. Register T12 can always be read by SW.
In edge-aligned mode, T12 only counts up, whereas in center-aligned mode, T12 can count up and down.

T12
Timer T12 Counter Register **(20_H)** **Reset Value: $0000\ 0000_H$**



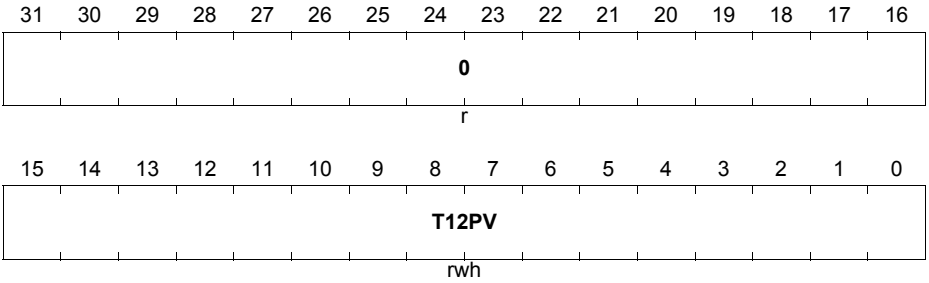
Field	Bits	Type	Description
T12CV	[15:0]	rwh	**Timer 12 Counter Value** This register represents the 16-bit counter value of Timer12.
0	[31:16]	r	**Reserved;** Returns 0 if read; should be written with 0.

Note: While timer T12 is stopped, the internal clock divider is reset in order to ensure reproducible timings and delays.

29.2.8.2 Period Register

Register T12PR contains the period value for timer T12. The period value is compared to the actual counter value of T12 and the resulting counter actions depend on the defined counting rules. This register has a shadow register and the shadow transfer is controlled by bit STE12. A read action by SW delivers the value that is currently used for the compare action, whereas the write action targets a shadow register. The shadow register structure allows a concurrent update of all T12-related values.

T12PR
Timer 12 Period Register **(24_H)** **Reset Value: 0000 0000_H**



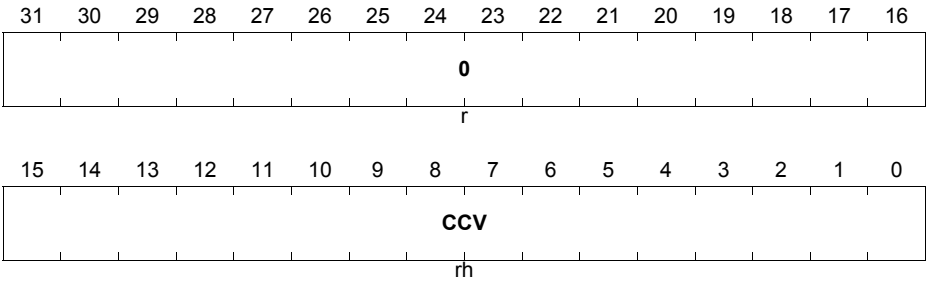
Field	Bits	Type	Description
T12PV	[15:0]	rwh	**T12 Period Value** The value T12PV defines the counter value for T12 leading to a period-match. When reaching this value, the timerT12 is set to zero (edge-aligned mode) or changes its count direction to down counting (center-aligned mode).
0	[31:16]	r	**Reserved;** Returns 0 if read; should be written with 0.

29.2.8.3 Capture/Compare Registers

In compare mode, the registers CC6xR (x = 0 - 2) are the actual compare registers for T12. The values stored in CC6xR are compared (all three channels in parallel) to the counter value of T12. In capture mode, the current value of the T12 counter register is captured by registers CC6xR if the corresponding capture event is detected.

CC6xR (x = 0-2)
Capture/Compare Register for Channel CC6x

(30_H + 4*x) **Reset Value: 0000 0000_H**

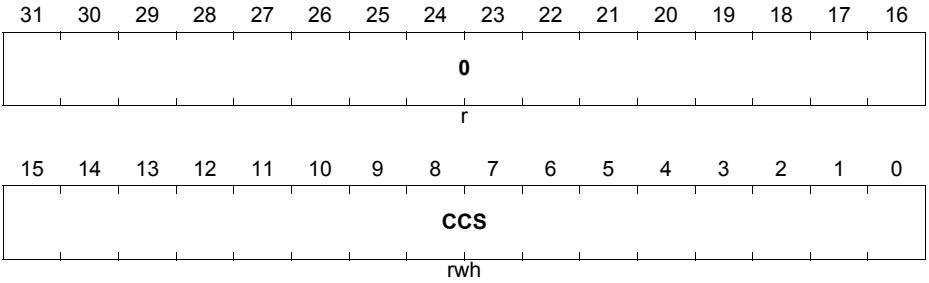


Field	Bits	Type	Description
CCV	[15:0]	rh	**Capture/Compare Value** In compare mode, the bit fields CCV contain the values, that are compared to the T12 counter value. In capture mode, the captured value of T12 can be read from these registers.
0	[31:16]	r	**Reserved;** Returns 0 if read; should be written with 0.

29.2.8.4 Capture/Compare Shadow Registers

The registers CC6xR can only be read by SW, the modification of the value is done by a shadow register transfer from register CC6xSR. The corresponding shadow registers CC6xSR can be read and written by SW. In capture mode, the value of the T12 counter register can also be captured by registers CC6xSR if the selected capture event is detected (depending on the selected capture mode).

CC6xSR (x=0-2)
Capture/Compare Shadow Reg. for Channel CC6x
(40_H+4*x) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
CCS	[15:0]	rwh	**Shadow Register for Channel x Capture/Compare Value** In compare mode, the bit fields contents of CCS are transferred to the bit fields CCV for the corresponding channel during a shadow transfer. In capture mode, the captured value of T12 can be read from these registers.
0	[31:16]	r	**Reserved;** Returns 0 if read; should be written with 0.

Note: The shadow registers can also be written by SW in capture mode. In this case, the HW capture event wins over the SW write if both happen in the same cycle (the SW write is discarded).

29.2.8.5 Dead-time Control Register

Register T12DTC controls the dead-time generation for the timer T12 compare channels. Each channel can be independently enabled/disabled for dead-time generation. If enabled, the transition from passive state to active state is delayed by the value defined by bit field DTM.
The dead time counters are clocked with the same frequency as T12.
This structure allows symmetrical dead-time generation in center-aligned and in edge-aligned PWM mode. A duty cycle of 50% leads to CC6x, COUT6x switched on for: 0.5 * period - dead time.

Note: The dead-time counters are not reset by bit T12RES, but by bit DTRES.

T12DTC
Dead-Time Control Register for Timer12

(28_H) **Reset Value: 0000 0000$_H$**

r	rh	rh	rh	r	rw	rw	rw	rw							

Field	Bits	Type	Description
DTM	[7:0]	rw	**Dead-Time** Bit field DTM determines the programmable delay between switching from the passive state to the active state of the selected outputs. The switching from the active state to the passive state is not delayed.
DTE2, DTE1, DTE0	10, 9, 8	rw	**Dead Time Enable Bits** Bits DTE0..DTE2 enable and disable the dead time generation for each compare channel (0, 1, 2) of timer T12. 0_B Dead-Time Counter x is disabled. The corresponding outputs switch from the passive state to the active state (according to the actual compare status) without any delay. 1_B Dead-Time Counter x is enabled. The corresponding outputs switch from the passive state to the active state (according to the compare status) with the delay programmed in bit field DTM.
DTR2, DTR1, DTR0	14, 13, 12	rh	**Dead Time Run Indication Bits** Bits DTR0..DTR2 indicate the status of the dead time generation for each compare channel (0, 1, 2) of timer T12. 0_B Dead-Time Counter x is currently in the passive state. 1_B Dead-Time Counter x is currently in the active state.
0	11, [31:15]	r	**Reserved;** Returns 0 if read; should be written with 0.

29.2.9 Capture/Compare Control Registers

29.2.9.1 Channel State Bits

The Compare State Register CMPSTAT contains status bits monitoring the current capture and compare state and control bits defining the active/passive state of the compare channels.

CMPSTAT
Compare State Register **(60_H)** **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
CC60ST, CC61ST, CC62ST, CC63ST [1]	0, 1, 2, 6	rh	**Capture/Compare State Bits** Bits CC6xST monitor the state of the capture/compare channels. Bits CC6xST (x = 0, 1, 2) are related to T12, bit CC63ST is related to T13. 0_B In compare mode, the timer count is less than the compare value. In capture mode, the selected edge has not yet been detected since the bit has been cleared by SW the last time. 1_B In compare mode, the counter value is greater than or equal to the compare value. In capture mode, the selected edge has been detected.
CCPOS60, CCPOS61, CCPOS62	3, 4, 5	rh	**Sampled Hall Pattern Bits** Bits CCPOS6x (x = 0, 1, 2) are indicating the value of the input Hall pattern that has been compared to the current and expected value. The value is sampled when the event HCRDY (Hall Compare Ready) occurs. 0_B The input CCPOSx has been sampled as 0. 1_B The input CCPOSx has been sampled as 1.
CC60PS, CC61PS, CC62PS, COUT60PS, COUT61PS, COUT62PS, COUT63PS [2]	8, 10, 12, 9, 11, 13, 14	rwh	**Passive State Select for Compare Outputs** Bits CC6xPS, COUT6xPS select the state of the corresponding compare channel, that is considered to be the passive state. During the passive state, the passive level (defined in register PSLR) is driven by the output pin. Bits CC6xPS, COUT6xPS (x = 0, 1, 2) are related to T12, bit CC63PS is related to T13. 0_B The corresponding compare signal is in passive state while CC6xST is 0. 1_B The corresponding compare signal is in passive state while CC6xST is 1. In capture mode, these bits are not used.

Field	Bits	Type	Description
T13IM[3]	15	rwh	**T13 Inverted Modulation** Bit T13IM inverts the T13 signal for the modulation of the CC6x and COUT6x (x = 0, 1, 2) signals. 0_B T13 output CC63_O is equal to CC63ST. 1_B T13 output CC63_O is equal to $\overline{\text{CC63ST}}$.
0	7, [31:16]	r	**Reserved;** Returns 0 if read; should be written with 0.

1) These bits are set and cleared according to the T12, T13 switching rules

2) These bits have shadow bits and are updated in parallel to the capture/compare registers of T12, T13 respectively. A read action targets the actually used values, whereas a write action targets the shadow bits.

3) This bit has a shadow bit and is updated in parallel to the compare and period registers of T13. A read action targets the actually used values, whereas a write action targets the shadow bit.

The Compare Status Modification Register CMPMODIF provides software-control (independent set and clear conditions) for the channel state bits CC6xST. This feature enables the user to individually change the status of the output lines by software, for example when the corresponding compare timer is stopped.

CMPMODIF
Compare State Modification Register

(64_H) **Reset Value: $0000\ 0000_H$**

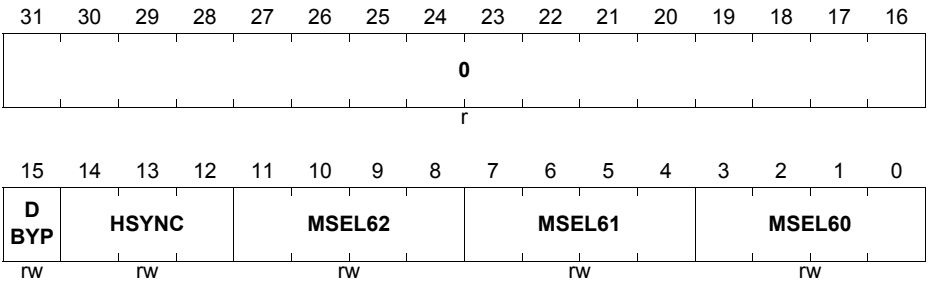
Field	Bits	Type	Description
MCC60S, **MCC61S,** **MCC62S,** **MCC63S,** **MCC60R,** **MCC61R,** **MCC62R,** **MCC63R**	0, 1, 2, 7, 8, 9, 10, 14	w	**Capture/Compare Status Modification Bits** These bits are used to bits to set (MCC6xS) or to clear (MCC6xR) the corresponding bits CC6xST by SW. This feature allows the user to individually change the status of the output lines by SW, e.g. when the corresponding compare timer is stopped. This allows a bit manipulation of CC6xST-bits by a single data write action. The following functionality of a write access to bits concerning the same capture/compare state bit is provided: [MCC6xR, MCC6xS] = 00_B Bit CC6xST is not changed. 01_B Bit CC6xST is set. 10_B Bit CC6xST is cleared. 11_B reserved
0	[5:3], 7, [13:11], [31:15]	r	**Reserved;** Returns 0 if read; should be written with 0.

29.2.9.2 T12 Mode Control Register

Register T12MSEL contains control bits to select the capture/compare functionality of the three channels of Timer T12.

T12MSEL
T12 Mode Select Register **(68_H)** **Reset Value: 0000 0000$_H$**



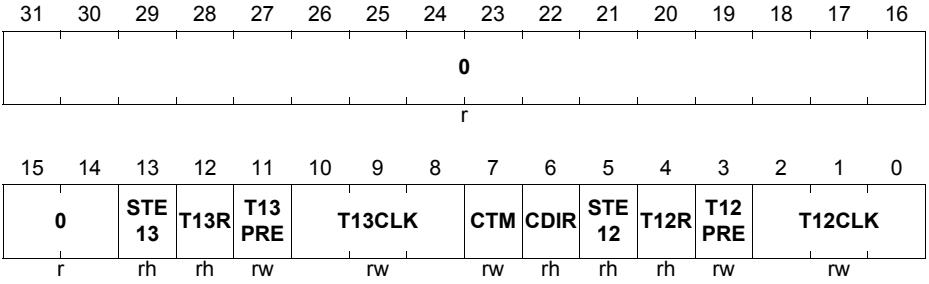
Field	Bits	Type	Description
MSEL60, MSEL61, MSEL62	[3:0], [7:4], [11:8]	rw	**Capture/Compare Mode Selection** These bit fields select the operating mode of the three T12 capture/compare channels. Each channel (x = 0, 1, 2) can be programmed individually for one of these modes (except for Hall Sensor Mode). Coding see **Table 29-5**.
HSYNC	[14:12]	rw	**Hall Synchronization** Bit field HSYNC defines the source for the sampling of the Hall input pattern and the comparison to the current and the expected Hall pattern bit fields. Coding see **Table 29-11**.
DBYP	15	rw	**Delay Bypass** DBYP controls whether the source signal for the sampling of the Hall input pattern (selected by HSYNC) is delayed by the Dead-Time Counter 0. 0_B The bypass is not active. Dead-Time Counter 0 is generating a delay after the source signal becomes active. 1_B The bypass is active. Dead-Time Counter 0 is not used for a delay.
0	[31:16]	r	**Reserved;** Returns 0 if read; should be written with 0.

29.2.9.3 Timer Control Registers

Register TCTR0 controls the basic functionality of both timers, T12 and T13.

Note: A write action to the bit fields T12CLK or T12PRE is only taken into account while the timer T12 is not running (T12R=0). A write action to the bit fields T13CLK or T13PRE is only taken into account while the timer T13 is not running (T13R=0).

TCTR0
Timer Control Register 0 **(70_H)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
T12CLK	[2:0]	rw	**Timer T12 Input Clock Select** Selects the input clock for timer T12 that is derived from the peripheral clock according to the equation $f_{T12} = f_{CC6} / 2^{<T12CLK>}$. 000_B $f_{T12} = f_{CC6}$ 001_B $f_{T12} = f_{CC6} / 2$ 010_B $f_{T12} = f_{CC6} / 4$ 011_B $f_{T12} = f_{CC6} / 8$ 100_B $f_{T12} = f_{CC6} / 16$ 101_B $f_{T12} = f_{CC6} / 32$ 110_B $f_{T12} = f_{CC6} / 64$ 111_B $f_{T12} = f_{CC6} / 128$
T12PRE	3	rw	**Timer T12 Prescaler Bit** In order to support higher clock frequencies, an additional prescaler factor of 1/256 can be enabled for the prescaler for T12. 0_B The additional prescaler for T12 is disabled. 1_B The additional prescaler for T12 is enabled.

Field	Bits	Type	Description
T12R	4	rh	**Timer T12 Run Bit**[1)] T12R starts and stops timer T12. It is set/cleared by SW by setting bits T12RR or T12RS or it is cleared by HW according to the function defined by bit field T12SSC. 0_B Timer T12 is stopped. 1_B Timer T12 is running.
STE12	5	rh	**Timer T12 Shadow Transfer Enable** Bit STE12 enables or disables the shadow transfer of the T12 period value, the compare values and passive state select bits and levels from their shadow registers to the actual registers if a T12 shadow transfer event is detected. Bit STE12 is cleared by hardware after the shadow transfer. A T12 shadow transfer event is a period-match while counting up or a one-match while counting down. 0_B The shadow register transfer is disabled. 1_B The shadow register transfer is enabled.
CDIR	6	rh	**Count Direction of Timer T12** This bit is set/cleared according to the counting rules of T12. 0_B T12 counts up. 1_B T12 counts down.
CTM	7	rw	**T12 Operating Mode** 0_B Edge-aligned Mode: T12 always counts up and continues counting from zero after reaching the period value. 1_B Center-aligned Mode: T12 counts down after detecting a period-match and counts up after detecting a one-match.

Field	Bits	Type	Description
T13CLK	[10:8]	rw	**Timer T13 Input Clock Select** Selects the input clock for timer T13 that is derived from the peripheral clock according to the equation $f_{T13} = f_{CC6} / 2^{<T13CLK>}$. 000_B $f_{T13} = f_{CC6}$ 001_B $f_{T13} = f_{CC6} / 2$ 010_B $f_{T13} = f_{CC6} / 4$ 011_B $f_{T13} = f_{CC6} / 8$ 100_B $f_{T13} = f_{CC6} / 16$ 101_B $f_{T13} = f_{CC6} / 32$ 110_B $f_{T13} = f_{CC6} / 64$ 111_B $f_{T13} = f_{CC6} / 128$
T13PRE	11	rw	**Timer T13 Prescaler Bit** In order to support higher clock frequencies, an additional prescaler factor of 1/256 can be enabled for the prescaler for T13. 0_B The additional prescaler for T13 is disabled. 1_B The additional prescaler for T13 is enabled.
T13R	12	rh	**Timer T13 Run Bit**[2)] T13R starts and stops timer T13. It is set/cleared by SW by setting bits T13RR orT13RS or it is set/cleared by HW according to the function defined by bit fields T13SSC, T13TEC and T13TED. 0_B Timer T13 is stopped. 1_B Timer T13 is running.
STE13	13	rh	**Timer T13 Shadow Transfer Enable** Bit STE13 enables or disables the shadow transfer of the T13 period value, the compare value and passive state select bit and level from their shadow registers to the actual registers if a T13 shadow transfer event is detected. Bit STE13 is cleared by hardware after the shadow transfer. A T13 shadow transfer event is a period-match. 0_B The shadow register transfer is disabled. 1_B The shadow register transfer is enabled.
0	[31:14]	r	**Reserved;** Returns 0 if read; should be written with 0.

1) A concurrent set/clear action on T12R (from T12SSC, T12RR or T12RS) will have no effect. The bit T12R will remain unchanged.

2) A concurrent set/cleared action on T13R (from T13SSC, T13TEC, T13RR or T13RS) will have no effect. The bit T12R will remain unchanged.

Register TCTR2 controls the single-shot and the synchronization functionality of both timers T12 and T13. Both timers can run in single-shot mode. In this mode they stop their counting sequence automatically after one counting period with a count value of zero. The single-shot mode and the synchronization feature of T13 to T12 allow the generation of events with a programmable delay after well-defined PWM actions of T12.

TCTR2
Timer Control Register 2 **(74_H)** **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
T12SSC	0	rw	**Timer T12 Single Shot Control** This bit controls the single shot-mode of T12. 0_B The single-shot mode is disabled, no HW action on T12R. 1_B The single shot mode is enabled, the bit T12R is cleared by HW if - T12 reaches its period value in edge-aligned mode - T12 reaches the value 1 while down counting in center-aligned mode. In parallel to the clear action of bit T12R, the bits CC6xST (x=0, 1, 2) are cleared.
T13SSC	1	rw	**Timer T13 Single Shot Control** This bit controls the single shot-mode of T13. 0_B No HW action on T13R 1_B The single-shot mode is enabled, the bit T13R is cleared by HW if T13 reaches its period value. In parallel to the clear action of bit T13R, the bit CC63ST is cleared.

Field	Bits	Type	Description
T13TEC	[4:2]	rw	**T13 Trigger Event Control** Bit field T13TEC selects the trigger event to start T13 (automatic set of T13R for synchronization to T12 compare signals) according to following combinations: 000_B no action 001_B set T13R on a T12 compare event on channel 0 010_B set T13R on a T12 compare event on channel 1 011_B set T13R on a T12 compare event on channel 2 100_B set T13R on any T12 compare event (ch. 0, 1, 2) 101_B set T13R upon a period-match of T12 110_B set T13R upon a zero-match of T12 (while counting up) 111_B set T13R on any edge of inputs CCPOSx
T13TED	[6:5]	rw	**Timer T13 Trigger Event Direction**[1)] Bit field T13TED delivers additional information to control the automatic set of bit T13R in the case that the trigger action defined by T13TEC is detected. 00_B reserved, no action 01_B while T12 is counting up 10_B while T12 is counting down 11_B independent on the count direction of T12
T12RSEL	[9:8]	rw	**Timer T12 External Run Selection** Bit field T12RSEL defines the event of signal T12HR that can set the run bit T12R by HW. 00_B The external setting of T12R is disabled. 01_B Bit T12R is set if a rising edge of signal T12HR is detected. 10_B Bit T12R is set if a falling edge of signal T12HR is detected. 11_B Bit T12R is set if an edge of signal T12HR is detected.

Field	Bits	Type	Description
T13RSEL	[11:10]	rw	**Timer T13 External Run Selection** Bit field T13RSEL defines the event of signal T13HR that can set the run bit T13R by HW. 00_B The external setting of T13R is disabled. 01_B Bit T13R is set if a rising edge of signal T13HR is detected. 10_B Bit T13R is set if a falling edge of signal T13HR is detected. 11_B Bit T13R is set if an edge of signal T13HR is detected.
0	7, [31:12]	r	**Reserved;** Returns 0 if read; should be written with 0;

1) Example:
If the timer T13 is intended to start at any compare event on T12 (T13TEC=100) the trigger event direction can be programmed to
- counting up >> a T12 channel 0, 1, 2 compare match triggers T13R only while T12 is counting up
- counting down >> a T12 channel 0, 1, 2 compare match triggers T13R only while T12 is counting down
- independent from bit CDIR >> each T12 channel 0, 1, 2 compare match triggers T13R

The timer count direction is taken from the value of bit CDIR. As a result, if T12 is running in edge-aligned mode (counting up only), T13 can only be started automatically if bit field T13TED=01 or 11.

Register TCTR4 provides software-control (independent set and clear conditions) for the run bits T12R and T13R. Furthermore, the timers can be reset (while running) and bits STE12 and STE13 can be controlled by software. Reading these bits always returns 0.

TCTR4

T13RES	10	w	**Timer T13 Reset** 0_B No effect on T13. 1_B The T13 counter register is cleared to zero. The switching of the output signals is according to the switching rules. Setting of T13RES has no impact on bit T13R.
T13CNT	13	w	**Timer T13 Count Event** 0_B No action 1_B If enabled (PISEL2), timer T13 counts one step.
T13STR	14	w	**Timer T13 Shadow Transfer Request** 0_B No action 1_B STE13 is set, enabling the shadow transfer.
T13STD	15	w	**Timer T13 Shadow Transfer Disable** 0_B No action 1_B STE13 is cleared without triggering the shadow transfer.
0	4, [12:11], [31:16]	r	**reserved;** returns 0 if read; should be written with 0;

Note: A simultaneous write of a 1 to bits that set and clear the same bit will trigger no action. The corresponding bit will remain unchanged.

29.3 Operating Timer T13

Timer T13 is implemented similarly to Timer T12, but only with one channel in compare mode. A 16-bit up-counter is connected to a channel register via a comparator, that generates a signal when the counter contents match the contents of the channel register. A variety of control functions facilitate the adaptation of the T13 structure to different application needs. In addition, T13 can be started synchronously to timer T12 events.

This section provides information about:

- T13 overview (see **Section 29.3.1**)
- Counting scheme (see **Section 29.3.2**)
- Compare mode (see **Section 29.3.3**)
- Compare output path (see **Section 29.3.4**)
- Shadow register transfer (see **Section 29.3.5**)
- T13 counter register description (see **Section 29.3.6**)

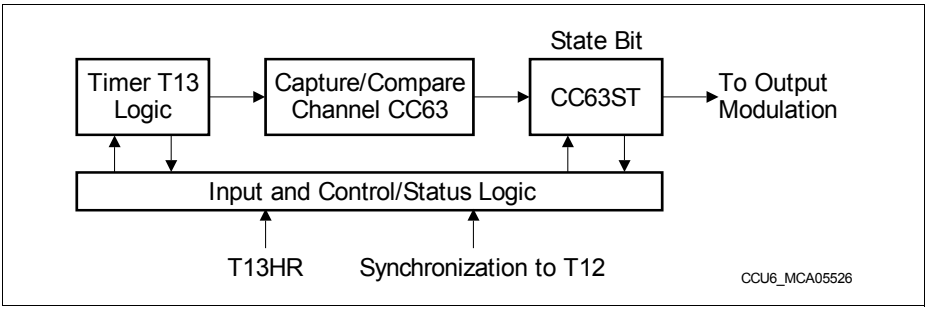

Figure 29-23 Overview Diagram of the Timer T13 Block

29.3.1 T13 Overview

Figure 29-24 shows a detailed block diagram of Timer T13. The functions of the timer T12 block are controlled by bits in registers **TCTR0**, **TCTR2**, and **PISEL2**.
Timer T13 receives its input clock, f_{T13}, from the module clock f_{CC6} via a programmable prescaler and an optional 1/256 divider or from an input signal T13HR. T13 can only count up (similar to the Edge-Aligned mode of T12).

Via a comparator, the timer T13 Counter Register **T13** is connected to the Period Register **T13PR**. This register determines the maximum count value for T13. When T13 reaches the period value, signal T13_PM (T13 Period Match) is generated and T13 is cleared to 0000_H with the next T13 clock edge. The Period Register receives a new period value from its Shadow Period Register, T13PS, that is loaded via software. The transfer of a new period value from the shadow register into T13PR is controlled via the 'T13 Shadow Transfer' control signal, T13_ST. The generation of this signal depends on the associated control bit STE13. Providing a shadow register for the period value as

well as for other values related to the generation of the PWM signal facilitates a concurrent update by software for all relevant parameters (refer to **Table 29.3.5**).
Another signal indicates whether the counter contents are equal to 0000_H (T13_ZM).

A Single-Shot control bit, T13SSC, enables an automatic stop of the timer when the current counting period is finished (see **Figure 29-26**).

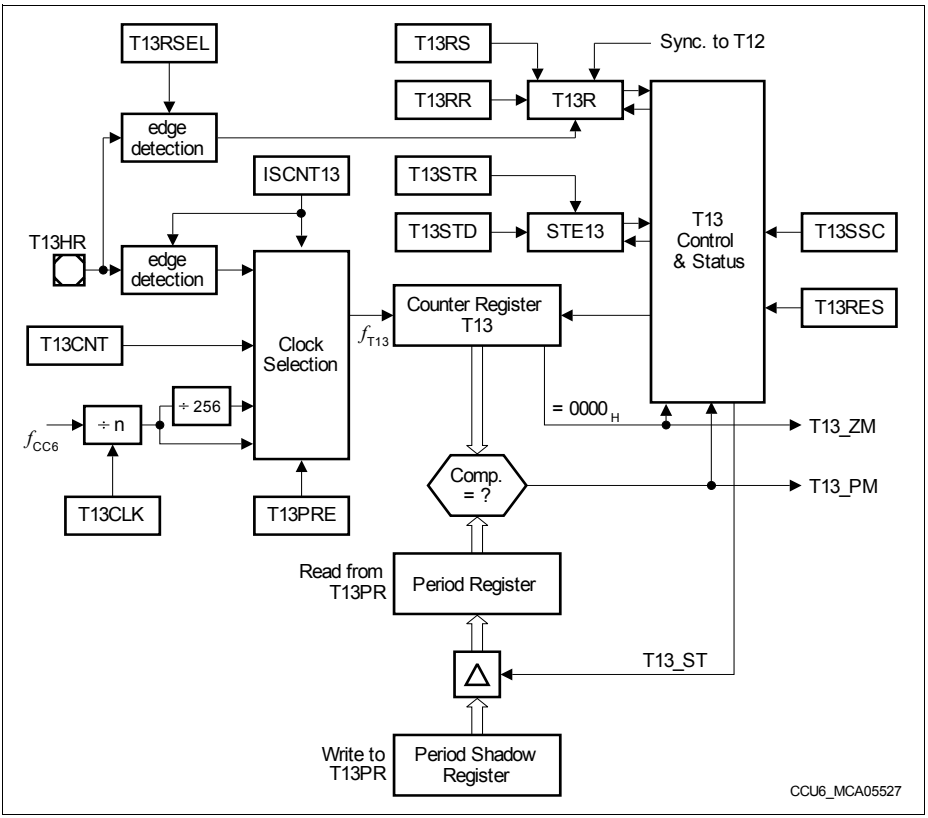

Figure 29-24 T13 Counter Logic and Period Comparators

The start or stop of T13 is controlled by the Run bit, T13R. This control bit can be set by software via the associated set/clear bits T13RS or T13RR in register **TCTR4**, or it is cleared by hardware according to preselected conditions (single-shot mode).
The timer T13 run bit T13R must not be set while the applied T13 period value is zero.
Bit T13R can be set automatically if an event of T12 is detected to synchronize T13 timings to T12 events, e.g. to generate a programmable delay via T13 after an edge of a T12 compare channel before triggering an AD conversion (T13 can trigger ADC

conversions).
Timer T13 can be cleared to 0000_H via control bit T13RES. Setting this write-only bit only clears the timer contents, but has no further effects, e.g., it does not stop the timer.

The generation of the T13 shadow transfer control signal, T13_ST, is enabled via bit STE13. This bit can be set or cleared by software indirectly through its associated set/reset control bits T13STR and T13STD.

Two bit fields, T13TEC and T13TED, control the synchronization of T13 to Timer T12 events. T13TEC selects the trigger event, while T13TED determines for which T12 count direction the trigger should be active.
While Timer T13 is running, write accesses to the count register T13 are not taken into account. If T13 is stopped, write actions to register T13 are immediately taken into account.

Note: The T13 Period Register and its associated shadow register are located at the same physical address. A write access to this address targets the Shadow Register, while a read access reads from the actual period register.

29.3.2 T13 Counting Scheme

This section describes the clocking and the counting capabilities of T13.

29.3.2.1 Clock Selection

In **Timer Mode** (**PISEL2**. ISCNT13 = 00_B), the input clock f_{T13} of Timer T13 is derived from the internal module clock f_{CC6} through a programmable prescaler and an optional 1/256 divider. The resulting prescaler factors are listed in **Table 29-6**. The prescaler of T13 is cleared while T13 is not running (**TCTR0**.T13R = 0) to ensure reproducible timings and delays.

Table 29-6 Timer T13 Input Clock Options

T13CLK	Resulting Input Clock f_{T13} Prescaler Off (T13PRE = 0)	Resulting Input Clock f_{T13} Prescaler On (T13PRE = 1)
000_B	f_{CC6}	f_{CC6} / 256
001_B	f_{CC6} / 2	f_{CC6} / 512
010_B	f_{CC6} / 4	f_{CC6} / 1024
011_B	f_{CC6} / 8	f_{CC6} / 2048
100_B	f_{CC6} / 16	f_{CC6} / 4096
101_B	f_{CC6} / 32	f_{CC6} / 8192
110_B	f_{CC6} / 64	f_{CC6} / 16384
111_B	f_{CC6} / 128	f_{CC6} / 32768

In **Counter Mode**, timer T13 counts one step:

- If a 1 is written to **TCTR4**.T13CNT and **PISEL2**.ISCNT13 = 01_B
- If a rising edge of input signal T13HR is detected and **PISEL2**.ISCNT13 = 10_B
- If a falling edge of input signal T13HR is detected and **PISEL2**.ISCNT13 = 11_B

29.3.2.2 T13 Counting

The period of the timer is determined by the value in the period Register T13PR according to the following formula:

$T13_{PER}$ = <Period-Value> + 1; in T13 clocks (f_{T13}) (29.3)

Timer T13 can only count up, comparable to the Edge-Aligned mode of T12. This leads to very simple ‘counting rule’ for the T13 counter:

- The counter is cleared with the next T13 clock edge if a Period-Match is detected. The counting direction is always upwards.

The behavior of T13 is illustrated in **Figure 29-25**.

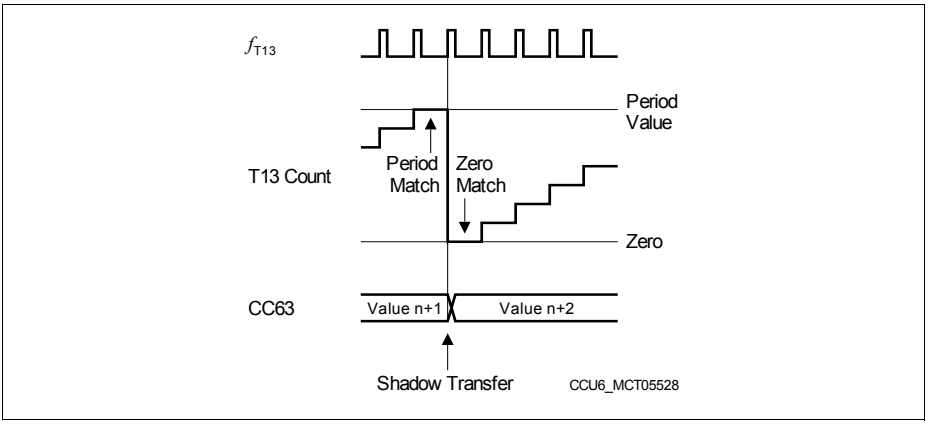

Figure 29-25 T13 Counting Sequence

29.3.2.3 Single-Shot Mode

In Single-Shot Mode, the timer run bit T13R is cleared by hardware. If bit T13SSC = 1, the timer T13 will stop when the current timer period is finished.

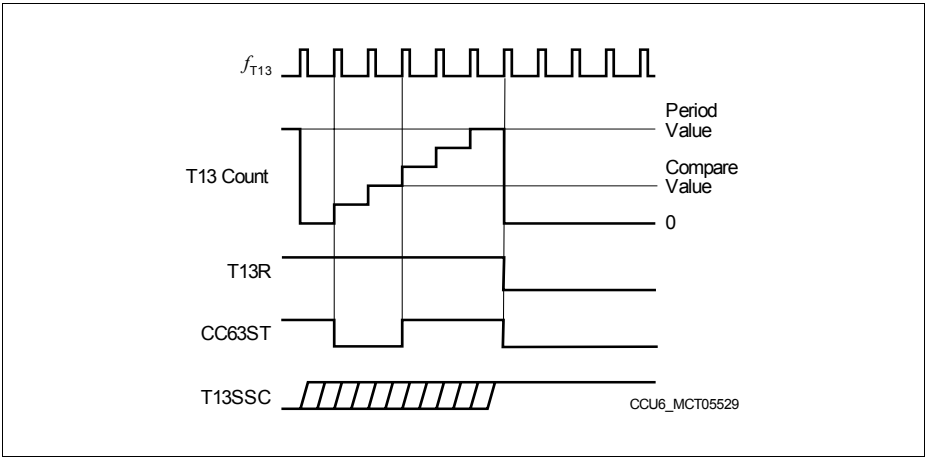

Figure 29-26 Single-Shot Operation of Timer T13

29.3.2.4 Synchronization to T12

Timer T13 can be synchronized to a T12 event. Bit fields T13TEC and T13TED select the event that is used to start Timer T13. The selected event sets bit T13R via HW, and T13 starts counting. Combined with the Single-Shot mode, this feature can be used to generate a programmable delay after a T12 event.

Figure 29-27 shows an example for the synchronization of T13 to a T12 event. Here, the selected event is a compare-match (compare value = 2) while counting up. The clocks of T12 and T13 can be different (other prescaler factor); the figure shows an example in which T13 is clocked with half the frequency of T12.

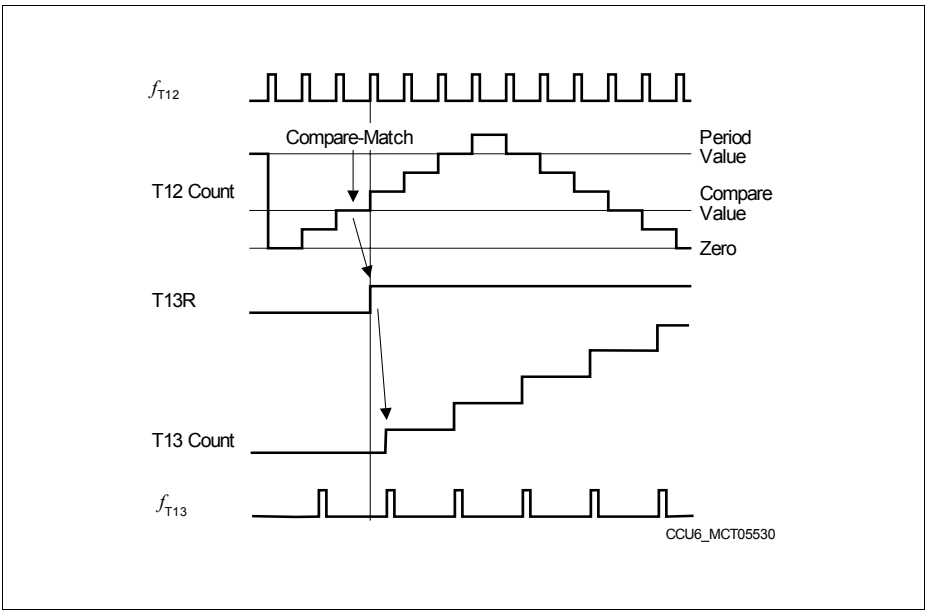

Figure 29-27 Synchronization of T13 to T12 Compare Match

Bit field T13TEC selects the trigger event to start T13 (automatic set of T13R for synchronization to T12 compare signals) according to the combinations shown in **Table 29-7**. Bit field T13TED additionally specifies for which count direction of T12 the selected trigger event should be regarded (see **Table 29-8**).

Table 29-7 T12 Trigger Event Selection

T13TEC	Selected Event
000_B	None
001_B	T12 Compare Event on Channel 0 (CM_CC60)
010_B	T12 Compare Event on Channel 1 (CM_CC61)
011_B	T12 Compare Event on Channel 2 (CM_CC62)
100_B	T12 Compare Event on any Channel (0, 1, 2)
101_B	T12 Period-Match (T12_PM)
110_B	T12 Zero-Match while counting up (T12_ZM and CDIR = 0)
111_B	Any Hall State Change

Table 29-8 T12 Trigger Event Additional Specifier

T13TED	Selected Event Specifier
00_B	Reserved, no action
01_B	Selected event is active while T12 is counting up (CDIR = 0)
10_B	Selected event is active while T12 is counting down (CDIR = 1)
11_B	Selected event is active independently of the count direction of T12

29.3.3 T13 Compare Mode

Associated with Timer T13 is one compare channel, that can perform compare operations with regard to the contents of the T13 counter.

Figure 29-23 gives an overview on the T13 channel in Compare Mode. The channel is connected to the T13 counter register via an equal-to comparator, generating a compare match signal when the contents of the counter matches the contents of the compare register.

The channel consists of the comparator and a double register structure - the actual compare register, **CC63R**, feeding the comparator, and an associated shadow register, **CC63SR**, that is preloaded by software and transferred into the compare register when signal T13 shadow transfer, T13_ST, gets active. Providing a shadow register for the compare value as well as for other values related to the generation of the PWM signal facilitates a concurrent update by software for all relevant parameters.

Associated with the channel is a State Bit, **CMPSTAT**.CC63ST, holding the status of the compare operation. **Figure 29-28** gives an overview on the logic for the State Bit.

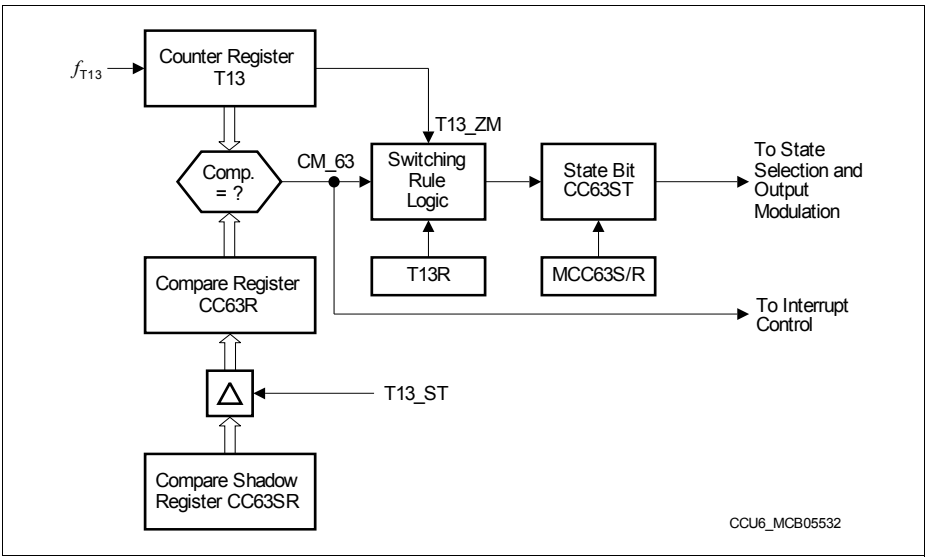

Figure 29-28 T13 State Bit Block Diagram

A compare interrupt event CM_63 is signaled when a compare match is detected. The actual setting of a State Bit has no influence on the interrupt generation.

The inputs to the switching rule logic for the CC63ST bit are the timer run bit (T13R), the timer zero-match signal (T13_ZM), and the actual individual compare-match signal CM_63. In addition, the state bit can be set or cleared by software via bits MCC63S and

MCC63R in register **CMPMODIF**.
A modification of the State Bit CC63ST by hardware is only possible while Timer T13 is running (T13R = 1). If this is the case, the following switching rules apply for setting and resetting the State Bit in Compare Mode:

State Bit **CC63ST is set** to 1

- with the next T13 clock (f_{T13}) after a compare-match (T13 is always counting up) (i.e., when the counter is incremented above the compare value);
- with the next T13 clock (f_{T13}) after a zero-match AND a parallel compare-match.

State Bit **CC63ST is cleared** to 0

- with the next T13 clock (f_{T13}) after a zero-match AND NO parallel compare-match.

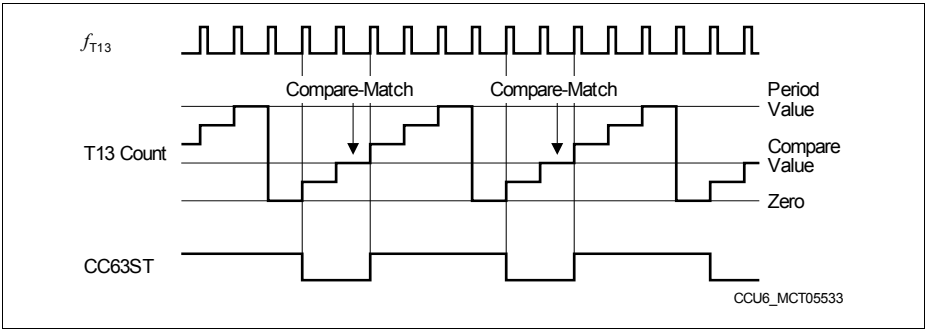

Figure 29-29 T13 Compare Operation

29.3.4 Compare Mode Output Path

Figure 29-30 gives an overview on the signal path from the channel State Bit CC63ST to its output pin COUT63. As illustrated, a user can determine the desired output behavior in relation to the current state of CC63ST. Please refer to Section 29.2.4.3 for detailed information on the output modulation for T12 signals.

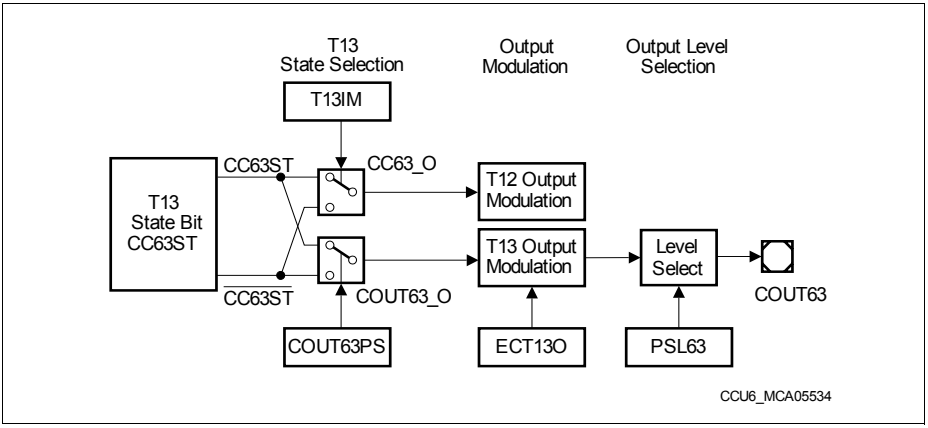

Figure 29-30 Channel 63 Output Path

The output line COUT63_O can generate a T13 PWM at the output pin COUT63. The signal CC63_O can be used to modulate the T12-related output signals with a T13 PWM. In order to decouple COUT63 from the internal modulation, the compare state leading to an active signal can be selected independently by bits T13IM and COUT63PS.

The last block of the data path is the Output Modulation block. Here, the modulation source T13 and the trap functionality are combined and control the actual level of the output pin COUT63 (see Figure 29-31):

- The **T13 related compare signal** COUT63_O delivered by the T13 state selection with the enable bit **MODCTR**.ECT13O
- The **trap state** TRPS with an individual enable bit **TRPCTR**.TRPEN13

If the modulation input signal COUT63_O is enabled (ECT13O = 1) and is at passive state, the modulated is also in passive state. If the modulation input is not enabled, the output is in passive state.
If the Trap State is active (TRPS = 1), then the output enabled for the trap signal (by TRPEN13 = 1) is set to the passive state.

The output of the modulation control block is connected to a level select block. It offers the option to determine the actual output level of a pin, depending on the state of the output line (decoupling of active/passive state and output polarity) as specified by the Passive State Select bit **PSLR**.PSL63. If the modulated output signal is in the passive

state, the level specified directly by PSL63 is output. If it is in the active state, the inverted level of PSL63 is output. This allows the user to adapt the polarity of an active output signal to the connected circuitry.

The PSL63 bit has a shadow register to allow for updates with the T13 shadow transfer signal (T13_ST) without undesired pulses on the output lines. A read action returns the actually used value, whereas a write action targets the shadow bit. Providing a shadow register for the PSL value as well as for other values related to the generation of the PWM signal facilitates a concurrent update by software for all relevant parameters.

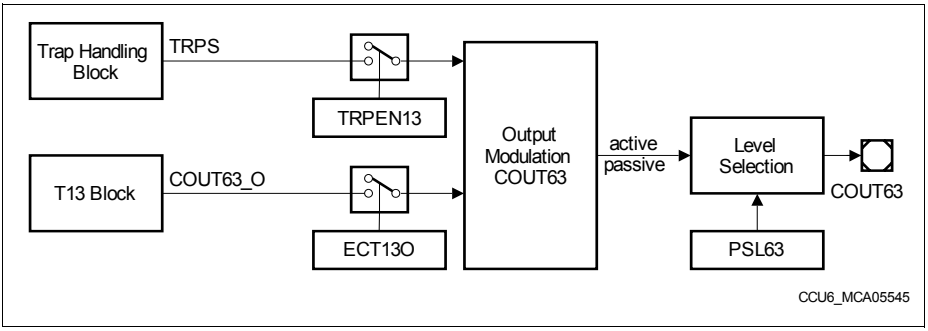

Figure 29-31 T13 Output Modulation

29.3.5 T13 Shadow Register Transfer

A special shadow transfer signal (T13_ST) can be generated to facilitate updating the period and compare values of the compare channel CC63 synchronously to the operation of T13. Providing a shadow register for values defining one PWM period facilitates a concurrent update by software for all relevant parameters. The next PWM period can run with a new set of parameters. The generation of this signal is requested by software via bit **TCTR0**.STE13 (set by writing 1 to the write-only bit **TCTR4**.T13STR, cleared by writing 1 to the write-only bit **TCTR4**.T13STD).
When signal T13_ST is active, a shadow register transfer is triggered with the next cycle of the T13 clock. Bit STE13 is automatically cleared with the shadow register transfer.
A T13 shadow register transfer takes place (T13_ST active):

- while timer T13 is not running (T13R = 0), or
- STE13 = 1 and a Period-Match is detected while T13R = 1

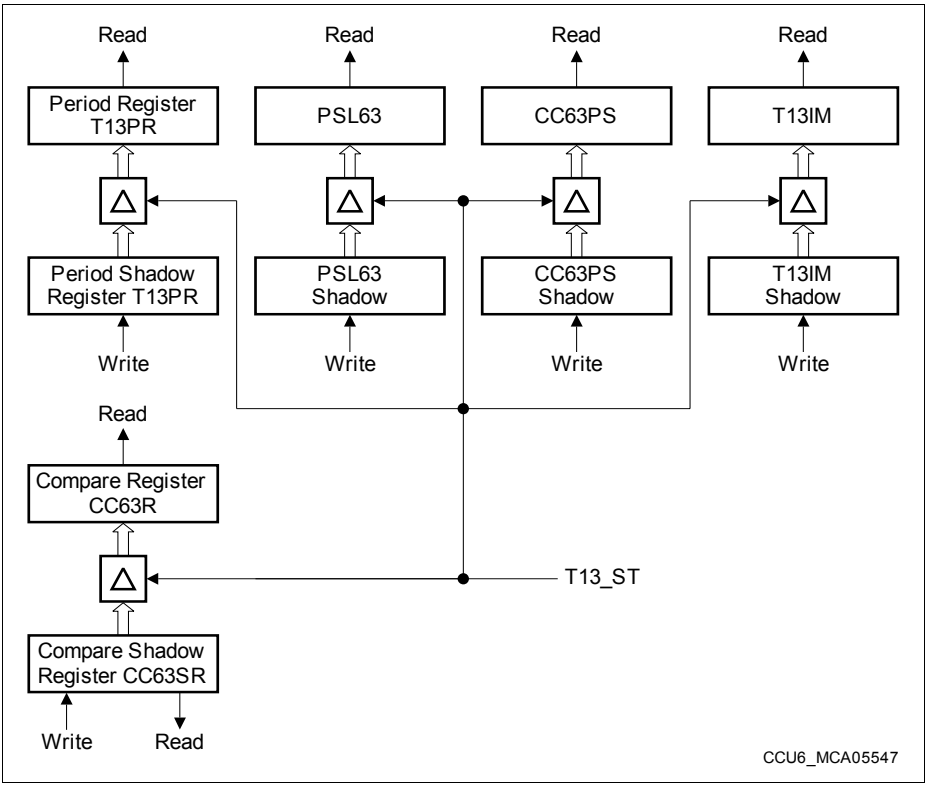

Figure 29-32 T13 Shadow Register Overview

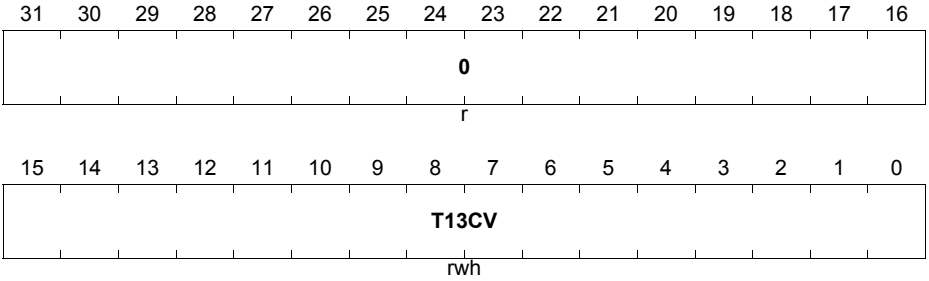
29.3.6 T13 related Registers

29.3.6.1 T13 Counter Register

The generation of the patterns for a single channel pulse width modulation (PWM) is based on timer T13. The registers related to timer T13 can be concurrently updated (with well-defined conditions) in order to ensure consistency of the PWM signal. T13 can be synchronized to several timer T12 events.
Timer T13 only supports compare mode on its compare channel CC63.
Register T13 represents the counting value of timer T13. It can only be written while the timer T13 is stopped. Write actions while T13 is running are not taken into account. Register T13 can always be read by SW.
Timer T13 only supports edge-aligned mode (counting up).

T13
Timer T13 Counter Register **(50_H)** **Reset Value: 0000 0000_H**



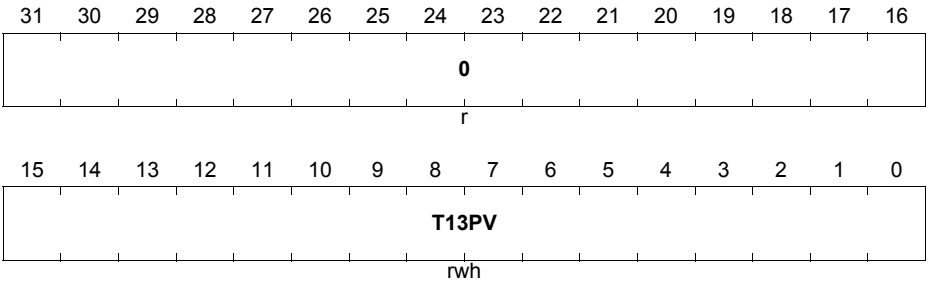
Field	Bits	Type	Description
T13CV	[15:0]	rwh	**Timer 13 Counter Value** This register represents the 16-bit counter value of Timer13.
0	[31:16]	r	**Reserved;** Returns 0 if read; should be written with 0.

Note: While timer T13 is stopped, the internal clock divider is reset in order to ensure reproducible timings and delays.

29.3.6.2 Period Register

Register T13PR contains the period value for timer T13. The period value is compared to the actual counter value of T13 and the resulting counter actions depend on the defined counting rules. This register has a shadow register and the shadow transfer is controlled by bit STE13. A read action by SW delivers the value currently used for the compare action, whereas the write action targets a shadow register. The shadow register structure allows a concurrent update of all T13-related values.

T13PR
Timer 13 Period Register **(54_H)** **Reset Value: 0000 0000_H**

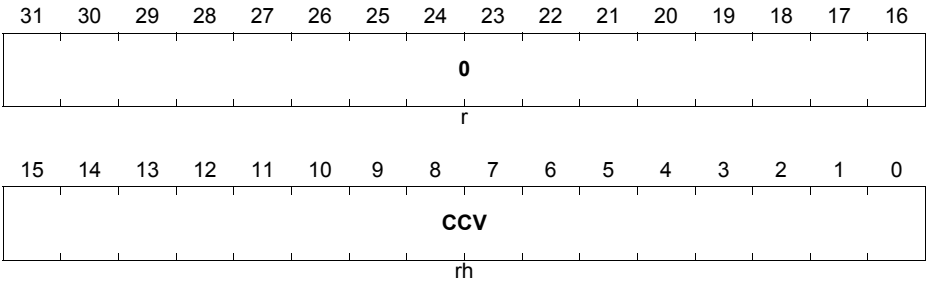


Field	Bits	Type	Description
T13PV	[15:0]	rwh	**T13 Period Value** The value T13PV defines the counter value for T13 leading to a period-match. When reaching this value, the timer T13 is set to zero.
0	[31:16]	r	**Reserved;** Returns 0 if read; should be written with 0.

29.3.6.3 Compare Register

Registers CC63R is the actual compare register for T13. The values stored in CC63R is compared to the counter value of T13. The State Bit CC63ST is located in register **CMPSTAT**.

CC63R
Compare Register for T13 **(58_H)** **Reset Value: 0000 0000$_H$**



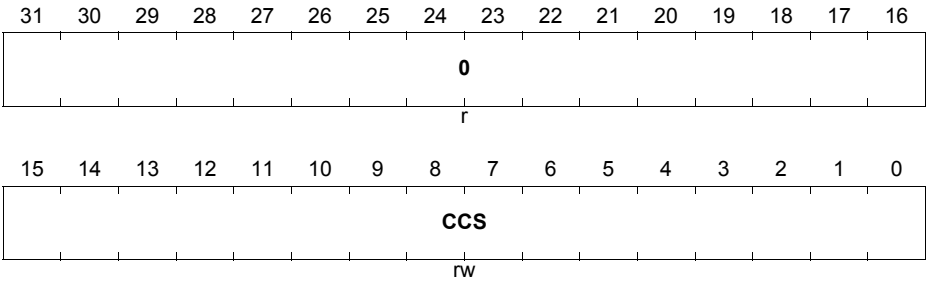
Field	Bits	Type	Description
CCV	[15:0]	rh	**Channel CC63 Compare Value** The bit field CCV contains the value, that is compared to the T13 counter value.
0	[31:16]	r	**Reserved;** Returns 0 if read; should be written with 0.

29.3.6.4 Compare Shadow Register

The register CC63R can only be read by SW, the modification of the value is done by a shadow register transfer from register CC63SR. The corresponding shadow register CC63SR can be read and written by SW.

CC63SR
Compare Shadow Register for T13

($5C_H$) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
CCS	[15:0]	rw	**Shadow Register for Channel CC63 Compare Value** The bit field contents of CCS is transferred to the bit field CCV during a shadow transfer.
0	[31:16]	r	**Reserved;** Returns 0 if read; should be written with 0.

29.4 Synchronous Start Feature

The T12 and T13 timers can be started synchronously through the T12HR and T13HR inputs of all CCU6x kernels.

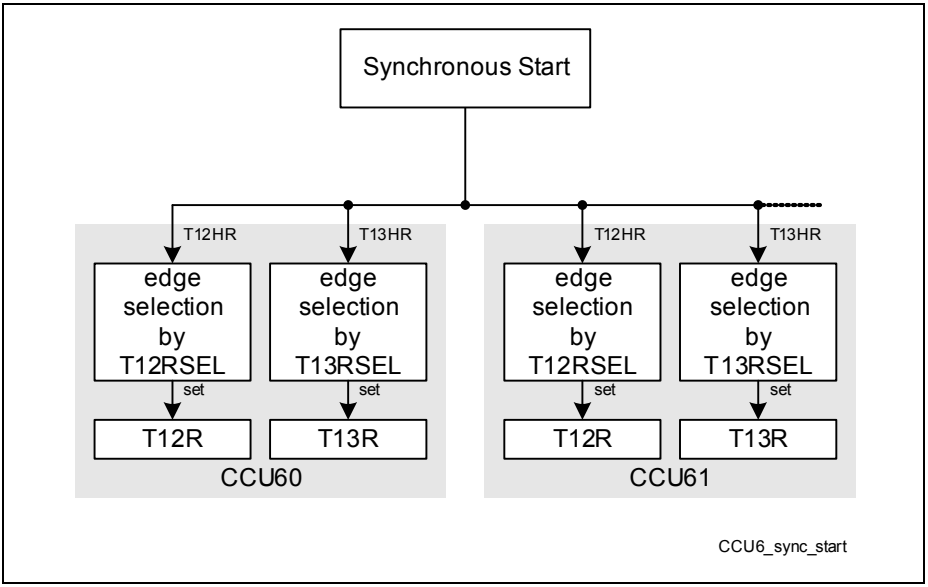


Figure 29-33 Synchronization Concept

29.5 Trap Handling

The trap functionality permits the PWM outputs to react on the state of the input signal CTRAP. This functionality can be used to switch off the power devices if the trap input becomes active (e.g. to perform an emergency stop). The trap handling and the effect on the output modulation are controlled by the bits in the trap control register **TRPCTR**. The trap flags TRPF and TRPS are located in register **IS** and can be set/cleared by SW by writing to registers **ISS** and **ISR**.
Figure 29-34 gives an overview on the trap function.

The Trap Flag TRPF monitors the trap input and initiates the entry into the Trap State. The Trap State Bit TRPS determines the effect on the outputs and controls the exit of the Trap State.
When a trap condition is detected ($\overline{\text{CTRAP}}$ = 0) and the input is enabled (TRPPEN = 1), both, the Trap Flag TRPF and the Trap State Bit TRPS, are set to 1 (trap state active). The output of the Trap State Bit TRPS leads to the Output Modulation Blocks (for T12 and for T13) and can there deactivate the outputs (set them to the passive state). Individual enable control bits for each of the six T12-related outputs and the T13-related output facilitate a flexible adaptation to the application needs.

There are a number of different ways to exit the Trap State. This offers SW the option to select the best operation for the application. Exiting the Trap State can be done either immediately when the trap condition is removed ($\overline{\text{CTRAP}}$ = 1 or TRPPEN = 0), or under software control, or synchronously to the PWM generated by either Timer T12 or Timer T13.

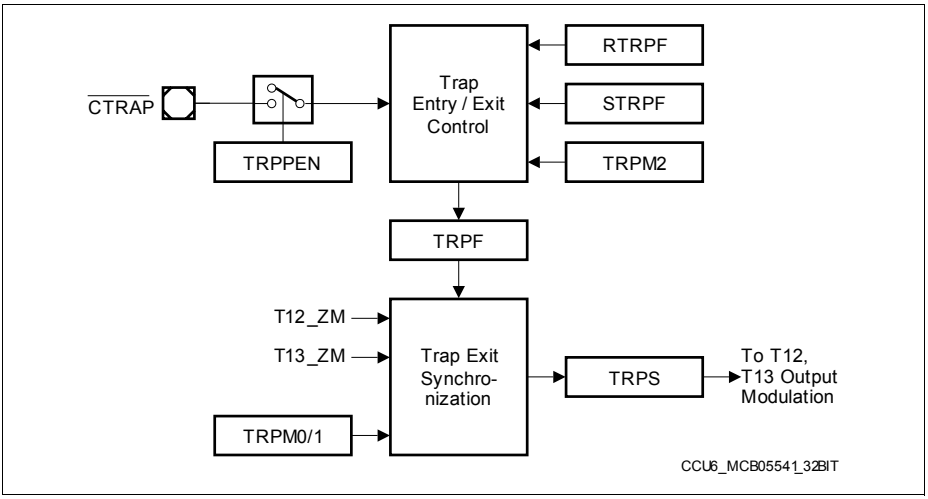

Figure 29-34 Trap Logic Block Diagram

Clearing of TRPF is controlled by the mode control bit TRPM2. If TRPM2 = 0, TRPF is automatically cleared by HW when $\overline{\text{CTRAP}}$ returns to the inactive level ($\overline{\text{CTRAP}}$ = 1) or if the trap input is disabled (TRPPEN = 0). When TRPM2 = 1, TRPF must be reset by SW after $\overline{\text{CTRAP}}$ has become inactive.

Clearing of TRPS is controlled by the mode control bits TRPM1 and TRPM0 (located in the Trap Control Register TRPCTR). A reset of TRPS terminates the Trap State and returns to normal operation. There are three options selected by TRPM1 and TRPM0. One is that the Trap State is left immediately when the Trap Flag TRPF is cleared, without any synchronization to timers T12 or T13. The other two options facilitate the synchronization of the termination of the Trap State to the count periods of either Timer T12 or Timer T13. **Figure 29-35** gives an overview on the associated operation.

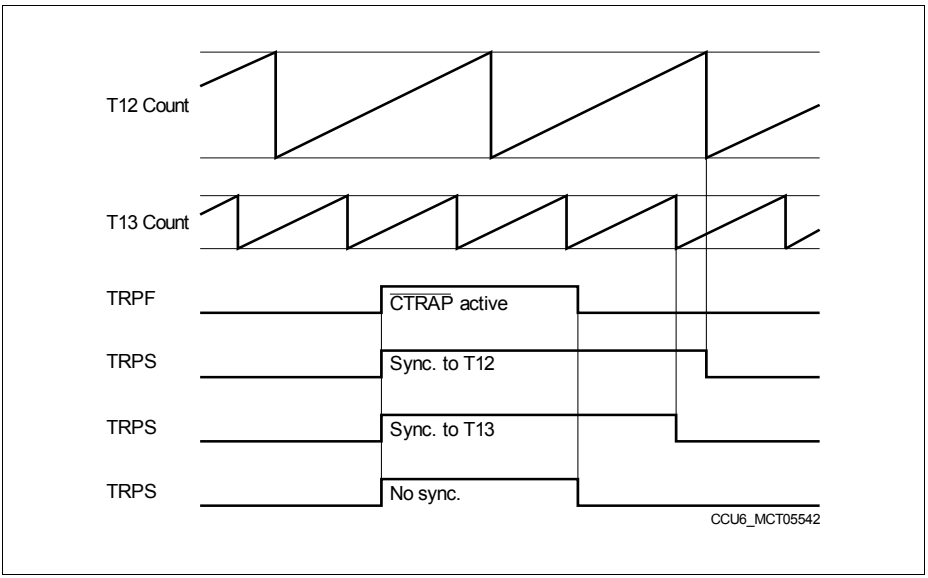

Figure 29-35 Trap State Synchronization (with TRPM2 = 0)

29.6 Multi-Channel Mode

The Multi-Channel mode offers the possibility to modulate all six T12-related output signals with one instruction. The bits in bit field **MCMOUT**.MCMP are used to specify the outputs that may become active. If Multi-Channel mode is enabled (bit **MODCTR**.MCMEN = 1), only those outputs may become active, that have a 1 at the corresponding bit position in bit field MCMP.
This bit field has its own shadow bit field **MCMOUTS**.MCMPS, that can be written by software. The transfer of the new value in MCMPS to the bit field MCMP can be triggered by, and synchronized to, T12 or T13 events. This structure permits the software to write the new value, that is then taken into account by the hardware at a well-defined moment and synchronized to a PWM signal. This avoids unintended pulses due to unsynchronized modulation sources.

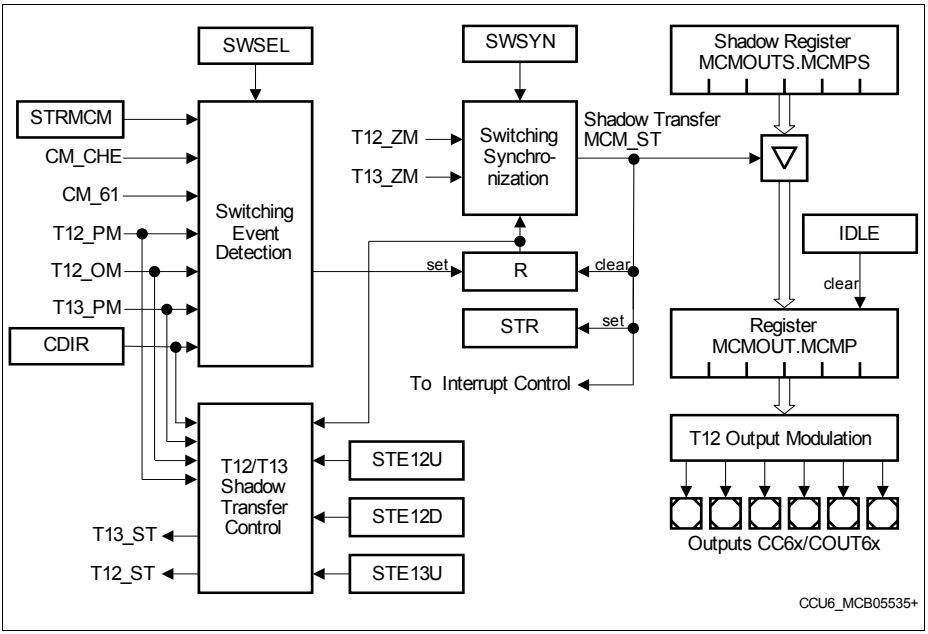

Figure 29-36 Multi-Channel Mode Block Diagram

Figure 29-36 shows the functional blocks for the Multi-Channel operation, controlled by bit fields in register **MCMCTR**. The event that triggers the update of bit field MCMP is chosen by SWSEL. In order to synchronize the update of MCMP to a PWM generated by T12 or T13, bit field SWSYN allows the selection of the synchronization event leading to the transfer from MCMPS to MCMP. Due to this structure, an update takes place with a new PWM period. A reminder flag R is set when the selected switching event occurs

(the event is not necessarily synchronous to the modulating PWM), and is cleared when the transfer takes place. This flag can be monitored by software to check for the status of this logic block. If the shadow transfer from MCMPS to MCMP takes place, bit **IS**.STR becomes set and an interrupt can be generated.
In addition to the Multi-Channel shadow transfer event MCM_ST, the shadow transfers for T12 (T12_ST) and T13 (T13_ST) can be generated to allow concurrent updates of applied duty cycles for T12 and/or T13 modulation and Multi-Channel patterns.

If it is explicitly desired, the update takes place immediately with the occurrence of the selected event when the direct synchronization mode is selected. The update can also be requested by software by writing to bit field MCMPS with the shadow transfer request bit STRMCM = 1. The option to trigger an update by SW is possible for all settings of SWSEL.
By using the direct mode and bit STRMCM = 1, the update takes place completely under software control.

