Legal Disclaimer

The information given in this document shall in no event be regarded as a guarantee of conditions or characteristics. With respect to any examples or hints given herein, any typical values stated herein and/or any information regarding the application of the device, Infineon Technologies hereby disclaims any and all warranties and liabilities of any kind, including without limitation, warranties of non-infringement of intellectual property rights of any third party.

Information

For further information on technology, delivery terms and conditions and prices, please contact the nearest Infineon Technologies Office (**www.infineon.com**).

Warnings

Due to technical requirements, components may contain dangerous substances. For information on the types in question, please contact the nearest Infineon Technologies Office.

Infineon Technologies components may be used in life-support devices or systems only with the express written approval of Infineon Technologies, if a failure of such components can reasonably be expected to cause the failure of that life-support device or system or to affect the safety or effectiveness of that device or system. Life support devices or systems are intended to be implanted in the human body or to support and/or maintain and sustain and/or protect human life. If they fail, it is reasonable to assume that the health of the user or other persons may be endangered.

Microcontrollers

TC1798 User´s Manual

Revision History: V1.1, 2011-03

Previous Version: V1.0	
Chapter	Subjects (major changes since last revision)
Changes from TC1798 UMV1.0 to TC1798 UM V1.1	
1	Introduction: • No functional changes
2	CPU: • No functional changes
3	SCU: • No functional changes
4	On-Chip System Buses and Bus Bridges: • XBARDBCON.Master description and increased bitfield to 6 bit
5	PMU: • Chapter ´Robust EEPROM Emulation´: Highlighted in the description of the robust EEPROM emulation that program VER flags should be ignored • Chapter ´Advice for EEPROM Emulation´ and ´Robust EEPROM Emulation´: Some minor fixes to the description of the EEPROM emulation. Replaced all “ignore SBE” by ignore correctable error and the same for DBE. Noted in the EEPROM advice that the “Other page” should be compared also. Noted how a marker should be programmed • Chapter ´Flash Read Access´: Corrected that data reads by Tricore from cached PFlash are not performed by BTR2 but BTR4
6	LMU: • No functional changes
7	Data Access Overlay: • No functional changes
8	Firmware: • No functional changes
9	Memory Maps: • No functional changes

TC1798 User´s Manual

Revision History: V1.1, 2011-03

10	General Purpose I/O Ports and Peripheral I/O Lines: • Added description of strong sharp minus and strong medium minus for Class A2 pads. • Added description for driver strength selection for Class B pads
11	PCP: • No functional module changes
12	DMA: • No functional module changes
13	SDMA: • No functional module changes
14	FCE: • Changed reset value of the FCE_CLC register
15	External Bus Unit: • No functional module changes
16	Interrupt System: • Changed text that target is to support CONECYC=´1´ up to the max fpi frequency • Corrected number of GPT12 interrupts from 4 to 6
17	System Timer: • No functional module changes
18	BMU • No functional module changes
19	OCDS: • No functional module changes
20	ASC: • No functional module changes
21	SSC: • No functional module changes
22	SSCG: • No functional module changes
23	MSC: • No functional module changes
24	MultiCAN: • No functional module changes

TC1798 User´s Manual

Revision History: V1.1, 2011-03

25	SENT: • No functional module changes
26	E-Ray: • No functional module changes
27	MLI: • Corrected description of register TCMDR • Maximum baud rate frequencies where replaced by a baud rate formula
28	GPTAv5: • No functional module changes
29	CCU6: • No functional module changes
30	GPT12: • No functional module changes
31	ADC: • No functional module changes
32	FADC: • No functional module changes

1.4.7 Micro Link Serial Bus Interface (MLI) 1-39
1.4.7.1 MLI Feature List 1-39
1.4.8 Single Edge Nibble Transmission (SENT) 1-41
1.4.8.1 SENT Kernel Description 1-41
1.4.9 SENT Feature Overview 1-42
1.4.10 General Purpose Timer Array (GPTAv5) 1-44
1.4.10.1 GPTA0 and GPTA1 Feature List 1-44
1.4.10.2 LTCA2 Feature List 1-46
1.4.11 Capture/Compare Unit 6 (CCU6) 1-47
1.4.11.1 Feature List. 1-47
1.4.12 General Purpose Timer (GPT12) 1-48
1.4.12.1 Feature List 1-49
1.4.13 External Bus Interface (EBU) 1-50
1.4.13.1 Feature List 1-50
1.4.14 Analog-to-Digital Converters (ADC/FADC) 1-51
1.4.15 ADC Module 1-51
1.4.15.1 Feature List 1-52
1.4.16 FADC Module 1-52
1.4.16.1 FADC Feature List 1-54
1.5 On-Chip Debug Support (OCDS) 1-55
1.5.1 On-Chip Debug Support 1-55
1.5.2 Real Time Trace 1-56
1.5.3 Calibration Support 1-56
1.5.4 Tool Interfaces 1-56
1.5.5 Self-Test Support 1-57
1.5.6 FAR Support 1-57

2 CPU Subsystem 2-1
2.1 TC1798 Processor Subsystem 2-1
2.2 Central Processing Unit Features 2-2

2.2.1 CPU Diagram . . . 2-4
2.2.2 Instruction Fetch Unit . . . 2-5
2.2.3 Execution Unit . . . 2-6
2.2.4 General Purpose Register File . . . 2-7
2.3 Summary of functional changes from TC1.3.1 . . . 2-8
2.4 CPU Implementation-Specific Features . . . 2-10
2.4.1 Context Save Areas . . . 2-10
2.4.2 Program Counter (PC) Register . . . 2-10
2.4.3 Store Buffers . . . 2-10
2.4.4 Interrupt System . . . 2-12
2.4.4.1 Interrupt Acknowledge Decoupling for Safety Systems . . . 2-12
2.4.5 Trap System . . . 2-12
2.4.6 Memory Integrity Error Handling . . . 2-13
2.4.6.1 Program Side Memories . . . 2-14
2.4.6.2 Data Side Memories . . . 2-16
2.5 CPU Subsystem Registers . . . 2-19
2.6 CPU Core Special Function Registers (CSFR) . . . 2-20
2.6.1 Registers . . . 2-22
2.7 CPU General Purpose Registers . . . 2-30
2.8 CPU Memory Protection Registers . . . 2-33
2.9 Temporal Protection Registers . . . 2-37
2.10 FPU Registers . . . 2-38
2.10.1 Registers . . . 2-39
2.11 Memory Integrity Registers . . . 2-40
2.11.1 Register Descriptions . . . 2-42
2.12 CPU Slave Interface (CPS) Registers . . . 2-59
2.12.1 Register Descriptions . . . 2-60
2.13 Core Debug and Performance Counter Registers . . . 2-62
2.14 Implementation Specific Reset Values . . . 2-65
2.15 CPU Instruction Timing . . . 2-66
2.15.1 Integer-Pipeline Instructions . . . 2-67
2.15.1.1 Simple Arithmetic Instruction Timings . . . 2-67
2.15.1.2 Multiply Instruction Timings . . . 2-71
2.15.1.3 Multiply Accumulate (MAC) Instruction Timing . . . 2-72
2.15.1.4 Control Flow Instruction Timing . . . 2-73
2.15.2 Load-Store Pipeline Instructions . . . 2-74
2.15.2.1 Address Arithmetic Timing . . . 2-74
2.15.2.2 CSA Control Flow Instruction Timing . . . 2-75
2.15.2.3 Load Instruction Timing . . . 2-75
2.15.2.4 Store Instruction Timing . . . 2-77
2.15.3 Floating Point Pipeline Timing . . . 2-78
2.16 Program Memory Interface (PMI) . . . 2-79
2.16.1 PMI Features . . . 2-79

2.16.2 Scratchpad RAM . . . 2-80
2.16.3 Instruction Cache . . . 2-80
2.16.4 Program Line Buffer . . . 2-82
2.16.5 CPU Slave Interface (CPS) . . . 2-82
2.16.6 PMI Registers . . . 2-82
2.16.6.1 PMI Register Descriptions . . . 2-83
2.17 Data Memory Interface (DMI) . . . 2-88
2.17.1 DMI Features . . . 2-88
2.17.2 Data Scratchpad RAM (DSPR) . . . 2-89
2.17.3 Data Cache . . . 2-89
2.17.4 DMI Trap Generation . . . 2-90
2.18 Memory Configuration . . . 2-92
2.18.1 DMI Registers . . . 2-93
2.18.1.1 DMI Register Descriptions . . . 2-94
2.19 Safety Features . . . 2-99
2.19.1 SRI Address Phase Error Injection . . . 2-99
2.19.2 SRI Data Phase Error Capture . . . 2-99
2.19.3 Safety Interrupt Acknowledge Decoupling . . . 2-99
2.19.4 Registers Implementing Safety Features . . . 2-100

3 System Control Unit (SCU) . . . 3-1
3.1 Clock System Overview . . . 3-2
3.1.1 Clock Generation Unit . . . 3-4
3.1.1.1 Overview . . . 3-4
3.1.1.2 Oscillator Circuit (OSC) . . . 3-5
3.1.1.3 Phase-Locked Loop (PLL) Module . . . 3-7
3.1.1.4 ERAY Phase-Locked Loop (PLL_ERAY) Module . . . 3-16
3.1.1.5 Clock Control Unit . . . 3-23
3.1.1.6 External Clock Output . . . 3-26
3.1.1.7 CGU Registers . . . 3-31
3.1.2 Module Clock Generation . . . 3-53
3.1.2.1 Clock Control Register CLC . . . 3-54
3.2 Reset Operation . . . 3-68
3.2.1 Overview . . . 3-68
3.2.2 Reset Types . . . 3-68
3.2.3 Reset Sources Overview . . . 3-69
3.2.4 Module Reset Behavior . . . 3-69
3.2.5 General Reset Operation . . . 3-70
3.2.6 Reset State Machine . . . 3-71
3.2.7 Reset Counters (RSTCNTA and RSTCNTD) . . . 3-72
3.2.8 De-assertion of a Reset . . . 3-73
3.2.8.1 Example1: . . . 3-73
3.2.8.2 Example2: . . . 3-73

3.2.8.3 Example3: . . . 3-73
3.2.9 Reset Triggers . . . 3-74
3.2.9.1 Specific Reset Triggers . . . 3-74
3.2.9.2 Configurable Reset Triggers . . . 3-74
3.2.10 Debug Specific Behavior . . . 3-74
3.2.11 EEC Reset Specific Behavior . . . 3-74
3.2.12 Reset Controller Registers . . . 3-75
3.2.12.1 Status Registers . . . 3-75
3.2.12.2 Configuration Registers . . . 3-77
3.3 External Interface . . . 3-82
3.3.1 External Service Requests (ESRx) . . . 3-82
3.3.1.1 ESRx as Reset Request Trigger . . . 3-82
3.3.1.2 ESRx as Reset Output . . . 3-83
3.3.1.3 ESR Registers . . . 3-84
3.3.2 External Request Unit (ERU) . . . 3-91
3.3.2.1 Introduction . . . 3-91
3.3.2.2 ERU Pin Connections . . . 3-93
3.3.2.3 External Request Select Unit (ERS) . . . 3-93
3.3.2.4 Event Trigger Logic (ETL) . . . 3-94
3.3.2.5 Connecting Matrix . . . 3-96
3.3.2.6 Output Gating Unit (OGU) . . . 3-98
3.3.2.7 ERU Output Connections . . . 3-102
3.3.2.8 External Request Unit Registers . . . 3-104
3.4 Power Management . . . 3-120
3.4.1 Power Management Overview . . . 3-120
3.4.2 Power Management Modes . . . 3-121
3.4.2.1 Idle Mode . . . 3-121
3.4.2.2 Sleep Mode . . . 3-122
3.4.3 Power Management Control and Status Register, PMCSR . . . 3-122
3.5 Software Boot Support . . . 3-125
3.5.1 Configuration done with Start-up . . . 3-125
3.5.2 Start-up Configuration Options . . . 3-125
3.5.3 Start-up Registers . . . 3-126
3.5.3.1 Start-up Status Register . . . 3-126
3.6 ECC Error Handling . . . 3-129
3.6.1 ECC Software Testing Support . . . 3-129
3.6.2 ECC Registers . . . 3-130
3.7 Die Temperature Measurement . . . 3-136
3.7.1 Die Temperature Sensor Register . . . 3-137
3.8 Watchdog Timer . . . 3-139
3.8.1 Watchdog Timer Overview . . . 3-139
3.8.2 Features of the Watchdog Timer . . . 3-139
3.8.3 The Endinit Function . . . 3-140

3.8.3.1 Password Access to WDT_CON0 . . . 3-142
3.8.3.2 Modify Access to WDT_CON0 . . . 3-143
3.8.3.3 Access to Endinit-Protected Registers . . . 3-144
3.8.4 Timer Operation . . . 3-145
3.8.4.1 Timer Modes . . . 3-145
3.8.4.2 WDT Reset Behavior . . . 3-146
3.8.4.3 WDT Operation During Power-Saving Modes . . . 3-148
3.8.4.4 Suspend Mode Support . . . 3-148
3.8.5 Watchdog Timer Registers . . . 3-149
3.8.5.1 Watchdog Timer Control Register 0 . . . 3-149
3.8.5.2 Watchdog Timer Control Register 1 . . . 3-151
3.8.5.3 Watchdog Timer Status Register . . . 3-152
3.9 Emergency Stop Output Control . . . 3-155
3.9.1 Emergency Stop Register . . . 3-157
3.10 Interrupt Generation . . . 3-159
3.10.1 Interrupt Control Registers . . . 3-160
3.11 NMI Trap Generation . . . 3-171
3.11.1 Trap Control Registers . . . 3-172
3.12 Miscellaneous System Control Register . . . 3-181
3.12.1 GPTA Input IN1 Control . . . 3-181
3.12.2 System Control Register . . . 3-181
3.12.3 Identification Registers . . . 3-183
3.12.4 Memory Test Register . . . 3-187
3.12.4.1 Register MEMTEST . . . 3-187
3.12.5 SCU Kernel Registers . . . 3-187
3.12.6 SCU Address Area . . . 3-193

4 On-Chip System Buses and Bus Bridges . . . 4-1
4.1 What is new . . . 4-1
4.2 SRI Crossbar (XBar_SRI) . . . 4-3
4.2.1 Introduction . . . 4-3
4.2.1.1 XBar_SRI Features . . . 4-5
4.2.2 SRI Transactions . . . 4-5
4.2.3 SRI Op-Codes . . . 4-6
4.2.4 SRI Error Conditions . . . 4-7
4.2.5 SRI Transaction ID Error Conditions . . . 4-7
4.2.6 Operational Overview . . . 4-8
4.2.6.1 Functional Blocks . . . 4-9
4.2.7 Functional Overview . . . 4-12
4.2.7.1 Arbitration Block . . . 4-12
4.2.7.2 Default Slave . . . 4-17
4.2.7.3 SRI ECC Error Handling . . . 4-18
4.2.7.4 Error Tracking Capability . . . 4-19

4.2.7.5 Debug Trigger Event Generation (OCDS Level 1) 4-21
4.2.7.6 Interrupt and Debug Events of the XBar_SRI Module 4-22
4.2.8 Implementation of the Cross Bar (XBar_SRI) in the TC1798 4-24
4.2.8.1 Mapping of SRI Master Modules to XBar_SRI Master Interfaces . 4-24
4.2.8.2 Mapping of SRI Slave modules to XBar_SRI Slave Interfaces . . . 4-25
4.2.8.3 TC1798 SRI Master / Slave Interconnection Matrix 4-26
4.2.8.4 Connection Master-Slave in XBar_SRI 4-26
4.2.9 SRI Crossbar Registers 4-28
4.2.9.1 TC1798 Control Registers 4-34
4.3 Shared Resource Interconnect to FPI Bus Interface (SFI Bridge) 4-64
4.3.1 Functional Overview 4-64
4.4 System Peripheral Bus 4-65
4.4.1 Overview 4-65
4.4.2 Bus Transaction Types 4-67
4.4.3 Reaction of a Busy Slave 4-67
4.4.4 Address Alignment Rules 4-68
4.4.5 FPI Bus Basic Operations 4-68
4.5 FPI Bus Control Unit (SBCU) 4-70
4.5.1 FPI Bus Arbitration 4-70
4.5.1.1 Arbitration on the System Peripheral Bus 4-70
4.5.1.2 Starvation Prevention 4-72
4.5.2 FPI Bus Error Handling 4-72
4.5.3 BCU Debug Support 4-75
4.5.3.1 Address Triggers 4-75
4.5.3.2 Signal Status Triggers 4-76
4.5.3.3 Combination of Triggers 4-77
4.5.3.4 BCU Breakpoint Generation Examples 4-77
4.5.4 System Bus Control Unit Registers 4-80
4.5.4.1 SBCU ID Register Description 4-82
4.5.4.2 SBCU Control Registers Descriptions 4-83
4.5.4.3 SBCU Error Registers Descriptions 4-84
4.5.4.4 SBCU OCDS Registers Descriptions 4-88
4.5.4.5 SBCU Service Request Control Register Description 4-102

5.6.1.1 PMU Identification . . . 5-28
5.6.2 Flash Registers . . . 5-30
5.6.2.1 Flash Status . . . 5-31
5.6.2.2 Flash Configuration Control . . . 5-40
5.6.2.3 Flash Read Buffer Configuration . . . 5-46
5.6.2.4 Flash Identification Register . . . 5-46
5.6.2.5 Flash Reservation Semaphore . . . 5-48
5.6.2.6 Margin Check Control . . . 5-50
5.6.2.7 Protection Configuration Indication . . . 5-52
5.6.2.8 Flash ECC Access . . . 5-60
5.6.2.9 SHE Secure Internal Flash Boot . . . 5-62
5.7 Application Hints . . . 5-64
5.7.1 Changes with Respect to Audo-NG and Audo-F . . . 5-64
5.7.2 Performing Flash Operations . . . 5-65
5.7.3 EEPROM Emulation With DFlash . . . 5-67
5.7.3.1 Robust EEPROM Emulation . . . 5-68
5.7.4 Performance Considerations . . . 5-68
5.7.5 Handling Flash Protection . . . 5-69
5.7.6 Cooperation with SHE . . . 5-70
5.7.7 Handling Errors . . . 5-71
5.7.7.1 Handling Errors During Operation . . . 5-71
5.7.7.2 Handling Errors During Startup . . . 5-75

5.7.8 Resets During Flash Operation 5-76
5.7.8.1 General Advice 5-77
5.7.8.2 Advice for EEPROM Emulation 5-77
5.7.8.3 Recovery From Aborted Logical Sector Erase (“ALSE”) 5-78
5.7.9 ECC 5-79

6 Local Memory Unit (LMU) 6-1
6.1 Feature List 6-1
6.2 Local Memory 6-1
6.3 Emulation Memory (EMEM) 6-2
6.4 Online Data Acquisition (OLDA) and its Overlay 6-3
6.5 Clock Control 6-3
6.6 LMU Registers 6-4

7 Data Access Overlay (OVC) 7-1
7.1 Basic Overlay Control 7-1
7.2 Online Data Acquisition (OLDA) and its Overlay 7-4
7.3 Enable Control of Overlay Blocks 7-4
7.4 Target and Overlay Memories 7-5
7.4.1 Target Memories 7-5
7.4.2 Internal Overlay Memory 7-5
7.4.3 Emulation Overlay Memory 7-6
7.4.4 External Overlay Memory 7-6
7.5 Change of Overlay Parameters and Overlay Start 7-6
7.6 Concurrent Matches and Access Performance 7-6
7.7 Overlay Control Registers 7-7

8 BootROM Content 8-1
8.1 Startup Software 8-1
8.1.1 Boot Options Summary 8-1
8.1.2 Startup Software Main Flow 8-2
8.1.2.1 Entering the Startup Software 8-3
8.1.2.2 Initial Handling of the Startup Configuration 8-3
8.1.2.3 Flash Rampup 8-3
8.1.2.4 Basic Device Settings 8-4
8.1.2.5 Select and Prepare Startup Modes 8-4
8.1.2.6 Final Chip Settings 8-6
8.1.2.7 Ending the SSW and Starting the User Code 8-8
8.1.3 Specific SSW Features 8-9
8.1.3.1 Header Check in Alternate Boot Modes 8-9
8.1.4 Startup Errors Handling 8-12
8.2 Bootstrap Loaders 8-13
8.2.1 Common Procedures for all Bootloaders 8-13
8.2.2 ASC Bootstrap loader 8-14

8.2.3 CAN Bootstrap Loader 8-14
8.3 Additional information and usage hints 8-16
8.3.1 Conditions upon user code start 8-16
8.3.2 RAMs Handling 8-16
8.3.3 Influencing the next SSW-execution 8-16
8.3.4 TC1798 registers modified by SSW 8-17

9 Memory Maps 9-1
9.1 What is new 9-2
9.2 How to Read the Address Maps 9-4
9.3 Contents of the Segments 9-6
9.4 Address Map of the On Chip Bus System 9-8
9.4.1 Segments 0 to 14 9-8
9.4.2 Segment 15 9-13
9.5 Memory Module Access Restrictions 9-21
9.6 Side Effects from Modules to Data Scratch Pad SRAM (DSPR) 9-22

10 General Purpose I/O Ports and Peripheral I/O Lines (Ports) 10-1
10.1 Basic Port Operation 10-3
10.2 Description Scheme for the Port IO Functions 10-5
10.3 Port Register Description 10-7
10.3.1 Port Input/Output Control Registers 10-11
10.3.2 Pad Driver Mode Register 10-16
10.3.3 Pin Function Decision Control Register 10-20
10.3.4 Port Output Register 10-21
10.3.5 Port Output Modification Register 10-22
10.3.6 Emergency Stop Register 10-24
10.3.7 Port Input Register 10-25
10.4 Port 0 10-27
10.4.1 Port 0 Configuration 10-27
10.4.2 Port 0 Function Table 10-28
10.4.3 Port 0 Registers 10-32
10.4.3.1 Port 0 Emergency Stop Register 10-32
10.5 Port 1 10-33
10.5.1 Port 1 Configuration 10-33
10.5.2 Port 1 Function Table 10-34
10.5.3 Port 1 Registers 10-37
10.5.3.1 Port 1 Emergency Stop Register 10-38

11 Peripheral Control Processor (PCP) 11-1
11.1 PCP Feature/Enhancement History List 11-1
11.1.1 Switchable Core Clock Ratio 11-2
11.2 Peripheral Control Processor Overview 11-2
11.2.1 High Integrity Operation 11-2
11.3 PCP Architecture 11-3
11.3.1 PCP Processor 11-4
11.3.2 PCP Code Memory 11-5
11.3.2.1 CMEM Protection 11-5
11.3.3 PCP Parameter RAM 11-5
11.3.3.1 PRAM Protection 11-6
11.3.4 FPI Bus Interface 11-6
11.3.5 PCP Interrupt Control Unit and Service Request Nodes 11-6
11.4 PCP Programming Model 11-8
11.4.1 General Purpose Register Set of the PCP 11-8
11.4.1.1 Register R0 11-9

11.4.1.2 Registers R1, R2, and R3 . . . 11-9
11.4.1.3 Registers R4 and R5 . . . 11-9
11.4.1.4 Register R6 . . . 11-10
11.4.1.5 Register R7 . . . 11-11
11.4.2 Contexts and Context Models . . . 11-13
11.4.2.1 Context Models . . . 11-13
11.4.2.2 Context Save Area . . . 11-16
11.4.2.3 Context Restore Operation for CR6 and CR7 . . . 11-19
11.4.2.4 Context Save Operation for CR6 and CR7 . . . 11-23
11.4.2.5 Initialization of the Contexts . . . 11-26
11.4.2.6 Context Save Optimization . . . 11-26
11.4.3 Channel Programs . . . 11-27
11.4.3.1 Channel Restart Mode . . . 11-27
11.4.3.2 Channel Resume Mode . . . 11-28
11.5 PCP Operation . . . 11-30
11.5.1 PCP Initialization . . . 11-30
11.5.2 Channel Invocation and Context Restore Operation . . . 11-30
11.5.3 Channel Exit and Context Save Operation . . . 11-31
11.5.3.1 Normal Exit . . . 11-31
11.5.3.2 Error Condition Channel Exit . . . 11-32
11.5.3.3 Debug Exit . . . 11-33
11.6 PCP Interrupt Operation . . . 11-34
11.6.1 Issuing Service Requests to CPU or PCP . . . 11-35
11.6.2 PCP Interrupt Control Unit . . . 11-35
11.6.3 PCP Service Request Nodes . . . 11-35
11.6.4 Issuing PCP Service Requests . . . 11-36
11.6.4.1 Service Request on EXIT Instruction . . . 11-37
11.6.4.2 Service Request on Suspension of Interrupt . . . 11-37
11.6.4.3 Service Request on Error . . . 11-38
11.6.4.4 Queue Full Operation . . . 11-38
11.7 PRAM Protection . . . 11-39
11.7.1 Protection of PRAM against FPI Writes . . . 11-41
11.7.2 Protection of PRAM against Internally Generated PRAM Writes . . . 11-41
11.7.2.1 Context Save Region Protection . . . 11-41
11.7.2.2 Protected Channel PRAM Protection . . . 11-42
11.8 FPI Interface . . . 11-42
11.8.1 Operation as an FPI Master . . . 11-42
11.8.2 Operation as an FPI Slave . . . 11-43
11.9 PCP Error Handling . . . 11-44
11.9.1 PRAM Protection Violation . . . 11-44
11.9.1.1 Enforced PRAM Partitioning . . . 11-44
11.9.1.2 Protected Channel PRAM . . . 11-45
11.9.2 FPI Write Window Violation . . . 11-45