Table 29-9 Multi-Channel Mode Switching Event Selection

SWSEL	Selected Event (see register MCMCTR)
000_B	No automatic event detection
001_B	Correct Hall Event (CM_CHE) detected at input signals CCPOSx without additional delay
010_B	T13 Period-Match (T13_PM)
011_B	T12 One-Match while counting down (T12_OM and CDIR = 1)
100_B	T12 Compare Channel 1 Event while counting up (CM_61 and CDIR = 0) to support the phase delay function by CC61 for block commutation mode.
101_B	T12 Period-Match while counting up (T12_PM and CDIR = 0)
110_B, 111_B	Reserved, no action

Table 29-10 Multi-Channel Mode Switching Synchronization

SWSYN	Synchronization Event (see register MCMCTR)
00_B	Direct Mode: the trigger event directly causes the shadow transfer
01_B	T13 Zero-Match (T13_ZM), the MCM shadow transfer is synchronized to a T13 PWM
10_B	T12 Zero-Match (T12_ZM), the MCM shadow transfer is synchronized to a T12 PWM
11_B	Reserved, no action

29.7 Hall Sensor Mode

For Brushless DC-Motors in block commutation mode, the Multi-Channel Mode has been introduced to provide efficient means for switching pattern generation. These patterns need to be output in relation to the angular position of the motor. For this, usually Hall sensors or Back-EMF sensing are used to determine the angular rotor position. The CCU6 provides three inputs, CCPOS0, CCPOS1, and CCPOS2, that can be used as inputs for the Hall sensors or the Back-EMF detection signals.

There is a strong correlation between the motor position and the output modulation pattern. When a certain position of the motor has been reached, indicated by the sampled Hall sensor inputs (the Hall pattern), the next, pre-determined Multi-Channel Modulation pattern has to be output. Because of different machine types, the modulation pattern for driving the motor can vary. Therefore, it is wishful to have a wide flexibility in defining the correlation between the Hall pattern and the corresponding Modulation pattern. Furthermore, a hardware mechanism significantly reduces the CPU for block-commutation.

The CCU6 offers the flexibility by having a register containing the currently assumed Hall pattern (CURH), the next expected Hall pattern (EXPH) and the corresponding output pattern (MCMP). A new Modulation pattern is output when the sampled Hall inputs match the expected ones (EXPH). To detect the next rotation phase (segment for block commutation), the CCU6 monitors the Hall inputs for changes. When the next expected Hall pattern is detected, the next corresponding Modulation pattern is output.

To increase for noise immunity (to a certain extend), the CCU6 offers the possibility to introduce a sampling delay for the Hall inputs. Some changes of the Hall inputs are not leading to the expected Hall pattern, because they are only short spikes due to noise. The Hall pattern compare logic compares the Hall inputs to the next expected pattern and also to the currently assumed pattern to filter out spikes.

For the Hall and Modulation output patterns, a double-register structure is implemented. While register **MCMOUT** holds the actually used values, its shadow register **MCMOUTS** can be loaded by software from a pre-defined table, holding the appropriate Hall and Modulation patterns for the given motor control.
A transfer from the shadow register into register MCMOUT can take place when a correct Hall pattern change is detected. Software can then load the next values into register MCMOUTS. It is also possible by software to force a transfer from MCMOUTS into MCMOUT.

Note: The Hall input signals CCPOSx and the CURH and EXPH bit fields are arranged in the following order:
CCPOS0 corresponds to CURH.0 (LSB) and EXPH.0 (LSB)
CCPOS1 corresponds to CURH.1 and EXPH.1
CCPOS2 corresponds to CURH.2 (MSB) and EXPH.2 (MSB)

29.7.1 Hall Pattern Evaluation

The Hall sensor inputs CCPOSx can be permanently monitored via an edge detection block (with the module clock f_{CC6}). In order to suppress spikes on the Hall inputs due to noise in rugged inverter environment, two optional noise filtering methods are supported by the Hall logic (both methods can be combined).

- Noise filtering with delay:
  For this function, the mode control bit fields MSEL6x for all T12 compare channels must be programmed to 1000_B and DBYP = 0. The selected event triggers Dead-Time Counter 0 to generate a programmable delay (defined by bit field DTM). When the delay has elapsed, the evaluation signal HCRDY becomes activated.
  Output modulation with T12 PWM signals is not possible in this mode.
- Noise filtering by synchronization to PWM:
  The Hall inputs are not permanently monitored by the edge detection block, but samples are taken only at defined points in time during a PWM period. This can be used to sample the Hall inputs when the switching noise (due to PWM) does not disturb the Hall input signals.

If neither the delay function of Dead-Time Counter 0 is not used for the Hall pattern evaluation nor the Hall mode for Brushless DC-Drive control is enabled, the timer T12 block is available for PWM generation and output modulation.

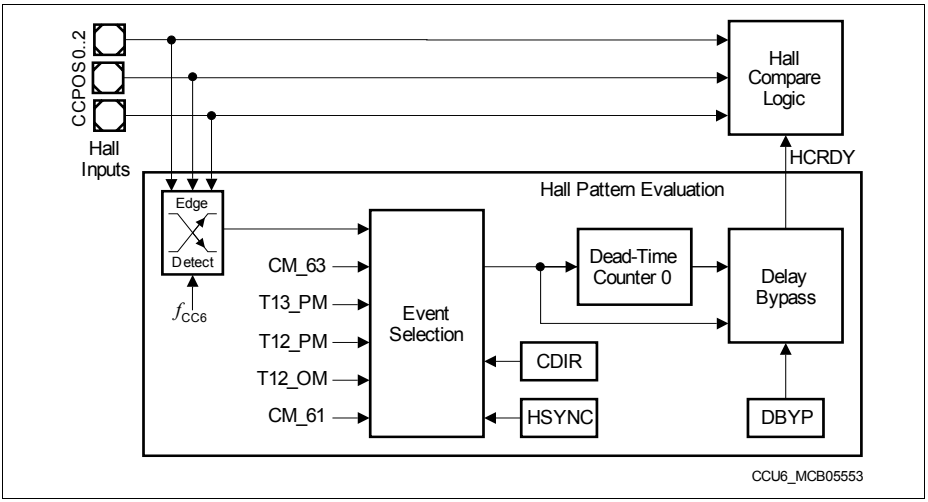

Figure 29-37 Hall Pattern Evaluation

If the evaluation signal HCRDY (Hall Compare Ready, see **Figure 29-38**) becomes activated, the Hall inputs are sampled and the Hall compare logic starts the evaluation of the Hall inputs.

Figure 29-37 illustrates the events for Hall pattern evaluation and the noise filter logic, Table 29-11 summarizes the selectable trigger input signals.

Table 29-11 Hall Sensor Mode Trigger Event Selection

HSYNC	Selected Event (see register T12MSEL)
000_B	Any edge at any of the inputs CCPOSx, independent from any PWM signal (permanent check).
001_B	A T13 Compare-Match (CM_63).
010_B	A T13 Period-Match (T13_PM).
011_B	Hall sampling triggered by HW sources is switched off.
100_B	A T12 Period-Match while counting up (T12_PM and CDIR = 0).
101_B	A T12 One-Match while counting down (T12_OM and CDIR = 1).
110_B	A T12 Compare-Match of compare channel CC61 while counting up (CM_61 and CDIR = 0).
111_B	A T12 Compare-Match of compare channel CC61 while counting down (CM_61 and CDIR = 1).

29.7.2 Hall Pattern Compare Logic

Figure 29-38 gives an overview on the double-register structure and the pattern compare logic. Software writes the next modulation pattern (MCMPS) and the corresponding current (CURHS) and expected (EXPHS) Hall patterns into the shadow register MCMOUTS. Register MCMOUT holds the actually used values CURH and EXPH. The modulation pattern MCMP is provided to the T12 Output Modulation block. The current (CURH) and expected (EXPH) Hall patterns are compared to the sampled Hall sensor inputs (visible in register **CMPSTAT**). Sampling of the inputs and the evaluation of the comparator outputs is triggered by the evaluation signal HCRDY (Hall Compare Ready), that is detailed in the next section.

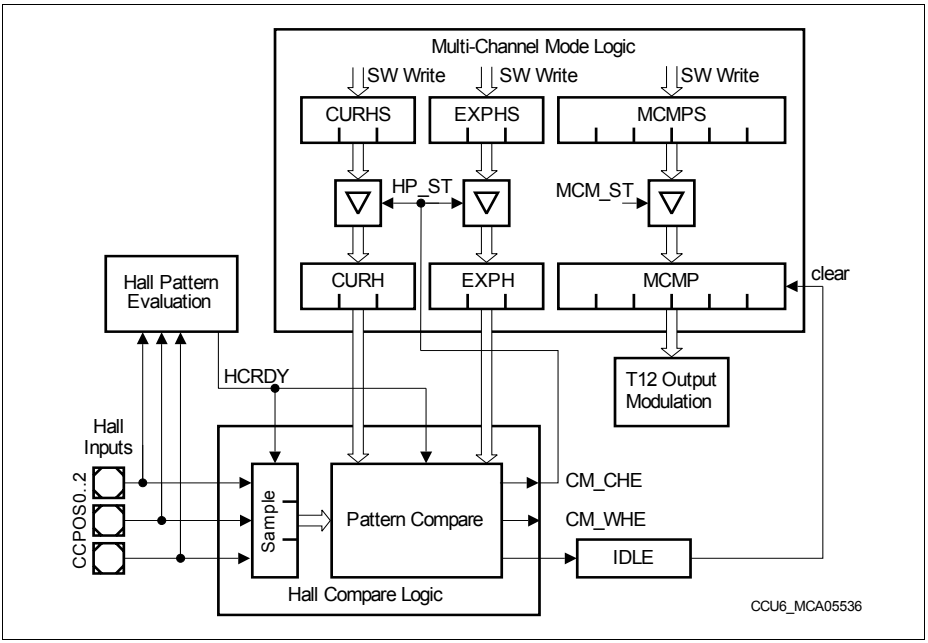

Figure 29-38 Hall Pattern Compare Logic

- If the sampled Hall pattern matches the value programmed in CURH, the detected transition was a spike (no Hall event) and no further actions are necessary.
- If the sampled Hall pattern matches the value programmed in EXPH, the detected transition was the expected event (correct Hall event CM_CHE) and the MCMP value has to change.
- If the sampled Hall pattern matches neither CURH nor EXPH, the transition was due to a major error (wrong Hall event CM_CWE) and can lead to an emergency shut down (IDLE).

At every correct Hall event (CM_CHE), the next Hall patterns are transferred from the shadow register MCMOUTS into MCMOUT (Hall pattern shadow transfer HP_ST), and a new Hall pattern with its corresponding output pattern can be loaded (e.g. from a predefined table in memory) by software into MCMOUTS. For the Modulation patterns, signal MCM_ST is used to trigger the transfer.
Loading this shadow register can also be done by writing MCMOUTS.STRHP = 1 (for EXPH and CURH) or MCMOUTS.STRMCMP = 1 (for MCMP).

29.7.3 Hall Mode Flags

Depending on the Hall pattern compare operation, a number of flags are set in order to indicate the status of the module and to trigger further actions and interrupt requests.

Flag **IS**.CHE (Correct Hall Event) is set by signal CM_CHE when the sampled Hall pattern matches the expected one (EXPH). This flag can also be set by SW by setting bit **ISS**.SCHE = 1. If enabled by bit **IEN**.ENCHE = 1, the set signal for CHE can also generate an interrupt request to the CPU. Bit field **INP**.INPCHE defines which service request output becomes activated in case of an interrupt request.To clear flag CHE, SW needs to write **ISR**.RCHE = 1.
Flag IS.WHE indicates a Wrong Hall Event. Its handling for flag setting and resetting as well as interrupt request generation are similar to the mechanism for flag CHE.
The implementation of flag STR is done in the same way as for CHE and WHE. This flag is set by HW by the shadow transfer signal MCM_ST (see also **Figure 29-36**).

Please note that for flags CHE, WHE, and STR, the interrupt request generation is triggered by the set signal for the flag. That means, a request can be generated even if the flag is already set. There is no need to clear the flag in order to enable further interrupt requests.

The implementation for the IDLE flag is different. It is set by HW through signal CM_WHE if enabled by bit ENIDLE. Software can also set the flag via bit SIDLE. As long as bit IDLE is set, the modulation pattern field MCMP is cleared to force the outputs to the passive state. Flag IDLE must be cleared by software by writing RIDLE = 1 in order to return to normal operation. To fully restart from IDLE mode, the transfer requests for the bit fields in register MCMOUTS to register MCMOUT have to be initiated by software via bits STRMCM and STRHP in register MCMOUTS. In this way, the release from IDLE mode is under software control, but can be performed synchronously to the PWM signal.

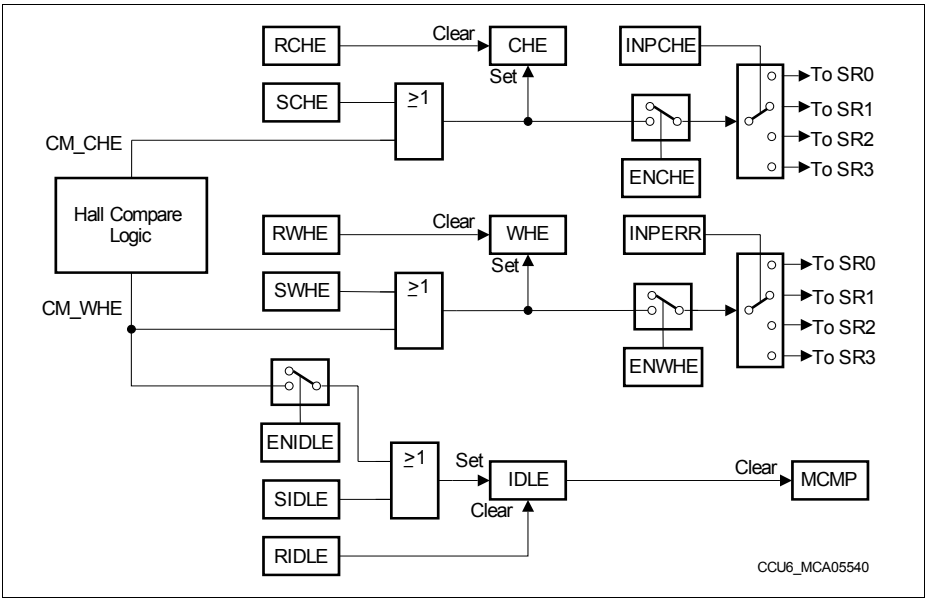

Figure 29-39 Hall Mode Flags

29.7.4 Hall Mode for Brushless DC-Motor Control

The CCU6 provides a mode for the Timer T12 Block especially targeted for convenient control of block commutation patterns for Brushless DC-Motors. This mode is selected by setting all **T12MSEL**.MSEL6x bit fields of the three T12 Channels to 1000_B.
In this mode, illustrated in **Figure 29-40**, channel CC60 is placed in capture mode to measure the time elapsed between the last two correct Hall events, channel CC61 in compare mode to provide a programmable phase delay between the Hall event and the application of a new PWM output pattern, and channel CC62 also in compare mode as first time-out criterion. A second time-out criterion can be built by the T12 period match event.

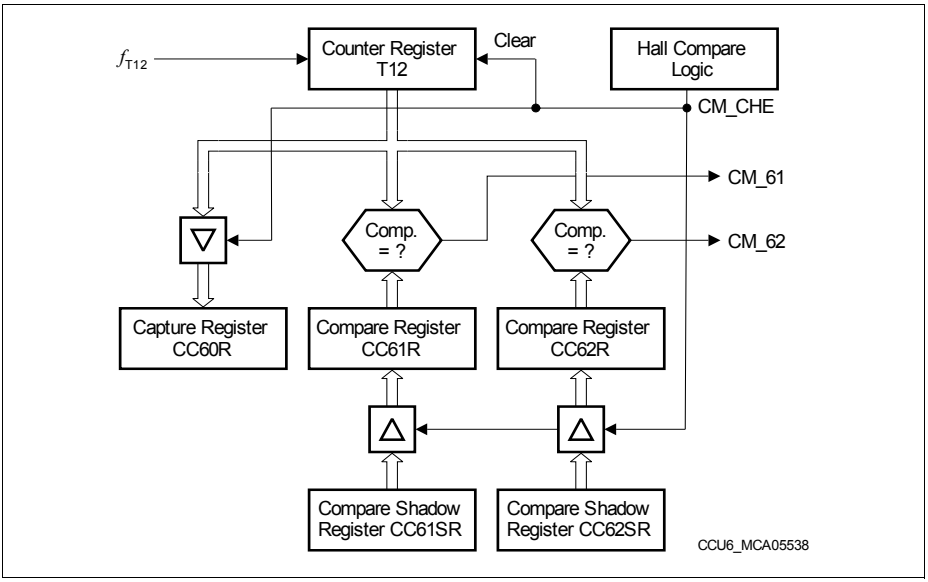

Figure 29-40 T12 Block in Hall Sensor Mode

The signal CM_CHE from the Hall compare logic is used to transfer the new compare values from the shadow registers CC6xSR into the actual compare registers CC6xR, performs the shadow transfer for the T12 period register, to capture the current T12 contents into register CC60R, and to clear T12.

Note: In this mode, the shadow transfer signal T12_ST is not generated. Not all shadow bits, such as the PSLy bits, will be transferred to their main registers. To program the main registers, SW needs to write to these registers while Timer T12 is stopped. In this case, a SW write actualizes both registers.

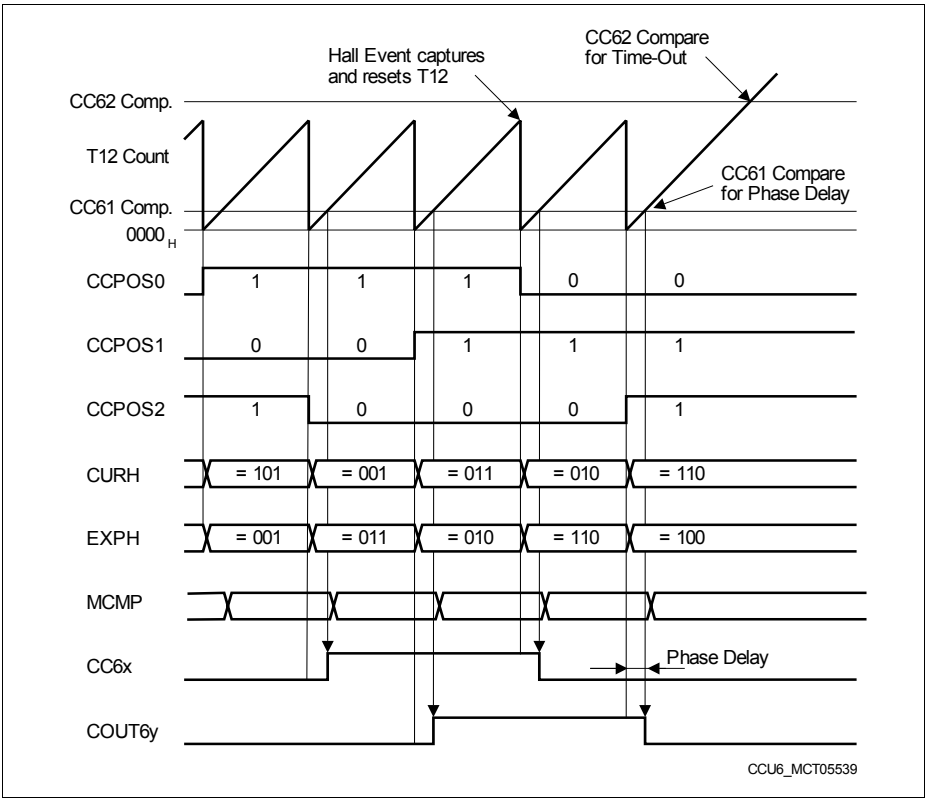

Figure 29-41 Brushless DC-Motor Control Example (all MSEL6x = 1000_B)

After the detection of an expected Hall pattern (CM_CHE active), the T12 count value is captured into channel CC60 (representing the actual rotor speed by measuring the elapsed time between the last two correct Hall events), and T12 is reset. When the timer reaches the compare value in channel CC61, the next multi-channel state is switched by triggering the shadow transfer of bit field MCMP (if enabled in bit field **SWEN**). This trigger event can be combined with the synchronization of the next multi-channel state to the PWM source (to avoid spikes on the output lines, see **Section 29.6**). This compare function of channel CC61 can be used as a phase delay from the position sensor input signals to the switching of the output signals, that is necessary if a sensorless back-EMF technique or Hall sensors are used. The compare value in channel CC62 can be used as a time-out trigger (interrupt), indicating that the actual motor speed is far below the desired destination value. An abnormal load change can be detected with this feature and PWM generation can be disabled.

29.8 Modulation Control Registers

29.8.1 Modulation Control

This register contains bits enabling the modulation of the corresponding output signal by PWM pattern generated by the timers T12 and T13. Furthermore, the multi-channel mode can be enabled as additional modulation source for the output signals.

0	6, 14, [31:16]	r	**Reserved;** Returns 0 if read; should be written with 0.

29.8.2 Trap Control Register

The register TRPCTR controls the trap functionality. It contains independent enable bits for each output signal and control bits to select the behavior in case of a trap condition. The trap condition is a low level on the $\overline{\text{CTRAP}}$ input pin, that is monitored (inverted level) by bit IS.TRPF. While TRPF=1 (trap input active), the trap state bit IS.TRPS is set to 1.

TRPCTR
Trap Control Register **(84_H)** **Reset Value: 0000 0000$_H$**

rw	rw	rw						r					rw	rw	rw

Field	Bits	Type	Description
TRPM1, TRPM0	1, 0	rw	**Trap Mode Control Bits 1, 0** These two bits define the behavior of the selected outputs when leaving the trap state after the trap condition has become inactive again. A synchronization to the timer driving the PWM pattern avoids unintended pulses when leaving the trap state. The combination [TRPM1, TRPM0] leads to: 00_B The trap state is left (return to normal operation) after TRPF has become 0 again when a zero-match of T12 (while counting up) is detected (synchronization to T12). 01_B The trap state is left (return to normal operation) after TRPF has become 0 again when a zero-match of T13 is detected (synchronization to T13). 10_B reserved 11_B The trap state is left (return to normal operation) immediately after TRPF has become 0 again without any synchronization to T12 or T13.
TRPM2	2	rw	**Trap Mode Control Bit 2** This bit defines how the trap flag TRPF can be cleared after the trap input condition ($\overline{\text{CTRAP}}$ = 0 and TRPPEN = 1) is no longer valid (either by $\overline{\text{CTRAP}}$ = 1 or by TRPPEN = 0). 0_B Automatic Mode: Bit TRPF is cleared by HW if the trap input condition is no longer valid. 1_B Manual Mode: Bit TRPF stays 0 after the trap input condition is no longer valid. It has to be cleared by SW by writing ISR.RTRPF = 1.

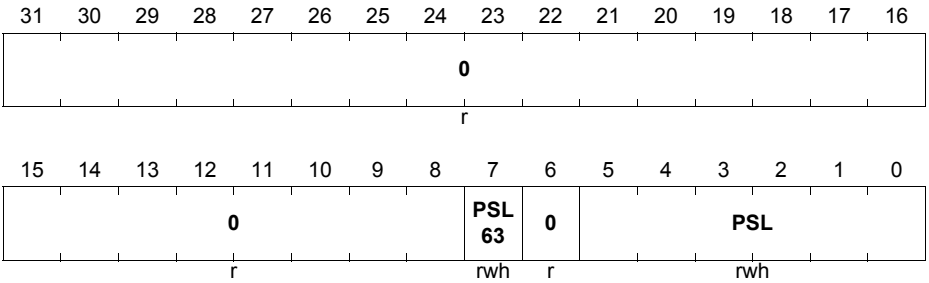
Field	Bits	Type	Description
TRPEN	[13:8]	rw	**Trap Enable Control** Setting a bit enables the trap functionality for the following corresponding output signals: TRPEN0 = TRPCTR.8 for output CC60 TRPEN1 = TRPCTR.9 for output COUT60 TRPEN2 = TRPCTR.10 for output CC61 TRPEN3 = TRPCTR.11 for output COUT61 TRPEN4 = TRPCTR.12 for output CC62 TRPEN5 = TRPCTR.13 for output COUT62 0_B The trap functionality of the corresponding output signal is disabled. The output state is independent from bit IS.TRPS. 1_B The trap functionality of the corresponding output signal is enabled. The output state is set to the passive while IS.TRPS=1.
TRPEN13	14	rw	**Trap Enable Control for Timer T13** 0_B The trap functionality for output COUT63 is disabled. The output state is independent from bit IS.TRPS. 1_B The trap functionality for output COUT63 is enabled. The output state is set to the passive while IS.TRPS=1.
TRPPEN	15	rw	**Trap Pin Enable** This bit enables the input (pin) function for the trap generation. An interrupt can only be generated if a falling edge is detected at pin $\overline{\text{CTRAP}}$ while TRPPEN = 1. 0_B The CCU6 trap functionality based on the input $\overline{\text{CTRAP}}$ is disabled. A CCU6 trap can only be generated by SW by setting bit TRPF. 1_B The CCU6 trap functionality based on the input $\overline{\text{CTRAP}}$ is enabled. A CCU6 trap can be generated by SW by setting bit TRPF or by $\overline{\text{CTRAP}}$=0.
0	[7:3], [31:16]	r	**Reserved;** Returns 0 if read; should be written with 0.

29.8.3 Passive State Level Register

Register PSLR defines the passive state level of the PWM outputs of the module. The passive state level is the value that is driven during the passive state of the output. During the active state, the corresponding output pin drives the active state level, that is the inverted passive state level. The passive state level permits to adapt the driven output levels to the driver polarity (inverted, not inverted) of the connected power stage. The bits in this register have shadow bit fields to permit a concurrent update of all PWM-related parameters (bit field PSL is updated with T12_ST, whereas PSL63 is updated with T13_ST). The actually used values can be read (attribute “rh”), whereas the shadow bits can only be written (attribute “w”).

PSLR

Passive State Level Register **(88_H)** **Reset Value: $0000\ 0000_H$**



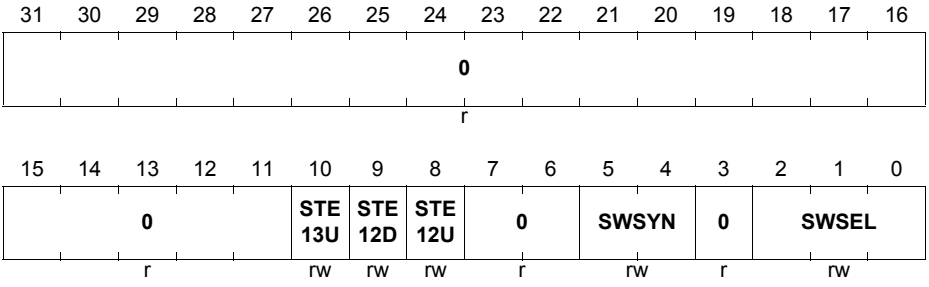
Field	Bits	Type	Description
PSL	[5:0]	rwh	**Compare Outputs Passive State Level** These bits define the passive level driven by the module outputs during the passive state. PSL0 = PSLR.0 for output CC60 PSL1 = PSLR.1 for output COUT60 PSL2 = PSLR.2 for output CC61 PSL3 = PSLR.3 for output COUT61 PSL4 = PSLR.4 for output CC62 PSL5 = PSLR.5 for output COUT62 0_B The passive level is 0. 1_B The passive level is 1.
PSL63	7	rwh	**Passive State Level of Output COUT63** This bit defines the passive level driven by the module output COUT63 during the passive state. 0_B The passive level is 0. 1_B The passive level is 1.
0	6, [31:8]	r	**Reserved;** Returns 0 if read; should be written with 0.

29.8.4 Multi-Channel Mode Registers

Register MCMCTR contains control bits for the multi-channel functionality.

MCMCTR
Multi-Channel Mode Control Register

(94_H) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
SWSEL	[2:0]	rw	**Switching Selection** Bit field SWSEL selects one of the following trigger request sources (next multi-channel event) for the shadow transfer MCM_ST from MCMPS to MCMP. The trigger request is stored in the reminder flag R until the shadow transfer is done and flag R is cleared automatically with the shadow transfer. The shadow transfer takes place synchronously with an event selected in bit field SWSYN. 000_B No trigger request will be generated 001_B Correct Hall pattern detected (CM_CHE) 010_B T13 period-match detected (while counting up) 011_B T12 one-match (while counting down) 100_B T12 channel 1 compare-match detected (phase delay function) 101_B T12 period match detected (while counting up) 110_B reserved, no trigger request will be generated 111_B reserved, no trigger request will be generated
SWSYN	[5:4]	rw	**Switching Synchronization** Bit field SWSYN defines the synchronization mechanism of the shadow transfer event MCM_ST if it has been requested before (flag R set by an event selected by SWSEL) and if MCMEN = 1. This feature permits the synchronization of the outputs to the PWM source, that is used for modulation (T12 or T13). 00_B Direct; the trigger event immediately leads to the shadow transfer 01_B A T13 zero-match triggers the shadow transfer 10_B A T12 zero-match (while counting up) triggers the shadow transfer 11_B reserved; no action
STE12U	8	rw	**Shadow Transfer Enable for T12 Upcounting** This bit enables the shadow transfer T12_ST if flag MCMOUT.R is set or becomes set while a T12 period match is detected while counting up. 0_B No action 1_B The T12_ST shadow transfer mechanism is enabled if MCMEN = 1.

Field	Bits	Type	Description
STE12D	9	rw	**Shadow Transfer Enable for T12 Downcounting** This bit enables the shadow transfer T12_ST if flag MCMOUT.R is set or becomes set while a T12 one match is detected while counting down. 0_B No action 1_B The T12_ST shadow transfer mechanism is enabled if MCMEN = 1.
STE13U	10	rw	**Shadow Transfer Enable for T13 Upcounting** This bit enables the shadow transfer T13_ST if flag MCMOUT.R is set or becomes set while a T13 period match is detected. 0_B No action 1_B The T13_ST shadow transfer mechanism is enabled if MCMEN = 1.
0	3, [7:6], [31:11]	r	**Reserved;** Returns 0 if read; should be written with 0.

Register MCMOUTS contains bits used as pattern input for the multi-channel mode and the Hall mode. This register is a shadow register (that can be read and written) for register MCMOUT, indicating the currently active signals.

MCMOUTS
Multi-Channel Mode Output Shadow Register

($8C_H$) **Reset Value: $0000\ 0000_H$**

w	r	rw			rw			w	r	rw					

Field	Bits	Type	Description
MCMPS	[5:0]	rw	**Multi-Channel PWM Pattern Shadow** Bit field MCMPS is the shadow bit field for bit field MCMP. The multi-channel shadow transfer is triggered by MCM_ST according to the transfer conditions defined by register MCMCTR.
STRMCM	7	w	**Shadow Transfer Request for MCMPS** Writing STRMCM = 1 leads to an immediate activation of MCM_ST to update bit field MCMP by the value of MCMPS. When read, this bit always delivers 0. 0_B No action. 1_B Bit field MCMP is updated.
EXPHS	[10:8]	rw	**Expected Hall Pattern Shadow** Bit field EXPHS is the shadow bit field for bit field EXPH. The shadow transfer takes place when a correct Hall event is detected (CM_CHE).
CURHS	[13:11]	rw	**Current Hall Pattern Shadow** Bit field CURHS is the shadow bit field for bit field CURH. The shadow transfer takes place when a correct Hall event is detected (CM_CHE).

Field	Bits	Type	Description
STRHP	15	w	**Shadow Transfer Request for the Hall Pattern** Writing STRHP = 1 leads to an immediate activation of HP_ST to update bit fields EXPH and CURH by EXPHS and CURHS. When read, this bit always delivers 0. 0_B No action. 1_B Bit fields EXPH and CURH are updated.
0	6, 14 [31:16]	r	**Reserved;** Returns 0 if read; should be written with 0.

MCMOUT
Multi-Channel Mode Output Register

(90_H) **Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0		**CURH**			**EXPH**			**0**	**R**	**MCMP**					
r		rh			rh			r	rh	rh					

Field	Bits	Type	Description
MCMP	[5:0]	rh	**Multi-Channel PWM Pattern** Bit field MCMP defines the output pattern for the multi-channel mode. If this mode is enabled by MODCTR.MCMEN = 1, the output state of all T12 related PWM outputs can be modified. This bit field is 0 while IS.IDLE = 1. MCMP0 = MCMOUT.0 for output CC60 MCMP1 = MCMOUT.1 for output COUT60 MCMP2 = MCMOUT.2 for output CC61 MCMP3 = MCMOUT.3 for output COUT61 MCMP4 = MCMOUT.4 for output CC62 MCMP5 = MCMOUT.5 for output COUT62 0_B The output is set to the passive state. A PWM generated by T12 or T13 are not taken into account. 1_B The output can be in the active state, depending on the enabled PWM modulation signals generated by T12, T13 and the trap state.
R	6	rh	**Reminder Flag** This flag indicates that the shadow transfer from MCMPS to MCMP has been requested by the selected trigger source. It is cleared when the shadow transfer takes place or while MCMEN=0. 0_B A shadow transfer MCM_ST is not requested. 1_B A shadow transfer MCM_ST is requested, but has not yet been executed, because the selected synchronization condition has not yet occurred.
EXPH	[10:8]	rh	**Expected Hall Pattern** Bit field EXPH is updated by a shadow transfer HP_ST from bit field EXPHS. If HCRDY = 1, EXPH is compared to the sampled CCPOSx inputs in order to detect the occurrence of the next desired (=expected) hall pattern or a wrong pattern. If the sampled hall pattern at the hall input pins is equal to bit field EXPH, a correct Hall event has been detected (CM_CHE).

Field	Bits	Type	Description
CURH	[13:11]	rh	**Current Hall Pattern** Bit field CURH is updated by a shadow transfer HP_ST from bit field CURHS. If HCRDY = 1, CURH is compared to the sampled CCPOSx inputs in order to detect a spike. If the sampled Hall pattern at the Hall input pins is equal to bit field CURH, no Hall event has been detected. If the sampled Hall input pattern is neither equal to CURH nor equal to EXPH, the Hall event was not the desired one and may be due to a fatal error (e.g. blocked rotor, etc.). In this case, a wrong Hall event has been detected (CM_WHE).
0	7, [31:14]	r	**Reserved;** Returns 0 if read; should be written with 0.

29.9 Interrupt Handling

This section describes the interrupt handling of the CCU6 module.

29.9.1 Interrupt Structure

The HW interrupt event or the SW setting of the corresponding interrupt set bit (in register ISS) sets the event indication flags (in register IS) and can trigger the interrupt generation. The interrupt pulse is generated independently from the interrupt status flag in register IS (it is not necessary to clear the related status bit to be able to generate another interrupt). The interrupt flag can be cleared by SW by writing to the corresponding bit in register ISR.

If enabled by the related interrupt enable bit in register IEN, an interrupt pulse can be generated on one of the four service request outputs (SR0 to SR3) of the module. If more than one interrupt source is connected to the same interrupt node pointer (in register INP), the requests are logically OR-combined to one common service request output (see **Figure 29-42**).

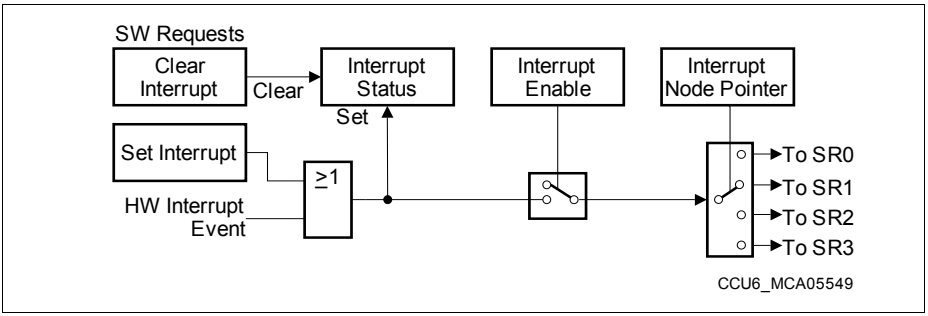

Figure 29-42 General Interrupt Structure

The available interrupt events in the CCU6 are shown in **Figure 29-43**.

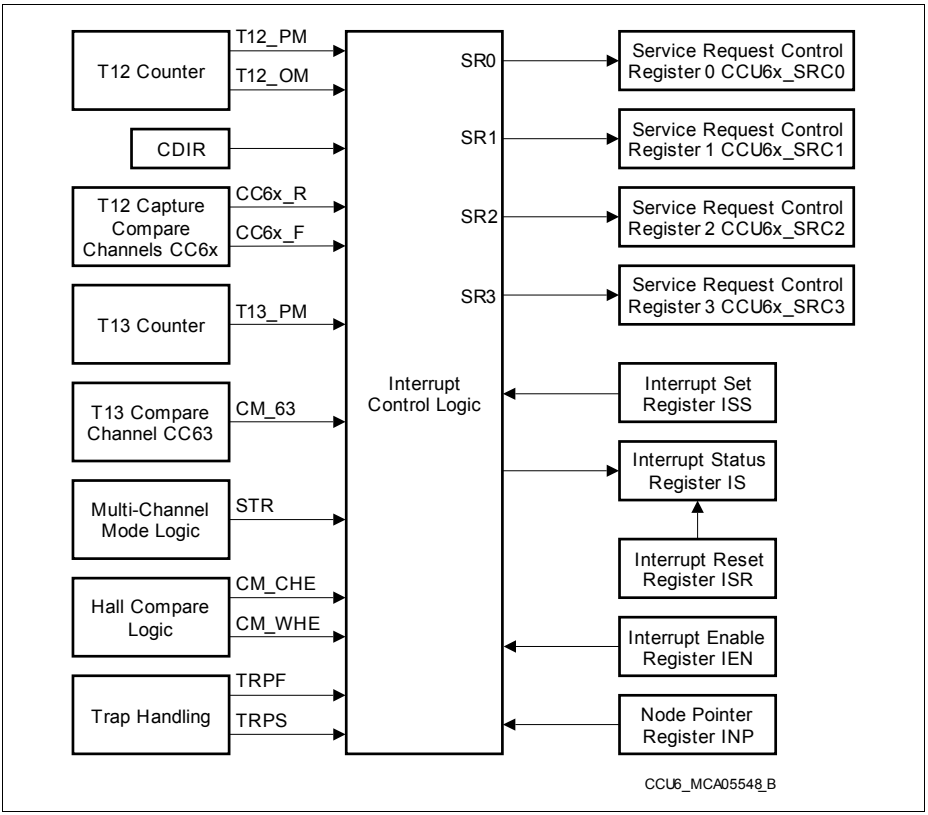

Figure 29-43 Interrupt Sources and Events

29.9.2 Interrupt Registers

29.9.2.1 Interrupt Status Register

Register IS contains the individual interrupt request bits. This register can only be read, write actions have no impact on the contents of this register. The SW can set or clear the bits individually by writing to the registers ISS (to set the bits) or to register ISR (to clear the bits).

The interrupt generation is independent from the value of the bits in register IS, e.g. the interrupt will be generated (if enabled) even if the corresponding bit is already set. The trigger for an interrupt generation is the detection of a set condition (by HW or SW) for the corresponding bit in register IS.

In compare mode (and hall mode), the timer-related interrupts are only generated while the timer is running (T1xR=1). In capture mode, the capture interrupts are also generated while the timer T12 is stopped.

Note: Not all bits in register IS can generate an interrupt. Other status bits have been added, that have a similar structure for their set and clear actions. It is recommended that SW checks the interrupt bits bit-wisely (instead of common OR over the bits).

IS
Interrupt Status Register **($A0_H$)** **Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh

Field	Bits	Type	Description
ICC60R, ICC61R, ICC62R	0, 2, 4	rh	**Capture, Compare-Match Rising Edge Flag** This bit indicates that event CC6x_R has been detected. This event occurs in compare mode when a compare-match is detected while T12 is counting up (CM_6x and CDIR = 0) and in capture mode when a rising edge is detected at the related input CC6xIN. 0_B The event has not yet been detected. 1_B The event has been detected.
ICC60F, ICC61F, ICC62F	1, 3, 5	rh	**Capture, Compare-Match Falling Edge Flag** This bit indicates that event CC6x_F has been detected. This event occurs in compare mode when a compare-match is detected while T12 is counting down (CM_6x and CDIR = 1) and in capture mode when a falling edge is detected at the related input CC6xIN. 0_B The event has not yet been detected. 1_B The event has been detected.
T12OM	6	rh	**Timer T12 One-Match Flag** This bit indicates that a timer T12 one-match while counting down (T12_OM and CDIR = 1) has been detected. 0_B The event has not yet been detected. 1_B The event has been detected.
T12PM	7	rh	**Timer T12 Period-Match Flag** This bit indicates that a timer T12 period-match while counting up (T12_PM and CDIR = 0) has been detected. 0_B The event has not yet been detected. 1_B The event has been detected.
T13CM	8	rh	**Timer T13 Compare-Match Flag** This bit indicates that a timer T13 compare-match (CM_63) has been detected. 0_B The event has not yet been detected. 1_B The event has been detected.
T13PM	9	rh	**Timer T13 Period-Match Flag** This bit indicates that a timer T13 period-match (T13_PM) has been detected. 0_B The event has not yet been detected. 1_B The event has been detected.

Field	Bits	Type	Description
TRPF	10	rh	**Trap Flag** This bit indicates if a trap condition (input $\overline{\text{CTRAP}}$ = 0 or by SW) is / has been detected. If TRPM2= 0, it becomes cleared automatically if $\overline{\text{CTRAP}}$ = 1 or TRPPEN = 0, whereas if TRPM2 = 1, it has to be cleared by writing RTRPF = 1. 0_B The trap condition has not been detected. 1_B The trap condition is / has been detected.
TRPS	11	rh	**Trap State**[1)] This bit indicates the actual trap state. It is set if TRPF = 1 and becomes cleared according to the mode selected in register TRPCTR. 0_B The trap state is not active. 1_B The trap state is active.
CHE	12	rh	**Correct Hall Event** This bit indicates that a correct Hall event (CM_CHE) has been detected. 0_B The event has not yet been detected. 1_B The event has been detected.
WHE	13	rh	**Wrong Hall Event** This bit indicates that a wrong Hall event (CM_WHE) has been detected. 0_B The event has not yet been detected. 1_B The event has been detected.
IDLE	14	rh	**IDLE State** If enabled by ENIDLE = 1, this bit is set together with bit WHE and it has to be cleared by SW. 0_B No action. 1_B Bit field MCMP is cleared, the selected outputs are set to passive state.
STR	15	rh	**Multi-Channel Mode Shadow Transfer Request** This bit indicates that a shadow transfer from MCMPS to MCMP (MCM_ST) has taken place. 0_B The event has not yet been detected. 1_B The event has been detected.
0	[31:16]	r	**Reserved;** Returns 0 if read; should be written with 0.

1) During the trap state, the selected outputs are set to the passive state. The logic level driven during the passive state is defined by the corresponding bit in register PSLR. Bits TRPS=1 and TRPF=0 can occur if the trap condition is no longer active but the selected synchronization has not yet taken place.

29.9.2.2 Interrupt Status Set Register

Register ISS contains individual interrupt request set bits to generate a CCU6 interrupt request by software. Writing a 1 sets the bit(s) in register IS at the corresponding bit position(s) and can generate an interrupt event (if available and enabled).
All bit positions read as 0.

ISS

The service request output that will be activated is selected by bit field INPCC6x.

Field	Bits	Type	Description
ENT12OM	6	rw	**Enable Interrupt for T12 One-Match** 0_B No interrupt will be generated if the set condition for bit T12OM in register IS occurs. 1_B An interrupt will be generated if the set condition for bit T12OM in register IS occurs. The service request output that will be activated is selected by bit field INPT12.
ENT12PM	7	rw	**Enable Interrupt for T12 Period-Match** 0_B No interrupt will be generated if the set condition for bit T12PM in register IS occurs. 1_B An interrupt will be generated if the set condition for bit T12PM in register IS occurs. The service request output that will be activated is selected by bit field INPT12.
ENT13CM	8	rw	**Enable Interrupt for T13 Compare-Match** 0_B No interrupt will be generated if the set condition for bit T13CM in register IS occurs. 1_B An interrupt will be generated if the set condition for bit T13CM in register IS occurs. The service request output that will be activated is selected by bit field INPT13.
ENT13PM	9	rw	**Enable Interrupt for T13 Period-Match** 0_B No interrupt will be generated if the set condition for bit T13PM in register IS occurs. 1_B An interrupt will be generated if the set condition for bit T13PM in register IS occurs. The service request output that will be activated is selected by bit field INPT13.
ENTRPF	10	rw	**Enable Interrupt for Trap Flag** 0_B No interrupt will be generated if the set condition for bit TRPF in register IS occurs. 1_B An interrupt will be generated if the set condition for bit TRPF in register IS occurs. The service request output that will be activated is selected by bit field INPERR.

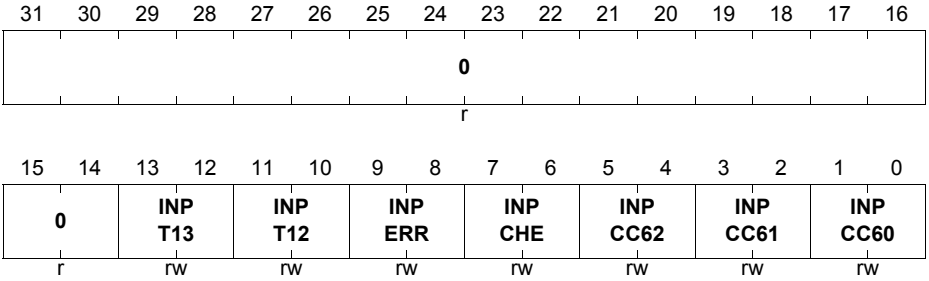
Field	Bits	Type	Description
ENCHE	12	rw	**Enable Interrupt for Correct Hall Event** 0_B No interrupt will be generated if the set condition for bit CHE in register IS occurs. 1_B An interrupt will be generated if the set condition for bit CHE in register IS occurs. The service request output that will be activated is selected by bit field INPCHE.
ENWHE	13	rw	**Enable Interrupt for Wrong Hall Event** 0_B No interrupt will be generated if the set condition for bit WHE in register IS occurs. 1_B An interrupt will be generated if the set condition for bit WHE in register IS occurs. The service request output that will be activated is selected by bit field INPERR.
ENIDLE	14	rw	**Enable Idle** This bit enables the automatic entering of the idle state (bit IDLE will be set) after a wrong hall event has been detected (bit WHE is set). During the idle state, the bit field MCMP is automatically cleared. 0_B The bit IDLE is not automatically set when a wrong hall event is detected. 1_B The bit IDLE is automatically set when a wrong hall event is detected.
ENSTR	15	rw	**Enable Multi-Channel Mode Shadow Transfer Interrupt** 0_B No interrupt will be generated if the set condition for bit STR in register IS occurs. 1_B An interrupt will be generated if the set condition for bit STR in register IS occurs. The service request output that will be activated is selected by bit field INPCHE.
0	11, [31:16]	r	**Reserved;** Returns 0 if read; should be written with 0.

29.9.2.5 Interrupt Node Pointer Register

Register INP contains the interrupt node pointers allowing a flexible interrupt handling. These bit fields define which service request output will be activated if the corresponding interrupt event occurs and the interrupt generation for this event is enabled.

INP

Interrupt Node Pointer Register **(AC_H)** **Reset Value: 0000 3940$_H$**



Field	Bits	Type	Description
INPCC60, INPCC61, INPCC62	[1:0], [3:2], [5:4]	rw	**Interrupt Node Pointer for Channel CC6x Interrupts** This bit field defines the service request output activated due to a set condition for bit CC6xR (if enabled by bit ENCC6xR) or for bit CC6xF (if enabled by bit ENCC6xF). 00_B Service request output SR0 is selected. 01_B Service request output SR1 is selected. 10_B Service request output SR2 is selected. 11_B Service request output SR3 is selected.
INPCHE	[7:6]	rw	**Interrupt Node Pointer for the CHE Interrupt** This bit field defines the service request output activated due to a set condition for bit CHE (if enabled by bit ENCHE) of for bit STR (if enabled by bit ENSTR). Coding see INPCC6x.
INPERR	[9:8]	rw	**Interrupt Node Pointer for Error Interrupts** This bit field defines the service request output activated due to a set condition for bit TRPF (if enabled by bit ENTRPF) or for bit WHE (if enabled by bit ENWHE). Coding see INPCC6x.
INPT12	[11:10]	rw	**Interrupt Node Pointer for Timer12 Interrupts** This bit field defines the service request output activated due to a set condition for bit T12OM (if enabled by bit ENT12OM) or for bit T12PM (if enabled by bit ENT12PM). Coding see INPCC6x.

Field	Bits	Type	Description
INPT13	[13:12]	rw	**Interrupt Node Pointer for Timer13 Interrupt** This bit field defines the service request output activated due to a set condition for bit T13CM (if enabled by bit ENT13CM) or for bit T13PM (if enabled by bit ENT13PM). Coding see INPCC6x.
0	[31:14]	r	**Reserved;** Returns 0 if read; should be written with 0.

29.9.3 Service Request Control Registers

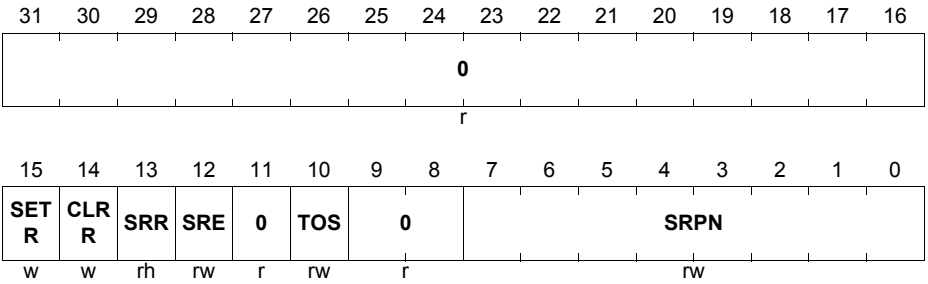
Each CC6x kernel has four service request outputs which are connected to four Service Request Nodes (SRN). Each SRN contains a Service Request Control Register.

CCU60_SRCx (x = 0-3)
CCU60 Service Request Control Register
(FC_H-x*4) **Reset Value: 0000 0000_H**

CCU61_SRCx (x = 0-3)
CCU61 Service Request Control Register
(FC_H-x*4) **Reset Value: 0000 0000_H**

CCU62_SRCx (x = 0-3)
CCU62 Service Request Control Register
(FC_H-x*4) **Reset Value: 0000 0000_H**

CCU63_SRCx (x = 0-3)
CCU63 Service Request Control Register
(FC_H-x*4) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
SRPN	[7:0]	rw	**Service Request Priority Number**

SRR	13	rh	**Service Request Flag**
CLRR	14	w	**Request Clear Bit**
SETR	15	w	**Request Set Bit**
0	[9:8], 11, [31:16]	r	**Reserved** Read as 0; should be written with 0.

29.10 General Module Operation

This section provides information about the:

- Configuration of the behavior of the different device operating modes (see mode control description in **Section 29.10.1**)
- Input selection (see **Section 29.10.2**)
- General register description (see **Section 29.10.4**)

29.10.1 Mode Control

The mode control concept for system control tasks, such as power saving, or suspend request for debugging, allows to program the module behavior under different device operating conditions. The behavior of a CCU6 kernel can be programmed for each of the device operating modes, that are requested by the global state control part of the SCU. Therefore, a CCU6 module provides a kernel state configuration register **KSCFG** defining the behavior in the following device operating modes:

- **Normal operation:**
  This operating mode is the default operating mode when neither a suspend request nor a clock-off request are pending. The module clock is not switched off and the CCU6 registers can be read or written. The kernel behavior is defined by KSCFG.NOMCFG.
- **Suspend mode:**
  This operating mode is requested when a suspend request (issued by a debugger through OCDS) is pending in the device. The module clock is not switched off and the CCU6 registers can be read or written. The kernel behavior is defined by KSCFG.SUMCFG.
- **Clock-off mode:**
  This operating mode is requested for power saving purposes. The module clock is switched off automatically when all kernels of the CCU6 module reached their specified state in a stop mode. In this case, CCU6 registers can not be accessed. The kernel behavior is defined by KSCFG.COMCFG. The clock-off mode is requested by a sleep request of the FPI bus.

The kernel distinguishes four different blocks (T12, T13, Hall logic, and trap logic). These blocks can be individually enabled for the request of stop mode 0 and stop mode 1 by the sensitivity bits **KSCSR**.SBx. If the request sensitivity is disabled, the block continues normal operation. If the request sensitivity is enabled, the block operates as specified for the selected stop mode.
The complete CCU6 acknowledge is given to the GSC when all four blocks have reached their defined end condition.

Table 29-12 CCU6 Functional Blocks

Block	Function	Sensitivity Bit
0	**Timer T12:** A functional enable is delivered until the specified stop condition is reached. Then, T12 stops counting and the CC6xIN input stages are frozen.	KSCSR.SB0
1	**Timer T13:** A functional enable is delivered until the specified stop condition is reached. Then, T13 stops counting.	KSCSR.SB1
2	**Hall Logic:** The hall logic is stopped immediately and the CCPOSx input stages are frozen.	KSCSR.SB2
3	**Trap Logic:** The trap logic is stopped immediately and the CTRAP input stage is frozen.	KSCSR.SB3

The behavior of the CCU6 kernel can be programmed for each of the device operating modes (normal operation and suspend mode). Therefore, it supports four kernel modes, as shown in **Table 29-13**.

Table 29-13 CCU6 Kernel Behavior

Kernel Mode	Kernel Behavior	Code
run mode 0	kernel operation as specified, no impact on CCU6 operation (same behavior for run mode 0 and run mode 1)	00_B
run mode 1		01_B

Table 29-13 CCU6 Kernel Behavior (cont'd)

Kernel Mode	Kernel Behavior	Code
stop mode 0	The sensitivity bits are taken into account for: **T12 block**: Timer T12 continues normal operation (if running) until they reach the end of the PWM period and then it stops (same stop condition as in single shot mode). When the timer stops, the CC6xIN inputs are frozen. **T13 block**: Timer T13 continues normal operation (if running) until they reach the end of the PWM period and then it stops (same stop condition as in single shot mode). **Hall logic block**: The CCPOSx input values are frozen. **Trap logic block**: The CTRAP input value is frozen.	10_B
stop mode 1	The output lines enabled for the trap condition are set to their passive values (similar to a trap state). The sensitivity bits are taken into account for: **T12 block**: Timer T12 stops immediately and CC6xIN inputs are frozen. **T13 block**: Timer T13 stops. **Hall logic block**: The CCPOSx input values are frozen. **Trap logic block**: The CTRAP input value is frozen.	11_B

Generally, bit field KSCFG.NOMCFG should be configured for run mode 0 as default setting for standard operation. If a CCU6 kernel should not react to a suspend request (and to continue operation as in normal mode), bit field KSCFG.SUMCFG has to be configured with the same value as KSCFG.NOMCFG. If a CCU6 kernel should show a different behavior and stop operation when a specific stop condition is reached, the code for stop mode 0 or stop mode 1 has to be written to KSCFG.SUMCFG.
A similar mechanism applies for the clock-off mode with the possibility to program the desired behavior by bit field KSCFG.COMCFG.

Note: The stop mode selection strongly depends on the application needs and it is very unlikely that different stop modes are required in parallel in the same application. As a result, only one stop mode type (either 0 or 1) should be used in the bit fields in register KSCFG. Do not mix stop mode 0 and stop mode 1 and avoid transitions from stop mode 0 to stop mode 1 (or vice versa) for the CCU6 module.

If the module clock is disabled by KSCFG.MODEN = 0 or in clock-off mode when the stop condition is reached (in stop mode 0 or 1), the module can not be accessed by read or write operations (except register KSCFG and KSCSR that can always be accessed). As a consequence, it can not be configured.
Please note that bit KSCFG.MODEN should only be set by SW while all configuration fields are configured for run mode 0.

29.10.2 Input Selection

Each CCU6 input signal can be selected from a vector of four or eight possible inputs by programming the port input select registers **PISEL0** and **PISEL2**. This permits to adapt the pin functionality of the device to the application requirements.
The output pins for the module output signals are chosen in the ports.

Naming convention:
The input vector CC60IN[D:A] for input signal CC60IN is composed of the signals CC60INA to CC60IND.

Note: All functional inputs of the CCU6 are synchronized to f_{CC6} before they affect the module internal logic. The resulting delay of $2/f_{CC6}$ and for asynchronous signals an additional uncertainty of $1/f_{CC6}$ have to be taken into account for precise timing calculation. An edge of an input signal can only be correctly detected if the high phase and the low phase of the input signal are both longer than $1/f_{CC6}$.

29.10.3 Input Monitoring

A selected event which occurs at each CCU6 input signal can be monitored through **IMON**.x. Every input signal can be included for the detection of a lost bit event (**IMON**.LBE) if enabled through its individual lost indicator enable bits (**LI**.yEN). The lost bit event occurs if a selected event occurs again with the previous event captured (IMON.x remains set) and its lost indicator is enabled for at least one of the monitored input signals. The lost bit event can be enabled (**LI**.LBEEN) for an interrupt to be generated at one of the SRx line, selected through **LI**.INPLBE. The LBE output signal of the kernel can be connected to a capture input to indicate when does the lost bit event happens. See **Section 29.12**.

The lost bit event can be used as a kind of interrupt or event watchdog to monitor if an action related to an event has been processed before a second event of the same type occurs. Like this, if a certain event is treated by an interrupt that should be monitored, the related indication flag has to be cleared by SW. If the SW has not yet cleared the flag and the event occurs again, the event is considered as being lost and another interrupt can be generated to inform the system about the loss. This can be also used to indicate that input events occur too often and the main task has not enough time to treat them.

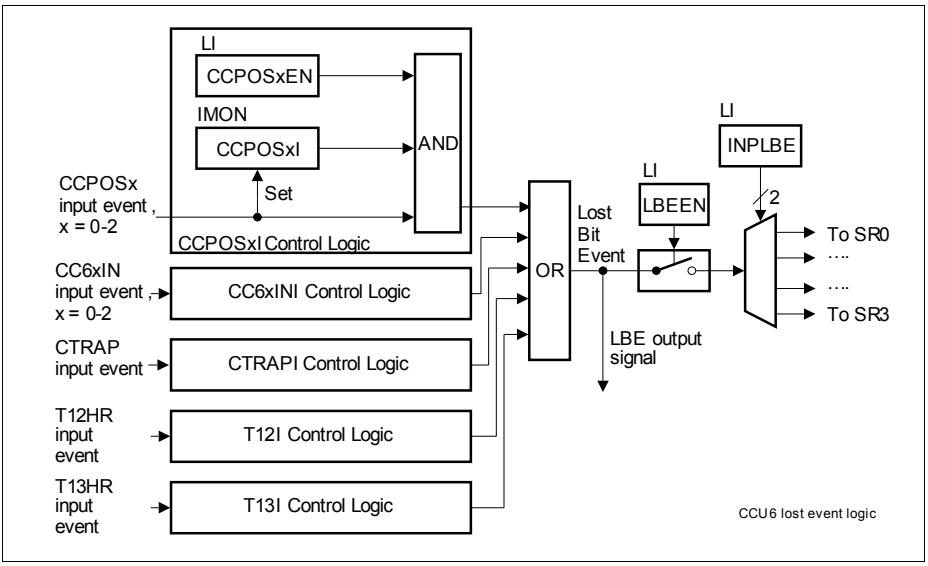

Figure 29-44 Lost Event Logic

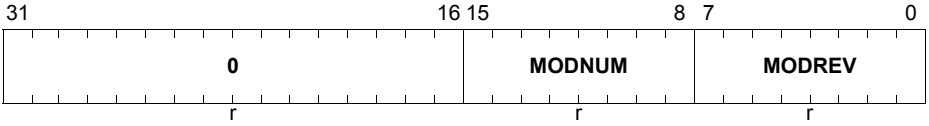
29.10.4 General Registers

29.10.4.1 ID Register

Reset value of the first version of ID register in TC1387 is 0000 5408$_H$.

The CCU6 Module Identification Register ID contains read-only information about the module identification number and its revision.

ID
Module Identification Register **(08_H)** **Reset Value: 0000 54XX$_H$**

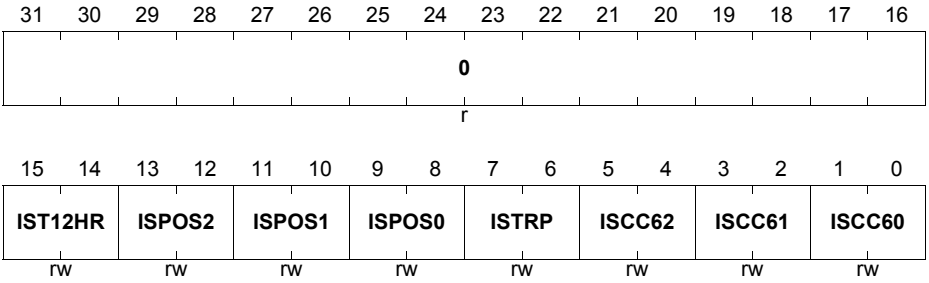


Field	Bits	Type	Description
MODREV	[7:0]	r	**Module Revision Number** MOD_REV defines the module revision number. The value of a module revision starts with 01_H (first revision), 02_H, 03_H, ... up to FF_H.
MODNUM	[15:8]	r	**Module Number Value** This bit field defines the module identification number for the CCU6: 54_H
0	[31:16]	r	**Reserved** Read as 0.

29.10.4.2 Port Input Select Registers

Registers PISEL0 and PISEL2 contain bit fields selecting the actual input signal for the module inputs.

PISEL0
Port Input Select Register 0 **(10_H)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
ISCC60	[1:0]	rw	**Input Select for CC60** This bit field defines the input signal used as CC60 capture input. 00_B The signal CC60INA is selected. 01_B The signal CC60INB is selected. 10_B The signal CC60INC is selected. 11_B The signal CC60IND is selected.
ISCC61	[3:2]	rw	**Input Select for CC61** This bit field defines the input signal used as CC61 capture input. 00_B The signal CC61INA is selected. 01_B The signal CC61INB is selected. 10_B The signal CC61INC is selected. 11_B The signal CC61IND is selected.
ISCC62	[5:4]	rw	**Input Select for CC62** This bit field defines the input signal used as CC62 capture input. 00_B The signal CC62INA is selected. 01_B The signal CC62INB is selected. 10_B The signal CC62INC is selected. 11_B The signal CC62IND is selected.

Field	Bits	Type	Description
ISTRP	[7:6]	rw	**Input Select for CTRAP** This bit field defines the input signal used as CTRAP input. 00_B The signal CTRAPA is selected. 01_B The signal CTRAPB is selected. 10_B The signal CTRAPC is selected. 11_B The signal CTRAPD is selected.
ISPOS0	[9:8]	rw	**Input Select for CCPOS0** This bit field defines the input signal used as CCPOS0 input. 00_B The signal CCPOS0A is selected. 01_B The signal CCPOS0B is selected. 10_B The signal CCPOS0C is selected. 11_B The signal CCPOS0D is selected.
ISPOS1	[11:10]	rw	**Input Select for CCPOS1** This bit field defines the input signal used as CCPOS1 input. 00_B The signal CCPOS1A is selected. 01_B The signal CCPOS1B is selected. 10_B The signal CCPOS1C is selected. 11_B The signal CCPOS1D is selected.
ISPOS2	[13:12]	rw	**Input Select for CCPOS2** This bit field defines the input signal used as CCPOS2 input. 00_B The signal CCPOS2A is selected. 01_B The signal CCPOS2B is selected. 10_B The signal CCPOS2C is selected. 11_B The signal CCPOS2D is selected.

Field	Bits	Type	Description
IST12HR	[15:14]	rw	**Input Select for T12HR** This bit field defines the input signal used as T12HR input. 00_B Either signal T12HRA (if T12EXT = 0) or T12HRE (if T12EXT = 1) is selected. 01_B Either signal T12HRB (if T12EXT = 0) or T12HRF (if T12EXT = 1) is selected. 10_B Either signal T12HRC (if T12EXT = 0) or T12HRG (if T12EXT = 1) is selected. 11_B Either signal T12HRD (if T12EXT = 0) or T12HRH (if T12EXT = 1) is selected.
0	[31:16]	r	**Reserved** Returns 0 if read, should be written with 0.

PISEL2

Port Input Select Register 2 **(14_H)** **Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r								rw	rw	rw		rw		rw	

Field	Bits	Type	Description
IST13HR	[1:0]	rw	**Input Select for T13HR** This bit field defines the input signal used as T13HR input. 00_B Either signal T13HRA (if T13EXT = 0) or T13HRE (if T13EXT = 1) is selected. 01_B Either signal T13HRB (if T13EXT = 0) or T13HRF (if T13EXT = 1) is selected. 10_B Either signal T13HRC (if T13EXT = 0) or T13HRG (if T13EXT = 1) is selected. 11_B Either signal T13HRD (if T13EXT = 0) or T13HRH (if T13EXT = 1) is selected.
ISCNT12	[3:2]	rw	**Input Select for T12 Counting Input** This bit field defines the input event leading to a counting action of T12. 00_B The T12 prescaler generates the counting events. Bit TCTR4.T12CNT is not taken into account. 01_B Bit TCTR4.T12CNT written with 1 is a counting event. The T12 prescaler is not taken into account. 10_B The timer T12 is counting each rising edge detected in the selected T12HR signal. 11_B The timer T12 is counting each falling edge detected in the selected T12HR signal.
ISCNT13	[5:4]	rw	**Input Select for T13 Counting Input** This bit field defines the input event leading to a counting action of T13. 00_B The T13 prescaler generates the counting events. Bit TCTR4.T13CNT is not taken into account. 01_B Bit TCTR4.T13CNT written with 1 is a counting event. The T13 prescaler is not taken into account. 10_B The timer T13 is counting each rising edge detected in the selected T13HR signal. 11_B The timer T13 is counting each falling edge detected in the selected T13HR signal.
T12EXT	6	rw	**Extension for T12HR Inputs** This bit extends the 2-bit field IST12HR. 0_B One of the signals T12HR[D:A] is selected. 1_B One of the signals T12HR[H:E] is selected.

Field	Bits	Type	Description
T13EXT	7	rw	**Extension for T13HR Inputs** This bit extends the 2-bit field IST13HR. 0_B One of the signals T13HR[D:A] is selected. 1_B One of the signals T13HR[H:E] is selected.
0	[31:8]	r	**Reserved;** Returns 0 if read; should be written with 0.

29.10.4.3 Kernel State Configuration Register

The kernel state configuration register KSCFG allows the selection of the desired kernel modes for the different device operating modes.
Bit fields KSCFG.NOMCFG and KSCFG.COMCFG are reset by an application (class 3) reset. Bit field KSCFG.SUMCFG is reset by a debug (class 1) reset.

*Note: The coding of the bit fields NOMCFG, SUMCFG and COMCFG are described in **Table 29-13**.*

KSCFG
Kernel State Configuration Register

(18_H) **Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BP COM	0	COMCFG		BP SUM	0	SUMCFG		BP NOM	0	NOMCFG		SUS REQ	ACK	BP MOD EN	MOD EN
w	r	rw		w	r	rw		w	r	rw		rh	rh	w	rw

Field	Bits	Type	Description
MODEN	0	rw	**Module Enable** This bit enables the module kernel clock and the module functionality. 0_B The module is switched off immediately (without respecting a stop condition). It does not react on mode control actions and the module clock is switched off. The module does not react on read accesses and ignores write accesses (except to KSCFG). 1_B The module is switched on and can operate. After writing 1 to MODEN, it is recommended to read register KSCFG to avoid pipeline effects in the control block before accessing other CCU6 registers.
BPMODEN	1	w	**Bit Protection for MODEN** This bit enables the write access to the bit MODEN. It always reads 0. 0_B MODEN is not changed. 1_B MODEN is updated with the written value.
ACK	2	rh	**Module Acknowledge** This bit monitors the state of the CCU6 module's acknowledge on incoming requests. 0_B The acknowledge is not activated, because at least one of the module kernels is in a transition phase. 1_B The acknowledge is activated, because all module kernels have reached the requested state.
SUSREQ	3	rh	**Suspend Request** This bit monitors the state of the CCU6 module's suspend request input, requested through OCDS. The value is only valid when there is no sleep request. In the event that there is a sleep request, the value is ignored and COMCFG is considered as the kernel mode. 0_B A suspend mode is not requested and bit field NOMCFG defines the CCU6 kernel mode. 1_B A suspend mode is requested and bit field SUMCFG defines the CCU6 kernel mode.

Field	Bits	Type	Description
NOMCFG	[5:4]	rw	**Normal Operation Mode Configuration** This bit field defines the kernel mode applied in normal operation mode. 00_B Run mode 0 is selected. 01_B Run mode 1 is selected. 10_B Stop mode 0 is selected. 11_B Stop mode 1 is selected.
BPNOM	7	w	**Bit Protection for NOMCFG** This bit enables the write access to the bit field NOMCFG. It always reads 0. 0_B NOMCFG is not changed. 1_B NOMCFG is updated with the written value.
SUMCFG	[9:8]	rw	**Suspend Mode Configuration** This bit field defines the kernel mode applied in suspend mode. Coding like NOMCFG.
BPSUM	11	w	**Bit Protection for SUMCFG** This bit enables the write access to the bit field SUMCFG. It always reads 0. 0_B SUMCFG is not changed. 1_B SUMCFG is updated with the written value.
COMCFG	[13:12]	rw	**Clock Off Mode Configuration** This bit field defines the kernel mode applied in clock-off mode. Coding like NOMCFG.
BPCOM	15	w	**Bit Protection for COMCFG** This bit enables the write access to the bit field COMCFG. It always reads 0. 0_B COMCFG is not changed. 1_B COMCFG is updated with the written value.
0	6, 10, 14, [31:16]	r	**Reserved** Returns 0 if read; should be written with 0.