11.9.3 Channel Watchdog 11-45
11.9.4 Invalid Opcode 11-45
11.9.5 Instruction Address Error 11-46

11.17.4 PCP Error/Debug Status Register, PCP_ES 11-71
11.17.5 PCP Interrupt Control Register, PCP_ICR 11-73
11.17.6 PCP Interrupt Threshold Register, PCP_ITR 11-76
11.17.7 PCP Interrupt Configuration Register, PCP_ICON 11-77
11.17.8 PCP Stall Status Register, PCP_SSR 11-79
11.17.9 SIST Mode Access Control Register, PCP_SMACON 11-81
11.17.10 Memory Integrity Error Control Register, PCP_MIECON 11-82
11.17.11 Memory Integrity Error Status Register for PRAM, PCP_MIESTATP 11-83
11.17.12 Memory Integrity Error Status Register for CMEM, PCP_MIESTATC 11-84
11.17.13 Register Protection Register, PCP_RPROT 11-85
11.17.14 CMEM Protection Register, PCP_CPROT 11-86

11.17.15 PRAM Protection Register, PCP_PPROT 11-87
11.17.16 FPI Write Window Register, PCP_FWWIN 11-91
11.17.17 PCP Service Request Control Registers m, PCP_SRC[1:0] 11-92
11.17.18 PCP Service Request Control Registers m, PCP_SRC[3:2] 11-94
11.17.19 PCP Service Request Control Registers m, PCP_SRC[8:4] 11-95
11.17.20 PCP Service Request Control Registers m, PCP_SRC[11:9] 11-96
11.18 PCP Instruction Set Details 11-98
11.18.1 Instruction Codes and Fields 11-98
11.18.1.1 Conditional Codes 11-99
11.18.1.2 Instruction Fields 11-100
11.18.2 Counter Operation for COPY Instruction 11-103
11.18.3 Counter Operation for BCOPY Instruction 11-104
11.18.4 Divide and Multiply Instructions 11-105
11.18.5 ADD, 32-bit Addition 11-106
11.18.6 AND, 32-bit Logical AND 11-107
11.18.7 BCOPY, DMA Operation 11-108
11.18.8 CHKB, Check Bit 11-109
11.18.9 CLR, Clear Bit 11-109
11.18.10 COMP, 32-bit Compare 11-110
11.18.11 COPY, DMA Instruction 11-111
11.18.12 DEBUG, Debug Instruction 11-112
11.18.13 DINIT, Divide Initialization 11-113
11.18.14 DSTEP, Divide Instruction 11-114
11.18.15 EXIT, Exit Instruction 11-115
11.18.16 INB, Insert Bit 11-116
11.18.17 JC, Jump Conditionally 11-117
11.18.18 JL, Jump Long Unconditional 11-118
11.18.19 LD, Load 11-118
11.18.20 LDL, Load 16-bit Value 11-120
11.18.21 MINIT, Multiply Initialization 11-120
11.18.22 MOV, Move Register to Register 11-121
11.18.23 Multiply Instructions 11-122
11.18.24 NEG, Negate 11-123
11.18.25 NOP, No Operation 11-123
11.18.26 NOT, Logical NOT 11-123
11.18.27 OR, Logical OR 11-124
11.18.28 PRAM Bit Operations 11-125
11.18.29 PRI, Prioritize 11-126
11.18.30 RL, Rotate Left 11-127
11.18.31 RR, Rotate Right 11-127
11.18.32 SET, Set Bit 11-128
11.18.33 SHL, Shift Left 11-128
11.18.34 SHR, Shift Right 11-129

11.18.35 ST, Store . . . 11-130
11.18.36 SUB, 32-bit Subtract . . . 11-131
11.18.37 XCH, Exchange . . . 11-132
11.18.38 XOR, 32-bit Logical Exclusive OR . . . 11-133
11.18.39 Flag Updates of Instructions . . . 11-134
11.18.40 Instruction Timing . . . 11-135
11.19 Instruction Encoding . . . 11-139
11.20 Programming of the PCP . . . 11-145
11.20.1 Initial PC of a Channel Program . . . 11-145
11.20.1.1 Channel Entry Table . . . 11-145
11.20.1.2 Channel Resume . . . 11-146
11.20.2 Channel Management for Small and Minimum Contexts . . . 11-147
11.20.3 Unused Registers as Global's or Constants . . . 11-147
11.20.4 Dispatch of Low Priority Tasks . . . 11-148
11.20.5 Code Reuse Across Channels (Call and Return) . . . 11-148
11.20.6 Case-like Code Switches (Computed Go-To) . . . 11-149
11.20.7 Simple DMA Operation . . . 11-149
11.20.7.1 COPY Instruction . . . 11-149
11.20.7.2 BCOPY Instruction (Burst Copy) . . . 11-150
11.21 PCP Programming Notes and Tips . . . 11-151
11.21.1 Notes on PCP Configuration . . . 11-151
11.21.2 General Purpose Register Use . . . 11-151
11.21.3 Use of Channel Interruption . . . 11-153
11.21.3.1 Dynamic Interrupt Masking . . . 11-153
11.21.3.2 Control of Channel Priority (CPPN) . . . 11-153
11.21.4 Implementing Divide Algorithms . . . 11-154
11.21.5 Implementing Multiply Algorithms . . . 11-155
11.22 Implementation of the PCP in the TC1798 . . . 11-157
11.22.1 PCP Memories . . . 11-157
11.22.2 BCOPY Instruction . . . 11-157
11.22.3 PCP Reset Operation . . . 11-157

12 Direct Memory Access Controller (DMA) . . . 12-1
12.1 What is new . . . 12-1

19 On-Chip Debug Support (OCDS) 19-1
19.1 Overview 19-1
19.2 OCDS Level 1 19-5
19.2.1 TriCore CPU OCDS Level 1 19-6
19.2.1.1 Basic Concept 19-6
19.2.1.2 Debug Event Generation 19-7
19.2.1.3 Debug Actions 19-8
19.2.1.4 TriCore OCDS Registers 19-8
19.2.2 PCP OCDS Level 1 19-9
19.2.3 SBCU OCDS Level 1 19-9
19.2.4 DMA/SDMA OCDS Level 1 19-9
19.3 Debug Interface (Cerberus) 19-10
19.3.1 RW Mode 19-10
19.3.2 Communication Mode 19-11
19.3.3 Triggered Transfers 19-11
19.3.4 Multi Core Break Switch 19-11
19.4 JTAG Interface 19-13
19.5 Device Access Port (DAP) 19-13
19.5.1 DAP Telegram Format 19-13
19.5.2 DAP Telegram Catalog 19-13
19.6 Cerberus and JTAG Registers 19-14

20 Asynchronous/Synchronous Serial Interface (ASC) 20-1
20.1 ASC Kernel Description 20-1
20.1.1 Overview 20-2
20.1.2 General Operation 20-3
20.1.3 Asynchronous Operation 20-4
20.1.3.1 Asynchronous Data Frames 20-5
20.1.3.2 Asynchronous Transmission 20-7
20.1.3.3 Asynchronous Reception 20-7
20.1.3.4 RXD/TXD Data Path Selection in Asynchronous Modes 20-8
20.1.4 Synchronous Operation 20-9
20.1.4.1 Synchronous Transmission 20-10
20.1.4.2 Synchronous Reception 20-10
20.1.4.3 Synchronous Timing 20-11
20.1.5 Baud Rate Generation 20-12

20.1.5.1 Baud Rates in Asynchronous Mode 20-13
20.1.5.2 Baud Rates in Synchronous Mode 20-16
20.1.6 Hardware Error Detection Capabilities 20-17
20.1.7 Interrupts 20-17
20.2 ASC Kernel Registers 20-19
20.2.1 Control Registers 20-20
20.2.2 Data Registers 20-28
20.3 ASC0/ASC1 Module Implementation 20-30
20.3.1 Interfaces of the ASC Modules 20-30
20.3.2 ASC0/ASC1 Module Related External Registers 20-32
20.3.2.1 Clock Control Register 20-33
20.3.2.2 Peripheral Input Select Register 20-35
20.3.2.3 Port Control Registers 20-37
20.3.2.4 Interrupt Control Registers 20-39
20.3.3 DMA Requests 20-40
20.3.4 Address Map 20-42
20.3.5 Application Hint Regarding the ATM Feature 20-44

21 Synchronous Serial Interface (SSC) 21-1
21.1 SSC Kernel Description 21-1
21.1.1 Overview 21-2
21.1.2 General Operation 21-3
21.1.2.1 Operating Mode Selection 21-5
21.1.2.2 Full-Duplex Operation 21-6
21.1.2.3 Half-Duplex Operation 21-9
21.1.2.4 Continuous Transfers 21-10
21.1.2.5 Parity Mode 21-11
21.1.2.6 Port Control 21-12
21.1.2.7 Baud Rate Generation 21-14
21.1.2.8 Slave Select Input Operation 21-16
21.1.2.9 Slave Select Output Generation Unit 21-17
21.1.2.10 Error Detection Mechanisms 21-20
21.1.2.11 Queued SSC Mode 21-24
21.2 SSC Kernel Registers 21-27
21.2.1 Module Identification Register 21-28
21.2.2 Control Registers 21-29
21.2.3 Data Registers 21-42
21.3 SSC0/SSC1/SSC2/SSC3 Module Implementation 21-43
21.3.1 Module Identification Registers 21-43
21.3.2 Interfaces of the SSC Modules 21-43
21.3.3 On-Chip Connections 21-46
21.3.4 SSC0/SSC1/SSC2/SSC3 Module Related External Registers 21-46
21.3.4.1 Clock Control 21-48

21.3.4.2 Port Control 21-53
21.3.4.3 Interrupt Control Registers 21-58
21.3.5 Address Map of the SSC Modules 21-59

22 Synchronous Serial Interface Guardian (SSCG) 22-1
22.1 Overview 22-1
22.1.1 General Operation 22-2
22.2 SSCG Kernel Description 22-3
22.2.1 Details on the Operation Principles and the Architecture 22-3
22.2.1.1 Monitoring the Slave Select and Serial Clock Signals 22-6
22.3 SSCG Kernel Registers, inherited from SSC 22-8
22.3.1 Module Identification Register 22-10
22.3.2 Control Registers 22-11
22.3.3 Data Registers 22-24
22.3.4 SSCG Specific Registers 22-25
22.4 SSCG0 Module Implementation 22-30
22.4.1 Module Identification Registers 22-30
22.4.2 Interfaces of the SSCG Modules 22-30
22.4.3 On-Chip Connections 22-32
22.4.3.1 Receive Input Selection 22-32
22.4.4 SSC0/SSC1 Module Related External Registers 22-33
22.4.4.1 Clock Control 22-34
22.4.4.2 Interrupt Control Registers 22-39
22.4.5 SSCG Address Map 22-40

23 Micro Second Channel (MSC) 23-1

26.9.4 Clock Control Register 26-268
26.9.5 Interrupt Registers 26-269

27 Micro Link Interface (MLI) 27-1
27.1 Functional Description 27-2
27.1.1 General Introduction 27-2
27.1.1.1 MLI Overview 27-2
27.1.1.2 Naming Conventions 27-4
27.1.1.3 MLI Communication Principles 27-6
27.1.2 MLI Frame Structure 27-10
27.1.2.1 General Frame Layout 27-11
27.1.2.2 Copy Base Address Frame 27-12
27.1.2.3 Write Offset and Data Frame 27-13
27.1.2.4 Optimized Write Frame 27-14
27.1.2.5 Discrete Read Frame 27-15
27.1.2.6 Optimized Read Frame 27-16
27.1.2.7 Command Frame 27-17
27.1.2.8 Answer Frame 27-18
27.1.3 Handshake Description 27-19
27.1.3.1 Handshake Signals 27-21
27.1.3.2 Error-free Handshake 27-21
27.1.3.3 Ready Delay Time 27-22
27.1.3.4 Non-Acknowledge Error 27-23
27.1.3.5 Signal Timing 27-24
27.1.4 Parity Generation 27-26

27.1.5 Address Prediction 27-26
27.2 Module Kernel Description 27-27
27.2.1 Frame Handling 27-27
27.2.1.1 Copy Base Address Frame 27-28
27.2.1.2 Write/Data Frames 27-30
27.2.1.3 Read Frames 27-34
27.2.1.4 Answer Frame 27-39
27.2.1.5 Command Frame 27-41
27.2.2 General MLI Features 27-44
27.2.2.1 Parity Check and Parity Error Indication 27-44
27.2.2.2 Non-Acknowledge Error 27-47
27.2.2.3 Address Prediction 27-47
27.2.2.4 Automatic Data Mode 27-48
27.2.2.5 Memory Access Protection 27-49
27.2.2.6 Triggered Command Transfers 27-49
27.2.2.7 Transmit Priority 27-50
27.2.2.8 Transmission Delay 27-50
27.2.3 Interface Description 27-51
27.2.3.1 Transmitter I/O Line Control 27-53
27.2.3.2 Receiver I/O Line Control 27-53
27.2.3.3 Connecting Several MLI Modules 27-55
27.2.4 MLI Service Request Generation 27-57
27.2.5 Transmitter Events 27-59
27.2.5.1 Parity/Time-out Error Event 27-60
27.2.5.2 Normal Frame Sent x Event 27-60
27.2.5.3 Command Frame Sent Events 27-61
27.2.6 Receiver Events 27-62
27.2.6.1 Discarded Read Answer Event 27-62
27.2.6.2 Memory Access Protection/Parity Error Event 27-63
27.2.6.3 Normal Frame Received/Move Engine Terminated Event 27-64
27.2.6.4 Interrupt Command Frame Event 27-65
27.2.6.5 Command Frame Received Event 27-66
27.2.7 Baud Rate Generation 27-67
27.2.8 Automatic Register Overwrite 27-68
27.3 Operating the MLI 27-69
27.3.1 Connection Setup 27-70
27.3.2 Local Transmitter and Pipe Setup 27-71
27.3.3 Remote Receiver Setup 27-71
27.3.4 Remote Transmitter and Local Receiver Setup 27-72
27.3.5 Delay Adjustment 27-73
27.3.6 Connection to DMA Mechanism 27-75
27.3.7 Connection of MLI to SPI 27-75
27.4 MLI Kernel Registers 27-77

27.4.1 General Module Registers 27-79
27.4.2 General Status/Control Registers 27-83
27.4.3 Access Protection Registers 27-90
27.4.4 Transmitter Control/Status Registers 27-92
27.4.5 Transmitter Pipe x Address Offset Register 27-103
27.4.6 Transmitter Interrupt Registers 27-107
27.4.7 Receiver Control/Status Registers 27-113
27.4.8 Receiver Address/Data Registers 27-117
27.4.9 Receiver Interrupt Registers 27-120
27.5 Implementation of the MLI0/MLI1 in TC1798 27-127
27.5.1 Interfaces of the MLI Modules 27-127
27.5.2 MLI Module External Registers 27-130
27.5.2.1 Automatic Register Overwrite 27-130
27.5.3 Module Clock Generation 27-131
27.5.4 Port Control and Connections 27-133
27.5.4.1 Input/Output Function Selection 27-133
27.5.5 On-Chip Connections 27-136
27.5.5.1 Service Request Output Connections 27-136
27.5.5.2 Break Signals 27-137
27.5.5.3 Trigger Input Signals 27-137
27.5.6 Access Protection 27-137
27.5.7 MLI0/MLI1 Transfer Window Address Maps 27-138
27.5.8 MLI0/MLI1 Address Map 27-139

28 General Purpose Timer Array (GPTA®v5) 28-1
28.1 What is new? 28-1
28.2 GPTA®v5 Overview 28-4
28.2.1 Functionality of GPTA0 and GPTA1 28-5
28.2.2 Functionality of LTCA2 28-7
28.3 GPTA0/GPTA1 Kernel Description 28-8
28.3.1 GTPA Units 28-9
28.3.2 Clock Generation Cells 28-10
28.3.2.1 Filter and Prescaler Cell (FPC) 28-12
28.3.2.2 Phase Discrimination Logic (PDL) 28-21
28.3.2.3 Duty Cycle Measurement Cell (DCM) 28-26
28.3.2.4 Digital Phase Locked Loop Cell (PLL) 28-30
28.3.2.5 Clock Distribution Cell (CDC) 28-35
28.3.3 Signal Generation Cells 28-38
28.3.3.1 Global Timers (GT) 28-38
28.3.3.2 Global Timer Cell (GTC) 28-55
28.3.3.3 Local Timer Cell (LTC00 to LTC62) 28-67
28.3.3.4 Local Timer Cell LTC63 28-79
28.3.3.5 Coherent Update 28-85

28.3.4 Input/Output Line Sharing Block (IOLS) 28-98
28.3.4.1 FPC Input Line Selection 28-102
28.3.4.2 GTC and LTC Output Multiplexer Selection 28-103
28.3.4.3 On-chip Trigger and Gating Output Multiplexer Selection 28-108
28.3.4.4 GTC Input Multiplexer Selection 28-111
28.3.4.5 LTC Input Multiplexer Selection 28-116
28.3.4.6 Multiplexer Register Array Programming 28-121
28.3.5 Interrupt Sharing Block (IS) 28-123
28.3.6 Pseudo Code Description of GPTA®v5 Kernel Functionality 28-126
28.3.6.1 FPC Algorithm 28-126
28.3.6.2 PDL-Algorithm 28-131
28.3.6.3 DCM-Algorithm 28-135
28.3.6.4 PLL-Algorithm 28-138
28.3.6.5 GT-Algorithm 28-140
28.3.6.6 GTC-Algorithm 28-141
28.3.6.7 LTC-Algorithm for Cells 0 to 62 28-146
28.3.6.8 LTC Algorithm for Cell 63 28-154
28.3.7 Programming of a GPTA®v5 Unit 28-158
28.4 GPTA0/1 Kernel Registers 28-160
28.4.1 GPTA®v5 Identification Register 28-166
28.4.2 FPC Registers 28-167
28.4.3 Phase Discriminator Registers 28-171
28.4.4 Duty Cycle Measurement Registers 28-173
28.4.5 Digital Phase Locked Loop Registers 28-177
28.4.6 Global Timer Registers 28-182
28.4.7 Clock Bus Register 28-185
28.4.8 Global Timer Cell Registers 28-187
28.4.9 Local Timer Cell Registers 28-192
28.4.10 Multiplexer Control Registers 28-207
28.4.11 Service Request Registers 28-223
28.5 LTCA Kernel Description 28-234
28.5.1 Local Timer Cell (LTC00 to LTC63) 28-235
28.5.2 Input/Output Line Sharing Block (IOLS) 28-235
28.5.2.1 Output Multiplexer 28-237
28.5.2.2 LTC Input Multiplexing Scheme 28-242
28.5.2.3 Multiplexer Register Array Programming 28-245
28.5.3 Interrupt Sharing Block (IS) 28-248
28.6 LTCA Kernel Registers 28-250
28.6.1 Bit Protection 28-251
28.6.2 Service Request Registers 28-252
28.6.3 Local Timer Cell Registers 28-252
28.6.4 I/O Sharing Block Registers 28-263
28.6.5 Multiplexer Control Registers 28-267

28.6.5.1 Output Multiplexer Control Registers 28-267
28.6.5.2 LTC Input Multiplexer Control Registers 28-270
28.7 GPTA®v5 Module Implementation 28-274
28.7.1 Interconnections of GPTA0/GPTA1/LTCA2 Units 28-274
28.7.2 GPTA®v5 Module External Registers 28-276
28.7.3 Port Control and Connections 28-276
28.7.3.1 I/O Port Line Assignment 28-276
28.7.3.2 Input/Output Function Selection 28-279
28.7.3.3 Emergency Control of GPTA®v5 Output Ports Lines 28-284
28.7.4 On-Chip Connections 28-286
28.7.4.1 Clock Bus Connections 28-286
28.7.4.2 MSC Controller Connections 28-287
28.7.4.3 Connections to SCU, MultiCAN, FADC, DMA, Ports 28-294
28.7.5 Module Clock Generation 28-296
28.7.5.1 Clock Control Registers 28-300
28.7.5.2 Fractional Divider Register 28-301
28.7.6 Limits of Cascading GTCs and LTCs 28-306
28.7.7 Interrupt Registers 28-307
28.7.8 GPTA Register Address Map 28-308
28.8 Revision History 28-311

29 Capture/Compare Unit 6 (CCU6) 29-1
29.1 Introduction 29-1
29.1.1 Feature Set Overview 29-2
29.1.2 Block Diagram 29-3
29.1.3 CCU6 Kernel Registers 29-4
29.2 Operating Timer T12 29-10
29.2.1 T12 Overview 29-11
29.2.2 T12 Counting Scheme 29-13
29.2.2.1 Clock Selection 29-13
29.2.2.2 Edge-Aligned / Center-Aligned Mode 29-14
29.2.2.3 Single-Shot Mode 29-16
29.2.3 T12 Compare Mode 29-17
29.2.3.1 Compare Channels 29-17
29.2.3.2 Channel State Bits 29-18
29.2.3.3 Hysteresis-Like Control Mode 29-23
29.2.4 Compare Mode Output Path 29-24
29.2.4.1 Dead-Time Generation 29-24
29.2.4.2 State Selection 29-26
29.2.4.3 Output Modulation and Level Selection 29-27
29.2.5 T12 Capture Modes 29-29
29.2.6 T12 Shadow Register Transfer 29-33
29.2.7 Timer T12 Operating Mode Selection 29-34

29.2.8 T12 related Registers 29-35
29.2.8.1 T12 Counter Register 29-35
29.2.8.2 Period Register 29-36
29.2.8.3 Capture/Compare Registers 29-37
29.2.8.4 Capture/Compare Shadow Registers 29-38
29.2.8.5 Dead-time Control Register 29-39
29.2.9 Capture/Compare Control Registers 29-41
29.2.9.1 Channel State Bits 29-41
29.2.9.2 T12 Mode Control Register 29-45
29.2.9.3 Timer Control Registers 29-46
29.3 Operating Timer T13 29-55
29.3.1 T13 Overview 29-55
29.3.2 T13 Counting Scheme 29-58
29.3.2.1 Clock Selection 29-58
29.3.2.2 T13 Counting 29-59
29.3.2.3 Single-Shot Mode 29-60
29.3.2.4 Synchronization to T12 29-61
29.3.3 T13 Compare Mode 29-63
29.3.4 Compare Mode Output Path 29-65
29.3.5 T13 Shadow Register Transfer 29-66
29.3.6 T13 related Registers 29-68
29.3.6.1 T13 Counter Register 29-68
29.3.6.2 Period Register 29-69
29.3.6.3 Compare Register 29-70
29.3.6.4 Compare Shadow Register 29-71
29.4 Synchronous Start Feature 29-72
29.5 Trap Handling 29-73
29.6 Multi-Channel Mode 29-75
29.7 Hall Sensor Mode 29-77
29.7.1 Hall Pattern Evaluation 29-78
29.7.2 Hall Pattern Compare Logic 29-80
29.7.3 Hall Mode Flags 29-81
29.7.4 Hall Mode for Brushless DC-Motor Control 29-83
29.8 Modulation Control Registers 29-85
29.8.1 Modulation Control 29-85
29.8.2 Trap Control Register 29-87
29.8.3 Passive State Level Register 29-90
29.8.4 Multi-Channel Mode Registers 29-91
29.9 Interrupt Handling 29-98
29.9.1 Interrupt Structure 29-98
29.9.2 Interrupt Registers 29-100
29.9.2.1 Interrupt Status Register 29-100
29.9.2.2 Interrupt Status Set Register 29-103

29.9.2.3 Status Reset Register 29-105
29.9.2.4 Interrupt Enable Register 29-107
29.9.2.5 Interrupt Node Pointer Register 29-109
29.9.3 Service Request Control Registers 29-112
29.10 General Module Operation 29-113
29.10.1 Mode Control 29-113
29.10.2 Input Selection 29-116
29.10.3 Input Monitoring 29-117
29.10.4 General Registers 29-118
29.10.4.1 ID Register 29-118
29.10.4.2 Port Input Select Registers 29-119
29.10.4.3 Kernel State Configuration Register 29-124
29.10.4.4 Kernel State Sensitivity Control Register 29-127
29.10.4.5 Module Configuration Register 29-128
29.10.4.6 Input Monitoring Register 29-130
29.10.4.7 Lost Indicator Register 29-133
29.11 Implementation 29-135
29.11.1 Address Map 29-135
29.11.1.1 Module Registers 29-136
29.11.2 Module Output Select 29-140
29.11.3 Synchronous Start 29-141
29.12 Digital Connections 29-142
29.12.1 Connections of CCU60 29-142
29.12.2 Connections of CCU61 29-146
29.12.3 Connections of CCU62 29-150
29.12.4 Connections of CCU63 29-154

30 The General Purpose Timer 12 (GPT12) 30-1
30.1 Timer Block GPT1 30-2
30.1.1 GPT1 Core Timer T3 Control 30-4
30.1.2 GPT1 Core Timer T3 Operating Modes 30-8
30.1.3 GPT1 Auxiliary Timers T2/T4 Control 30-15
30.1.4 GPT1 Auxiliary Timers T2/T4 Operating Modes 30-21
30.1.5 GPT1 Clock Signal Control 30-31
30.1.6 GPT1 Timer Registers 30-34
30.1.7 Interrupt Control for GPT1 Timers 30-35
30.2 Timer Block GPT2 30-37
30.2.1 GPT2 Core Timer T6 Control 30-39
30.2.2 GPT2 Core Timer T6 Operating Modes 30-42
30.2.3 GPT2 Auxiliary Timer T5 Control 30-46
30.2.4 GPT2 Auxiliary Timer T5 Operating Modes 30-50
30.2.5 GPT2 Register CAPREL Operating Modes 30-55
30.2.6 GPT2 Clock Signal Control 30-61

30.2.7 GPT2 Timer Registers 30-64
30.2.8 Interrupt Control for GPT2 Timers and CAPREL 30-66
30.3 Miscellaneous Registers 30-68
30.4 GPT12 Kernel Register Overview 30-72
30.5 Implementation of the GPT12 Modules 30-74
30.5.1 Address Map 30-74
30.5.2 Module Connections 30-74

31 Analog to Digital Converter (ADC) 31-1
31.1 Introduction 31-1
31.1.1 ADC Block Diagram 31-2
31.1.2 Feature Set 31-3
31.1.3 Abbreviations 31-4
31.1.4 ADC Kernel Overview 31-5
31.1.5 Conversion Request Unit 31-7
31.1.6 Conversion Result Unit 31-9
31.1.7 Interrupt Structure 31-10
31.1.8 Electrical Models 31-11
31.1.8.1 Input Signal Path 31-11
31.1.8.2 Reference Path 31-12
31.1.9 Transfer Characteristics and Error Definitions 31-14
31.2 Operating the ADC 31-15
31.2.1 Register Overview 31-16
31.2.2 Mode Control 31-21
31.2.3 Module Activation and Power Saving Modes 31-23
31.2.4 Clocking Scheme 31-24
31.2.5 ADC Module Registers 31-25
31.2.5.1 Clock Control Register 31-25
31.2.5.2 Kernel State Configuration Register 31-26
31.2.5.3 Service Request Control Registers 31-28
31.2.6 General ADC Kernel Registers 31-29
31.2.6.1 Request Source Input Registers 31-29
31.2.6.2 Module Identification Register 31-32
31.2.6.3 Interrupt Activation Register 31-33
31.2.6.4 Global Control 31-34
31.2.6.5 Global Configuration 31-37
31.2.6.6 Global Status 31-39
31.2.7 Request Source Arbiter 31-42
31.2.7.1 Request Source Priority 31-43
31.2.7.2 Conversion Start Modes 31-44
31.2.8 Arbiter Registers 31-47
31.2.8.1 Arbitration Slot Enable Register 31-47
31.2.8.2 Request Source Priority Register 31-48

31.2.9 Scan Request Source Handling 31-50
31.2.9.1 Overview 31-50
31.2.9.2 Scan Sequence Operation 31-51
31.2.9.3 Request Source Event and Interrupt 31-52
31.2.10 Scan Request Source Registers 31-54
31.2.10.1 Conversion Request Control Registers 31-54
31.2.10.2 Conversion Request Pending Registers 31-56
31.2.10.3 Conversion Request Mode Registers 31-57
31.2.11 Sequential Request Source Handling 31-60
31.2.11.1 Overview 31-61
31.2.11.2 Sequential Source Operation 31-62
31.2.11.3 Request Source Event and Interrupt 31-63
31.2.12 Sequential Source Registers 31-65
31.2.12.1 Queue Mode Registers 31-65
31.2.12.2 Queue Status Registers 31-68
31.2.12.3 Queue 0 Registers 31-70
31.2.12.4 Queue Backup Registers 31-72
31.2.12.5 Queue Input Registers 31-74
31.2.13 Channel-Related Functions 31-76
31.2.13.1 Input Classes 31-76
31.2.13.2 Reference Selection 31-77
31.2.13.3 Alias Feature 31-77
31.2.13.4 Limit Checking 31-78
31.2.13.5 Channel Event Interrupts 31-80
31.2.14 Channel-Related Registers 31-81
31.2.14.1 Channel Control Registers 31-81
31.2.14.2 Input Class Registers 31-83
31.2.14.3 Alias Register 31-84
31.2.14.4 Limit Check Boundary Registers 31-85
31.2.14.5 Channel Flag Register 31-86
31.2.14.6 Channel Flag Clear Register 31-87
31.2.14.7 Channel Event Node Pointer Registers 31-88
31.2.15 Conversion Result Handling 31-90
31.2.15.1 Storage of Conversion Results 31-90
31.2.15.2 Wait-for-Read Mode 31-92
31.2.15.3 Result Event Interrupts 31-93
31.2.15.4 Result FIFO Buffer 31-94
31.2.15.5 Data Reduction Filter 31-96
31.2.15.6 Result Data Filter 31-98
31.2.16 Conversion Result-Related Registers 31-100
31.2.16.1 Result Register 0 31-100
31.2.16.2 Result Registers 1 to 15 31-102
31.2.16.3 Valid Flag Register 31-104

31.2.16.4 Result Control Registers 31-105
31.2.16.5 Event Flag Register 31-107
31.2.16.6 Event Flag Clear Register 31-109
31.2.16.7 Event Node Pointer Registers 31-110
31.2.17 Multiplexer Test Support 31-113
31.2.18 External Multiplexer Control 31-114
31.2.19 Synchronized Conversions for Parallel Sampling 31-117
31.2.20 Equidistant Sampling 31-120
31.2.21 Access Protection 31-122
31.2.22 Broken Wire Detection 31-123
31.2.23 Additional Feature Registers 31-125
31.2.23.1 Access Protection Register 31-125
31.2.23.2 External Multiplexer Control 31-126
31.2.23.3 Synchronization Control Register 31-130
31.2.23.4 Broken Wire Detection Enable Register 31-132
31.2.23.5 Broken Wire Detection Configuration Register 31-133
31.3 Implementation 31-134
31.3.1 Request Sources in TC1798 31-134
31.3.2 Address Map 31-134
31.3.3 Result Data Filter 31-135
31.3.4 ADC Module Connections 31-136
31.3.4.1 ADC0 Connections 31-137
31.3.4.2 ADC1 Connections 31-143
31.3.4.3 ADC2 Connections 31-149
31.3.4.4 ADC3 Connections 31-155
31.3.4.5 Service Request Connections 31-161
31.3.4.6 Kernel Synchronization 31-162

32 Fast Analog to Digital Converter (FADC) 32-1
32.1 FADC Short Description 32-2
32.2 FADC Kernel Description 32-5
32.2.1 Analog Input Stage Configurations 32-5
32.2.2 Result Representation 32-7
32.2.3 Conversion Timing 32-7
32.2.4 Channel Triggers 32-8
32.2.5 Channel Timer 32-11
32.2.6 Conversion Control 32-12
32.2.6.1 Static Channel Priority 32-12
32.2.6.2 Dynamic Priority Assignment 32-12

32.4.4 Clock Control 32-67

1 Introduction

This User´s Manual describes the Infineon TC1798, a 32-bit microcontroller DSP, based on the Infineon TriCore Architecture.

1.1 About this Document

This document is designed to be read primarily by design engineers and software engineers who need a detailed description of the interactions of the TC1798 functional units, registers, instructions, and exceptions.

This TC1798 User´s Manual describes the features of the TC1798 with respect to the TriCore Architecture. Where the TC1798 directly implements TriCore architectural functions, this manual simply refers to those functions as features of the TC1798. In all cases where this manual describes a TC1798 feature without referring to the TriCore Architecture, this means that the TC1798 is a direct implementation of the TriCore Architecture.

Where the TC1798 implements a subset of TriCore architectural features, this manual describes the TC1798 implementation, and then describes how it differs from the TriCore Architecture. Such differences between the TC1798 and the TriCore Architecture are documented in the section covering each such subject.

1.1.1 Related Documentations

A complete description of the TriCore architecture is found in the document entitled “TriCore Architecture Manual”. The architecture of the TC1798 is described separately this way because of the configurable nature of the TriCore specification: Different versions of the architecture may contain a different mix of systems components. The TriCore architecture, however, remains constant across all derivative designs in order to preserve compatibility.

This User´s Manuals together with the “TriCore Architecture Manual” are required to understand the complete TC1798 micro controller functionality.

1.1.2 Text Conventions

This document uses the following text conventions for named components of the TC1798:

- Functional units of the TC1798 are given in plain UPPER CASE. For example: “The SSC supports full-duplex and half-duplex synchronous communication”.
- Pins using negative logic are indicated by an overline. For example: “The external reset pin, $\overline{\text{ESR0}}$, has a dual function.”.
- Bit fields and bits in registers are in general referenced as “Module_Register name.Bit field” or “Module_Register name.Bit”. For example: “The Current CPU Priority Number bit field CPU_ICR.CCPN is cleared”. Most of the

register names contain a module name prefix, separated by an underscore character "_" from the actual register name (for example, "ASC0_CON", where "ASC0" is the module name prefix, and "CON" is the kernel register name). In chapters describing the kernels of the peripheral modules, the registers are mainly referenced with their kernel register names. The peripheral module implementation sections mainly refer to the actual register names with module prefixes.

- Variables used to describe sets of processing units or registers appear in mixed upper and lower cases. For example, register name "MSGCFGn" refers to multiple "MSGCFG" registers with variable n. The bounds of the variables are always given where the register expression is first used (for example, "n = 0-31"), and are repeated as needed in the rest of the text.
- The default radix is decimal. Hexadecimal constants are suffixed with a subscript letter "H", as in 100_H. Binary constants are suffixed with a subscript letter "B", as in: 111_B.
- When the extent of register fields, groups register bits, or groups of pins are collectively named in the body of the document, they are represented as "NAME[A:B]", which defines a range for the named group from B to A. Individual bits, signals, or pins are given as "NAME[C]" where the range of the variable C is given in the text. For example: CFG[2:0] and SRPN[0].
- Units are abbreviated as follows:
  - **MHz** = Megahertz
  - **µs** = Microseconds
  - **kBaud, kbit** = 1000 characters/bits per second
  - **MBaud, Mbit** = 1,000,000 characters/bits per second
  - **Kbyte, KB** = 1024 bytes of memory
  - **Mbyte, MB**= 1048576 bytes of memory

  In general, the k prefix scales a unit by 1000 whereas the K prefix scales a unit by 1024. Hence, the Kbyte unit scales the expression preceding it by 1024. The kBaud unit scales the expression preceding it by 1000. The M prefix scales by 1,000,000 or 1048576, and µ scales by .000001. For example, 1 Kbyte is 1024 bytes, 1 Mbyte is 1024 × 1024 bytes, 1 kBaud/kbit are 1000 characters/bits per second, 1 MBaud/Mbit are 1000000 characters/bits per second, and 1 MHz is 1,000,000 Hz.
- Data format quantities are defined as follows:
  - **Byte** = 8-bit quantity
  - **Half-word** = 16-bit quantity
  - **Word** = 32-bit quantity
  - **Double-word** = 64-bit quantity

1.1.3 Reserved, Undefined, and Unimplemented Terminology

In tables where register bit fields are defined, the following conventions are used to indicate undefined and unimplemented function. Furthermore, types of bits and bit fields are defined using the abbreviations as shown in **Table 1-1**.

Table 1-1 Bit Function Terminology

Function of Bits	Description
Unimplemented, Reserved	Register bit fields named **0** indicate unimplemented functions with the following behavior. • Reading these bit fields returns 0. • These bit fields should be written with 0 if the bit field is defined as r or rh. • These bit fields have to be written with 0 if the bit field is defined as rw. These bit fields are reserved. The detailed description of these bit fields can be found in the register descriptions.
rw	The bit or bit field can be read and written.
rwh	As rw, but bit or bit field can be also set or reset by hardware.
r	The bit or bit field can only be read (read-only).
w	The bit or bit field can only be written (write-only). A read to this register will always give a default value back.
rh	This bit or bit field can be modified by hardware (read-hardware, typical example: status flags). A read of this bit or bit field give the actual status of this bit or bit field back. Writing to this bit or bit field has no effect to the setting of this bit or bit field.
s	Bits with this attribute are “sticky” in one direction. If their reset value is once overwritten by software, they can be switched again into their reset state only by a reset operation. Software cannot switch this type of bit into its reset state by writing the register. This attribute can be combined to “rws” or “rwhs”.
f	Bits with this attribute are readable only when they are accessed by an instruction fetch. Normal data read operations will return other values.

1.1.4 Register Access Modes

Read and write access to registers and memory locations are sometimes restricted. In memory and register access tables, the terms as defined in **Table 1-2** are used.

Table 1-2 Access Terms

Symbol	Description
U	Access Mode: Access permitted in User Mode 0 or 1.
	Reset Value: Value or bit is not changed by a reset operation.
SV	Access permitted in Supervisor Mode.
R	Read-only register.
32	Only 32-bit word accesses are permitted to this register/address range.
E	Endinit-protected register/address.
PW	Password-protected register/address.
NC	No change, indicated register is not changed.
BE	Indicates that an access to this address range generates a Bus Error.
nBE	Indicates that no Bus Error is generated when accessing this address range, even though it is either an access to an undefined address or the access does not follow the given rules.
nE	Indicates that no Error is generated when accessing this address or address range, even though the access is to an undefined address or address range. True for CPU accesses (MTCR/MFCR) to undefined addresses in the CSFR range.

1.1.5 Abbreviations and Acronyms

The following acronyms and terms are used in this document:

ADC	Analog-to-Digital Converter
AGPR	Address General Purpose Register
ALU	Arithmetic and Logic Unit
ASC	Asynchronous/Synchronous Serial Controller
BCU	Bus Control Unit
BMU	Bus Monitor Unit
BROM	Boot ROM & Test ROM
CAN	Controller Area Network
CMEM	PCP Code Memory
CISC	Complex Instruction Set Computing
CPS	CPU Slave Interface

CPU	Central Processing Unit
CRC	Cyclic Redundancy Code
CSA	Context Save Area
CSFR	Core Special Function Register
CCU6	Capture Compare Unit 6
DAP	Device Access Port
DAS	Device Access Server
DCACHE	Data Cache
DFLASH	Data Flash Memory
DGPR	Data General Purpose Register
DMA	Direct Memory Access
DMI	Data Memory Interface
DSPR	Data Scratch Pad RAM
EBU	External Bus Interface
ECC	Error Correction Code
EMI	Electro-Magnetic Interference
FADC	Fast Analog-to-Digital Converter
FAM	Flash Array Module
FCE	Flexible CRC Engine
FCS	Flash Command State Machine
FIM	Flash Interface and Control Module
FM-PLL	PLL with Frequency Modulation support
FPI	Flexible Peripheral Interconnect (Bus)
FPU	Floating Point Unit
GPIO	General Purpose Input/Output
GPR	General Purpose Register
GPT12	General Purpose Timer 12
GPTA	General Purpose Timer Array
ICACHE	Instruction Cache
I/O	Input / Output
JTAG	Joint Test Action Group = IEEE1149.1
LTC	Local Timer Cell

MCHK	Memory Checker module
MLI	Micro Link Interface
MMU	Memory Management Unit
MSB	Most Significant Bit
MSC	Micro Second Channel
NC	Not Connected
NMI	Non-Maskable Interrupt
OCDS	On-Chip Debug Support
OVRAM	Overlay Memory
PCP	Peripheral Control Processor
PLL	Phase Locked Loop
PFLASH	Program Flash Memory
PMI	Program Memory Interface
PMU	Program Memory Unit
PRAM	PCP Parameter RAM
PSPR	Program Scratch Pad RAM
RAM	Random Access Memory
RISC	Reduced Instruction Set Computing
SBCU	System Peripheral Bus Control Unit
SCU	System Control Unit
SENT	Single Edge Nibble Transmission
SHE	Secure Hardware Extension
SFR	Special Function Register
SPB	System Peripheral Bus
SRI	Shared Resource Interconnect
SRAM	Static Data Memory
SRN	Service Request Node
SSC	Synchronous Serial Controller
SSCG	Synchronous Serial Controller Guardian
STM	System Timer

WDT	Watchdog Timer
XBar, XBar_SRI	Cross Bar Interconnect, based on the Shared Resource Interconnect protocol

1.2 System Architecture of the TC1798

The TC1798 combines three powerful technologies within one silicon die, achieving new levels of power, speed, and economy for embedded applications:

- Reduced Instruction Set Computing (RISC) processor architecture
- Digital Signal Processing (DSP) operations and addressing modes
- On-chip memories and peripherals

DSP operations and addressing modes provide the computational power necessary to efficiently analyze complex real-world signals. The RISC load/store architecture provides high computational bandwidth with low system cost. On-chip memory and peripherals are designed to support even the most demanding high-bandwidth real-time embedded control-systems tasks.

Additional high-level features of the TC1798 include:

- Efficient memory organization: instruction and data scratch memories, caches
- Serial communication interfaces – flexible synchronous and asynchronous modes
- Peripheral Control Processor – standalone data operations and interrupt servicing
- DMA and SDMA Controller – DMA operations and interrupt servicing
- Secure Hardware Extension
- Flexible CRC Engine
- Bus Monitor Unit
- General-purpose timers
- High-performance on-chip buses
- On-chip debugging and emulation facilities
- Flexible interconnections to external components
- Flexible power-management

The TC1798 is a high-performance microcontroller with TriCore CPU, program and data memories, buses, bus arbitration, an interrupt controller, a peripheral control processor and a DMA controller and several on-chip peripherals. The TC1798 is designed to meet the needs of the most demanding embedded control systems applications where the competing issues of price/performance, real-time responsiveness, computational power, data bandwidth, and power consumption are key design elements.

The TC1798 offers several versatile on-chip peripheral units such as serial controllers, timer units, and Analog-to-Digital converters. Within the TC1798, all these peripheral units are connected to the TriCore CPU/system via the Flexible Peripheral Interconnect (FPI) Bus and the Local Memory Bus (SRI). Several I/O lines on the TC1798 ports are reserved for these peripheral units to communicate with the external world.

1.2.1 TC1798 Block Diagram

Figure 1-1 shows the block diagram of the TC1798. Pls. note that not all features that are shown in the block diagram are available in the other TC1798 package variants.

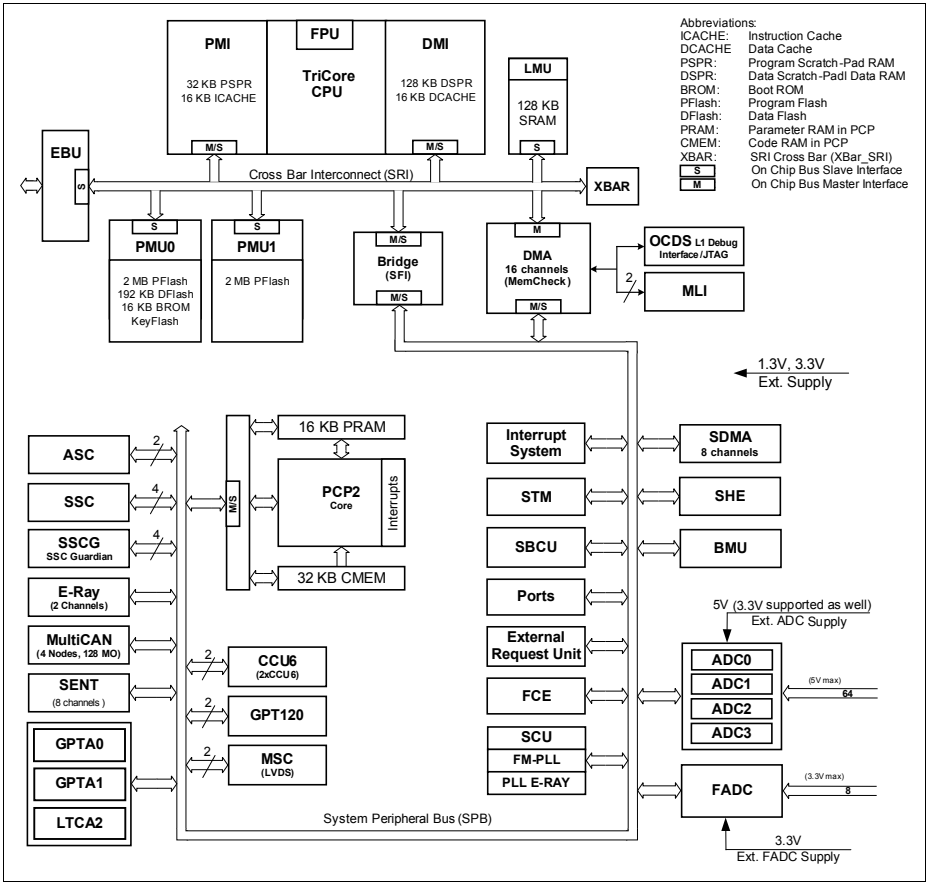

Figure 1-1 TC1798 Block Diagram

1.2.2 CPU Cores of the TC1798

The TC1798 includes a high Performance CPU and a Peripheral Control Processor.

1.2.2.1 High-performance 32-bit CPU

This chapter gives an overview of the TriCore 1.6 architecture.

TriCore (TC1.6) Architectural Highlights

- Unified RISC MCU/DSP
- 32-bit architecture with 4 Gbytes unified data, program, and I/O address space
- 32 general purpose registers with fast automatic context-switching
- Multiply-accumulate unit able to sustain 2 MAC operations per cycle.
- Fully pipelined Floating point unit
- Saturating integer arithmetic
- Bit handling
- Packed data operations
- Zero overhead loop
- Dedicated integer divide unit.
- Precise exceptions
- Flexible power management
- Flexible memory protection system

High-efficiency TriCore Instruction Set

- Powerful instruction set
- Freely mixable 16-bit and 32-bit instructions for reduced code size
- Data types include: Boolean, array of bits, character, signed and unsigned integer, integer with saturation, signed fraction, double-word integers, and IEEE-754 single-precision floating point
- Data formats include: Bit, 8-bit byte, 16-bit half-word, 32-bit word, and 64-bit double-word
- Flexible and efficient addressing mode for high performance and code density

Integrated CPU related On-Chip Memories

- Instruction memory:
  - 32 Kbyte Instruction Scratch-Pad RAM (PSPR)
  - 16 Kbyte Instruction Cache (ICACHE)
- Data memory:
  - 128 Kbyte Data Scratch-Pad RAM (DSPR)
  - 16 Kbyte Data Cache (DACHE)
- All memories are ECC protected

1.2.2.2 High-performance 32-bit Peripheral Control Processor

The PCP is a flexible Peripheral Control Processor optimized for interrupt handling and thus unloading the CPU.

Features

- Data move between any two memory or I/O locations
- Data move with predefined limit supported
- Read-Modify-Write capabilities
- Full computation capabilities including basic MUL/DIV
- Read/move data and accumulate it to previously read data
- Read two data values and perform arithmetic or logical operation and store result
- Bit-handling capabilities (testing, setting, clearing)
- Flow control instructions (conditional/unconditional jumps, breakpoint)
- Programmable write protection for Code Memory and Parameter Memory
- Programmable limit of FPI addresses than can be written by the PCP
- Dedicated Interrupt System
- PCP SRAMs with ECC protection
- High Integrity Operation support

Integrated PCP related On-Chip Memories

- 32 Kbyte Code Memory (CMEM)
- 16 Kbyte Parameter Memory (PRAM)

1.3 On-Chip System Units

The TC1798 microcontroller offers several versatile on-chip system peripheral units such as DMA controller modules (DMA, SDMA), embedded Flash modules (PMU0, PMU1), Flexible CRC Engine (FCE), System Timer Unit (STM), System Control Unit (SCU), Overlay Control Unit (OVC), Local Memory Unit (LMU), Bus Monitor Unit (BMU), Interrupt System and Ports modules.

1.3.1 Flexible Interrupt System

The TC1798 includes a programmable interrupt system with the following features:

1.3.1.1 Feature List

The interrupt system provides the following features:

- Fast interrupt response
- Hardware arbitration
- Independent interrupt systems for CPU and PCP
- Programmable service request nodes (SRNs)
- Each SRN can be mapped to the CPU or PCP interrupt system
- Flexible interrupt-prioritizing scheme with 255 interrupt priority levels per interrupt system

1.3.2 Direct Memory Access Controller (DMA)

The TC1798 includes a fast and flexible DMA controller with 16 independant DMA channels.

1.3.2.1 Feature List

The DMA controller provides the following features:

- 16 independent DMA channels
  - 2 DMA Sub-Blocks with (8 DMA channels per DMA Sub-Block)
  - DMA Sub-Blocks with support of parallel channel execution (1 channel per Sub-Block, both Sub-Blocks in parallel)
  - Up to 16 selectable request inputs per DMA channel
  - 2-level programmable priority of DMA channels within the DMA Sub-Block
  - Software and hardware DMA request
  - Hardware requests by selected on-chip peripherals and external inputs
- 3-level programmable priority of the DMA Sub-Blocks at the on chip bus interfaces
- Buffer capability for move actions on the buses (at least 1 move per bus is buffered)
- Individually programmable operation modes for each DMA channel
  - Single Mode: stops and disables DMA channel after a predefined number of DMA transfers

  - Continuous Mode: DMA channel remains enabled after a predefined number of DMA transfers; DMA transaction can be repeated
  - Programmable address modification
  - Two shadow register modes (with / w/o automatic re-set and direct write access).
- Full 32-bit addressing capability of each DMA channel
  - 4 Gbyte address range
  - Data block move supports > 32 Kbyte moves per DMA transaction
  - Circular buffer addressing mode with flexible circular buffer sizes
- Programmable data width of DMA transfer/transaction: 8-bit, 16-bit, or 32-bit
- Register set for each DMA channel
  - Source and destination address register
  - Channel control and status register
  - Transfer count register
- Flexible interrupt generation (the service request node logic for the MLI channels is also implemented in the DMA modules)
- DMA module is working on SPB frequency, SRI interface on CPU frequency.
- Dependant on the target/destination address, Read/write requests from the Move Engines are directed to the SPB, LMB, MLIs or to the the Cerberus.

1.3.3 Safe Direct Memory Access Controller

The TC1798 includes a fast and flexible Safe DMA controller with 8 independant DMA channels. Additionally to the normal DMA channels, the Safe DMA channels extended with CRC features for the read data, source and destination address.