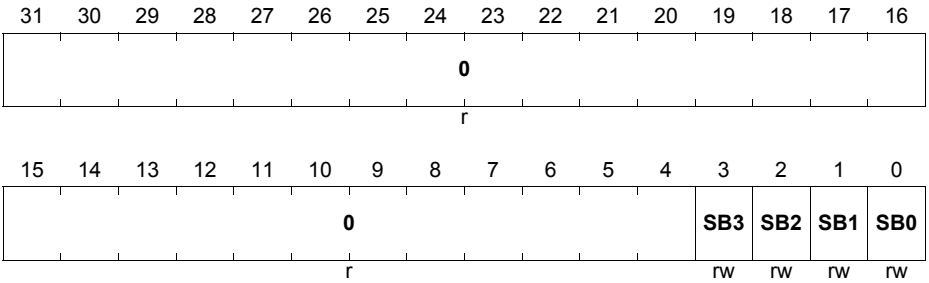
Note: The bit protection bits BPxxx allow partly modification of the configuration bits with a single write operation (without the need of a read-modify-write mechanism handled by the CPU).

29.10.4.4 Kernel State Sensitivity Control Register

The kernel state control sensitivity register bits define which internal block is effected by stop modes 0 and 1.

KSCSR
Kernel State Control Sensitivity Register

($1C_H$) **Reset Value: $0000\ 0000_H$**

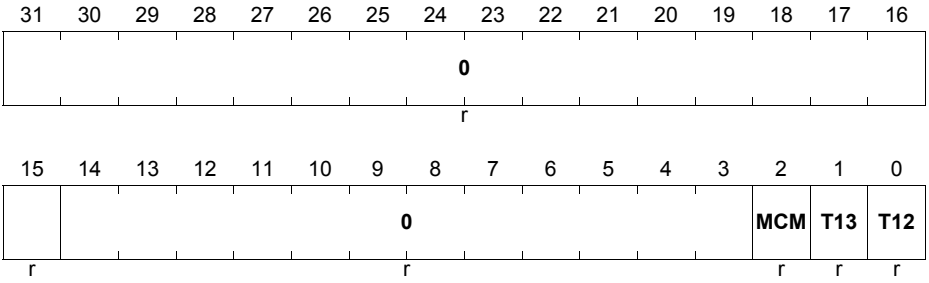


Field	Bits	Type	Description
SB0, **SB1,** **SB2,** **SB3**	0, 1, 2, 3	rw	**Sensitivity Block x** This bit defines if block x of the CCU6 kernel is sensitive to stop mode 0 or stop mode 1. The functional definition of the blocks is given in **Table 29-12**. 0_B Block x is not sensitive to stop mode 0 or stop mode 1 and behaves like in run mode 0. It continues normal operation without respecting the defined stop condition. 1_B Block x is sensitive to stop mode 0 or stop mode 1. It is respecting the defined stop condition.
0	[31:4]	r	**Reserved;** Returns 0 if read; should be written with 0.

29.10.4.5 Module Configuration Register

The module configuration register contains bits describing the functionality that is available in the CCU6 module.

MCFG
Module Configuration Register (04_H) Reset Value: 0000 0007_H



Field	Bits	Type	Description
T12	0	r	**T12 Available** This bit indicates if the T12 block is available. 0_B The T12 block is not available. A write access to T12PR is ignored. 1_B The T12 block is available. A write access to T12PR is executed.
T13	1	r	**T13 Available** This bit indicates if the T13 block is available. 0_B The T13 block is not available. A write access to T13PR is ignored. 1_B The T13 block is available. A write access to T13PR is executed.
MCM	2	r	**Multi-Channel Mode Available** This bit indicates if the multi-channel mode functionality is available. 0_B The multi-channel mode functionality is not available. A write access to MCMOUTS is ignored. 1_B The multi-channel mode functionality is available. A write access to MCMOUTS is executed.
0	[31:3]	r	**Reserved;** read as 0; should be written with 0.

Note: The MCFG register can be modified only if the signal which comes from the watchdog timer mechanism allows.

29.10.4.6 Input Monitoring Register

The input monitoring register monitors the occurence of a selected event for the input signals. If a hardware event triggers the setting of bit IMON.x and the same bit is written with 1 via software at the same time, then the corresponding bit is cleared (software overrules hardware). The lost bit event is indicated if an event is detected again at one or more input signals with its lost indicator enabled.

Note: The register is only applicable in capture modes if the edges are selected through T12MSEL.MSEL6x.

IMON
Input Monitoring Register **(98_H)** **Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Bits	Type	Description
LBE	0	rwh	**Lost Bit Event** This bit determines if a lost bit event has occured. A lost bit event occurs when a selected event occurs again with the previous event captured (IMON.x remains set) and its lost indicator is enabled, for at least one of the monitored input signals. The bit can be cleared by writing a 1 to the same bit position, while writing a 0 has no effect. 0_B The lost bit event has not occured. 1_B The lost bit event has occured.
CCPOSxI (x = 0 -2)	x + 1	rwh	**Event indication for input signal CCPOSx** The bit determines if the selected event has occured via an edge detection. The bit can be cleared by writing a 1 to the same bit position, while writing a 0 has no effect. 0_B A selected event has not occured. 1_B Edge detection indicates a selected event has occured. *Note: The dedicated edge is indicated for a selected event if Hysteretic-like Control or Capture modes are initialised in T12MSEL.MSEL6x. If these modes are not selected, then all edges will be indicated as an event for the inputs.*
CC6xINI (x = 0 -2)	x + 4	rwh	**Event indication for input signal CC6xIN** The bit determines if the selected event has occured via an edge detection. The bit can be cleared by writing a 1 to the same bit position, while writing a 0 has no effect. 0_B A selected event has not occured. 1_B Edge detection indicates a selected event has occured.
CTRAPI	7	rwh	**Event indication for input signal CTRAP** The bit determines if the selected event has occured via an edge detection. The bit can be cleared by writing a 1 to the same bit position, while writing a 0 has no effect. 0_B An event has not occured. 1_B Edge detection indicates an event has occured.

Field	Bits	Type	Description
T12HRI	8	rwh	**Event indication for input signal T12HR** The bit determines if the selected event has occured via an edge detection. The bit can be cleared by writing a 1 to the same bit position, while writing a 0 has no effect. 0_B An event has not occured. 1_B Edge detection indicates an event has occured.
T13HRI	9	rwh	**Event indication for input signal T13HR** The bit determines if the selected event has occured via an edge detection. The bit can be cleared by writing a 1 to the same bit position, while writing a 0 has no effect. 0_B An event has not occured. 1_B Edge detection indicates an event has occured.
0	[31:10]	r	**Reserved;** Returns 0 if read; should be written with 0.

29.10.4.7 Lost Indicator Register

The lost indicator register has the lost indicator enable bits for its detected event at the input signals. The lost bit event can then be enabled as an output signal through one of the service request lines.

LI

Lost Indicator Register **($9C_H$)** **Reset Value: $0000\ 0000_H$**

Field	Bits	Type	Description
CCPOSxEN (x = 0 -2)	x + 1	rw	**Lost Indicator Enable for input signal CCPOSx** This bit determines if the monitored event at the input signal is enabled for the detection of a lost bit event. 0_B Input signal is disabled for a lost bit event detection. 1_B Input signal is enabled for a lost bit event detection.
CC6xINEN (x = 0 -2)	x + 4	rw	**Lost Indicator Enable for input signal CC6xIN** This bit determines if the monitored event at the input signal is enabled for the detection of a lost bit event. 0_B Input signal is disabled for a lost bit event detection. 1_B Input signal is enabled for a lost bit event detection.

Field	Bits	Type	Description
CTRAPEN	7	rw	**Lost Indicator Enable for inputsignal CTRAP** This bit determines if the monitored event at the input signal is enabled for the detection of a lost bit event. 0_B Input signal is disabled for a lost bit event detection. 1_B Input signal is enabled for a lost bit event detection.
T12HREN	8	rw	**Lost Indicator Enable for input signal T12HR** This bit determines if the monitored event at the input signal is enabled for the detection of a lost bit event. 0_B Input signal is disabled for a lost bit event detection. 1_B Input signal is enabled for a lost bit event detection.
T13HREN	9	rw	**Lost Indicator Enable for input signal T13HR** This bit determines if the monitored event at the input signal is enabled for the detection of a lost bit event. 0_B Input signal is disabled for a lost bit event detection. 1_B Input signal is enabled for a lost bit event detection.
LBEEN	13	rw	**Interrupt Enable for Lost Bit Event** This bit determines if a SRx line is activated if lost bit event is detected. 0_B Lost bit event is disabled for the activation of a SRx line. 1_B Lost bit event is enabled for the activation of a SRx line.
INPLBE	[15:14]	rw	**Interrupt Node Pointer for lost bit event** This bit field defines which service request output line is selected to output an lost event alert for an enabled lost bit event. 00_B Service request output SR0 is selected. 01_B Service request output SR1 is selected. 10_B Service request output SR2 is selected. 11_B Service request output SR3 is selected.
0	0, [12:10], [31:16]	r	**Reserved;** Returns 0 if read; should be written with 0.

29.11 Implementation

This chapter describes the implementation of the CCU6 modules in the TC1798 device.

- Address map (see **Section 29.11.1**)
- Module output select (see **Section 29.11.2**)
- Synchronous start (see **Section 29.11.3**)
- Digital Connections (see **Section 29.12**)

29.11.1 Address Map

There are four CCU6 kernels in the TC1798, namely CCU60 to CCU63. The CCU6061 module consists of CCU60 and CCU61 kernels , while CCU6263 module consists of CCU62 and CCU63 kernels.

Table 29-14 Registers Address Space

Module	Base Address	End Address	Note
CCU60	F000 3000$_H$	F000 30FF$_H$	CCU6061 : consists of CCU60 and CCU61 kernels
CCU61	F000 3100$_H$	F000 31FF$_H$	CCU6061 : consists of CCU60 and CCU61 kernels

Table 29-15 Registers Overview - CCU6 Module Registers

Register Short Name	Register Long Name	Offset Addr.	Access Mode		Reset Value	Page
			Read	Write		
CCU6061 and CCU6263 Module Registers (only available in the address range of CCU60 and CCU62, respectively)						
CCU60_MOSEL	CCU60 Module Output Select Register	0C$_H$	U, SV	U, SV	0000 0000$_H$	29-136
CCU62_MOSEL	CCU62 Module Output Select Register	0C$_H$	U, SV	U, SV	0000 0000$_H$	29-138

29.11.1.1 Module Registers

Module Output Select Register

MOSEL contains bit fields to select the output signal from the CCU6061 or CCU6263 for the trigger signals to the ADCx modules.

CCU60_MOSEL
CCU60 Module Output Select Register($0C_H$) **Reset Value: $0000\ 0000_H$**

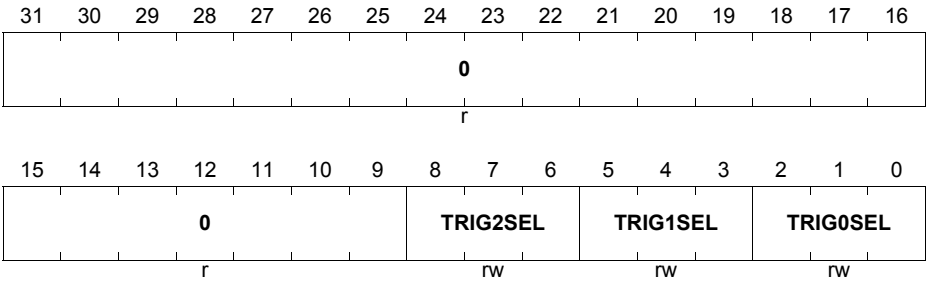
Field	Bits	Type	Description
TRIG0SEL	[2:0]	rw	**Output Trigger Select for CCU6061 TRIG0** This bit field defines the output signal from the module pair used as the trigger signal to ADCx inputs. 000_B The signal CCU60_COUT63 is selected. 001_B The signal CCU61_COUT63 is selected. 010_B The signal CCU60_CC60 is selected. 011_B The signal CCU61_CC60 is selected. 100_B The signal CCU60_SR1 is selected. 101_B The signal CCU61_SR1 is selected. 110_B The signal CCU60_SR3 is selected. 111_B The signal CCU61_SR3 is selected.
TRIG1SEL	[5:3]	rw	**Output Trigger Select for CCU6061 TRIG1** This bit field defines the output signal from the module pair used as the trigger signal to ADCx inputs. 000_B The signal CCU60_COUT63 is selected. 001_B The signal CCU61_COUT63 is selected. 010_B The signal CCU60_CC61 is selected. 011_B The signal CCU61_CC61 is selected. 100_B The signal CCU60_SR1 is selected. 101_B The signal CCU61_SR1 is selected. 110_B The signal CCU60_SR3 is selected. 111_B The signal CCU61_SR3 is selected.
TRIG2SEL	[8:6]	rw	**Output Trigger Select for CCU6061 TRIG2** This bit field defines the output signal from the module pair used as the trigger signal to ADCx inputs. 000_B The signal CCU60_COUT63 is selected. 001_B The signal CCU61_COUT63 is selected. 010_B The signal CCU60_CC62 is selected. 011_B The signal CCU61_CC62 is selected. 100_B The signal CCU60_SR1 is selected. 101_B The signal CCU61_SR1 is selected. 110_B The signal CCU60_SR3 is selected. 111_B The signal CCU61_SR3 is selected.
0	[31:9]	r	**Reserved** Returns 0 if read, should be written with 0.

CCU62_MOSEL

CCU62 Module Output Select Register($0C_H$) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
TRIG0SEL	[2:0]	rw	**Output Trigger Select for CCU6263 TRIG0** This bit field defines the output signal from the module pair used as the trigger signal to ADCx inputs. 000_B The signal CCU62_COUT63 is selected. 001_B The signal CCU63_COUT63 is selected. 010_B The signal CCU62_CC60 is selected. 011_B The signal CCU63_CC60 is selected. 100_B The signal CCU62_SR1 is selected. 101_B The signal CCU63_SR1 is selected. 110_B The signal CCU62_SR3 is selected. 111_B The signal CCU63_SR3 is selected.
TRIG1SEL	[5:3]	rw	**Output Trigger Select for CCU6263 TRIG1** This bit field defines the output signal from the module pair used as the trigger signal to ADCx inputs. 000_B The signal CCU62_COUT63 is selected. 001_B The signal CCU63_COUT63 is selected. 010_B The signal CCU62_CC61 is selected. 011_B The signal CCU63_CC61 is selected. 100_B The signal CCU62_SR1 is selected. 101_B The signal CCU63_SR1 is selected. 110_B The signal CCU62_SR3 is selected. 111_B The signal CCU63_SR3 is selected.

Field	Bits	Type	Description
TRIG2SEL	[8:6]	rw	**Output Trigger Select for CCU6263 TRIG2** This bit field defines the output signal from the module pair used as the trigger signal to ADCx inputs. 000_B The signal CCU62_COUT63 is selected. 001_B The signal CCU63_COUT63 is selected. 010_B The signal CCU62_CC62 is selected. 011_B The signal CCU63_CC62 is selected. 100_B The signal CCU62_SR1 is selected. 101_B The signal CCU63_SR1 is selected. 110_B The signal CCU62_SR3 is selected. 111_B The signal CCU63_SR3 is selected.
0	[31:9]	r	**Reserved** Returns 0 if read, should be written with 0.

29.11.2 Module Output Select

For CCU6061 module, there are 3 trigger signals which are selectable from the output signals from CCU60 and CCU61 kernels. Similarly, CCU6263 module allows up to 3 output trigger signals from CCU62 and CCU63 kernels.

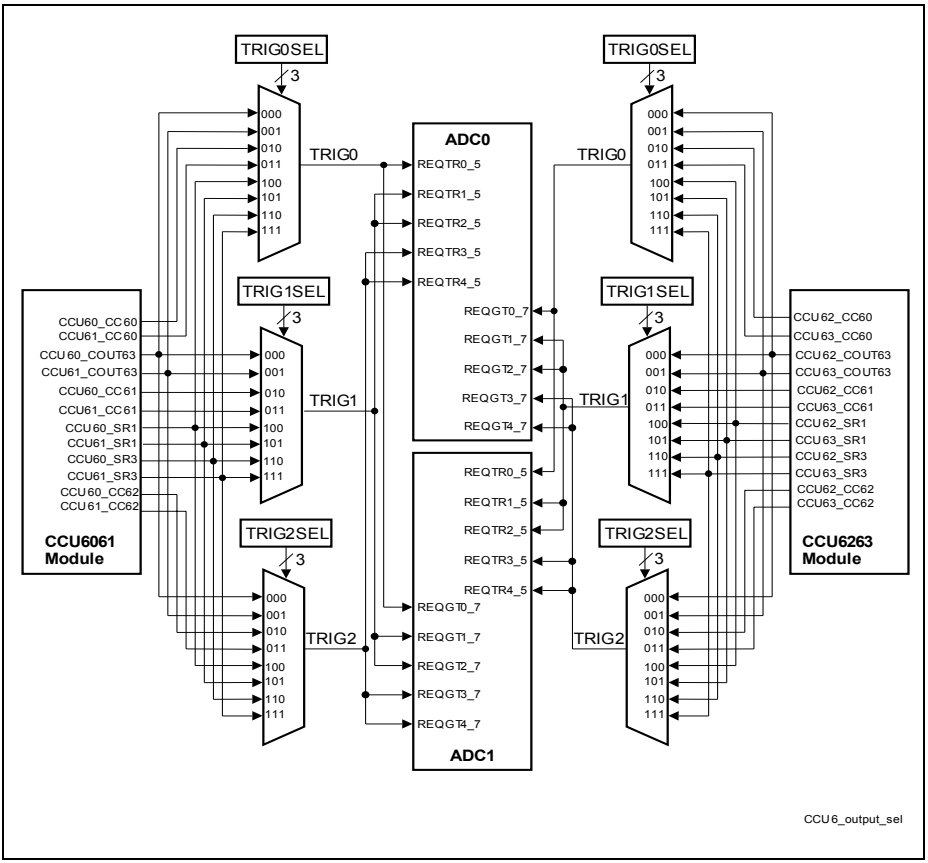


Figure 29-45 Output select trigger

29.11.3 Synchronous Start

Synchronous start of the capture/compare timers are supported by control bits SYSCON.CCTRIG0 and SYSCON.CCTRIG1 in the SCU module. Bit SYSCON.CCTRIG0 is connected to the T12HR and T13HR for CCU60 and CCU61 kernels while bit SYSCON.CCTRIG1 is connected to the T12HR and T13HR for CCU62 and CCU63 kernels.

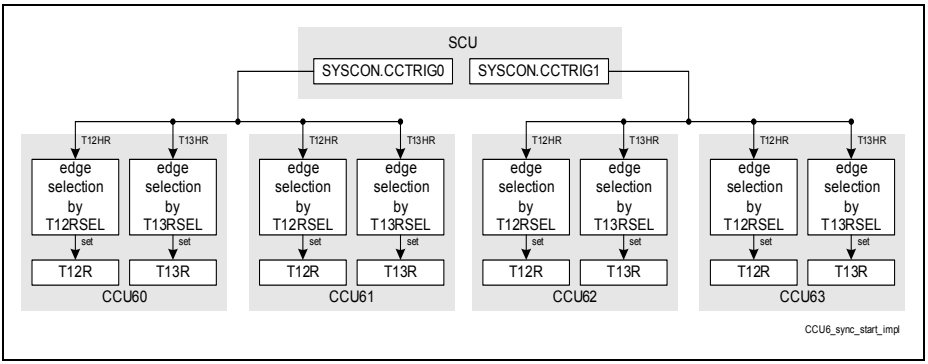

Figure 29-46 Synchronization Concept in TC1798

29.12 Digital Connections

The following tables show the digital connections of the CCU6x modules with other modules or pins in the TC1798 device.
Each input signal can be selected among 4 or 8 possible input lines, e.g. the input vector for input signal CC60IN is composed of CC60IN[D:A], whereas the input vectors for T12HR and T13HR are composed of T12HR[H:A] and T13HR[H:A]. The following sections refer to the interface signals.

Note: All functional inputs of the CCU6 are synchronized to f_{CC6} before they can affect the module internal logic. The resulting delay of $2/f_{CC6}$ and an uncertainty of $1/f_{CC6}$ have to be taken into account for precise timing calculation.
An edge of an input signal can only be correctly detected if both, the high phase and the low phase of the input signal are each longer than $1/f_{CC6}$.

29.12.1 Connections of CCU60

This table describes the module interconnections of CCU60.

30 The General Purpose Timer 12 (GPT12)

The General Purpose Timer 12 consist out of the blocks GPT1 and GPT2, that have a very flexible multifunctional timer structures which may be used for timing, event counting, pulse width measurement, pulse generation, frequency multiplication, and other purposes. They incorporate five 16-bit timers that are grouped into the two timer blocks GPT1 and GPT2. Each timer in each block may operate independently in a number of different modes such as Gated Timer or Counter Mode, or may be concatenated with another timer of the same block. Each block has alternate input/output functions and specific interrupts associated with it.

Note: Input signals can be selected from several sources by register PISEL.

Block GPT1 contains three timers/counters: The core timer T3 and the two auxiliary timers T2 and T4. The maximum resolution is $f_{GPT}/4$. The auxiliary timers of GPT1 may optionally be configured as reload or capture registers for the core timer. These registers are listed in **Section 30.1.6**.

- $f_{GPT}/4$ maximum resolution
- 3 independent timers/counters
- Timers/counters can be concatenated
- 4 operating modes:
  - Timer Mode
  - Gated Timer Mode
  - Counter Mode
  - Incremental Interface Mode
- Reload and Capture functionality
- Separate interrupts

Block GPT2 contains two timers/counters: The core timer T6 and the auxiliary timer T5. The maximum resolution is $f_{GPT}/2$. An additional Capture/Reload register (CAPREL) supports capture and reload operation with extended functionality. These registers are listed in **Section 30.2.7**.

The following list summarizes the features which are supported:

- $f_{GPT}/2$ maximum resolution
- 2 independent timers/counters
- Timers/counters can be concatenated
- 3 operating modes:
  - Timer Mode
  - Gated Timer Mode
  - Counter Mode
- Extended capture/reload functions via 16-bit capture/reload register CAPREL
- Separate interrupts

30.1 Timer Block GPT1

All three timers of block GPT1 (T2, T3, T4) can run in one of 4 basic modes: Timer Mode, Gated Timer Mode, Counter Mode, or Incremental Interface Mode. All timers can count up or down. Each timer of GPT1 is controlled by a separate control register TxCON.

Each timer has an input pin TxIN (alternate pin function) associated with it, which serves as the gate control in Gated Timer Mode, or as the count input in Counter Mode. The count direction (up/down) may be programmed via software or may be dynamically altered by a signal at the External Up/Down control input TxEUD (alternate pin function). An overflow/underflow of core timer T3 is indicated by the Output Toggle Latch T3OTL, whose state may be output on the associated pin T3OUT (alternate pin function). The auxiliary timers T2 and T4 may additionally be concatenated with the core timer T3 (through T3OTL) or may be used as capture or reload registers for the core timer T3.

The current contents of each timer can be read or modified by the CPU by accessing the corresponding timer count registers T2, T3, or T4. When any of the timer registers is written to by the CPU in the state immediately preceding a timer increment, decrement, reload, or capture operation, the CPU write operation has priority in order to guarantee correct results.

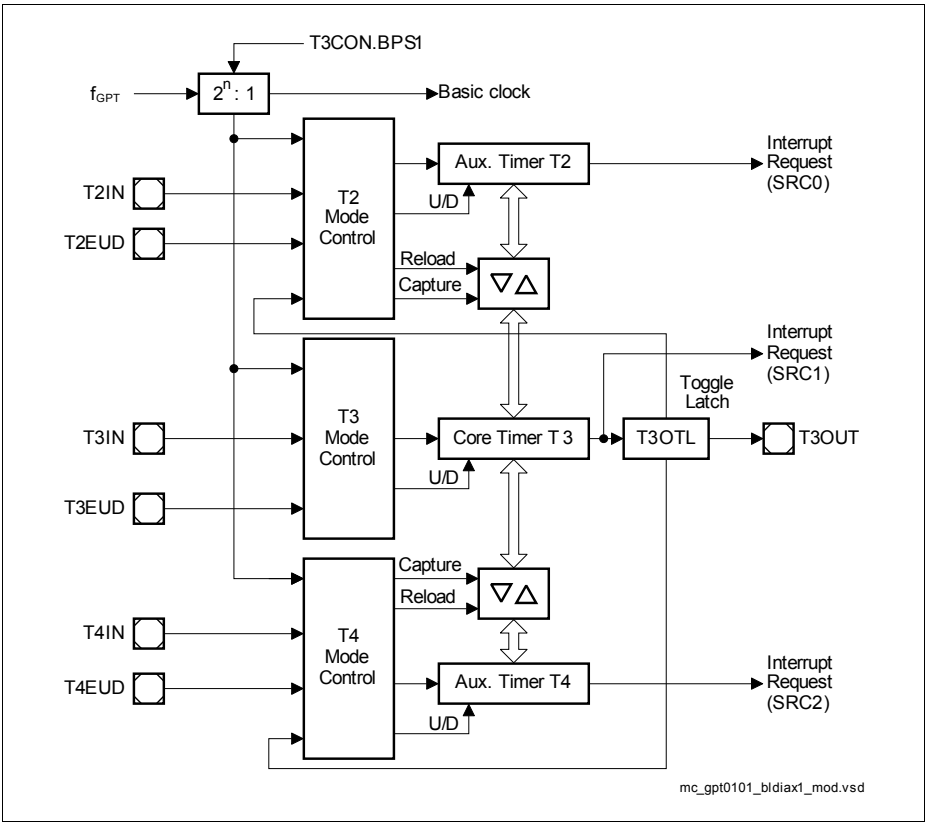

Figure 30-1 GPT1 Block Diagram

Note: The GPT1 block uses a finite state machine to control the actions. Since multiple interactions are possible between the timers (T2, T3, T4), these elements are processed sequentially. However, all actions are normally completed within one basic clock cycle. The GPT1 state machine has 8 states (4 states when BPS1 = 01_B) and processes the timers in the order T3 - T2 (all actions except capture) - T4 - T2 (capture).

30.1.1 GPT1 Core Timer T3 Control

The current contents of the core timer T3 are reflected by its count register T3. This register can also be written to by the CPU, for example, to set the initial start value.

T3CON

1) See **Table 30-1** for encoding of bits T3UD and T3UDE.

Timer T3 Run Control

The core timer T3 can be started or stopped by software through bit T3R (Timer T3 Run Bit). This bit is relevant in all operating modes of T3. Setting bit T3R will start the timer, clearing bit T3R stops the timer.

In Gated Timer Mode, the timer will only run if T3R = 1 and the gate is active (high or low, as programmed).

Note: When bit T2RC or T4RC in timer control register T2CON or T4CON is set, bit T3R will also control (start and stop) the auxiliary timer(s) T2 and/or T4.

Count Direction Control

The count direction of the GPT1 timers (core timer and auxiliary timers) can be controlled either by software or by the external input pin TxEUD (Timer Tx External Up/Down Control Input). These options are selected by bits TxUD and TxUDE in the respective control register TxCON. When the up/down control is provided by software (bit TxUDE = 0), the count direction can be altered by setting or clearing bit TxUD. When bit TxUDE = 1, pin TxEUD is selected to be the controlling source of the count direction. However, bit TxUD can still be used to reverse the actual count direction, as shown in **Table 30-1**. The count direction can be changed regardless of whether or not the timer is running.

Note: When pin TxEUD is used as external count direction control input, it must be configured as input (its corresponding direction control bit must be cleared).

Table 30-1 GPT1 Timer Count Direction Control

Pin TxEUD	Bit TxUDE	Bit TxUD	Count Direction	Bit TxRDIR
X	0	0	Count Up	0
X	0	1	Count Down	1
0	1	0	Count Up	0
1	1	0	Count Down	1
0	1	1	Count Down	1
1	1	1	Count Up	0

Timer 3 Output Toggle Latch

The overflow/underflow signal of timer T3 is connected to a block named ‘Toggle Latch’, shown in the timer mode diagrams. **Figure 30-2** illustrates the details of this block. An overflow or underflow of T3 will clock two latches: The first latch represents bit T3OTL in control register T3CON. The second latch is an internal latch toggled by T3OTL’s output. Both latch outputs are connected to the input control blocks of the auxiliary timers T2 and T4. The output level of the shadow latch will match the output level of T3OTL, but is delayed by one clock cycle. When the T3OTL value changes, this will result in a temporarily different output level from T3OTL and the shadow latch, which can trigger the selected count event in T2 and/or T4.

When software writes to T3OTL, both latches are set or cleared simultaneously. In this case, both signals to the auxiliary timers carry the same level and no edge will be detected. Bit T3OE (overflow/underflow output enable) in register T3CON enables the state of T3OTL to be monitored via an external pin T3OUT. When T3OTL is linked to an external port pin (must be configured as output), T3OUT can be used to control external HW. If T3OE = 1, pin T3OUT outputs the state of T3OTL. If T3OE = 0, pin T3OUT outputs a high level (as long as the T3OUT alternate function is selected for the port pin).

The trigger signals can serve as an input for the counter function or as a trigger source for the reload function of the auxiliary timers T2 and T4.

As can be seen from **Figure 30-2**, when latch T3OTL is modified by software to determine the state of the output line, also the internal shadow latch is set or cleared accordingly. Therefore, no trigger condition is detected by T2/T4 in this case.

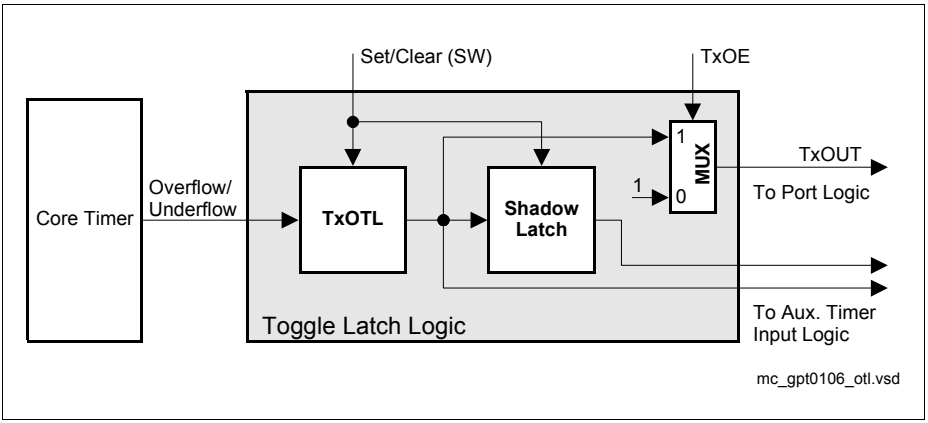

Figure 30-2 Block Diagram of the Toggle Latch Logic of Core Timer T3

30.1.2 GPT1 Core Timer T3 Operating Modes

Timer T3 can operate in one of several modes.

Timer 3 in Timer Mode

Timer Mode for the core timer T3 is selected by setting bitfield T3M in register T3CON to 000_B. In Timer Mode, T3 is clocked with the module's input clock f_{GPT} divided by two programmable prescalers controlled by bitfields BPS1 and T3I in register T3CON. Please see **Section 30.1.5** for details on the input clock options.

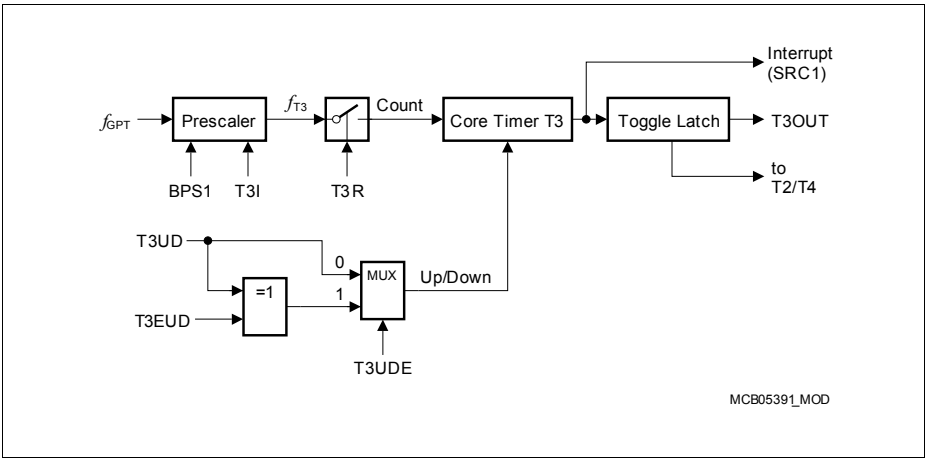

Figure 30-3 Block Diagram of Core Timer T3 in Timer Mode

Gated Timer Mode

Gated Timer Mode for the core timer T3 is selected by setting bitfield T3M in register T3CON to 010_B or 011_B. Bit T3M.0 (T3CON.3) selects the active level of the gate input. The same options for the input frequency are available in Gated Timer Mode as in Timer Mode (see **Section 30.1.5**). However, the input clock to the timer in this mode is gated by the external input pin T3IN (Timer T3 External Input).
To enable this operation, the associated pin T3IN must be configured as input, that is, the corresponding direction control bit must contain 0.

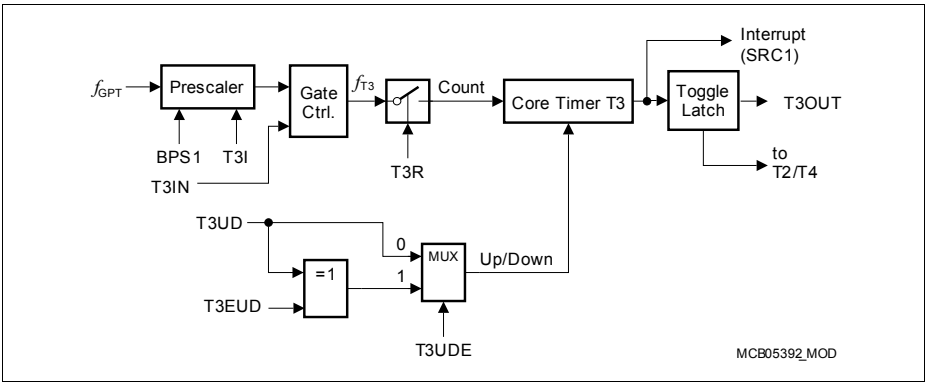

Figure 30-4 Block Diagram of Core Timer T3 in Gated Timer Mode

If T3M = 010_B, the timer is enabled when T3IN shows a low level. A high level at this line stops the timer. If T3M = 011_B, line T3IN must have a high level in order to enable the timer. Additionally, the timer can be turned on or off by software using bit T3R. The timer will only run if T3R is 1 and the gate is active. It will stop if either T3R is 0 or the gate is inactive.

Note: A transition of the gate signal at pin T3IN does not cause an interrupt request via SRC1.

Counter Mode

Counter Mode for the core timer T3 is selected by setting bitfield T3M in register T3CON to 001_B. In Counter Mode, timer T3 is clocked by a transition at the external input pin T3IN. The event causing an increment or decrement of the timer can be a positive, a negative, or both a positive and a negative transition at this line. Bitfield T3I in control register T3CON selects the triggering transition (see **Table 30-2**).

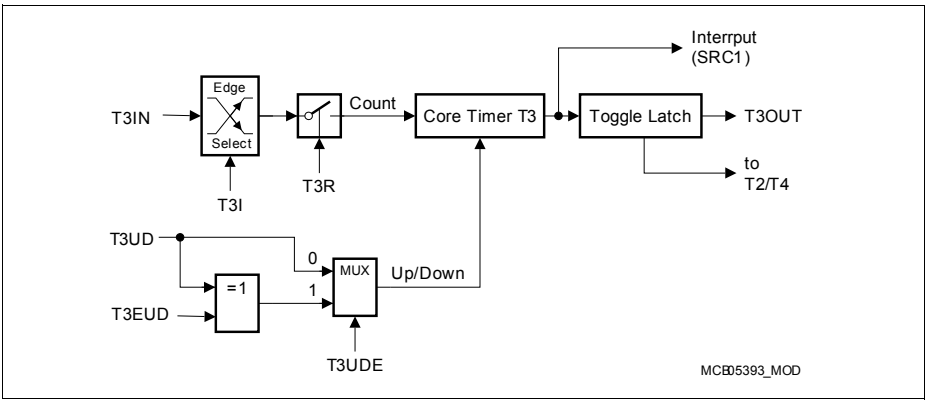

Figure 30-5 Block Diagram of Core Timer T3 in Counter Mode

Table 30-2 GPT1 Core Timer T3 (Counter Mode) Input Edge Selection

T3I	Triggering Edge for Counter Increment/Decrement
000_B	None. Counter T3 is disabled
001_B	Positive transition (rising edge) on T3IN
010_B	Negative transition (falling edge) on T3IN
011_B	Any transition (rising or falling edge) on T3IN
$1XX_B$	Reserved. Do not use this combination

For Counter Mode operation, pin T3IN must be configured as input (the respective direction control bit DPx.y must be 0). The maximum input frequency allowed in Counter Mode depends on the selected prescaler value. To ensure that a transition of the count input signal applied to T3IN is recognized correctly, its level must be held high or low for a minimum number of module clock cycles before it changes. This information can be found in **Section 30.1.5**.

Incremental Interface Mode

Incremental Interface Mode for the core timer T3 is selected by setting bitfield T3M in register T3CON to 110_B or 111_B. In Incremental Interface Mode, the two inputs associated with core timer T3 (T3IN, T3EUD) are used to interface to an incremental encoder. T3 is clocked by each transition on one or both of the external input pins to provide 2-fold or 4-fold resolution of the encoder input.

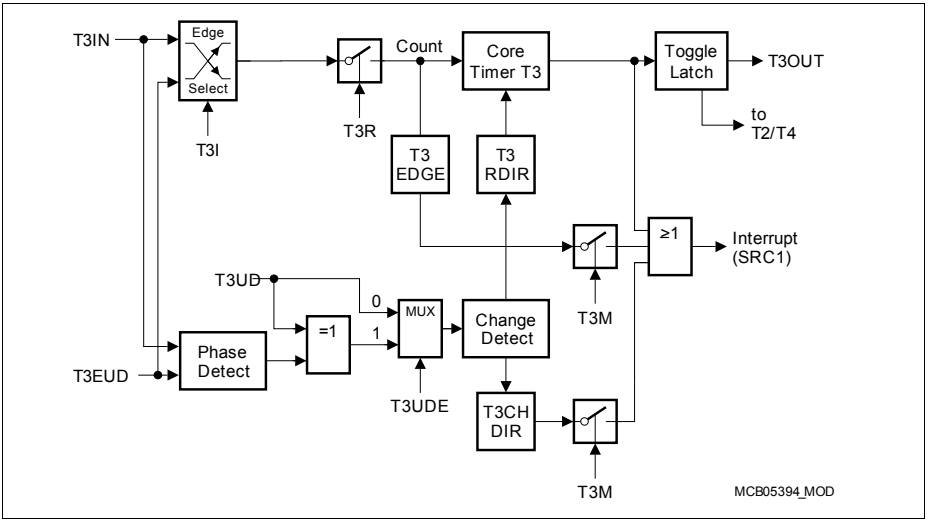

Figure 30-6 Block Diagram of Core Timer T3 in Incremental Interface Mode

Bitfield T3I in control register T3CON selects the triggering transitions (see **Table 30-3**). The sequence of the transitions of the two input signals is evaluated and generates count pulses as well as the direction signal. So T3 is modified automatically according to the speed and the direction of the incremental encoder and, therefore, its contents always represent the encoder's current position.

The interrupt request generation can be selected: In Rotation Detection Mode (T3M = 110_B), an interrupt request is generated each time the count direction of T3 changes. In Edge Detection Mode (T3M = 111_B), an interrupt request is generated each time a count edge for T3 is detected. Count direction, changes in the count direction, and count requests are monitored by status bits T3RDIR, T3CHDIR, and T3EDGE in register T3CON.

Table 30-3 Core Timer T3 (Incremental Interface Mode) Input Edge Selection

T3I	Triggering Edge for Counter Increment/Decrement
000_B	None. Counter T3 stops.
001_B	Any transition (rising or falling edge) on T3IN.
010_B	Any transition (rising or falling edge) on T3EUD.
011_B	Any transition (rising or falling edge) on any T3 input (T3IN or T3EUD).
$1XX_B$	Reserved. Do not use this combination.

The incremental encoder can be connected directly to the TC1798 without external interface logic. In a standard system, however, comparators will be employed to convert the encoder's differential outputs (such as A, $\overline{A}$) to digital signals (such as A). This greatly increases noise immunity.

Note: The third encoder output T0, that indicates the mechanical zero position, may be connected to an external interrupt input and trigger a reset of timer T3.
If input T4IN is available, T0 can be connected there and clear T3 automatically without requiring an interrupt.

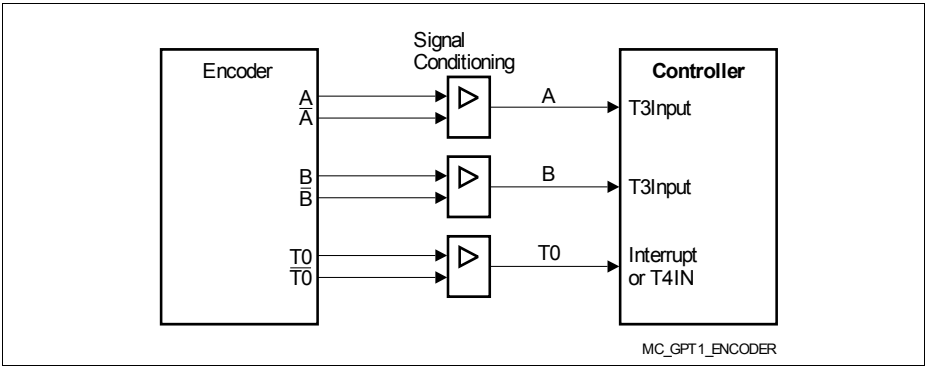

Figure 30-7 Connection of the Encoder to the TC1798

For Incremental Interface Mode operation, the following conditions must be met:

- Bitfield T3M must be 110_B or 111_B.
- Both pins T3IN and T3EUD must be configured as input.
- Pin T4IN must be configured as input, if used for T0.
- Bit T3UDE must be 1 to enable automatic external direction control.

The maximum count frequency allowed in Incremental Interface Mode depends on the selected prescaler value. To ensure that a transition of any input signal is recognized

correctly, its level must be held high or low for a minimum number of module clock cycles before it changes. This information can be found in **Section 30.1.5**.

As in Incremental Interface Mode two input signals with a 90° phase shift are evaluated, their maximum input frequency can be half the maximum count frequency.

In Incremental Interface Mode, the count direction is automatically derived from the sequence in which the input signals change, which corresponds to the rotation direction of the connected sensor. **Table 30-4** summarizes the possible combinations.

Table 30-4 GPT1 Core Timer T3 (Incremental Interface Mode) Count Direction

Level on Respective other Input	T3IN Input		T3EUD Input	
	Rising ↑	Falling ↓	Rising ↑	Falling ↓
High	Down	Up	Up	Down
Low	Up	Down	Down	Up

Figure 30-8 and **Figure 30-9** give examples of T3's operation, visualizing count signal generation and direction control. They also show how input jitter is compensated, which might occur if the sensor rests near to one of its switching points.

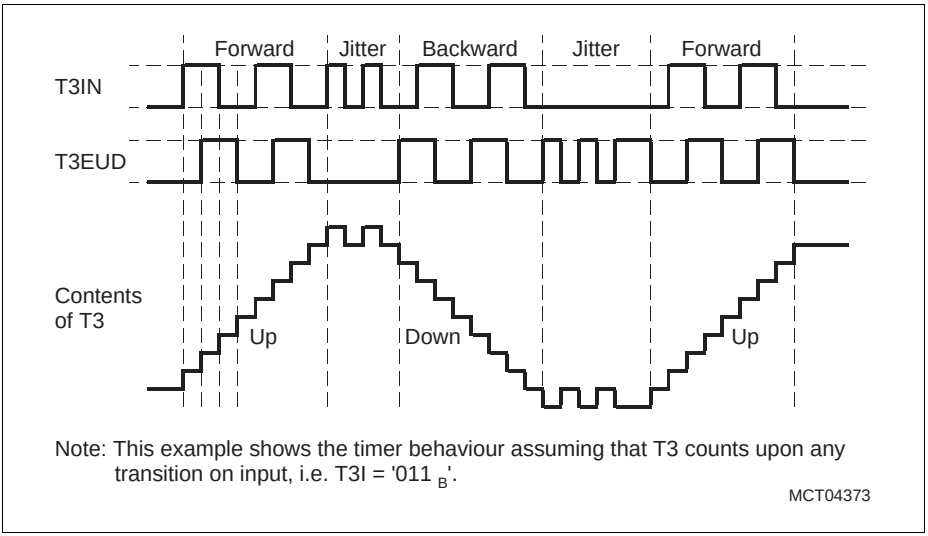

Figure 30-8 Evaluation of Incremental Encoder Signals, 2 Count Inputs

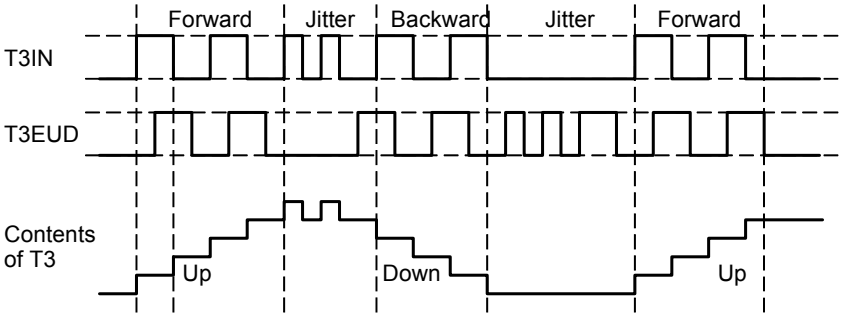

Figure 30-9 Evaluation of Incremental Encoder Signals, 1 Count Input

Note: Timer T3 operating in Incremental Interface Mode automatically provides information on the sensor's current position. Dynamic information (speed, acceleration, deceleration) may be obtained by measuring the incoming signal periods (see ***"Combined Capture Modes" on Page 30-59****).*

30.1.3 GPT1 Auxiliary Timers T2/T4 Control

Auxiliary timers T2 and T4 have exactly the same functionality. They can be configured for Timer Mode, Gated Timer Mode, Counter Mode, or Incremental Interface Mode with the same options for the timer frequencies and the count signal as the core timer T3. In addition to these 4 counting modes, the auxiliary timers can be concatenated with the core timer, or they may be used as reload or capture registers in conjunction with the core timer. The start/stop function of the auxiliary timers can be remotely controlled by the T3 run control bit. Several timers may thus be controlled synchronously.

The current contents of an auxiliary timer are reflected by its count register T2 or T4, respectively. These registers can also be written to by the CPU, for example, to set the initial start value.

The individual configurations for timers T2 and T4 are determined by their control registers T2CON and T4CON, that are organized identically. Note that functions which are present in all 3 timers of block GPT1 are controlled in the same bit positions and in the same manner in each of the specific control registers.

Note: The auxiliary timers have no output toggle latch and no alternate output function.

0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

Timer T2/T4 Run Control

Each of the auxiliary timers T2 and T4 can be started or stopped by software in two different ways:

- Through the associated timer run bit (T2R or T4R). In this case it is required that the respective control bit TxRC = 0.
- Through the core timer's run bit (T3R). In this case the respective remote control bit must be set (TxRC = 1).

The selected run bit is relevant in all operating modes of T2/T4. Setting the bit will start the timer, clearing the bit stops the timer.

In Gated Timer Mode, the timer will only run if the selected run bit is set and the gate is active (high or low, as programmed).

Note: If remote control is selected T3R will start/stop timer T3 and the selected auxiliary timer(s) synchronously.

Count Direction Control

The count direction of the GPT1 timers (core timer and auxiliary timers) is controlled in the same way, either by software or by the external input pin TxEUD. Please refer to the description in **Table 30-1**.

Note: When pin TxEUD is used as external count direction control input, it must be configured as input (its corresponding direction control bit must be cleared).

30.1.4 GPT1 Auxiliary Timers T2/T4 Operating Modes

The operation of the auxiliary timers in the basic operating modes is almost identical with the core timer's operation, with very few exceptions. Additionally, some combined operating modes can be selected.

Timers T2 and T4 in Timer Mode

Timer Mode for an auxiliary timer Tx is selected by setting its bitfield TxM in register TxCON to 000_B.

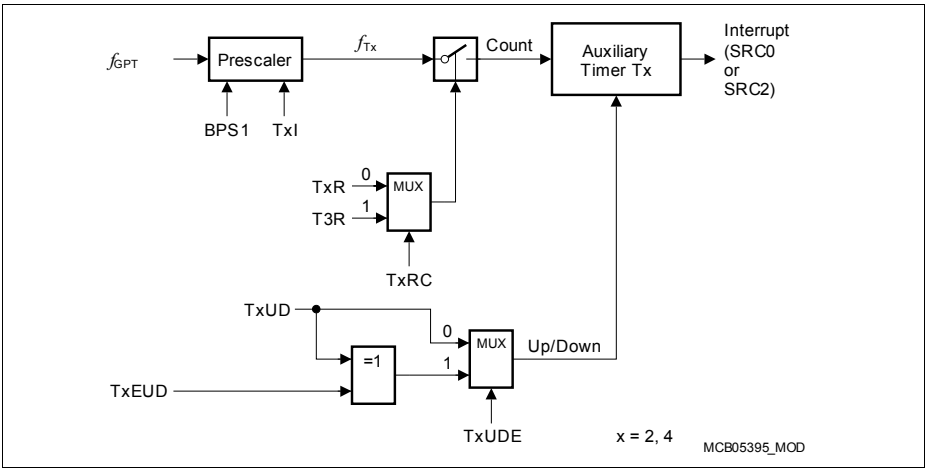

Figure 30-10 Block Diagram of an Auxiliary Timer in Timer Mode

Timers T2 and T4 in Gated Timer Mode

Gated Timer Mode for an auxiliary timer Tx is selected by setting bitfield TxM in register TxCON to 010_B or 011_B. Bit TxM.0 (TxCON.3) selects the active level of the gate input.

Note: A transition of the gate signal at TxIN does not cause an interrupt request. Interrupts of timer 2 are handled by register SRC0 and interrupts of timer 4 are handled by register SRC2.

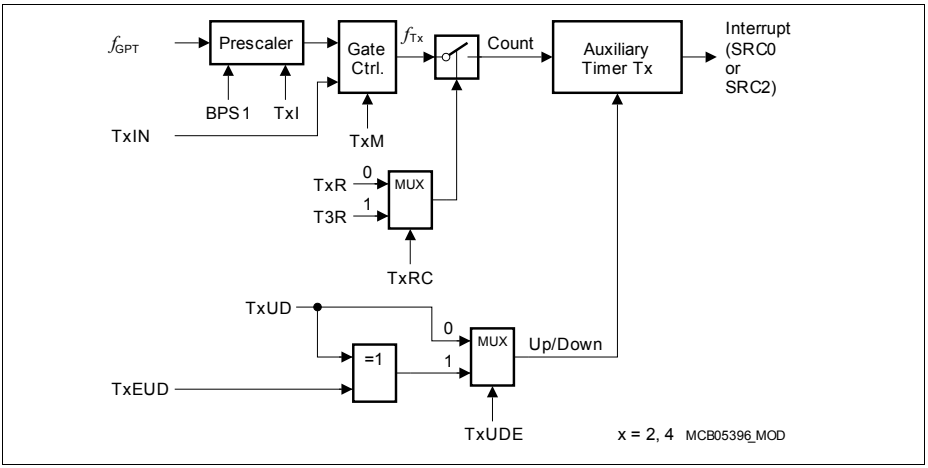

Figure 30-11 Block Diagram of an Auxiliary Timer in Gated Timer Mode

Note: There is no output toggle latch for T2 and T4.
Start/stop of an auxiliary timer can be controlled locally or remotely.

Timers T2 and T4 in Counter Mode

Counter Mode for an auxiliary timer Tx is selected by setting bitfield TxM in register TxCON to 001_B. In Counter Mode, an auxiliary timer can be clocked either by a transition at its external input line TxIN, or by a transition of timer T3's toggle latch T3OTL. The event causing an increment or decrement of a timer can be a positive, a negative, or both a positive and a negative transition at either the respective input pin or at the toggle latch. Bitfield TxI in control register TxCON selects the triggering transition (see **Table 30-5**).

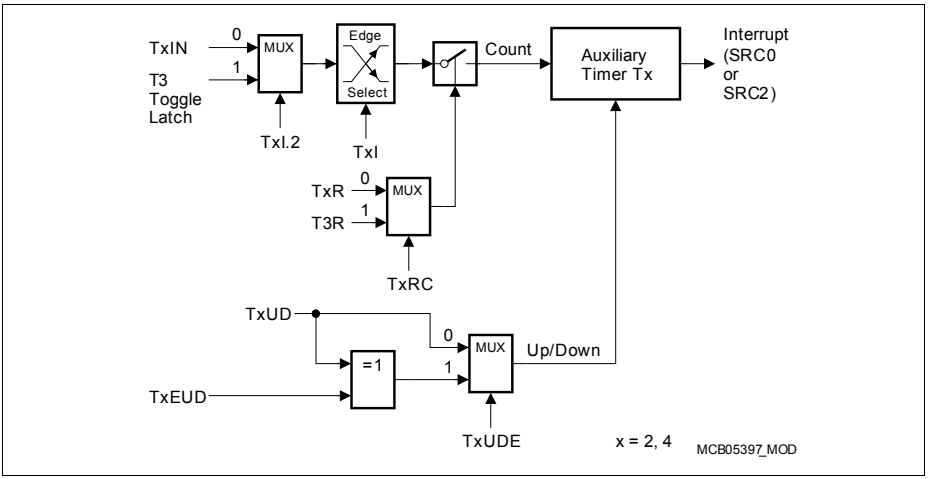

Figure 30-12 Block Diagram of an Auxiliary Timer in Counter Mode

Table 30-5 GPT1 Auxiliary Timer (Counter Mode) Input Edge Selection

T2I/T4I	Triggering Edge for Counter Increment/Decrement
$X00_B$	None. Counter Tx is disabled
001_B	Positive transition (rising edge) on TxIN
010_B	Negative transition (falling edge) on TxIN
011_B	Any transition (rising or falling edge) on TxIN
101_B	Positive transition (rising edge) of T3 toggle latch T3OTL
110_B	Negative transition (falling edge) of T3 toggle latch T3OTL
111_B	Any transition (rising or falling edge) of T3 toggle latch T3OTL

Note: Only state transitions of T3OTL which are caused by the overflows/underflows of T3 will trigger the counter function of T2/T4. Modifications of T3OTL via software will NOT trigger the counter function of T2/T4.

For counter operation, pin TxIN must be configured as input. The maximum input frequency allowed in Counter Mode depends on the selected prescaler value. To ensure that a transition of the count input signal applied to TxIN is recognized correctly, its level must be held high or low for a minimum number of module clock cycles before it changes. This information can be found in **Section 30.1.5**.

Timers T2 and T4 in Incremental Interface Mode

Incremental Interface Mode for an auxiliary timer Tx is selected by setting bitfield TxM in the respective register TxCON to 110_B or 111_B. In Incremental Interface Mode, the two inputs associated with an auxiliary timer Tx (TxIN, TxEUD) are used to interface to an incremental encoder. Tx is clocked by each transition on one or both of the external input pins to provide 2-fold or 4-fold resolution of the encoder input.

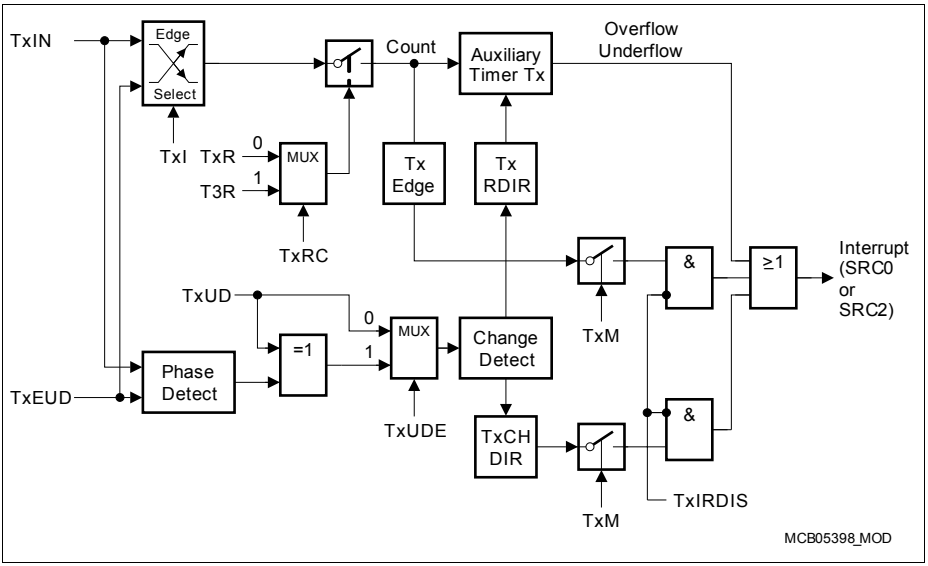

Figure 30-13 Block Diagram of an Auxiliary Timer in Incremental Interface Mode

The operation of the auxiliary timers T2 and T4 in Incremental Interface Mode and the interrupt generation are the same as described for the core timer T3. The descriptions, figures and tables apply accordingly.

*Note: Timers T2 and T4 operating in Incremental Interface Mode automatically provide information on the sensor's current position. For dynamic information (speed, acceleration, deceleration) see **"Combined Capture Modes" on Page 30-59**).*

Timer Concatenation

Using the toggle bit T3OTL as a clock source for an auxiliary timer in Counter Mode concatenates the core timer T3 with the respective auxiliary timer. This concatenation forms either a 32-bit or a 33-bit timer/counter, depending on which transition of T3OTL is selected to clock the auxiliary timer.

- **32-bit Timer/Counter:** If both a positive and a negative transition of T3OTL are used to clock the auxiliary timer, this timer is clocked on every overflow/underflow of the core timer T3. Thus, the two timers form a 32-bit timer.
- **33-bit Timer/Counter:** If either a positive or a negative transition of T3OTL is selected to clock the auxiliary timer, this timer is clocked on every second overflow/underflow of the core timer T3. This configuration forms a 33-bit timer (16-bit core timer + T3OTL + 16-bit auxiliary timer).
  As long as bit T3OTL is not modified by software, it represents the state of the internal toggle latch, and can be regarded as part of the 33-bit timer.

The count directions of the two concatenated timers are not required to be the same. This offers a wide variety of different configurations.

T3, which represents the low-order part of the concatenated timer, can operate in Timer Mode, Gated Timer Mode or Counter Mode in this case.

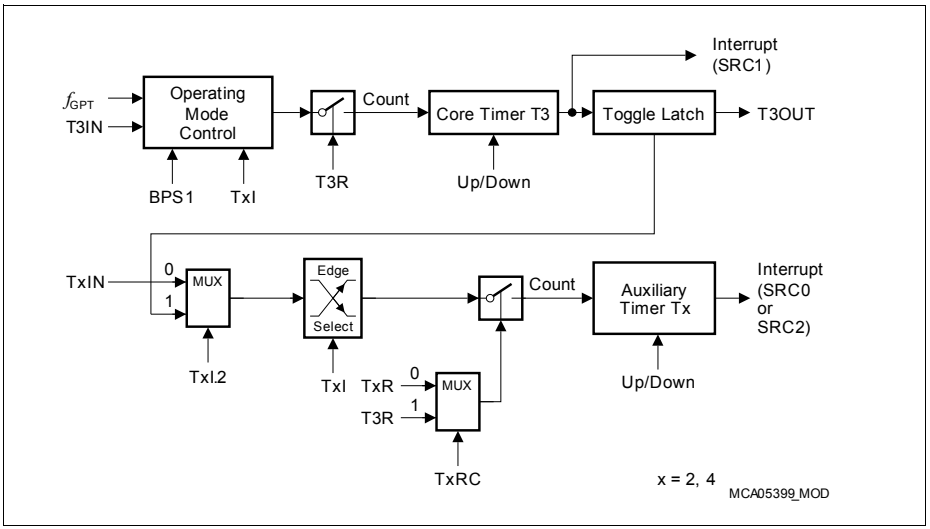

Figure 30-14 Concatenation of Core Timer T3 and an Auxiliary Timer

When reading the low and high parts of the concatenated timer, care must be taken to obtain consistent values in particular after a timer overflow/underflow (e.g. one part may already have considered an overflow, while the other has not).

Note: This is a general issue when reading multi-word results with consecutive instructions, and not necessarily unique to the GPT12 module architecture.

The following algorithm may be used to read concatenated GPT1 timers, represented by TIMER_HIGH (for auxiliary timer, here T2) and TIMER_LOW (for core timer T3). The high part is read twice, and reading of the low part is repeated if two different values were read for the high part:

- TIMER_HIGH_TMP = T2
- TIMER_LOW = T3
- Wait two basic clock cycles (to allow increment/decrement of auxiliary timer in case of core timer overflow/underflow) - see **Table 30-6**
- TIMER_HIGH = T2
- If TIMER_HIGH is not equal to TIMER_HIGH_TMP then TIMER_LOW = T3

After execution of this algorithm, TIMER_HIGH and TIMER_LOW represent a consistent time stamp of the concatenated timers.

The equivalent number of system clock cycles corresponding to two basic clock cycles is shown in **Table 30-6**.

Table 30-6 Number of System Clock Cycles to Wait for Two Basic Clock Cycles

Block Prescaler	BPS1 = 01_B	BPS1 = 00_B	BPS1 = 11_B	BPS1 = 10_B
Number of system clocks	8	16	32	64

In case the required timer resolution can be achieved with different combinations of the Block Prescaler BPS1 and the Individual Prescalers TxI, the variant with the smallest value for the Block Prescaler may be chosen to minimize the waiting time.

Auxiliary Timer in Reload Mode

Reload Mode for an auxiliary timer Tx is selected by setting bitfield TxM in the respective register TxCON to 100_B. In Reload Mode, the core timer T3 is reloaded with the contents of an auxiliary timer register, triggered by one of two different signals. The trigger signal is selected the same way as the clock source for Counter Mode (see **Table 30-5**), i.e. a transition of the auxiliary timer's input TxIN or the toggle latch T3OTL may trigger the reload.

Note: When programmed for Reload Mode, the respective auxiliary timer (T2 or T4) stops independently of its run flag T2R or T4R.
The timer input pin TxIN must be configured as input if it shall trigger a reload operation.

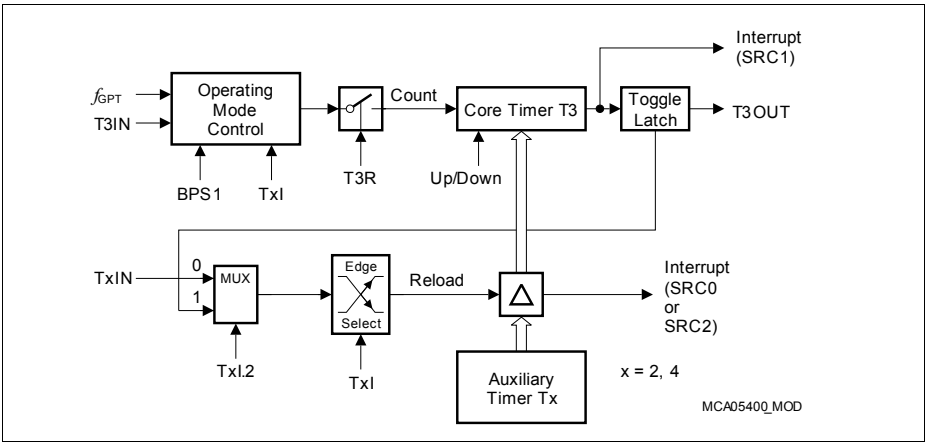

Figure 30-15 GPT1 Auxiliary Timer in Reload Mode

Upon a trigger signal, T3 is loaded with the contents of the respective timer register (T2 or T4) and the respective service request flag (SRR) is set.

Note: When a T3OTL transition is selected for the trigger signal, the service request flag will also be set upon a trigger, indicating T3's overflow or underflow. Modifications of T3OTL via software will NOT trigger the counter function of T2/T4.

To ensure that a transition of the reload input signal applied to TxIN is recognized correctly, its level must be held high or low for a minimum number of module clock cycles, detailed in **Section 30.1.5**.

The Reload Mode triggered by the T3 toggle latch can be used in a number of different configurations. The following functions can be performed, depending on the selected active transition:

- If both a positive and a negative transition of T3OTL are selected to trigger a reload, the core timer will be reloaded with the contents of the auxiliary timer each time it overflows or underflows. This is the standard Reload Mode (reload on overflow/underflow).
- If either a positive or a negative transition of T3OTL is selected to trigger a reload, the core timer will be reloaded with the contents of the auxiliary timer on every second overflow or underflow.
- Using this "single-transition" mode for both auxiliary timers allows to perform very flexible Pulse Width Modulation (PWM). One of the auxiliary timers is programmed to reload the core timer on a positive transition of T3OTL, the other is programmed for a reload on a negative transition of T3OTL. With this combination the core timer is alternately reloaded from the two auxiliary timers.

Figure 30-16 shows an example for the generation of a PWM signal using the “single-transition” reload mechanism. T2 defines the high time of the PWM signal (reloaded on positive transitions) and T4 defines the low time of the PWM signal (reloaded on negative transitions). The PWM signal can be output on pin T3OUT if T3OE = 1. With this method, the high and low time of the PWM signal can be varied in a wide range.

Note: The output toggle latch T3OTL is accessible via software and may be changed, if required, to modify the PWM signal.
However, this will NOT trigger the reloading of T3.

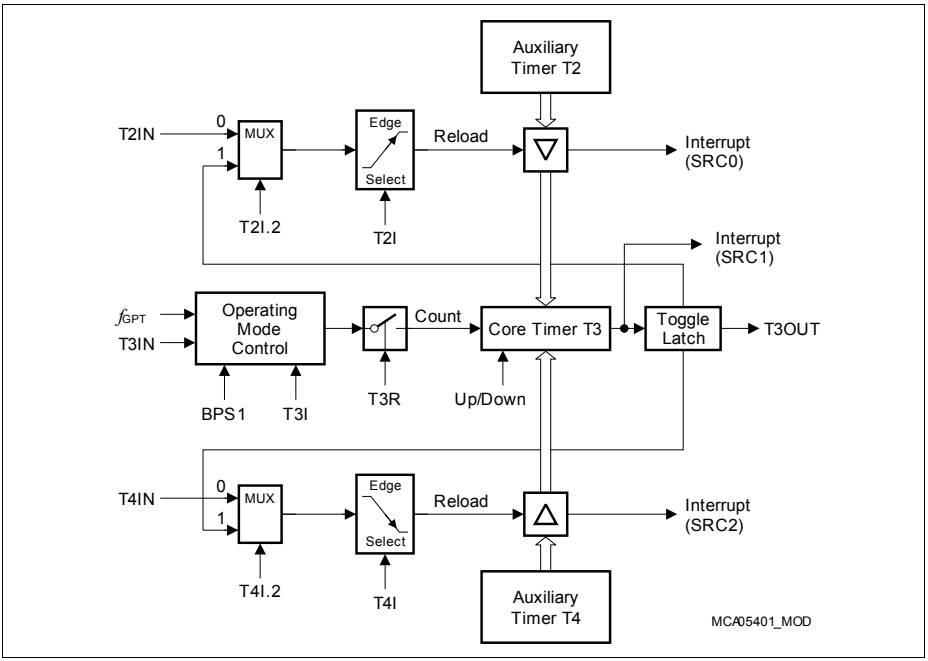

Figure 30-16 GPT1 Timer Reload Configuration for PWM Generation

Note: Although possible, selecting the same reload trigger event for both auxiliary timers should be avoided. In such a case, both reload registers would try to load the core timer at the same time. If this combination is selected, T2 is disregarded and the contents of T4 is reloaded.

The implementation of the GPT1 finite state machine may require special consideration in following applications:

- Reading T3 by Software with T2/T4 in Reload Mode
- Reload of T3 from T2 with setting BPS1 = 01_B and T3I = 000_B

When T2 or T4 are used to reload T3 on overflow/underflow, and T3 is read by software on the fly, the following unexpected values may be read from T3:

- When T3 is counting up, 0000_H or 0001_H may be read from T3 directly after an overflow, although the reload value in T2/T4 is higher (0001_H may be read in particular if BPS1 = 01_B and T3I = 000_B).
- When T3 is counting down, $FFFF_H$ or $FFFE_H$ may be read from T3 directly after an underflow, although the reload value in T2/T4 is lower ($FFFE_H$ may be read in particular if BPS1 = 01_B and T3I = 000_B).

Note: All timings derived from T3 in this configuration (e.g. distance between interrupt requests, PWM waveform on T3OUT, etc.) are accurate except for the specific case described below.