1.3.3.1 Feature List

The SDMA provides the following features:

- 8 independent DMA channels
  - 8 DMA channels in the DMA Sub-Block
  - Up to 16 selectable request inputs per DMA channel
  - 2-level programmable priority of DMA channels within the DMA Sub-Block
  - Software and hardware DMA request
  - Hardware requests by selected on-chip peripherals and external inputs
-
- Upper and lower address boundary checking of the source and destination address.
- 3-level programmable priority of the DMA Sub-Block at the on chip bus interfaces
- Buffer capability for move actions on the buses (at least 1 move per bus is buffered)
- Individually programmable operation modes for each DMA channel
  - Single Mode: stops and disables DMA channel after a predefined number of DMA transfers
  - Continuous Mode: DMA channel remains enabled after a predefined number of DMA transfers; DMA transaction can be repeated

  - Programmable address modification
  - Two shadow register modes (with / w/o automatic re-set and direct write access).
- Full 32-bit addressing capability of each DMA channel
  - 4 Gbyte address range
  - Data block move supports > 32 Kbyte moves per DMA transaction
  - Circular buffer addressing mode with flexible circular buffer sizes
- Programmable data width of DMA transfer/transaction: 8-bit, 16-bit, or 32-bit
- Register set for each DMA channel
  - Source and destination address register
  - Channel control and status register
  - Transfer count register
- Generation of unique CRC checksums for source and destination addresses.
- Generation of in-line CRC checksum for read data.
- Flexible interrupt generation
- DMA module is working on SPB frequency.

1.3.4 Flexible CRC Engine (FCE)

The Flexible CRC Engine (FCE) module provides a parallel implementation of one or more Cyclic Redundancy Code (CRC) algorithms. The standard CRC polynomial implemented in the FCE module is the IEEE 802.3 ethernet CRC32. The FCE is meant to be used as an hardware acceleration engine for software applications or operating systems services (compatible with Autosar CRC “specification of CRC Routines”) using CRC signatures.

1.3.4.1 Feature List

The FCE provides the following features:

- Two CRC polynomials:
  - IEEE 802.3 CRC32 ethernet polynomial: 0x82608EDB (CRC kernel 0)
  - CRC32C Castagnoli: 0xD419CC15 (CRC kernel 1)
- Parallel CRC implementation (32-bits wide)
  - Data blocks to be computed by FCE shall be a multiple of 32-bits
  - Start address of Data blocks to be computed by FCE shall be at least 32-bits aligned
- Register Interface compliant with Autosar specification for CRC routines. Enables to support reentrant software routines via a software-based save/restore mechanism.
- Extended register interface to control reliability of FCE execution.
- Redundant implementation of critical control registers
- Error notification scheme via dedicated interrupt node
- Support of hardware configuration:

– Each CRC kernel supports as generic parameter the degree of the polynomial (POLY_DEGREE) directly controlling the width of the FCE data path. Only 32, 16 and 8 are allowed.
– FCE is designed as a multi - CRC kernel structure supporting concurrent operation of each CRC - kernel.

1.3.5 System Timer (STM)

The TC1798's STM is designed for global system timing applications requiring both high precision and long range.

1.3.5.1 Feature List

The System Timer provides the following features:

- Free-running 56-bit counter
- All 56 bits can be read synchronously
- Different 32-bit portions of the 56-bit counter can be read synchronously
- Flexible interrupt generation based on compare match with partial STM content
- Counting starts automatically after a reset operation
- STM registers are reset by an application reset if bit ARSTDIS.STMDIS is cleared. If bit ARSTDIS.STMDIS is set, the STM registers are not reset.[1)]
- STM can be halted in debug/suspend mode

Special STM register semantics provide synchronous views of the entire 56-bit counter, or 32-bit subsets at different levels of resolution.

The maximum clock period is $2^{56} \times f_{STM}$. At f_{STM} = 90 MHz, for example, the STM counts 25.39 years before overflowing. Thus, it is capable of continuously timing the entire expected product life time of a system without overflowing.

The STM can be optionally disabled for power-saving purposes, or suspended for debugging purposes via its clock control register. In suspend mode of the TC1798 (initiated by writing an appropriate value to STM_CLC register), the STM clock is stopped but all registers are still readable.

Due to the 56-bit width of the STM, it is not possible to read its entire content with one instruction. It needs to be read with two load instructions. Since the timer would continue to count between the two load operations, there is a chance that the two values read are not consistent (due to possible overflow from the low part of the timer to the high part between the two read operations). To enable a synchronous and consistent reading of the STM content, a capture register (STM_CAP) is implemented. It latches the content of the high part of the STM each time when one of the registers STM_TIM0 to STM_TIM5 is read. Thus, STM_CAP holds the upper value of the timer at exactly the same time

1) "STM registers" means all registers except STM_CLC, STM_SRC0, and STM_SRC1.

when the lower part is read. The second read operation would then read the content of the STM_CAP to get the complete timer value.

The content of the 56-bit System Timer can be compared against the content of two compare values stored in the STM_CMP0 and STM_CMP1 registers. Interrupts can be generated on a compare match of the STM with the STM_CMP0 or STM_CMP1 registers.

Figure 1-2 provides an overview on the STM module. It shows the options for reading parts of STM content.

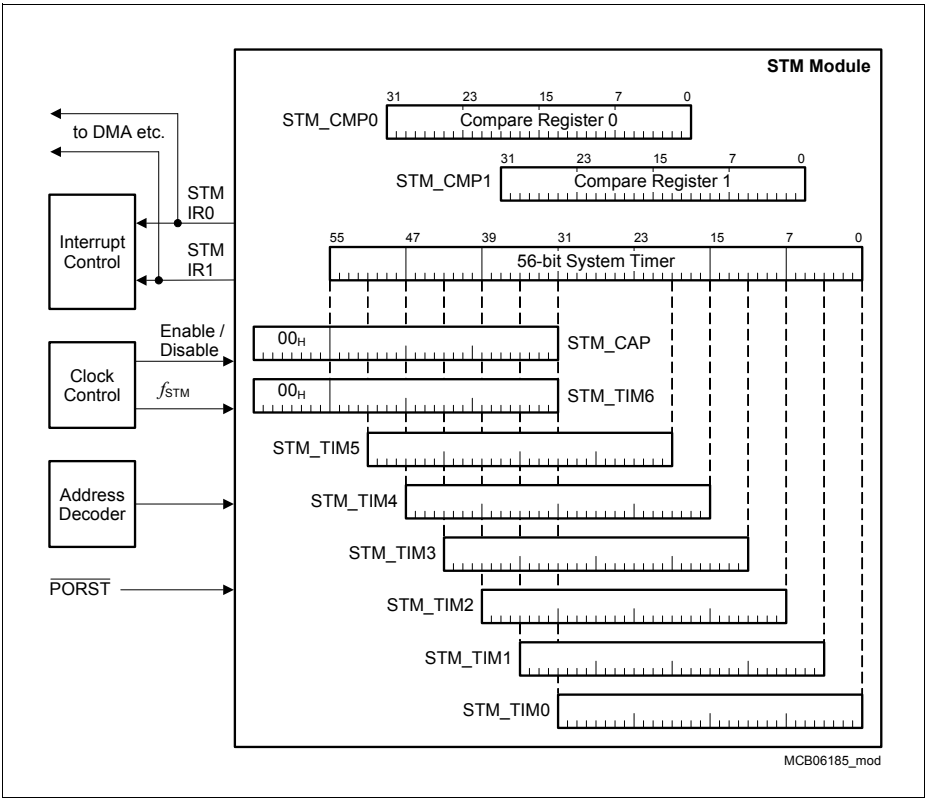

Figure 1-2 General Block Diagram of the STM Module Registers

1.3.6 System Control Unit (SCU)

The following SCU introduction gives an overview about the TC1798 System Control Unit (SCU).

The System Control Unit (SCU) of the TC1798 handles all system control tasks beside the debug related tasks which are controlled by the OCDS/Cerberus.

The SCU contains the following functional sub-blocks:

- Clock Control
- Reset Operation
- External Interface
- Power Management
- Software Boot Support
- SRAM ECC Control
- Die Temperature Measurement
- Watchdog Timer
- Emergency Stop Control
- NMI Trap Generation

1.3.6.1 Clock Generation Unit (CGU)

The Clock Generation Unit (CGU) allows a very flexible clock generation for the TC1798. During user program execution the frequency can be programmed for an optimal ratio between performance and power consumption.

1.3.6.2 Features of the Watchdog Timer (WDT)

The main features of the WDT are summarized here.

- 16-bit Watchdog counter
- Selectable input frequency: $f_{FPI}/256$ or $f_{FPI}/16384$
- 16-bit user-definable reload value for normal Watchdog operation, fixed reload value for Time-Out and Prewarning Modes
- Incorporation of the ENDINIT bit and monitoring of its modifications
- Sophisticated Password Access mechanism with fixed and user-definable password fields
- Access Error Detection: Invalid password (during first access) or invalid guard bits (during second access) trigger the Watchdog reset generation
- Overflow Error Detection: An overflow of the counter triggers the Watchdog reset generation
- Watchdog function can be disabled; access protection and ENDINIT monitor function remain enabled
- Double Reset Detection: If a Watchdog induced reset occurs twice, a severe system malfunction is assumed and the TC1798 is held in reset until a system / class 0 reset occurs. This prevents the device from being periodically reset if, for instance,

connection to the external memory has been lost such that even system initialization could not be performed

1.3.6.3 Reset Operation

The following reset request triggers are available:

- 1 External power-on hardware reset request trigger; $\overline{\text{PORST}}$, (cold reset)
- 2 External System Request reset triggers; $\overline{\text{ESR0}}$ and $\overline{\text{ESR1}}$ (cold/warm reset)
- Watchdog Timer (WDT) reset request trigger, (warm reset)
- Software reset (SW), (warm reset)
- Debug (OCDS) reset request trigger, (warm reset)
- JTAG reset (special reset)
- Resets via the JTAG interface

Note: The JTAG and OCDS resets are described in the OCDS chapter.

There are two basic types of reset request triggers:

- Trigger sources that do not depend on a clock, such as the $\overline{\text{PORST}}$. This trigger force the device into an asynchronous reset assertion independently of any clock. The activation of an asynchronous reset is asynchronous to the system clock, whereas its de-assertion is synchronized.
- Trigger sources that need a clock in order to be asserted, such as the input signals $\overline{\text{ESR0}}$, $\overline{\text{ESR1}}$, and $\overline{\text{ESR2}}$, the WDT trigger, the parity trigger, or the SW trigger.

1.3.6.4 External Interface (ESR, ERU)

The SCU provides interface pads for system purpose. Various functions are covered by these pins. Due to the different tasks some of the pads can not be shared with other functions but most of them can be shared with other functions. The following functions are covered by the SCU controlled pads:

- Reset request triggers
- Reset indication
- Trap request triggers
- Interrupt request triggers
- Non SCU module triggers

The first three points are covered by the ESR pads and the last two points by the ERU pads.

1.3.6.5 Die Temperature Measurement (DTS)

The Die Temperature Sensor (DTS) generates a measurement result that indicates directly the current temperature. The result of the measurement can be read via an DTS register.

1.3.7 General Purpose I/O Ports and Peripheral I/O Lines (Ports)

The TC1798 has port connections to interface with its peripherals and external devices. As an input port line, the digital signal from other parts of a circuit can be read. Alternatively, the port can act as output to control or signal to other peripherals or devices.

The TC1798 has a port structure where each port line has a number of control and data bits, enabling flexible usage of the line. If a peripheral unit uses a GPIO port line as a bi-directional I/O line, each port pin can be configured for input or output operation.

In input mode, it is possible to activate the internal weak pull-up, pull-down, or no input pull device. Input signals are connected directly to the various inputs of the peripheral units. Push-pull or open drain out put modes are available for selection. In addition, the pad output driver strength can be programmed individually for each port line. The pads are also capable to be configured for different pad levels.

When the port is in output mode, the digital level of the pin can be read by software through the input path or a peripheral can use the pin level as an input.The output multiplexer selects the signal source for the GPIO line when used as output. If the pin is used as general-purpose output, the multiplexer is switched to the Output Data Register Pn_OUT. The logic state of a port line can be set, cleared or toggled bit-wise.

When selected as general-purpose output line, the actual logic level at the pin can be examined and compared against the applied output level. This can be used to detect some electrical failures at the pin caused through external circuitry.

1.3.7.1 Feature List

The Port modules provide the following features:

- Digital General-Purpose Input/Output (GPIO) port lines
- Input/output functionality individually programmable for each port line
- Programmable input characteristics (pull-up, pull-down, no pull device)
- Pad output driver strength can be programmed individually for each port port line to minimize EMI (weak, medium, strong)
- Programmable output characteristics (push-pull, open drain)
- Programmable alternate output functions
- Output lines of each port can be updated port-wise or set/reset/toggled bit-wise

1.3.8 Program Memory Unit (PMU)

The Program Memory Unit “PMU” is part of the processor subsystem. The PMUs control the Flash memory and the Boot ROM.

The devices of the Audo-Max have at least one Program Memory Unit. This is named “PMU0”. With increasing Flash memory more PMUs are added which are named “PMU1”, and so on.

The TC1798 includes 2 PMUs (PMU0, PMU1). The exact configuration of each PMU is described in the PMU chapter in this document. Derived devices with a reduced set of memories may exist. Their configuration is contained in the data sheet.

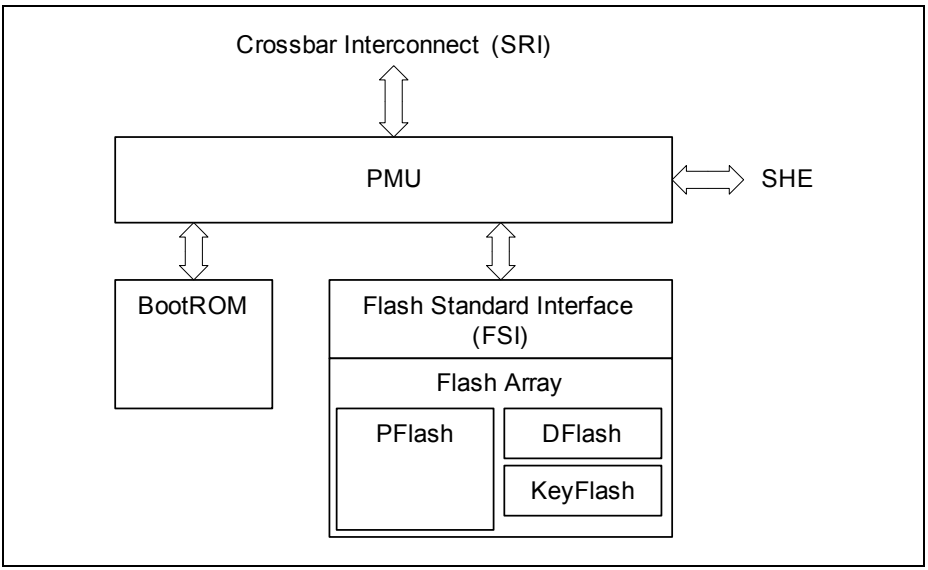

Figure 1-3 PMU Basic Block Diagram

1.3.8.1 Feature List

The PMU modules provides the following features:

- BootROM (“BROM”), only in PMU0.
- Program Flash (“PFlash”):
  - PMU0: 2 MByte.
  - PMU1: 2 MByte.
- Data Flash (“DFlash”):
  - PMU0: 192 KByte.
- Security Flash for SHE (“KeyFlash”).
- SRI slave interface for all assigned Flash memories and registers.

- Flash command control.
- Flash and BROM access control.
- Tuning Protection.
- Interface to security module SHE.

1.3.9 Secure Hardware Extension (SHE)

The SHE module realizes the functionality defined by HIS as “SHE” (Secure Hardware Extension). The storage of keys is done by the PMU0.

For further information please contact your Infineon representative.

1.3.10 Local Memory Unit (LMU)

The Local Memory Unit is an SRI peripheral providing access to volatile memory resources. It’s primary purpose is to provide 128 Kbytes of local memory for general purpose usage but it will also provide access to the separate block of emulation and debug memory (EMEM) provided in the Emulation Devices.

1.3.10.1 Feature List

An overview of the features implemented in the LMU follows:

- 128 Kbytes of SRAM
  - organised as 64 bit words
  - support for burst access
  - support of single data access (byte, half word, word accesses and double word)
  - ECC protection
- Interface to the EMEM of the ED device.
- OLDA region support.

1.3.11 Data Access Overlay (OVC)

The data overlay functionality provides the capability to redirect data accesses by the TriCore to program memory (internal Program Flash or external memory) to the SRAM in the Local Memory Unit (LMU), or to the Emulation Memory in Emulation Device ED, or to the external memory. This functionality makes it possible, for example, to modify the application's test and calibration parameters (which are typically stored in the program memory) during run time of a program. Note that read and write data accesses from/to program memory are redirected.

1.3.11.1 Feature List

The Data Access Overlay provides the following features:

- 16 overlay ranges ("blocks") configurable for Program Flash and external memory
- Supports usage of LMU SRAM (128 KB) as internal overlay memory
- Support of up to 512 Kbyte overlay/calibration memory in Emulation Device (EMEM)
- Support of up to 2 MB overlay memory in external memory (EBU space)
- Support of Online Data Acquisition into range of up to 32 KB and of its overlay
- Support of different overlay memory selections for every enabled overlay block
- Sizes of overlay blocks selectable from 16 byte to 512 Kbyte
- All configured overlay ranges can be enabled with only one register write access
- Programmable flush (invalidate) control for data cache in DMI

1.4 On-Chip Peripheral Units of the TC1798

The TC1798 microcontroller offers several versatile on-chip peripheral units such as serial controllers, timer units, and Analog-to-Digital converters. Several I/O lines on the TC1798 ports are reserved for these peripheral units to communicate with the external world.

On-Chip Peripheral Units

- Two Asynchronous/Synchronous Serial Channels (ASC) with baud-rate generator, parity, framing and overrun error detection
- Four Synchronous Serial Channels (SSC) with programmable data length and shift direction
- Four SSC Guardian modules (SSCG, one related to each SSC module)
- Two Micro Second Bus Interfaces (MSC) for serial communication
- One CAN Module with four CAN nodes (MultiCAN) for high-efficiency data handling via FIFO buffering and gateway data transfer
- Two Micro Link Serial Bus Interfaces (MLI) for serial multiprocessor communication
- Two General Purpose Timer Arrays (GPTA) with a powerful set of digital signal filtering and timer functionality to accomplish autonomous and complex Input/Output management. One additional Local Timer Cell Array (LCTA).
- Four CapCom 6 Unit modules (CCU6)
- Two General Purpose 12 Timer Units (GPT12)
- One SENT module (SENT) with support of 8 serial communication lines
- Four Analog-to-Digital Converter Units (ADC) with 8-bit, 10-bit, or 12-bit resolution.
- One fast Analog-to-Digital Converter Unit (FADC)
- One FlexRay™ module with 2 channels (E-Ray).
- One External Bus Interface (EBU)

1.4.1 Asynchronous/Synchronous Serial Interfaces (ASC)

The TC1798 includes two Asynchronous/Synchronous Serial Interfaces, ASC0 and ASC1. Both ASC modules have the same functionality.

Figure 1-5 shows a global view of the Asynchronous/Synchronous Serial Interface (ASC).

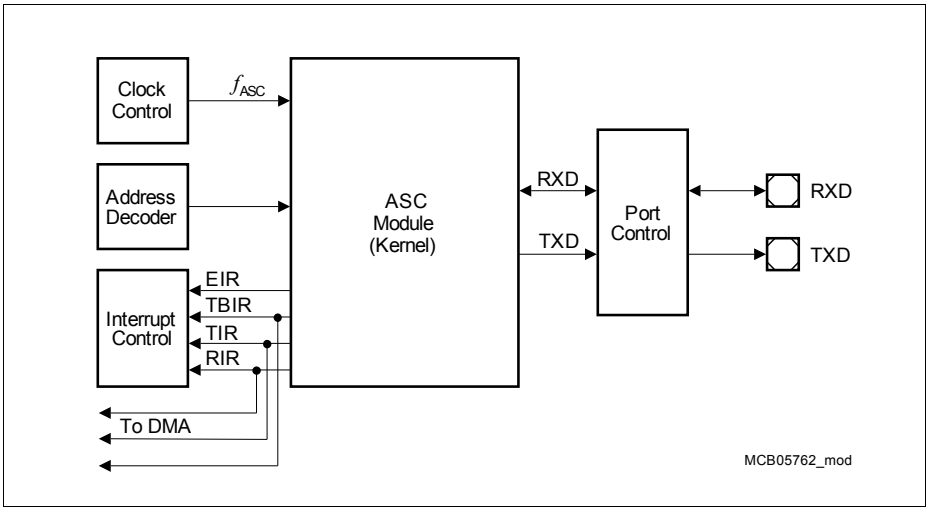

Figure 1-4 General Block Diagram of the ASC Interface

The ASC provides serial communication between the TC1798 and other microcontrollers, microprocessors, or external peripherals.

The ASC supports full-duplex asynchronous communication and half-duplex synchronous communication. In Synchronous Mode, data is transmitted or received synchronous to a shift clock that is generated by the ASC internally. In Asynchronous Mode, 8-bit or 9-bit data transfer, parity generation, and the number of stop bits can be selected. Parity, framing, and overrun error detection are provided to increase the reliability of data transfers. Transmission and reception of data is double-buffered. For multiprocessor communication, a mechanism is included to distinguish address bytes from data bytes. Testing is supported by a loop-back option. A 13-bit baud rate generator provides the ASC with a separate serial clock signal, which can be accurately adjusted by a prescaler implemented as fractional divider.

1.4.1.1 Feature List

The ASC module provides the following features:

- Full-duplex asynchronous operating modes
  - 8-bit or 9-bit data frames, LSB first
  - Parity-bit generation/checking
  - One or two stop bits
  - Baud rate from 6.875 Mbit/s to 1.64 bit/s (@ 110 MHz module clock)
  - Multiprocessor mode for automatic address/data byte detection
  - Loop-back capability

- Half-duplex 8-bit synchronous operating mode
  - Baud rate from 13.75 Mbit/s to 1119 bit/s (@ 110 MHz module clock)
- Double-buffered transmitter/receiver
- Interrupt generation
  - On a transmit buffer empty condition
  - On a transmit last bit of a frame condition
  - On a receive buffer full condition
  - On an error condition (frame, parity, overrun error)
- Implementation features
  - Connections to DMA Controller
  - Connections of receiver input to GPTA (LTC) for baud rate detection and LIN break signal measuring

1.4.2 High-Speed Synchronous Serial Interfaces (SSC)

The TC1798 includes four High-Speed Synchronous Serial Interfaces, SSC0, SSC1, SSC2 and SSC3. All SSC modules have the same functionality.

Figure 1-5 shows a global view of the of the Synchronous Serial interface (SSC).

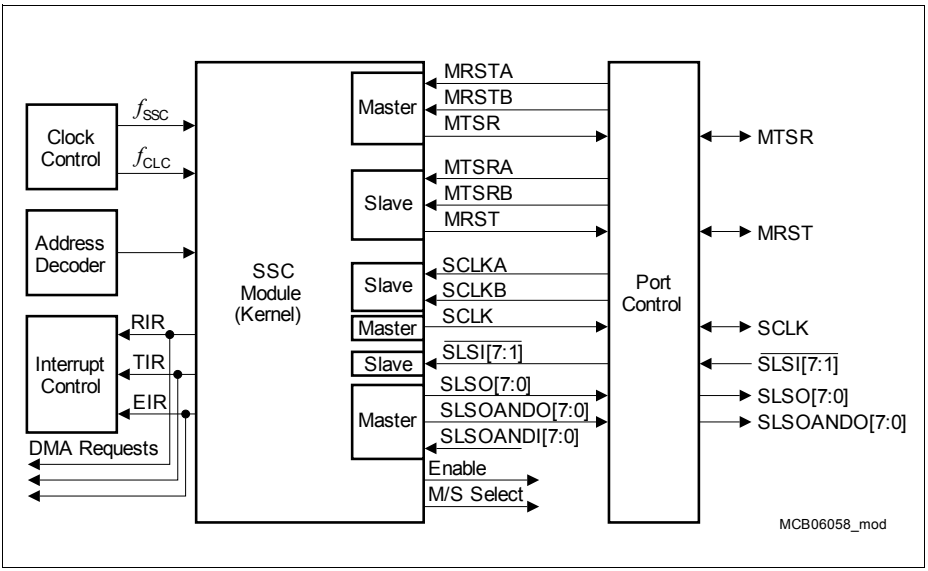

Figure 1-5 General Block Diagram of the SSC Interface

The SSC supports full-duplex and half-duplex serial synchronous communication up to 55.0 Mbit/s (@ 110.0 MHz module clock, Master Mode). The serial clock signal can be generated by the SSC itself (Master Mode) or can be received from an external master (Slave Mode). Data width, shift direction, clock polarity and phase are programmable. This allows communication with SPI-compatible devices. Transmission and reception of data is double-buffered. A shift clock generator provides the SSC with a separate serial clock signal. Seven slave select inputs are available for Slave Mode operation. Eight programmable slave select outputs (chip selects) are supported in Master Mode.