Workaround:

- When T3 counts up, and value_x < reload value is read from T3, value_x should be replaced with the reload value for further calculations.
- When T3 counts down, and value_x > reload value is read from T3, value_x should be replaced with the reload value for further calculations.

Alternatively, if the intention is to identify the overflow/underflow of T3, the T3 interrupt request may be used.

When T2 is used to reload T3 in the configuration with BPS1 = 01_B and T3I = 000_B (i.e. fastest configuration/highest resolution of T3), the reload of T3 is performed with a delay of one basic clock cycle.

Workaround 1:

To compensate the delay and achieve correct timing,

- increment the reload value in T2 by 1 when T3 is configured to count up,
- decrement the reload value in T2 by 1 when T3 is configured to count down.

Workaround 2:

Use T4 instead of T2 as reload register for T3. In this configuration the reload of T3 is not delayed, i.e. the effect described above does not occur with T4.

Auxiliary Timer in Capture Mode

Capture Mode for an auxiliary timer Tx is selected by setting bitfield TxM in the respective register TxCON to 101_B. In Capture Mode, the contents of the core timer T3 are latched into an auxiliary timer register in response to a signal transition at the respective auxiliary timer's external input pin TxIN. The capture trigger signal can be a positive, a negative, or both a positive and a negative transition.

The two least significant bits of bitfield TxI select the active transition (see **Table 30-5**). Bit 2 of TxI is irrelevant for Capture Mode and must be cleared (TxI.2 = 0).

Note: When programmed for Capture Mode, the respective auxiliary timer (T2 or T4) stops independently of its run flag T2R or T4R.

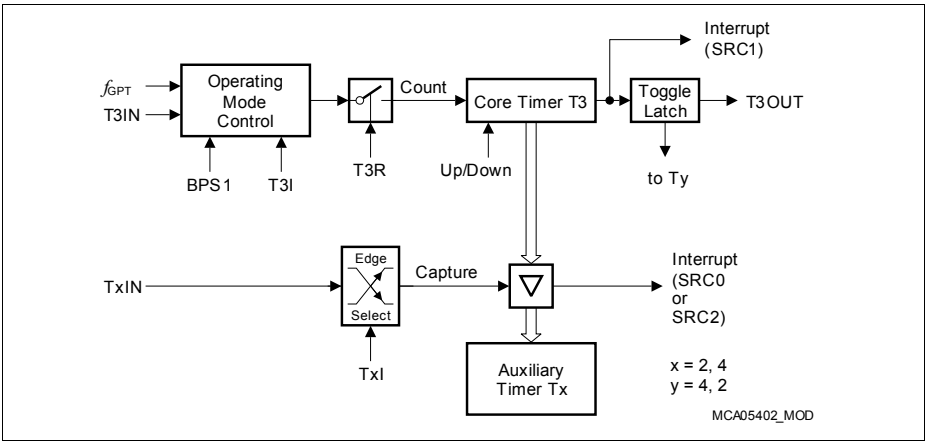

Figure 30-17 GPT1 Auxiliary Timer in Capture Mode

Upon a trigger (selected transition) at the corresponding input pin TxIN the contents of the core timer are loaded into the auxiliary timer register and the associated service request flag SRR will be set.

For Capture Mode operation, the respective timer input pin TxIN must be configured as input. To ensure that a transition of the capture input signal applied to TxIN is recognized correctly, its level must be held high or low for a minimum number of module clock cycles, detailed in **Section 30.1.5**.

30.1.5 GPT1 Clock Signal Control

All actions within the timer block GPT1 are triggered by transitions of its basic clock. This basic clock is derived from the system clock by a basic block prescaler, controlled by bitfield BPS1 in register T3CON (see **Figure 30-1**). The count clock can be generated in two different ways:

- **Internal count clock**, derived from GPT1's basic clock via a programmable prescaler, is used for (Gated) Timer Mode.
- **External count clock**, derived from the timer's input pin(s), is used for Counter Mode.

For both ways, the basic clock determines the maximum count frequency and the timer's resolution:

Table 30-7 Basic Clock Selection for Block GPT1

Block Prescaler[1]	BPS1 = 01_B	BPS1 = 00_B[2]	BPS1 = 11_B	BPS1 = 10_B
Prescaling Factor for GPT1: F(BPS1)	F(BPS1) = 4	F(BPS1) = 8	F(BPS1) = 16	F(BPS1) = 32
Maximum External Count Frequency	$f_{GPT}/8$	$f_{GPT}/16$	$f_{GPT}/32$	$f_{GPT}/64$
Input Signal Stable Time	$4 \times t_{GPT}$	$8 \times t_{GPT}$	$16 \times t_{GPT}$	$32 \times t_{GPT}$

1) Please note the non-linear encoding of bitfield BPS1.

2) Default after reset.

Internal Count Clock Generation

In Timer Mode and Gated Timer Mode, the count clock for each GPT1 timer is derived from the GPT1 basic clock by a programmable prescaler, controlled by bitfield TxI in the respective timer's control register TxCON.

The count frequency f_{Tx} for a timer Tx and its resolution r_{Tx} are scaled linearly with lower clock frequencies, as can be seen from the following formula:

$$f_{Tx} = \frac{f_{GPT}}{F(BPS1) \times 2^{<TxI>}} \qquad r_{Tx}[\mu s] = \frac{F(BPS1) \times 2^{<TxI>}}{f_{GPT}[MHz]} \tag{30.1}$$

The effective count frequency depends on the common module clock prescaler factor F(BPS1) as well as on the individual input prescaler factor $2^{<TxI>}$. **Table 30-8** summarizes the resulting overall divider factors for a GPT1 timer that result from these cascaded prescalers.

Table 30-8 GPT1 Overall Prescaler Factors for Internal Count Clock

Individual Prescaler for Tx	Common Prescaler for Module Clock[1]			
	$BPS1 = 01_B$	$BPS1 = 00_B$	$BPS1 = 11_B$	$BPS1 = 10_B$
$TxI = 000_B$	4	8	16	32
$TxI = 001_B$	8	16	32	64
$TxI = 010_B$	16	32	64	128
$TxI = 011_B$	32	64	128	256
$TxI = 100_B$	64	128	256	512
$TxI = 101_B$	128	256	512	1024
$TxI = 110_B$	256	512	1024	2048
$TxI = 111_B$	512	1024	2048	4096

1) Please note the non-linear encoding of bitfield BPS1.

External Count Clock Input

The external input signals of the GPT1 block are sampled with the GPT1 basic clock (see **Figure 30-1**). To ensure that a signal is recognized correctly, its current level (high or low) must be held active for at least one complete sampling period, before changing. A signal transition is recognized if two subsequent samples of the input signal represent different levels. Therefore, a minimum of two basic clock periods are required for the sampling of an external input signal. Thus, the maximum frequency of an input signal must not be higher than half the basic clock.

Table 30-9 summarizes the resulting requirements for external GPT1 input signals.

Table 30-9 GPT1 External Input Signal Limits

GPT1 Basic Clock = 10 MHz		Input Frequ. Factor	GPT1 Divider BPS1	Input Phase Duration	GPT1 Basic Clock = 40 MHz	
Max. Input Frequency	Min. Level Hold Time				Max. Input Frequency	Min. Level Hold Time
1.25 MHz	400 ns	$f_{GPT}/8$	01_B	$4 \times t_{GPT}$	5.0 MHz	100 ns
625.0 kHz	800 ns	$f_{GPT}/16$	00_B	$8 \times t_{GPT}$	2.5 MHz	200 ns
312.5 kHz	1.6 µs	$f_{GPT}/32$	11_B	$16 \times t_{GPT}$	1.25 MHz	400 ns
156.25 kHz	3.2 µs	$f_{GPT}/64$	10_B	$32 \times t_{GPT}$	625.0 kHz	800 ns

These limitations are valid for all external input signals to GPT1, including the external count signals in Counter Mode and Incremental Interface Mode, the gate input signals in Gated Timer Mode, and the external direction signals.

30.1.6 GPT1 Timer Registers

T2
Timer 2 Register **(34_H)** **Reset Value: 0000 0000_H**

30.2 Timer Block GPT2

Both timers of block GPT2 (T5, T6) can run in one of 3 basic modes: Timer Mode, Gated Timer Mode, or Counter Mode. All timers can count up or down. Each timer of GPT2 is controlled by a separate control register TxCON.

Each timer has an input pin TxIN (alternate pin function) associated with it, which serves as the gate control in Gated Timer Mode, or as the count input in Counter Mode. The count direction (up/down) may be programmed via software or may be dynamically altered by a signal at the External Up/Down control input TxEUD (alternate pin function). An overflow/underflow of core timer T6 is indicated by the Output Toggle Latch T6OTL, whose state may be output on the associated pin T6OUT (alternate pin function). The auxiliary timer T5 may additionally be concatenated with core timer T6 (through T6OTL).

The Capture/Reload register CAPREL can be used to capture the contents of timer T5, or to reload timer T6. A special mode facilitates the use of register CAPREL for both functions at the same time. This mode allows frequency multiplication. The capture function is triggered by the input pin CAPIN, or by GPT1 timer's T3 input lines T3IN and T3EUD. The reload function is triggered by an overflow or underflow of timer T6.

The current contents of each timer can be read or modified by the CPU by accessing the corresponding timer count registers T5 or T6. When any of the timer registers is written by the CPU in the state immediately preceding a timer increment, decrement, reload, or capture operation, the CPU write operation has priority in order to guarantee correct results.

The interrupts of GPT2 are controlled through the Service Request Control Registers SRC3, SRC4, and SRC5.

*Note: The timing requirements for external input signals can be found in **Section 30.2.6**, **Section 30.5** summarizes the module interface signals, including pins.*

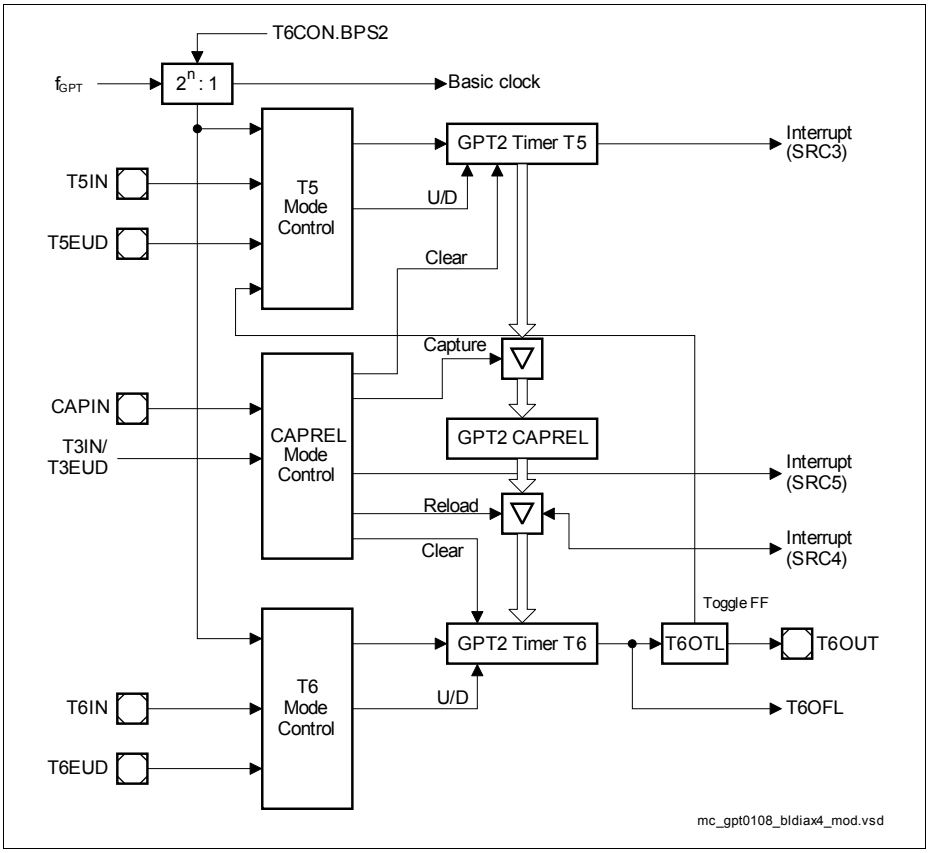

Figure 30-18 GPT2 Block Diagram

Note: The GPT2 module uses a finite state machine to control the actions. Since multiple interactions are possible between the timers (T5, T6) and register CAPREL, these elements are processed sequentially. However, all actions are normally completed within one basic clock cycle. The GPT2 state machine has 4 states (1 states when BPS1 = 01_B) and processes T6 before T5.

30.2.1 GPT2 Core Timer T6 Control

The current contents of the core timer T6 are reflected by its count register T6. This register can also be written to by the CPU, for example, to set the initial start value.

The core timer T6 is configured and controlled via its control register T6CON.

1) See **Table 30-10** for coding of bits T6UD and T6UDE

Timer T6 Run Control

The core timer T6 can be started or stopped by software through bit T6R (timer T6 run bit). This bit is relevant in all operating modes of T6. Setting bit T6R will start the timer, clearing bit T6R stops the timer.

In Gated Timer Mode, the timer will only run if T6R = 1 and the gate is active (high or low, as programmed).

Note: When bit T5RC in timer control register T5CON is set, bit T6R will also control (start and stop) the Auxiliary Timer T5.

Count Direction Control

The count direction of the GPT2 timers (core timer and auxiliary timer) can be controlled either by software or by the external input pin TxEUD (Timer Tx External Up/Down Control Input). These options are selected by bits TxUD and TxUDE in the respective control register TxCON. When the up/down control is provided by software (bit TxUDE = 0), the count direction can be altered by setting or clearing bit TxUD. When bit TxUDE = 1, pin TxEUD is selected to be the controlling source of the count direction. However, bit TxUD can still be used to reverse the actual count direction, as shown in **Table 30-10**. The count direction can be changed regardless of whether or not the timer is running.

Table 30-10 GPT2 Timer Count Direction Control

Pin TxEUD	Bit TxUDE	Bit TxUD	Count Direction
X	0	0	Count Up
X	0	1	Count Down
0	1	0	Count Up
1	1	0	Count Down
0	1	1	Count Down
1	1	1	Count Up

Timer 6 Output Toggle Latch

The overflow/underflow signal of timer T6 is connected to a block named ‘Toggle Latch’, shown in the timer mode diagrams. **Figure 30-19** illustrates the details of this block. An overflow or underflow of T6 will clock two latches: The first latch represents bit T6OTL in control register T6CON. The second latch is an internal latch toggled by T6OTL’s output. Both latch outputs are connected to the input control block of the auxiliary timer T5. The output level of the shadow latch will match the output level of T6OTL, but is delayed by one clock cycle. When the T6OTL value changes, this will result in a temporarily different output level from T6OTL and the shadow latch, which can trigger the selected count event in T5.

When software writes to T6OTL, both latches are set or cleared simultaneously. In this case, both signals to the auxiliary timers carry the same level and no edge will be detected. Bit T6OE (overflow/underflow output enable) in register T6CON enables the state of T6OTL to be monitored via an external pin T6OUT. When T6OTL is linked to an external port pin (must be configured as output), T6OUT can be used to control external HW. If T6OE = 1, pin T6OUT outputs the state of T6OTL. If T6OE = 0, pin T6OUT outputs a high level (while it selects the timer output signal).

As can be seen from **Figure 30-19**, when latch T6OTL is modified by software to determine the state of the output line, also the internal shadow latch is set or cleared accordingly. Therefore, no trigger condition is detected by T5 in this case.

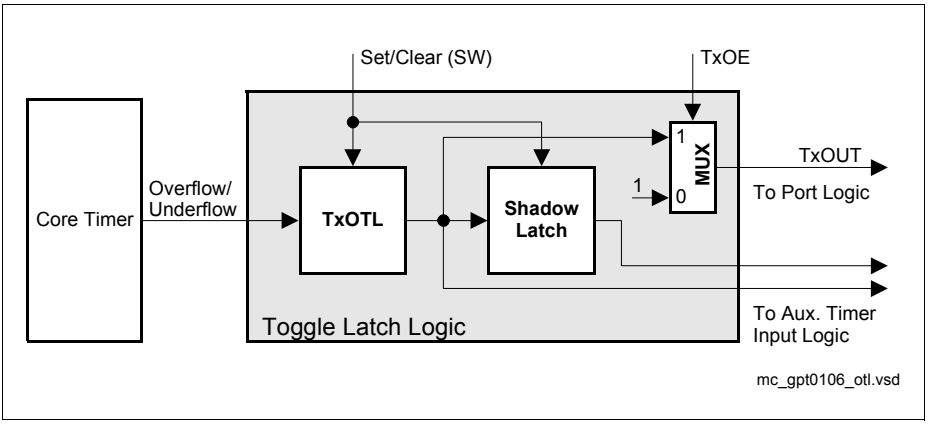

Figure 30-19 Block Diagram of the Toggle Latch Logic of Core Timer T6

30.2.2 GPT2 Core Timer T6 Operating Modes

Timer T6 can operate in one of several modes.

Timer 6 in Timer Mode

Timer Mode for the core timer T6 is selected by setting bitfield T6M in register T6CON to 000_B. In this mode, T6 is clocked with the module's input clock f_{GPT} divided by two programmable prescalers controlled by bitfields BPS2 and T6I in register T6CON. Please see **Section 30.2.6** for details on the input clock options.

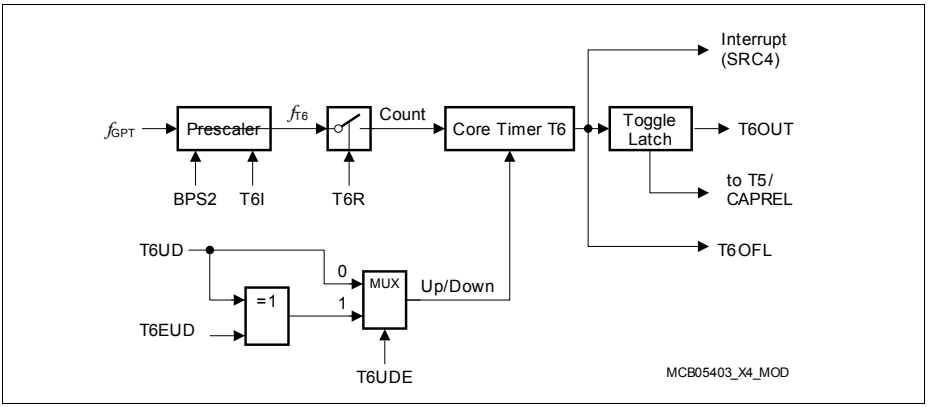

Figure 30-20 Block Diagram of Core Timer T6 in Timer Mode

Gated Timer Mode

Gated Timer Mode for the core timer T6 is selected by setting bitfield T6M in register T6CON to 010_B or 011_B. Bit T6M.0 (T6CON.3) selects the active level of the gate input. The same options for the input frequency are available in Gated Timer Mode as in Timer Mode (see **Section 30.2.6**). However, the input clock to the timer in this mode is gated by the external input pin T6IN (Timer T6 External Input).
To enable this operation, the associated pin T6IN must be configured as input (the corresponding direction control bit must contain 0).

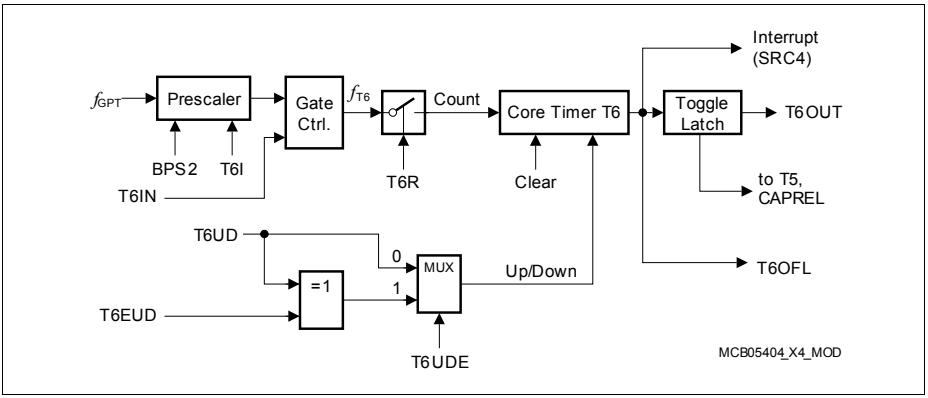

Figure 30-21 Block Diagram of Core Timer T6 in Gated Timer Mode

If T6M = 010_B, the timer is enabled when T6IN shows a low level. A high level at this line stops the timer. If T6M = 011_B, line T6IN must have a high level in order to enable the timer. Additionally, the timer can be turned on or off by software using bit T6R. The timer will only run if T6R is 1 and the gate is active. It will stop if either T6R is 0 or the gate is inactive.

Note: A transition of the gate signal at pin T6IN does not cause an interrupt request.

Counter Mode

Counter Mode for the core timer T6 is selected by setting bitfield T6M in register T6CON to 001_B. In Counter Mode, timer T6 is clocked by a transition at the external input pin T6IN. The event causing an increment or decrement of the timer can be a positive, a negative, or both a positive and a negative transition at this line. Bitfield T6I in control register T6CON selects the triggering transition (see **Table 30-11**).

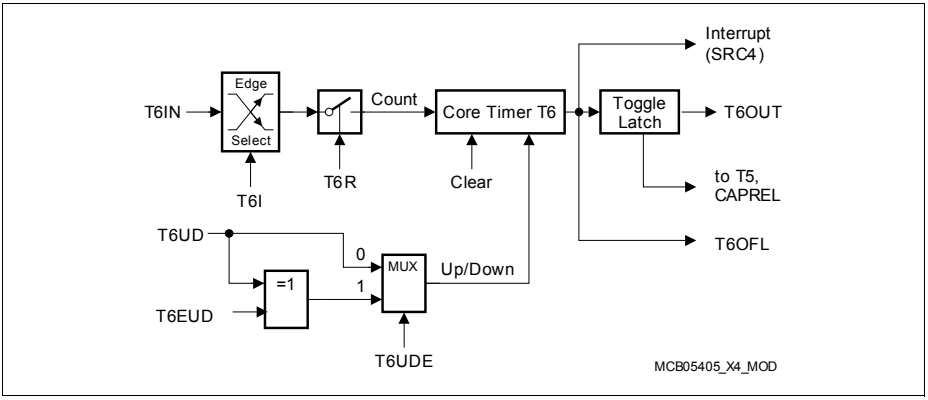

Figure 30-22 Block Diagram of Core Timer T6 in Counter Mode

Table 30-11 GPT2 Core Timer T6 (Counter Mode) Input Edge Selection

T6I	Triggering Edge for Counter Increment/Decrement
000_B	None. Counter T6 is disabled
001_B	Positive transition (rising edge) on T6IN
010_B	Negative transition (falling edge) on T6IN
011_B	Any transition (rising or falling edge) on T6IN
$1XX_B$	Reserved. Do not use this combination

For Counter Mode operation, pin T6IN must be configured as input. The maximum input frequency allowed in Counter Mode depends on the selected prescaler value. To ensure that a transition of the count input signal applied to T6IN is recognized correctly, its level must be held high or low for a minimum number of module clock cycles before it changes. This information can be found in **Section 30.2.6**.

30.2.3 GPT2 Auxiliary Timer T5 Control

Auxiliary timer T5 can be configured for Timer Mode, Gated Timer Mode, or Counter Mode with the same options for the timer frequencies and the count signal as the core timer T6. In addition to these 3 counting modes, the auxiliary timer can be concatenated with the core timer. The contents of T5 may be captured to register CAPREL upon an external or an internal trigger. The start/stop function of the auxiliary timers can be remotely controlled by the T6 run control bit. Several timers may thus be controlled synchronously.

The current contents of the auxiliary timer are reflected by its count register T5. This register can also be written to by the CPU, for example, to set the initial start value.

The individual configurations for timer T5 are determined by its control register T5CON. Some bits in this register also control the function of the CAPREL register. Note that functions which are present in all timers of block GPT2 are controlled in the same bit positions and in the same manner in each of the specific control registers.

Note: The auxiliary timer has no output toggle latch and no alternate output function.

Field	Bits	Type	Description
0	11	rw	**Reserved** Have be written with 0.
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

1) See **Table 30-10** for encoding of bits T5UD and T5UDE.

2) To define the respective trigger source signal, also bit CT3 must be regarded (see **Table 30-14**).

3) Rising edge must be selected if capturing is triggered by the internal GPT1 read signals (see register PISEL and **"Combined Capture Modes" on Page 30-59**).

Timer T5 Run Control

The auxiliary timer T5 can be started or stopped by software in two different ways:

- Through the associated timer run bit (T5R). In this case it is required that the respective control bit T5RC = 0.
- Through the core timer's run bit (T6R). In this case the respective remote control bit must be set (T5RC = 1).

The selected run bit is relevant in all operating modes of T5. Setting the bit will start the timer, clearing the bit stops the timer.

In Gated Timer Mode, the timer will only run if the selected run bit is set and the gate is active (high or low, as programmed).

Note: If remote control is selected T6R will start/stop timer T6 and the auxiliary timer T5 synchronously.

30.2.4 GPT2 Auxiliary Timer T5 Operating Modes

The operation of the auxiliary timer in the basic operating modes is almost identical with the core timer's operation, with very few exceptions. Additionally, some combined operating modes can be selected.

Timer T5 in Timer Mode

Timer Mode for the auxiliary timer T5 is selected by setting its bitfield T5M in register T5CON to 000_B.

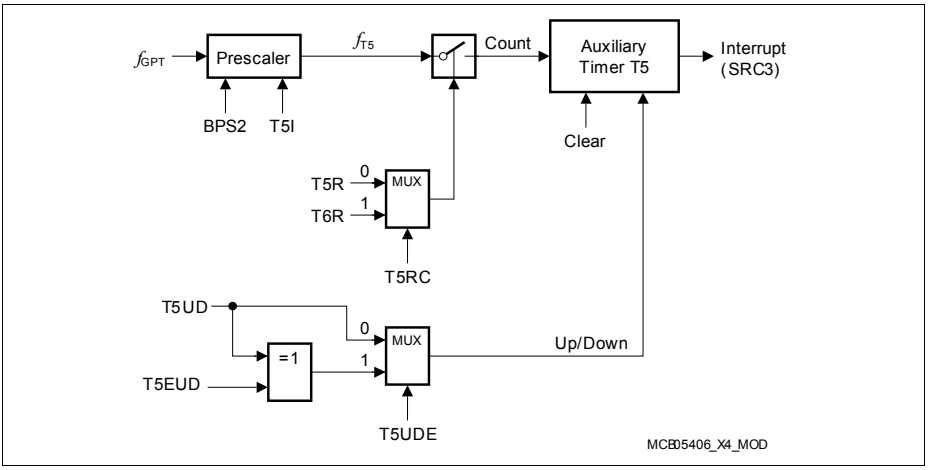

Figure 30-23 Block Diagram of Auxiliary Timer T5 in Timer Mode

Timer T5 in Gated Timer Mode

Gated Timer Mode for the auxiliary timer T5 is selected by setting bitfield T5M in register T5CON to 010_B or 011_B. Bit T5M.0 (T5CON.3) selects the active level of the gate input.

Note: A transition of the gate signal at line T5IN does not cause an interrupt request.

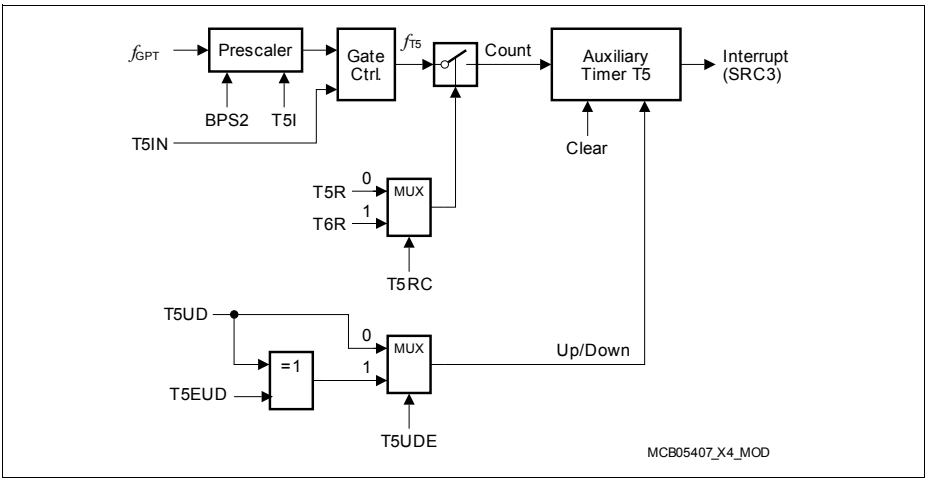

Figure 30-24 Block Diagram of Auxiliary Timer T5 in Gated Timer Mode

Note: There is no output toggle latch for T5.
Start/stop of the auxiliary timer can be controlled locally or remotely.

Timer T5 in Counter Mode

Counter Mode for auxiliary timer T5 is selected by setting bitfield T5M in register T5CON to 001_B. In Counter Mode, the auxiliary timer can be clocked either by a transition at its external input line T5IN, or by a transition of timer T6's toggle latch T6OTL. The event causing an increment or decrement of a timer can be a positive, a negative, or both a positive and a negative transition at either the respective input pin or at the toggle latch. Bitfield T5I in control register T5CON selects the triggering transition (see **Table 30-12**).

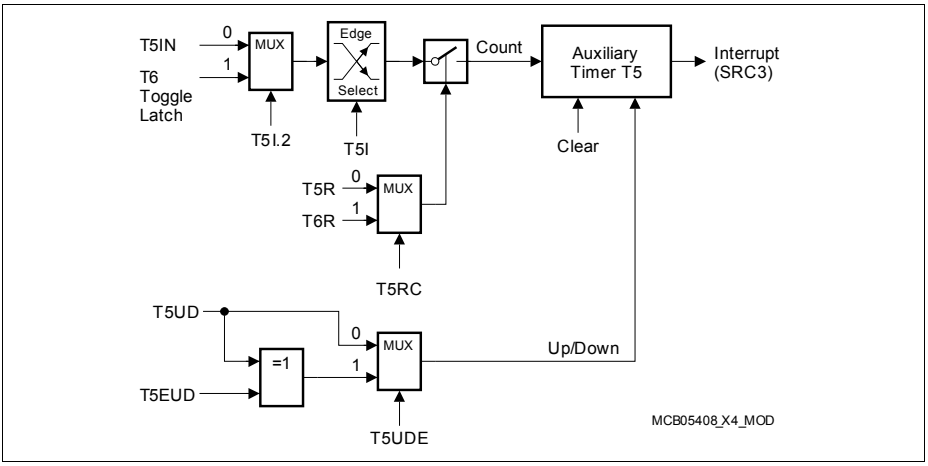

Figure 30-25 Block Diagram of Auxiliary Timer T5 in Counter Mode

Table 30-12 GPT2 Auxiliary Timer (Counter Mode) Input Edge Selection

T5I	Triggering Edge for Counter Increment/Decrement
$X00_B$	None. Counter T5 is disabled
001_B	Positive transition (rising edge) on T5IN
010_B	Negative transition (falling edge) on T5IN
011_B	Any transition (rising or falling edge) on T5IN
101_B	Positive transition (rising edge) of T6 toggle latch T6OTL
110_B	Negative transition (falling edge) of T6 toggle latch T6OTL
111_B	Any transition (rising or falling edge) of T6 toggle latch T6OTL

Note: Only state transitions of T6OTL which are caused by the overflows/underflows of T6 will trigger the counter function of T5. Modifications of T6OTL via software will NOT trigger the counter function of T5.

For counter operation, pin T5IN must be configured as input (the respective direction control bit DPx.y must be 0). The maximum input frequency allowed in Counter Mode depends on the selected prescaler value. To ensure that a transition of the count input signal applied to T5IN is recognized correctly, its level must be held high or low for a minimum number of module clock cycles before it changes. This information can be found in **Section 30.2.6**.

Timer Concatenation

Using the toggle bit T6OTL as a clock source for the auxiliary timer in Counter Mode concatenates the core timer T6 with the auxiliary timer T5. This concatenation forms either a 32-bit or a 33-bit timer/counter, depending on which transition of T6OTL is selected to clock the auxiliary timer.

- **32-bit Timer/Counter:** If both a positive and a negative transition of T6OTL are used to clock the auxiliary timer, this timer is clocked on every overflow/underflow of the core timer T6. Thus, the two timers form a 32-bit timer.
- **33-bit Timer/Counter:** If either a positive or a negative transition of T6OTL is selected to clock the auxiliary timer, this timer is clocked on every second overflow/underflow of the core timer T6. This configuration forms a 33-bit timer (16-bit core timer + T6OTL + 16-bit auxiliary timer).
  As long as bit T6OTL is not modified by software, it represents the state of the internal toggle latch, and can be regarded as part of the 33-bit timer.

The count directions of the two concatenated timers are not required to be the same. This offers a wide variety of different configurations.

T6, which represents the low-order part of the concatenated timer, can operate in Timer Mode, Gated Timer Mode or Counter Mode in this case.

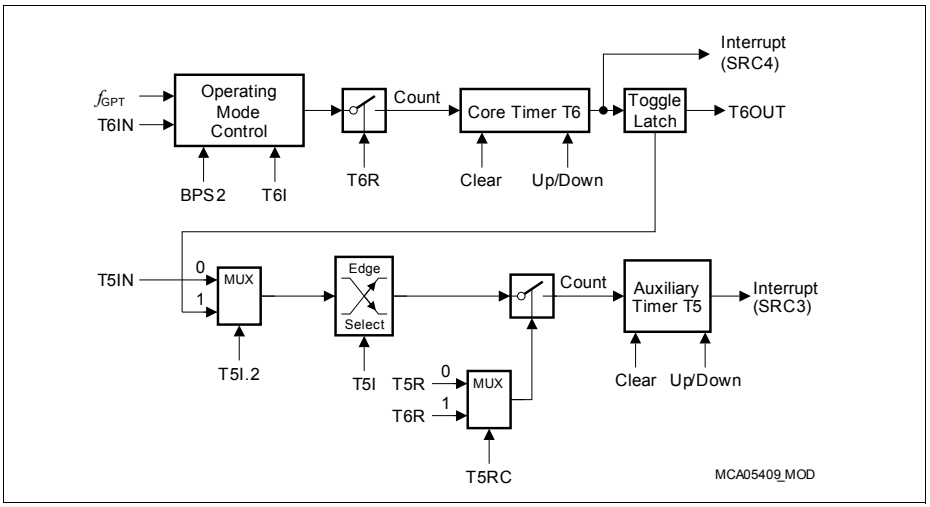

Figure 30-26 Concatenation of Core Timer T6 and Auxiliary Timer T5

When reading the low and high parts of the concatenated timer, care must be taken to obtain consistent values in particular after a timer overflow/underflow (e.g. one part may already have considered an overflow, while the other has not).

Note: This is a general issue when reading multi-word results with consecutive instructions, and not necessarily unique to the GPT12 module architecture.

The following algorithm may be used to read concatenated GPT1 timers, represented by TIMER_HIGH (for auxiliary timer, here T5) and TIMER_LOW (for core timer T6). The high part is read twice, and reading of the low part is repeated if two different values were read for the high part:

- TIMER_HIGH_TMP = T5
- TIMER_LOW = T6
- Wait two basic clock cycles (to allow increment/decrement of auxiliary timer in case of core timer overflow/underflow) - see **Table 30-13**
- TIMER_HIGH = T5
- If TIMER_HIGH is not equal to TIMER_HIGH_TMP then TIMER_LOW = T6

After execution of this algorithm, TIMER_HIGH and TIMER_LOW represent a consistent time stamp of the concatenated timers.

The equivalent number of system clock cycles corresponding to two basic clock cycles is shown in **Table 30-13**.

Table 30-13 Number of System Clock Cycles to Wait for Two Basic Clock Cycles

Block Prescaler	BPS2 = 01_B	BPS2 = 00_B	BPS2 = 11_B	BPS2 = 10_B
Number of system clocks	4	8	16	32

In case the required timer resolution can be achieved with different combinations of the Block Prescaler BPS2 and the Individual Prescalers TxI, the variant with the smallest value for the Block Prescaler may be chosen to minimize the waiting time. E.g. in order to run T6 at f_{FPI}/512, select BPS2 = 00_B, T6I = 111_B, and insert 8 NOPs (or other instructions) to ensure the required waiting time before reading TIMER_HIGH the second time.

30.2.5 GPT2 Register CAPREL Operating Modes

The Capture/Reload register CAPREL can be used to capture the contents of timer T5, or to reload timer T6. A special mode facilitates the use of register CAPREL for both functions at the same time. This mode allows frequency multiplication. The capture function is triggered by the input pin CAPIN, by GPT1 timer's T3 input lines T3IN and T3EUD, or by read accesses to GPT1 timers. The reload function is triggered by an overflow or underflow of timer T6.

In addition to the capture function, the capture trigger signal can also be used to clear the contents of timers T5 and T6 individually.

The functions of register CAPREL are controlled via several bit(field)s in the timer control registers T5CON and T6CON.

GPT2 Capture/Reload Register CAPREL in Capture Mode

Capture Mode for register CAPREL is selected by setting bit T5SC in control register T5CON (set bitfield CI in register T5CON to a non-zero value to select a trigger signal). In Capture Mode, the contents of the auxiliary timer T5 are latched into register CAPREL in response to a signal transition at the selected external input pin(s). Bit CT3 selects the external input line CAPIN or the input lines T3IN and/or T3EUD of GPT1 timer T3 as the source for a capture trigger. Either a positive, a negative, or both a positive and a negative transition at line CAPIN can be selected to trigger the capture function, or transitions on input T3IN or input T3EUD or both inputs, T3IN and T3EUD. The active edge is controlled by bitfield CI in register T5CON. **Table 30-14** summarizes these options.

Table 30-14 CAPREL Register Input Edge Selection

CT3	CI	Triggering Signal/Edge for Capture Mode
X	00_B	None. Capture Mode is disabled.
0	01_B	Positive transition (rising edge) on CAPIN.[1)]
0	10_B	Negative transition (falling edge) on CAPIN.
0	11_B	Any transition (rising or falling edge) on CAPIN.
1	01_B	Any transition (rising or falling edge) on T3IN.
1	10_B	Any transition (rising or falling edge) on T3EUD.
1	11_B	Any transition (rising or falling edge) on T3IN or T3EUD.

1) Rising edge must be selected if capturing is triggered by the internal GPT1 read signals (see register PISEL and **"Combined Capture Modes" on Page 30-59**).

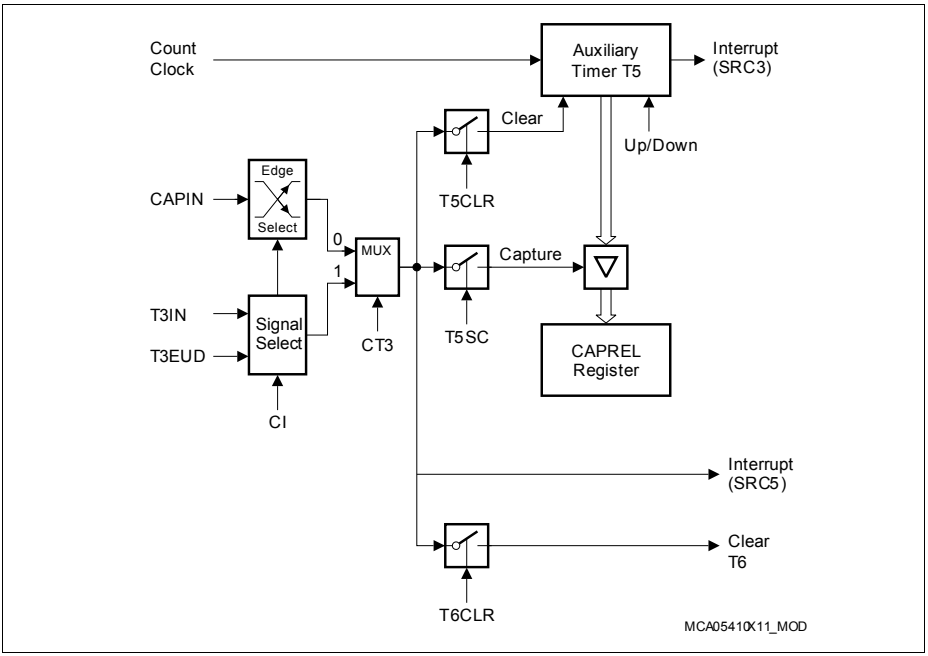

Figure 30-27 GPT2 Register CAPREL in Capture Mode

When a selected trigger is detected, the contents of the auxiliary timer T5 are latched into register CAPREL and the interrupt request is activated. The same event can optionally clear timer T5 and/or timer T6. This option is enabled by bit T5CLR in register T5CON and bit T6CLR in register T6CON, respectively. If TxCLR = 0 the contents of timer Tx is not affected by a capture. If TxCLR = 1 timer Tx is cleared after the current timer T5 value has been latched into register CAPREL.

Note: Bit T5SC only controls whether or not a capture is performed. If T5SC is cleared the external input pin(s) can still be used to clear timer T5 and/or T6, or as external interrupt input(s). This interrupt is controlled by the CAPREL interrupt control register SRC5.

When capture triggers T3IN or T3EUD are enabled (CT3 = 1), register CAPREL captures the contents of T5 upon transitions of the selected input(s). These values can be used to measure T3's input signals. This is useful, for example, when T3 operates in Incremental Interface Mode, in order to derive dynamic information (speed, acceleration) from the input signals.

For Capture Mode operation, the selected pins CAPIN, T3IN, or T3EUD must be configured as input. To ensure that a transition of a trigger input signal applied to one of

these inputs is recognized correctly, its level must be held high or low for a minimum number of module clock cycles, detailed in **Section 30.2.6**.

GPT2 Capture/Reload Register CAPREL in Reload Mode

Reload Mode for register CAPREL is selected by setting bit T6SR in control register T6CON. In Reload Mode, the core timer T6 is reloaded with the contents of register CAPREL, triggered by an overflow or underflow of T6. This will not activate the interrupt request SRC5.SRR associated with the CAPREL register. However, an interrupt request will be activated, indicating the overflow/underflow of T6.

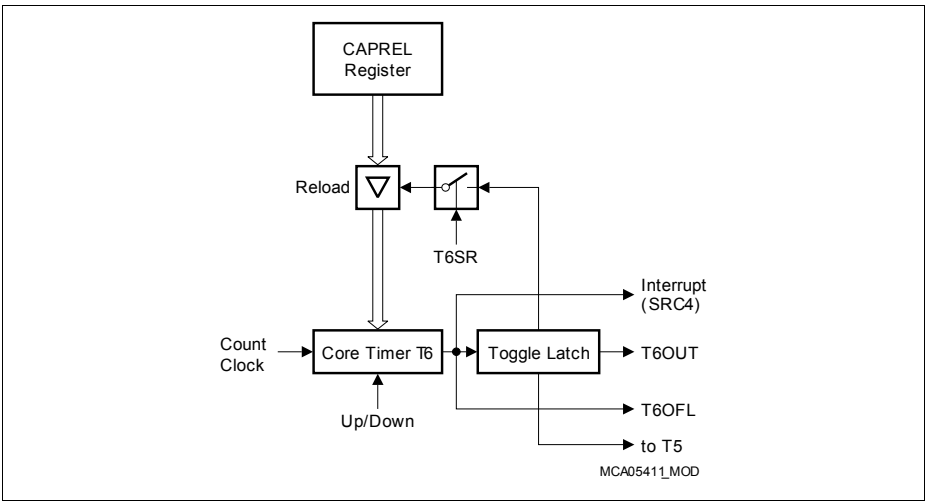

Figure 30-28 GPT2 Register CAPREL in Reload Mode

GPT2 Capture/Reload Register CAPREL in Capture-And-Reload Mode

Since the reload function and the capture function of register CAPREL can be enabled individually by bits T5SC and T6SR, the two functions can be enabled simultaneously by setting both bits. This feature can be used to generate an output frequency that is a multiple of the input frequency.

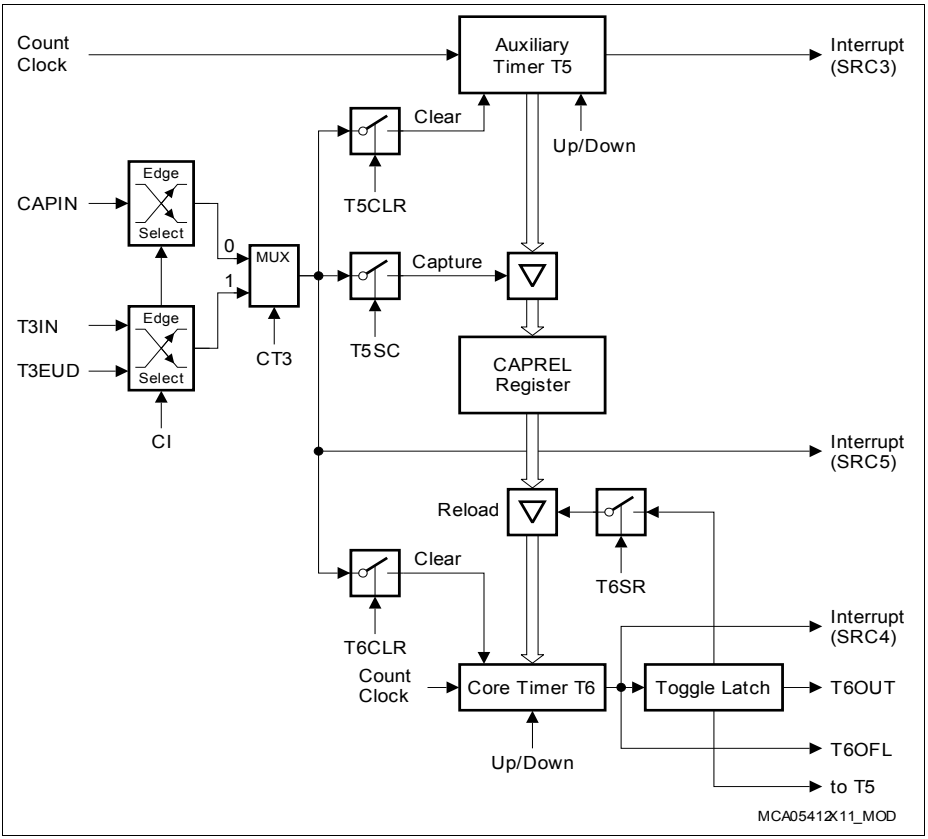

Figure 30-29 GPT2 Register CAPREL in Capture-And-Reload Mode

This combined mode can be used to detect consecutive external events which may occur aperiodically, but where a finer resolution, that means, more ‘ticks’ within the time between two external events is required.

For this purpose, the time between the external events is measured using timer T5 and the CAPREL register. Timer T5 runs in Timer Mode counting up with a frequency of e.g. $f_{GPT}/32$. The external events are applied to pin CAPIN. When an external event occurs,

the contents of timer T5 are latched into register CAPREL and timer T5 is cleared (T5CLR = 1). Thus, register CAPREL always contains the correct time between two events, measured in timer T5 increments. Timer T6, which runs in Timer Mode counting down with a frequency of e.g. $f_{GPT}/4$, uses the value in register CAPREL to perform a reload on underflow. This means, the value in register CAPREL represents the time between two underflows of timer T6, now measured in timer T6 increments. Since (in this example) timer T6 runs 8 times faster than timer T5, it will underflow 8 times within the time between two external events. Thus, the underflow signal of timer T6 generates 8 'ticks'. Upon each underflow, the interrupt request SRC4.SRR will be activated and bit T6OTL will be toggled. The state of T6OTL may be output on pin T6OUT. This signal has 8 times more transitions than the signal which is applied to pin CAPIN.

Capture Correction

A certain deviation of the output frequency is generated by the fact that timer T5 will count actual time units (e.g. T5 running at 1 MHz will count up to the value $64_H/100_D$ for a 10 kHz input signal), while T6OTL will only toggle upon an underflow of T6 (i.e. the transition from 0000_H to $FFFF_H$). In the above mentioned example, T6 would count down from 64_H, so the underflow would occur after 101 timing ticks of T6. The actual output frequency then is 79.2 kHz, instead of the expected 80 kHz.

Another possibility is to use T6 overflows. In this case, T5 counts down and T6 counts up. Upon a signal transition on pin CAPIN, the count value in T5 is captured into CAPREL and T5 is cleared to 0000_H. In its next clock cycle, T5 underflows to $FFFF_H$, and continues to count down with the following clocks. T6 is reloaded from CAPREL upon an overflow, and continues to count up with its following clock cycles (8 times faster in the above example). In this case, T5 and T6 count the same number of steps with their respective internal count frequency.

In the above example, T5 running at 1 MHz will count down to the value $FF9C_H/-100_D$ for a 10 kHz input signal applied at CAPIN, while T6 counts up from $FF9C_H$ through $FFFF_H$ to 0000_H. So the overflow occurs after 100 timing ticks of T6, and the actual output frequency at T6OUT then is the expected 80 kHz.

However, in this case CAPREL does not directly contain the time between two CAPIN events, but rather its 2's complement. Software will have to convert this value, if it is required for the operation.

Combined Capture Modes

For incremental interface applications in particular, several timer features can be combined to obtain dynamic information such as speed, acceleration, or deceleration. The current position itself can be obtained directly from the timer register (T2, T3, T4).

The time information to determine the dynamic parameters is generated by capturing the contents of the free-running timer T5 into register CAPREL. Two trigger sources for this event can be selected:

- Capture trigger on sensor signal transitions
- Capture trigger on position read operations

Capturing on sensor signal transitions is available for timer T3 inputs. This mode is selected by setting bit CT3 and selecting the intended signal(s) via bitfield CI in register T5CON. CAPREL then indicates the time between two selected transitions (measured in T5 counts).

Capturing on position read operations is available for timers T2, T3, and T4. This mode is selected by clearing bit CT3 and selecting the rising edge via bitfield CI in register T5CON. Bitfield ISCAPIN in register PISEL then selects either a read access from T3 or a read access from any of T2 or T3 or T4. CAPREL then indicates the time between two read accesses.

These operating modes directly support the measurement of position and rotational speed. Acceleration and deceleration can then be determined by evaluating subsequent speed measurements.

30.2.6 GPT2 Clock Signal Control

All actions within the timer block GPT2 are triggered by transitions of its basic clock. This basic clock is derived from the system clock by a basic block prescaler, controlled by bitfield BPS2 in register T6CON (see **Figure 30-18**). The count clock can be generated in two different ways:

- **Internal count clock**, derived from GPT2's basic clock via a programmable prescaler, is used for (Gated) Timer Mode.
- **External count clock**, derived from the timer's input pin(s), is used for Counter Mode.

For both ways, the basic clock determines the maximum count frequency and the timer's resolution:

Table 30-15 Basic Clock Selection for Block GPT2

Block Prescaler[1]	BPS2 = 01_B	BPS2 = 00_B[2]	BPS2 = 11_B	BPS2 = 10_B
Prescaling Factor for GPT2: F(BPS2)	F(BPS2) = 2	F(BPS2) = 4	F(BPS2) = 8	F(BPS2) = 16
Maximum External Count Frequency	$f_{GPT}/4$	$f_{GPT}/8$	$f_{GPT}/16$	$f_{GPT}/32$
Input Signal Stable Time	$2 \times t_{GPT}$	$4 \times t_{GPT}$	$8 \times t_{GPT}$	$16 \times t_{GPT}$

1) Please note the non-linear encoding of bitfield BPS2.

2) Default after reset.

Internal Count Clock Generation

In Timer Mode and Gated Timer Mode, the count clock for each GPT2 timer is derived from the GPT2 basic clock by a programmable prescaler, controlled by bitfield TxI in the respective timer's control register TxCON.

The count frequency f_{Tx} for a timer Tx and its resolution r_{Tx} are scaled linearly with lower clock frequencies, as can be seen from the following formula:

$$f_{Tx} = \frac{f_{GPT}}{F(BPS2) \times 2^{<TxI>}} \qquad r_{Tx}[\mu s] = \frac{F(BPS2) \times 2^{<TxI>}}{f_{GPT}[MHz]} \tag{30.2}$$

The effective count frequency depends on the common module clock prescaler factor F(BPS2) as well as on the individual input prescaler factor $2^{<TxI>}$. **Table 30-16** summarizes the resulting overall divider factors for a GPT2 timer that result from these cascaded prescalers.

Table 30-16 GPT2 Overall Prescaler Factors for Internal Count Clock

Individual Prescaler for Tx	Common Prescaler for Module Clock[1]			
	BPS2 = 01_B	BPS2 = 00_B	BPS2 = 11_B	BPS2 = 10_B
TxI = 000_B	2	4	8	16
TxI = 001_B	4	8	16	32
TxI = 010_B	8	16	32	64
TxI = 011_B	16	32	64	128
TxI = 100_B	32	64	128	256
TxI = 101_B	64	128	256	512
TxI = 110_B	128	256	512	1024
TxI = 111_B	256	512	1024	2048

1) Please note the non-linear encoding of bitfield BPS2.

Table 30-17 lists a timer's parameters (such as count frequency, resolution, and period) resulting from the selected overall prescaler factor and the applied system frequency. Note that some numbers may be rounded.

Table 30-17 GPT2 Timer Parameters

FPI_Bus Clock = 10 MHz			Overall Divider Factor	FPI_Bus Clock = 40 MHz		
Frequency	Resolution	Period		Frequency	Resolution	Period
5.0 MHz	200 ns	13.11 ms	2	20.0 MHz	50 ns	3.28 ms
2.5 MHz	400 ns	26.21 ms	4	10.0 MHz	100 ns	6.55 ms
1.25 MHz	800 ns	52.43 ms	8	5.0 MHz	200 ns	13.11 ms
625.0 kHz	1.6 µs	104.9 ms	16	2.5 MHz	400 ns	26.21 ms
312.5 kHz	3.2 µs	209.7 ms	32	1.25 MHz	800 ns	52.43 ms
156.25 kHz	6.4 µs	419.4 ms	64	625.0 kHz	1.6 µs	104.9 ms
78.125 kHz	12.8 µs	838.9 ms	128	312.5 kHz	3.2 µs	209.7 ms
39.06 kHz	25.6 µs	1.678 s	256	156.25 kHz	6.4 µs	419.4 ms
19.53 kHz	51.2 µs	3.355 s	512	78.125 kHz	12.8 µs	838.9 ms
9.77 kHz	102.4 µs	6.711 s	1024	39.06 kHz	25.6 µs	1.678 s
4.88 kHz	204.8 µs	13.42 s	2048	19.53 kHz	51.2 µs	3.355 s

External Count Clock Input

The external input signals of the GPT2 block are sampled with the GPT2 basic clock (see **Figure 30-18**). To ensure that a signal is recognized correctly, its current level (high or low) must be held active for at least one complete sampling period, before changing. A signal transition is recognized if two subsequent samples of the input signal represent different levels. Therefore, a minimum of two basic clock periods are required for the sampling of an external input signal. Thus, the maximum frequency of an input signal must not be higher than half the basic clock.

Table 30-18 summarizes the resulting requirements for external GPT2 input signals.

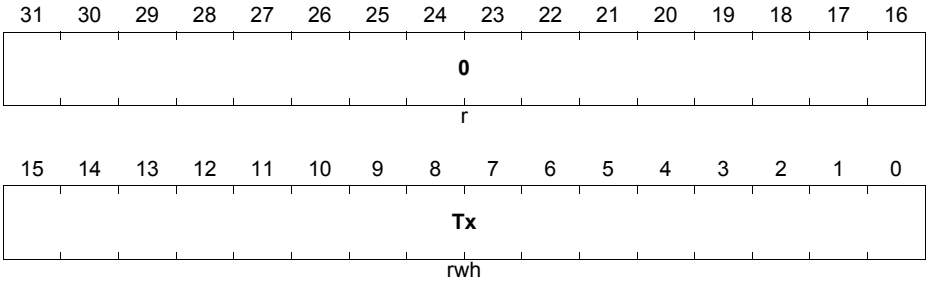
Table 30-18 GPT2 External Input Signal Limits

FPI_Bus Clock = 10 MHz		Input Frequ. Factor	GPT2 Divider BPS2	Input Phase Duration	FPI_Bus Clock = 40 MHz	
Max. Input Frequency	Min. Level Hold Time				Max. Input Frequency	Min. Level Hold Time
2.5 MHz	200 ns	$f_{GPT}/4$	01_B	$2 \times t_{GPT}$	10.0 MHz	50 ns
1.25 MHz	400 ns	$f_{GPT}/8$	00_B	$4 \times t_{GPT}$	5.0 MHz	100 ns
625.0 kHz	800 ns	$f_{GPT}/16$	11_B	$8 \times t_{GPT}$	2.5 MHz	200 ns
312.5 kHz	1.6 µs	$f_{GPT}/32$	10_B	$16 \times t_{GPT}$	1.25 MHz	400 ns

These limitations are valid for all external input signals to GPT2, including the external count signals in Counter Mode and the gate input signals in Gated Timer Mode.

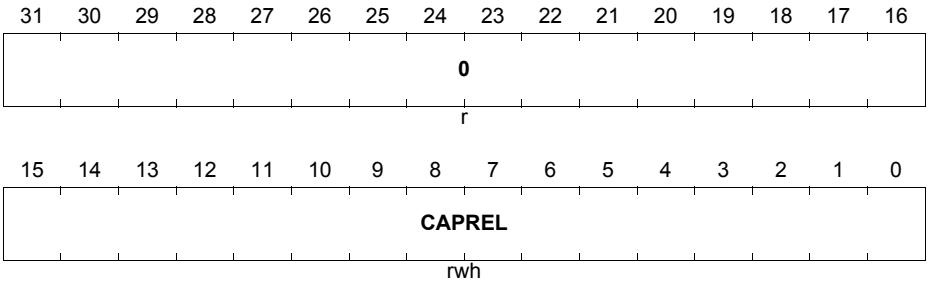
30.2.7 GPT2 Timer Registers

T5
Timer 5 Register **(40_H)** **Reset Value: 0000 0000$_H$**
T6
Timer 6 Register **(44_H)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
Tx	[15:0]	rwh	**Timer x** Contains the current value of Timer x.
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

CAPREL
Capture and Reload Register **(30_H)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
CAPREL	[15:0]	rwh	**Current reload value or Captured value**

Field	Bits	Type	Description
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

30.2.8 Interrupt Control for GPT2 Timers and CAPREL

When a timer overflows from $FFFF_H$ to 0000_H (when counting up), or when it underflows from 0000_H to $FFFF_H$ (when counting down), its service request flag (SRR) in register SRCx will be set. Whenever a transition according to the selection in bit field CI is detected at pin CAPIN, interrupt request flag SRR in register SRC5 is set.

Interrupts of timer 5 are connected with register SRC3.

Interrupts of timer 6 are connected with register SRC4.

Interrupts of the CAPREL function are connected with register SRC5.

SRC3
Service Request Control 3 Register ($F0_H$) Reset Value: 0000 0000_H

SRC4
Service Request Control 4Register (EC_H) Reset Value: 0000 0000_H

SRC5
Service Request Control 5 Register ($E8_H$) Reset Value: 0000 0000_H

30.5 Implementation of the GPT12 Modules

This chapter describes the implementation of the GPT12 modules in the TC1798 device.

30.5.1 Address Map

There are two GPT12 kernels in the TC1798, namely GPT120 and GPT121.

Table 30-20 Registers Address Space

Module	Base Address	End Address	Note
GPT120	$F000\ 3400_H$	$F000\ 34FF_H$	
GPT121	$F000\ 3500_H$	$F000\ 35FF_H$	

30.5.2 Module Connections

The following tables show the digital connections of the GPT12 modules with other modules or pins in the TC1798 device.
The GPT module is clocked with the FPI_Bus clock, so $f_{GPT} = f_{FPI}$.

31 Analog to Digital Converter (ADC)

The **A**nalog to **D**igital **C**onverter module (ADC) of the TC1798 allows the conversion of analog input values into discrete digital values based on the successive approximation method. With this method, the conversion result is elaborated bit by bit, starting with the most significant bit. As a consequence, an analog to digital conversion requires a certain number of clock cycles.

This chapter is structured as follows:

- Introduction (see **Section 31.1**)
- Operating the ADC (see **Section 31.2**)
- Module implementation in TC1798 (see **Section 31.3**)

31.1 Introduction

This section gives an overview about the feature set of the ADC module and introduces the general structure. It describes the:

- ADC block diagram (see **Section 31.1.1**)
- Feature set description (see **Section 31.1.2**)
- Abbreviations (see **Section 31.1.3**)
- Kernel overview (see **Section 31.1.4**)
- Conversion request handling (see **Section 31.1.5**)
- Conversion result handling (see **Section 31.1.6**)
- Interrupt structure (see **Section 31.1.7**)
- Electrical models (see **Section 31.1.8**)
- Transfer characteristics and error definitions (see **Section 31.1.9**)

31.1.1 ADC Block Diagram

The ADC module contains four independent kernels (ADC0, ADC1, ADC2, ADC3) that can operate autonomously or can be synchronized to each other. An ADC kernel is a unit used to convert an analog input signal into a digital value and provides means for triggering conversions, data handling and storage.
With this structure, parallel conversion of up to four analog input channels is supported.

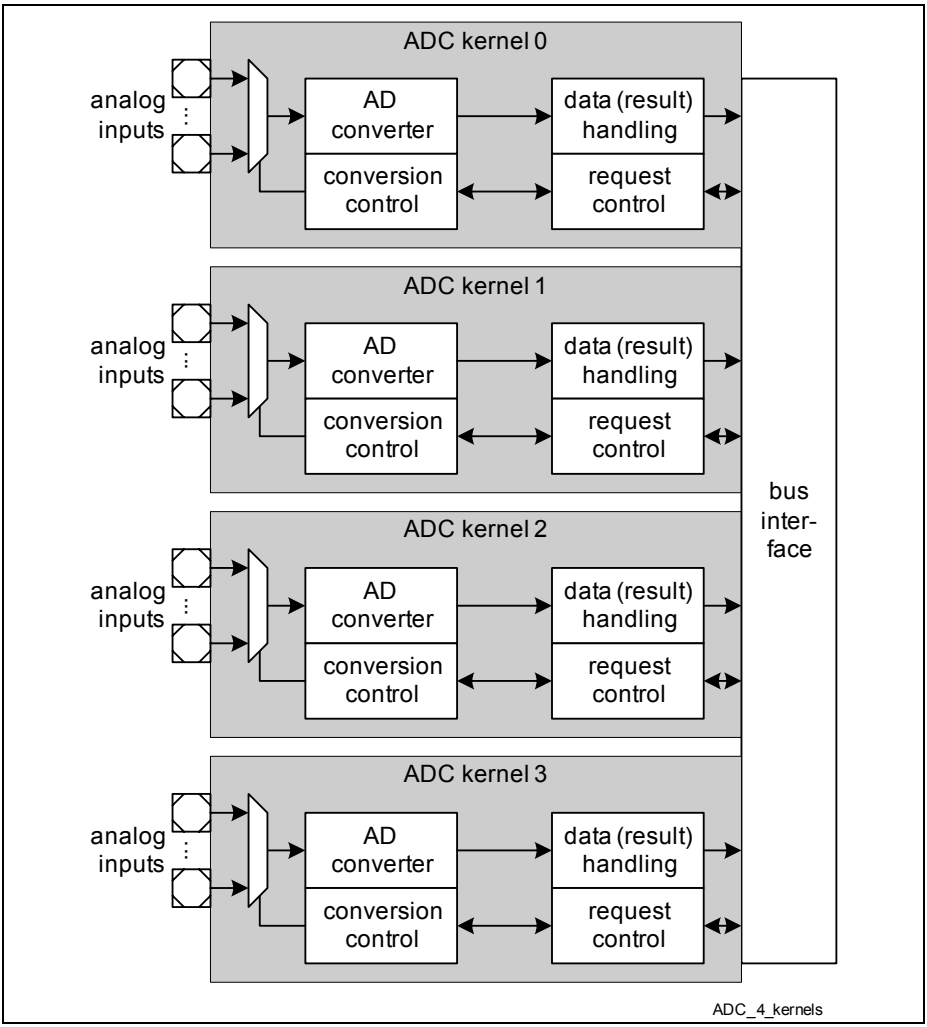

Figure 31-1 ADC Module Block Diagram

31.1.2 Feature Set

Features of each ADC kernel:

- Analog supply voltage range from 3.3 V (minimum) to 5 V (nominal) for V_{DDM}
- Input voltage range from 0 V to analog supply voltage V_{DDM}
- Input multiplexer for a maximum of 16 possible analog input channels
- One standard reference input (V_{AREF}) and one alternative reference input (CH0) available
- Broken wire detection support for each input channel
- Multiplexer test support for input channels with odd channel numbers
- 5 conversion request sources for external or timer-driven events, auto-scan, programmable sequences, SW-driven conversions, etc.
- Synchronization of the ADC kernels for concurrent conversion starts and parallel sampling and measuring of analog input signals, e.g. for phase current measurements in AC drives
- Control capability for an external analog multiplexer, respecting the additional set up time
- Adjustable sampling times to accommodate output impedance of different analog signal sources (sensors, etc.)
- Possibility to cancel running conversions on demand with automatic restart
- Flexible interrupt generation (possibility of DMA support)
- Limit checking to reduce interrupt load (e.g. for temperature measurements or overload detection, only values exceeding a programmable level lead to an interrupt)
- Programmable data reduction filter, e.g. for digital anti-aliasing filtering, by adding a programmable number of conversion results
- Independent result registers (16 independent registers)
- Programmable result data filter providing 3rd order FIR or 1st order IIR filter structure
- Support of conversion result FIFO mechanism to allow a longer interrupt latency
- Support of suspend and power saving modes
- Individually programmable reference selection for each channel, e.g. to allow measurements of 3.3 V and 5 V signals in the full measurement range with the same ADC kernel (with exception of dedicated channels always referring to V_{AREF})

31.1.3 Abbreviations

The following acronyms and terms are used in the ADC chapter:

Table 31-1 Abbreviations in ADC chapter

Abbreviation	Meaning
ADC	analog to digital converter
DMA	direct memory access mechanism
DNL	differential non-linearity error
FIFO	first-in-first-out data buffer mechanism
FIR	finite impulse resonse (digital filter)
INL	integral non-linearity error
IIR	infinite impulse resonse (digital filter)
LSB_n	finest granularity of the analog value in digital format, represented by one least significant bit of the conversion result with n bits resolution (measurement range divided in 2^n equally distributed steps)
SCU	system control unit of the device
TUE	total unadjusted error

31.1.4 ADC Kernel Overview

Each ADC kernel comprises:

- An **analog to digital converter** with a maximum of 16 analog inputs (CH0 - CH15). This block selects an input signal and translates the analog voltage into a digital value.
  Not all analog input channels are necessarily available in all packages, please refer to the implementation description in **Section 31.3**.
- A **conversion control** unit defining the conversion parameters like the length of the sample phase, the resolution and the reference for each conversion. The length of the sample phase and the resolution depend on the type of sensor (or other analog sources) connected to the ADC. These values are similar for several channels and, therefore, are grouped together to form the so-called input classes. Each channel can be individually assigned to an input class to define these parameters.
  The conversion control also handles the start conditions for the conversions, such as the immediate start (cancel-inject-repeat), overwrite of former results (wait-for-read), or synchronization of the ADC kernels (parallel conversions).
  Additionally, an external analog multiplexer can be controlled by the output signals EMUX[2:0] of dedicated ADC kernels.
- A **request control** unit defining which analog input channel has to be converted next. It contains 5 request sources that can trigger conversions depending on different events, such as edges of PWM or timer signals or events at port pins. Each request source can trigger either 1, up to 4, or up to 16 conversions in a sequence.
- A **result handling** unit providing 16 result registers for the conversion results. The conversion result of each analog input channel can be directed to one of the result registers to be stored there. The result handling block also supports data reduction (e.g. for digital anti-aliasing filtering) by automatically adding up to 4 conversion results before informing the CPU that new data is available.
  Additionally, the results registers can be concatenated to FIFO structures to provide storage capability for more than one conversion result without overwriting previous data. This feature also helps to handle CPU latency effects.
- An **interrupt generation** unit issuing interrupt requests to the CPU depending on ADC events. The interrupt generation in the ADC kernels support different mechanisms, e.g. some interrupts can be coupled to a value range of the conversion result (limit checking), some interrupts can be used to transport conversion data to locations in memory for further treatment, and other interrupts are generated after a complete sequence of conversions.

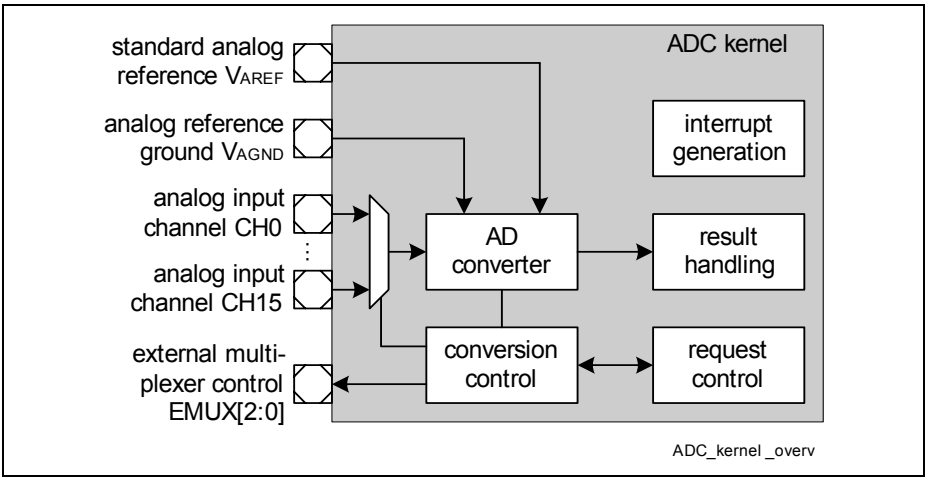

Figure 31-2 ADC Kernel Block Diagram

31.1.5 Conversion Request Unit

The conversion request unit of each ADC kernel autonomously handles the generation of conversion requests.
It contains 5 independent request sources that are connected to several modules to trigger the start of a conversion. A request source defines the analog input channel to be converted if a defined event occurs. For example, a trigger pulse from a timer unit generating a PWM signal can start the conversion of a single input channel or a programmed sequence of input channels.
Depending on the application, the request sources can be triggered by different events, either issued by other modules or under SW control. As a consequence, there can be two or more conversion requests pending at the same time. To allow the user to adapt the request source mechanism to the application needs, the trigger capability, the channel number(s) to be converted, and the priority can be individually programmed for each request source.
An arbiter block regularly scans the request sources for pending conversion requests and acts upon the conversion request with the highest priority. This conversion request is forwarded to the converter to start the conversion of the requested channel.

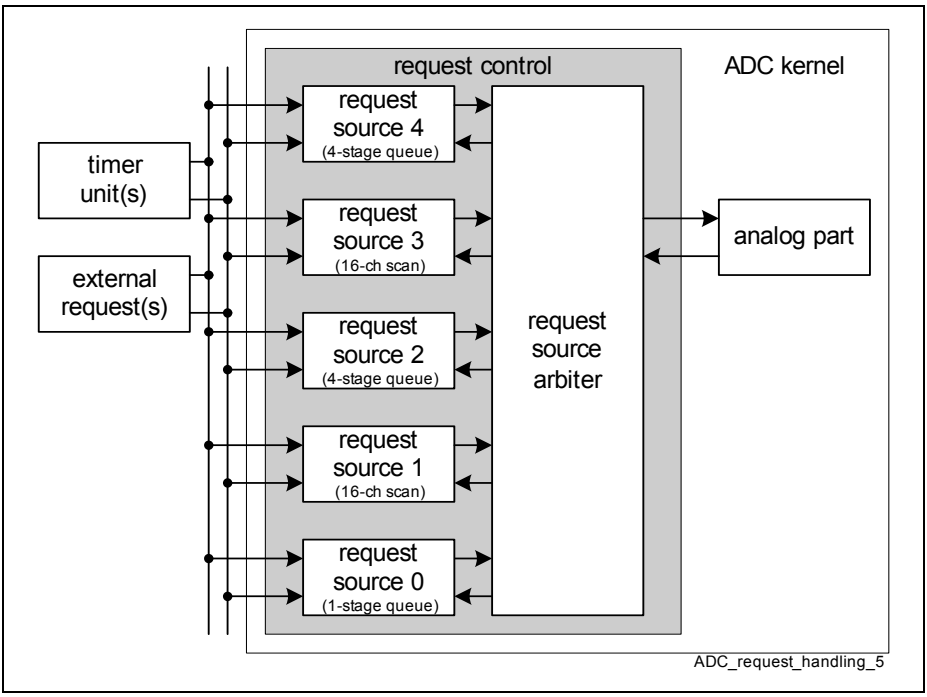

Figure 31-3 Conversion Request Unit

The functional characteristics of the request sources are adapted to the most common application requirements. In all request sources, a continuous operation or a single-shot operation can be selected. For continuous operation, the programmed sequence of conversions requests are continuously issued (once started), whereas in single-shot mode, each sequence of conversion requests has to be explicitly started. The trigger for a conversion request or a sequence can be handled under SW control or can be synchronized to ADC-external events, such as timer signals or port pins. For each request source, the user can select an input signal (from 8 possible signals REQTRx_[7:0]) as trigger input REQTRx and an input signal (from 8 possible signals REQGTx_[7:0]) as gating input REQGTx.

- **Request source 0** (1-stage sequential source) can issue a conversion request for a single input channel. The channel number can directly be programmed.
  This mechanism could be used for SW-controlled conversion requests or HW-triggered conversions of a single input channel. If programmed with a high priority, it can interrupt the sequences of the other request sources to inject a single conversion.
- **Request sources 1 and 3** (16-channel scan sources) can issue conversion requests for a sequence of up to 16 input channels. It can be programmed which channel takes part in this sequence. The sequence always starts with the highest enabled channel number and continues towards lower channel numbers (order defined by the channel number, each channel can be converted only once per sequence).
  This mechanism could be used to scan input channels permanently or on a regular time base. For example, if programmed with a low priority, some input channels can be scanned in a background task to update information that is not time-critical.
- **Request sources 2 and 4** (4-stage sequential sources) can issue a conversion request for a sequence of up to 4 input channels. The channel numbers can be freely programmed, especially multiple conversions of the same channel within the sequence are supported.
  This mechanism could be used to support application-specific conversion sequences that can not be covered by the scanning mechanism of request sources 1 or 3. Especially for timing-critical sequences containing multiple conversions of the same channel, one of these request sources should be used. For example, if programmed with a medium priority, some input channels can be converted when a specified event occurs (e.g. synchronized to a PWM) while the scan of other input channels of the background task (handled by request source 1) is interrupted.

31.1.6 Conversion Result Unit

The conversion result unit comprises for each ADC kernel:

- A set of **16 result registers** for storing the conversion results. A pointer mechanism for each analog input channel distributes the conversion results to the result registers. Especially for auto-scan applications, this feature simplifies DMA use (only one DMA channel needed to transfer a complete auto-scan sequence into the device memory).
- The result registers provide **valid flags** to indicate if new data has been stored since it has been read out (new data indication).
- A **result FIFO mechanism** for conversion results handling with a “relaxed” CPU timing. Result registers not directly used as target for a conversion result can be concatenated to form a result FIFO. This structure allows to store a sequence of conversion results before the CPU has to interact.
- A **digital anti-aliasing or data reduction filter**, accumulating a programmable number of conversion results before generating a result event interrupt.
  This feature can be used to avoid CPU intervention on each conversion result if a certain number of conversion results are added before further treatment, especially for fast conversions sequences and averaging of results.
- A **wait-for-read mechanism** can be enabled independently for each result register to delay conversions targeting a result register that has not yet been read out.
- A **flexible interrupt generation** based on result register events. A result register event occurs if a new valid data word becomes available in a result register and can be read out. Especially when using data reduction or digital anti-aliasing filtering, the result register event indicates that the final result is available.
- **Debugger support** for ADC result registers supporting read out of ADC conversion results without changing the result status (new data indication).

31.1.7 Interrupt Structure

Each ADC kernel provides 8 independent service request output signals (ADCx_SR[7:0]) used for interrupt handling. The interrupt generation inside the ADC kernel is based on three different types of events.

- **Channel events:**
  A channel event is detected if a conversion is finished and the conversion result is within a programmable value range.
  This type of event can be used to check if analog input values are inside or out of a nominal operating range, especially to reduce CPU load for background tasks. This allows the user to interrupt the CPU only if the specified conversion result range is met (or not met) instead of comparing each result by SW.
- **Result events:**
  A result event is detected if a new result is available in a result register and can be read out, e.g. to store the data in memory for further treatment by SW.
  This type of event can be used to trigger a read action by the CPU (or DMA). Especially when using data reduction or digital anti-aliasing filtering, not all finished conversion leads to a new result. Furthermore, when using a result FIFO, a result event decouples the CPU (DMA) read out from the channel events and tolerates a higher interrupt latency. The result register structure allows to use a single DMA channel for a complete auto-scan sequence by triggering the read out by a result event (if the conversion results of all channels taking part in the auto-scan sequence target the same result register, e.g. with FIFO mechanism or with a wait-for-read condition to avoid data loss).
- **Request source events:**
  A request source event is detected if a scan source has completely finished the requested conversion sequence. For a sequential source, the user can define where inside a conversion sequence a request source event is generated.
  This type of event can be used to inform the CPU that a conversion sequence has reached a defined state and SW can start the treatment of the related results in a block.

Each ADC event is indicated by a dedicated flag that can be cleared by SW. An interrupt can be generated (if enabled) for each event, independently from the status of the corresponding event indication flag. This structure ensures efficient DMA handling of ADC events (the ADC event can generate an interrupt without the need to clear the indication flag). A node pointer mechanism allows the user to group interrupts events by selecting which service request output signals SRx becomes activated by which event. Each ADC event can be individually directed to one of the service request output signals to adapt easily to application needs.

Note: A conversion can lead to three interrupts, one of each type. In this case, the ADC module first triggers the request source event interrupt, then the channel event interrupt, followed by the result event interrupt (all within a few f_{ADC} clock cycles).

31.1.8 Electrical Models

Each conversion of an analog input voltage into a digital value consists of two consecutive phases. During the sample phase, the input voltage is sampled and prepared for the following conversion phase. A simplified model for the sample phase describes the input signal path, whereas a second simplified model for the conversion phase is related to the reference voltage handling.

31.1.8.1 Input Signal Path

The ADC kernel in the TC1798 is based on one switched capacitor field for measurement with a total capacity represented by C_{AIN} and a small static capacitor at each input pin. During the sample phase, the capacitor field C_{AIN} is connected to one of the analog input CHx via an input multiplexer. The multiplexer is modeled by ideal switches and series resistors R_{AIN}. Only the switch to the selected analog input is closed during the sample phase. During the conversion phase or while no conversion is running (ADC is idle), all switches are open. The voltage at the analog input channel CHx is represented by V_{AINx}.

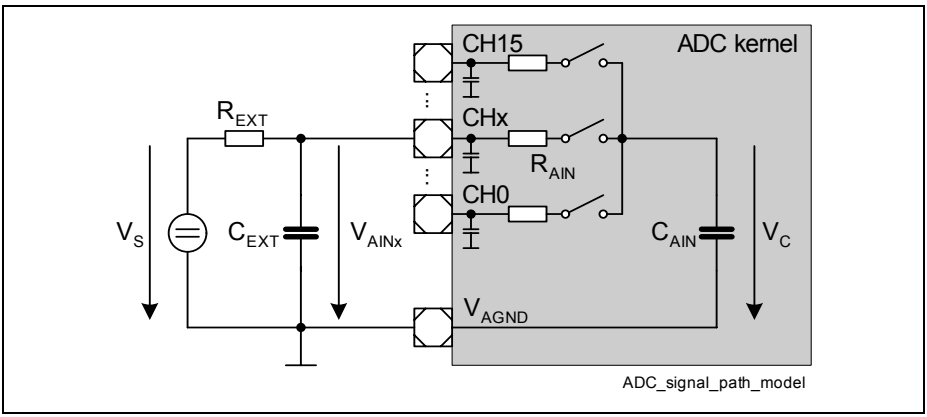

Figure 31-4 Signal Path Model

A simplified model for the analog input signal path is given in **Figure 31-4**. An analog voltage source (value V_S) with an internal impedance of R_{EXT} delivers the analog input that should be converted.

During the sample phase the corresponding switch is closed and the capacitor field C_{AIN} is charged. Due to the low-pass behavior of the resulting RC combination, the voltage V_C to be actually converted does not immediately follow V_S. The value R_{EXT} of the analog voltage source and the desired precision of the conversion strongly define the required length of the sample phase.

To reduce the influence of R_{EXT} and to filter input noise, it is recommended to introduce

a fast external blocking capacitor C_{EXT} at the analog input pin of the ADC. Like this, mainly C_{EXT} delivers the charge during the sample phase. This structure allows a significantly shorter sample phase than without a blocking capacitor, because the low-pass time constant defining the sample time is mainly given by the values of R_{AIN} and C_{AIN}.

Additionally, the capacitor C_{AIN} is automatically precharged to a voltage of approximately the half of the standard reference voltage V_{AREF} to minimize the average difference between V_{AINx} and V_C at the beginning of a sample phase. Due to varying parameters and parasitic effects, the precharge voltage of C_{AIN} is typically smaller than V_{AREF} / 2.

On the other hand, the charge redistribution between C_{EXT} and C_{AIN} leads to a voltage change of V_{AINx} during the sample phase. In order to keep this voltage change lower than 1 LSB_n, it is recommended to use an external blocking capacitor C_{EXT} in the range of at least $2^n \times C_{AIN}$.

The resulting low-pass filter of R_{EXT} and C_{EXT} should be dimensioned in a way to allow V_{AINx} to follow V_S between two sample phases of the same analog input channel.

Please note that, especially at high temperatures, the analog input structure of an ADC can lead to a leakage current and introduces an error due to a voltage drop over R_{EXT}. The ADC input leakage current increases if the input voltage level is close to the analog supply ground V_{SSM} or to the analog power supply V_{DDM}. It is recommended to use an operating range for the input voltage between approximately 3% and 97% of V_{DDM} to reduce input leakage values.

Furthermore, the leakage is influenced by an overload condition at adjacent analog inputs. During an overload condition, an input voltage exceeding the supply range is applied at an input and the built-in protection circuit limits the resulting input voltage. This leads to an overload current through the protection circuit that is translated (by a coupling factor) into an additional leakage at adjacent inputs.

31.1.8.2 Reference Path

During the conversion phase, parts of the capacitor field C_{AIN} are switched to a reference input or to V_{AGND}. The ADC kernel supports two possible reference inputs, V_{AREF} as standard reference and CH0 as alternative reference. The reference selection between both possibilities is handled individually for each analog input channel. For example, this structure allows conversions of 5 V and 3.3 V based analog input signals with the same ADC kernel.

A high accuracy of the conversion results requires a stable and noise-free reference voltage and analog supply voltages during the conversion phase. Instable voltages or noise on the supply or reference inputs lead to a reduced conversion accuracy. Please note that noise can also be introduced into the ADC module by other modules, e.g. by switching of neighboring pins. It is strongly recommended to carefully decouple analog from digital signal domains.

Due to the switching of parts of C_{AIN}, the ADC requires a dynamic current at the selected reference input. Thus, the impedance R_{AREF} of the reference voltage source V_R has to

be low enough to supply the reference current during the conversion phase. An external blocking capacitor C_{AREF} should be used to supply the peak currents and to minimize the current delivered by the reference source.

Due to the charge redistribution between C_{AREF} and parts of C_{AIN}, the voltage V_{AREF} decreases during the conversion phase. In order to limit the error introduced by this effect to 1/2 LSB_n, the external blocking capacitor C_{AREF} for the reference input should be at least $2^n \times C_{AIN}$.

The reference current I_{AREF} introduces a voltage drop at R_{AREF} that should not be neglected for the calculation of the overall accuracy. The average reference current during a conversion depends on the reference voltage level and the time t_{CONV} between two conversion starts.

$I_{AREF} = C_{AIN} \times V_{AREF} / t_{CONV}$

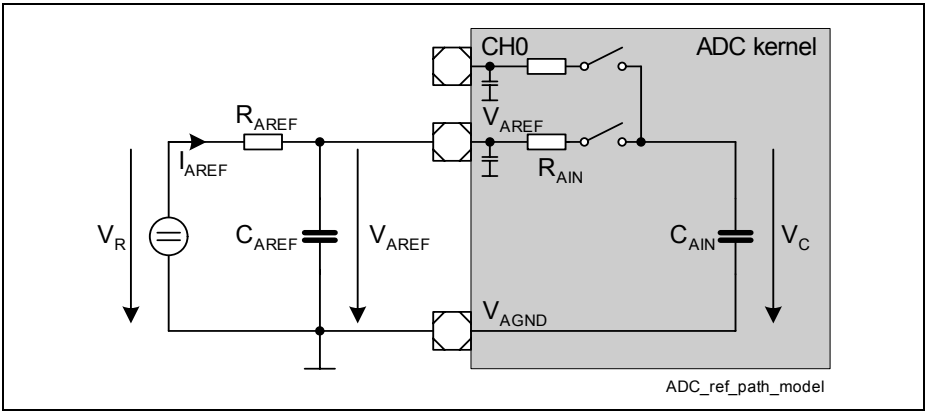

Figure 31-5 Reference Path Model

31.1.9 Transfer Characteristics and Error Definitions

The ideal transfer characteristic of the ADC translates a continuous analog input voltage into a discrete digital value out of a result range of 2^n steps for n bit resolution over a measurement range between 0 and a reference voltage. Each digital value in the available result range (from 0 to 2^n-1) represents an input voltage range that is defined by the reference voltage divided by 2^n. This range (called quantization step) represents the smallest granularity (called LSB_n) that can be handled by the ADC. Due to the discrete character of the digital result, each ADC conversion result has a system-inherent quantization uncertainty of ± 0.5 LSB_n. According to the ideal transfer characteristics, the first digital transition (between the digital values 0 and 1) takes place when the analog input reaches 0.5 LSB_n.
An analog input voltage above the reference voltage leads to a saturation of the digital result at 2^n-1.

Deviations of the conversion result from the ideal transfer characteristics can appear:

- An **offset error** is the deviation from the ideal transfer characteristics for an input voltage close to 0. It describes the difference between 0.5 LSB_n and the input voltage where the first digital transition (between the values of 0 and 1) occurs.
- A **gain error** is the deviation from the ideal transfer characteristics for an input voltage close to the reference voltage. It describes the difference between the reference voltage and the input voltage where the last digital transition (between the values of 2^n-2 and 2^n-1) occurs.
- A **differential non-linearity error** (DNL) describes the variations in the analog input voltage between two adjacent digital conversion results, over the full measurement range. If each step between the digital conversion results x and x+1 is exactly 1 LSB_n, the DNL value is zero. If the DNL value is lower than 1 LSB_n, the possibility of missing codes is excluded. A missing code occurs if not all values of the possible conversion result range can be reached.
- An **integral non-linearity error** (INL) describes the maximum difference between the transfer characteristics between the first and the last point of the measurement range and the real transfer characteristics (without quantization uncertainty, offset and gain errors).
- The **total unadjusted error** (TUE) describes the maximum deviation between a real conversion result and the ideal transfer characteristics over a given measurement range. Since some of these errors noted above can compensate each other, the TUE value generally is much less than the sum of the individual errors.
  The TUE also covers production process variations and internal noise effects (if switching noise is generated by the system, this generally leads to an increased TUE value).

31.2 Operating the ADC

This section describes the kernel functions and how to operate the kernel. It provides the functional descriptions and the associated register descriptions.

- Register overview (see **Section 31.2.1**)

General module, kernel and arbiter operation:

- Enabling the ADC module for configuration of the behavior for the different device operating modes (see mode control description in **Section 31.2.2**).
- Enabling the converter for operation or selecting the desired power saving mode (see **Section 31.2.3**)
- Selecting the appropriate frequency for the converter and for the request source arbiter (see **Section 31.2.4**).
- ADC module registers (see **Section 31.2.5**)
- General ADC kernel registers (see **Section 31.2.6**)
- Configuring the request source arbiter (see **Section 31.2.7**)
- Arbiter registers (see **Section 31.2.8**)

Request source operation:

- Scan request source handling (see **Section 31.2.9**)
- Scan request source registers (see **Section 31.2.10**)
- Sequential request source handling (see **Section 31.2.11**)
- Sequential request source registers (see **Section 31.2.12**)

Channel and result register operation:

- Configuring the channel-related functions (see **Section 31.2.13**)
- Channel-related registers (see **Section 31.2.14**)
- Conversion result handling (see **Section 31.2.15**)
- Conversion request handling (see **Section 31.2.16**)

Additional features:

- Multiplexer test support (see **Section 31.2.17**)
- External multiplexer control (see **Section 31.2.18**)
- Synchronization for parallel conversions (see **Section 31.2.19**)
- Equidistant sampling (see **Section 31.2.20**)
- Access protection (see **Section 31.2.21**)
- Broken-wire detection (see **Section 31.2.22**)
- Additional feature registers (see **Section 31.2.23**)

31.2.1 Register Overview

Table 31-2 shows all registers required for programming the ADC module. It summarizes the ADC kernel registers and defines their relative addresses and the reset values. The relative addresses have to be added to the base addresses for the ADC kernels (see Section 31.3) to obtain the absolute address for each register. Each ADC kernel is located in an address window of 4 * 256 bytes.
All registers can be accessed with 8 bit, 16 bit, or 32 bit wide accesses.

The prefix "**ADCx_**" has to be added to the register names in this table for each ADC kernel to distinguish registers of the different kernels. In this naming convention, x indicates the kernel number (e.g. ADC0_ for the ADC0 kernel and "ADC1_" for the ADC1 kernel).
The registers that are implemented only once in the ADC module are located in the address range of ADC0.

All ADC registers (including KSCFG.NOMCFG and KSCFG.COMCFG) are reset by an application reset (class 3), whereas bit field KSCFG.SUMCFG is reset by a debug reset (class 1).

Note: Register bits marked "w" always deliver 0 when read.

Access rights within the address range of an ADC kernel:

- Read or write access to defined register addresses: U, SV
- Accesses to empty addresses: reserved, BE

1) The absolute register address is calculated as follows:
Module Base Address + Offset Address (shown in this column)

31.2.2 Mode Control

The mode control concept for system control tasks, such as suspend request for debugging, allows to program the module behavior under different device operating conditions. The behavior of the ADC kernels can be programmed for each of the device operating modes. It is advantageous that the ADC kernels of an ADC module show an identical behavior regarding the device operating modes (e.g. to avoid that a non-suspended kernel waits for a suspended kernel to start a synchronized conversion). Therefore, the ADC module has a common associated register **ADC0_KSCFG** defining the behavior of all kernels of the module in the following device operating modes:

- **Normal operation:**
  This operating mode is the default operating mode when no suspend request is pending. The kernel behavior is defined by KSCFG.NOMCFG.
- **Suspend mode:**
  This operating mode is requested when a suspend request (issued by a debugger) is pending in the device. The kernel behavior is defined by KSCFG.SUMCFG.

For the ADC module, the following internal actions can be influenced by mode control:

- A current conversion of an analog value:
  If the request control unit has found a pending conversion request, the conversion can be started. This start has to be enabled by the mode control. If the current kernel mode allows the conversion start (run modes 0 and 1), it will be executed. If the kernel mode does not allow a start (stop modes 0 and 1), the conversion is not started. The start request is not cancelled, but frozen. A “frozen” conversion is started as programmed if the kernel mode is changed to a run mode again.
- An arbiter round:
  The start of a new arbiter round has to be enabled by the kernel modes. In stop mode 1, a new arbiter round will not start.

The behavior of the ADC kernels can be programmed for each of the device operating modes (normal operation, suspend mode). Therefore, the ADC kernels support four kernel modes, as shown in **Table 31-3**.

Table 31-3 ADC Kernel Behavior

Kernel Mode	Kernel Behavior	Code
run mode 0	kernel operation as specified, no impact on data transfer (same behavior for run mode 0 and run mode 1)	00_B
run mode 1		01_B

Table 31-3 ADC Kernel Behavior (cont'd)

Kernel Mode	Kernel Behavior	Code
stop mode 0	A currently running AD conversion is completely finished and the result is treated. Pending conversion request to start a new conversion are not taken into account (but not deleted). They start conversions after entering a run mode as programmed. The arbiter continues as programmed.	10_B
stop mode 1	Like stop mode 0, but the arbiter is stopped after it has finished its arbitration round.	11_B

Generally, bit field KSCFG.NOMCFG should be configured for run mode 0 as default setting for standard operation. If the ADC kernels should not react to a suspend request (and to continue operation as in normal mode), bit field KSCFG.SUMCFG has to be configured with the same value as KSCFG.NOMCFG. If the ADC kernels should show a different behavior and stop operation when a specific stop condition is reached, the code for stop mode 0 or stop mode 1 has to be written to KSCFG.SUMCFG.

Note: The stop mode selection strongly depends on the application needs and it is very unlikely that different stop modes are required in parallel in the same application. As a result, only one stop mode type (either 0 or 1) should be used in the bit fields in register KSCFG. Do not mix stop mode 0 and stop mode 1 and avoid transitions from stop mode 0 to stop mode 1 (or vice versa) for the ADC module.

31.2.3 Module Activation and Power Saving Modes

The converter of the ADC supports specific power down modes allowing an automatic reduction of the power consumption between two conversions. The following modes are determined by bit field **GLOBSTR**.ANON:

- ANON = 00_B: **Converter switched off** (default after reset)
  The complete converter is switched off and held in its reset state, conversions are not possible. To start a conversion, ANON has to be programmed to the desired mode. A maximum wake-up time of about 10 µs has to be respected before starting a conversion. Furthermore, digital logic blocks are set to their initial state.
- ANON = 01_B and 10_B: **Reserved**
  These modes are reserved and must not be selected.
- ANON = 11_B: **Normal operation**
  Conversions are always possible with the desired sample time. The converter stays active permanently.

31.2.4 Clocking Scheme

The different parts of an ADC kernel are driven by clock signals that are based on the clock f_{ADC} of the bus that is used to access the ADC module.

- The analog clock f_{ADCI} is used as internal clock for the converter and defines the conversion length and the sample time. It can be adjusted by programming bit field **GLOBCTR**.DIVA.
- The digital clock f_{ADCD} is used for the arbiter and defines the duration of an arbiter round. It can be adjusted by programming bit field **GLOBCTR**.DIVD.
- All other digital structures (such as interrupts, etc.) are directly driven by the module clock f_{ADC}.

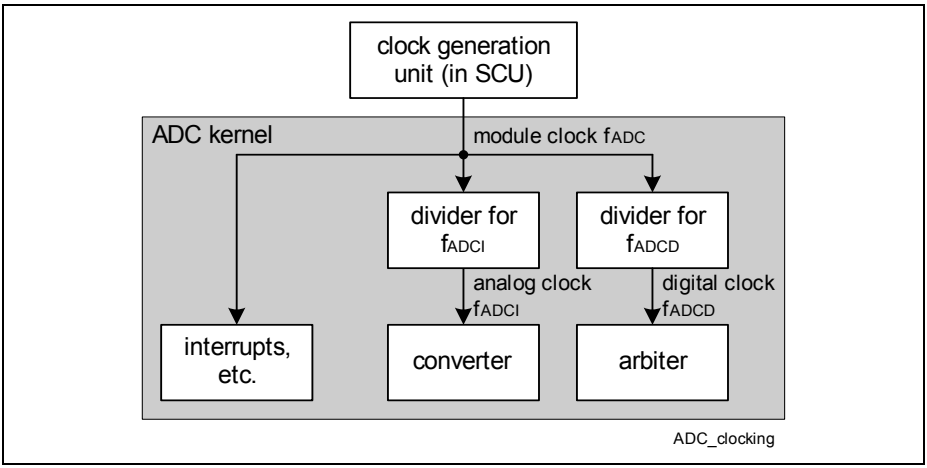

Figure 31-6 Clocking Scheme

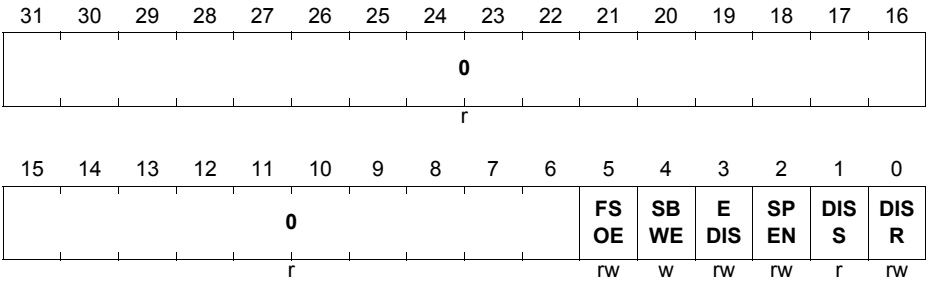
Note: If the clock generation for the converter of the ADC falls below a minimum value or is stopped during a running conversion, the conversion result can be corrupted. For correct ADC results, the frequency of f_{ADCI} must not exceed the range indicated in the electrical characteristics chapter.

31.2.5 ADC Module Registers

31.2.5.1 Clock Control Register

The clock control register allows the programmer to control (enable/disable) the clock signals to the ADC module.

ADC0_CLC
ADC Clock Control Register **(000_H)** **Reset Value: 0000 0003_H**



Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module.
DISS	1	r	**Module Disable Status Bit** Bit indicates the current status of the module.
SPEN	2	rw	**Module Suspend Enable for OCDS** Used to enable the suspend mode
EDIS	3	rw	**Sleep Mode Enable Control** Used to control module's sleep mode.
SBWE	4	w	**Module Suspend Bit Write Enable for OCDS** Determines whether SPEN and FSOE are write-protected.
FSOE	5	rw	**Fast Switch Off Enable** Used to switch off fast clock in Suspend Mode.
0	[31:6]	r	**Reserved;** returns 0 if read; should be written with 0.

Note: After a hardware reset operation, the f_{CLC} and f_{ADC} clocks are switched off and the ADC module is disabled (DISS set).

31.2.5.2 Kernel State Configuration Register

The kernel state configuration register KSCFG allows the selection of the desired kernel modes. The ADC kernels are controlled by the same register ADC0_KSCFG.
All bits in KSCFG, except KSCFG.SUMCFG are reset by an application (class3) reset. Bit field KSCFG.SUMCFG is reset by the debug reset.
If a module should be switched off, SW can program a stop mode in bit field NOMCFG and check for ACK = 1 afterwards.

*Note: The coding of the bit fields NOMCFG, SUMCFG and COMCFG is described in **Table 31-3**.*

ADC0_KSCFG

r				w	r	rw		w	r	rw		rh	rh	r	

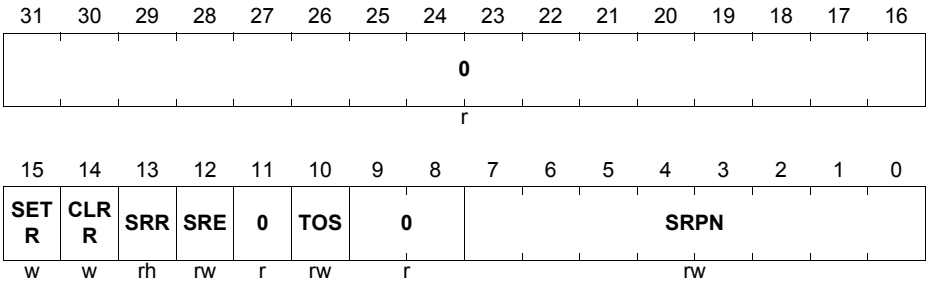
Field	Bits	Type	Description
ACK	2	rh	**Module Acknowledge** This bit monitors the state of the ADC module's acknowledge on incoming requests. 0_B The acknowledge is not activated, because at least one of the module kernels is in a transition phase. 1_B The acknowledge is activated, because all module kernels have reached the requested state.
SUSREQ	3	rh	**Suspend Request** This bit monitors the state of the ADC module's suspend request input. 0_B A suspend mode is not requested and bit field NOMCFG defines the ADC kernel mode. 1_B A suspend mode is requested and bit field SUMCFG defines the ADC kernel mode.

Field	Bits	Type	Description
NOMCFG	[5:4]	rw	**Normal Operation Mode Configuration** This bit field defines the kernel mode applied in normal operation mode. 00_B Run mode 0 is selected. 01_B Run mode 1 is selected. 10_B Stop mode 0 is selected. 11_B Stop mode 1 is selected.
BPNOM	7	w	**Bit Protection for NOMCFG** This bit enables the write access to the bit field NOMCFG. It always reads 0. 0_B The bit field NOMCFG is not changed. 1_B The bit field NOMCFG is updated with the written value.
SUMCFG	[9:8]	rw	**Suspend Mode Configuration** This bit field defines the kernel mode applied in suspend mode. Coding like NOMCFG.
BPSUM	11	w	**Bit Protection for SUMCFG** This bit enables the write access to the bit field SUMCFG. It always reads 0. 0_B The bit field SUMCFG is not changed. 1_B The bit field SUMCFG is updated with the written value.
0	[1:0], 6, 10, [31:12]	r	**Reserved** Read as 0; should be written with 0.

31.2.5.3 Service Request Control Registers

The service request control registers of the ADC module are located in the address range of ADC0.

ADC0_SRCx (x = 0-8)
ADC Service Request Control Register x
($3FC_H$ - x*4) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
SRPN	[7:0]	rw	**Service Request Priority Number**
TOS	10	rw	**Type of Service Control**
SRE	12	rw	**Service Request Enable**
SRR	13	rh	**Service Request Flag**
CLRR	14	w	**Request Clear Bit**
SETR	15	w	**Request Set Bit**
0	[9:8], 11, [31:16]	r	**Reserved** Read as 0; should be written with 0.

Note: Additional details on service request nodes and the service request control registers are described in the TC1798 System Units part (Volume 1).

31.2.6 General ADC Kernel Registers

31.2.6.1 Request Source Input Registers

The setting of the request source input registers selects the desired input signal for the gating and trigger signals of the request sources. The status of the selected inputs is monitored. Additionally, the edge sensitivity for the trigger signal and the timer mode for equidistant sampling can be enabled/disabled.

The actual connections depending on the device implementation, please refer to the implementation description in **Section 31.3** for details.

Note: Signals from a synchronous domain can of course be connected to inputs with a synchronization stage. The additional synchronization delay of two ADC module clock cycles and an additional uncertainty of one ADC module clock cycle for asynchronous signals have to be taken into account when using a synchronization stage.

RSIRx (x = 0 - 4)

Request Source x Input Register (010_H + x * 4) **Reset Value: 0000 0000_H**

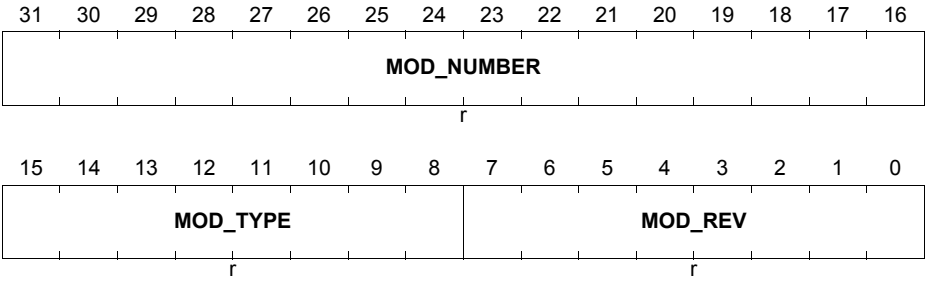
The inputs selected by codes $1XX_H$ are considered as asynchronous to the ADC module. 000_B The input signal REQTRx_0 is selected. 001_B The input signal REQTRx_1 is selected. 010_B The input signal REQTRx_2 is selected. 011_B The input signal REQTRx_3 is selected. 100_B The input signal REQTRx_4 is selected. 101_B The input signal REQTRx_5 is selected. 110_B The input signal REQTRx_6 is selected. 111_B The input signal REQTRx_7 is selected.
FEN	12	rw	**Falling Edge Enable of Source x** This bit enables the request trigger for falling edges of the selected REQTRx signal for request source x. 0_B The request trigger with a falling edge is disabled. 1_B The request trigger with a falling edge is enabled.
REN	13	rw	**Rising Edge Enable of Source x** This bit enables the request trigger for rising edges of the selected REQTRx signal for request source x. 0_B The request trigger with a rising edge is disabled. 1_B The request trigger with a rising edge is enabled.
TRI	15	rh	**Trigger Input of Source x** This flag monitors the status of the selected trigger signal REQTRx for request source x. 0_B The selected trigger signal is 0. 1_B The selected trigger signal is 1.
0	3, [6:5], 11, 14, [31:16]	r	**Reserved** Read as 0; should be written with 0.

31.2.6.2 Module Identification Register

ID
Module Identification Register **(008_H)** **Reset Value: $005A\ C001_H$**



Field	Bits	Type	Description
MOD_REV	[7:0]	r	**Module Revision** This bit field indicates the revision number of the module implementation (depending on the design step). The given value of 00_H is a placeholder for the actual number. Bits [3:0] refer to the version of the digital part and bits [7:4] indicate the version of the analog part (anid).
MOD_TYPE	[15:8]	r	**Module Type**
MOD_NUMBER	[31:16]	r	**Module Number**

31.2.6.3 Interrupt Activation Register

The interrupt activation register contains bit locations allowing to activate one or more service request outputs SR[7:0] of the ADC kernel. Writing a 1 to a bit position x activates the corresponding SRx line. All bit positions read as 0.

INTR
Interrupt Activation Register (204_H) Reset Value: $0000\ 0000_H$

ARBM	0			ARBRND		ANON		DIVD		DIVA					
rw	rw			rw		rw		rw		rw					

Field	Bits	Type	Description
DIVA	[5:0]	rw	**Divider Factor for Analog Internal Clock** This bit field defines the number of f_{ADC} clock cycles to generate the f_{ADCI} clock for the converter (used as internal base for the conversions and the sample time calculation). The minimum divider is 4. 00_H $f_{ADCI} = f_{ADC} / 4$ 01_H $f_{ADCI} = f_{ADC} / 4$ 02_H $f_{ADCI} = f_{ADC} / 4$ 03_H $f_{ADCI} = f_{ADC} / 4$ 04_H $f_{ADCI} = f_{ADC} / 4$ 05_H $f_{ADCI} = f_{ADC} / 5$ 06_H $f_{ADCI} = f_{ADC} / 6$ 07_H $f_{ADCI} = f_{ADC} / 7$ ... $3F_H$ $f_{ADCI} = f_{ADC} / 63$

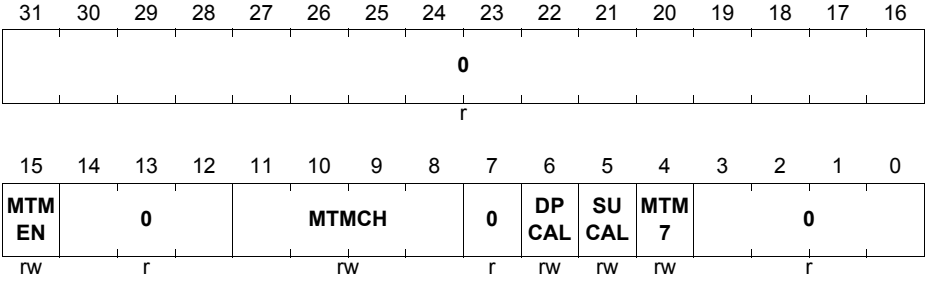
Field	Bits	Type	Description
DIVD	[7:6]	rw	**Divider Factor for Digital Arbiter Clock** This bit field defines the number of f_{ADC} clock cycles within each arbitration slot (each arbitration slots last one periods of f_{ADCD}). It is recommended to use the default setting 00_B to obtain the minimum arbiter reaction time. 00_B $f_{ADCD} = f_{ADC}$ 01_B $f_{ADCD} = f_{ADC} / 2$ 10_B $f_{ADCD} = f_{ADC} / 3$ 11_B $f_{ADCD} = f_{ADC} / 4$
ANON	[9:8]	rw	**Analog Part Switched On** This bit field defines the setting of bit field **GLOBSTR**.ANON (bit description see there) if this kernel is the synchronization master or without synchronization feature. For a synchronization slave, this bit field is not taken into account.
ARBRND	[11:10]	rw	**Arbitration Round Length** This bit field defines the number of arbitration slots per arbitration round (arbitration round length = t_{ARB}). 00_B An arbitration round contains 4 arbitration slots ($t_{ARB} = 4 / f_{ADCD}$). 01_B An arbitration round contains 8 arbitration slots ($t_{ARB} = 8 / f_{ADCD}$). 10_B An arbitration round contains 16 arbitration slots ($t_{ARB} = 16 / f_{ADCD}$). 11_B An arbitration round contains 20 arbitration slots ($t_{ARB} = 20 / f_{ADCD}$).

Field	Bits	Type	Description
ARBM	15	rw	**Arbitration Mode** This bit field defines whether the arbiter runs permanently or only while at least one conversion request is pending. 0_B The arbiter runs permanently. This setting has to be chosen in a synchronization slave (see **Section 31.2.19**) and for equidistant sampling using the signal ARBCNT (see **Section 31.2.20**). 1_B The arbiter only runs if at least one conversion request of an enabled request source is pending. This setting leads to a reproducible latency from an incoming request to the conversion start if the converter is idle. Synchronized conversions are not supported.
0	[14:12], [31:16]	r	**Reserved** Read as 0; should be written with 0.

31.2.6.5 Global Configuration

The global configuration register configures the general ADC kernel setting.

GLOBCFG
Global Configuration Register (034_H) Reset Value: $0000\ 0000_H$



Field	Bits	Type	Description
MTM7	4	rw	**Multiplexer Test Mode for Channel 7** This bit enables/disables the multiplexer test mode for the input channel 7, see **Section 31.2.17**. This feature is independent of the current mode of the ADC (ANON, selected channel for conversion). 0_B The multiplexer test mode is disabled. The analog input CH7 can be used for normal measurements. 1_B The multiplexer test mode is enabled. The analog input CH7 is internally connected to ground via voltage divider based on an additional resistor.[1)]
SUCAL	5	rw	**Start-Up Calibration** The transition from 0 to 1 of this bit starts the start-up calibration phase of the analog part. This should be done after reset before starting the first conversion to reduce analog errors. During the calibration phase (indicated by **GLOBSTR**.CAL = 1), conversions must not be started. It can take a few f_{ADC} clock cycles before bit CAL is set after a rising edge of SUCAL. 0_B Start-up calibration can be started. 1_B Start-up calibration has been started.

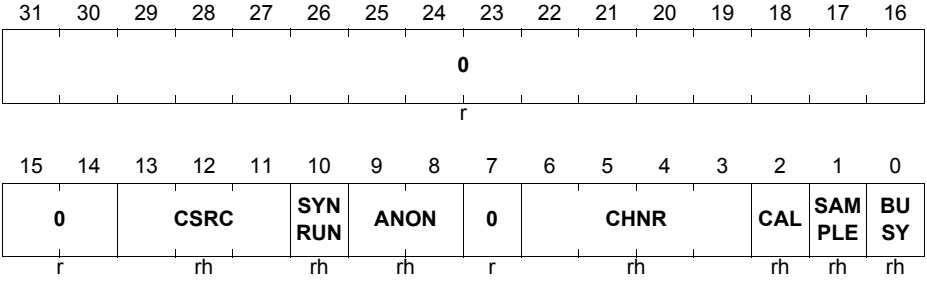
Field	Bits	Type	Description
DPCAL	6	rw	**Disable Post Calibration** This bit enables/disables the automatic post calibration of the analog part. 0_B The automatic post calibration is enabled. 1_B The automatic post calibration is disabled.
MTMCH	[11:8]	rw	**Multiplexer Test Mode Channel** This bit field defines the input channel number that can be enabled for multiplexer test mode in addition to channel CH7 (a value of 000001_B defines channel CH1, 000011_B channel CH3, 000101_B channel CH5, etc.). The multiplexer test mode is enabled for the selected input if MTMEN = 1.
MTMEN	15	rw	**Multiplexer Test Mode Enable** This bit enables the multiplexer test mode for the channel number selected by MTMCH. If an even channel number is selected, this bit is internally considered as 0. 0_B The multiplexer test mode for the selected input channel is disabled. This analog input can be used for normal measurements. 1_B The multiplexer test mode for the selected input channel is enabled. This analog input is internally connected to ground via voltage divider based on an additional resistor.[1)]
0	[3:0], 7, [14:12], [31:16]	r	**Reserved** Read as 0; should be written with 0.

1) Please refer to the AC/DC chapter for the value of the grounding resistor and its current capability.

31.2.6.6 Global Status

The status control register contains bits indicating the current status of a conversion.

GLOBSTR
Global Status Register **(038_H)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
BUSY	0	rh	**Analog Part Busy** This bit indicates that a conversion is currently active. 0_B The analog part is idle. 1_B A conversion is currently active.
SAMPLE	1	rh	**Sample Phase** This bit indicates that an analog input signal is currently sampled. 0_B The analog part is not in the sampling phase. 1_B The analog part is in the sampling phase.
CAL	2	rh	**Calibration Phase** This bit indicates that the analog part is in the startup calibration phase. 0_B The analog part is not in the calibration phase. 1_B The analog part is in the calibration phase.
CHNR	[6:3]	rh	**Channel Number** This bit field indicates which analog input channel is currently converted. This information is updated when a new conversion is started.

Field	Bits	Type	Description
ANON	[9:8]	rh	**Analog Part Switched On** This bit field defines the operation mode of the converter. It monitors either bit field GLOBCTR.ANON of the same ADC kernel (in master mode or without synchronization feature) or bit field GLOBCTR.ANON of the ADC kernel selected as synchronization master for this kernel (in slave mode). This ensures that all kernels of a synchronization group can be controlled with a single write operation to bit field GLOBCTR of the synchronization master. 00_B The analog part is switched off and conversions are not possible. To achieve a minimal power consumption, the internal analog circuitry is in its power-down state and the generation of f_{ADCI} and f_{ADCD} is stopped (counters set to an initial value). Furthermore, the arbiter finishes its current arbitration round (if running) and then remains in the idle state. 01_B reserved, do not use 10_B reserved, do not use 11_B The analog part of the ADC module is switched on and conversions are possible.
SYNRUN	10	rh	**Synchronous Conversion Running** This bit indicates that a synchronous (= parallel) conversion is currently running. 0_B There is no synchronous conversion running (either there is no conversion currently running or a parallel conversion has not been requested). A running conversion can be cancelled and repeated in case of a new incoming conversion request with higher priority. 1_B A synchronous conversion is running. This conversion can not be cancelled while running. Higher priority requests can trigger conversions only after the end of the currently running synchronous conversion.

Field	Bits	Type	Description
CSRC	[13:11]	rh	**Currently Converted Request Source** This bit field indicates the arbitration slot number of the current conversion (if BUSY = 1, a conversion is still running) or of the last conversion (if BUSY = 0, no conversion is running). This bit field is updated with each conversion start. 000_B The channel requested by the request source of arbitration slot 0 is (has been) converted. 001_B The channel requested by the request source of arbitration slot 1 is (has been) converted. ... 110_B The channel requested by the request source of arbitration slot 6 is (has been) converted. 111_B The channel requested by a synchronous injection is (has been) converted.
0	7, [31:14]	r	**Reserved** Read as 0; should be written with 0.

31.2.7 Request Source Arbiter

The request source arbiter evaluates which analog input channel has to be converted. Therefore, it regularly polls the request sources one after the other for pending conversion requests. The polling sequence is based on time slots with programmable length, called arbitration slots. If a request source is disabled or if no request source is available for an arbitration slot, the slot is considered as being empty and has no influence on the evaluation of the arbitration winner. After reset, all request sources are disabled and have to be enabled by bits in register **ASENR** to take part in the arbitration process.

The number of arbitration slots forming an arbitration round can be programmed to obtain a similar arbiter timing for different devices, even if the number of available request sources differs from one device to another. At the end of each arbitration round, the arbiter has determined the request source with the highest priority and a pending conversion request. This arbitration result is stored as arbitration winner for further actions. If a conversion is started in an arbitration round, this arbitration round does not deliver an arbitration winner.

In the TC1798, the following request sources are available:

- **Request source 0** in arbitration slot 0: **1-stage sequential source**
  This request source can issue a conversion request for a single input channel.
- **Request source 1** in arbitration slot 1: **16-channel scan source**
  This request source can issue a conversion request sequence of up to 16 input channels in a defined order.
- **Request source 2** in arbitration slot 2: **4-stage sequential source**
  This request source can issue a conversion request sequence of up to 4 input channels in a freely programmable order.
- **Request source 3** in arbitration slot 3: **16-channel scan source**
  This request source can issue a conversion request sequence of up to 16 input channels in a defined order.
- **Request source 4** in arbitration slot 4: **4-stage sequential source**
  This request source can issue a conversion request sequence of up to 4 input channels in a freely programmable order.
- Last arbitration slot of the arbitration round: **Synchronization source**
  In this slot, the arbiter checks for a synchronized request from another ADC kernel and does not evaluate any internal request source. A request for a synchronized conversion is always handled with the highest priority in a synchronization slave kernel (pending requests from other sources are not considered).

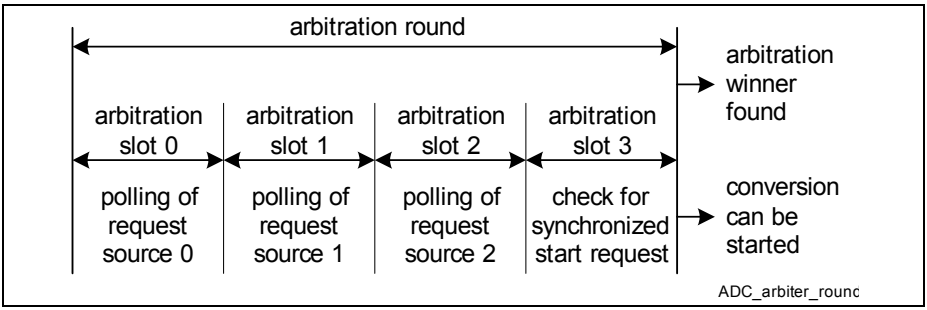


Figure 31-7 Arbitration Round with 4 Arbitration Slots

The period t_{ARB} of an arbitration round is given by:
$t_{ARB} = N \times (GLOBCTR.DIVD + 1) / f_{ADC}$
with N being 4, 8, 16, or 20 as defined by **GLOBCTR**.ARBRND

The period of the arbitration round introduces a timing granularity to detect an incoming conversion request signal and the earliest point to start the related conversion. This granularity can introduce a jitter of maximum one arbitration round. The jitter can be reduced by minimizing the period of an arbitration round (numbers of arbitration slots and their length).

To achieve a reproducible reaction time (constant delay without jitter) between the trigger event of a conversion request (e.g. by a timer unit or due to an external event) and the start of the related conversion, mainly the following two options exist. For both options, the converter has to be idle and other conversion requests must not be pending for at least one arbiter round before the trigger event occurs:

- If bit **GLOBCTR**.ARBM = 0, the **arbiter runs permanently**. In this mode, synchronized conversions of more than one ADC kernel are possible.
  The trigger for the conversion triggers has to be generated synchronously to the arbiter timing. Incoming triggers should have exactly n-times the granularity of the arbiter (n = 1, 2, 3, ...). In order to allow some flexibility, the duration of an arbitration slot can be programmed in cycles of f_{ADC}.
- If bit **GLOBCTR**.ARBM = 1, the **arbiter stops after an arbitration round** when no conversion request have been found pending any more. The arbiter is started again if at least one enabled request source indicates a pending conversion request. The trigger of a conversion request does need not to be synchronous to the arbiter timing. In this mode, parallel conversions are not possible for synchronization slave kernels.

31.2.7.1 Request Source Priority

Each request source has an individually programmable priority to be able to adapt to different applications (see registers **RSPR0**, **RSPR4**). The priorities define the order the request sources are handled by the arbiter if two or more request sources indicate

pending conversion requests at the same time.
Starting with request source 0, the arbiter checks if an enabled request source has a pending request for a conversion. The arbitration winner is the request source with a pending conversion request and the highest priority that has been found first in an arbitration round.

31.2.7.2 Conversion Start Modes

To start the requested conversion of the arbitration winner, the following aspects are automatically taken into consideration by the arbiter:

- If the converter is currently idle (no conversion running), the conversion of the arbitration winner is started immediately.
- If a conversion is currently running, the arbitration winner is compared to the priority of the currently running conversion. In the case that the current conversion has the same or a higher priority, it is completed. Then, the conversion of the arbitration winner is started.
- If a conversion is currently running, the arbitration winner is compared to the priority of the currently running conversion. In the case that the current conversion has the lower priority and the arbiter winner has been programmed for **wait-for-start mode**, the currently running conversion is completed. Then, the conversion of the arbitration winner is started.
  This mode can be used if the timing requirement for the higher priority conversions allow a jitter (between t3 and t4 in **Figure 31-8**) in the range of a running conversion.
- If a conversion is currently running, the arbitration winner is compared to the priority of the currently running conversion. In the case that the current conversion has the lower priority and the arbiter winner has been programmed for **cancel-inject-repeat mode**, the current conversion is aborted immediately if a new request with a higher priority has been found, unless both requests target the same result register with wait-for-read active (see **Section 31.2.15.2**). The conversion of the arbitration winner is started after the abort action. The aborted conversion request is restored in the request source that has requested the aborted conversion. As a consequence, it takes part again in the next arbitration round.
  Please note that the abort mechanism can take between 1 and 3 f_{ADCI} cycles, depending on the state of the current conversion.
  This mode can be used if higher priority conversions only tolerate a small jitter (between t8 and t9 in **Figure 31-8**).

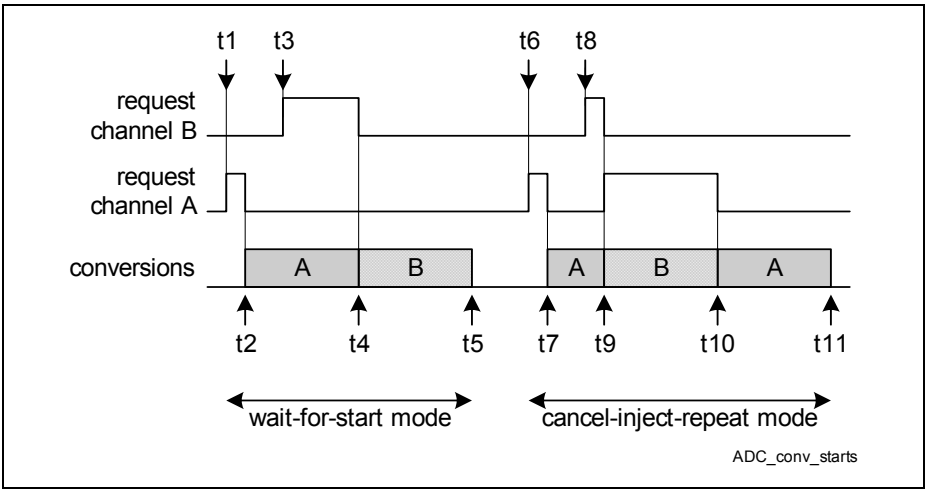

Figure 31-8 Conversion Start Modes

The conversion start mode can be individually programmed for each request source by bits in registers **RSPR0** and **RSPR4** and is applied to all channels requested by the source. **Figure 31-8** shows the influence of both conversion start modes on the conversion sequence if two request sources generate conversion requests. In this example, channel A is issued by a request source with a lower priority than the request source requesting the conversion of channel B.

- t1: The trigger event for channel A occurs and a conversion request is activated.
- t2: At the end of the arbitration round, channel A is determined as arbitration winner, the conversion of channel A is started. With the start of the conversion, the related conversion request is cleared.
- t3: The trigger event for channel B occurs and a conversion request is activated. In wait-for-read mode, the currently running conversion of channel A is finished normally.
- t4: After the conversion of channel A is finished, the conversion of channel B is started. With the start of the conversion, the related conversion request is cleared.
- t5: The conversion of channel B is finished.
- t6: The trigger event for channel A occurs and a conversion request is activated.
- t7: At the end of the arbitration round, channel A is determined as arbitration winner, the conversion of channel A is started. With the start of the conversion, the related conversion request is cleared.
- t8: The trigger event for channel B occurs and a conversion request is activated.
- t9: At the end of the arbitration round, channel B is determined as arbitration winner. In cancel-inject-repeat mode, the currently running conversion of channel A is aborted and the conversion of channel B is started. With the abort of the conversion,

the related conversion request is set again. With the start of the conversion, the related conversion request is cleared.

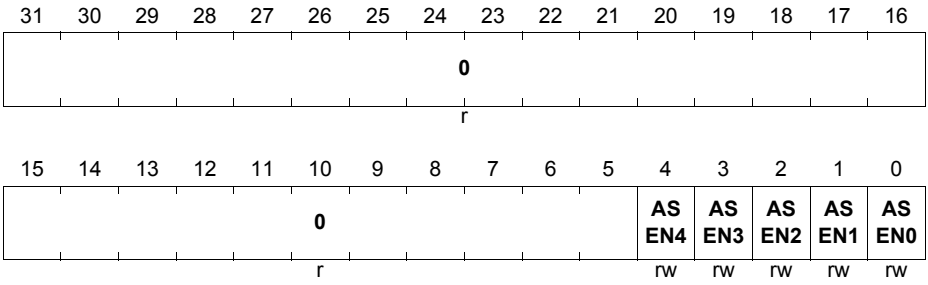
- t10: The conversion of channel B is finished. In the meantime, the pending request for channel A has been identified as arbitration winner and the conversion of channel A is started. With the start of the conversion, the related conversion request is cleared.
- t11: The conversion of channel A is finished.

31.2.8 Arbiter Registers

31.2.8.1 Arbitration Slot Enable Register

The arbitration slot enable register contains bits to enable/disable the conversion request treatment in the arbitration slots.

ASENR
Arbitration Slot Enable Register ($03C_H$) Reset Value: $0000\ 0000_H$



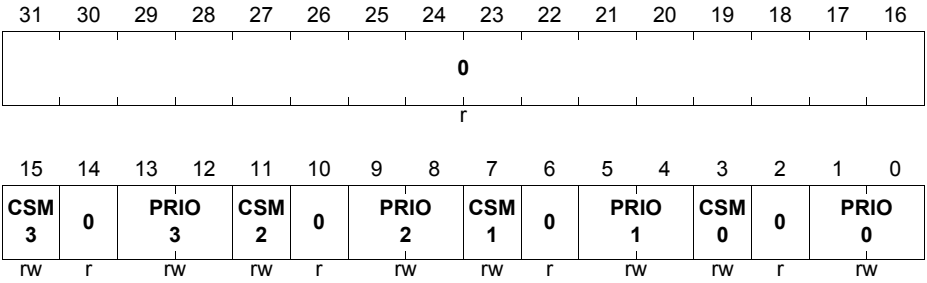
Field	Bits	Type	Description
ASENx (x = 0-4)	x	rw	**Arbitration Slot x Enable** Each bit enables an arbitration slot of the arbiter round. ASEN0 enables the arbitration slot 0, ASEN1 the slot 1, etc. If an arbitration slot is disabled, it is considered as being empty. The request bits of the request sources are not modified by write actions to ASENR. 0_B The corresponding arbitration slot is disabled and is not taken into account by the arbiter. Conversions are not requested, even for the request source(s) with pending request bit(s). 1_B The corresponding arbitration slot is enabled. Conversions are requested for the request source(s) with pending request bit(s).
0	[31:5]	r	**Reserved** Read as 0; should be written with 0.

31.2.8.2 Request Source Priority Register

The request source priority registers contain bits to define the request source priority and the conversion start mode.

RSPR0

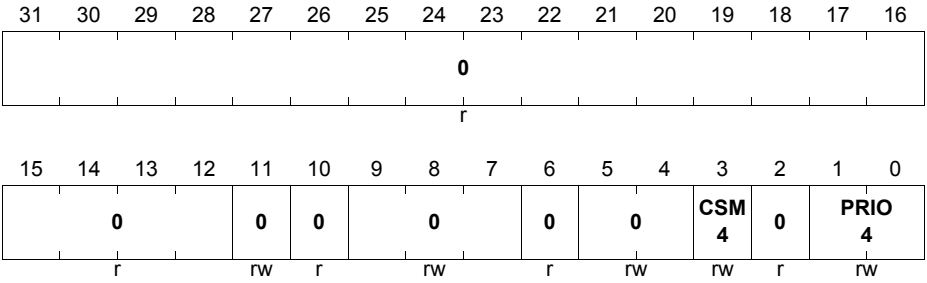
Request Source Priority Register 0 (040_H) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
PRIO0, PRIO1, PRIO2, PRIO3	[1:0], [5:4], [9:8], [13:12]	rw	**Priority of Request Source x** This bit field defines the priority of the conversion request source x, located in arbitration slot x. 00_B Lowest priority is selected. ... 11_B Highest priority is selected.
CSM0, CSM1, CSM2, CSM3	3, 7, 11, 15	rw	**Conversion Start Mode of Request Source x** This bit defines the conversion start mode of the conversion request source x, located in arbitration slot x. 0_B The wait-for-start mode is selected. 1_B The cancel-inject-repeat mode is selected.
0	2, 6, 10, 14, [31:16]	r	**Reserved** Read as 0; should be written with 0.

RSPR4

Request Source Priority Register 4 (044_H) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
PRIO4	[1:0]	rw	**Priority of Request Source 4** This bit field defines the priority of the conversion request source 4, located in arbitration slot 4. 00_B Lowest priority is selected. ... 11_B Highest priority is selected.
CSM4	3	rw	**Conversion Start Mode of Request Source 4** This bit defines the conversion start mode of the conversion request source 4, located in arbitration slot 4. 0_B The wait-for-start mode is selected. 1_B The cancel-inject-repeat mode is selected.
0	[5:4], [9:7], 11	rw	**Reserved** These bits are reserved for future use and have to be written with 000_B.
0	2, 6, 10, [31:12]	r	**Reserved** Read as 0; should be written with 0.

31.2.9 Scan Request Source Handling

A scan request source can issue conversion requests for a sequence of up to 16 input channels. It can be programmed individually for each input channel if it takes part in the scan sequence. The scan sequence always starts with the highest enabled channel number and continues towards lower channel numbers (order defined by the channel number, each channel can be converted only once per sequence).

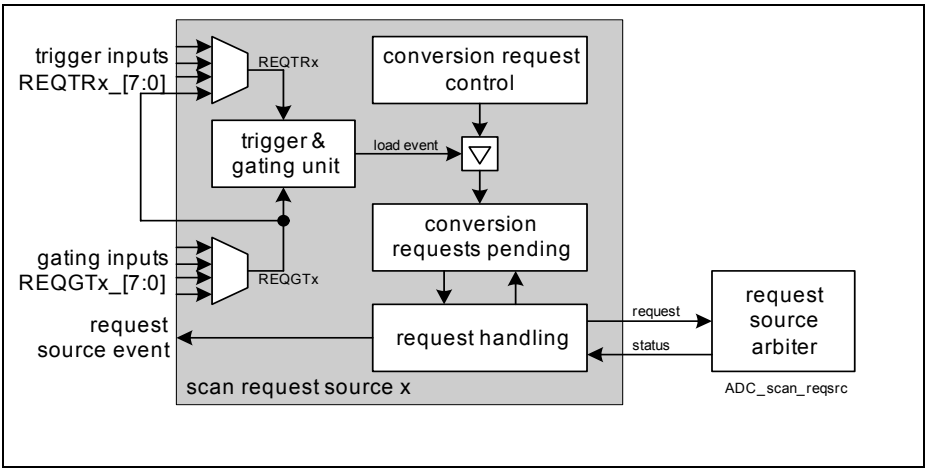


Figure 31-9 Scan Request Source

31.2.9.1 Overview

A scan request source performs the:

- Conversion request control:
  The conversion request control defines if an analog input channel takes part in the scan sequence (see bits in registers **CRCR1**, **CRCR3**). The programmed register value is kept unchanged by an ongoing scan sequence.
- Conversion request pending:
  The pending conversion requests indicate if an input channel has to be converted in an ongoing scan sequence (see bits in registers **CRPR1**, **CRPR3**). A conversion request can only be issued to the request source arbiter if at least one pending bit is set. With each conversion start that has been triggered by the scan request source, the corresponding pending bit is automatically cleared. The scan sequence is considered finished and a request source event is generated if the last conversion triggered by the scan source is finished and all pending bits have been cleared.
- Request handling:
  The request handling blocks interfaces with the request source arbiter. It requests conversion due to pending bits in the scan sequence and handles the conversion

status information. If a conversion triggered by the scan request source is aborted due to a conversion request from another request source with a higher priority, the corresponding pending bit is automatically set. This mechanism ensures that an aborted conversion takes part in the next arbitration round and does not get lost. The control of the scan sequence is done based on bits in registers **CRMR1**, **CRMR3**.

- Trigger and gating signal handling:
  The trigger and gating unit interfaces with signals and modules outside the ADC module that can request conversions. For example, a timer unit can issue a request signal to synchronize conversions to PWM events. A load event starts a scan sequence by modifying the request pending bits according to the request control bits.

31.2.9.2 Scan Sequence Operation

To **operate a scan request source**, the following aspects should be taken into account:

- The bits in register CRCRx have to be programmed to define the channels participating in the scan sequence.
- If a trigger or gating function by external signals is desired, the gating and trigger inputs have to be defined by bit fields in the related registers **RSIRx (x = 0 - 4)**, the value of x defines the number of the arbitration slot where the scan source is connected. Also the edge selection for the trigger event is done in these registers.
- The gating mechanism has to be defined by CRMRx.ENGT.
- The corresponding arbitration slot has to be enabled to accept conversion requests from the scan source (see register **ASENR**).
- The load event has to be defined by bits in CRMRx to start a scan sequence.
- If a load event occurs while CRMRx.LDM = 0, the content of CRCRx is copied to CRPRx (overwrite). This setting allows starting a new scan sequence and to “forget” remaining pending bits if a load event occurs while a scan sequence is running.
- If a load event occurs while CRMRx.LDM = 1, the content of CRCRx is bit-wisely logical OR-combined to CRPRx (no overwrite). This setting allows starting a new scan sequence without “forgetting” remaining pending bits if a load event occurs while a scan sequence is running.

To **start a scan sequence**, the following mechanisms are supported to generate a load event:

- An external trigger signal can be selected to start a scan sequence controlled by HW by an external module or signal, e.g. a timer unit or an input pin. The trigger feature is enabled by CRMRx.ENTR = 1. The load event is generated if the selected edge is detected at the selected trigger input REQTRx. The edge selection is done in register RSIRx.
- A load event is generated under SW control by writing CRMRx.LDEV = 1. This mechanism starts a scan sequence without modifying the bits in register CRCRx. A data write action to CRCRx does not lead to a load event (first prepare the channel control, then start the sequence).

- If SW writes data to register CRPRx, the written data is stored in register CRCRx and a load event is generated automatically. This mechanism starts a scan sequence with the channels defined by the written data (the sequence is defined and started with a single data write action, e.g. under DMA control).
- A load event is generated each time a scan sequence has finished and the request source event occurs if bit CRMRx.SCAN = 1. This setting leads to a permanent repetition of the scan sequence.

To **stop or abort an ongoing scan sequence**, the following mechanisms are supported:

- An external gating signal can be selected to stop and to continue a scan sequence at any point in time controlled by an external module or signal, e.g. a timer unit or an input pin. The gating feature can be enabled and the polarity of the gating signal REQGTx can be selected by CRMRx.ENGT. The gating mechanism does not modify the contents of the conversion pending bits, but only prevents the request handling block from issuing conversion requests to the arbiter.
- The arbiter can be disabled by SW for this arbiter slot by clearing the corresponding bit **ASENR**.ASENx. This mechanism does not modify the contents of the conversion pending bits, but only prevents the arbiter from accepting requests from the request handling block.
- The pending request bits can be cleared by writing bit CRMRx.CLRPND = 1. It is recommended to stop the scan sequence before clearing the pending bits.

31.2.9.3 Request Source Event and Interrupt

A request source event of a scan source occurs if the last conversion of a scan sequence is finished (all pending bits = 0). A request source event interrupt can be generated based on a request source event according to the structure shown in **Figure 31-10**. If a request source event is detected, it sets the corresponding indication flag in register **EVFR**. These flags can also be set by writing a 1 to the corresponding bit position, whereas writing 0 has no effect. Additionally, a gated event flag **EVFR**.GFSx indicates that a request source interrupt has been activated. The indication flags can be cleared by SW by writing a 1 to the corresponding bit position in register **EVFCR**.

The service request output ADCy_SRx that is selected by the request source event interrupt node pointer bit fields in register **EVNPR** becomes activated each time the related request source event is detected and the interrupt generation is enabled for this event in registers **CRCR1** (for request source 1) or **CRCR3** (for request source 3).
A service request output can be activated under SW control by writing **INTR**.SISRx.

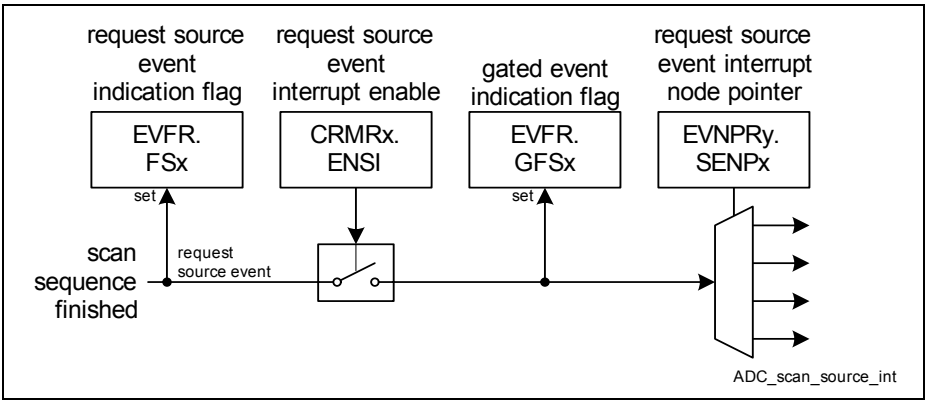

Figure 31-10 Interrupt Generation of a Scan Request Source

31.2.10 Scan Request Source Registers

31.2.10.1 Conversion Request Control Registers

These registers contain the control and status bits of a scan request source. In the TC1798, two scan sources are available (sources 1 and 3). The index describes the number of the arbitration slot where the request source is taking part in the arbitration.