1.4.2.1 Feature List

The SSC module provides the following features:

- Master and Slave Mode operation
  - Full-duplex or half-duplex operation
  - Automatic pad control possible
- Flexible data format

  - Programmable number of data bits: 2 to 16 data bits (with parity: 1 to 15 data bits)
  - Programmable shift direction: LSB or MSB shift first
  - Programmable clock polarity: Idle low or idle high state for the shift clock
  - Programmable clock/data phase: Data shift with leading or trailing edge of the shift clock
- Baud rate generation
  - Master Mode: 55.0 Mbit/s to 839.3 bit/s (@ 110 MHz module clock)
  - Slave Mode: 27.5 Mbit/s to 839.3 bit/s (@ 110 MHz module clock)
- Interrupt generation
  - On a transmitter empty condition
  - On a receiver full condition
  - On an error condition (receive, phase, baud rate, transmit error, parity error)
- Queued SSC Mode supports control and data handling by the DMA controller
- Flexible SSC pin configuration
- Hardware supported parity mode
  - Individually selectable for transmit and receive frames
  - Even/odd parity selection
- Seven slave select inputs $\overline{\text{SLSI}}$[7:1] in Slave Mode
- Eight programmable slave select outputs SLSO[7:0] in Master Mode
  - Automatic SLSO generation with programmable timing
  - Programmable active level and enable control
  - Combinable with SLSO output signals from other SSC modules

1.4.3 Synchronous Serial Interface Guardian (SSCG)

Figure 1-6 shows a sub-system consisting of
- one SSC module SSC0
- one SSCG module SSCG0

This sub-system can be analyzed independently of the rest of the chip. One chip can contain one or more such subsystems. The SSCG module monitors the output signals of the corresponding SSC module and in case of a mismatch between the expected and the ongoing signals, it raises an error.

The TC1798 includes four High-Speed Synchronous Serial Interfaces, SSC0, SSC1, SSC2 and SSC3 and four guardians respectively. All SSCx/SSCGx subsistems provide the same functionality.

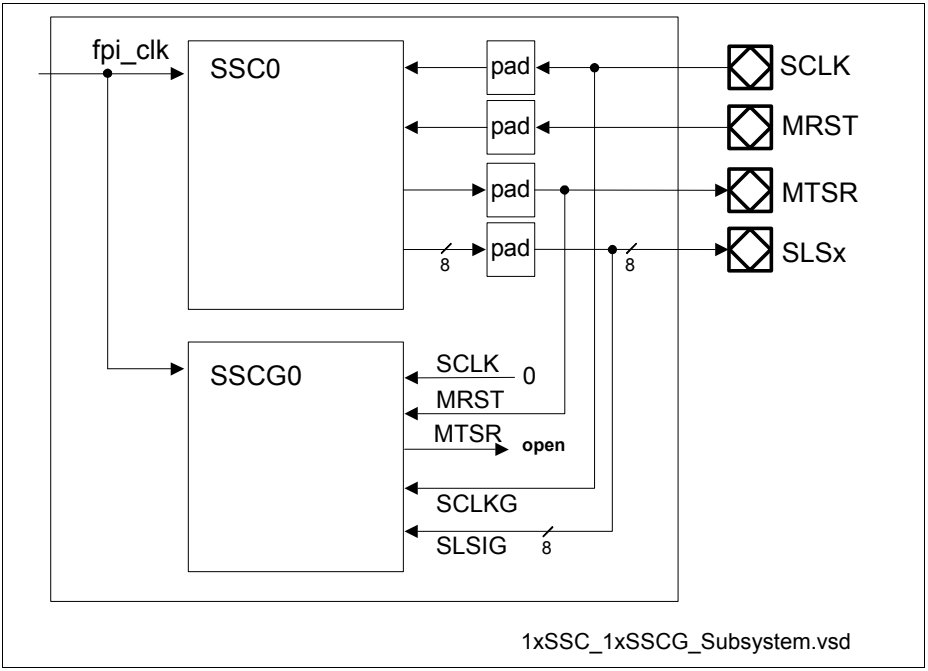

Figure 1-6 General Block Diagram of an SSC / SSCG Sub-System

1.4.3.1 Feature List

The SSCG module provides the following features:

- All output signals of the SSC monitored: data, clock and slave selects.
- Signals monitored after the output driver; it is included in the monitored loop

- Maximum monitored baud-rate of 4 MBaud .

1.4.4 Micro Second Channel Interface (MSC)

The TC1798 includes two Micro Second Channel interfaces, MSC0 and MSC1. Both MSC modules have the same functionality.

The Micro Second Channel (MSC) interface provides serial communication links typically used to connect power switches or other peripheral devices. The serial communication link includes a fast synchronous downstream channel and a slow asynchronous upstream channel. **Figure 1-7** shows a global view of the interface signals of an MSC interface.

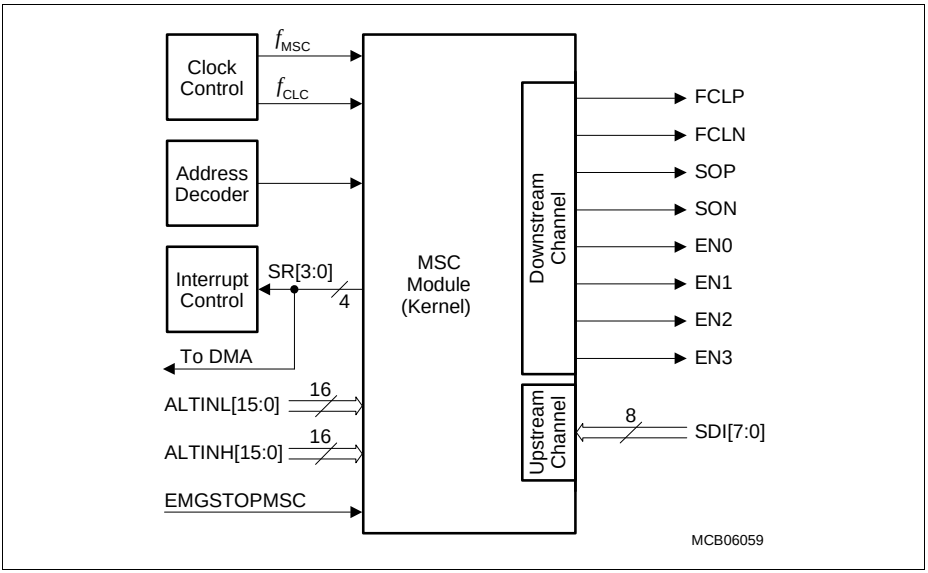

Figure 1-7 General Block Diagram of the MSC Interface

The downstream and upstream channels of the MSC module communicate with the external world via nine I/O lines. Eight output lines are required for the serial communication of the downstream channel (clock, data, and enable signals). One out of eight input lines SDI[7:0] is used as serial data input signal for the upstream channel. The source of the serial data to be transmitted by the downstream channel can be MSC register contents or data that is provided on the ALTINL/ALTINH input lines. These input lines are typically connected with other on-chip peripheral units (for example with a timer unit such as the GPTA). An emergency stop input signal makes it possible to set bits of the serial data stream to dedicated values in an emergency case.

Clock control, address decoding, and interrupt service request control are managed outside the MSC module kernel. Service request outputs are able to trigger an interrupt or a DMA request.

1.4.4.1 Feature List

The Micro Second Bus module provides the following features:

- Fast synchronous serial interface to connect power switches in particular, or other peripheral devices via serial buses
- High-speed synchronous serial transmission on downstream channel
  - Serial output clock frequency: $f_{FCL} = f_{MSC}/2$ (f_{MSCmax} = 110 MHz)
  - Fractional clock divider for precise frequency control of serial clock f_{MSC}
  - Command, data, and passive frame types
  - Start of serial frame: Software-controlled, timer-controlled, or free-running
  - Transmission with or without SEL bit
  - Flexible chip select generation indicates status during serial frame transmission
  - Emergency stop without CPU intervention
- Low-speed asynchronous serial reception on upstream channel
  - Baud rate: f_{MSC} divided by 4, 8, 16, 32, 64, 128, or 256 (f_{MSCmax} = 110 MHz)
  - Standard asynchronous serial frames
  - Programmable upstream data frame length (16 or 12 bits)
  - Parity error checker
  - 8-to-1 input multiplexer for SDI lines
  - Built-in spike filter on SDI lines
- Selectable pin types of downstream channel interface:
  four LVDS differential output drivers or four digital GPIO pins

1.4.5 FlexRay™ Protocol Controller (E-Ray)

The E-Ray IP-module performs communication according to the FlexRay™ [1] protocol specification v2.1. With maximum specified clock the bitrate can be programmed to values up to 10 Mbit/s. Additional bus driver (BD) hardware is required for connection to the physical layer.

1.4.5.1 E-Ray Kernel Description

Figure 1.4.5.1 shows a global view of the E-Ray interface.

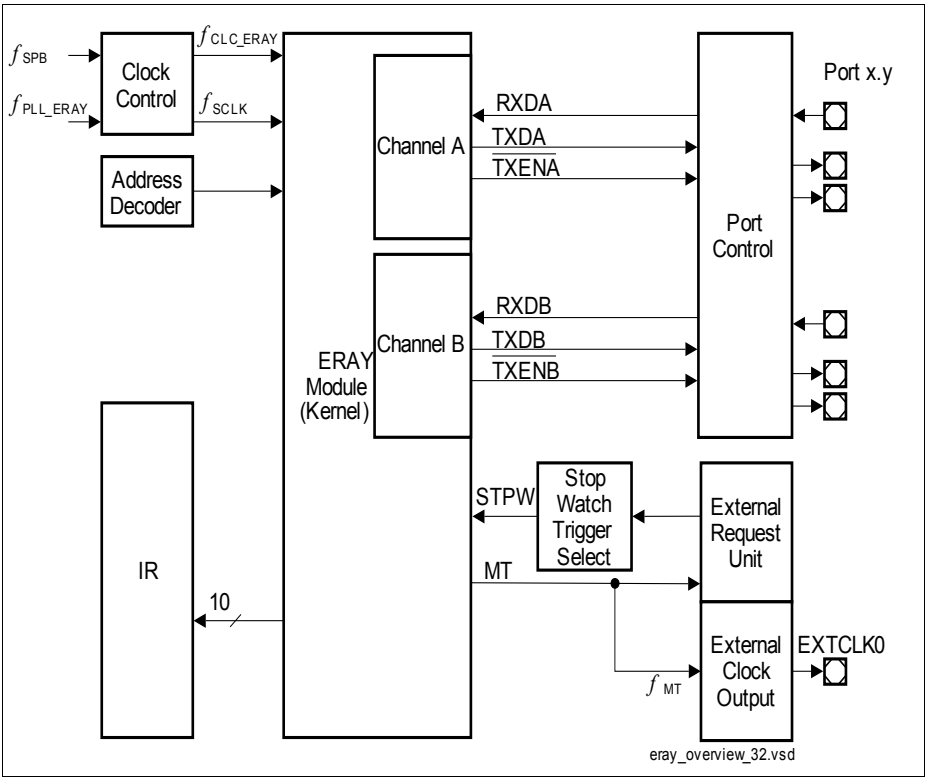

Figure 1-8 General Block Diagram of the E-Ray Interface

1) *Infineon®, Infineon Technologies®, are trademarks of Infineon Technologies AG. FlexRay™* is a trademark of FlexRay Consortium.

The E-Ray module communicates with the external world via three I/O lines each channel. The RXDAx and RXDBx lines are the receive data input signals, TXDA and TXDB lines are the transmit output signals, $\overline{\text{TXENA}}$ and $\overline{\text{TXENB}}$ the transmit enable signals.

Clock control, address decoding, and service request control are managed outside the E-Ray module kernel.

1.4.5.2 Overview

For communication on a FlexRay™ network, individual Message Buffers with up to 254 data byte are configurable. The message storage consists of a single-ported Message RAM that holds up to 128 Message Buffers. All functions concerning the handling of messages are implemented in the Message Handler. Those functions are the acceptance filtering, the transfer of messages between the two FlexRay™ Channel Protocol Controllers and the Message RAM, maintaining the transmission schedule as well as providing message status information.

The register set of the E-Ray IP-module can be accessed directly by an external Host via the module's Host interface. These registers are used to control/configure/monitor the FlexRay™ Channel Protocol Controllers, Message Handler, Global Time Unit, System Universal Control, Frame and Symbol Processing, Network Management, Service Request Control, and to access the Message RAM via Input / Output Buffer.

1.4.5.3 Features List

The E-Ray IP-module provides the following features:

- Conformance with FlexRay™ protocol specification v2.1
- Data rates of up to 10 Mbit/s on each channel
- Up to 128 Message Buffers configurable
- 8 Kbyte of Message RAM for storage of e.g. 128 Message Buffers with max. 48 byte data field or up to 30 Message Buffers with 254 byte Data Sections
- Configuration of Message Buffers with different payload lengths possible
- One configurable receive FIFO
- Each Message Buffer can be configured as receive buffer, as transmit buffer or as part of the receive FIFO
- Host access to Message Buffers via Input and Output Buffer.
  Input Buffer: Holds message to be transferred to the Message RAM
  Output Buffer: Holds message read from the Message RAM
- Filtering for slot counter, cycle counter, and channel
- Maskable module service requests
- Network Management supported
- Four service request lines

- Automatic delayed read access to Output Command Request Register (OBCR) if a data transfer from Message RAM to Output Shadow Buffer (initiated by a previous write access to the OBCR) is ongoing.
- Automatic delayed read access to Input Command Request Register (IBCR) if a data transfer from Input Shadow Buffer to Message RAM to (initiated by a previous write access to the IBCR) is ongoing.
- Four Input Buffer for building up transmission Frames in parallel.
- Flag indicating which Input Buffer is currently accessible by the host.

1.4.6 MultiCAN Controller

The MultiCAN module provides four independent CAN nodes, representing four serial communication interfaces. There is a TTCAN extension available on the node 0. The number of available message objects is 128.

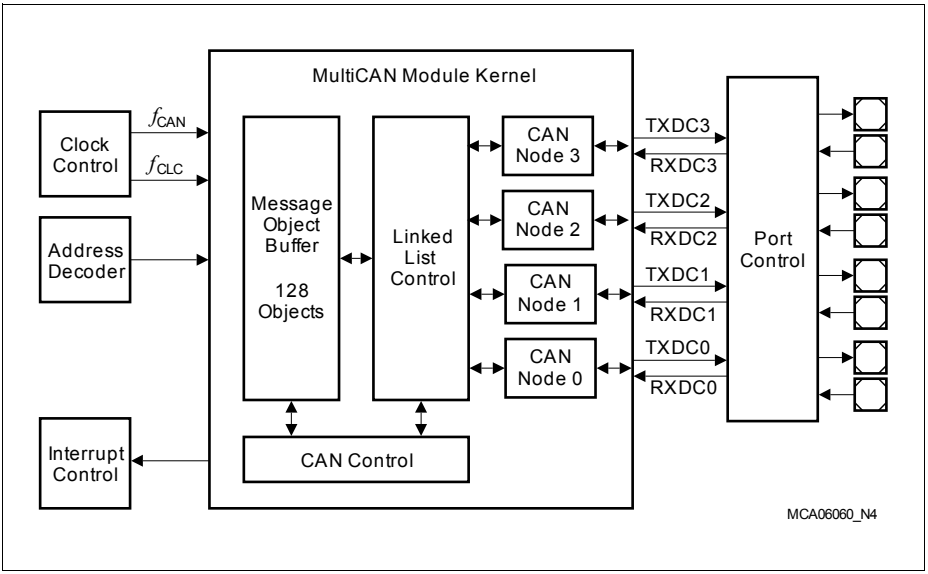

Figure 1-9 Overview of the MultiCAN Module

The MultiCAN module contains four independently operating CAN nodes with Full-CAN functionality that are able to exchange Data and Remote Frames via a gateway function. Transmission and reception of CAN frames is handled in accordance to CAN specification V2.0 B (active). Each CAN node can receive and transmit standard frames with 11-bit identifiers as well as extended frames with 29-bit identifiers.

All four CAN nodes share a common set of message objects. Each message object can be individually allocated to one of the CAN nodes. Besides serving as a storage container for incoming and outgoing frames, message objects can be combined to build gateways between the CAN nodes or to set up a FIFO buffer.

The message objects are organized in double-chained linked lists, where each CAN node has its own list of message objects. A CAN node stores frames only into message objects that are allocated to the message object list of the CAN node, and it transmits only messages belonging to this message object list. A powerful, command-driven list controller performs all message object list operations.

The bit timings for the CAN nodes are derived from the module timer clock (f_{CAN}) and are programmable up to a data rate of 1 Mbit/s. External bus transceivers are connected to a CAN node via a pair of receive and transmit pins.

1.4.6.1 MultiCAN Feature List

The Mulitican module provides the following features:

- Compliant with ISO 11898
- CAN functionality according to CAN specification V2.0 B active
- Dedicated control registers for each CAN node
- Data transfer rates up to 1 Mbit/s
- Flexible and powerful message transfer control and error handling capabilities
- Advanced CAN bus bit timing analysis and baud rate detection for each CAN node via a frame counter
- Full-CAN functionality: A set of 128 message objects can be individually
  - Allocated (assigned) to any CAN node
  - Configured as transmit or receive object
  - Setup to handle frames with 11-bit or 29-bit identifier
  - Identified by a timestamp via a frame counter
  - Configured to remote monitoring mode
- Advanced Acceptance Filtering
  - Each message object provides an individual acceptance mask to filter incoming frames
  - A message object can be configured to accept standard or extended frames or to accept both standard and extended frames
  - Message objects can be grouped into four priority classes for transmission and reception
  - The selection of the message to be transmitted first can be based on frame identifier, IDE bit and RTR bit according to CAN arbitration rules, or on its order in the list
- Advanced message object functionality
  - Message objects can be combined to build FIFO message buffers of arbitrary size, limited only by the total number of message objects
  - Message objects can be linked to form a gateway that automatically transfers frames between 2 different CAN buses. A single gateway can link any two CAN nodes. An arbitrary number of gateways can be defined
- Advanced data management
  - The message objects are organized in double-chained lists
  - List reorganizations can be performed at any time, even during full operation of the CAN nodes
  - A powerful, command-driven list controller manages the organization of the list structure and ensures consistency of the list

  - Message FIFOs are based on the list structure and can easily be scaled in size during CAN operation
  - Static allocation commands offer compatibility with MultiCAN applications that are not list-based
- Advanced interrupt handling
  - Up to 16 interrupt output lines are available. Interrupt requests can be routed individually to one of the 16 interrupt output lines
  - Message post-processing notifications can be combined flexibly into a dedicated register field of 256 notification bits
- Module internal SRAM with ECC protection

1.4.6.2 TTCAN Feature List

The MultiCAN module provides the following TTCAN features

- Full support of basic cycle and system matrix functionality
- Support of reference messages level 1 and level 2
- Usable as time master
- Arbitration windows supported in time-triggered mode
- Global time information available
- CAN node 0 can be configured either for event-driven or time-triggered mode
- Built-in scheduler mechanism and a timing synchronization unit
- Write protection for scheduler timing data memory
- Timing-related interrupt functionality
- Parity protection for scheduler memory

1.4.7 Micro Link Serial Bus Interface (MLI)

This TC1798 contains two Micro Link Serial Bus Interfaces, MLI0 and MLI1.

The Micro Link Interface (MLI) is a fast synchronous serial interface to exchange data between microcontrollers or other devices, such as stand-alone peripheral components. **Figure 1-10** shows how two microcontrollers are typically connected together via their MLI interfaces.

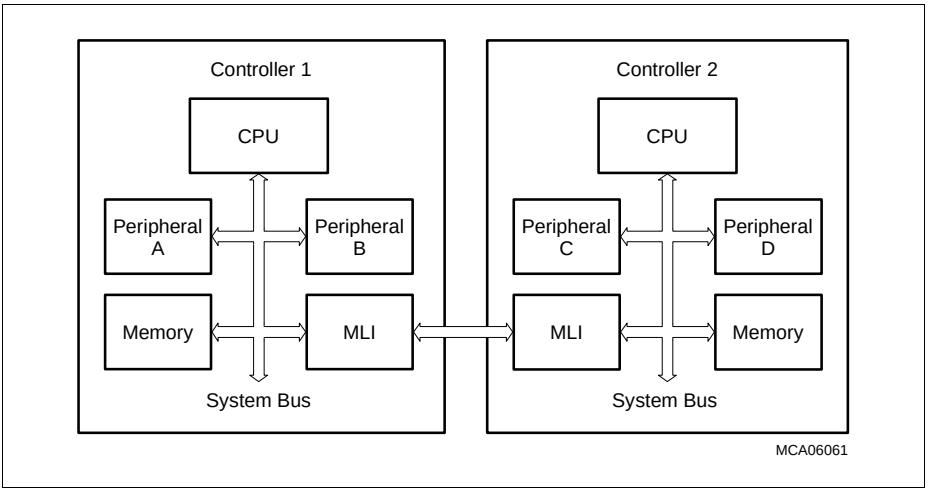

Figure 1-10 Typical Micro Link Interface Connection

1.4.7.1 MLI Feature List

The MLI module provides the following features:

- Synchronous serial communication between an MLI transmitter and an MLI receiver
- Different system clock speeds supported in MLI transmitter and MLI receiver due to full handshake protocol (4 lines between a transmitter and a receiver)
- Fully transparent read/write access supported (= remote programming)
- Complete address range of target device available
- Specific frame protocol to transfer commands, addresses and data
- Error detection by parity bit
- 32-bit, 16-bit, or 8-bit data transfers supported
- Programmable baud rate: $f_{MLI}/2$ (max. $f_{MLI} = f_{FPI}$)
- Address range protection scheme to block unauthorized accesses
- Multiple receiving devices supported

Figure 1-11 shows a general block diagram of the MLI module.

The MLI transmitter and MLI receiver communicate with other MLI receivers and MLI transmitters via a four-line serial connection each. Several I/O lines of these connections are available outside the MLI module kernel as a four-line output or input vector with index numbering A, B, C and D. The MLI module internal I/O control blocks define which signal of a vector is actually taken into account and also allow polarity inversions (to adapt to different physical interconnection means)

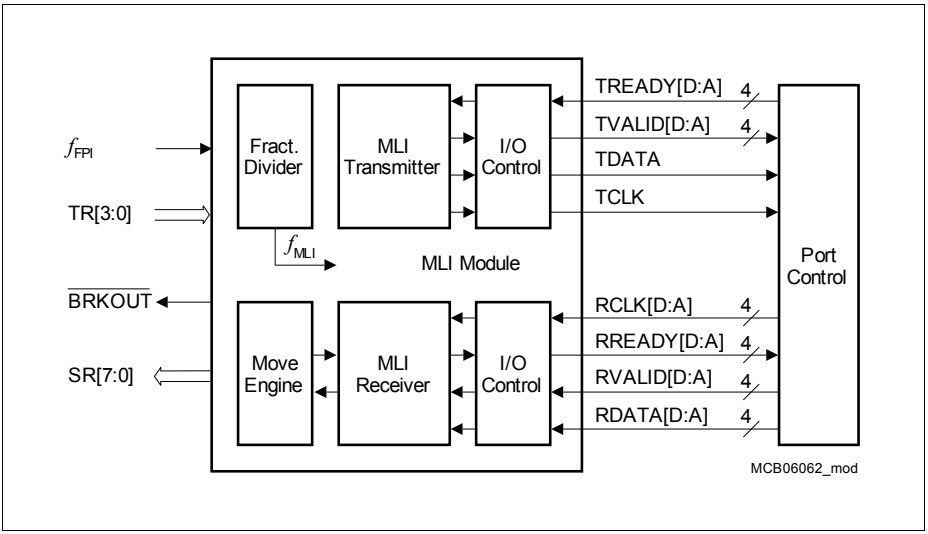

Figure 1-11 General Block Diagram of the MLI Modules

1.4.8 Single Edge Nibble Transmission (SENT)

This chapter describes the SENT Interface of the TC1798.

1.4.8.1 SENT Kernel Description

Figure 1-12 shows a global view of the SENT interface.

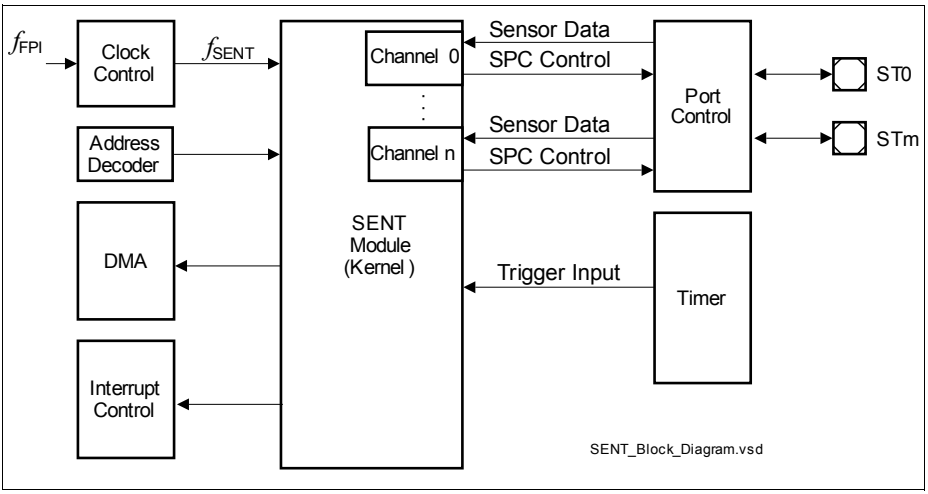

Figure 1-12 General Block Diagram of the SENT Interface

The SENT module communicates with the external world via one I/O line for each channel. The STx lines are the receive data input signals. They overlay ADC inputs. If the optional SPC mode is used, they can be used on a port configured with an open drain transistor. This way the optional SPC data can be transmitted and the line is used bidirectionally. In case of an external transceiver, receive and transmit path can be routed to two different ports.

1.4.9 SENT Feature Overview

The SENT interface provides a serial communication link typically used to connect sensors or other peripheral devices.

Clock control, address decoding, and service request control are managed by the SENT module kernel.

The SENT IP-module performs communication according to the SENT specification J2716 FEB2008.

While staying compliant to this standard, it is able to cover as well the Short PWM Code (SPC) protocol extensions. This enhances the standardized SENT protocol defined by J2716 FEB2008. SPC enables the use of enhanced protocol functionality like “synchronous”, “range selection” and “ID selection” protocol mode.

Receive data on a SENT channel can be set up according to the underlying application. In particular the number of nibbles forming one value is configurable.

The message storage consists of two 32-bit registers for each channel, representing a flexible double buffer system.

In SPC mode, maintaining the sample and transmission schedule as well as providing message status information is support.

The register set of the SENT module can be accessed directly by the CPU for configuration, data read out and status query.

The SENT IP-module supports the following features:

Feature List

The SENT module provides the following features:

- Conformance with SENT protocol specification J2716 FEB2008
- Data rates of up to 65,8 kbit/s at 3 µs tick length and 6 data nibbles on each channel
- Support of standard tick times (3 µs through 90 µs) and
- Message tick time programmable between 1 µs and 90 µs
- 8 SENT channels working independently in parallel
- Status nibble optionally included in the checksum (default not included)
- Sticky interrupt flags, error interrupt optional (default disabled)
- Configurable frame length (default is 24 bit), max data size is 32 bits
- Serial data processing optional (default: disabled)
- Option for bigger frame lengths (must still be fix for each application)
- transparent mode (nibble CRCs are written to the receive control register for SW processing)
- Support of SPC
- Support of trailing Pause Nibble of any length (even longer than 70 ticks)
- Indication of system status: STOP, INITIALIZED, RUNNING, SYNCHRONIZED

- The receiver module will monitor the message for the following error conditions:
  - Calibration pulse length deviates more than +/-25% from the nominal 56 ticks
  - Too many or too few nibbles between calibration pulses.
  - Checksum error.
  - Successive calibration pulse differ by more than 1.5625%
  - Any nibble data values measured as < 0 or >15.
- When any of those errors is detected, the receiver module shall declare that a message error has occurred and ignore the entire message.
- Any of those errors shall cause the receiver to begin searching for a valid calibration pulse to re synchronize.
- Option to enable/disable the check of the next calibration pulse before validation of received data
- Digital Glitch filter suppressing noise
- Buffer overrun detection
- Optional output inversion for use of external open drain transistor
- Optional input inversion for use of external open transistor for level shifting
- Interrupt on status nibble violation
- Programmable Nibble sorting to support LSN or HSN first and relief CPU

1.4.10 General Purpose Timer Array (GPTAv5)

The TC1798 contains the two General Purpose Timer Arrays (GPTA0 and GPTA1) with identical functionality, plus the additional Local Timer Cell Array (LTCA2).

The GPTA provides a set of timer, compare, and capture functionalities that can be flexibly combined to form signal measurement and signal generation units. They are optimized for tasks typical of engine, gearbox, and electrical motor control applications, but can also be used to generate simple and complex signal waveforms required for other industrial applications.

1.4.10.1 GPTA0 and GPTA1 Feature List

The General Purpose Timer Arrays (GPTA0 and GPTA1) each provides a set of hardware modules required for high-speed digital signal processing:

- Filter and Prescaler Cells (FPC) support input noise filtering and prescaler operation.
- Phase Discrimination Logic units (PDL) decode the direction information output by a rotation tracking system.
- Duty Cycle Measurement Cells (DCM) provide pulse-width measurement capabilities.
- A Digital Phase Locked Loop unit (PLL) generates a programmable number of GPTA module clock ticks during an input signal's period.
- Global Timer units (GT) driven by various clock sources are implemented to operate as a time base for the associated Global Timer Cells.
- Global Timer Cells (GTC) can be programmed to capture the contents of a Global Timer on an external or internal event. A GTC may also be used to control an external port pin depending on the result of an internal compare operation. GTCs can be logically concatenated to provide a common external port pin with a complex signal waveform.
- Local Timer Cells (LTC) operating in Timer, Capture, or Compare Mode may also be logically tied together to drive a common external port pin with a complex signal waveform. LTCs – enabled in Timer Mode or Capture Mode – can be clocked or triggered by various external or internal events.
- On-chip Trigger and Gating Signals (OTGS) can be configured to provide trigger or gating signals to integrated peripherals (GPTA0 only).

Input lines can be shared by an LTC and a GTC to trigger their programmed operation simultaneously.

The following list summarizes the specific features of the GPTA units.

Clock Generation Unit

- Filter and Prescaler Cell (FPC)
  – Six independent units

  - Three basic operating modes:
    Prescaler, Delayed Debounce Filter, Immediate Debounce Filter
  - Selectable input sources:
    Port lines, GPTA module clock, FPC output of preceding FPC cell
  - Selectable input clocks:
    GPTA module clock, prescaled GPTA module clock, DCM clock, compensated or uncompensated PLL clock.
  - f_{GPTA}/2 maximum input signal frequency in Filter Modes
- Phase Discriminator Logic (PDL)
  - Two independent units
  - Two operating modes (2- and 3- sensor signals)
  - f_{GPTA}/4 maximum input signal frequency in 2-sensor Mode, f_{GPTA}/6 maximum input signal frequency in 3-sensor Mode
- Duty Cycle Measurement (DCM)
  - Four independent units
  - 0 - 100% margin and time-out handling
  - f_{GPTA} maximum resolution
  - f_{GPTA}/2 maximum input signal frequency
- Digital Phase Locked Loop (PLL)
  - One unit
  - Arbitrary multiplication factor between 1 and 65535
  - f_{GPTA} maximum resolution
  - f_{GPTA}/2 maximum input signal frequency
- Clock Distribution Unit (CDU)
  - One unit
  - Provides nine clock output signals:
    f_{GPTA}, divided f_{GPTA} clocks, FPC1/FPC4 outputs, DCM clock, LTC prescaler clock

Signal Generation Unit

- Global Timers (GT)
  - Two independent units
  - Two operating modes (Free-Running Timer and Reload Timer)
  - 24-bit data width
  - f_{GPTA} maximum resolution
  - f_{GPTA}/2 maximum input signal frequency
- Global Timer Cell (GTC)
  - 32 units related to the Global Timers
  - Two operating modes (Capture, Compare and Capture after Compare)
  - 24-bit data width
  - f_{GPTA} maximum resolution
  - f_{GPTA}/2 maximum input signal frequency
- Local Timer Cell (LTC)

– 64 independent units
– Three basic operating modes (Timer, Capture and Compare) for 63 units
– Special compare modes for one unit
– 16-bit data width
– f_{GPTA} maximum resolution
– f_{GPTA}/2 maximum input signal frequency

Interrupt Sharing Unit

- 143 interrupt sources, generating up to 46 service requests

On-chip Trigger Unit

- 16 on-chip trigger signals

I/O Sharing Unit

- Interconnecting inputs and outputs from internal clocks, FPC, GTC, LTC, ports, and MSC interface

1.4.10.2 LTCA2 Feature List

The Local Timer Cell Array (LTCA2) provides a set of hardware modules required for high-speed digital signal processing:

- Local Timer Cells (LTC) operating in Timer, Capture, or Compare Mode may also be logically tied together to drive a common external port pin with a complex signal waveform. LTCs – enabled in Timer Mode or Capture Mode – can be clocked or triggered by various external or internal events.

The following list summarizes the specific features of the LTCA unit.

The Local Timer Arrays (LTCA2) provides a set of hardware modules required for high-speed digital signal processing:

Signal Generation Unit

- Local Timer Cell (LTC)
  – 64 independent units
  – Three basic operating modes (Timer, Capture and Compare)
  – Special compare modes for one unit
  – 16-bit data width
  – f_{GPTA} maximum resolution
  – f_{GPTA}/2 maximum input signal frequency

I/O Sharing Unit

- Interconnecting inputs and outputs from internal clocks, LTC, ports, and MSC interface

1.4.11 Capture/Compare Unit 6 (CCU6)

The CAPCOM6 provides two independent timers (T12, T13), which can be used for PWM generation, especially for AC-motor control. Additionally, special control modes for block commutation and multi-phase machines are supported.

CCU6061 module consists of CCU60 and CCU61 kernels while CCU6263 consists of CCU62 and CCU63 kernels.

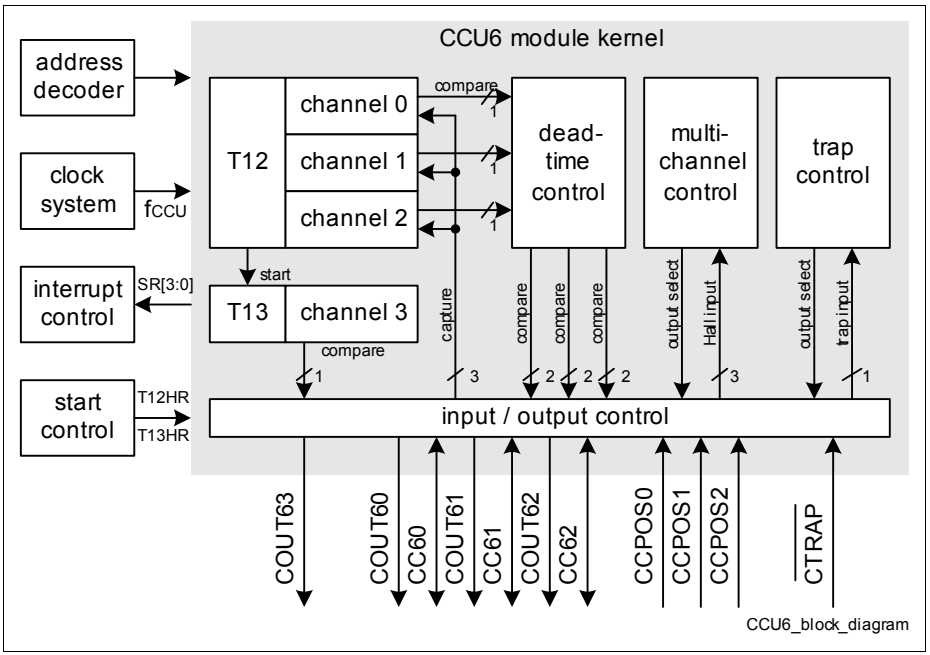

Figure 1-13 CCU6 Block Diagram

1.4.11.1 Feature List

The CCU6 module provides the following features:

Timer 12 Features

- Three capture/compare channels, each channel can be used either as capture or as compare channel.

- Generation of a three-phase PWM supported (six outputs, individual signals for highside and lowside switches)
- 16 bit resolution, maximum count frequency = peripheral input clock
- Dead-time control for each channel to avoid short-circuits in the power stage
- Concurrent update of the required T12/13 registers
- Center-aligned and edge-aligned PWM can be generated
- Single-shot mode supported
- Many interrupt request sources
- Hysteresis-like control mode
- Synchronized start supported (triggered by an external SCU signal through T12HR input for each CCU6 module)

Timer 13 Features

- One independent compare channel with one output
- 16 bit resolution, maximum count frequency = peripheral input clock
- Can be synchronized to T12
- Interrupt generation at period-match and compare-match
- Single-shot mode supported
- Synchronized start supported (triggered by an external SCU signal through T13HR input for each CCU6 module)

Additional Features

- Block commutation for Brushless DC-drives implemented
- Position detection via Hall-sensor pattern
- Automatic rotational speed measurement for block commutation
- Integrated error handling
- Fast emergency stop without CPU load via external signal ($\overline{\text{CTRAP}}$)
- Control modes for multi-channel AC-drives
- Output levels can be selected and adapted to the power stage

The timer T12 can work in capture and/or compare mode for its three channels. The modes can also be combined. The timer T13 can work in compare mode only. The multi-channel control unit generates output patterns which can be modulated by timer T12 and/or timer T13. The modulation sources can be selected and combined for the signal modulation.

1.4.12 General Purpose Timer (GPT12)

The GPT12E unit represents a very flexible multifunctional timer/counter structure which may be used for many different time related tasks such as event timing and counting, pulse width and duty cycle measurements, pulse generation, or pulse multiplication. Its functionality includes enhanced incremental interface modes and clock prescaler support.

1.4.12.1 Feature List

The GPT12E module provides the following features.

- Timer Block GPT1:
  - Maximum resolution peripheral input clock / 4
  - clock prescaler support
  - 3 independent timers/counters (T2, T3, T4).
  - Timers/counters can be concatenated.
  - 4 operating modes (timer, gated timer, counter, incremental).
  - enhanced incremental interface modes
  - Separate interrupt request lines.
- Timer Block GPT2:
  - Maximum resolution peripheral input clock / 2
  - clock prescaler support
  - 2 independent timers/counters (T5, T6).
  - Timers/counters can be concatenated.
  - 3 operating modes (timer, gated timer, counter).
  - Extended capture/reload functions via 16-bit Capture/Reload register CAPREL
  - Separate interrupt request lines.

1.4.13 External Bus Interface (EBU)

The External Bus Unit (EBU) of the TC1798 controls the accesses from the CPU and peripheral units to external memories.

1.4.13.1 Feature List

The EBU module provides the following features:

- 64-bit internal SRI interface
- 32-bit external bus interface
  - interface can be configured to support memory devices with 32 bit, 16 bit and 8 bit databus connections
  - Support for 3.3 V and 2.5 V memory devices
  - Limited support for 1.8 V memories
  - Flexibly programmable access parameters (e.g. control signal pulse width ,bus turnaround time, burst length for synchronous memories).
  - Different Device settings available for read and write accesses
  - Programmable address range for each chip select line.
- Support for multiple device access protocols
  - asynchronous memories e.g. SRAM, peripheral devices
  - synchronous devices e.g. burst NOR flash, PSRAM
  - DDR NOR flash e.g. LPDDR-NVM (Jedec 42.4), ONFI 2.0 (both at limited frequency using 1.8 V I/O supply).
- Scalable external bus timing
  - Derived from SRI frequency (f_{CPU}) by dividers internal to the EBU.
  - Can also be derived from the Flexray clock.
  - Maximum 75 MHz
- Data buffering supported
  - Read/write buffer

1.4.14 Analog-to-Digital Converters (ADC/FADC)

The TC1798 includes Analog to Digital Converter modules)ADC)and one Fast Analog to Digital Converter (FADC).

1.4.15 ADC Module

The analog to digital converter module (ADC) allows the conversion of analog input values into discrete digital values based on the successive approximation method.
This module contains 4 independent kernels (ADC0, ADC1, ADC2, ADC3) that can operate autonomously or can be synchronized to each other. An ADC kernel is a unit used to convert an analog input signal (done by an analog part) and provides means for triggering conversions, data handling and storage (done by a digital part).

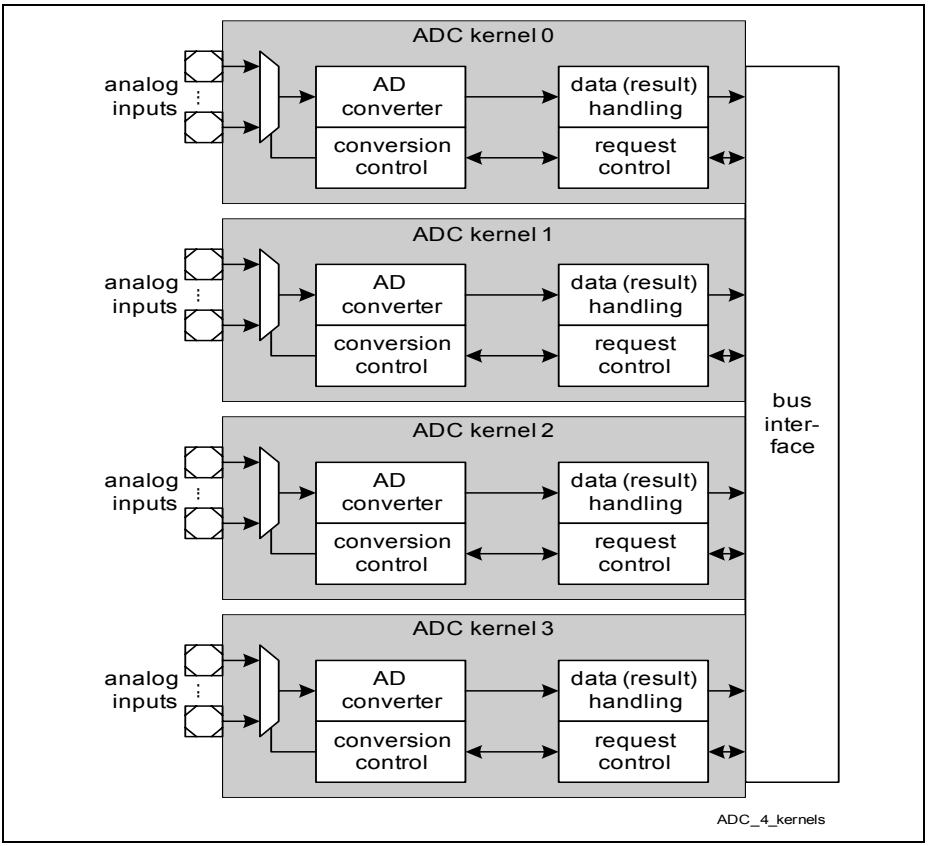

Figure 1-14 ADC Module with four ADC Kernels

1.4.15.1 Feature List

Each ADC kernel provides the following features:

- Analog supply voltage range from 3.3 V (minimum) to 5 V (nominal) for V_{DDM}
- Input voltage range from 0 V to analog supply voltage V_{DDM}
- Input multiplexer for a maximum of 16 possible analog input channels
- One standard reference input (V_{AREF}) and one alternative reference input (CH0) available
- Broken wire detection support for each input channel
- Multiplexer test support for input channels with odd channel numbers
- 5 conversion request sources for external or timer-driven events, auto-scan, programmable sequences, SW-driven conversions, etc.
- Synchronization of the ADC kernels for concurrent conversion starts and parallel sampling and measuring of analog input signals, e.g. for phase current measurements in AC drives
- Control capability for an external analog multiplexer, respecting the additional set up time
- Adjustable sampling times to accommodate output impedance of different analog signal sources (sensors, etc.)
- Possibility to cancel running conversions on demand with automatic restart
- Flexible interrupt generation (possibility of DMA support)
- Limit checking to reduce interrupt load (e.g. for temperature measurements or overload detection, only values exceeding a programmable level lead to an interrupt)
- Programmable data reduction filter, e.g. for digital anti-aliasing filtering, by adding a programmable number of conversion results
- Independent result registers (16 independent registers)
- Support of conversion result FIFO mechanism to allow a longer interrupt latency
- Programmable result data filter providing 3rd order FIR or 1st order IIR filter structure
- Support of suspend and power saving modes
- Individually programmable reference selection for each channel, e.g. to allow measurements of 3.3 V and 5 V signals in the full measurement range with the same ADC kernel (with exception of dedicated channels always referring to V_{AREF})

1.4.16 FADC Module

As shown in **Figure 1-15**, the main FADC functional blocks are:

- An Input Structure containing the differential inputs and impedance control.
- An A/D Converter Stage responsible for the analog-to-digital conversion including an input multiplexer to select between the channel amplifiers
- A Data Reduction Unit containing programmable anti-aliasing and data reduction filters
- A Channel Trigger Control block determining the trigger and gating conditions for the FADC channels

- A Channel Timer for each channel to independently trigger the conversions
- An A/D Control block responsible for the overall FADC functionality

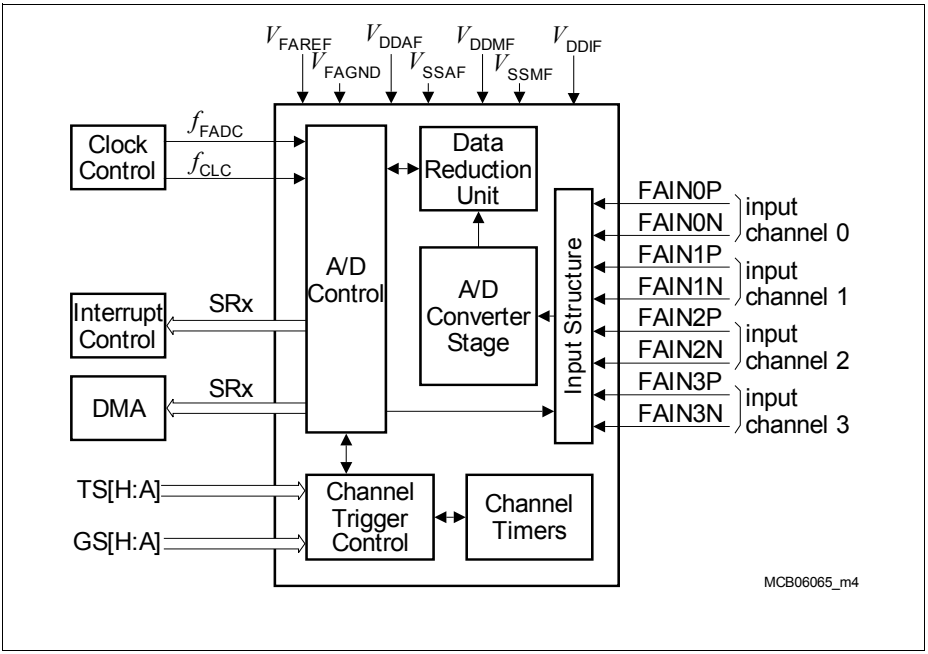

Figure 1-15 Block Diagram of the FADC Module with 4 Input Channels

FADC Power Supply and References

The FADC module is supplied by the following power supply and reference voltage lines:

- V_{DDMF} / V_{SSMF}: FADC Analog Channel Amplifier Power Supply (3.3 V)
- V_{DDIF} / V_{SSMF}: FADC Analog Input Stage Power Supply (3.3 - 5 V), the V_{DDIF} supply does not appear as supply pin, because it is internally connected to the V_{DDM} supply of the ADC that is sharing the FADC input pins.
- V_{DDAF} / V_{SSAF}: FADC Analog Part Power Supply (1.3 V), to be fed in externally
- V_{FAREF} / V_{FAGND}: FADC Reference Voltage (3.3 V max.) and FADC Reference Ground

Input Structure

The input structure of the FADC in the TC1798 contains:

- A differential analog input stage for each input channel to select the input impedance (differential or single-ended measurement) and to decouple the FADC input signal from the pins.
- All input channels are overlaid with ADC1 input signals (AN24 - AN31).

- A channel amplifier for each input channel with a settling time (about 5µs) when changing the characteristics of an input stage (changing between unused, differential, single-ended N, or single-ended P mode).

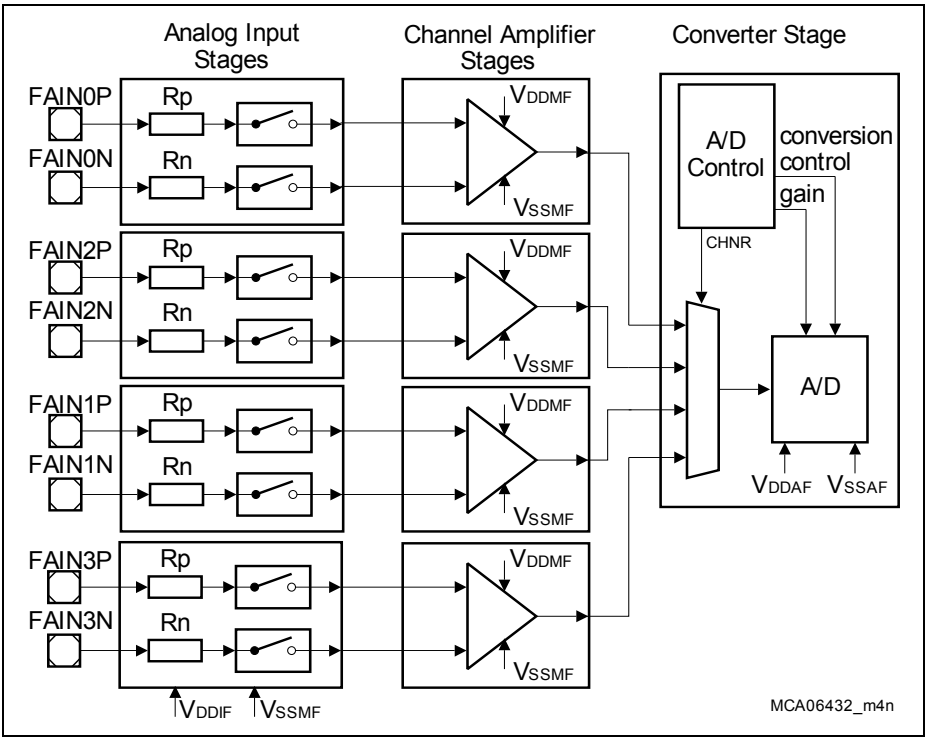

Figure 1-16 FADC Input Structure in TC1798

1.4.16.1 FADC Feature List

The FADC module provides the following features

- Extreme fast conversion, 21 cycles of f_{FADC} clock
- 10-bit A/D conversion (higher resolution can be achieved by averaging of consecutive conversions in digital data reduction filter)
- Successive approximation conversion method
- All differential input channels with impedance control
- All FADC inputs are overlaid with ADC1 inputs
- Each differential input channel can also be used as single-ended input
- Offset calibration support for each channel
- Programmable gain of 1, 2, 4, or 8 for each channel

- Free-running (Channel Timers) or triggered conversion modes
- Trigger and gating control for external signals
- Built-in Channel Timers for internal triggering
- Channel timer request periods independently selectable for each channel
- Selectable, programmable digital anti-aliasing and data reduction filter block with four independent filter units

1.5 On-Chip Debug Support (OCDS)

The TC1798 contains resources for different kinds of “debugging”, covering needs from software development to real-time-tuning. These resources are either embedded in specific modules (e.g. breakpoint logic of the TriCore) or part of a central peripheral (known as CERBERUS).