The conversion request control register contains the bits that are copied to the pending register when the load event occurs. This register can be accessed at two different addresses. One address for read and write access is given for CRCRx (attribute “rw”), leading to a data write to the bits in CRCRx without an automatic load event. The second address only used for write actions is given for CRPRx (additional attribute “h”), leading to a data write to the bits in CRCRx with an automatic load event one clock cycle later.

CRCR1
Conversion Request 1 Control Register
(090_H) **Reset Value: 0000 0000$_H$**

CRCR3
Conversion Request 3 Control Register
($0B0_H$) **Reset Value: 0000 0000$_H$**

Field	Bits	Type	Description
CHx (x = 0-15)	x	rwh	**Channel Bit x** Each bit corresponds to one analog input channel, the channel number CHx is defined by the bit position x in this register. The corresponding bit x in the conversion request pending register will be overwritten by this bit (LDM = 0) or bit-wisely OR-combined with this bit (LDM = 1) when the load event occurs. 0_B The analog channel CHx will not be requested for conversion by this request source. 1_B The analog channel CHx will be requested for conversion by this request source.
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

31.2.10.2 Conversion Request Pending Registers

The conversion request pending register contains the bits that are requesting a conversion of the corresponding analog channel.
A read operation to CRPRx delivers the pending bits (attribute “rh”). A write operation to CRPRx leads to a data write to the bits in CRCRx with an automatic load event generation (additional attribute “w”).

CRPR1
Conversion Request 1 Pending Register

Field	Bits	Type	Description
CHPx (x = 0-15)	x	rwh	**Channel Pending Bit x** Write view: A write to this address targets the bits in register **CRCR1** (for CRPR1) or **CRCR3** (for CRPR3). Read view: Each bit corresponds to one analog channel, the channel number CHx is defined by the bit position in the register. 0_B The analog channel CHx is not requested for conversion by this request source. 1_B The analog channel CHx is requested for conversion by this request source.
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

31.2.10.3 Conversion Request Mode Registers

The conversion request mode registers contain bits to configure the desired operating mode of the scan request sources.

CRMR1
Conversion Request 1 Mode Register
(098_H) **Reset Value: $0000\ 0000_H$**

CRMR3
Conversion Request 3 Mode Register
($0B8_H$) **Reset Value: $0000\ 0000_H$**

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0						LDEV	CLRPND	REQGT	0	LDM	SCAN	ENSI	ENTR	ENGT	
r						w	w	rh	r	rw	rw	rw	rw	rw	

Field	Bits	Type	Description
ENGT	[1:0]	rw	**Enable Gate** This bit field enables the gating functionality for the request source. 00_B The request source does not issue conversion requests. 01_B The request source issues conversion requests if at least one pending bit is set. 10_B The request source issues conversion requests if at least one pending bit is set and the selected gating signal REQGTx = 1. 11_B The request source issues conversion requests if at least one pending bit is set and the selected gating signal REQGTx = 0.

Field	Bits	Type	Description
ENTR	2	rw	**Enable External Trigger** This bit enables the external trigger possibility. If enabled, the load event takes place if the selected edge is detected at the external trigger input REQTRx. 0_B The external trigger is disabled. 1_B The external trigger is enabled.
ENSI	3	rw	**Enable Source Interrupt** This bit enables the request source interrupt generation if a request source event occurs (last pending conversion is finished). 0_B The request source interrupt is disabled. 1_B The request source interrupt is enabled.
SCAN	4	rw	**Autoscan Enable** This bit enables a permanent scan functionality. If enabled, the load event is automatically generated if a request source event occurs. 0_B The permanent scan functionality is disabled. 1_B The permanent scan functionality is enabled.
LDM	5	rw	**Load Event Mode** This bit defines the transfer mechanism triggered by the load event. 0_B With the load event, the value of register CRCRx is copied to the pending register CRPRx (overwrite). 1_B With the load event, the value of register CRCRx is bit-wisely logical OR combined to the pending register CRPRx.
REQGT	7	rh	**Request Gate Level** This bit monitors the level at the REQGTx input. 0_B The level is 0. 1_B The level is 1.
CLRPND	8	w	**Clear Pending Bits** 0_B No action. 1_B The bits in register CRPRx are cleared.
LDEV	9	w	**Generate Load Event** 0_B No action. 1_B A load event is generated.

Field	Bits	Type	Description
0	6, [31:10]	r	**Reserved** Read as 0; should be written with 0.

31.2.11 Sequential Request Source Handling

Sequential request sources have been introduced to allow short conversion sequences with freely programmable channel numbers (contrary to a scan request source with a fixed conversion order for the enabled channels). Two versions of the sequential sources are available in each ADC kernel:

- Request sources in arbitration slots 2 and 4:
  These request sources can handle a sequence of up to 4 input channels (4-stage queue for 4 entries). This mechanism could be used to support application-specific conversion sequences, especially for timing-critical sequences containing multiple conversions of the same channel.
- Request source in arbitration slot 0:
  This request source can handle a single input channel (1-stage queue for 1 entry). This mechanism could be used for SW-controlled conversion requests or HW-triggered conversions of a single input channel (to “inject” a single conversion into a running sequence).

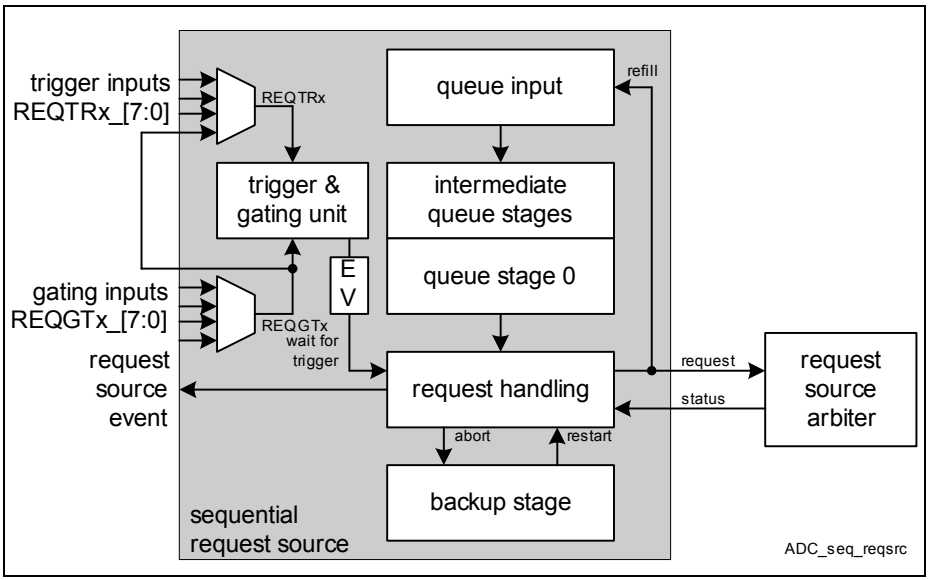

Figure 31-11 Sequential Request Source

The internal structure and the handling of the sequential sources is similar for both versions. The programmed sequence is stored in a queue buffer (based on a FIFO mechanism) with at least one queue stage (stage 0) and a backup stage for aborted conversions. The only difference between both versions is given by the number of intermediate queue stages for storing the sequence. The request source in arbitration

slot 0 does not provide intermediate queue stages (1-stage queue with only queue stage 0), whereas the ones in arbitration slots 2 and 4 provides 3 intermediate queue stages in additional to queue stage 0 (leading to a 4-stage queue each).

31.2.11.1 Overview

A sequential request source performs the:

- Queue input:
  The queue input represents the programming interface where the sequence is defined (see **QINR0**, **QINR2**, **QINR4**). It does not provide any buffer capability, but handles the filling of the queue buffer (queue stage 0 plus optional intermediate queue stages) by writing data to it. The contents of the queue stages can not be directly modified by program, except by the command for flushing the complete queue.
  The queue input also handles the refill mechanism, an automatic re-insertion of a started conversion from queue stage 0 (including the control parameters) as new queue input. This feature allows a single setup (by SW) of a conversion sequence and multiple repetitions of the same sequence without the need to re-program it each time. A conversion sequence is repeated if all queue entries of the sequence are setup for refill mode.
- Queue stage 0:
  The contents of this queue stage defines which channel will be requested next for a conversion (see **Q0R0**, **Q0R2**, **Q0R4**). It also defines if the request should be triggered by an external event or if the requested conversion should follow the previous one as soon as possible. It also enables the request source interrupt generation after the conversion.
  The contents of this queue stage is cleared when the requested conversion is started and the next queue entry can be handled (if available).
- Queue backup stage:
  The queue backup stage is used to store the request control parameters when a conversion requested by this request source is aborted. A validation bit indicates that the aborted conversion has to be requested next (before the current contents of queue stage 0) to maintain the original sequence (see **QBUR0**, **QBUR2**, **QBUR4**).
- Request handling:
  The request handling block interfaces with the request source arbiter. It requests a conversion due to a valid information in queue stage 0 and handles the conversion status information. The control of the queue sequence is done based on bits in registers **QMR0**, **QMR2**, and **QMR4** (for the arbitration slot x).
- Trigger and gating signal handling:
  The trigger and gating unit interfaces with signals and modules outside the ADC module that can request conversions. For example, a timer unit can issue a request signal to synchronize conversions to PWM events. A trigger event can start a conversion request for the entry in queue stage 0 (see **QMR0**, **QMR2**, **QMR4**). An

event flag QSRx.EV indicates that a trigger event has been detected (selected edge of selected trigger input signal REQTRx if enabled by QMRx.ENTR or write action with QMRx.TREV = 1). This bit is cleared with each conversion start requested by this source or by writing bits CEV = 1, FLUSH = 1, or CLRV = 1.

31.2.11.2 Sequential Source Operation

To **operate a sequential request source**, the following aspects should be taken into account:

- The sequence has to be initialized by writing to the queue input **QINR0** (for arbitration slot 0), **QINR2** (for arbitration slot 2), or **QINR4** (for arbitration slot 4) when using the refill mechanism. Each write access corresponds to one conversion request.
  The desired sequence should be completely initialized before enabling the request source, because with enabled refill feature, write accesses by SW to QINRx are not allowed.
- If a trigger or gating function by external signals is desired, the gating and trigger inputs have to be defined by bit fields in the related registers **RSIRx (x = 0 - 4)**, the value of x defines the number of the arbitration slot where the request source is connected. Also the edge selection for the trigger event is done in these registers.
- The gating mechanism has to be defined by QMRx.ENGT.
- The corresponding arbitration slot has to be enabled to accept conversion requests from the sequential source (see register **ASENR**).

To **start a sequence** of a sequential request source, the following mechanisms are supported:

- An external trigger signal can be selected to start a scan sequence controlled by HW by an external module or signal, e.g. a timer unit or an input pin. The trigger feature is enabled by QMRx.ENTR = 1. The trigger event is generated if the selected edge is detected at the selected trigger input.
- A trigger event is generated under SW control by writing QMRx.TREV = 1. This mechanism starts a request if queue stage 0 contains valid data (or the queue backup stage respectively).
- A write operation to a queue input leads to a (new) valid queue entry. If the queue is empty (no valid entry), the written data arrives in queue stage 0 and starts a conversion request (if enabled by QMRx.ENGT and without waiting for an external trigger). If the refill mechanism is used, the queue inputs must not be written while the queue is running. Write operations to a completely filled queue are ignored.

To **stop or abort an ongoing sequence** of a sequential request source, the following mechanisms are supported:

- An external gating signal can be selected to stop and to continue a sequence at any point in time controlled by an external module or signal, e.g. a timer unit or an input pin. The gating feature can be enabled and the polarity of the gating signal REQGTx can be selected by QMRx.ENGT. The gating mechanism does not modify the queue

entries, but only prevents the request handling block from issuing conversion requests to the arbiter.

- The arbiter can be disabled by SW for this arbiter slot by clearing the corresponding bit **ASENR**.ASENx. This mechanism does not modify the queue entries, but only prevents the arbiter from accepting requests from the request handling block.
- The next pending queue entry is cleared by writing bit QMRx.CLRV = 1. It is recommended to stop the sequence before clearing a queue entry (ENGT = 00_B). If the queue backup stage contains a valid entry, this one is cleared, otherwise a valid entry in queue register 0 is cleared.
- All queue entries are cleared by writing bit QMRx.FLUSH = 1. It is recommended to stop the sequence before clearing queue entries.

31.2.11.3 Request Source Event and Interrupt

A request source event occurs when a conversion that has been requested by this source is completely finished. The interrupt enable bits are located in the queue 0 register (if this has not been a repeated start after an abort) or in the queue backup register (if this has been a repeated start after an abort), e.g. see **Q0R0** for request source 0) or in the queue backup register (if this has been a repeated start after an abort, e.g. see **QBUR0** for request source 0).
A request source event interrupt can be generated based on a request source event according to the structure shown in **Figure 31-12**. If a request source event is detected, it sets the corresponding indication flag in register **EVFR**. These flags can also be set by writing a 1 to the corresponding bit position, whereas writing 0 has no effect. The indication flags can be cleared by SW by writing a 1 to the corresponding bit position in register **EVFCR**.

The service request output ADCy_SRx that is selected by the request source event interrupt node pointer bit fields in register **EVNPR** becomes activated each time the related request source event is detected.
A service request output can be activated under SW control by writing **INTR**.SISRx.

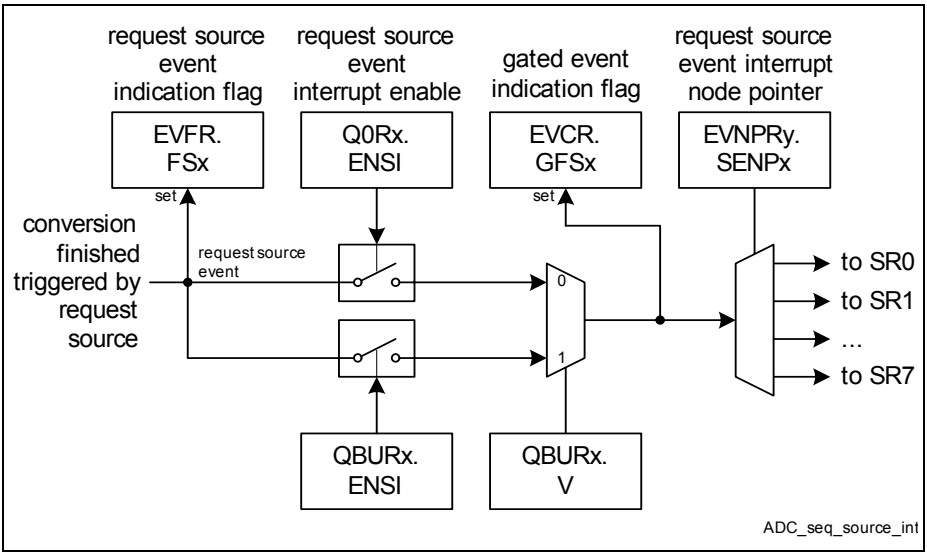

Figure 31-12 Interrupt Generation of a Sequential Request Source

31.2.12 Sequential Source Registers

31.2.12.1 Queue Mode Registers

These registers contain the control and status bits of a sequential source. The index describes the number of the arbitration slot where the request source is taking part in the arbitration.

*Note: Before SW modifies the queue content by QMRx.CLRV or QMRx.FLUSH, all HW actions related to this queue have to be finished. Therefore, the arbitration slot has to be disabled and SW has to wait for at least two arbitration rounds (to be sure that this request source can no longer be an arbitration winner). Then, it has to check **GLOBSTR**.CRSC and **GLOBSTR**.BUSY to be sure that a conversion triggered by this request source is no longer running. Then SW can read QBURx and Q0Rx and can start modification of the queue content.*

QMR0
Queue 0 Mode Register **(080_H)** **Reset Value: $0000\ 0000_H$**

r				w	w	w	w	r					rw	rw	

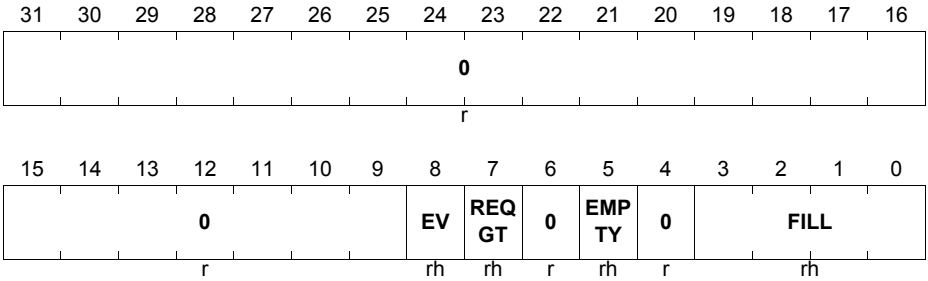
Field	Bits	Type	Description
ENGT	[1:0]	rw	**Enable Gate** This bit field enables the gating functionality for the request source. 00_B The request source does not issue conversion requests. 01_B The request source issues conversion requests if a valid conversion request is pending in the queue 0 register or in the backup register. 10_B The request source issues conversion requests if a valid conversion request is pending in the queue 0 register or in the backup register and the selected gating signal REQGTx = 1. 11_B The request source issues conversion requests if a valid conversion request is pending in the queue 0 register or in the backup register and the selected gating signal REQGTx = 0.
ENTR	2	rw	**Enable External Trigger** This bit enables the external trigger possibility. 0_B The external trigger is disabled and the trigger event is not generated. 1_B The external trigger is enabled and a trigger event is generated if the selected edge is detected at the selected trigger input signal for REQTRx.
CLRV	8	w	**Clear V Bit** 0_B No action. 1_B The next pending valid queue entry in the sequence and the event flag EV are cleared. If there is a valid entry in the queue backup register (QBURx.V = 1), this entry is cleared, otherwise the entry in queue register 0 is cleared.

Field	Bits	Type	Description
TREV	9	w	**Trigger Event** 0_B No action. 1_B A trigger event is generated by SW. If the a valid entry in the request source waits for a trigger event, a conversion request is started.
FLUSH	10	w	**Flush Queue** 0_B No action. 1_B All entries in the queue (including the backup stage) and the event flag EV are cleared. The queue contains no more valid entry.
CEV	11	w	**Clear Event Flag** 0_B No action. 1_B Bit EV is cleared.
0	[7:3], [31:12]	r	**Reserved** Read as 0; should be written with 0.

31.2.12.2 Queue Status Registers

The queue status registers contain bits indicating the status of the sequential source. The filling level and the empty information refer to the queue intermediate stages (if available) and to the queue register 0. An aborted conversion stored in the backup stage is not indicated by these bits (therefore, see QBURx.V).

QSR0
Queue 0 Status Register **(084_H)** **Reset Value: 0000 0020_H**
QSR2
Queue 2 Status Register **($0A4_H$)** **Reset Value: 0000 0020_H**
QSR4
Queue 4 Status Register **($0C4_H$)** **Reset Value: 0000 0020_H**



Field	Bits	Type	Description
FILL	[3:0]	rh	**Filling Level**[1)] This bit field indicates how many queue entries are valid in the sequential source. It is incremented each time a new entry is written to QINRx or by an enabled refill mechanism. It is decremented each time a requested conversion has been started. A new entry is ignored if the filling level has reached its maximum value. 00_B EMPTY = 1:There is no valid entry in the queue. EMPTY = 0:There is 1 valid entries in the queue. 01_B There are 2 valid entries in the queue. 10_B There are 3 valid entries in the queue. 11_B There are 4 valid entries in the queue.

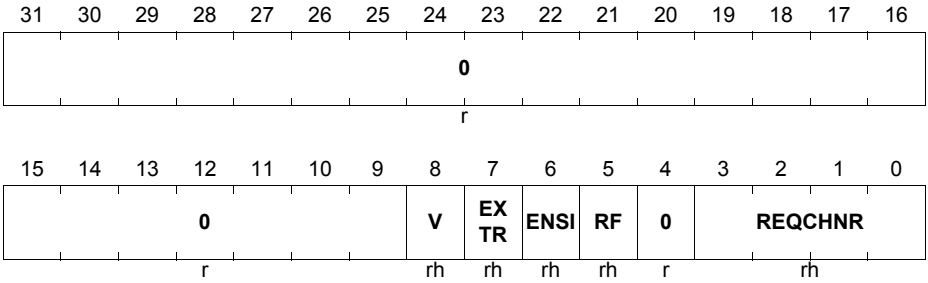
Field	Bits	Type	Description
EMPTY	5	rh	**Queue Empty** This bit indicates if the sequential source contains valid entries. 0_B There are FILL+1 valid entries in the queue. 1_B There are no valid entries (queue is empty).
REQGT	7	rh	**Request Gate Level** This bit monitors the level at the REQGTx input. 0_B The level is 0. 1_B The level is 1.
EV	8	rh	**Event Detected** This bit indicates that an event has been detected while at least one valid entry has been in the queue (queue register 0 or backup stage). Once set, this bit is cleared automatically when the requested conversion is started. 0_B A trigger event has not been detected. 1_B A trigger event has been detected.
0	4, 6, [31:9]	r	**Reserved** Read as 0; should be written with 0.

1) This bit field is always 00_B for the 1-stage queue in arbitration slot 0.

31.2.12.3 Queue 0 Registers

The queue x registers 0 monitor the status of the current sequential request (queue stage 0).

Q0R0
Queue 0 Register 0 **(088_H)** **Reset Value: 0000 0000$_H$**
Q0R2
Queue 2 Register 0 **($0A8_H$)** **Reset Value: 0000 0000$_H$**
Q0R4
Queue 4 Register 0 **($0C8_H$)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
REQCHNR	[3:0]	rh	**Request Channel Number** This bit field indicates the channel number that will be or is currently requested.
RF	5	rh	**Refill** This bit indicates if the pending request is discarded after the conversion start or if it is automatically refilled into the queue input of the request queue. 0_B The request is discarded after the conversion start. 1_B The request is refilled into the queue after the conversion start.
ENSI	6	rh	**Enable Source Interrupt** This bit indicates if a request source interrupt is generated when the conversion is finished. 0_B The request source interrupt generation is disabled. 1_B The request source interrupt generation is enabled.

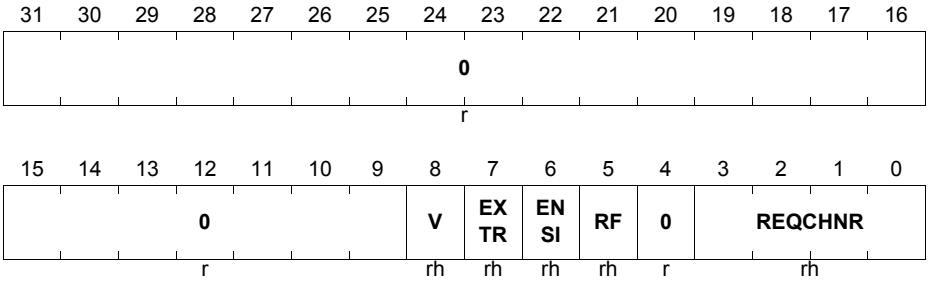
Field	Bits	Type	Description
EXTR	7	rh	**External Trigger** This bit indicates if a valid queue entry immediately leads to a conversion request or if the request handler waits for a trigger event. 0_B The request handler does not wait for a trigger event. 1_B The request handler waits for a trigger event.
V	8	rh	**Request Channel Number Valid** This bit indicates if the queue register 0 contains a valid queue entry. 0_B The queue entry is not valid and does not lead to a conversion request. 1_B The queue entry is valid and leads to a conversion request.
0	4, [31:9]	r	**Reserved** Read as 0; should be written with 0.

31.2.12.4 Queue Backup Registers

The queue backup registers monitor the status of an aborted sequential request.

The registers QBURx and QINRx share the same register address. A read operation at this register address will deliver the “rh” bits of register QBURx. A write operation to this address will target register QINRx.

QBUR0
Queue 0 Backup Register **($08C_H$)** **Reset Value: 0000 0000_H**
QBUR2
Queue 2 Backup Register **($0AC_H$)** **Reset Value: 0000 0000_H**
QBUR4
Queue 4 Backup Register **($0CC_H$)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
REQCHNR	[3:0]	rh	**Request Channel Number** This bit field contains the channel number of an aborted conversion that has been requested by this request source.
RF	5	rh	**Refill** This bit contains the refill bit of an aborted conversion that has been requested by this request source.
ENSI	6	rh	**Enable Source Interrupt** This bit contains the request source event interrupt enable bit of an aborted conversion that has been requested by this request source.

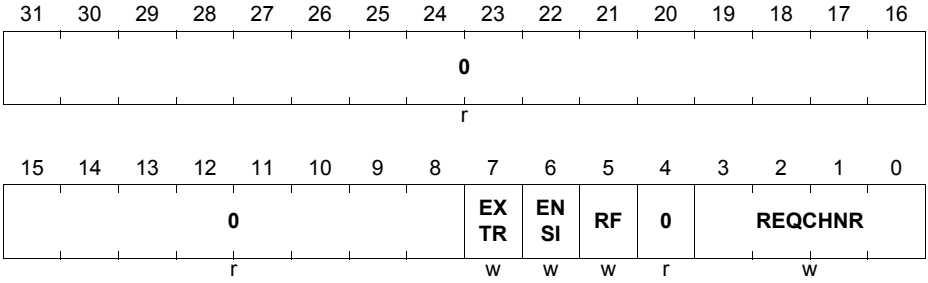
Field	Bits	Type	Description
EXTR	7	rh	**External Trigger** This bit contains the external trigger bit of an aborted conversion that has been requested by this request source.
V	8	rh	**Request Channel Number Valid** This bit indicates if the entry in the queue backup register is valid (REQCHNR, RF, TR and ENSI are valid). Bit V is set if a running conversion that has been requested by this request source is aborted. It is cleared when the repeated conversion is started. 0_B The backup register does not contain a valid entry. 1_B The backup register contains a valid entry. It will be requested before a valid entry in queue register 0 will be requested.
0	4, [31:9]	r	**Reserved** Read as 0; should be written with 0.

31.2.12.5 Queue Input Registers

The queue input registers are the entry registers for sequential requests for each sequential source (queue).

The registers QBURx and QINRx share the same register address. A read operation at this register address will deliver the “rh” bits of register QBURx. A write operation to this address will target the “w” bits in register QINRx.

QINR0
Queue 0 Input Register **($08C_H$)** **Reset Value: $0000\ 0000_H$**
QINR2
Queue 2 Input Register **($0AC_H$)** **Reset Value: $0000\ 0000_H$**
QINR4
Queue 4 Input Register **($0CC_H$)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
REQCHNR	[3:0]	w	**Request Channel Number** This bit field defines the requested channel number.
RF	5	w	**Refill** This bit defines the refill functionality for this queue entry. 0_B The content of this queue entry is not entered again in QINRx when the related conversion is started. 1_B The content of this queue entry is automatically entered again in QINRx when the related conversion is started.

Field	Bits	Type	Description
ENSI	6	w	**Enable Source Interrupt** This bit defines the request source event interrupt functionality. 0_B A request source event interrupt is not generated if the related conversion is finished. 1_B A request source event interrupt is generated if the related conversion is finished.
EXTR	7	w	**External Trigger** This bit defines the external trigger functionality. 0_B A valid queue entry immediately leads to a conversion request. 1_B A valid queue entry waits for a trigger event to occur before issuing a conversion request.
0	4, [31:8]	r	**Reserved** Read as 0; should be written with 0.

31.2.13 Channel-Related Functions

The channel control unit defines the conversion settings, that can be programmed individually for each analog input channel. Therefore, a channel control register **CHCTRx (x = 0 - 15)** is associated to each analog input channel CHx. After the arbiter has determined the channel to be converted, the defined settings are applied to the AD converter, comprising information about:

- **Conversion parameters:**
  Bit field ICLSEL defines which input class is taken into account for the conversion (see **Section 31.2.13.1**).
- **Reference selection:**
  Bit field REFSEL defines which reference input is used for the conversion (see **Section 31.2.13.2**)
- **Channel event handling:**
  Bit fields LCC, BNDASEL, and BNDBSEL define which boundaries are used for limit checking (see **Section 31.2.13.4**) and which channel event leads to a channel event interrupt (see **Section 31.2.13.5**).
- **Synchronous conversion request:**
  Bit SYNC defines if the channel triggers a synchronized conversion (see **Section 31.2.19**).
- **Alias feature:**
  In addition to the general channel control, the ADC kernel supports a mechanism (named alias feature, see **Section 31.2.13.3**) to redirect a conversion request to another channel number.

31.2.13.1 Input Classes

An input class defines the length of the sample phase and the resolution of the conversion. In most applications, the characteristics of the input circuitries (RC input low-pass filter and impedance of the signal source) are quite similar for several analog input signals, leading to similar timings for the sample phase of these channels. As a consequence, input channels with similar parameters can be grouped together to form an input class.
All channels with the same ICLSEL setting belong to the same input class and have the same sample phase length and resolution. In the TC1798, 4 input classes are supported. Registers **INPCRx (x = 0 - 3)** can be programmed to adjust the sample time and the resolution to the application requirements independently for each input class.
The default setting of these registers lead to the minimum sample phase length of 2 f_{ADCI} cycles and conversions with 10 bits resolution. If this default setting fits to the application requirements, bit fields **CHCTRx (x = 0 - 15)**.ICLSEL and registers **INPCRx (x = 0 - 3)** need not to be changed.

31.2.13.2 Reference Selection

The conversion result of the ADC is always referring to a reference voltage. The maximum digital result value (full scale) is obtained if the analog input voltage equals the reference voltage. In order to support more than one measurement range with full scale digital representation, the user can select between the standard reference input V_{AREF} and an alternative reference input at the analog input channel CH0 for each ADC kernel. The reference selection can be individually programmed for each input channel.
This feature can be used to connect 5 V based sensors and 3.3 V based sensors to the same ADC kernel. In this case, one set of input channels refers to the standard reference input, whereas the other one refers to the voltage level at input CH0.
Please note that the smallest granularity 1 LSB_n for n bit resolution refers to the selected reference voltage. The granularity becomes very small if a low reference voltage is applied, and as a consequence, the resulting TUE increases due to noise effects. Therefore it is recommended to avoid small reference voltages.

31.2.13.3 Alias Feature

The ADC kernel provides an alias feature, allowing a re-direction of conversion requests for channels CH0 or CH1 to other channel numbers. This feature can be used to measure the same input channel and to store the conversion results in two different result registers.

- The same signal can be measured twice without the need to read out the conversion result to avoid data loss. This allows triggering both conversions quickly one after the other and being independent from CPU interrupt latency.
- The sensor signal is connected to only one input channel (instead of two analog inputs). This saves input pins in low-cost applications and only the leakage of one input has to be considered in the error calculation.
- Even if the analog input CH0 is used as alternative reference (see **Figure 31-13**), the internal trigger and data handling features for channel CH0 can be used.
- The channel settings for both conversions can be different (boundary values, interrupts, etc.).
- If a sequential conversion request source has been set up, a conversion request for channels CH0 or CH1 can be easily directed to other input channels without flushing the queue.

In typical low-cost AC-drive applications, only one common current sensor is used to determine the phase currents. Depending on the applied PWM pattern, the measured value has different meanings and the sample points have to be precisely located in the PWM period. **Figure 31-13** shows an example where the sensor signal is connected to one input channel (CHx) but two conversions are triggered for two different channels (CHx and CH0). With the alias feature, a conversion request for CH0 leads to a conversion of the analog input CHx instead of CH0, but taking into account the settings for CH0. Although the same analog input (CHx) has been measured, the conversion

results can be stored and read out from the result registers RESRx (conversion triggered for CHx) and RESRy (conversion triggered for CH0). Additionally, different interrupts or limit boundaries can be selected, enabled or disabled.

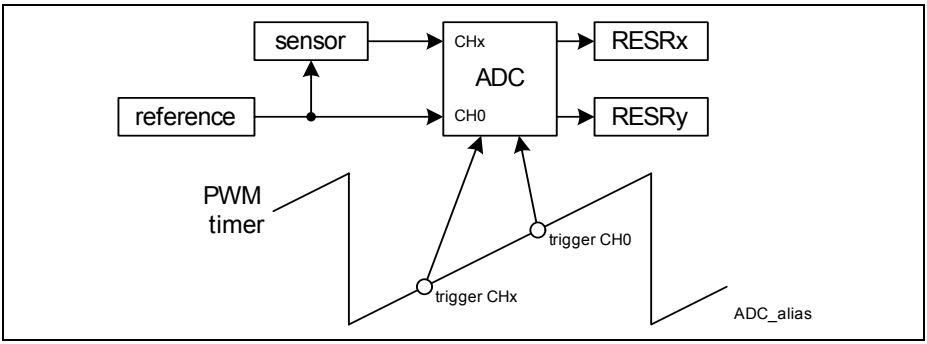


Figure 31-13 Alias Feature

31.2.13.4 Limit Checking

The limit checking mechanism automatically compares each conversion result to two boundary values (boundaries A and B). For each channel, the user can select these boundaries from a set of 4 programmable values (**LCBR0** to **LCBR3**).
With this structure, the conversion result range is split into three areas:

- Area I: The conversion result is below or equal to both boundaries.
- Area II: The conversion result is above one boundary and below or equal to the other boundary.
- Area III: The conversion result is above both boundaries.

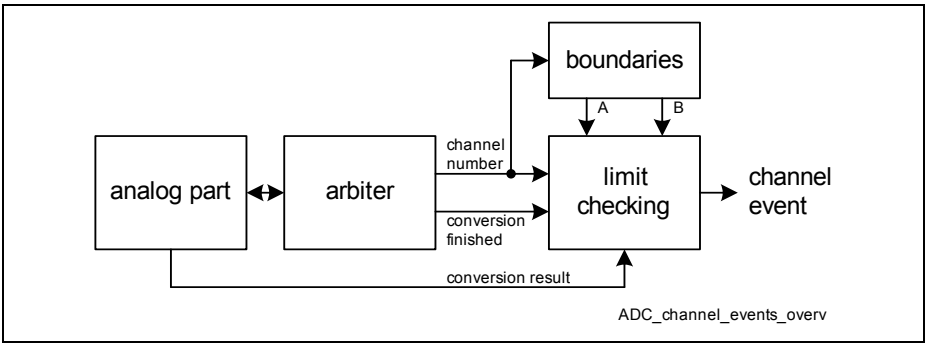

Figure 31-14 Channel Event Generation

Bit field LCC in the channel control register defines the condition to generate a channel event, leading to a channel event interrupt:

- LCC = 000_B: No trigger, the channel event generation is disabled.
- LCC = 001_B: A channel event is generated if the conversion result is not in area I.
- LCC = 010_B: A channel event is generated if the conversion result is not in area II.
- LCC = 011_B: A channel event is generated if the conversion result is not in area III.
- LCC = 100_B: A channel event is always generated (regardless of the boundaries).
- LCC = 101_B: A channel event is generated if the conversion result is in area I.
- LCC = 110_B: A channel event is generated if the conversion result is in area II.
- LCC = 111_B: A channel event is generated if the conversion result is in area III.

Figure 31-15 shows an example for limit checking where channel events are generated only if the conversion results are not in the normal operating range defined by area II (LCC = 010_B).

Typical applications for limit checking are temperature monitoring or overcurrent sensing. As long as the measured temperature value is below a boundary value, the CPU does not need to be informed. In this case, a channel event should be generated only if the conversion result is in area III (LCC = 111_B) to indicate an over-temperature condition. If the conversion of the analog temperature input signal is part of an auto-scan sequence autonomously triggered on a regular time base, the CPU load for the temperature monitoring is zero until the over-temperature condition is detected.

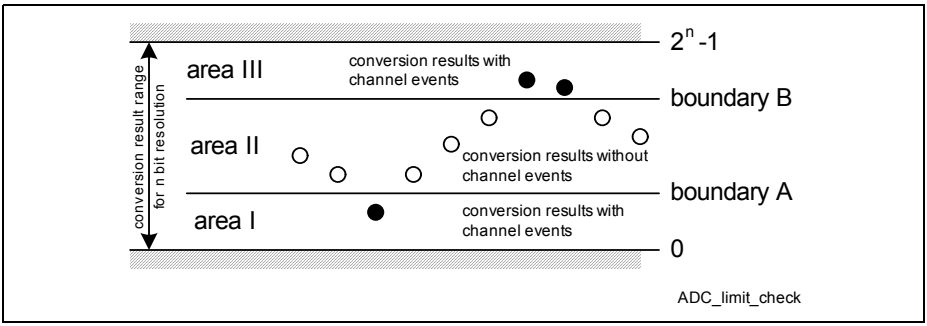

Figure 31-15 Limit Checking

Note: It is also possible to select the same boundary register for boundaries A and B. In this case, the conversion result range is split into two ranges (area II is empty).

31.2.13.5 Channel Event Interrupts

A channel event interrupt can be generated based on a channel event according to the structure shown in **Figure 31-16**. If a channel event is detected, it sets the corresponding indication flag FCx in register **CHFR**. These flags can also be set by writing a 1 to the corresponding bit position, whereas writing 0 has no effect. The indication flags can be cleared by SW by writing a 1 to the corresponding bit position in register **CHFCR**.

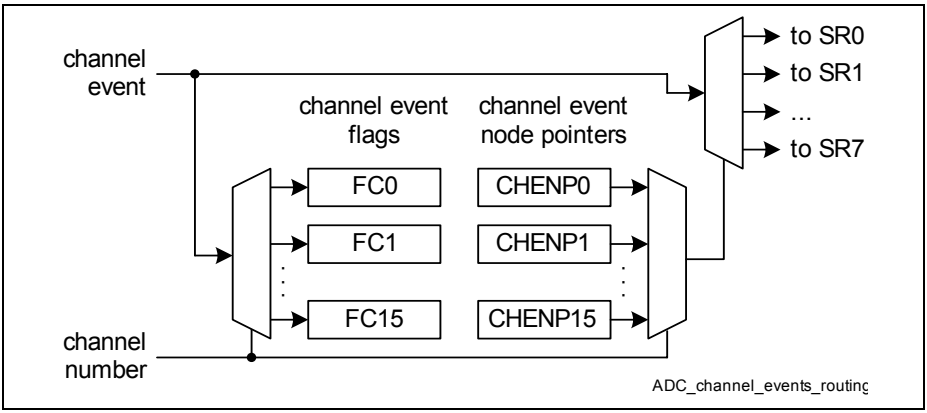

Figure 31-16 Channel Event Interrupt Generation

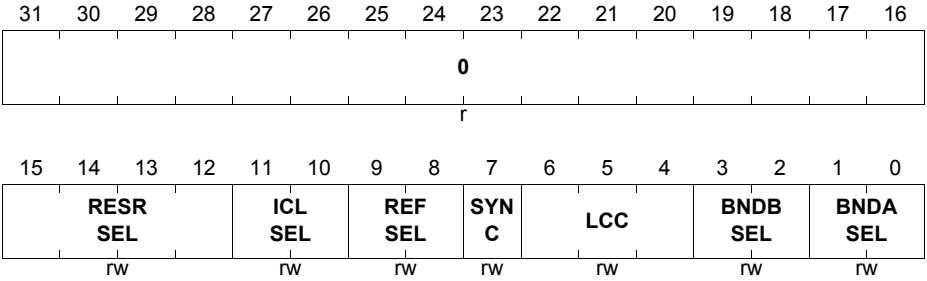
The service request output ADCy_SRx that is selected by the channel node pointer bit fields in registers **CHENPR0**, or **CHENPR8** is activated each time the related channel event is detected.
A service request output can be activated under SW control by writing **INTR**.SISRx.

31.2.14 Channel-Related Registers

31.2.14.1 Channel Control Registers

The channel control registers contain bits to select the targeted result register, to control the limit check mechanism and to select an input class.
The channel control register 0 defines the settings for the input channel 0, etc.

CHCTRx (x = 0 - 15)
Channel x Control Register **(100_H + x * 4)** **Reset Value: 0000 0000_H**



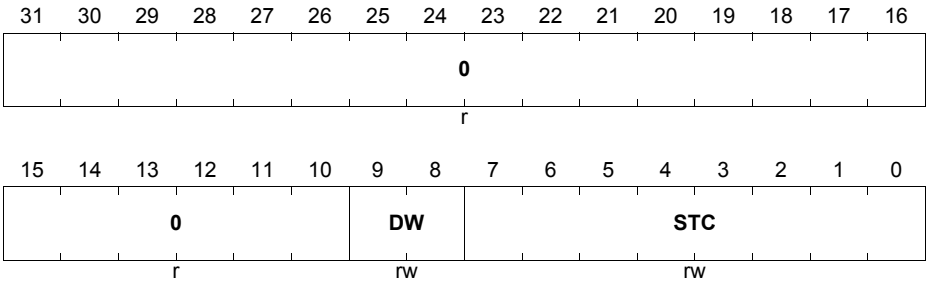
Field	Bits	Type	Description
BNDASEL	[1:0]	rw	**Boundary A Selection** This bit field defines which boundary will be taken as boundary A for the limit checking. 00_B The value given by LCBR0 is selected. 01_B The value given by LCBR1 is selected. 10_B The value given by LCBR2 is selected. 11_B The value given by LCBR3 is selected.
BNDBSEL	[3:2]	rw	**Boundary B Selection** This bit field defines which boundary will be taken as boundary B for the limit checking. 00_B The value given by LCBR0 is selected. 01_B The value given by LCBR1 is selected. 10_B The value given by LCBR2 is selected. 11_B The value given by LCBR3 is selected.
LCC	[6:4]	rw	**Limit Check Control** This bit field defines the behavior of the limit checking mechanism. Please refer to the coding in **Section 31.2.13.4** on **Page 31-78**.

Field	Bits	Type	Description
SYNC	7	rw	**Synchronization Request** This bit defines if a conversion request for this channel leads to a synchronized (parallel) conversion with other ADC kernels. This bit is only taken into account if the ADC kernel is a potential conversion master (**SYNCTR**.STSEL = 00), otherwise it is considered to be 0. 0_B This channel does not request a synchronized conversion. 1_B This channel requests a synchronized conversion if the ADC kernel is a potential synchronization master.
REFSEL	[9:8]	rw	**Reference Input Selection** This bit field defines the reference source for this channel. 00_B The standard reference input V_{AREF} is selected. 01_B The alternative reference input CH0 is selected. 10_B reserved, do not use 11_B reserved, do not use
ICLSEL	[11:10]	rw	**Input Class Selection** These bits are used to select the input class. 00_B The input class 0 is selected. 01_B The input class 1 is selected. 10_B The input class 2 is selected. 11_B The input class 3 is selected.
RESRSEL	[15:12]	rw	**Result Register Selection** This bit field defines which result register will be the target of a conversion of this channel. 0_H Result register 0 is selected. 1_H Result register 1 is selected. ... F_H Result register 15 is selected.
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

31.2.14.2 Input Class Registers

The input class registers contain bits to control the sample time and the resolution for each input class.
The input class register 0 defines the settings for the input class 0, etc.

INPCRx (x = 0 - 3)
Input Class Register x **(050_H + x * 4)** **Reset Value: 0000 0000_H**

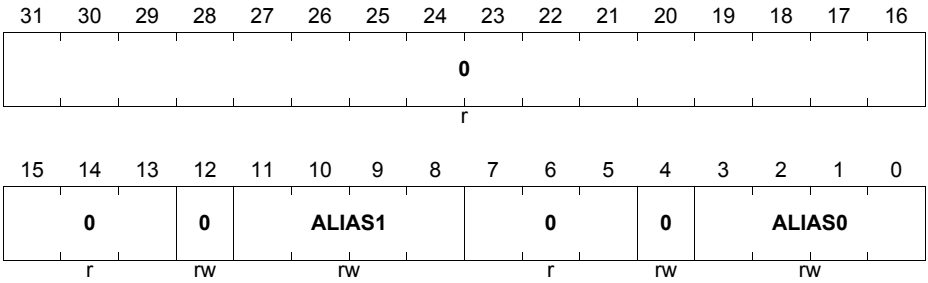


Field	Bits	Type	Description
STC	[7:0]	rw	**Sample Time Control** This bit field defines the additional length of the sample phase, given in analog clock cycles f_{ADCI}. A minimum sample phase of 2 analog clock cycles is extended by the programmed value. sample phase length = (2 + STC) / f_{ADCI}
DW	[9:8]	rw	**Data Width** This bit field defines how many bits are converted for the result. The MSBs of conversion results with different DW settings are left aligned in the result bit fields. Bit positions that are not converted are 0. 00_B The result is 10 bits wide. 01_B The result is 12 bits wide. 10_B The result is 8 bits wide. 11_B reserved
0	[31:10]	r	**Reserved** Read as 0; should be written with 0.

31.2.14.3 Alias Register

The alias register contains bits to change a requested channel number from CH0 and CH1 to another channel number, see also **Section 31.2.13.3**. The programmed alias channel number is replacing the internally requested number for analog input multiplexer (of the converter). The internally requested channel number is taken into account for all other internal actions and the synchronization request.

ALR0
Alias Register 0 **(210_H)** **Reset Value: $0000\ 0100_H$**



Field	Bits	Type	Description
ALIAS0	[3:0]	rw	**Alias Value for CH0 Conversion Requests** The channel indicated in this bit field is converted instead of channel CH0. The conversion is done with the settings defined for channel CH0.
ALIAS1	[11:8]	rw	**Alias Value for CH1 Conversion Requests** The channel indicated in this bit field is converted instead of channel CH1. The conversion is done with the settings defined for channel CH1.
0	4, 12	rw	**Reserved for Future Use** Bit is reserved for future use and has to be written with 0_B.
0	[7:5], [31:13]	r	**Reserved** Read as 0; should be written with 0.

31.2.14.4 Limit Check Boundary Registers

The bit fields in these registers define compare value (boundary) for the limit checking unit. The reset values of the boundaries are defined as 10%, 90%, 33% and 66% of the complete result range (the MSB located at bit position 11) of each conversion.

LCBR0
Limit Check Boundary Register 0 **($0F0_H$)** **Reset Value: $0000\ 0198_H$**

31.2.15 Conversion Result Handling

The result generation part handles the:

- Storage of the conversion results (see **Section 31.2.15.1**)
- Wait-for-read mode (see **Section 31.2.15.2**)
- Result event interrupts (see **Section 31.2.15.3**)
- Result FIFO buffer (see **Section 31.2.15.4**)
- Data reduction or anti-aliasing filtering (see **Section 31.2.15.5**)

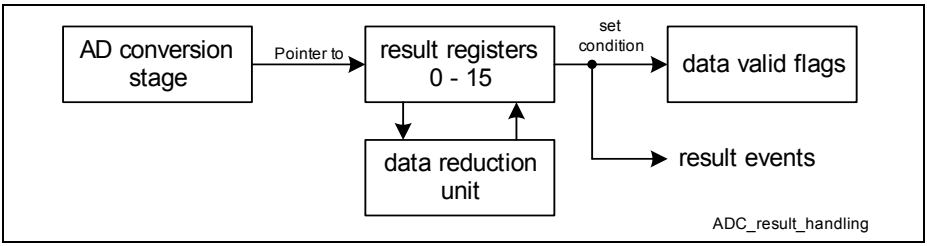

Figure 31-17 Conversion Result Handling

31.2.15.1 Storage of Conversion Results

For each analog input channel, the associated channel control register **CHCTRx (x = 0 - 15)** contains a pointer bit field (RESRSEL) defining the result register to store the conversion result of this channel. This structure allows the user to direct conversion results of different channels to one or more result registers. Depending on the application needs (data reduction, auto-scan, alias feature, result FIFO, etc.), the user can distribute the conversion results to minimize CPU load or to be more tolerant against interrupt latency.

An individual data valid flag **VFR**.VFx for each result register indicates that “new” valid data has been stored in the corresponding result register and can be read out.

Due to different result handling mechanisms, the conversion result can be represented in different ways:

- **Data reduction filter disabled:**
  The conversion result is maximum 12 bits wide with the MSB of the conversion result being always at bit position 11 and the remaining LSBs filled with 0.
  The data valid flag is set and a result event occurs each time a new conversion result is stored in the result register.
  It is possible to share a result register among several analog input channels.
- **Data reduction filter enabled:**
  The conversion result is maximum 12 bits wide with the MSB of the conversion result being always at bit position 11 and the remaining LSBs filled with 0. The additional bits [13:12] show the MSBs of the data accumulation.

The data valid flag is set and a result event occurs each time a data reduction sequence is finished and the final result is available in the result register.

In order to support a wait-for-read and FIFO buffer features, the valid flag has to be cleared automatically when SW does a read access or the result is transferred into another FIFO element (if result FIFO buffering is enabled).
This behavior is contradictory to debugging requirements. For debugging, it has to be possible to introduce read or write commands into the normal program flow, e.g. to monitor conversion results. If a debugger reads out a result register, it would change the status of the conversion result from valid = “new” (not yet read out) to “old” (already read out). This would have an undesired impact on the application.
Therefore, the read views with “D” deliver the same value as the read views without “D”, but without clearing the valid bit. As a result, a debugger using read views with “D” can monitor the conversion results without influencing their status for the application.

To allow debugger accesses without the risk of data sequence corruption, two different result register read views are supported. The read views refer to the same result register contents, but show a different behavior according to the address that has been read:

- Standard read view **RESR0** and **RESRx (x = 1 - 15)**:
  A read action clears the corresponding valid bit.
- Read view **RESRD0** and **RESRDx (x = 1 - 15)** for debugger:
  A read action does not clear the corresponding valid bit.

31.2.15.2 Wait-for-Read Mode

The wait-for-read mode is a feature of a result register allowing the CPU (or DMA) to treat each conversion result independently without the risk of data loss. Data loss could occur if the CPU does not read a conversion result from a result register before a new result overwrites the previous one.
Especially for auto-scan conversion sequences (or other sequences with “relaxed” timing requirements), the wait-for-read offers the possibility to request a conversion sequence according to an event (HW or SW), but to start a new conversion according to the CPU capability to read the formerly converted result.

If wait-for-read mode is enabled for a result register by setting bit WFR in register **RCRx (x = 0 - 15)**, a request source does not generate a conversion request while the targeted result register contains valid data (indicated by the valid flag VFx = 1) or if a currently running conversion targets the same result register.
A new conversion request is generated only after the targeted result register has been read out.
If two request sources target the same result register with wait-for-read selected, a lower priority request started before the higher priority source has requested its conversion can not be interrupted by the higher priority request. If a higher priority request targets a different result register, the lower priority conversion can be cancelled and repeated afterwards.

31.2.15.3 Result Event Interrupts

A result event interrupt can be generated based on a result event according to the structure shown in **Figure 31-18**. If a result event is detected, it sets the corresponding indication flag in register **EVFR**. These flags can also be set by writing a 1 to the corresponding bit position, whereas writing 0 has no effect. The indication flags can be cleared by SW by writing a 1 to the corresponding bit position in register **EVFCR**.

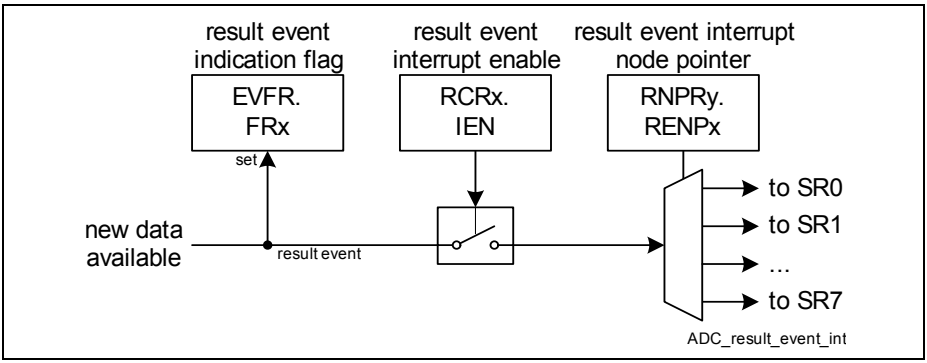

Figure 31-18 Result Event Interrupt Generation

The service request output ADCy_SRx that is selected by the result event interrupt node pointer bit fields in registers **RNPR0** or **RNPR8** issues an interrupt each time the related result event is detected.
A service request output can be activated under SW control by writing **INTR**.SISRx.

31.2.15.4 Result FIFO Buffer

If a result register is not used as direct target for a conversion result, it can be concatenated with other result registers of the same ADC kernel to form a result FIFO buffer (first-in-first-out buffer mechanism). This allows to store measurement results and to read them out later with a “relaxed” CPU access timing. It is possible to set up more than one FIFO buffer structure with the available result registers.
A FIFO structure can be built by at least two “neighbor” result registers with the indices x and z = x+1, where result register z represents the input and result register x represents the output of the FIFO buffer. The conversion result has to be delivered by the converter stage to the FIFO input, whereas the buffered data has to be read out from the FIFO output.
The FIFO buffer function can be enabled by setting bit FEN in registers **RCRx (x = 0 - 15)**.

In the example shown in **Figure 31-19**, the result registers have been configured to form two FIFO buffers with two buffer stages (result registers 0/1 and 6/7, respectively), one FIFO buffer with three buffer stages (result registers 2/3/4), whereas result register 5 is used as “normal” result register without additional FIFO buffer functionality.

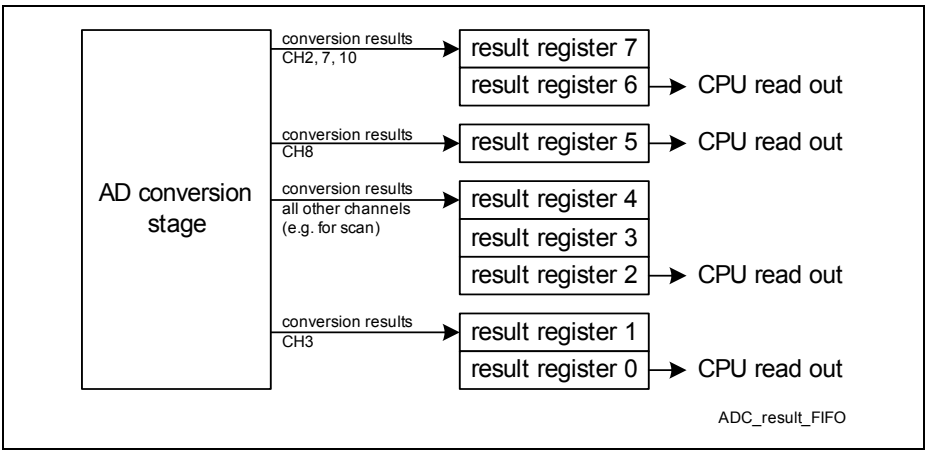

Figure 31-19 Result FIFO Buffers

If more than two result neighbor registers are concatenated to a FIFO buffer (from result register z to result register x, with z > x), the one with the highest index (z) is always the input and the one with the lowest index (x) is always the output. All intermediate result registers y (x < y < z) are used as intermediate FIFO stages without data input or data output functionality.

Result register features for each FIFO buffer:

- Result register z (**FIFO buffer input**):
  This result register can be enabled for data reduction. The wait-for-read mode is supported to avoid data loss if the FIFO is full. Result event interrupt generation is not supported. Must not be read at a read view modifying the valid bit.
- Result register y (**intermediate buffer stage**):
  This/these result register(s) must not be enabled neither for wait-for-read mode, nor for data reduction. Result event interrupt generation is not supported. Must not be read at a read view modifying the valid bit, nor be the target of a conversion result.
- Result register x (**FIFO buffer output**):
  This result register can be enabled for result event interrupt generation to inform the CPU that new data can be read out from this register location. Data reduction and wait-for-read are not supported and have to be disabled. Must not be the target of a conversion result.
  If enabled, a result interrupt is generated for each data word in the FIFO.

31.2.15.5 Data Reduction Filter

The data reduction filter can be used as digital filter for anti-aliasing or decimation purposes. It can accumulate a maximum of 4 conversion results to generate a final result.

Each result register can be individually enabled for data reduction. The feature is controlled by bit field DRCTR in registers **RCRx (x = 0 - 15)**. The actual status is given by bit field DRC (data reduction counter) in the related result register.
Conversion delivering results to other result registers do not influence the data reduction filter of result register x. As a consequence, other channels can be converted between two conversions targeting result register x.

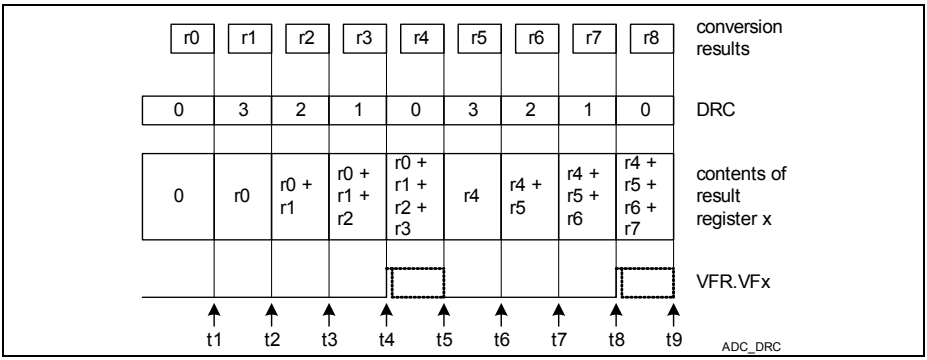

Figure 31-20 Data Reduction Filter

In the example given in **Figure 31-20**, a data reduction sequence of 4 accumulated conversion results is shown. The data reduction is based on three rules:

- Each time bit field DRC is 0 and a conversion targeting result register x is completed (t1, t5, t9), the contents of bit field RCRx.DRCTR is loaded into bit field DRC and the conversion result is stored in result register x.
- Each time bit field DRC is not 0 and a conversion targeting result register x is completed (t2, t3, t4 for the first final result and t6, t7, t8 for the next one), bit field DRC is decremented by 1 and the conversion result is added to the value already stored in result register x.
- Each time bit field DRC is 0 after decrementing or after loading it with RCRx.DRCTR = 0 (t4 for the first final result and t8 for the next one), the valid bit for the result register x becomes set and a result register event occurs.

The final result of a data reduction sequence has to be read out from result register x before the next data reduction sequence starts (interval between t4 and t5, or t8 and t9 respectively). With the read out of the final result from this register, the valid flag is automatically cleared.
If this interval is too short, it is recommended to associate a second result register z to

result register x by enabling the result FIFO mechanism for result register x, see **Figure 31-21** (z = x + 1). In this case, result register x is loaded with the final result elaborated by result register z when a data reduction sequence is finished. The final result has to be read out from result register x before the next data reduction sequence is finished (interval between t4 and t8).

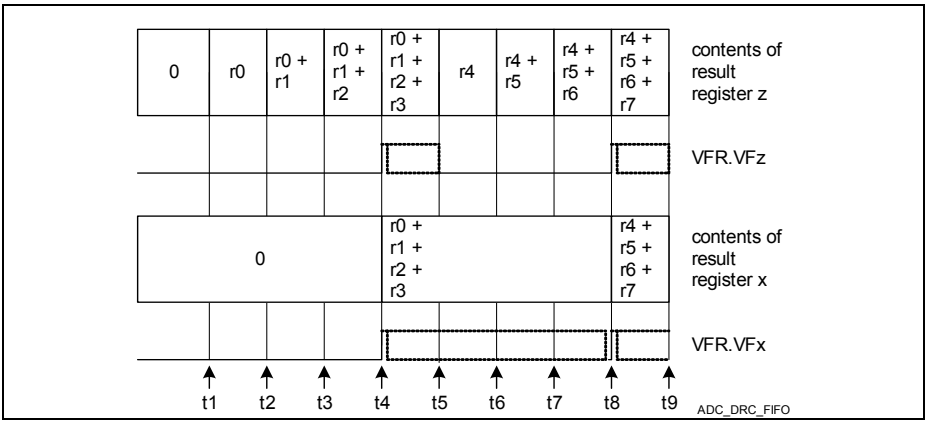

Figure 31-21 Data Reduction Filter with Result FIFO

31.2.15.6 Result Data Filter

A certain number of the result registers can be individually enabled for data filtering. As the result registers can be individually assigned to the channels, these filters can be selected for all channels within the same ADC kernel. Conversions delivering results to other result registers do not influence the value of this data filter activated at result register x. As a consequence, other channels can be converted between two conversions targeting result register x.

There are two different filter types implemented:

- A third order FIR filter with adjustable coefficients
- A first order IIR filter with adjustable coefficients

The result buffer are cleared as long as no result data filter is selected by parameter DRCTR in register **RCRx (x = 0 - 15)**. Only the output of this data filter can be used together with the result FIFO buffer function, described in **Section 31.2.15.4**.

FIR (finite impulse response) Filter

Each FIR filter contains three filter tab coefficients a, b and c and two result buffer (RB1 and RB2) for storing the intermediate values. **Figure 31-22** shows the structure of the filter.

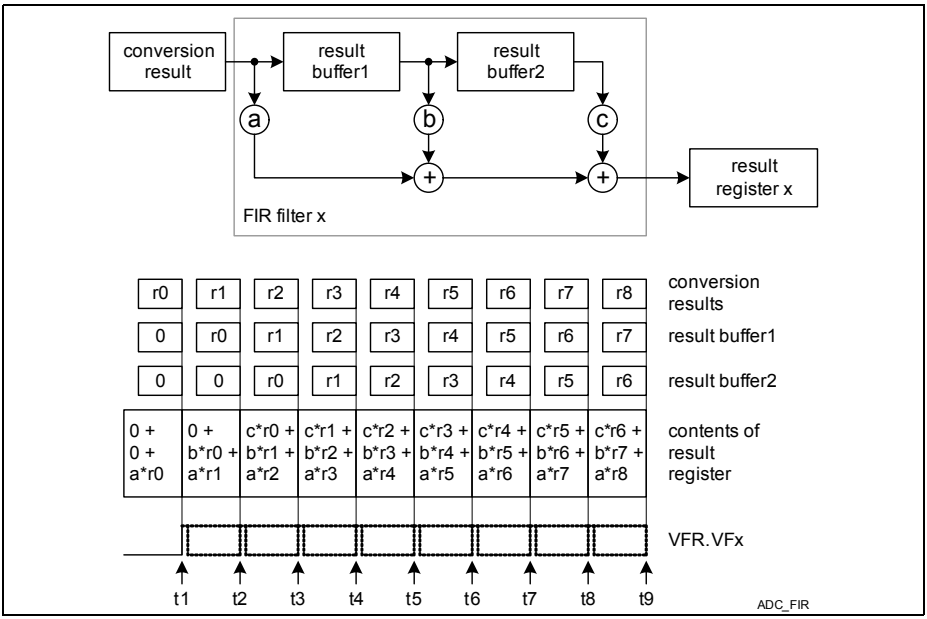

Figure 31-22 FIR Filter

The values from the result buffer and the conversion result are added to the result register according to their coefficients. There are predefined coefficients selectable in register **RCRx (x = 0 - 15)**, which cause a gain of 3 or 4 to the ADC result leading to a 14 bit value. The valid flag (**VFR**.VFx) indicates a valid result, at the first sample after activation and the result is valid for each sample.

IIR (infinite impulse response) Filter

The IIR filter contains two filter tab coefficients a and b. **Figure 31-23** shows the structure of the filter.

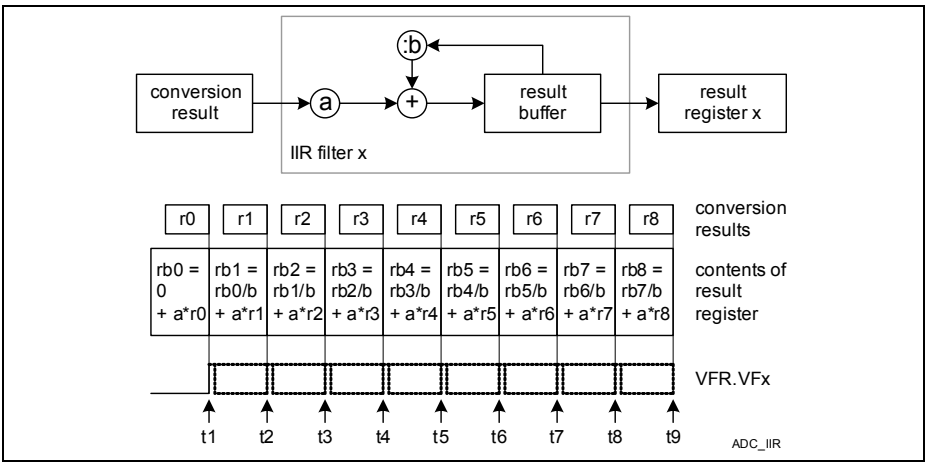

Figure 31-23 IIR Filter

This IIR filter represents a first order low pass filter. The conversion result is added a-times to the fractional (:b) amount of the previous value of the result buffer which is copied to the associated result register.

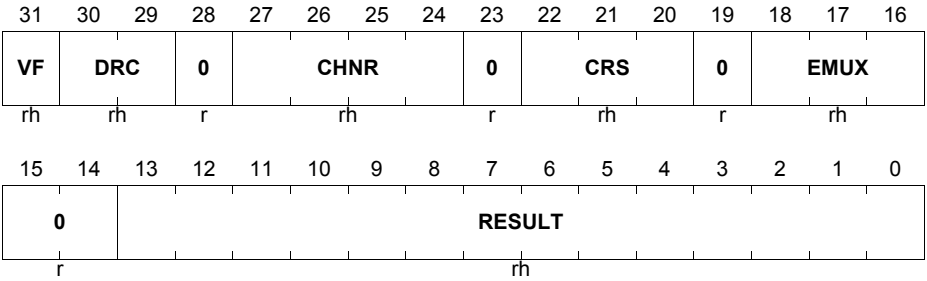
There are predefined coefficients selectable in register **RCRx (x = 0 - 15)**, which cause a gain of 4 to the ADC result leading to a 14 bit value. The valid flag (**VFR**.VFx) indicates a valid result, at the first sample after activation and the result is valid for each sample.

31.2.16 Conversion Result-Related Registers

31.2.16.1 Result Register 0

The result registers deliver the conversion results and associated information.
Additionally to this information, result register RESR0 also indicates the setting of an external analog multiplexer. The conversion results of the channel used with an external multiplexer have to be directed to RESR0 in order to indicate the multiplexer setting used during the conversion. If this information is not necessary, the conversion result can be directed to any other result register.
The valid flag VF indicates that a result register contains updated data and can be used to poll for new data. The valid flag of a result register is cleared automatically if at least the low byte of register RESR0 is read, whereas it is left unchanged when reading RESRD0.

RESR0
Result Register 0 **(180_H)** **Reset Value: 0000 0000_H**
RESRD0
Result Register 0 for Debugging **($1C0_H$)** **Reset Value: 0000 0000_H**



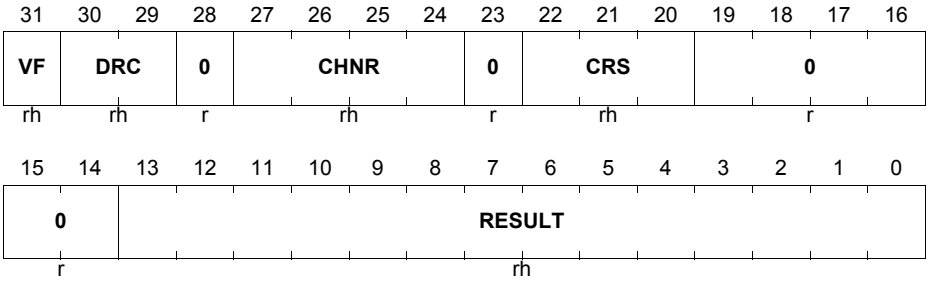
Field	Bits	Type	Description
RESULT	[13:0]	rh	**Conversion Result** This bit field contains the conversion result, or respectively, the result of the data reduction filter.
EMUX	[18:16]	rh	**External Multiplexer Setting** This bit field indicates the external multiplexer setting leading to the result stored in bit field RESULT.

Field	Bits	Type	Description
CRS	[22:20]	rh	**Converted Request Source** This bit field indicates the request source that has requested the conversion leading to the result stored in bit field RESULT. 000_B The conversion was requested by source 0. 001_B The conversion was requested by source 1. 010_B The conversion was requested by source 2. 011_B The conversion was requested by source 3. 100_B The conversion was requested by source 4. else reserved
CHNR	[27:24]	rh	**Channel Number** This bit field contains the channel number of the latest register update.
DRC	[30:29]	rh	**Data Reduction Counter** This bit field indicates how many conversion results have still to be accumulated to generate the final result for data reduction. The valid flag is automatically set when this bit field becomes 0. It can be cleared by SW by writing a 1 to the related bit position in register VFR. 00_B The final result is available in the result register. The valid flag is automatically set when this bit field is set to 0. 01_B 1 more conversion result has to be added to obtain the final result in the result register. 10_B 2 more conversion results have to be added to obtain the final result in the result register. 11_B 3 more conversion results have to be added to obtain the final result in the result register.
VF	31	rh	**Valid Flag** This bit indicates that bit field RESULT has been updated with valid data since it has been read out. It is another view of the corresponding bit in register VFR. 0_B The result register has not been updated. 1_B The result register has been updated.
0	[15:14], 19, 23, 28	r	**Reserved** Read as 0; should be written with 0.

31.2.16.2 Result Registers 1 to 15

The result registers deliver the conversion results and associated information.
The valid flag VF indicates that the result register contain updated data and can be used to poll for new data. The valid flag of a result register is cleared automatically if at least the low byte of register RESRx is read, whereas it is left unchanged when reading RESRDx.