1.5.1 On-Chip Debug Support

The classic software debug approach (start/stop, single-stepping) is supported by several features labelled “OCDS Level 1”:

- Run/stop and single-step execution independently for TriCore and PCP.
- Means to request all kinds of reset without usage of sideband pins.
- Halt-after-Reset for repeatable debug sessions.
- Different Boot modes to use application software not yet programmed to the Flash.
- A total of eight hardware breakpoints for the TriCore based on instruction or data address.
- TriCore OCDS logic fully independent of the memory protection system.
- Unlimited number of software breakpoints (DEBUG instruction) for TriCore and PCP.
- Debug event generated by access to a specific address via the system peripheral bus or the SRI cross connect.
- Tool access to all SFRs and internal memories independent of the Cores.
- Two central Break Switches to collect debug events from all modules (TriCore, PCP, DMA, SRI, BCU, break input pins) and distribute them selectively to breakable modules (TriCore, PCP, break output pins).
- Central Suspend Switch to suspend parts of the system (TriCore, PCP, Peripherals) instead if breaking them as reaction to a debug event.
- Dedicated interrupt resources to handle debug events inside TriCore (breakpoint trap, software interrupt) and Cerberus (can trigger PCP), e.g. for implementing Monitor programs.
- Access to all OCDS Level 1 resources also for TriCore and PCP themselves for debug tools integrated into the application code.
- Triggered Transfer of data in response to a debug event; if target is programmed to be a device interface simple variable tracing can be done.

- In depth performance analysis and profiling support given by the Emulation Device through MCDS Event Counters driven by a variety of trigger signals (e.g. cache hit, wait state, interrupt accepted).

1.5.2 Real Time Trace

For detailed tracing of the system's behavior a pin-compatible Emulation Device will be available.[1)]

1.5.3 Calibration Support

Two main use cases are catered for by resources in addition the OCDS Level 1 infrastructure: Overlay of non-volatile on-chip memory and non-intrusive signaling:

- On-chip SRAM for Overlay (allocated from LMU RAM pool).
- Can be split into up to 16 blocks which can overlay independent memory regions during data reads (e.g. on-chip Flash).
- Changing the configuration is triggered by a single SFR access to maintain consistency.
- Overlay configuration switch does not require the TriCore to be stopped or suspended.
- Invalidation of the Data Cache (maintaining write-back data) can be done concurrently with the same SFR.
- 768 KB additional Overlay RAM on Emulation Device, shared with the trace functionality.
- A dedicated trigger SFR with 32 independent status bits is provided to centrally post requests from application code to the host computer.
- The host is notified automatically when the trigger SFR is updated by the TriCore or PCP. No polling via a system bus is required.

1.5.4 Tool Interfaces

Three options exist for the communication channel between Tools (e.g. Debugger, Calibration Tool) and TC1798:

- Two wire DAP (Device Access Port) protocol for long connections or noisy environments.
- Four (or five) wire JTAG (IEEE 1149.1) for standardized manufacturing tests.
- CAN (plus software linked into the application code) for low bandwidth deeply embedded purposes.
- DAP and JTAG are clocked by the tool.
- Bit clock up to 40 MHz for JTAG, up to 80 MHz for DAP.

1) The OCDS L2 interface of AudoNG is not available.

- Hot attach (i.e. physical disconnect/reconnect of the host connection without reset of the TC1798) for all interfaces.
- Infineon standard DAS (Device Access Server) implementation for seamless, transparent tool access over any supported interface.
- Lock mechanism to prevent unauthorized tool access to critical application code.

1.5.5 Self-Test Support

Some manufacturing tests can be invoked by the application (e.g. after power-on) if needed:

- Hardware-accelerated checksum calculation (e.g. for Flash content).
- RAM tests optimized for the implemented architecture.

1.5.6 FAR Support

To efficiently locate and identify faults after integration of a TC1798 into a system special functions are available:

- Boundary Scan (IEEE 1149.1) via JTAG and DAP.
- SSCM (Single Scan Chain Mode) for structural scan testing of the chip itself.
- SPD (Single Pin DAP) protocol via CAN0 pins.

2 CPU Subsystem

The TC1798 processor contains a TriCore 1.6 CPU. This chapter describes the implementation-specific options of the CPU, and should be read in conjunction with the TriCore Architecture Manual, which describes the complete TriCore Architecture including the register and instruction set.

2.1 TC1798 Processor Subsystem

The diagram below shows the block diagram of the processor subsystem.

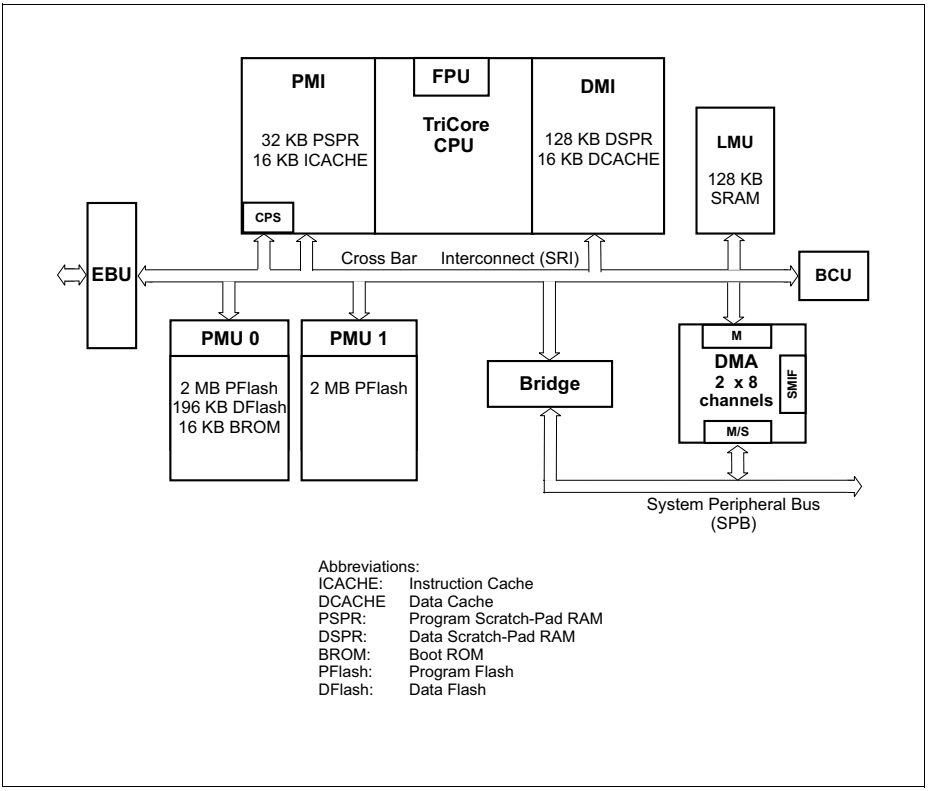

Figure 2-1 TC1798 Processor Subsystem Block Diagram

2.2 Central Processing Unit Features

The 330 MHz TriCore TC1798 CPU includes:

Architecture

- 32-bit load store architecture
- 4 Gbyte address range (2^{32})
- 16-bit and 32-bit instructions for reduced code size
- Data types:
  - Boolean, integer with saturation, bit array, signed fraction, character, double-word integers, signed integer, unsigned integer, IEEE-754 single-precision floating point
- Data formats:
  - Bit, byte (8-bits), half-word (16-bits), word (32-bits), double-word (64-bits)
- Byte and bit addressing
- Little-endian byte ordering for data, memory and CPU registers
- Multiply and Accumulate (MAC) instructions: Dual 16×16, 16×32, 32×32
- Saturation integer arithmetic
- Packed data
- Addressing modes:
  - Absolute, circular, bit reverse, long + short, base + offset with pre- and post-update
- Instruction types:
  - Arithmetic, address arithmetic, comparison, address comparison, logical, MAC, shift, coprocessor, bit logical, branch, bit field, load/store, packed data, system
- General Purpose Register Set (GPRS):
  - Sixteen 32-bit data registers
  - Sixteen 32-bit address registers
  - Three 32-bit status and program counter registers (PSW, PC, PCXI)
- Core Debug support (OCDS):
  - Level 1, supported in conjunction with the CPS block
  - Level 3, supported in conjunction with the MCDS block (Emulation Device only).
- Flexible memory protection system providing multiple protection sets with multiple protection ranges per set.
- Temporal protection system allowing time bounded real time operation.

Implementation

- Most instructions executed in 1 cycle
- Branch instructions in 1, 2 or 3 cycles (using branch prediction)
- Wide memory interface for fast context switch
- Automatic context save-on-entry and restore-on-exit for: subroutine, interrupt, trap
- Four memory protection register sets
- Dual instruction issuing (in parallel into Integer Pipeline and Load/Store Pipeline)
- Third pipeline for loop instruction only (zero overhead loop)

- Single precision Floating Point Unit
- Dedicated Integer divide unit

2.2.1 CPU Diagram

The Central Processing Unit (CPU) comprises of an Instruction Fetch Unit, an Execution Unit, a General Purpose Register File (GPR), a CPU Slave interface (CPS), and Floating Point Unit (FPU).

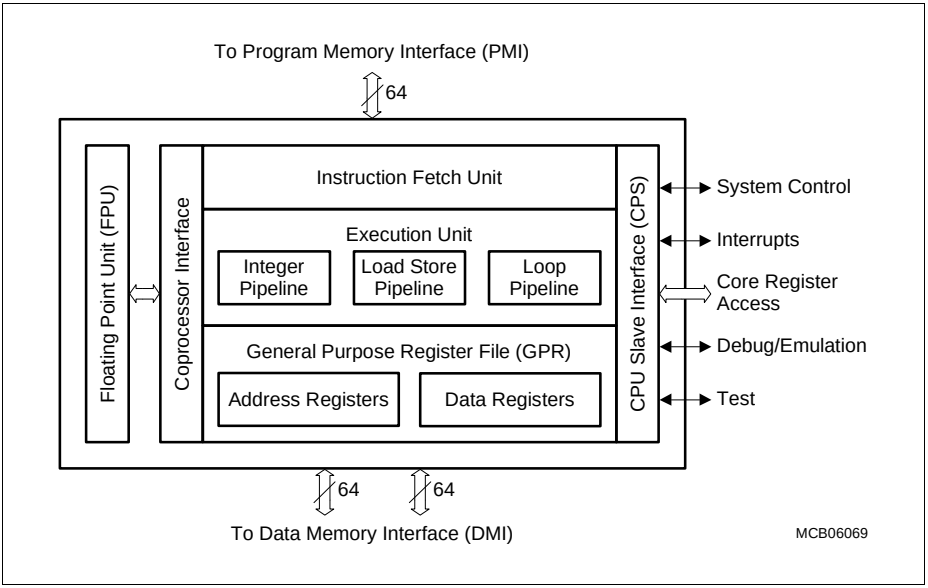

Figure 2-2 CPU Block Diagram

2.2.2 Instruction Fetch Unit

The Instruction Fetch Unit pre-fetches and aligns incoming instructions from the 64-bit wide Program Memory Interface (PMI). Instructions are placed in predicted program order in the Issue fifo. The Issue fifo buffers up to six instructions and directs the instruction to the appropriate execution pipeline.

The Instruction Protection Unit checks the validity of accesses to the PMI and the integrity of incoming instructions fetched from the PMI.

The branch unit examines the fetched instructions for branch conditions and predicts the most likely execution path based on previous branch behavior. The Program Counter Unit (PC) is responsible for updating the program counters.

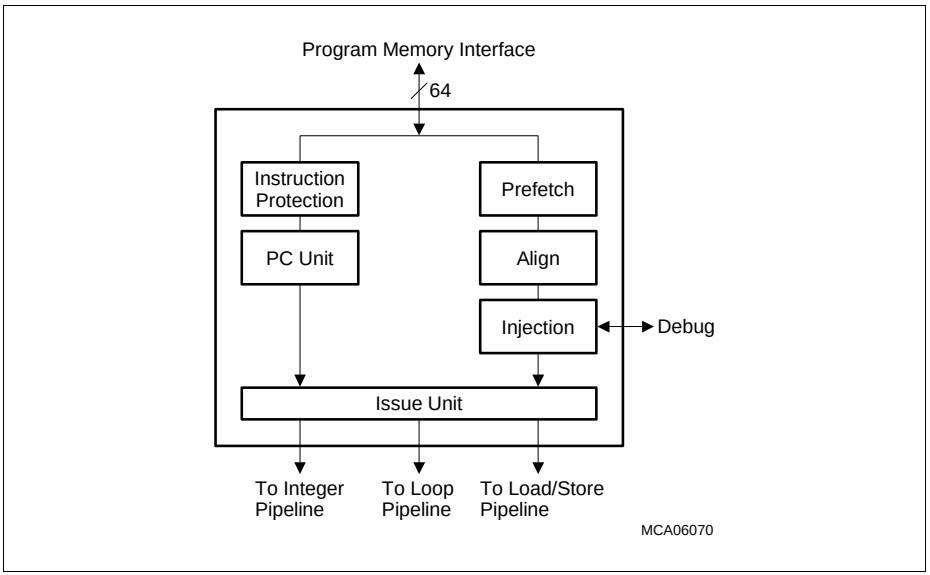

Figure 2-3 Instruction Fetch Unit

2.2.3 Execution Unit

The Execution Unit contains the Integer Pipeline, the Load/Store Pipeline and the Loop Pipeline. All three pipelines operate in parallel, permitting up to three instructions to be executed in one clock cycle. In the execution unit all instructions pass through a decode stage followed by two execute stages. Pipeline hazards (stalls) are minimised by the use of forwarding paths between pipeline stages allowing the results of one instruction to be used by a following instruction as soon as the result becomes available.

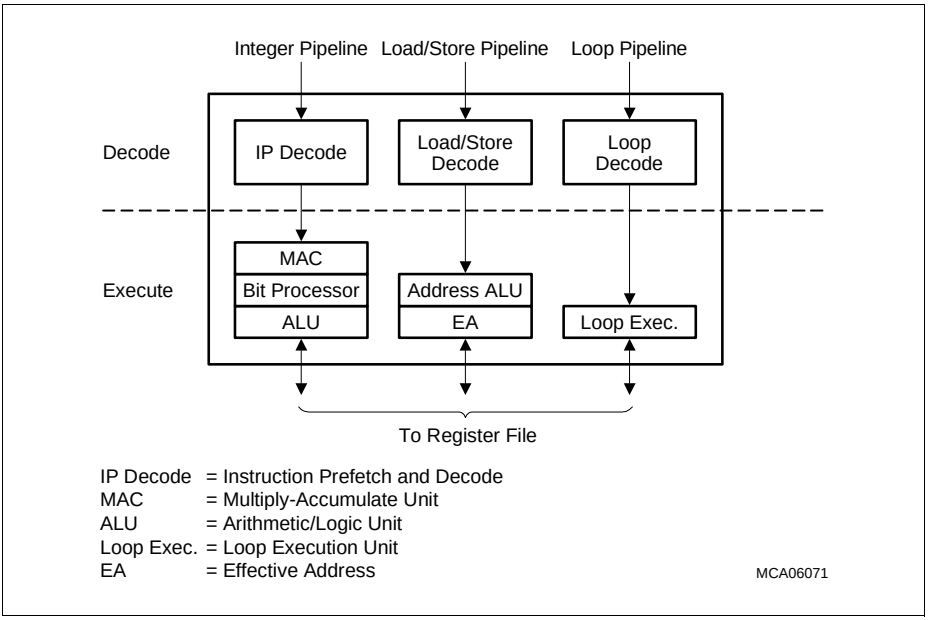

Figure 2-4 Execution Unit

2.2.4 General Purpose Register File

The CPU has a General Purpose Register (GPR) file, divided into an Address Register File (registers A0 through A15) and a Data Register File (registers D0 through D15).

The data flow for instructions issued to the Load/Store Pipeline is steered through the Address Register File.

The data flow for instructions issued to/from the Integer Pipeline and for data load/store instructions issued to the Load/Store Pipeline is steered through the Data Register File.

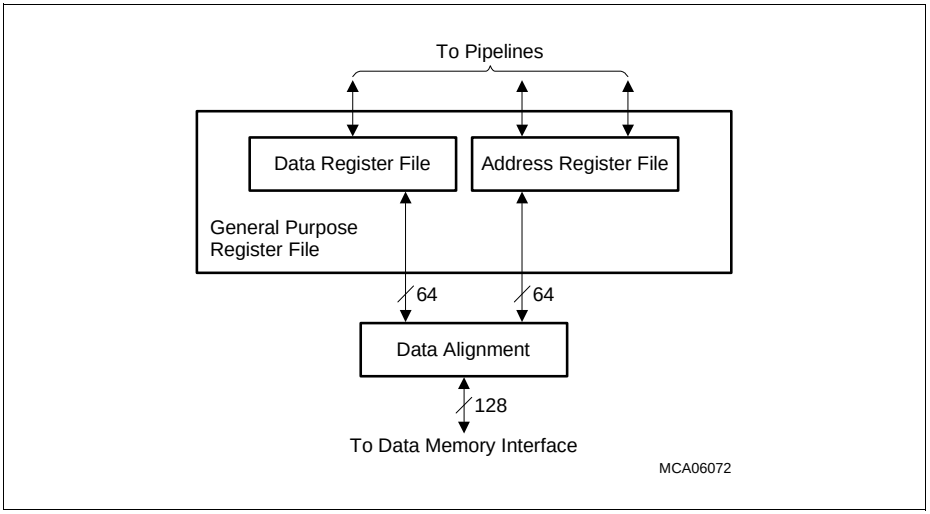

Figure 2-5 General Purpose Register File

2.3 Summary of functional changes from TC1.3.1

To achieve higher frequencies the TriCore1.6 pipeline is increased from 4 to 6 stages.

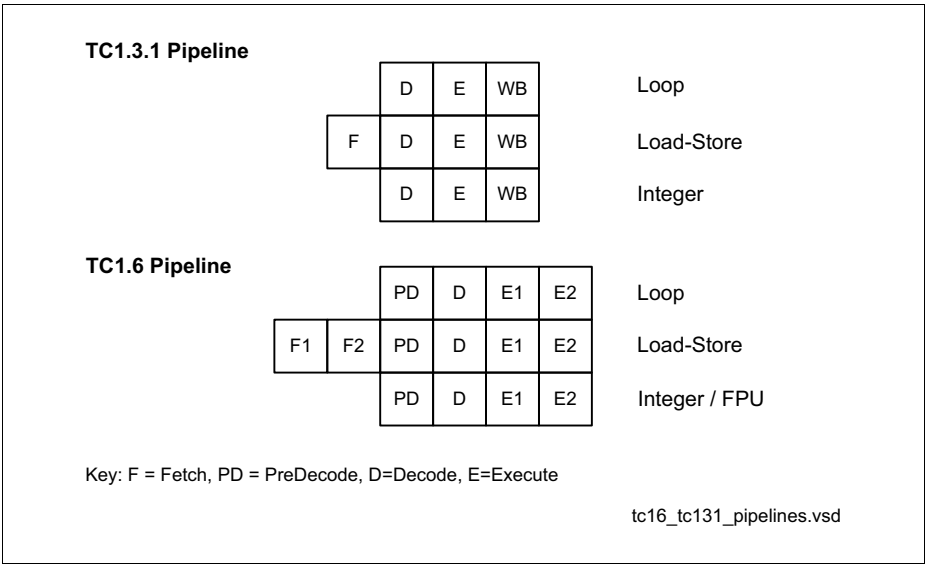

Figure 2-6 TC1.6 and TC1.3.1 Pipelines

To mitigate the effects on performance of the longer pipeline the following fetch and branch features are implemented.

- FIFO decoupled fetch and execute stages.
- Dynamic branch prediction using combined bimodal predictor table and branch target buffer.
- Loop aware branch prediction.

One effect of the longer pipeline is to increase the load-use penalty to 1 from 0. This necessitates re-scheduling of code to achieve optimum performance.

Other significant adaptations to the existing TC1.3.1 CPU are as follows:

- Fully Pipelined Floating Point Unit (FPU)
  – Most floating point instructions now have a repeat rate of 1
- Improved debug system - now decoupled from protection system.
  – 8 comparators proving up to 4 ranges, selectable for PC or load-store address
- Expanded and enhanced memory protection unit (MPU)
  – 16 data ranges and 8 code ranges shared between 4 protection sets.
- New Temporal protection system.

  - Guards against task runtime overrun.
- New Safe Interrupt mode.
  - Interrupt acknowledge decoupled from interrupt entry.
- New instructions for improved Interrupt and Data Cache manipulation support.
  - Disable, restore, CACHEI.I
- New instructions for Fast Integer Divide
  - DIV, DIV.U
- New Instructions for fast call and return with minimal saving of state.
  - FCALL, FCALLA, FCALLI, FRET
- Long offset addressing mode introduced for byte, half word and address accesses.
  - LD.BU, LD.B, LD.HU, LD.H, ST.B, ST.H, ST.A
- Extended range of 16 bit jumps
  - JEQ, JNE
- Increased flexibility in the system address map.
- Full SECDED ECC protection for all scratch, cache and tag memory structures.
- Cache and Scratch memory systems now entirely separated.
  - Cache memories may be mapped as additional scratch.

2.4 CPU Implementation-Specific Features

This section describes the implementation-specific features of the CPU. For a complete description of all registers, refer to the TriCore Architecture Manual.

2.4.1 Context Save Areas

Context Save Areas (CSA) may be placed in DSPR or external memory (cached or uncached).

The CPU uses a uniform context-switching method for function calls, interrupts and traps. In all cases the Upper Context of the task is automatically saved and restored by hardware. Saving and restoring of the Lower Context may be optionally performed by software.

CSA Placement in DSPR

The actual timing of context operations is dependent upon the placement of the Context Save Areas. Maximum performance is achieved when the Context Save Area is placed in DSPR. In this case all context save and restores operations take four cycles.

CSA Placement in Cached External Memory

In this case, the timing is also dependent on the state of the Data Cache. The best case Data Cache operation occurs when context saves do not incur a cache line writeback, and context restores hit in the data cache. In this case all context saves and restores take eight cycles.

2.4.2 Program Counter (PC) Register

The Program Counter (PC) holds the address of the instruction that is currently fetched and forwarded to the CPU pipelines. The CPU handles updates of the PC automatically.

Software can use the current value of the PC for various tasks, such as performing code address calculations. Reading the PC through software executed by the CPU must only be done with an MFCR instruction. Such a read will return the PC of the MFCR instruction itself. Explicit writes to the PC through an MTCR instruction must not be done due to possible unexpected behavior of the CPU.

The CPU must not perform Load/Store instructions to the mapped address of the PC in Segment 15. A MEM trap will be generated in such a case. Bit 0 of the PC register is read-only and hard-wired to 0.

2.4.3 Store Buffers

To increase performance the TC1.6 CPU implements store buffering to decouple memory write operations from CPU instruction execution. All stores from the CPU are placed in the store buffer prior to being written to local memory or transferred via the bus

system. Write data is taken from the store buffers and written to memory when the target memory or bus interface becomes available. In normal operation the CPU will prioritise memory load operations over store operations in order to improve performance unless:-

- The store buffer is full.
- The load is to peripheral space and a store to peripheral space exists in the store buffer. (In order peripheral space access).
- The load or store is part of an atomic operation.

Typically the operation of the store buffer is invisible to the end user. If there is a requirement that data is written to memory prior to execution of a subsequent instruction then a DSYNC instruction may be used to flush the store buffers.

To further improve performance consecutive byte writes to the same half word location are merged in the store buffer.

The TC1.6 CPU store buffer can hold the data for up to 6 stores.

Store buffer operation may be disabled be setting the SMACON.IODT bit. This should not be done in normal execution as it will severely limit performance.

2.4.4 Interrupt System

An interrupt request can be generated by the on-chip peripheral units, or it can be generated by external events. Requests can be targeted to either the CPU, or to the Peripheral Control Processor (PCP).

The interrupt system evaluates service requests for priority and to identify whether the CPU (or PCP) should receive the request. The highest-priority service request is then presented to the CPU (or PCP) by way of an interrupt.

The term “interrupt” is used generally to mean an event directed to the CPU, while the term “service request” describes an event that can be directed to either the CPU or the PCP.

2.4.4.1 Interrupt Acknowledge Decoupling for Safety Systems

In order to improve plausibility checks on Interrupt Service Routines (ISR) a modification to the Interrupt Controller (ICU) is introduced.

When an interrupt service request node (SRN) is arbitrated the ICU sends an acknowledge indicating which SRN is the winner. Upon reception of the information the winner SRN automatically clears the request flag. This happens before the ISR executes. Therefore the ISR can't directly double check if the node corresponding to it's interrupt level was active or not.

The TriCore1.6 implements a new mode where the feedback after an arbitration round is controlled by software, allowing an ISR to make consistency checks and then enabling the ICU to proceed with terminating the arbitration round and enabling further interrupts.

On Entering an interrupt the BIT SAFEINT.INT (0xFE30, bit-0) is set. The CPU holds off acknowledging the interrupt until this bit is cleared by a software write. Note that this delays re-arbitration and hence will impact interrupt performance.

Interrupt acknowledge decoupling is enabled by the COMPAT.INT bit. By default the standard, non-decoupled solution is selected.

2.4.5 Trap System

The following traps have implementation-specific properties.

UOPC - Unimplemented Opcode (TIN 2)

The UOPC trap is raised on optional MMU instructions, coprocessor two and coprocessor three instructions.

OPD - Invalid Operand (TIN 3)

The CPU raised OPD traps for instructions that take even-odd register pairs as an operand where if the operand specifier is odd.