RESRx (x = 1 - 15)
Result Register x **(180_H + x * 4)** **Reset Value: 0000 0000_H**
RESRDx (x = 1 - 15)
Result Register x for Debugging **($1C0_H$ + x * 4)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
RESULT	[13:0]	rh	**Conversion Result** This bit field contains the conversion result, or respectively, the result of the data reduction filter.
CRS	[22:20]	rh	**Converted Request Source** This bit field indicates the request source that has requested the conversion leading to the result stored in bit field RESULT. 000_B The conversion was requested by source 0. 001_B The conversion was requested by source 1. 010_B The conversion was requested by source 2. 011_B The conversion was requested by source 3. 100_B The conversion was requested by source 4. else reserved
CHNR	[27:24]	rh	**Channel Number** This bit field contains the channel number of the latest register update.

Field	Bits	Type	Description
DRC	[30:29]	rh	**Data Reduction Counter** This bit field indicates how many conversion results have still to be accumulated to generate the final result for data reduction. The valid flag is automatically set and a result event is generated when this bit field becomes 0 (by decrementing or by reload). Bit field DRC is cleared by writing the related **VFR**.VFx = 1. 00_B The final result is available in the result register. 01_B 1 more conversion result has to be added to obtain the final result in the result register. 10_B 2 more conversion results have to be added to obtain the final result in the result register. 11_B 3 more conversion results have to be added to obtain the final result in the result register.
VF	31	rh	**Valid Flag** This bit indicates that bit field RESULT has been updated with valid data since it has been read out. It is another view of the corresponding bit in register VFR. 0_B The result register has not been updated. 1_B The result register has been updated.
0	[19:14], 23, 28	r	**Reserved** Read as 0; should be written with 0.

31.2.16.3 Valid Flag Register

The valid flag register contains the flags indicating that the corresponding result register contents are valid (valid = “new” = not read out).
These bits are another (condensed) view of the valid flags in the result registers.

VFR
Valid Flag Register **(200_H)** **Reset Value: $0000\ 0000_H$**

Field	Bits	Type	Description
FRx (x = 0 - 15)	x	rwh	**Event Flag for Result Register x** Flag FRx indicates that a result event of result register x has been detected. Writing a 0 has no effect, whereas writing a 1 sets the written bit position without generating an interrupt. Bit FRx is cleared by writing EVFCR.CFRx = 1. 0_B An event of result register x has not yet been detected. 1_B An event of result register x has been detected.
FSx (x = 0 - 4)	x + 16	rwh	**Event Flag for Request Source x** Flag FSx indicates that a request source event of request source x has been detected. Writing a 0 has no effect, whereas writing a 1 sets the written bit position without generating an interrupt. Bit FSx is cleared by writing EVFCR.CFSx = 1. 0_B An event of request source x has not yet been detected. 1_B An event of request source x has been detected.

Field	Bits	Type	Description
GFSx (x = 0 - 4)	x + 24	rh	**Gated Event Flag for Request Source x** Flag GFSx indicates that a request source event of request source x has been detected while the related interrupt was enabled. Writing to this bit position has no effect. Bit GFSx is cleared by writing EVFCR.CFSx = 1. 0_B An event of request source x has not yet been detected or the related interrupt was not enabled. 1_B An event of request source x has been detected while the related event interrupt was enabled.
0	[23:21], [31:29]	r	**Reserved** Read as 0; should be written with 0.

31.2.16.6 Event Flag Clear Register

Writing a 1 to a bit position in register EVFCR clears the corresponding event flag in register EVFR. If a hardware event triggers the setting of bit EVFR.x and software writes EVFCR.x = 1, bit EVFR.x is cleared (software overrules hardware).

EVFCR

31.2.17 Multiplexer Test Support

A specific multiplexer test mode has been implemented for the analog input CH7 that can be enabled during run time by the user to check the connection to the sensor.

- **Multiplexer test mode disabled** (**GLOBCFG**.MTM7 = 0):
  The switch for the voltage divider and static load R_{MTM7} is open. The analog input CH7 can be used for normal measurements.
- **Multiplexer test mode enabled** (**GLOBCFG**.MTM7 = 1):
  The switch for the voltage divider and static load R_{MTM7} is closed. The analog input CH7 is loaded by a resulting resistance and the measured voltage is reduced by a voltage divider.
  Please refer to the AC/DC chapter for the value of the resulting grounding resistor and its current capability.

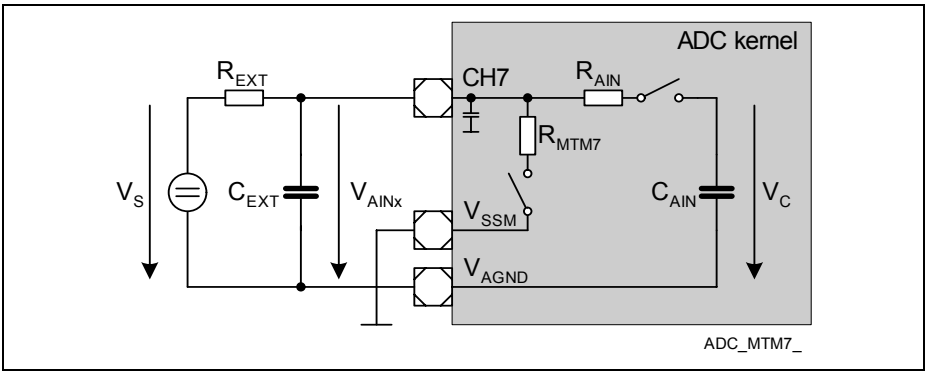

Figure 31-24 Multiplexer Test Mode for CH7

In addition to the multiplexer test support for channel CH7 based on bit MTM7, one of the input channels listed below can also be enabled for the same function. The additional channel number is selected by bit field GLOBCFG.MTMCH and the test mode becomes enabled for this channel if GLOBCFG.MTMEN = 1.

The following channels can be selected for the additional multiplexer test mode support: CH1, CH3, CH5, CH7, CH9, CH11, CH13, CH15

The channels with an even channel number do not support this test mode, even if their channel number is selected and MTMEN = 1.
The multiplexer test mode for input channel CH7 can be activated by both mechanisms.

31.2.18 External Multiplexer Control

If an application requires more analog inputs channels than available on the TC1798, the ADC kernel supports an extension of analog channels by adding an external analog multiplexer. Three output signals EMUX[2:0] are delivered by the ADC kernel to control the settings of an external analog multiplexer. They can be used to extend the number of analog input channels by adding an external 1-out-of-8 multiplexer.
The external multiplexer control behavior is defined by the bits in register **EMCTR**.
The current setting of EMUX[2:0] is given by bit field EMUX. If another extended input channel should be converted, bit field SETEMUX has to be programmed to the desired value or the scan function has to be enabled. The SETEMUX value is automatically applied with the start of the next conversion of the related analog ADC input channel.

In the example shown in **Figure 31-25** and in the description below, the analog input CH7 has been extended, leading to additional analog inputs named CH70 to CH77. The channel number where the external multiplexer is connected to is defined by bit field EMUXCHNR.

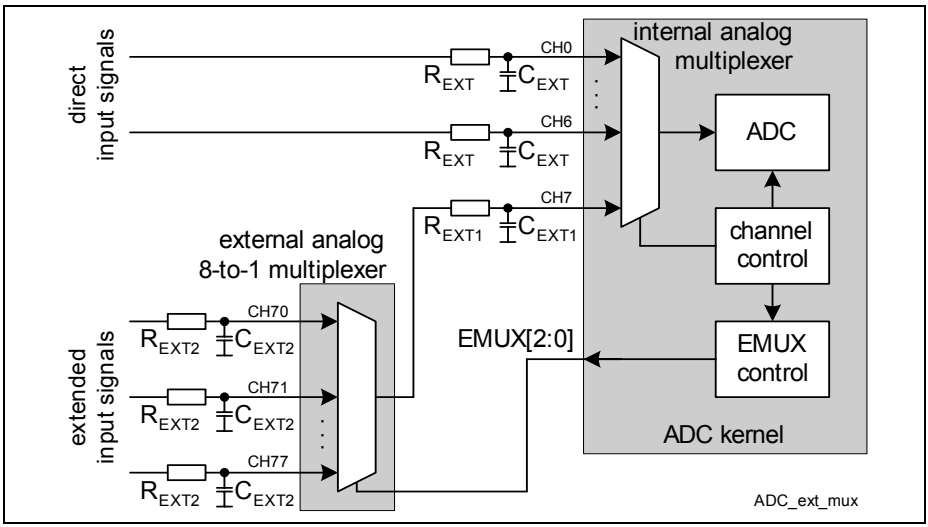

Figure 31-25 External Analog Multiplexer

If the external multiplexer is located far from the ADC analog input, it is recommended to introduce an RC filter R_{EXT1}-C_{EXT1} directly at the analog input CH7 of the ADC. If needed for signal filtering, local RC filters R_{EXT2}-C_{EXT2} can be optionally added at the inputs of the external analog multiplexer.
If the external multiplexer is located close to the analog ADC input, the components R_{EXT1} and C_{EXT1} are not necessarily needed. In this case it is strongly recommended to

introduce RC filters (R_{EXT2}, C_{EXT2}) at the multiplexer inputs.
Please note that each RC filter limits the bandwidth of the analog input signal.

The RC filters used with an external multiplexer may lead to another impedance “seen” by the ADC analog input CH7 than for the other (direct) analog inputs. The adaptation of the sample phase length can be done by using a different input class with a different value for the sample phase extension. This value can be adapted to execute conversions with an EMUX[2:0] setting that has changed a sufficiently long time before the conversion of CH7 starts. “A sufficiently long time before” signifies that signal transitions at the analog ADC input due to changing multiplexer setting are finished and the input signal is stable enough.
After changing the EMUX[2:0] setting of the external multiplexer, an additional settling time has to elapse before the switched analog signal is stable and can be measured. To compensate for this settling time, an alternative sample phase length (instead of the one given by the input class) is automatically applied for the first conversion of CH7 after EMUX[2:0] has changed. The alternative sample phase length can be programmed by bit field **EMCTR**.EMSAMPLE. If the first conversion of CH7 after the EMUX[2:0] setting has changed is aborted due to a higher priority request, the repeated conversion of CH7 also uses the value of EMSAMPLE. The settling time is considered to be finished after the complete conversion of CH7.

The external multiplexer control block supports different modes, that are programmed by the bits in register **EMCTR**:

- **SW control** without any HW interaction (EMUXEN = 0):
  The automatic control of the external multiplexer setting and of the sampling time is disabled. Bit field EMUX is permanently updated with the value of SETEMUX. The changes of EMUX are related to write actions to SETEMUX and not to conversion timing. The setting of EMSAMPLE is not taken into account. It is recommended to write the start value of the first scan sequence to SETEMUX while EMUXEN = 0.
- **HW control without scan** (EMUXEN = 1, SCANEN = 0):
  The update of EMUX with the value of SETEMUX happens with each conversion start of the channel selected by EMUXCHNR. For the first conversion with a new EMUX value, the setting of EMSAMPLE is applied.
- **HW control with single-input scan** (EMUXEN = 1, SCANEN = 1, TROEN = 0):
  The update of EMUX with a new value happens after each conversion of the channel selected by EMUXCHNR. For each update, EMUX is automatically decremented by 1. If EMUX = 0, it is reloaded with the value of SETEMUX for the next update. For each conversion of the selected channel, the setting of EMSAMPLE is applied.
  With this setting, an autoscan sequence requesting the conversion of the channel defined by EMUXCHNR leads to one conversion of the channel connected to the external multiplexer. As a result, for each completed auto scan sequence, another EMUX setting is applied.
  Assuming inputs 1, 2, 70, 71, and 72 being selected for scan, the following sequence will be executed: 1, 2, 72, 1, 2, 71, 1, 2, 70, 1, 2, 72, 1, 2, 71, 1, 2, 70, 1, 2, 72, ...

- **HW control with multi-input scan** (EMUXEN = 1, SCANEN = 1, TROEN = 1):
  The update of EMUX with a new value happens after each conversion of the channel selected by EMUXCHNR. For each update, EMUX is automatically decremented by 1. If EMUX = 0, it is reloaded with the value of SETEMUX for the next update. For each conversion of the selected channel, the setting of EMSAMPLE is applied.
  With enabled trigger option, the external multiplexer control block triggers a new conversion request each time a conversion is started of the channel defined by EMUXCHNR while EMUX > 0.
  In a scan request source, the corresponding pending bit becomes set, whereas in a sequential request source, the content of the backup stage becomes valid (V bit of backup stage becomes set).
  With this setting, all external multiplexer inputs are scanned during a single autoscan sequence, starting with the channel indicated by SETEMUX (same update rate of all channels of this sequence).
  Assuming inputs 1, 2, 70, 71, and 72 being selected for scan, the following sequence will be executed: 1, 2, 72, 71, 70, 1, 2, 72, 71, 70, 1, 2, 72, 71, 70, 1, 2, 72, ...

31.2.19 Synchronized Conversions for Parallel Sampling

The independent ADC kernels implemented in the TC1798 can be synchronized for simultaneous (parallel) measurements of analog input channels. While no parallel conversion is requested, the kernels can work independently.
The synchronization mechanism for parallel conversions ensures that the sample phases of the related channel start simultaneously. Different values for the resolution and the sample phase length of each kernel for a parallel conversion are supported.
A parallel conversion can be requested individually for each input channel (also several channels can be enabled for parallel conversions). In the example shown in the figure below, input channels CH3 of the ADC kernels ADC0 and ADC1 are converted synchronously, whereas other input channels do not lead to parallel conversions.

This leads to the following structure:

- A **synchronization master** ADC kernel can request a conversion of an analog channel. If this channel is selected for a synchronized conversion, it is also requested in the connected slave ADC kernel(s).
- A **synchronization slave** ADC kernel reacts to incoming synchronized conversion requests from its master. While no incoming master requests are active, the slave kernel can convert its own requests.
- All ADC kernels in an ADC module being similar, each kernel can be set up to be a synchronization master or a synchronization slave (depending on the application needs, such as trigger capability of request sources).
- A synchronization master can synchronize several slave kernels, whereas a slave kernel can only be synchronized to one master kernel.

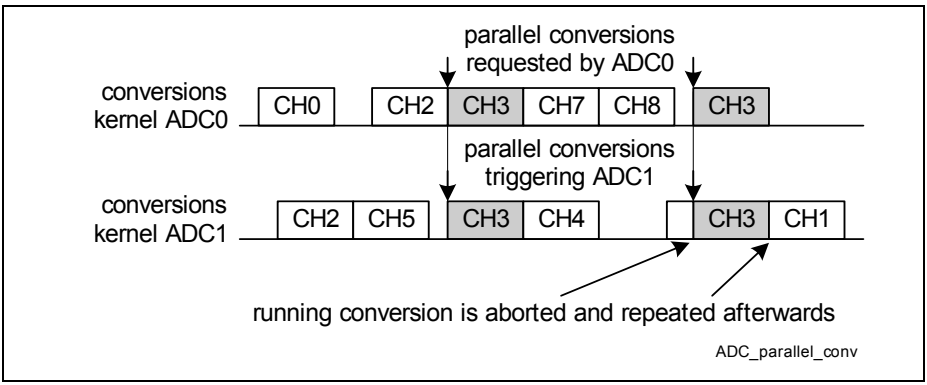

Figure 31-26 Parallel Conversions

The term “conversion group” has been introduced to define the kernel behavior allowing parallel sampling:

- Kernels in the same conversion group can execute parallel conversions.
- A conversion group contains at least 1 ADC kernel and can contain a maximum of all ADC kernels of the ADC module.
- Each conversion group contains exactly one synchronization master kernel that issues a parallel conversion request and defines the internal frequencies f_{ADCI} and f_{ADCD} and the channel number for a parallel conversion of the conversion group.
- All other kernels in a conversion group are synchronization slaves and have to be programmed with the same values of **GLOBCTR**.DIVA, DIVD and ARBRND as the synchronization master.
- If there is no need for parallel conversions, each kernel can be considered to form an own conversion group with only an ADC kernel as synchronization master, but without any synchronization slave.
- The channel number and the synchronization request are issued by the synchronization master to the kernels in the same synchronization group if a conversion is requested with **CHCTRx (x = 0 - 15)**.SYNC = 1 in the synchronization master kernel. Synchronization slaves can not issue synchronization requests.
- Once started, a parallel conversion can not be aborted.
- A parallel conversion request is always handled with highest priority and cancel-inject-repeat mode in a synchronization slave (see **Section 31.2.7.2**).
- Bit **GLOBCTR**.ARBM has to be 0 for synchronization slaves.
- The wait-for-read mode is supported for the master kernel, whereas the setting is ignored in the slave kernels (previous results may be overwritten).

The synchronization request issuing mechanism of the master to the slave kernels is based on bit field **GLOBSTR**.ANON. The information given by **GLOBCTR**.ANON is distributed by the synchronization master to all kernels in the conversion group (the bit fields **SYNCTR**.STSEL of all kernels must be programmed in a way that all kernels refer to the same information). In addition to the ANON information, the master delivers the requested channel number to the slave (not explicitly shown in **Figure 31-27**).
The start of the converters of all kernels of a conversion group is based on signals indicating when a kernel is ready and can start the sample phase of a parallel conversion. Bit **SYNCTR**.EVALRx defines if a kernel has to wait for the other kernel(s) (to allow parallel conversions) or can start without waiting (no parallel conversions possible). To support parallel conversions, all ready signals of the kernels of a conversion group have to be considered.

The alias feature is independent of synchronized conversions. All kernels of a conversion group request the same channel number (defined by the master), but can convert analog signals from different inputs. The requested channel number can be redirected by its alias setting. E.g., if the channel number requested in a conversion group is channel CH0, but for a kernel, an alternative reference is connected to this input,

the actually converted analog input can be changed to any value. This can be done by programming bit field ALIAS0 accordingly.

Note: A parallel conversion in a slave ADC should not target a result register that is already used for data reduction of other channels.

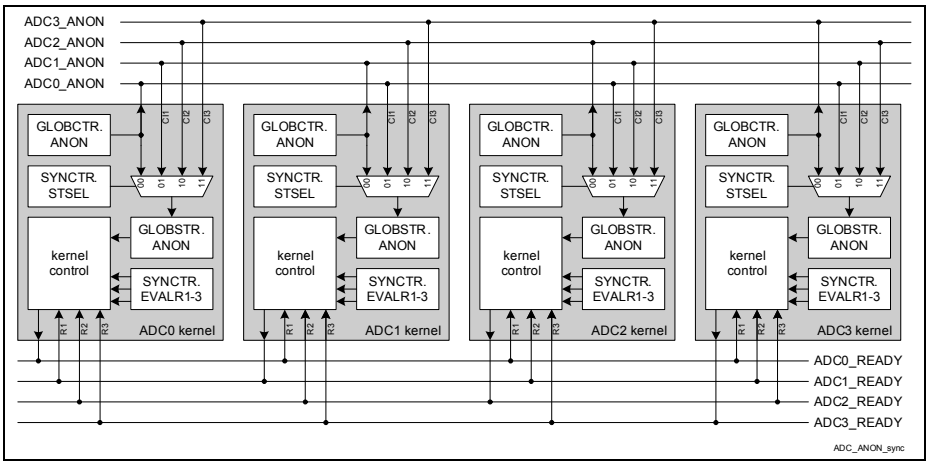

Figure 31-27 Synchronization via ANON and Ready Signals

The connections of the ADCx_ANON and ADCx_READY signals, as well as the programming hints for register EMCTR are described in the implementation chapter, see **Section 31.3**.

31.2.20 Equidistant Sampling

Each ADC kernel supports equidistant sampling of one (or more) analog input channels, e.g. for audio purposes or digital filters.

Therefore, each request source can be programmed to take part in the arbitration round and to win the arbitration (depending on the programmed priority levels), but without starting the conversion immediately. The exact start point of the conversion is given by a control signal (generated outside the ADC module, e.g. by a timer module) that is selected as trigger input REQTRx of request source x. Equidistant sampling is ensured if the REQTRx signal is generated synchronously to the arbiter timing, mainly for the arbiter. Each ADC kernel provides an output ARBCNT, that is activated once per arbitration round to count the arbiter cycles as timing base for the equidistant sampling by a timer located outside the ADC module.

A requested equidistant conversion can start its sampling phase if the converter is idle and the arbiter has decided which channel to convert. To ensure that the converter is idle, the arbiter decides which channel to convert (winner of the arbitration round), but it waits for the timer control signal to really start the measurement (preface time). If the request source selected for equidistant sampling has been programmed with the highest priority, no other request source can disturb the equidistant sampling.

The interpretation of the trigger signal REQTRx for equidistant sampling is enabled by selecting timer mode in the corresponding request source input register (RSIRx.TMEN = 1). The frequency of signal REQTRx defines the sampling rate and its high time defines the length of the preface time interval where the corresponding request source takes part in the arbitration. During the preface time, the currently running conversion can be finished. It has to be programmed to a value allowing the converter to become idle.

If signal ARBCNT is used as counting input signal for a timer, the arbiter has to be programmed to run permanently (GLOBCTR.ARBM = 0). If the timer has an independent time base, the arbiter can be stopped while no requests are pending. The preface time has to be longer than one arbitration round.

Depending on the request source requesting equidistant sampling, one or more channels can be converted one after the other. The order of the requested channels being fixed by the request source, the equidistant sampling is also supported for several channels. It is also possible to do equidistant sampling for more than one request source in parallel if the preface times and the equidistant conversions do not overlap.

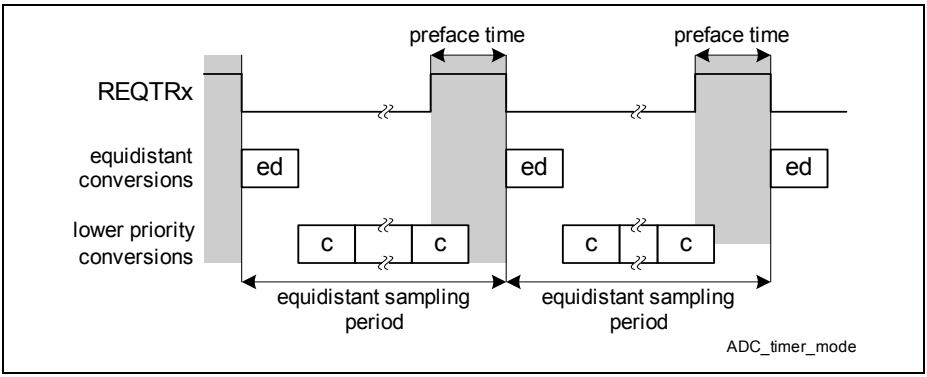

Figure 31-28 Timer Mode for Equidistant Sampling

31.2.21 Access Protection

An access protection scheme has been implemented to avoid unintended modification of some ADC control registers. It can be enabled by bits in register **APR** that itself is protected by the ENDINIT mechanism.
If the access protection is enabled for a group of registers and a write access occurs to one of them, the write access is discarded, the targeted register is not modified, the written data is ignored and the error flag ACCERR is set.
The protected ADC registers are located in one of the following register groups (registers not listed below can not be protected):

- Register group 0:
  GLOBCTR
- Register group 1:
  GLOBCFG, **EMCTR**, **RSIRx (x = 0 - 4)**, **ALR0**
- Register group 2:
  ASENR, **RSPR0**, **RSPR4**, **INPCRx (x = 0 - 3)**, **SYNCTR**
- Register group 3:
  CHCTRx (x = 0 - 15)
- Register group 4:
  RCRx (x = 0 - 15), **VFR**, **LCBR0**, **LCBR1**, **LCBR2**, **LCBR3**
- Register group 5:
  CHENPR0, **CHENPR8**, **EVNPR**, **RNPR0**, **RNPR8**, **INTR**, **CHFR**, **EVFR**

31.2.22 Broken Wire Detection

To support self-test in safety-critical applications, each ADC kernel provides a broken wire detection mechanism to check the connection of sensors or other voltage sources to the analog inputs of the ADC kernels.

This mechanism allows to prepare the capacitor field C_{AIN} before starting the sample phase and the conversion phase. A preparation phase is added to each conversion of an input channel with **BWDENR**.ENx = 1 (the broken wire detection can be individually enabled for each input channel CH0 to CH15).

An analog to digital conversion consists of the following phases:

- **Optional preparation phase:**
  If a channel is enabled for broken wire detection, the capacitor field C_{AIN} is connected to the analog input CHx defined by **BWDCFGR**.CHP before the sample phase starts. The preparation phase length is identical to the sample phase length for this conversion.
  If a channel is disabled for broken wire detection, the preparation phase is omitted (default setting).
- **Sample phase:**
  During this phase, the capacitor field C_{AIN} is connected to one of the analog inputs CHx via an input multiplexer (see **Section 31.1.8.1**). The request sources and the arbiter define which analog input has the highest priority.
- **Conversion phase:**
  During this phase, the capacitor field C_{AIN} is not connected to an analog input and the analog to digital conversion takes place. At the end of this phase, C_{AIN} is loaded to about $V_{AREF}/2$.

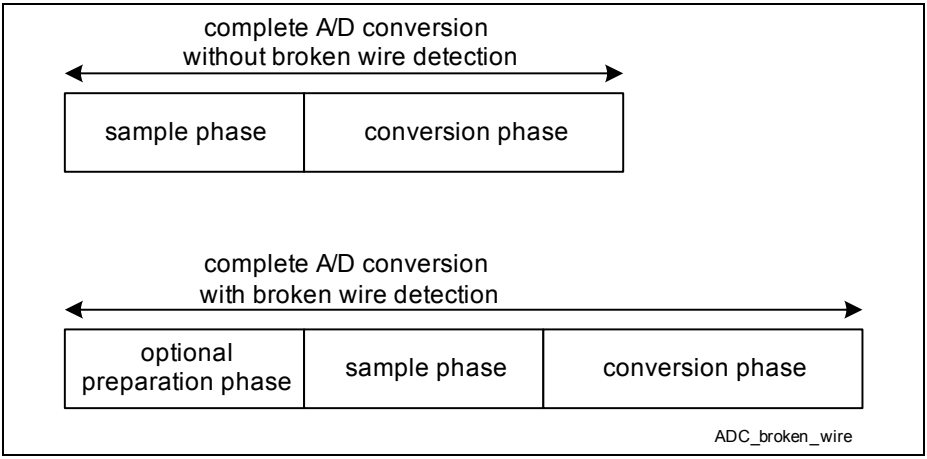

Figure 31-29 Broken Wire Detection

The broken wire detection mechanism allows to apply a voltage outside the expected measurement value range of the connected sensor. If the actual digital conversion result is located outside the expected measurement range (e.g. by using limit checking) with enabled broken wire detection, a defective connection has been detected. It is recommended to ensure enough margin between the voltage applied during the preparation phase and the sensors output range to minimize the effects of parasitics and leakage.

Input channels CH30 (V_{AGND}) and CH31 (V_{AREF}) have been especially introduced to allow the selection of the maximum or the minimum voltage of the measurement range.

Note: The length of the complete analog to digital conversion is increased by the length of the preparation phase if the broken wire detection is enabled. This influences the timing of conversion sequences.

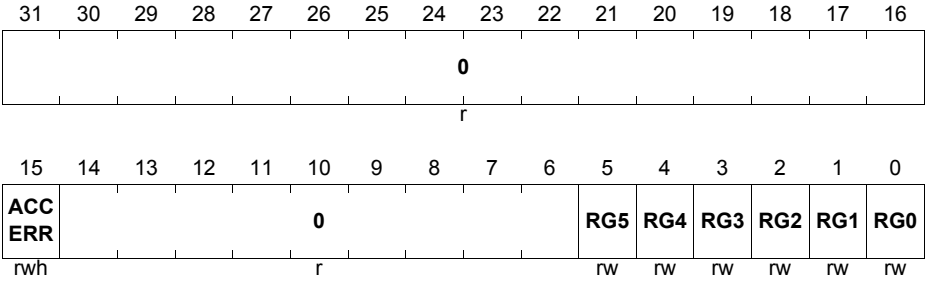
The preparation phase is introduced as additional presample phase (same behavior as the standard sampling phase, but with the possibility to select a different channel number). The analog part provides additional inputs for the channel number to be used during the presample phase and an enable line. The channel number is directly connected to BWDCFGR.CHP, whereas the enable line corresponds to the BWDENR.ENx bit for the arbitration winner CH x. The analog part expects these values at the beginning of the conversion (like all other signals) and automatically handles the insertion of the presample phase (handled like two consecutive sample phases with different channel numbers (but same length) before starting the conversion phase).

31.2.23 Additional Feature Registers

31.2.23.1 Access Protection Register

The access protection register APR contains bits to enable/disable modification of ADC control/configuration registers by write accesses. Register APR itself is protected by the ENDINIT mechanism.

APR
Access Protection Register **(218_H)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
RGx (x = 0 - 5)	x	rw	**Register Group x** This bit enables/disables write accesses to registers of register group x. 0_B Write actions to register group x are enabled and can modify the register contents. 1_B Write actions to register group x are disabled and do not modify the register contents.
ACCERR	15	rwh	**Access Error** This flag indicates a violation of the access protection mechanism for the ADC kernel. It can be cleared by writing 1 to this bit position. Writing 0 has no effect. 0_B A write access to a protected register group has not been detected. 1_B A write access to a protected register group has been detected and discarded.
0	[31:16], [14:6]	r	**Reserved** Read as 0; should be written with 0.

31.2.23.2 External Multiplexer Control

The external multiplexer control register defines the settings of the external analog multiplexer.

EMCTR

External Multiplexer Control Register (220_H) **Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0								EMUXEN	SCANEN	TROEN	0	EMUXCHNR			
r								rw	rw	rw	r	rw			

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
EMSAMPLE								0	EMUX			0	SETEMUX		
rw								r	rh			r	rw		

Field	Bits	Type	Description
SETEMUX	[2:0]	rw	**Setting of External Multiplexer** If the external multiplexer control is disabled, EMUX is loaded with the SETEMUX value. If enabled, the following two options are available: Scan Mode disabled: This bit field defines the input of the external multiplexer that will be selected for the next conversion of the channel selected by EMUXCHNR. Bit field EMUX will be updated by SETEMUX at the beginning of the next conversion of this channel. Scan Mode enabled: This bit field defines the start value of the scan of the external multiplexer inputs. The scan starts with the programmed input down to input 0. Bit field EMUX is updated by SETEMUX at the end of the conversion of this channel if EMUX = 0.

Field	Bits	Type	Description
EMUX	[6:4]	rh	**Current Setting for External Multiplexer** This bit field defines the input of the external multiplexer selected for conversion. Its value is available at the output lines EMUX[2:0]. If the external multiplexer control is disabled, EMUX is loaded with the SETEMUX value. If enabled, the following two options are available: Scan Mode disabled: This bit field becomes updated by SETEMUX at the beginning of the conversion of the channel selected by EMUXCHNR. Scan Mode enabled: This bit field is decremented by 1 at the end of the conversion of the channel selected by EMUXCHNR. After reaching 0, it is reloaded with the value of bit field SETEMUX.
EMSAMPLE	[15:8]	rw	**External Multiplexer Sampling Time** This bit field defines the alternative sample phase length in the case the external multiplexer setting has changed with the start of a conversion with enabled external multiplexer (the value given by the selected input class is not taken into account). A minimum sample phase of 2 analog clock cycles is extended by the programmed value. sample phase length = (2 + EMSAMPLE) / f_{ADCI}
EMUXCHNR	[19:16]	rw	**Channel Number for External Multiplexer** If external multiplexer control is enabled (EMUXEN = 1), this bit field defines the analog ADC input channel connected to the external analog multiplexer.

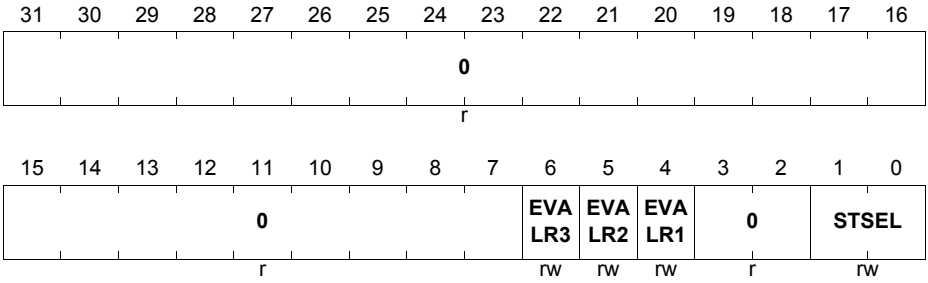
Field	Bits	Type	Description
TROEN	21	rw	**Trigger Option Enable** This bit selects the scan mode behavior of the external multiplexer (if enabled). Description see **Section 31.2.18**. 0_B Single-input scan is selected. The trigger option is disabled (no automatic trigger of more conversions of CHx). 1_B Multi-input scan is selected. The trigger option is enabled leading to an automatic scan through the externally connected multiplexer inputs by automatically triggering additional conversions of CHx until EMUX = 0.
SCANEN	22	rw	**Scan Enable** This bit enables/disables the automatic scan of the inputs of the external multiplexer for conversions of the channel selected by bit field EMUXCHNR (taken into account only if EMUXEN=1). 0_B The scan mode is disabled. Bit field EMUX is updated by bit field SETEMUX at the beginning of a conversion of the selected channel. If bit EMUX is changed, the value of EMSAMPLE is applied. 1_B The scan mode is enabled. Bit field EMUX is decremented by 1 for each conversion of the selected channel. After reaching 0, bit field EMUX is updated by bit field SETEMUX. The value of EMSAMPLE is always applied for the selected channel. It is recommended to write the start value of the first scan sequence to SETEMUX while EMUXEN=0.

Field	Bits	Type	Description
EMUXEN	23	rw	**External Multiplexer Control Enable** This bit enables/disables the automatic control of the external multiplexer. 0_B The external multiplexer control by HW is disabled. Bit field EMUX is immediately updated under SW control by writing to SETEMUX. The settings of SCANEN and TROEN are ignored. 1_B The external multiplexer control is enabled. The update of EMUX is under HW control respecting the conversion timings.
0	3, 7, 20, [31:24]	r	**Reserved** Read as 0; should be written with 0.

31.2.23.3 Synchronization Control Register

The synchronization control register contains bits controlling the synchronization between several kernels for parallel conversions. The programming of register SYNCTR in the kernels of a conversion group has to be done while the bit fields **GLOBCTR**.ANON = 00_B in all ADC kernels of the conversion group. Bit field **GLOBCTR**.ANON of the synchronization master can be set to 11_B afterwards.
The bits EVALRx are only taken into account if a synchronized, parallel conversion is requested by a master. This ensures that the conversions of the ADC kernels of the same synchronization group are started at the same time for parallel sampling (although a kernel might be idle, the master and all its connected slaves have to wait for all of them being ready).

SYNCTR
Synchronization Control Register (048_H) Reset Value: 0000 0000_H



Field	Bits	Type	Description
STSEL	[1:0]	rw	**Start Selection** This bit field controls the synchronization mechanism of the ADC kernel. 00_B The kernel is a synchronization master. The kernels own bit field GLOBCTR.ANON is taken into account. 01_B The kernel is a synchronization slave. The control information at input CI1 is taken into account instead. 10_B The kernel is a synchronization slave. The control information at input CI2 is taken into account instead. 11_B The kernel is a synchronization slave. The control information at input CI3 is taken into account instead.

Field	Bits	Type	Description
EVALR1	4	rw	**Evaluate Ready Input R1** This bit defines if a kernel is considered to be part of a synchronization group. Parallel conversions can only be started if the synchronization master and all slaves of the conversion group indicate that they are ready to start a parallel conversion. 0_B The ready input R1 is not considered for the start of a parallel conversion of this conversion group. 1_B The ready input R1 is considered for the start of a parallel conversion of this conversion group.
EVALR2	5	rw	**Evaluate Ready Input R2** This bit defines if a kernel is considered to be part of a synchronization group. Parallel conversions can only be started if the synchronization master and all slaves of the conversion group indicate that they are ready to start a parallel conversion. 0_B The ready input R2 is not considered for the start of a parallel conversion of this conversion group. 1_B The ready input R2 is considered for the start of a parallel conversion of this conversion group.
EVALR3	6	rw	**Evaluate Ready Input R3** This bit defines if a kernel is considered to be part of a synchronization group. Parallel conversions can only be started if the synchronization master and all slaves of the conversion group indicate that they are ready to start a parallel conversion. 0_B The ready input R3 is not considered for the start of a parallel conversion of this conversion group. 1_B The ready input R3 is considered for the start of a parallel conversion of this conversion group.
0	[3:2], [31:7]	r	**Reserved** Read as 0; should be written with 0.

31.2.23.4 Broken Wire Detection Enable Register

The broken wire detection enable register defines if a channel is enabled for broken wire detection by introducing an additional preparation phase to the sample phase (see **Section 31.2.22**). The channel number refers to the arbitration winner (can be directed to another input by the alias feature).

BWDENR
Broken Wire Detection Enable Register

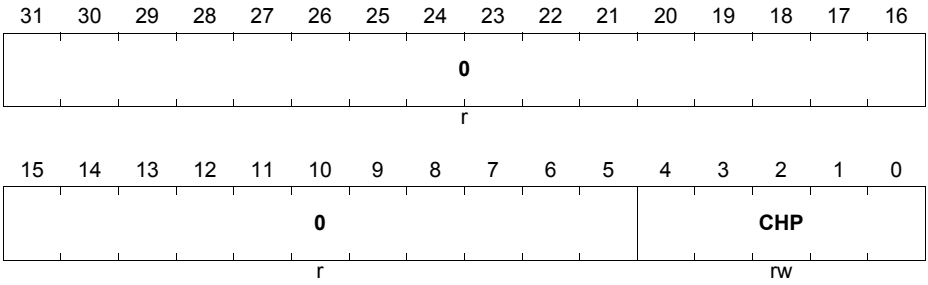
Field	Bits	Type	Description
ENx (x=0-15)	x	rw	**Broken Wire Detection Enable for Channel CHx** This bit defines if the broken wire detection is enabled for CHx. 0_B The broken wire detection is disabled. 1_B The broken wire detection is enabled.
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

31.2.23.5 Broken Wire Detection Configuration Register

The broken wire detection configuration register defines which channel number is used for the additional preparation phase.

BWDCFGR
Broken Wire Detection Configuration Register
(228_H) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
CHP	[4:0]	rw	**Channel Number for Preparation Phase** This bit field defines which input channel is used for the preparation phase for the broken wire detection.
0	[31:5]	r	**Reserved** returns 0 if read; should be written with 0;

31.3 Implementation

This chapter describes the implementation of the ADC kernels in the TC1798 device. It contains the following sections:

- Request sources (see **Section 31.3.1**)
- Address map (see **Section 31.3.2**)
- Result Data Filter (see **Section 31.3.3**)
- Connections to modules and pins (see **Section 31.3.4**)

31.3.1 Request Sources in TC1798

In each ADC kernel 5 request sources are implemented. They are numbered source 0 to source 4, with source x being evaluated in arbitration slot x. Each request source has the possibility to select one trigger input REQTRx out of a vector REQTRx_[7:0] and one gating input REQGTx out of a vector REQGTx_[7:0]. Each input vector contains 8 possible input signals, but not all of them are necessarily connected.

- Source 0: 1-stage sequential source
- Source 1: Parallel source for up to 16 channels
- Source 2: 4-stage sequential source
- Source 3: Parallel source for up to 16 channels
- Source 4: 4-stage sequential source

31.3.2 Address Map

The common KSCFG register of the ADC module can be accessed in the address range of kernel ADC0. The corresponding address in the range of kernel ADC1 to ADC3 is not used and delivers a dummy value when read.
The ADC kernels are available at the following base addresses:

Table 31-4 Registers Address Space

Module	Base Address	End Address	Note
ADC0	$F010\ 1000_H$	$F010\ 13FF_H$	
ADC1	$F010\ 1400_H$	$F010\ 17FF_H$	
ADC2	$F010\ 1800_H$	$F010\ 1BFF_H$	
ADC3	$F010\ 1C00_H$	$F010\ 1FFF_H$	

Table 31-5 Registers Overview

Register Short Name	Register Long Name	Offset Address	Page Number
please refer to register table in Section 31.2.1		H	

31.3.3 Result Data Filter

The implementation of the result data filter as part of the result handling is individual for each ADC kernel. The result register numbers providing a data filter have been chosen in order to allow the maximum number of FIFO stages (e.g. the filtered result of RESR15 can be FIFO-buffered in RESR14).
The result data filter are available at the following ADC kernels:

Table 31-6 Availability of Result Data Filter in the ADC Kernels

ADC Kernel	Number of Data Filter	Result Registers with Data Filter
ADC0	4	RESR3, RESR7, RESR11, RESR15
ADC1	4	RESR3, RESR7, RESR11, RESR15
ADC2	8	RESR1, RESR3, RESR5, RESR7, RESR9, RESR11 RESR13, RESR15
ADC3	0	-

31.3.4 ADC Module Connections

In addition to the standard signals of the interface between the analog and the digital parts, some side band signals have been introduced.
The ADC module consists of four ADC kernels. All kernels support the feature set listed above and share a common ADC0_KSCFG register. The kernels can be synchronized to each other for parallel sampling.

The channels CH4, CH5, CH6, and CH7 of ADC0 and the channels CH0 of all ADC kernels are always converted referring to the V_{AREF} input of the corresponding ADC kernel. For these channels, the programmed alternative reference selection is not taken into account. All other channels are converted with respect to the selected reference.

31.3.4.1 ADC0 Connections

Signals of the ADC module referring to the kernel of ADC0 are generally named with the prefix ADC0_.

The kernel ADC0 has its own reference inputs ADC0_V_{AGND} and ADC0_V_{AREF}. Depending on the package, these lines can be available as independent pins for high pin count packages or can be combined with the corresponding inputs of the other kernels for low pin count packages.
The respective voltage supply lines of all ADC analog parts are connected together.

Table 31-7 ADC0 Connections to Analog Part in TC1798

ADC0 Signal of Analog Part	from/to Module or Pin	Input or Output	Can be used to/as
V_{DDM}	V_{DDM}	I	analog power supply 3.3V - 5V
V_{DDA}	V_{DDMF}	I	analog power supply for comparator, connected to FADC 3.3V supply
V_{SSM}	V_{SSM}	I	analog power ground
V_{AREF}	V_{AREF}	I	positive analog reference
V_{AGND}	V_{AGND}	I	negative analog reference, combined with other kernels
CH0	AN0	I	analog input channel 0
CH1	AN1	I	analog input channel 1
CH2	AN2	I	analog input channel 2
CH3	AN3	I	analog input channel 3
CH4	AN4	I	analog input channel 4

1) In case of input signals, the lines marked "I" don't contain synchronization stages, whereas the lines marked "I (s)" contain synchronization stages (so they can directly handle asynchronous input signals). A signal connected to an input line marked "I"has to be delivered from a block located in the same clock domain as the ADC (the signal has to be synchronous to the ADC clock domain).

31.3.4.5 Service Request Connections

Each ADC kernel provides the service request output lines ADCy_SR[7:0]. The ADC module's service request outputs ADC_SR[11:0] are generated based on these lines according to the following table. If a line ADCy_SRx can be activated by more than one ADC kernel, the corresponding request lines of the ADC kernels are logical OR-combinations of the kernel outputs.
The wiring of the ADC_SRx signals to the DMA channels is given in the DMA chapter.
The signal ADCy_SR7 of each ADC kernel is available as input for the request sources for this kernel. Additionally, ADC0_SR7 is connected to ADC1 inputs, ADC1_SR7 is connected to ADC2 and ADC2_SR7 is connected to ADC3 inputs.
The common signal ADC_SR6 is available as input for the request sources of all kernels.

Table 31-15 ADC Module Service Request Generation

Module Service Request Output	from ADC0 Kernel	from ADC1 Kernel	from ADC2 Kernel	from ADC3 Kernel	Service Request Node
ADC_SR0	ADC0_SR0	ADC1_SR0	-	-	ADC0_SRC0
ADC_SR1	ADC0_SR1	ADC1_SR1	-	-	ADC0_SRC1
ADC_SR2	ADC0_SR2	ADC1_SR2	-	-	ADC0_SRC2
ADC_SR3	ADC0_SR3	ADC1_SR3	-	-	ADC0_SRC3
ADC_SR4	ADC0_SR4	ADC1_SR4	ADC2_SR4	ADC3_SR4	ADC0_SRC4
ADC_SR5	ADC0_SR5	ADC1_SR5	ADC2_SR5	ADC3_SR5	ADC0_SRC5
ADC_SR6	ADC0_SR6	ADC1_SR6	ADC2_SR6	ADC3_SR6	-
ADC_SR7	ADC0_SR7	ADC1_SR7	ADC2_SR7	ADC3_SR7	-
ADC_SR8	-	-	ADC2_SR0	ADC3_SR0	ADC0_SRC6
ADC_SR9	-	-	ADC2_SR1	ADC3_SR1	ADC0_SRC7
ADC_SR10	-	-	ADC2_SR2	ADC3_SR2	ADC0_SRC8
ADC_SR11	-	-	ADC2_SR3	ADC3_SR3	-

31.3.4.6 Kernel Synchronization

The independent ADC kernels of the ADC module can be synchronized to each other by selecting the corresponding connections. The table below shows the setting of the bits in the synchronization control registers in the ADC to allow synchronization. A kernel can operate completely autonomously if it is configured as master ADC. A slave ADC can be synchronized by the selected master ADC.

Note: A master ADC can synchronize several slave ADCs, whereas a slave ADC can only be synchronized by one master ADC.

Table 31-16 SYNCTR Setting for Kernel Synchronization

Operating Mode	SYNCTR. EVALR3	SYNCTR. EVALR2	SYNCTR. EVALR1	SYNCTR. STSEL
ADC0 Kernel (values to be programmed to ADC0_SYNCTR)				
no sync	0	0	0	00_B
master of only ADC1	0	0	1	00_B
master of only ADC2	0	1	0	00_B
master of only ADC3	1	0	0	00_B

32 Fast Analog to Digital Converter (FADC)

The TC1798 contains a fast analog to digital converter (FADC) with differential input channels, thus allowing sampling of high frequency signals. For slow and mid-range frequency signals, an anti-aliasing filter by data reduction is implemented to avoid expensive external filters.

- Functional description of the FADC Kernel (see **Section 32.2**)
- FADC kernel register descriptions (see **Section 32.3**)
- TC1798 implementation-specific details and registers of the FADC module, including on-chip interconnections, service request control, address decoding, and clock control (see **Section 32.4**)

*Note: The FADC Kernel register names described in **Section 32.3** are referenced in the TC1798 User´s Manual by the module name prefix "FADC_" for the FADC interface.*

32.1 FADC Short Description

General Features

- Extreme fast conversion, 21 cycles of f_{FADC} clock (262.5 ns @ f_{FADC} = 80 MHz)
- 10-bit A/D conversion (higher resolution can be achieved by averaging of consecutive conversions in digital data reduction filter)
- Successive approximation conversion method
- Each differential input channel can also be used as single-ended input
- Offset calibration support for each channel
- Programmable gain of 1, 2, 4, or 8 for each channel
- Free-running (Channel Timers) or triggered conversion modes
- Trigger and gating control for external signals
- Built-in Channel Timers for internal triggering
- Channel timer request periods independently selectable for each channel
- Selectable, programmable digital anti-aliasing and data reduction filter block with four independent filter units

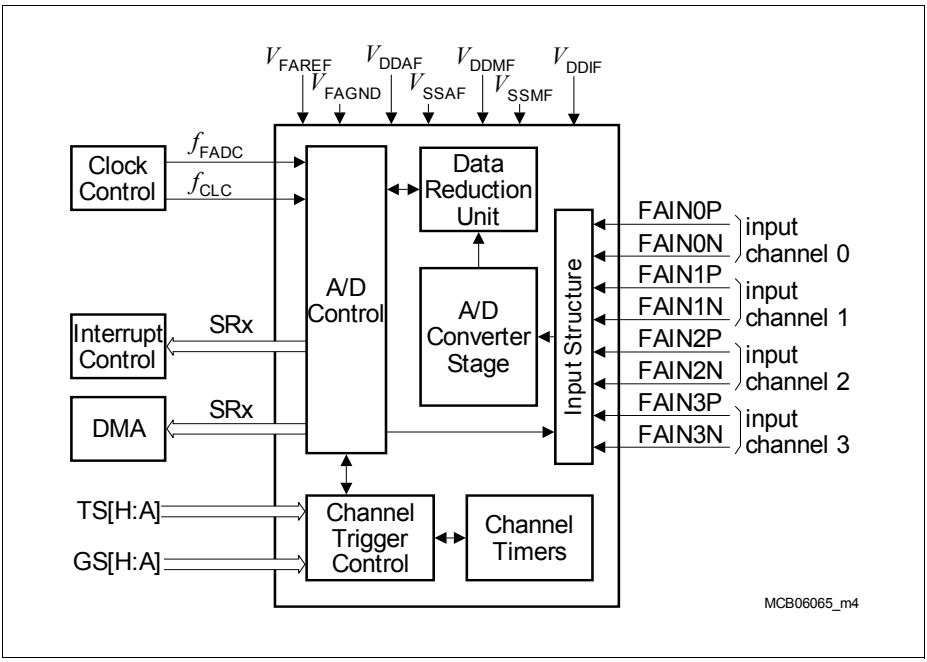

Figure 32-1 Block Diagram of the FADC Module with 4 Input Channels

As shown in **Figure 32-1**, the main FADC functional blocks are:

- An Input Structure containing the differential inputs and impedance control.
- An A/D Converter Stage responsible for the analog-to-digital conversion including an input multiplexer to select between the channel amplifiers
- A Data Reduction Unit containing programmable anti-aliasing and data reduction filters
- A Channel Trigger Control block determining the trigger and gating conditions for the FADC channels
- A Channel Timer for each channel to independently trigger the conversions
- An A/D Control block responsible for the overall FADC functionality

The analog block of the FADC in the TC1798 contains:

- A differential analog input stage for each input channel to select the input impedance (differential or single-ended measurement) and to decouple the FADC input signal from the pins. It is supplied by V_{DDIF} / V_{SSMF} (3.3 V - 5 V).
  The V_{DDIF} supply does not appear as supply pin in the pin list, because it is internally connected to the V_{DDM} supply of the ADC that is sharing the FADC input pins.
- A channel amplifier with a settling time of about 5µs if its configuration is changed by SW (changing between unused, differential, single-ended N, or single-ended P mode). It is supplied by V_{DDMF} / V_{SSMF} (3.3 V) .
- A 10-bit analog converter stage supplied by V_{DDAF} / V_{SSAF} (1.2 V)externally. The inputs for the FADC reference voltage (3.3 V max.) and the FADC reference ground V_{FAREF} / V_{FAGND} are connected to pins.

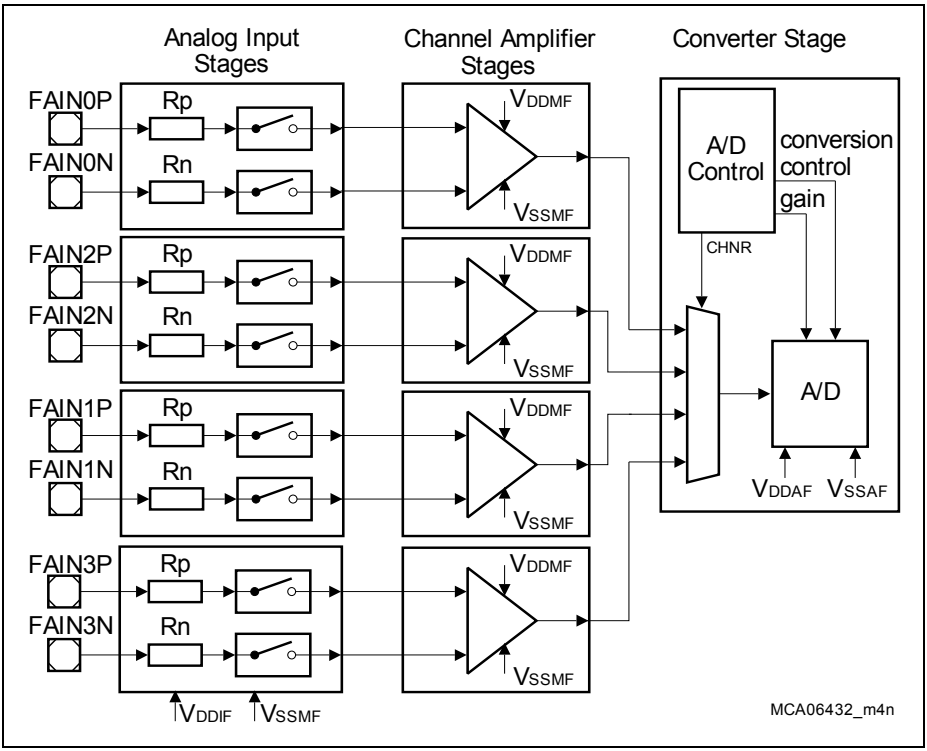

Figure 32-2 FADC Input Structure in TC1798

Note: The analog voltages of the FADC have to be stable and noise-free to ensure a high quality of the conversions.

32.2 FADC Kernel Description

The FADC kernel description covers the following items:

- Analog input stage configurations (see **Section 32.2.1**)
- Conversion timing (see **Section 32.2.3**)
- Channel triggers (see **Section 32.2.4**)
- Channel timers (see **Section 32.2.5**)
- Conversion control (see **Section 32.2.6**)
- Data reduction unit (see **Section 32.2.7**)
- Neighbor channel trigger (see **Section 32.2.8**)
- Offset calibration (see **Section 32.2.9**)
- Interrupt generation (see **Section 32.2.10**)

32.2.1 Analog Input Stage Configurations

The analog input stage makes it possible to control the input impedance by selecting different configurations independently for each FADC channel x. These combinations are shown in **Figure 32-3**.

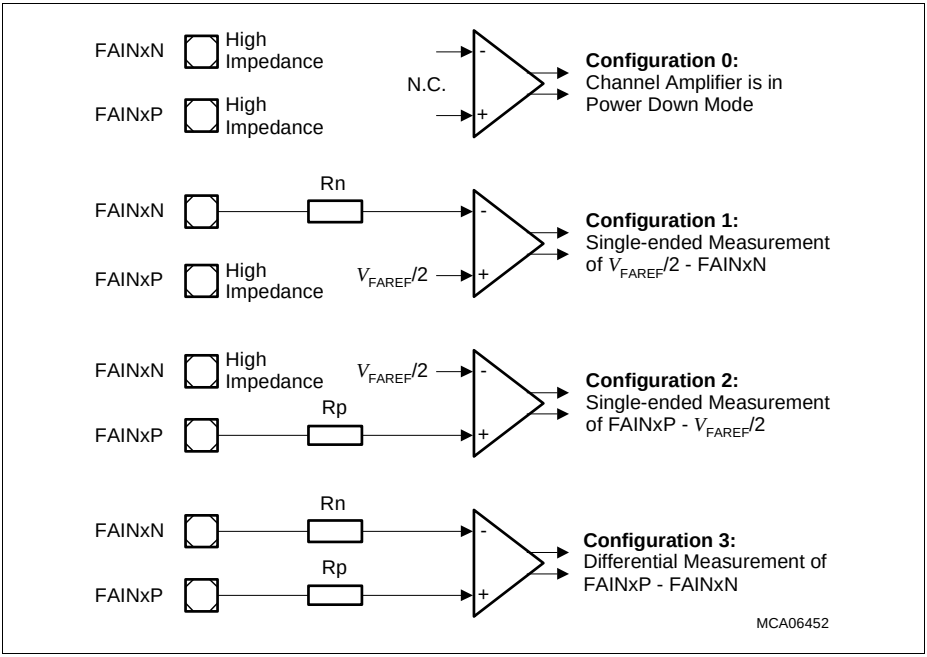

Figure 32-3 Analog Input Stage Configurations

Note: Due to the temperature characteristics of offset and gain of the internal amplifiers a TUE (total unadjusted error) cannot be specified. The input impedance for R_p and R_n is defined in the TC1798 Data Sheet.

Note: The analog input lines of the FADC can also be used as input lines for other ADCs. If both (regular ADC and FADC) are connected to the same pin at the same time, the input impedances of the analog inputs must be taken into account in order to minimize signal distortions and measurement errors.

Configuration 0: Channel Not Used (ACRx.ENP = ACRx.ENN = 0)

FADC channel x inputs FAINxP and FAINxN are in a high impedance state. The channel amplifier of the analog input stage is in power-down mode if both connected input channels are switched off for measurements.

Configuration 1: Single-ended of FAINxN (ACRx.ENP = 0 and ACRx.ENN = 1)

This configuration enables the single-ended measurement mode for $V_{VAREF}/2$ - FAINxN: The positive analog input FAINxP is disconnected is in a high impedance state. The negative analog input FAINxN is connected to the channel amplifier (input impedance is determined by R_n). The positive input of the channel amplifier is connected to $V_{FAREF}/2$ (1.65 V with V_{FAREF} = 3.3 V). If the voltage at the negative input FAINxN varies, the FADC will deliver conversion results as follows (gain = 1 selected by ACRx.GAIN = 00_B):

- FAINxN = 0 V: FADC conversion result is 768
- FAINxN = 3.3 V: FADC conversion result is 256

To cover the full range of the measurement result in this single-ended measurement mode, a gain of 2 must be selected (ACRx.GAIN = 01_B). With gain = 2, the FADC will deliver conversion results as follows:

- FAINxN = 0 V: FADC conversion result is 1023
- FAINxN = 3.3 V: FADC conversion result is 0

The voltage at the disconnected positive analog input FAINxP has no influence on the conversion result.

Configuration 2: Single-ended of FAINxP (ACRx.ENP = 1 and ACRx.ENN = 0)

This configuration enables the single-ended measurement mode for FAINxP - $V_{VAREF}/2$. The negative analog input FAINxN is disconnected and in a high impedance state. The positive analog input FAINxP is connected to the channel amplifier (input impedance is determined by R_p). The negative input of the channel amplifier is connected to $V_{FAREF}/2$ (1.65 V with V_{FAREF} = 3.3 V). If the voltage at the positive input FAINxP varies, the FADC will deliver conversion results as follows (gain = 1 selected by ACRx.GAIN = 00_B):

- FAINxP = 0 V: FADC conversion result is 256
- FAINxP = 3.3 V: FADC conversion result is 768

To cover the full range of the measurement result in this single-ended measurement mode, a gain of 2 must be selected (ACRx.GAIN = 01_B). With gain = 2, the FADC will deliver conversion results as follows:

- FAINxP = 0 V: FADC conversion result is 0
- FAINxP = 3.3 V: FADC conversion result is 1023

The voltage at the disconnected negative analog input FAINxN has no influence on the conversion result.

Configuration 3: Differential Measurement (ACRx.ENP = ACRx.ENN = 1)

This configuration enables the differential measurement mode for FAINxP - FAINxN. Both analog inputs, FAINx.N and FAINxP, are connected to the channel amplifier inputs. Their impedances are determined by R_n and R_p. The full measurement range is available.

32.2.2 Result Representation

The conversion result for FADC channel x is given by the following equations:

$$\text{Conversion Result } V_{Mx} = \text{GAIN}_x \times ((V_{FAINxP} - V_{FAREFM}) + (V_{FAREFM} - V_{FAINxN})) \quad (32.1)$$

$$\text{with } V_{FAREFM} = V_{FAGND} + (V_{FAREF} - V_{FAGND})/2$$

The absolute value of the result V_{Mx} is limited to V_{FAREF}. The mapping of the conversion result V_{Mx} to the result RCHx.ADRES is as follows:

$V_{Mx} = -V_{FAREF}$	leads to RCHx.ADRES = 0
$V_{Mx} = 0$	leads to RCHx.ADRES = 512
$V_{Mx} = +V_{FAREF}$	leads to RCHx.ADRES = 1023

For single-ended measurements, the following values are taken into account:

- if ENP_x = 0 then $V_{FAINxP} = V_{FAREFM}$
- if ENN_x = 0 then $V_{FAINxN} = V_{FAREFM}$

Note: In Multiplexer Test Mode (GCR.MUXTM = 1), the channel amplifiers are disconnected from the converter stage. The measured conversion result in multiplexer test mode is 512 plus/minus the offset of the converter stage.

32.2.3 Conversion Timing

The conversion time of the FADC is determined by the frequency of clock f_{FADC}. The conversion time including sampling, converting, and storing of the conversion result takes 21 periods of f_{FADC}.

32.2.4 Channel Triggers

As shown **Figure 32-4**, the trigger behavior of an FADC channel x is determined by its channel x trigger control logic. An FADC channel x can be triggered by three trigger sources:

- External trigger source input signal, selectable from an input vector TS[H:A]
- Internal channel x timer trigger signal
- Internal neighbor channel trigger signal

If one of these trigger sources is selected, becomes active, and the gating logic is programmed to enable trigger signals (signal ECHTIMx set), the conversion request flag CRFx becomes set indicating a valid request for FADC channel x.
The gating source input and gating mode selection logic generate an enable signal for channel x timer that determines whether any of the three conversion trigger signal sources is allowed to set the channel x conversion request flag CRFx. It can select an input signal from the input vector GS[H:A].
The control logic does the following tasks, independently in each of the FADC channels:

- Gating source input selection (CFGRx.GSEL)
- Gating mode selection (CFGRx.GM)
- Trigger source input selection (CFGRx.TSEL)
- Trigger mode selection (CFGRx.TM)
- Channel timer request generation
- Conversion request flag set/clear

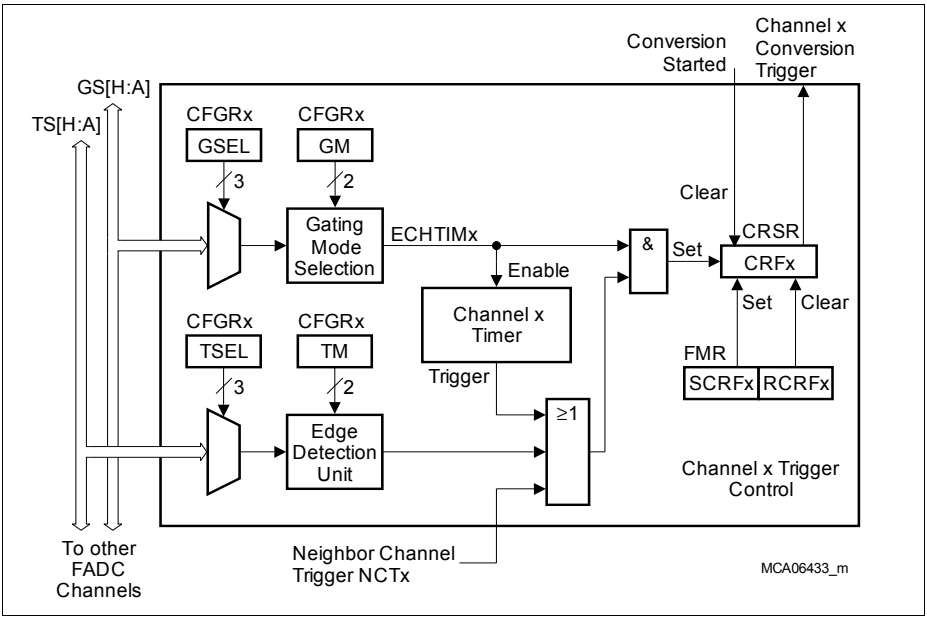

Figure 32-4 Channel Trigger Control Logic

Table 32-1 describes the possible gating modes (enabled, disabled, active gating source input polarity) of an FADC channel.

Table 32-1 Gating Modes

CFGRx.GM	Gating Mode
00_B	Conversion requests are disabled and Channel Timer is stopped. Bit CRSR.CRFx never becomes set (by hardware).
01_B	Conversion requests and Channel Timer are always enabled. Bit CRSR.CRFx becomes set by hardware with each active trigger signal.
10_B	When gating source input GSn = 1 (as selected by CFGRx.GSEL), the Channel Timer is enabled and the conversion request bit CRSR.CRFx becomes set by hardware with each active trigger signal.
11_B	When gating source input GSn = 0 (as selected by CFGRx.GSEL), the Channel Timer is enabled and the conversion request bit CRSR.CRFx becomes set by hardware with each active trigger signal.

An edge detection unit determines which edge of the trigger source input signal (as selected by CFGRx.TSEL) is generating a conversion request trigger signal. Rising, falling or both edges can be selected for trigger signal generation.

Table 32-2 Trigger Modes

CFGRx.TM	Trigger Mode
00_B	No trigger signal generated.
01_B	A conversion request trigger signal is generated on a rising edge of trigger source input TSn (selected by CFGRx.TSEL).
10_B	A conversion request trigger signal is generated on a falling edge of trigger source input TSn (selected by CFGRx.TSEL).
11_B	A conversion request trigger signal is generated on a rising or falling edge of trigger source input TSn (selected by CFGRx.TSEL).

The Conversion Request Flag CRSR.CRFx is cleared by hardware when the conversion of channel x is started. Bit CRFx can be also set or cleared by software via bits in the Flag Modification Register FMR. Writing a 1 to FMR.SCRF sets CRFx. Writing a 1 to FMR.RCRF clears CRFx (independently of FMR.SCRF).

32.2.5 Channel Timer

Each of the FADC channels contains an 8-bit Channel Timer that can be used to generate periodic conversion requests. The Channel Timer is built up by a decrementing counter that is reloaded with a programmable value. When the Channel Timer reaches zero while running, a Channel Timer trigger event is generated and the Channel Timer is reloaded with the reload value CFGRx.CTREL when the requested conversion is started. With the start of the A/D conversion, request bit CRSR.CRFx is cleared. Note that the request flag is set by a timer trigger event only if the gating condition is met (signal ECHTIMx in **Figure 32-4** set).

A clock divider, fed by the module clock f_{FADC} and common for all Channel Timers, generates several clock signals with different periods. Bit field CFGRx.CTF selects whether or not the channel x timer clock f_{CTx} is enabled and, if enabled, determines the frequency of channel x timer input clock f_{CTx}.

While the Channel Timer is disabled (CFGRx.CTM = 00_B) or if the gating condition is not met (gating line ECHTIMx delivers 0), the channel x timer value is set to 04_H. This value ensures a fast conversion trigger after the gating becomes enabled, but prevents unintended conversion starts in case of short pulses (bouncing) at the gating input.

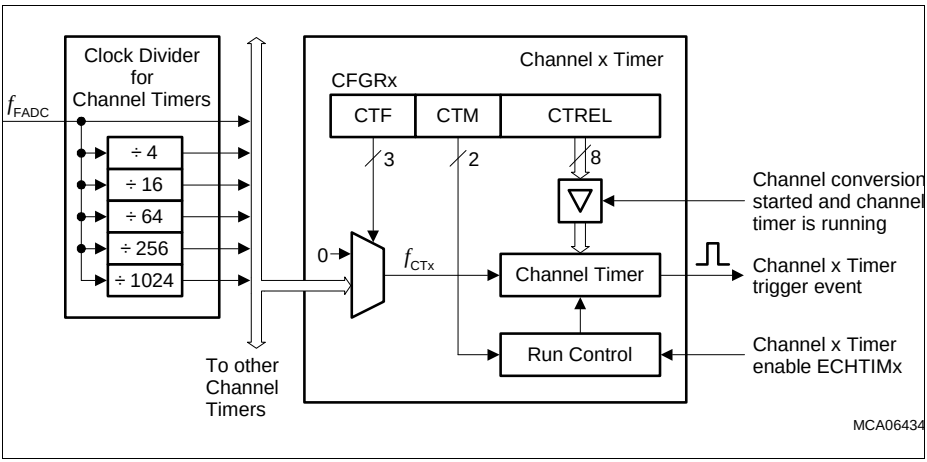

Figure 32-5 Channel Timer Block Diagram

Due to the common divider, the first event at the trigger output of CHTIMx after the start has a maximum jitter of one clock cycle of the selected channel x timer clock f_{CTx}.

A Channel x Timer input clock pulse at f_{CTx} is ignored if it occurs in the f_{FADC} clock cycle directly after the Channel x Timer has reached 0. If there is at least one f_{FADC} clock cycle between two Channel x Timer input clock pulses, all Channel x Timer input clock pulses

are taken into account. This leads to a Channel x Timer reload value (CFGRx.CTREL) whose definition depends on the ratio of f_{FADC} / f_{CTx}:

$f_{FADC} / f_{CTx} = 1$	Channel x timer divide factor = CTREL + 2
$1 < f_{FADC} / f_{CTx} < 2$	Not recommended to be used!
$2 \leq f_{FADC} / f_{CTx}$	Channel x timer divide factor = CTREL + 1

In case of a f_{FADC} / f_{CTx} ratio between 1 and 2, a mixture of both divide factor definitions occurs depending on the divider ratio as programmed by the fractional divider value. Therefore, it is recommended that this ratio should not be used.

32.2.6 Conversion Control

A conversion is started when at least one of the CRSR.CRFx bits is set. A running conversion cannot be aborted and is indicated by the busy flag CRSR.BSYx set. The corresponding bit CRSR.CRFx is reset by hardware when the conversion starts.

32.2.6.1 Static Channel Priority

If more than one conversion request flag CRSR.CRFx (x = 0-3) is set, the channels are converted according to a priority scheme as defined by the bit field GCR.CRPRIO (without respecting the status of the current filter sequences).

Table 32-3 Static Channel Request Priority

Priority	GCR.CRPRIO			
	00_B	01_B	10_B	11_B
High	Channel 0	Channel 1	Channel 2	Channel 3
	Channel 1	Channel 2	Channel 3	Channel 0
	Channel 2	Channel 3	Channel 0	Channel 1
Low	Channel 3	Channel 0	Channel 1	Channel 2

32.2.6.2 Dynamic Priority Assignment

If dynamic priority assignment is enabled (GCR.DPAEN = 1), a channel that has the only active gate signal (signal ECHTIMx in **Figure 32-4**) among the four channels gets the highest priority (GCR.CRPRIO is set to the number of the channel). If more than one channel gating signal is active, GCR.CRPRIO is not changed automatically. In this case, it can be changed by software.

32.2.6.3 Clock Generation

The FADC module is provided with two clock signals: f_{CLC} and f_{FADC}. Clock f_{CLC} is used inside the FADC kernel for control purposes such as clocking of control logic, register operations, trigger detection, or filter calculation.
The clock rate of f_{FADC} is programmable. It is used inside the FADC kernel for the Channel Timers and other internal timings.

32.2.6.4 Suspend Mode Behavior

When a suspend/idle mode request is generated for the FADC module via the fractional divider, a currently running conversion is completely finished (not aborted) and, if selected, a filter calculation still takes place. Thereafter, no new conversion will be started and the state of the FADC module is frozen until the suspend/idle mode request is released again. If enabled, the related interrupts are signaled.
If suspend mode is needed, it is recommended to use to the suspend control by the fractional divider and not by the CLC register.

32.2.6.5 Alias Feature

The alias feature is mainly meant for emulation purposes and does not need to be used in standard applications. It allows a reassignment of the channel to be converted with respect to the channel number that has been requested for conversion. This feature can be used to redirect conversion requests to other input channels without changing the request SW. For example, a SW from TC1766 (with only the two input channels 0 and 1), can be adapted to either channels 0 and 1 (compatibility to older products) or to channels 2 and 3 instead. Especially when emulating several different devices with a common emulation chip, the channel reassignment allows compatible SW usage with different channel wiring to pins.

The setting of the input stages (incl. calibration information) is defined by register ACRx of the input channel that is requested (no alias-mapping). I.e. the ACRx register of the actually converted channel is used as it is permanently conntected to its channel. The result handling (incl. interrupts) also refers to the requested channel number. The alias feature is only taken into account as channel number for the conversion start.

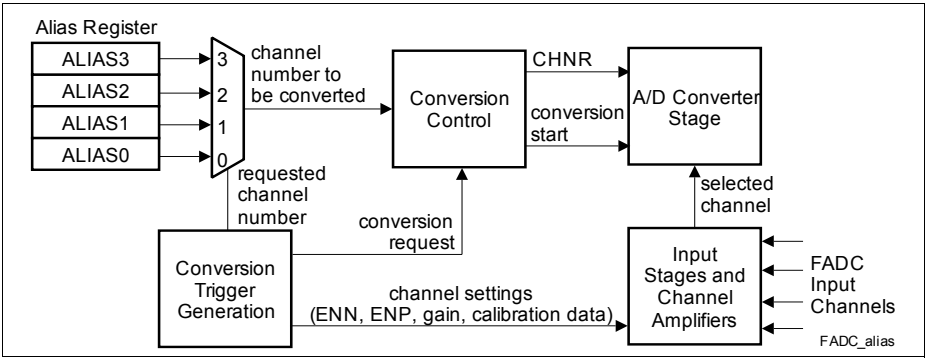

Figure 32-6 Alias Feature

32.2.7 Data Reduction Unit

A Data Reduction Unit is implemented in the FADC that operates as anti-aliasing filter. This unit allows the number of conversion data requests that are issued to the CPU or other bus masters to be reduced by adding multiple conversion results according to a certain algorithm and presenting it to the CPU or other bus masters with a reduced conversion request rate.

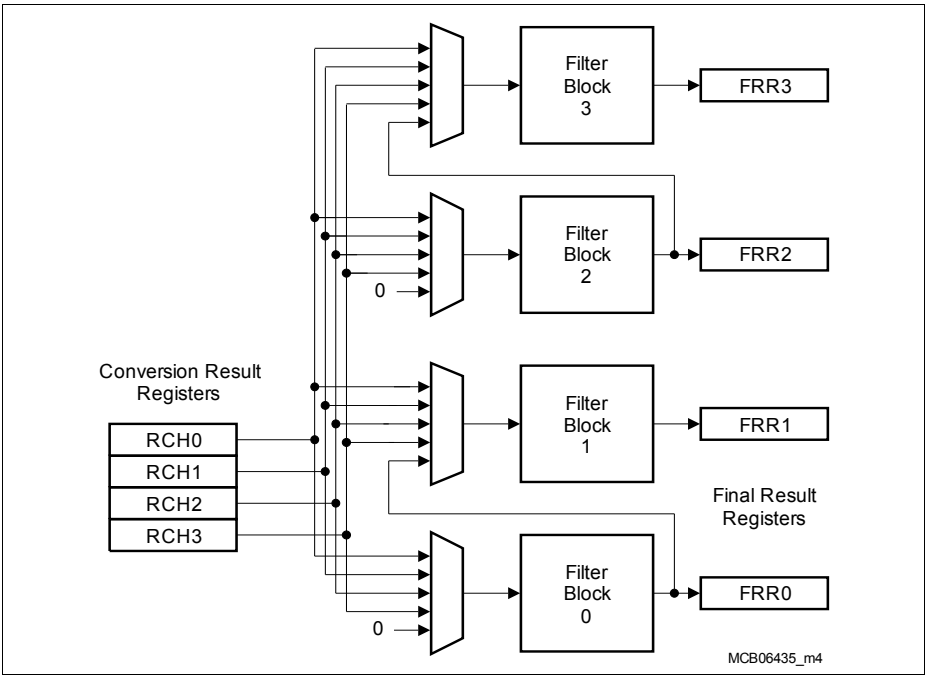

Figure 32-7 TC1798 FADC Filter Blocks

The Data Reduction Unit contains four filter blocks. Each filter block allows selection of its input data source. The input data sources are the conversion result registers of the four A/D converter channels.

Filter blocks can also be concatenated (block 0 and block 1 can be concatenated, same for block 2 and block 3). When the result of a filter operation is stored in one of the final result registers, a service request can be generated. Each filter block basically contains adder logic and intermediate storage registers that allow support for typical digital filter operations such as moving average calculations with intermediate results.

32.2.7.1 Filter Block Structure

The filter block consists of an adder and several result registers for calculating filter output data from the filter input data. For filter n, the Current Result Register CRRn is used for adding up conversion results. After a programmable number of conversion results have been added, the contents of CRRn are stored as intermediate result in the Intermediate Result Register IRR1n. The three intermediate result registers operate like a pipeline. Before IRR1n is overwritten, IRR2n is transferred to IRR3n, and IRR1n is transferred to IRR2n. The Final Result Register FRRn stores the sum that is built by the contents of the current result register and the intermediate result registers.

All result registers of the filter block can be read at any time. Please note that only one intermediate result register is available in filter block 1 (IRR11) and in filter block 3 (IRR13).

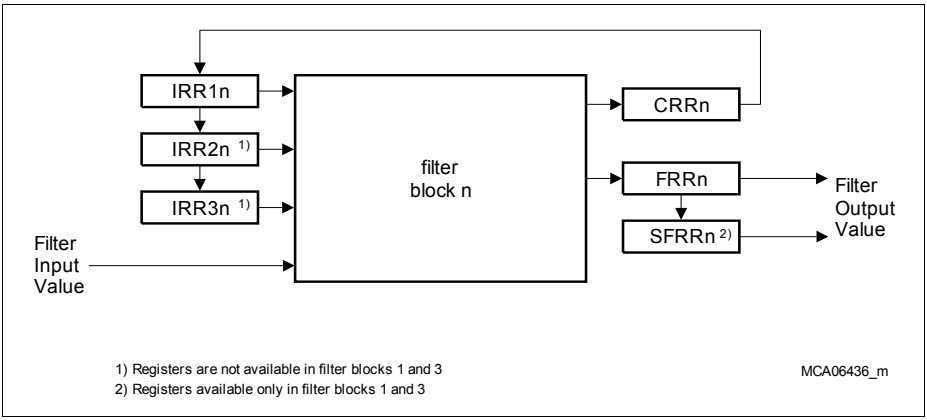

Figure 32-8 Filter Block Structure

32.2.7.2 Filter Block Operation

A filter block can be used for data-reduction or anti-aliasing filtering of the conversion results (n indicates the number of the filter block). It performs a combination of data reduction by adding and a moving average operation.

- A continuous A/D conversion is running on channel x.
- The filter input selection is set to channel x (FCRn.INSEL = 100_B + x).
- The addition length is controlled by FCRn.ADDL defining how many conversion results are added to build one intermediate result (intermediate cycle).

- The moving average length is controlled by FCRn.MAVL defining how many intermediate results are taken into account for a moving average to build the final result (final result cycle).

Intermediate Result Calculation

Each incoming conversion result is added to the content of CRRn until the programmed number of conversion results have been summed up in CRRn. At that point, CRRn contains a new intermediate result and the calculation of the next final result value by moving average is started. Then CRRn is cleared automatically after the final result cycle to be prepared for the first conversion result for the next intermediate cycle.
Before the filter operation of continuous conversion results of channel x is started, the filter block n has to be cleared (writing GCR.RSTFn = 1) after programming the filter control bit fields.

Final Result Calculation

The calculation of a final result is started when an intermediate cycle has been finished. The new intermediate result (stored in CRRn) and the contents of the intermediate registers IRRnx are added to build the final result in FRRn. The number of intermediate results taking part in the moving average operation to build the final result is programmable, the maximum is given by:

- Filter block 0: FRR0 := CRR0 + IRR10 + IRR20 + IRR30
- Filter block 1: FRR1 := CRR1 + IRR11
- Filter block 2: FRR2 := CRR2 + IRR12 + IRR22 + IRR32
- Filter block 3: FRR3 := CRR3 + IRR13

At the end of the final result cycle, the contents of IRR2n are transferred into IRR3n, then the contents of IRR1n into IRR2n, then the contents of CRRn into IRR10 (for filter blocks 0 and 2). The former contents of IRR3n are lost.
Bit field FCRn.MAVL determines the number of intermediate results that are used for the final result calculation. For filter blocks 1 and 3, only two bit combinations are valid and the intermediate result registers IRR2n and 3n are not available and handled as if they were 0.

Each update of a result register FRRn with a new final result value generates a filter block n service request.

32.2.7.3 Filter Concatenation

Filter block 1 and 3 allow filter concatenation to support more filter stages. Filter 1 can be programmed to use the result value of filter 0, similar for filter blocks 2 and 3.

Filter blocks 0 and 2 operate with the following parameters:

- Intermediate results are calculated based on the conversion results of one of the input channels (FCRn.INSEL = $1XX_B$).

- An intermediate cycle can contain a maximum of 8 conversion results.
- A final result cycle can contain a maximum of 4 intermediate results.

Filter blocks 1 and 3 operate with the following parameters:

- Intermediate results are based on the final results of filter block 0 (for filter block 1) and of filter block 2 (for filter block 3). Filter block concatenation is enabled by FCRn.INSEL = 010_B.
- An intermediate cycle can contain a maximum of 8 conversion results.
- A final result cycle can contain a maximum of 2 intermediate results.

32.2.7.4 Width of Result Registers

The additions executed in filter 0 and filter 1 together with the possible maximum values of the filter parameters determine the width of the current, intermediate, and final result registers (same for filter blocks 2 and 3).

In addition to the final result registers FRR1 and FRR3 with 20 bit width, another view is available that is shifted by 5 bit positions to the right, given by registers SFRR1 and SFRR3. This allows a representation of the data within a 16 bit word for further digital data handling.

Table 32-4 Data Width of Result Registers

Register Long Name	Register Short Name	Result Width
Filter 0 Current Result Register	CRR0	13-bit
Filter 0 Intermediate Result Register 1	IRR10	
Filter 0 Intermediate Result Register 2	IRR20	
Filter 0 Intermediate Result Register 3	IRR30	
Filter 0 Final Result Register	FRR0	15-bit
Filter 1 Current Result Register	CRR1	18-bit
Filter 1 Intermediate Result Register 1	IRR11	
Filter 1 Final Result Register	FRR1	20-bit
Filter 1 Shifted Final Result Register	SFRR1	15-bit
Filter 2 Current Result Register	CRR2	13-bit
Filter 2 Intermediate Result Register 1	IRR12	
Filter 2 Intermediate Result Register 2	IRR22	
Filter 2 Intermediate Result Register 3	IRR32	
Filter 2 Final Result Register	FRR2	15-bit
Filter 3 Current Result Register	CRR3	18-bit
Filter 3 Intermediate Result Register 1	IRR13	
Filter 3 Final Result Register	FRR3	20-bit
Filter 3 Shifted Final Result Register	SFRR3	15-bit

32.2.8 Neighbor Channel Trigger

The neighbor channel trigger feature allows the concatenation of channel conversions. This means that the start of a conversion for one channel can generate multiple channel trigger requests for the other three channels. A channel conversion request flag of a neighbor channel becomes only set by a neighbor channel trigger request if the gating condition (gating mode selection output at high level in **Figure 32-4**) in the corresponding neighbor channel is valid.

All neighbor channel trigger enable bits ENxy are located in the Neighbor Channel Trigger Register NCTR. Index “x” indicates the number of the channel that starts a neighbor channel trigger. Index “y” is the number of the neighbor channel to be triggered.

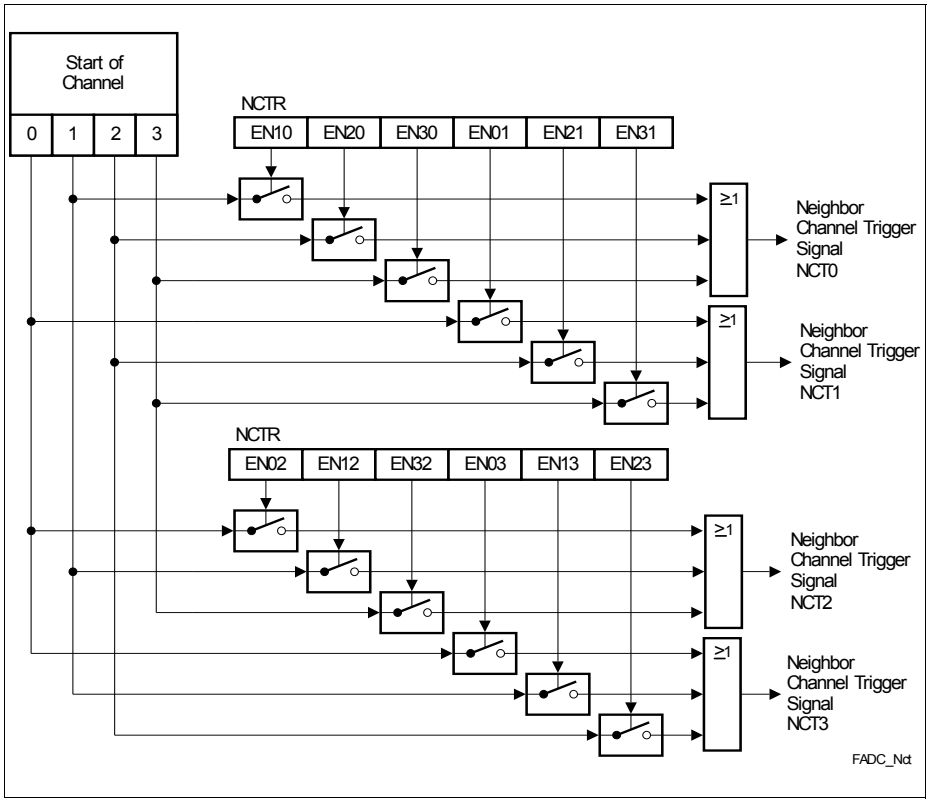

Figure 32-9 Neighbor Channel Trigger

32.2.9 Calibration

The calibration is used to minimize the error of the FADC conversion results independently for each channel. The output of each channel amplifier can be adjusted to deliver a minimum offset value for zero input voltage difference. The channel which is calibrated is selected by GCR.CALCH. The calibration mode is selected by GCR.CALMODE. During the calibration process of a channel, the other channels can be used in normal conversion mode without restrictions.

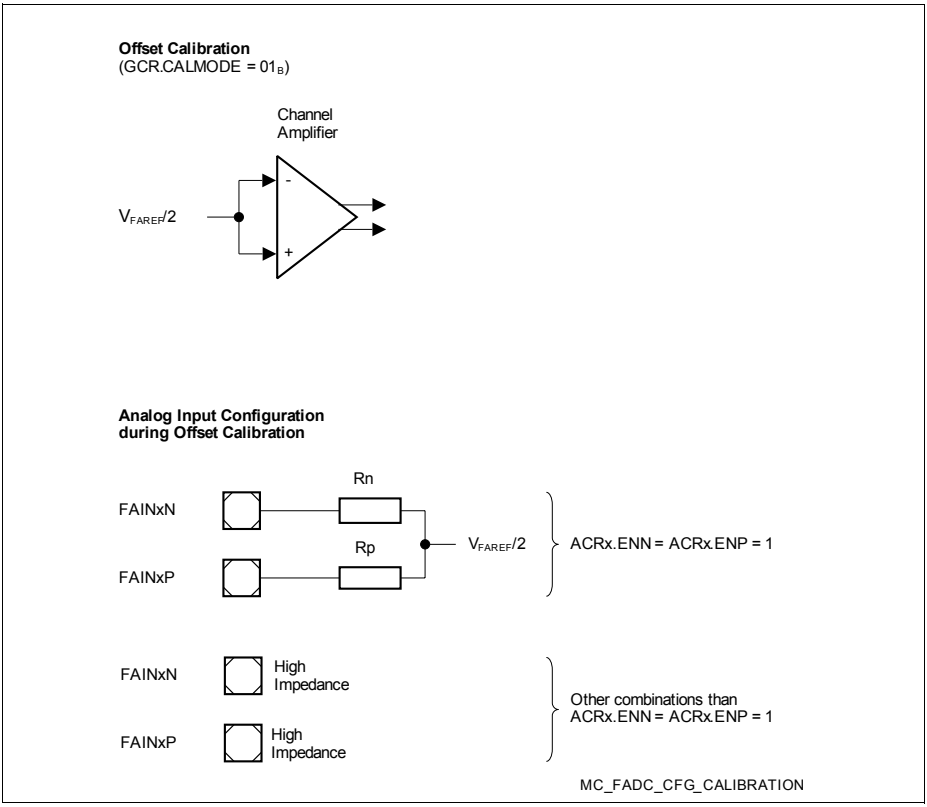

Figure 32-10 Analog Input and Channel Amplifier Configuration at Calibration

Figure 32-10 shows the channel amplifier configuration as well as the analog input pin configurations that are selected during offset and gain calibration. Note that in the calibration modes, the impedance of the analog inputs depends on the settings of the ENN and ENP bits of the corresponding Channel x Analog Control Register ACRx.

32.2.9.1 Offset Calibration

When offset calibration is selected (GCR.CALMODE = 01_B), the channel amplifier inputs of the selected channel are both connected to $V_{FAREF}/2$. After enabling a channel amplifier for offset calibration, a delay of minimum 5 µs must be respected before starting a conversion for this channel. The conversion result must be compared by software with the tolerated offset value (a conversion result with zero offset is equal to 512). If the conversion result exceeds the tolerated range, bit field ACRx.CALOFF (with x specifying the calibrated channel) can be adjusted and a new conversion can be started. The calibration process is finished when the conversion result is in the tolerated offset range. After switching back to normal mode for channel x, a delay of minimum 5 µs must be respected before starting a new conversion for this channel.

32.2.10 Interrupt Generation

A flexible service request control structure is implemented in the FADC. The FADC provides the channel conversion request sources and the filter block request sources, that can be programmed to generate one of four service request output signals SR[3:0]. The service request compressor also makes it possible to assign more than one service request source to one service request output.

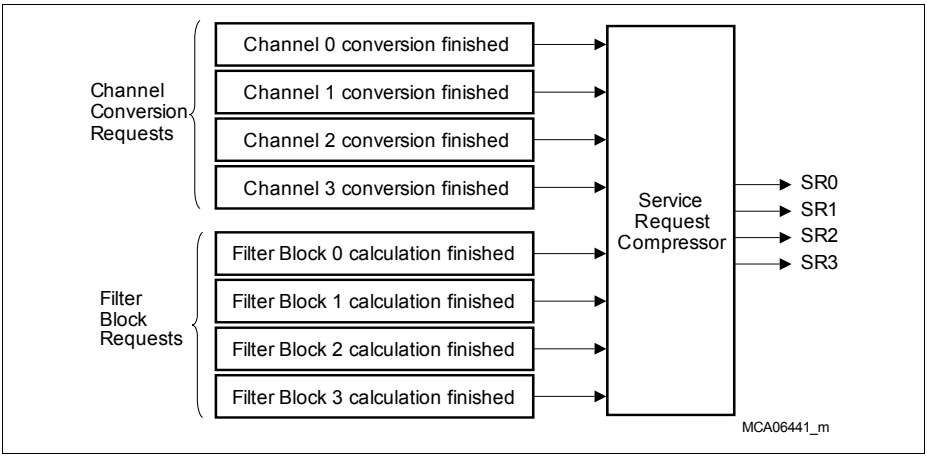

Figure 32-11 Service Request Configuration

All service requests are controlled by an identical control logic. This control logic as shown in **Figure 32-12** provides the following functionality:

- Service Request Flag
- Set/Clear Request Flag Control Bits
- Service Request Enable Bit
- Service Request Node Pointer

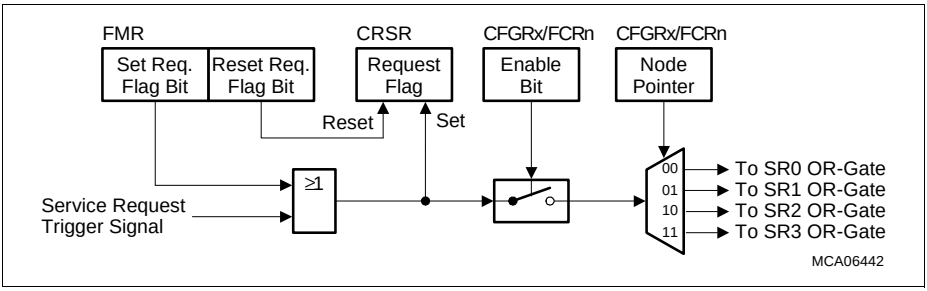

Figure 32-12 Service Request Control Logic

The request flag is always set by hardware when the corresponding request event occurs. It can also be set or cleared by software when writing a 1 to the corresponding set/clear request flag bit in the Flag Modification Register FMR. Finally, a service request event is directed to one of the four service request output lines SR[3:0] when the corresponding service request enable bit IEN is set. The service request node pointer determines which of the service request output lines SR[3:0] becomes activated.

Table 32-5 lists the six service request sources of the FADC Module with its related control and status flags/bits.

Table 32-5 Service Request Control/Status Bits/Flags

Service Request Source	Request Flag	Enable Bit	Set Request Bit / Clear Request Bit	Service Request Node Pointer
Channel x Conversion Request (x = 0-3)	CRSR.IRQx	CFGRx.IEN	FMR.SIRQx / FMR.RIRQx	CFGRx.INP
Filter Block n Request (n = 0-3)	CRSR.IRQFn	FCRn.IEN	FMR.SIRQFn / FMR.RIRQFn	FCRn.INP

In the service request compressor logic shown in **Figure 32-13**, the inputs of one SRx OR-gate are connected to all demultiplexer outputs with identical INP node pointer value. Therefore, one service request event can be only assigned to one of the four service request outputs, but one service request output can be used by multiple service request events.

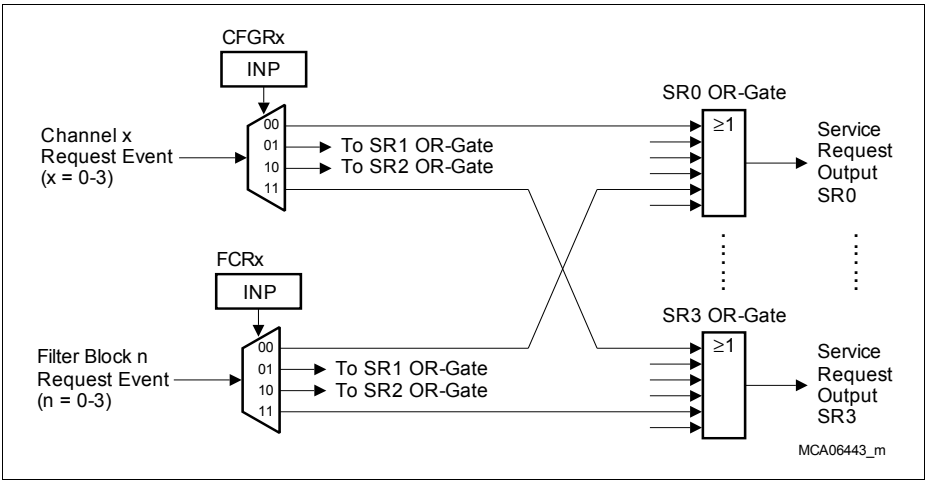

Figure 32-13 Service Request Compressor Logic

Depending on the implementation of the FADC Module in a specific micro controller, the service request output signals SR[3:0] can either be connected to an interrupt node (controlled by a service request control register) or can be used as DMA request input of a DMA controller unit. The TC1798 specific request output connections are described in the FADC implementation chapter.

32.3 FADC Register Description

This section describes the kernel registers of the FADC module. All FADC kernel register names described in this section will be referenced in other parts of the TC1798 User´s Manual by the module name prefix “FADC_”.

All registers can accessed with 8-bit, 16-bit, or 32-bit read or write operations.

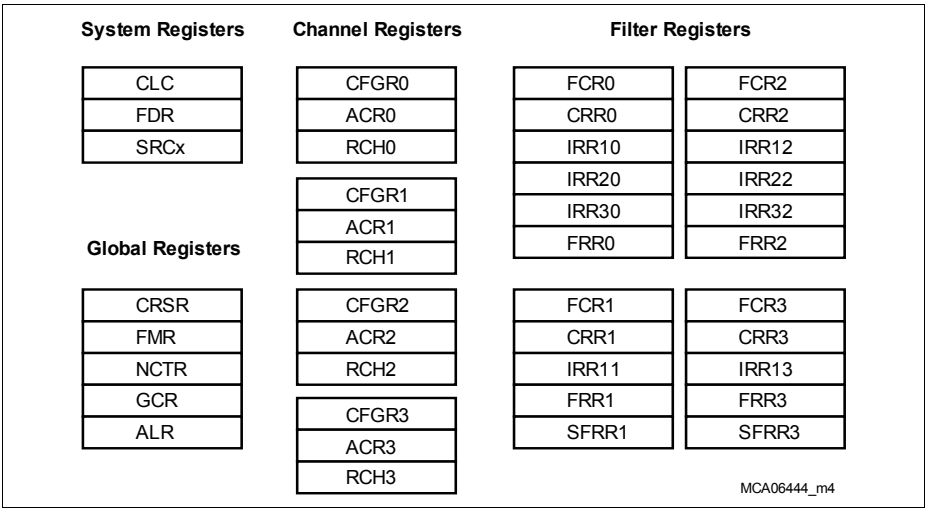

Figure 32-14 FADC Kernel Registers

Access rights within the address range of an FADC kernel:

- Read access to defined register addresses: U, SV
- Write access to defined register addresses: U, SV
- Accesses to empty addresses: reserved, BE

1) The absolute register address is calculated as follows:
Module Base Address + Offset Address (shown in this column)

32.3.1 System Registers

32.3.1.1 Clock Control Register

The Clock Control Register allows the programmer to control (enable/disable) the clock signal f_{CLC} under certain conditions. After a reset operation, the FADC module is disabled and its module clock signal f_{CLC} is switched off.

CLC
Clock Control Register (000_H) Reset Value: 0000 0003$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

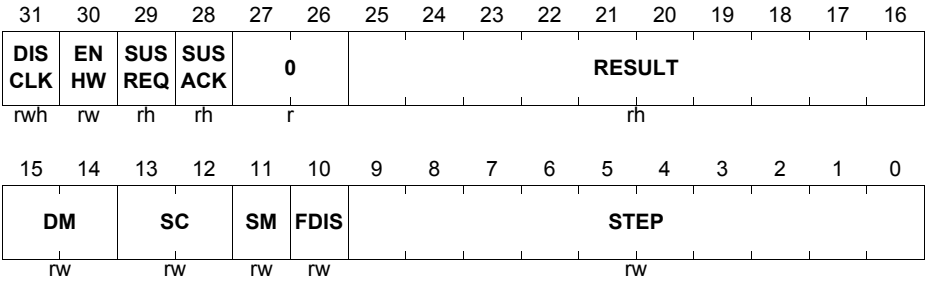
0										FSOE	SBWE	EDIS	SPEN	DISS	DISR

Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module.
DISS	1	r	**Module Disable Status Bit** Bit indicates the current status of the module.
SPEN	2	rw	**Module Suspend Enable for OCDS** Used to enable the suspend mode.
EDIS	3	rw	**Sleep Mode Enable Control** Used to control module's sleep mode.
SBWE	4	w	**Module Suspend Bit Write Enable for OCDS** Determines whether SPEN and FSOE are write-protected.
FSOE	5	rw	**Fast Switch Off Enable** Used for fast clock switch off in Suspend Mode.
0	[31:6]	r	**Reserved** Read as 0. Should be written with 0.

32.3.1.2 Fractional Divider Register

The Fractional Divider Register allows the programmer to control the clock rate of the module clock f_{FADC}.

FDR
Fractional Divider Register **($00C_H$)** **Reset Value: $0000\ 0000_H$**



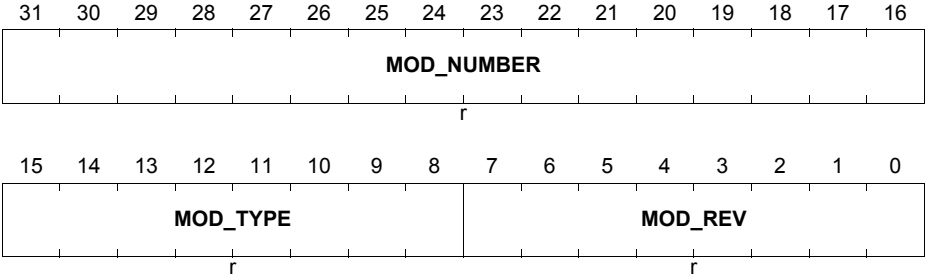
Field	Bits	Type	Description
STEP	[9:0]	rw	**Step Value** Reload or addition value for RESULT.
FDIS	10	rw	**Freeze Disable** This bit controls the freeze function for this module. 0_B Module operates on corrected clock, with reduced modulation jitter 1_B Module operates on uncorrected clock with full modulation jitter
SM	11	rw	**Suspend Mode** SM selects between granted or immediate suspend mode.
SC	[13:12]	rw	**Suspend Control** This bit field determines the behavior of the fractional divider in suspend mode.
DM	[15:14]	rw	**Divider Mode** This bit field selects normal divider mode, fractional divider mode, and off-state.
RESULT	[25:16]	rh	**Result Value** Bit field for the addition result.
SUSACK	28	rh	**Suspend Mode Acknowledge** Indicates state of SPNDACK signal.

Field	Bits	Type	Description
SUSREQ	29	rh	**Suspend Mode Request** Indicates state of SPND signal.
ENHW	30	rw	**Enable Hardware Clock Control** Controls operation of ECEN input and DISCLK bit. Should be always written with 0.
DISCLK	31	rwh	**Disable Clock** Hardware controlled disable for f_{FADC} signal.
0	10, [27:26]	r	**Reserved** Read as 0. Should be written with 0.

32.3.1.3 Module Identification Register

The register table can be found on **Page 32-26**.

ID
Module Identification Register **(008_H)** **Reset Value: $0027\ C000_H$**



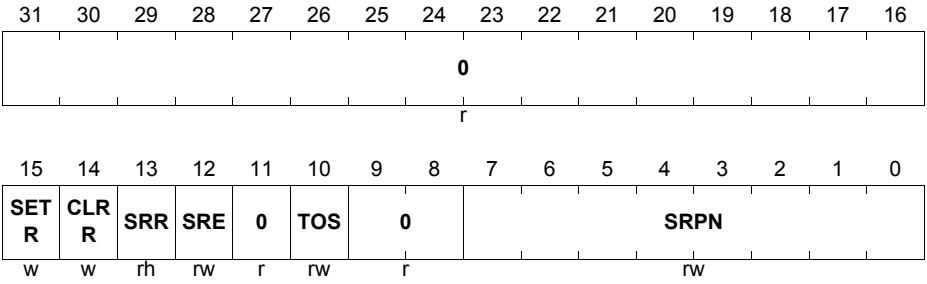
Field	Bits	Type	Description
MOD_REV	[7:0]	r	**Module Revision** This bit field indicates the revision number of the module implementation (depending on the design step). The given value of 00_H is a placeholder for the actual number. Bits [3:0] refer to the version of the digital part and bits [7:4] indicate the version of the analog part (anid).
MOD_TYPE	[15:8]	r	**Module Type**
MOD_NUMBER	[31:16]	r	**Module Number**

32.3.1.4 Service Request Control Registers

Each of the interrupts of the FADC is controlled by a service request control register.

SRCx (x = 0-3)
Service Request Control Register x

($0FC_H$ - x*4_H) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
SRPN	[7:0]	rw	**Service Request Priority Number**
TOS	10	rw	**Type of Service Control**
SRE	12	rw	**Service Request Enable**
SRR	13	rh	**Service Request Flag**
CLRR	14	w	**Request Clear Bit**
SETR	15	w	**Request Set Bit**
0	[9:8], 11, [31:16]	r	**Reserved** Read as 0. Should be written with 0.

32.3.2 Global Registers

32.3.2.1 Conversion Request Status Register

The Conversion Request Status Register CRSR contains the flags for monitoring the state of pending conversions and the interrupt request flags.

CRSR
Conversion Request Status Register (010_H) **Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0								IRQF3	IRQF2	IRQF1	IRQF0	IRQ3	IRQ2	IRQ1	IRQ0
r								rh	rh	rh	rh	rh	rh	rh	rh

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0				BSY3	BSY2	BSY1	BSY0	0				CRF3	CRF2	CRF1	CRF0
r				rh	rh	rh	rh	r				rh	rh	rh	rh

Field	Bits	Type	Description
CRFx (x = 0-3)	x	rh	**Conversion Request Flag** This bit monitors whether a conversion request is pending for channel x. CRFx is set by hardware when a trigger event is detected while the gating condition delivers 1. CRFx is automatically cleared by hardware when a conversion of the channel x is started. 0_B A conversion of channel x has not been requested. 1_B A conversion of channel x has been requested. Bits CRFx can be set/cleared by software via bits FMR.RCRFx and FMR.SCRFx. If a set and a clear condition for CRFx occur simultaneously (generated by hardware and/or software), the clear condition always wins.

Field	Bits	Type	Description
BSYx (x = 0-3)	8 + x	rh	**Busy Flag** This bit indicates if a conversion is currently running for channel x. 0_B A conversion is not running. 1_B A conversion is running.
IRQx (x = 0-3)	16 + x	rh	**Interrupt Request Flag** This bit indicates that a conversion of channel x has been finished since it has been cleared by software. Interrupt requests can also be generated while IRQx is still set. An interrupt can only be generated when CFGRx.IEN = 1. 0_B A conversion has not been finished. 1_B A conversion has been finished. Bits IRQx can be set/cleared by software via bits FMR.SIRQx and FMR.RIRQx.
IRQFn (n = 0-3)	20 + n	rh	**Interrupt Request Flag for Filter n** This bit indicates that a filter sequence of filter n has been finished (new final result is available) since it has been cleared by software. Interrupt requests can also be generated while IRQ is still set. An interrupt can only be generated when FCRn.IEN = 1. 0_B A filter sequence has not been finished. 1_B A filter sequence has been finished. Bits IRQFn can be set/cleared by software via bits FMR.SIRQFn and FMR.RIRQFn.
0	[7:4], [15:12], 24[31:24]	r	**Reserved** Read as 0. Should be written with 0.

32.3.2.2 Flag Modification Register

The bits of the Flag Modification Register FMR allow the flags of the conversion request status register to be set/cleared by software.
If a clear and set request are issued at the same time, the target flag is cleared. It is recommended to avoid writing both bit positions (for set and for clear) of the same target bit with 1 within the same write operation.

FMR
Flag Modification Register **(014_H)** **Reset Value: 0000 0000$_H$**

0				EN13	EN12	0	EN10	0				EN03	EN02	EN01	0
r							rw	r						rw	r

Field	Bits	Type	Description
EN01	1	rw	**Enable Neighbor Channel Trigger 01** This bit enables the neighbor channel trigger for channel 1 when a conversion of channel 0 is started. 0_B No action. 1_B A trigger will be generated.
EN02	2	rw	**Enable Neighbor Channel Trigger 02** This bit enables the neighbor channel trigger for channel 2 when a conversion of channel 0 is started. 0_B No action. 1_B A trigger will be generated.
EN03	3	rw	**Enable Neighbor Channel Trigger 03** This bit enables the neighbor channel trigger for channel 3 when a conversion of channel 0 is started. 0_B No action. 1_B A trigger will be generated.
EN10	8	rw	**Enable Neighbor Channel Trigger 10** This bit enables the neighbor channel trigger for channel 0 when a conversion of channel 1 is started. 0_B No action. 1_B A trigger will be generated.

Field	Bits	Type	Description
EN12	10	rw	**Enable Neighbor Channel Trigger 12** This bit enables the neighbor channel trigger for channel 2 when a conversion of channel 1 is started. 0_B No action. 1_B A trigger will be generated.
EN13	11	rw	**Enable Neighbor Channel Trigger 13** This bit enables the neighbor channel trigger for channel 3 when a conversion of channel 1 is started. 0_B No action. 1_B A trigger will be generated.
EN20	16	rw	**Enable Neighbor Channel Trigger 20** This bit enables the neighbor channel trigger for channel 0 when a conversion of channel 2 is started. 0_B No action. 1_B A trigger will be generated.
EN21	17	rw	**Enable Neighbor Channel Trigger 21** This bit enables the neighbor channel trigger for channel 1 when a conversion of channel 2 is started. 0_B No action. 1_B A trigger will be generated.
EN23	19	rw	**Enable Neighbor Channel Trigger 23** This bit enables the neighbor channel trigger for channel 3 when a conversion of channel 2 is started. 0_B No action. 1_B A trigger will be generated.
EN30	24	rw	**Enable Neighbor Channel Trigger 30** This bit enables the neighbor channel trigger for channel 0 when a conversion of channel 3 is started. 0_B No action. 1_B A trigger will be generated.
EN31	25	rw	**Enable Neighbor Channel Trigger 31** This bit enables the neighbor channel trigger for channel 1 when a conversion of channel 3 is started. 0_B No action. 1_B A trigger will be generated.

Field	Bits	Type	Description
EN32	26	rw	**Enable Neighbor Channel Trigger 32** This bit enables the neighbor channel trigger for channel 2 when a conversion of channel 3 is started. 0_B No action. 1_B A trigger will be generated.
0	0, [7:4], 9, [15:12], 18, [23:20], [31:27]	r	**Reserved** Read as 0. Should be written with 0.

Note: The hardware does not check whether the enable bits are set in such a way as to describe a loop of conversion requests (e.g. 0 triggers 2, 2 triggers 3 and 3 triggers 0, etc.). It is in the responsibility of the user to set these bits in an appropriate way.

32.3.2.4 Global Control Register

The Global Control Register GCR contains bits used to reset the Channel Timers, the filters and to control global FADC settings.

GCR
Global Control Register **($01C_H$)** **Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0				CALCH		CALMODE		0		ANON	MUXTM	RESWEN	DPAEN	CRPRIO	
r				rw		rw		r		rw	rw	rw	rw	rwh	

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0			RSTF3	RSTF2	RSTF1	RSTF0	RCD	0				RCT3	RCT2	RCT1	RCT0
r			w	w	w	w	w	r				w	w	w	w

Field	Bits	Type	Description
RCTx (x = 0-3)	x	w	**Reload Channel Timer** 0_B Channel x Timer will not be changed. 1_B Channel x Timer will be loaded with its reload value.
RCD	8	w	**Reset Common Divider** 0_B The common divider will not be changed. 1_B The common divider will be cleared.
RSTFn (n = 0-3)	9 + n	w	**Reset Filter n** 0_B The contents of filter n will not be changed. 1_B The contents of filter n will be cleared. The values of the bits in the filter registers will be cleared, except bit field CRRn.AC that is loaded with the value of FCRn.ADDL.

Field	Bits	Type	Description
CRPRIO	[17:16]	rwh	**Conversion Request Priority** This bit field determines the priority of the conversion requests if more than one channel is requested. If the dynamic priority assignment is enabled, the priority is automatically changed as a function of the gating inputs. The priority of the channels is: 00_B Channel 0 before channel 1 before channel 2 before channel 3 01_B Channel 1 before channel 2 before channel 3 before channel 0 10_B Channel 2 before channel 3 before channel 0 before channel 1 11_B Channel 3 before channel 0 before channel 1 before channel 2
DPAEN	18	rw	**Dynamic Priority Assignment Enable** If the dynamic priority assignment is enabled, the priority bit field CRPRIO is automatically changed as a function of the gating input signals. In this case, the channel that is active while the other three channels are not active gets the highest priority. 0_B The dynamic priority assignment is disabled. 1_B The dynamic priority assignment is enabled.
RESWEN	19	rw	**Result Write Enable** This bit enables a write action to the result registers RCHx (x = 0-3) of the FADC. 0_B Write accesses to the result registers are not taken into account. The written data is discarded. 1_B Write accesses to the result registers are taken into account. The former value of the written result register is overwritten by the write data. If a filter is sensitive to the written result register, the written value is taken as new filter input value.

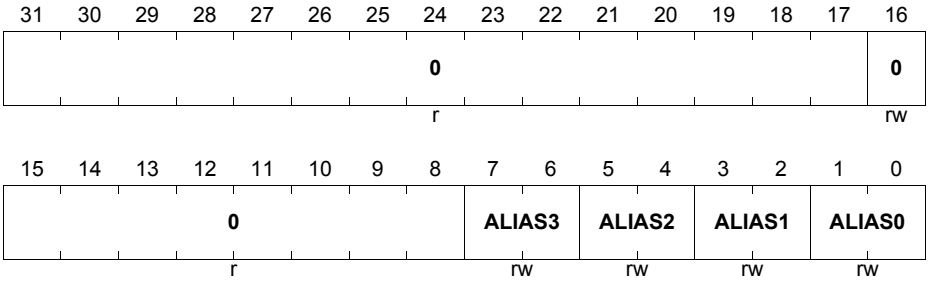
Field	Bits	Type	Description
MUXTM	20	rw	**Multiplexer Test Mode** The input multiplexer to select a channel for the conversion can be tested by opening all multiplexer inputs. In multiplexer test mode, the channel amplifiers are not connected to the converter stage. 0_B The multiplexer test mode is disabled. 1_B The multiplexer test mode is enabled.
ANON	21	rw	**Analog Part ON** This bit enables the analog part of the FADC. This bit must be set to convert the analog input signal to a digital value. 0_B The complete analog part is in power-down mode, the amplifiers and comparators are switched off. Conversions are not possible. 1_B The analog part is enabled.
CALMODE	[25:24]	rw	**Calibration Mode** This bit field enables the calibration for offset and gain for the channel selected by CALCH. 00_B No calibration process is running. All channels are in normal mode (default after reset). 01_B The analog channel selected by CALCH is in offset calibration mode. The other channels are in normal mode. 10_B Reserved 11_B Reserved
CALCH	[27:26]	rw	**Calibration Channel** This bit field selects the channel for the calibration process determined by CALMODE. The setting of CALCH is only taken into account while a calibration process is running. 00_B The analog input channel 0 is selected for a calibration process. 01_B The analog input channel 1 is selected for a calibration process. 10_B The analog input channel 2 is selected for a calibration process. 11_B The analog input channel 3 is selected for a calibration process.

Field	Bits	Type	Description
0	[7:4], [15:13], [23:22], [31:28]	r	**Reserved** Read as 0. Should be written with 0.

32.3.2.5 Alias Register

The Alias Register contains bit fields allowing a re-assignment of the requested channel number to the actually converted channel.

ALR
Alias Register **(054_H)** **Reset Value: 0000 00E4$_H$**



Field	Bits	Type	Description
ALIAS0	[1:0]	rw	**Alias of Channel 0** This bit field defines which channel is converted if a trigger for channel 0 occurs. 00_B Channel 0 will be converted (default). 01_B Channel 1 will be converted. 10_B Channel 2 will be converted. 11_B Channel 3 will be converted.
ALIAS1	[3:2]	rw	**Alias of Channel 1** This bit field defines which channel is converted if a trigger for channel 1 occurs. 00_B Channel 0 will be converted. 01_B Channel 1 will be converted (default). 10_B Channel 2 will be converted. 11_B Channel 3 will be converted.
ALIAS2	[5:4]	rw	**Alias of Channel 2** This bit field defines which channel is converted if a trigger for channel 2 occurs. 00_B Channel 0 will be converted. 01_B Channel 1 will be converted. 10_B Channel 2 will be converted (default). 11_B Channel 3 will be converted.

Field	Bits	Type	Description
ALIAS3	[7:6]	rw	**Alias of Channel 3** This bit field defines which channel is converted if a trigger for channel 3 occurs. 00_B Channel 0 will be converted. 01_B Channel 1 will be converted. 10_B Channel 2 will be converted. 11_B Channel 3 will be converted (default).
0	16	rw	**Placeholder Bit** This bit position is a placeholder for further extensions and should be written with 0.
0	[31:17], [15:8]	r	**Reserved** Read as 0. Should be written with 0.

32.3.3 Channel Registers

32.3.3.1 Channel Configuration Registers

The Channel x Configuration Register CFGRx contains the bits for the selection of the trigger source, the gating source, and other channel settings of channel x.

CFGRx (x = 0-3)
Channel x Configuration Register (020_H+x*4_H) **Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	CTF			CTM		TM		GM		TSEL			GSEL		
r	rw			rw		rw		rw		rw			rw		

Field	Bits	Type	Description
GSEL	[2:0]	rw	**Gating Selection** This bit field selects the gating source input signal for channel x. 000_B Gating source input signal GSA selected 001_B Gating source input signal GSB selected 010_B Gating source input signal GSC selected 011_B Gating source input signal GSD selected 100_B Gating source input signal GSE selected 101_B Gating source input signal GSF selected 110_B Gating source input signal GSG selected 111_B Gating source input signal GSH selected

Field	Bits	Type	Description
TSEL	[5:3]	rw	**Trigger Selection** This bit field selects the trigger source input signal for channel x. 000_B Trigger source input signal TSA selected 001_B Trigger source input signal TSB selected 010_B Trigger source input signal TSC selected 011_B Trigger source input signal TSD selected 100_B Trigger source input signal TSE selected 101_B Trigger source input signal TSF selected 110_B Trigger source input signal TSG selected 111_B Trigger source input signal TSH selected
GM	[7:6]	rw	**Gating Mode** This bit field determines the functionality of the gating (enable) signal. It determines whether and under which condition the generation of conversion requests by trigger signals is possible. 00_B Conversion requests are disabled and the Channel Timer is stopped. CRFx never becomes set (by hardware). 01_B Conversion requests and the Channel Timer are always enabled. CRFx becomes set by hardware with each active trigger signal. 10_B Conversion requests and the Channel Timer are enabled only if the gating source input (as selected by CFGRx.GSEL) is at high level. 11_B Conversion requests and the Channel Timer are enabled only if the gating source input (as selected by CFGRx.GSEL) is at low level.

Field	Bits	Type	Description
TM	[9:8]	rw	**Trigger Mode** This bit field enables the triggering and determines the edge of the trigger source input signal that generates a conversion trigger signal. 00_B No conversion trigger signals are generated. Edge detection unit is switched off. 01_B A conversion request is generated (if gating enabled) on a rising edge of a trigger source input (as selected by CFGRx.TSEL). 10_B A conversion request is generated (if gating enabled) on a falling edge of a trigger source input (as selected by CFGRx.TSEL). 11_B A conversion request is generated (if gating enabled) on both, rising and falling, edges of a trigger source input (as selected by CFGRx.TSEL).
CTM	[11:10]	rw	**Channel Timer Mode** This bit determines the operating mode of channel x timer. 00_B Channel x timer is switched off. 01_B Channel timer is permanently running. 10_B Channel timer is running only if ECHTIMx = 1. 11_B Reserved A Channel Timer trigger event is generated each time the channel x timer value reaches 00_H. While the Channel Timer is not running (CTM = 00_B or signal ECHTIMx = 0), the Channel Timer is loaded with 04_H.
CTF	[14:12]	rw	**Channel Timer Frequency** This bit field controls the channel x timer input clock f_{CT} (enable control and frequency selection). 000_B f_{CTx} is disabled. 001_B f_{CTx} is enabled with frequency f_{FADC}. 010_B f_{CTx} is enabled with frequency f_{FADC} / 4. 011_B f_{CTx} is enabled with frequency f_{FADC} / 16. 100_B f_{CTx} is enabled with frequency f_{FADC} / 64. 101_B f_{CTx} is enabled with frequency f_{FADC} / 256. 110_B f_{CTx} is enabled with frequency f_{FADC} / 1024. 111_B Reserved; do not use this combination.

Field	Bits	Type	Description
CTREL	[23:16]	rw	**Channel Timer Reload Value** This bit field determines the reload value of the Channel Timer CHTIMx, see **Section 32.2.5**. If CTREL = 0, no trigger event is generated.
INP	[29:28]	rw	**Interrupt Node Pointer** This bit field selects which service request output line will be activated when a conversion of channel x is finished while CFGRx.IEN is set. 00_B Service request output SR0 is selected. 01_B Service request output SR1 is selected. 10_B Service request output SR2 is selected. 11_B Service request output SR3 is selected.
IEN	31	rw	**Interrupt Enable** This bit enables the generation of a service request when a conversion of channel x is finished. 0_B Channel x conversion service request generation is disabled. 1_B Channel x conversion service request generation is enabled.
0	15, [27:24], 30	r	**Reserved** Read as 0. Should be written with 0.

32.3.3.2 Analog Control Registers

The Channel x Analog Control Register ACRx contains the bits that control the analog input stage.

ACRx (x = 0-3)
Channel x Analog Control Register

(030_H+x*4_H) **Reset Value: 0000 0000_H**

r	rw		rw	r	rw			r				rw	rw	rw	

Field	Bits	Type	Description
GAIN	[1:0]	rw	**Amplifier Gain** This bit field determines the amplifier gain for channel x. 00_B The selected amplifier gain is 1. 01_B The selected amplifier gain is 2. 10_B The selected amplifier gain is 4. 11_B The selected amplifier gain is 8.
ENP	2	rw	**Enable Positive Input** This bit enables the voltage measurement on the FAINxP analog input. 0_B Analog input FAINxP is high-impedance. The upper half of the measuring range is not available. 1_B Analog input FAINxP line is connected to the channel amplifier. The upper half of the measuring range is available.

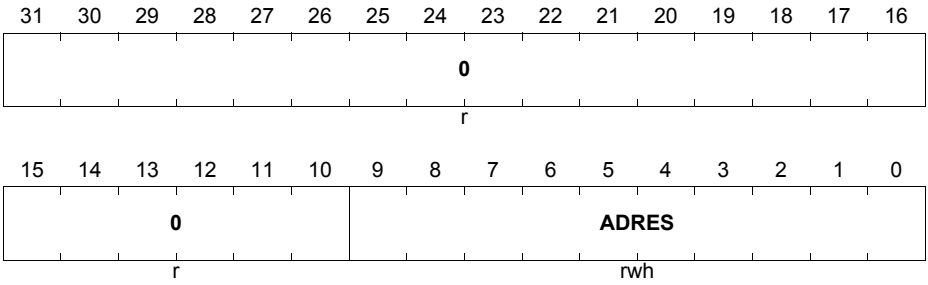
Field	Bits	Type	Description
ENN	3	rw	**Enable Negative Input** This bit enables the voltage measurement on the FAINxN analog input. 0_B Analog input FAINxN is high-impedance. The lower half of the measuring range is not available. 1_B Analog input FAINxN line is connected to the channel amplifier. The lower half of the measuring range is available.
CALOFF[2:0]	[10:8]	rw	**Calibrate Offset** This bit field determines the value applied for the offset calibration for channel x. The calibrate offset value is composed by the most significant bit CALOFF3 and bit field CALOFF[2:0], resulting in a 4-bit bit field CALOFF[3:0].
CALOFF3	12	rw	
0	[7:4], 11, [14:13], [31:15]	r	**Reserved** Read as 0. Should be written with 0.

32.3.3.3 Conversion Result Registers

The Channel x Conversion Result Register RCHx contains the conversion result of channel x.

RCHx (x = 0-3)
Channel x Conversion Result Register

(040_H+x*4_H) **Reset Value: 0000 0000_H**



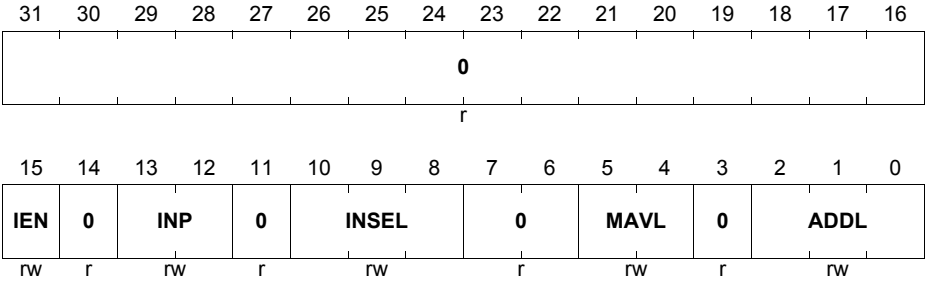
Field	Bits	Type	Description
ADRES	[9:0]	rwh	**AD Conversion Result** This bit field contains the conversion result of channel x. ADRES can only be overwritten by software if GCR.RESWEN = 1.
0	[31:10]	r	**Reserved** Read as 0. Should be written with 0.

32.3.4 Filter Registers

32.3.4.1 Filter Control Registers

Filter blocks are controlled by bits in the Filter n Control Registers FCRn.

FCRn (n = 0-3)
Filter n Control Register **(060_H+n*20_H)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
ADDL	[2:0]	rw	**Addition Length** This bit field determines the number of filter input values that are added to obtain one intermediate result. 000_B Each filter input value is considered as intermediate result. 001_B 2 filter input values are added up. 010_B 3 filter input values are added up. 011_B 4 filter input values are added up. 100_B 5 filter input values are added up. 101_B 6 filter input values are added up. 110_B 7 filter input values are added up. 111_B 8 filter input values are added up.

Field	Bits	Type	Description
MAVL	[5:4]	rw	**Moving Average Length** This bit field determines the number of intermediate results that are added up for a final result. 00_B No moving average is selected. Each intermediate result is considered as final result value: FRRn.FR = CRRn.CR 01_B A moving average of 2 values is selected. The final result is calculated by 2 values: FRRn.FR = CRRn.CR + IRR1n.IR 10_B A moving average of 3 values is selected. The final result is calculated by 3 values: FRRn.FR = CRRn.CR + IRR1n.IR + IRR2n.IR 11_B A moving average of 4 values is selected. The final result is calculated by 4 values: FRRn.FR = CRRn.CR + IRR1n.IR + IRR2n.IR + IRR3n.IR Bit combinations 10_B and 11_B are not available in filter blocks 1 and 3 and must not be selected there.

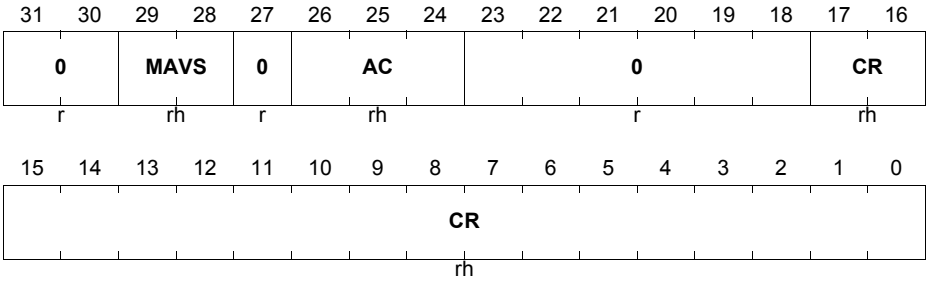
Field	Bits	Type	Description
INSEL	[10:8]	rw	**Input Selection** This bit field enables the filter block and determines which input value is taken for filter block n. For the settings 010_B, set FORM = 00_B. 000_B The filter block is disabled. Intermediate and final sum calculations are not executed. The filter register values are not changed (except by a filter block reset). 001_B Any conversion result of any channel is taken as new filter input value. 010_B Filter block 0: filter is stopped (as 000_B). Filter block 1: filter input value is the output value (final result) of filter block 0. Filter block 2: filter is stopped (as 000_B). Filter block 3: filter input value is the output value (final result) of filter block 2. 011_B Reserved 100_B Channel 0 conversion result is taken as filter input value. 101_B Channel 1 conversion result is taken as filter input value. 110_B Channel 2 conversion result is taken as filter input value. 111_B Channel 3 conversion result is taken as filter input value. *Note: Channel 2/3 is only applicable for FADC modules having 4 channels*
INP	[13:12]	rw	**Interrupt Node Pointer** This bit field selects which service request output line will be activated when a final result of filter block n is available while bit IEN is set. 00_B Service request output SR0 selected 01_B Service request output SR1 selected 10_B Service request output SR2 selected 11_B Service request output SR3 selected
IEN	15	rw	**Interrupt Enable** This bit enables the generation of a new final result service request of filter block n. 0_B Service request generation disabled 1_B Service request generation enabled

Field	Bits	Type	Description
0	3, [7:6], 11, 14, [31:16]	r	**Reserved** Read as 0. Should be written with 0.

32.3.4.2 Current Result Registers

The Current Result Registers CRRn store the current result of filter n. Further, status information of filter block n can be read from CRRn.

CRRn (n = 0-3)
Filter n Current Result Register (064_H + n * 20_H) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
CR	[17:0]	rh	**Current Result** This bit field (significant bits [12:0] for filter 0 and 2, [17:0] for filter 1 and 3) contains the right-aligned current result value of filter 0. CR is cleared when writing GCR.RSTFn = 1.
AC	[26:24]	rh	**Addition Count** This bit field indicates the number of additions of filter input values with remain to be executed before the next intermediate result register transfer occurs. AC is loaded with the value of FCRn.ADDL for a new addition sequence, also when writing GCR.RSTFn = 1.

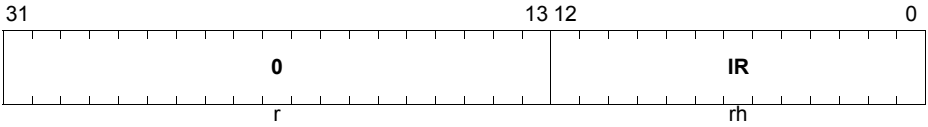
Field	Bits	Type	Description
MAVS	[29:28]	rh	**Moving Average State** This bit field indicates how many intermediate registers transfers remain to be executed for the generation of the next final result. MAVS = 0 indicates the end of a filter calculation operation. Since the filter calculation is executed very fast in comparison to a conversion, MAVS > 0 can be interpreted only as a kind of calculation busy flag. Therefore, it is recommended to read a valid filter result from register FRRn only when the corresponding interrupt request flag CRSR.IRQFn is set. MAVS is reset when writing GCR.RSTFn = 1.
0	[23:18], 27, [31:30]	r	**Reserved** Read as 0. Should be written with 0.

32.3.4.3 Intermediate Result Registers

The Intermediate Result Registers IRRmn hold the intermediate results y of filter n.

IRRy0 (y = 1-3)
Filter 0 Intermediate Result Register y
(064_H+y*4_H) **Reset Value: 0000 0000_H**

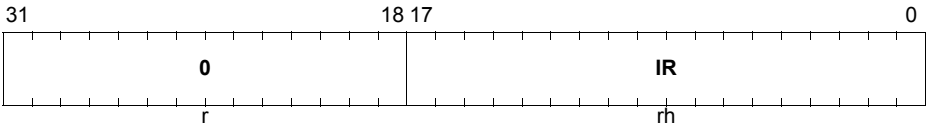
IRRy2 (y = 1-3)
Filter 2 Intermediate Result Register y
($0A4_H$+y*4_H) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
IR	[12:0]	rh	**Intermediate Result** This bit field contains the right-aligned intermediate result. IR is cleared when writing GCR.RSTFn = 1.
0	[31:13]	rh	**Reserved** Read as 0. Should be written with 0.

IRR11
Filter 1 Intermediate Result Register 1
(088_H) **Reset Value: 0000 0000_H**

IRR13
Filter 3 Intermediate Result Register 1
($0C8_H$) **Reset Value: 0000 0000_H**

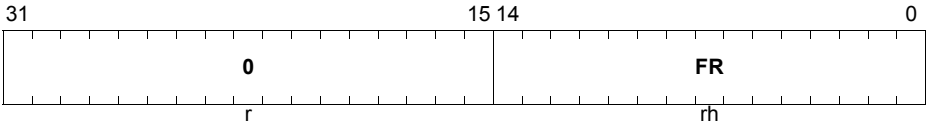


Field	Bits	Type	Description
IR	[17:0]	rh	**Intermediate Result** This bit field contains the right-aligned intermediate result. IR is reset when writing GCR.RSTFn = 1.
0	[31:18]	rh	**Reserved** Read as 0. Should be written with 0.

32.3.4.4 Final Result Registers

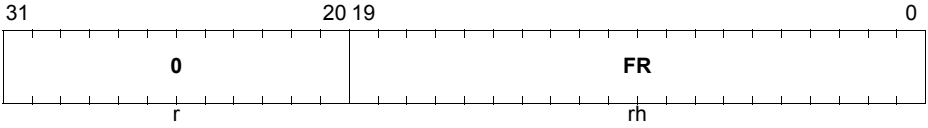
The Final Result Registers FRRn hold the final results of filter block n. The data width being different for the filter block 0 and 2 from the one from data blocks 1 and 3, two different register layouts are necessary.

FRR0
Filter 0 Final Result Register **(074_H)** **Reset Value: 0000 0000_H**
FRR2
Filter 2 Final Result Register **($0B4_H$)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
FR	[14:0]	rh	**Final Result** This bit field contains the right-aligned final result. FR is cleared when writing GCR.RSTFn = 1.
0	[31:15]	rh	**Reserved** Read as 0. Should be written with 0.

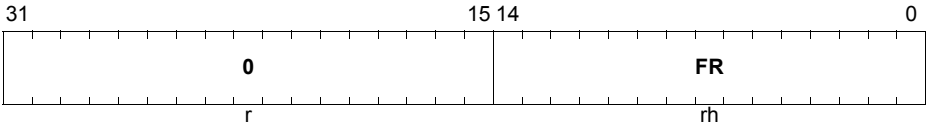
FRR1
Filter 1 Final Result Register **(094_H)** **Reset Value: 0000 0000_H**
FRR3
Filter 3 Final Result Register **($0D4_H$)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
FR	[19:0]	rh	**Final Result** This bit field contains the right-aligned final result. FR is cleared when writing GCR.RSTFn = 1.
0	[31:20]	rh	**Reserved** Read as 0. Should be written with 0.

The Shifted Final Result Registers SFRRn hold the final results of filter blocks 1 and 3 that are shifted right by 5 bit positions. The data representation allows the use of 16-bit data operations for further treatment.

SFRR1
Filter 1 Shifted Final Result Register (098_H) **Reset Value: $0000\ 0000_H$**
SFRR3
Filter 3 Shifted Final Result Register ($0D8_H$) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
FR	[14:0]	rh	**Final Result** This bit field contains the right-aligned final result from the corresponding final result register FRRn shifted right by 5 bit positions. FR is cleared when writing GCR.RSTFn = 1.
0	[31:15]	rh	**Reserved** Read as 0. Should be written with 0.

32.4 Implementation of FADC

This section describes the implementation of the FADC module in the TC1798.

32.4.1 Register Overview

All FADC kernel register names described in this section are referenced in other parts of the TC1798 User´s Manual by the module name prefix “FADC_”.

Table 32-7 Registers Address Space - FADC Module

Module	Base Address	End Address	Note
FADC	$F010\ 0400_H$	$F010\ 05FF_H$	-

Table 32-8 Registers Overview

Register Short Name	Register Long Name	Offset Address	Page Number
intentionally left blank, please refer to register table in Section 32.3		H	

32.4.2 FADC Connections

The following table shows the analog connections of the FADC kernel with other modules or pins in the TC1798 device.

Table 32-9 Connections to FADC Analog Part in TC1798

FADC Signal of Analog Part	from/to Module or Pin	Input or Output	Can be used to/as
V_{DDIF}	V_{DDM}	I	analog power supply 3 V - 5.5 V of input stage, connected to the power supply of the ADC
V_{DDMF}	V_{DDA}	I	analog power supply 3.3 V
V_{SSMF}	V_{SSMF}	I	analog power ground
V_{DDAF}	V_{DDAF}	I	analog power supply 1.2 V
V_{SSAF}	V_{SSM}	I	analog power ground
V_{FAREF}	V_{FAREF}	I	positive analog reference,
V_{FAGND}	V_{FAGND}	I	negative analog reference,
FAIN0P	AN64	I	analog input P channel 0
FAIN0N	AN65	I	analog input N channel 0
FAIN1P	AN66	I	analog input P channel 1
FAIN1N	AN67	I	analog input N channel 1
FAIN2P	AN68	I	analog input P channel 2
FAIN2N	AN69	I	analog input N channel 2
FAIN3P	AN70	I	analog input P channel 3
FAIN3N	AN71	I	analog input N channel 3

The following table shows the digital connections of the FADC kernel with other modules or pins in the TC1798 device.

Table 32-10 Connections of FADC Digital Part in TC1798

FADC Signal of Digital Part	from/to Module or Pin	Input or Output	Can be used to/as
Gating Inputs			
GSA	REQ0	I	P1.0P1.0P1.0P1.0

Table 32-10 Connections of FADC Digital Part in TC1798 (cont'd)

FADC Signal of Digital Part	from/to Module or Pin	Input or Output	Can be used to/as
GSB	REQ4	I	P7.0
GSC	PDOUT2	I	ERU
GSD	PDOUT3	I	ERU
GSE	TRIG11	I	GPTA
GSF	TRIG13	I	GPTA
GSG	TRIG15	I	GPTA
GSH	TRIG17	I	GPTA
Trigger Inputs			
TSA	REQ1	I	P1.1
TSB	REQ5	I	P7.1
TSC	IOUT2	I	ERU
TSD	IOUT3	I	ERU
TSE	TRIG00	I	GPTA
TSF	TRIG02	I	GPTA
TSG	TRIG04	I	GPTA
TSH	TRIG06	I	GPTA
Others			
FADC_ SR[3:0]	interrupt controller, DMA	O	service request output lines of FADC (service request)

32.4.3 Service Request Connections

The FADC kernel provides 4 service request output lines FADC_SR[3:0]. All 4 lines are connected to the DMA (for more details, refer to DMA chapter).

Table 32-11 FADC Service Request Connections in TC1798

Service Request Signal	Connected to Service Request Node
FADC_SR[0]	FADC_SRC0
FADC_SR[1]	FADC_SRC1
FADC_SR[2]	FADC_SRC2
FADC_SR[3]	FADC_SRC3

32.4.4 Clock Control

The FADC module is provided with two clock signals:

- f_{CLC}
  This is the module clock that is used inside the FADC kernel for control purposes such as clocking of control logic and register operations. The frequency of f_{CLC} is always identical to the system clock frequency f_{FPI}. The clock control register FADC_CLC makes it possible to enable/disable f_{CLC}.
- f_{FADC}
  This clock is the module clock that is used in the FADC as the clock for the channel timer and other internal timings, such as the conversion timing. The fractional divider registers FADC_FDR controls the frequency of f_{FADC} and allows it to be enabled/disabled independently of f_{CLC}.

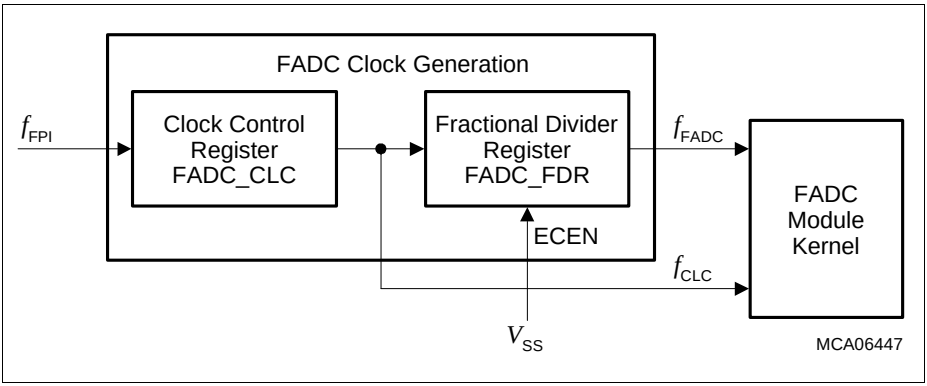


Figure 32-15 FADC Clock Generation

The following formulas define the frequency of f_{FADC}:

$$f_{FADC} = f_{FPI} \times \frac{1}{n} \quad \text{with n = 1024 - FDR.STEP} \tag{32.2}$$

$$f_{FADC} = f_{FPI} \times \frac{n}{1024} \quad \text{with n = 0-1023} \tag{32.3}$$

Equation (32.2) is valid for FADC_FDR.DM = 01_B (normal divider mode).

Equation (32.3) is valid for FADC_FDR.DM = 10_B (fractional divider mode).