DSE - Data Access Synchronous Error (TIN 2)

The Data Access Synchronous Bus Error (DSE) trap is generated by the DMI module when a load access from the CPU encounters certain error conditions, such as a Bus error, or an out-of-range access to DSPR. When a DSE trap is generated, the exact cause of the error can be determined by reading the Data Synchronous Trap Register, DSTR. For details of possible error conditions and the corresponding flag bits in DSTR, see **“DMI Trap Generation” on Page 2-90**.

DAE - Data Access Asynchronous Error (TIN 3)

The Data Access Asynchronous Error Trap (DAE) is generated by the DMI module when a store or cache management access from the CPU encounters certain error conditions, such as an Bus error. When a DAE trap is generated, the exact cause of the error can be determined by reading the Data Asynchronous Trap Register, DATR. For details of possible error conditions and the corresponding flag bits in DATR, see **“DMI Trap Generation” on Page 2-90**.

PIE Program Memory Integrity Error (TIN 5)

The PIE trap is raised whenever an uncorrectable memory integrity error is detected in an instruction fetch from a local memory. The trap is synchronous to the erroneous instruction. The trap is of Class-4 and has a TIN of 5.

Program memories are protected from memory integrity errors on a 64 bit basis. A PIE trap is raised when an attempt is made to execute an instruction from any 64bit fetch group containing a memory integrity error.

The PIEAR and PIETR registers may be interrogated to determine the source of any error more precisely.

DIE Data Memory Integrity Error (TIN 6)

The DIE trap is raised whenever an uncorrectable memory integrity error is detected in a data access to a local memory. The trap is of Class-4 and has a TIN of 6.

DIE traps are always asynchronous independent of the operation which encountered the error.

A DIE trap is raised if any memory half word accessed by a load/store operation contains an uncorrectable error. The DIEAR and DIETR registers may be interrogated to determine the source of any error more precisely.

2.4.6 Memory Integrity Error Handling

The TriCore 1.6 contains integrated support for the detection and handling of memory integrity errors. The handling of memory integrity errors for the various memory types in TriCore 1.6 is as follows:

2.4.6.1 Program Side Memories

The program side memories of the TriCore 1.6 core consist of two independent memory structures:- The Program Scratchpad RAM (PSPR) and Instruction Cache (ICACHE). Both memory structures are ECC protected from memory integrity errors on a 64bit basis with ECC calculated across both address and data. Any sub-64bit write access to the PSPR from the Bus interface is converted to a 64bit Read-Modify-Write sequence by the PMI module.

Program Scratchpad RAM (PSPR)

The Scratchpad RAM of TriCore 1.6 is protected from memory integrity errors on a 64bit basis with ECC calculated across address and data. Eight ECC bits are required per 64 bits stored.

Uncorrectable memory integrity error detection in the PSPR is enabled by setting MIECON.PSMIEE to one. When MIECON.PSMIEE is zero all uncorrectable memory integrity errors are ignored. Error correction is enabled by setting the MIECON2.PSMSECE to one. When the MIECON2.PSMSECE is zero all errors are treated as uncorrectable. If a correctable error is detected during a memory read and error correction is enabled via the MIECON2.PSMSECE then the read data will be corrected and the CCPIER.CCPIE_U counter incremented to record the fact the an unresolved correctable program integrity error has been detected. (The error is considered unresolved as the memory itself is not updated with the corrected value).

For instruction fetch requests from the TriCore CPU to PSPR, the ECC bits are read along with the data bits and are passed to the CPU along with their corresponding instructions. Whenever an attempt is made to issue an instruction containing an uncorrectable memory integrity error a synchronous PIE trap is raised. The trap handler is then responsible for correcting the memory entry and re-starting program execution.

For PSPR read operations from the Bus interface, either from the DMI module or another Bus master agent, an access that results in the detection of an uncorrectable memory integrity error in the requested data causes a bus error to be returned for the bus transaction. Since the TriCore CPU may not be involved in the transaction, a separate error is also flagged to the SCU module to optionally generate an NMI trap back to the core.

Writes to program scratchpad memory are only ever performed from the bus interface. For write operations of 64bit size or greater, the ECC bit values are pre-computed based on the 64-bit granularity and written to the scratch memory in parallel with the data. For sub 64bit write operations the memory transaction is transformed into a 64bit read-modify-write sequence inside the PMI module. As such, sub-64 bit write operations may result in the detection of uncorrectable memory integrity errors, which are handled as standard read operations.

Instruction Cache (ICACHE)

The Scratchpad RAM of TriCore 1.6 is protected from memory integrity errors on a 64bit basis with ECC calculated across address and data. The instruction cache stores eight ECC bits per 64 bits.

Uncorrectable memory integrity error detection in the ICache is enabled by setting MIECON.PCMIEE to one. When MIECON.PCMIEE is zero all uncorrectable memory integrity errors are ignored. Error correction is enabled by setting the MIECON2.PCMSECE to one. When the MIECON2.PCMSECE is zero all errors are treated as uncorrectable. If a correctable error is detected during a memory read and error correction is enabled via the MIECON2.PCMSECE then the read data will be corrected and the CCPIER.CCPIE_U counter incremented to record the fact the an unresolved correctable program integrity error has been detected. (The error is considered unresolved as the memory itself is not updated with the corrected value).

For instruction fetch requests from the TriCore CPU to ICACHE, the ECC bits are read along with the data bits of all cache ways, and an uncorrectable error signal generated for each 64 bits of each cache way. In the case of a tag hit, the uncorrectable error signals for the corresponding cache way are passed to the core along with their corresponding instructions. Whenever an attempt is made to issue an instruction containing an uncorrectable error a synchronous PIE trap is raised. The trap handler is then responsible for checking the source of the memory integrity error.

Program Tag (PTag)

The program tag stores a 21-bit tag field for each of the cache ways in a set. As such the program tag is written with 21-bit granularity and six ECC bits are associated with each 21-bit tag way.

Uncorrectable memory integrity error detection in the PTAG is enabled by setting MIECON.PTMIEE to one. When MIECON.PTMIEE is zero all uncorrectable memory integrity errors are ignored. Error correction is enabled by setting the MIECON2.PTMSECE to one. When the MIECON2.PTMSECE is zero all errors are treated as uncorrectable. If a correctable error is detected during a memory read and error correction is enabled via the MIECON2.PTMSECE then the read data will be corrected and the CCPIER.CCPIE_U counter incremented to record the fact the an unresolved correctable program integrity error has been detected. (The error is considered unresolved as the memory itself is not updated with the corrected value).

For instruction fetch requests from the TriCore CPU to ICACHE, the program tag ECC bits are read along with the data bits and an error flag is computed. A way hit is triggered only if the tag address comparison succeeds, the valid bit is set and no ECC error in the associated tag way is detected, any other result is considered a miss. In the normal case where no error is detected in either cache way then the cache line is filled/refilled as normal. In the case where an error is detected the cache controller replacement algorithm forces the way indicating an error to be replaced. Since such errors are

otherwise transparent to the TriCore CPU, the CCPIE_R counter is incremented to allow counting of such error corrections if required. In the case where one cache way flags a cache hit, and another cache way detects an uncorrectable ECC error, the error condition is masked and has no effect on the memory integrity error handling mechanisms.

2.4.6.2 Data Side Memories

The data side memories of the TriCore 1.6 core consist of two separate memory structures:- The Data Scratchpad RAM (DSPR) and Data Cache (DCache). Both memory structures are ECC protected from memory integrity errors on a per-half word basis. Any byte write access to either DSPR or DCache is converted to a halfword Read-Modify-Write sequence. The transformation of such byte accesses to atomic sequences is performed within the DMI rather than the CPU core itself. In normal operation isolated byte write transactions to the data memories result in no additional stall cycles.

Data Scratchpad Ram (DSPR)

The DSPR of TriCore 1.6 is protected from memory integrity errors on a per-halfword basis. The DSPR is ECC protected, six ECC bits are required per half-word stored.

Uncorrectable memory integrity error detection in the DSPR is enabled by setting MIECON.DSMIEE to one. When MIECON.DSMIEE is zero all uncorrectable memory integrity errors are ignored. Error correction is enabled by setting the MIECON2.DSMSECE to one. When the MIECON2.DSMSECE is zero all errors are treated as uncorrectable. If a correctable error is detected during a memory read and error correction is enabled via the MIECON2.DSMSECE then the read data will be corrected and the CCPIER.CCDIE_U counter incremented to record the fact the an unresolved correctable data integrity error has been detected. (The error is considered unresolved as the memory itself is not updated with the corrected value).

For data load requests from the TriCore CPU to DSPR, the ECC bits are read along with the data bits and an uncorrectable error signal is generated for each half-word. If an error is detected associated with any of the data half-words passed to the core an error is flagged to the core. If such an error condition is detected an asynchronous DIE trap is raised. The trap handler is then responsible for correcting the memory entry, or for taking alternative action (such as system soft reset) if correction of the data is not possible.

For DSPR read operations from the Bus interface, either from the PMI module or another Bus master agent, an access that results in the detection of an uncorrectable error in the requested data half-words causes a bus error to be returned for the bus transaction. Since the TriCore CPU may not be involved in the transaction, a separate error is also flagged to the SCU module to optionally generate an NMI trap back to the core.

For write operations to DSPR of half-word size or greater, the ECC bits are pre-calculated and written to the memory in parallel with the data bits. For byte write operations the memory transaction is transformed into a half-word read-modify-write

sequence inside the DMI module. As such, byte write operations may result in the detection of uncorrectable memory integrity errors, which are handled as per standard read operations.

Data Cache (DCache)

The data cache stores six ECC bits per half-word.

Uncorrectable memory integrity error detection in the DCache is enabled by setting MIECON.DCMIEE to one. When MIECON.DCMIEE is zero all uncorrectable memory integrity errors are ignored. Error correction is enabled by setting the MIECON2.DCMSECE to one. When the MIECON2.DCMSECE is zero all errors are treated as uncorrectable. If a correctable error is detected during a memory read and error correction is enabled via the MIECON2.DCMSECE then the read data will be corrected and the CCPIER.CCDIE_U counter incremented to record the fact the an unresolved correctable data integrity error has been detected. (The error is considered unresolved as the memory itself is not updated with the corrected value).

For data load requests from the TriCore CPU to DCache, the ECC bits are read along with the data bits of both cache ways, and an uncorrectable error flag computed for each half-word of each cache way. In the case where an error is detected with any of the requested data half-words in a cache way which has a corresponding tag hit, an error is flagged to the core. If such an error condition is detected an asynchronous DIE trap is raised. The trap handler is then responsible for correcting the memory entry, or for taking alternative action (such as system soft reset) if correction of the data is not possible.

For write operations of half-word size or greater, the check bits are pre-calculated and written to the memory in parallel with the data bits. For byte write operations the memory transaction is transformed into a half-word read-modify-write sequence inside the DMI module. As such, byte write operations may result in the detection of uncorrectable memory integrity errors as for read operations.

For cache line writeback, uncorrectable error detection is performed as dirty data is transferred to the store buffers. In all cases (normal cache line eviction, cachex.xx instruction) where an error condition is detected in a valid cache line a DIE trap is raised. The trap handler is then responsible for taking corrective action (such as system soft reset) since correction of the data is not possible.

Data Tag (DTag)

The data tag stores a 20-bit tag address for each cache way in a set. As such the data tags are written with 20-bit granularity and six ECC bits are associated with each 20-bit tag address.

Uncorrectable memory integrity error detection in the DTAG is enabled by setting MIECON.DTMIEE to one. When MIECON.DTMIEE is zero all uncorrectable memory integrity errors are ignored. Error correction is enabled by setting the

MIECON2.DTMSECE to one. When the MIECON2.DTMSECE is zero all errors are treated as uncorrectable. If a correctable error is detected during a memory read and error correction is enabled via the MIECON2.DTMSECE then the read data will be corrected and the CCPIER.CCDIE_U counter incremented to record the fact the an unresolved correctable data integrity error has been detected. (The error is considered unresolved as the memory itself is not updated with the corrected value).

For data load or store requests from the TriCore CPU to DCache, the data tag ECC bits are read along with the data bits and an uncorrectable error flag is computed. A way hit is triggered only if the tag address comparison succeeds, the tag location is valid and no uncorrectable error in the associated tag way is detected, any other result is considered a miss. In the normal case where no error is detected in either tag way then the cache line is filled/refilled as normal. In the case of a cache miss where an error is detected in one of the tag ways and the cache line does not contain dirty data the cache controller replacement algorithm forces the way indicating an error to be replaced when the refill operation returns. Since such errors are otherwise transparent to the TriCore CPU, the CCDIE_R counter is incremented to allow counting of such error corrections if required. In the case where one cache way flags a cache hit, and the another way detects an uncorrectable error, the error condition is masked and has no effect on the memory integrity error handling mechanisms. If a cache miss occurs, with an uncorrectable error detected on the associated data tag way and dirty data detected, then an asynchronous DIE trap is signalled to the core and any writeback / refill sequence aborted. The trap handler is responsible for invalidating the cache line and processing any associated dirty data if possible, or taking other corrective action. Similar action is taken for forced cache writeback using the cache manipulation instructions.

2.5 CPU Subsystem Registers

This section describes the implementation-specific features of the CPU Subsystem registers listed in **Table 2-1**. For complete descriptions of all registers refer to the TriCore Architecture Manual.

Table 2-1 CPU Subsystem Registers

Registers	Purpose	Description
CPU Core Special Function Registers (CSFRs)	Program state information, context and stack management, interrupt and trap control, system control	see **Page 2-20**
CPU General Purpose Registers (GPRs)	General Purpose Address and Data Registers	see **Page 2-30**
CPU Memory Protection Registers (CSFRs)	Memory protection control and mode selection	see **Page 2-33**
FPU Registers (CSFRs)	Support for the standard floating point instructions.	see **Page 2-38**
Memory Integrity Registers (CSFRs)	Integrity and Protection Core Special Function Registers.	see **Page 2-40**
CPU Slave Interface (CPS) Registers	Software break control and software service request control	see **Page 2-59**
Core Debug Registers (CSFRs)	Debug control	see **Page 2-62**
Implementation Specific Reset Values	Reset values for CPU registers not defined in this chapter	see **Page 2-65**
Program Memory Interface Registers (PMI CSFRs)	PMI instruction cache control, status and trap information	see **Page 2-82**
Data Memory Interface Registers (DMI CSFRs)	DMI data cache control, status and trap information	see **Page 2-93**

2.6 CPU Core Special Function Registers (CSFR)

Figure 2-7 shows the CSFR registers of the TC1798.

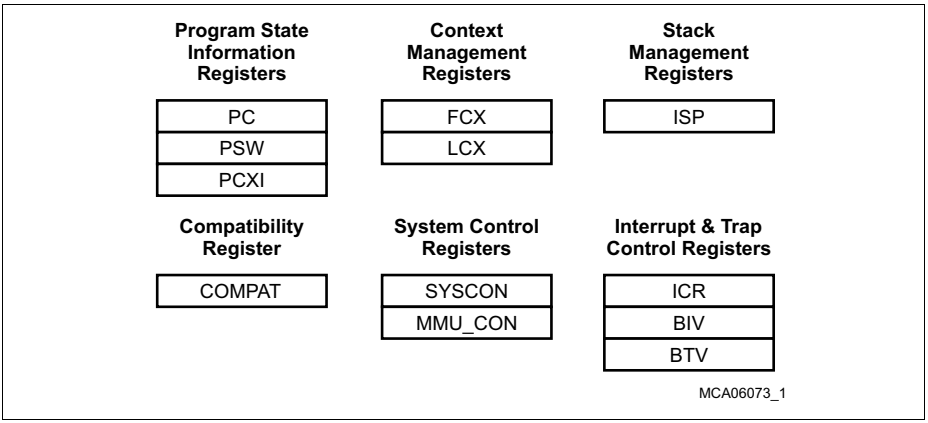

Figure 2-7 CSFR Registers

Table 2-2 Core Special Function Registers

Short Name	Description	Offset Address	Access Mode		Reset Value
			Read	Write	
MMU_CON	MMU Configuration Register	8000_H	U, SV, 32	SV, 32	Class 3 Reset 0000 8000_H
PCXI	Previous Context Information Register	$FE00_H$	U, SV, 32	SV, 32	Class 3 Reset 0000 0000_H
PSW	Program Status Word Register	$FE04_H$	U, SV, 32	SV, 32	Class 3 Reset 0000 $0B80_H$
PC	Program Counter Register	$FE08_H$	U, SV, 32	SV, 32	Class 3 Reset XXXX $XXXX_H$
SYSCON	System Configuration Register	$FE14_H$	U, SV, 32	SV, 32	Class 3 Reset 0000 0000_H

BIV	Interrupt Vector Table Pointer Register	$FE20_H$	U, SV, 32	SV, E, 32	Class 3 Reset 0000 0000_H
BTV	Trap Vector Table Pointer Register	$FE24_H$	U, SV, 32	SV, E, 32	Class 3 Reset A000 0100_H

Table 2-2 Core Special Function Registers (cont'd)

Short Name	Description	Offset Address	Access Mode		Reset Value
			Read	Write	
ISP	Interrupt Stack Pointer Register	$FE28_H$	U, SV, 32	SV, E, 32	Class 3 Reset $0000\ 0100_H$
ICR	ICU Interrupt Control Register	$FE2C_H$	U, SV, 32	SV, 32	Class 3 Reset $0000\ 0000_H$
FCX	Free Context List Head Pointer Register	$FE38_H$	U, SV, 32	SV, 32	Class 3 Reset $0000\ 0000_H$
LCX	Free Context List Limit Pointer Register	$FE3C_H$	U, SV, 32	SV, 32	Class 3 Reset $0000\ 0000_H$
PMA0	Physical Memory Attributes	$801C_H$	U, SV, 32	SV, E, 32	Class 3 Reset $C000\ 03FF_H$
COMPAT	Compatibility Control Register	9400_H	U, SV, 32	SV, E, 32	Class 3 Reset $FFFF\ FFFF_H$

2.6.1 Registers

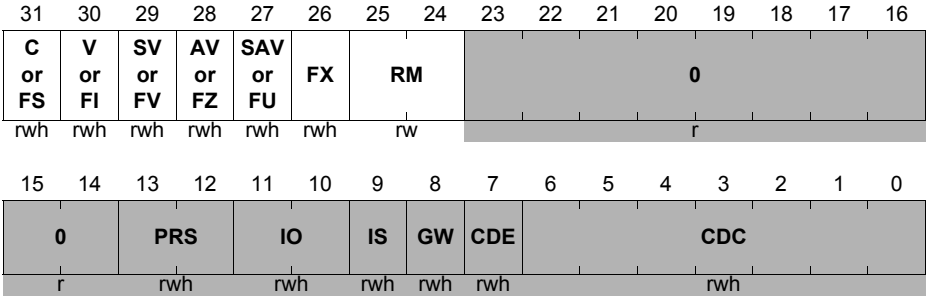
The implementation-specific Program Status Word Register (PSW) is an extension of the PSW description in the TriCore Architecture Manual. The status flags used for FPU operations overlay the status flags used for Arithmetic Logic Unit (ALU) operations.

Program Status Word Register

Note: The non-shaded areas in the register description define the implementation-specific bits/bit fields. The shaded areas are defined in the TriCore Architecture Manual.]

PSW

Program Status Word Register (F7E1 FE04$_H$) Reset Value: 0000 0B80$_H$



Field	Bits	Type	Description
RM	[25:24]	rw	**FPU Rounding Mode Selection**
FX	26	rwh	**FPU Inexact Flag**
SAV	27	rh	**Sticky Advance Overflow Flag**
FU		rwh	**FPU Underflow Flag**
AV	28	rwh	**Advance Overflow Flag**
FZ			**FPU Divide by Zero Flag**
SV	29	rwh	**Sticky Overflow Flag**
FV			**FPU Overflow Flag**
V	30	rwh	**Overflow Flag**
FI			**FPU Invalid Operation Flag**
C	31	rwh	**Carry Flag**
FS			**FPU Some Exception Flag**

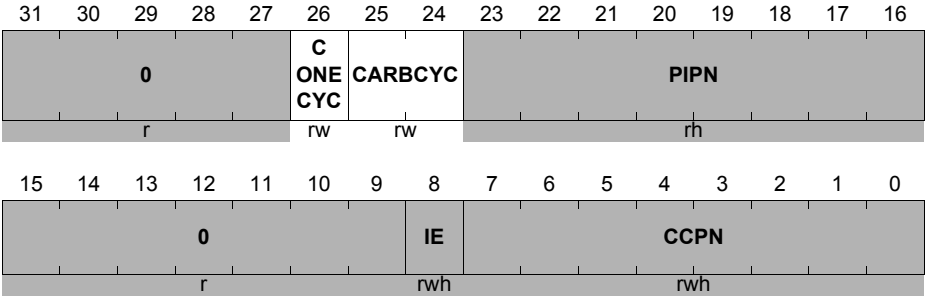
Interrupt Control Register

The Interrupt Control Register (ICR) is an implementation-specific CFSR. Its Arbitration Cycle Control implementation-specific details are defined in bits 24 to 26.

Note: The non-shaded areas in the register description define the implementation-specific bits/bit fields. The shaded areas are defined in the TriCore Architecture Manual.

ICR

Interrupt Control Register (F7E1 FE2C$_H$) Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
CARBCYC	[25:24]	rw	**Number of Arbitration Cycles** CARBCYC controls the number of arbitration cycles used to determine the request with the highest priority. 00_B 4 arbitration cycles (default) 01_B 3 arbitration cycles 10_B 2 arbitration cycles 11_B 1 arbitration cycles
CONECYC	26	rw	**Number of Clocks per Arbitration Cycle Control** The CONECYC bit determines the number of system clocks per arbitration cycle. This bit should be set to 1 only for system designs utilizing low system clock frequencies. 0_B 2 clocks per arbitration cycle 1_B 1 clock per arbitration cycle

MMU Configuration Register

The MMU Configuration Register (MMU_CON) register indicates the non-availability of the TriCore Memory Management Unit (bit NOMMU is always set).

Note: To aid debug the TriCore 1.6 implements the MMU_ASI register.

Note: The non-shaded areas in the register description define the implementation-specific bits/bit fields. The shaded areas are defined in the TriCore Architecture Manual.

MMU_CON
MMU Configuration Register (F7E1 8000$_H$) Reset Value: 0000 8000$_H$

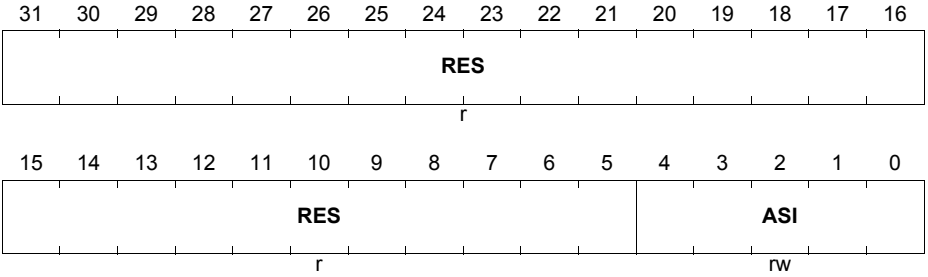
Field	Bits	Type	Description
NOMMU	15	r	**MMU Exists** 0_B MMU is available. 1_B MMU is not available. All other bits of MMU_CON are undefined. *Note:* The MMU is not available in TC1798.

Address Space Identifier Register (MMU_ASI)

The Memory Management Unit (MMU), Address Space Identifier (ASI) register description.

MMU_ASI
Address Space Identifier Register

(F7E1 8004$_H$) **Reset Value: 0000 001F$_H$**

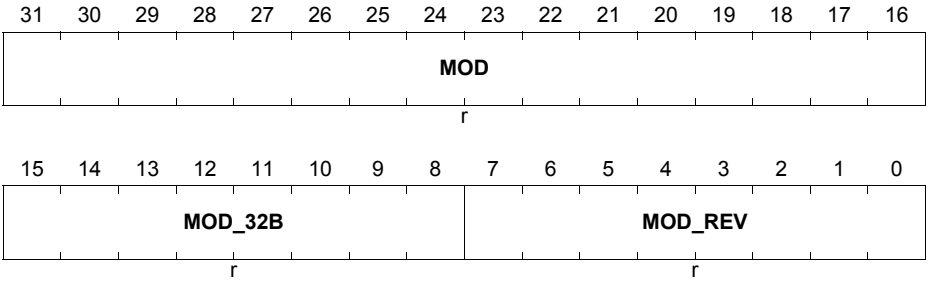


Field	Bits	Type	Description
RES	[31:5]	r	**Reserved**
ASI	[4:0]	rw	**Address Space Identifier** The ASI register contains the Address Space Identifier of the current process.

CPU Identification Register

CPU_ID
CPU Identification Register

(F7E1 FE18$_H$) **Reset Value: 00C0 C003$_H$**



Field	Bits	Type	Description
MOD_REV	[7:0]	r	**Revision Number** 03$_H$ Reset value
MOD_32B	[15:8]	r	**32-Bit Module Enable** C0$_H$ A value of C0$_H$ in this field indicates a 32-bit module with a 32-bit module ID register.
MOD	[31:16]	r	**Module Identification Number** 00C0$_H$ For module identification

Physical Memory Attributes Register

The Physical Memory Attributes PMA0 register defines the physical memory attribute for each segment in the physical address space. The register is ENDINIT protected and can be read with the MFCR instruction and written by the MTCR instruction. Note that when changing the value of the PMA0 register both the instruction and data caches should be invalidated, a dsync should be executed immediately prior to the MTCR with an ISYNC instruction executed immediately following. This is required to maintain coherency of the processors view of memory.

The physical memory attribute of a segment n in the physical address space, is defined by the bit field ATT[1:0][n]. For example, the segment F_H has the physical attributes defined by bit field ATT[1:0][F_H]. This refers to bit 15 of the ATT[1][n] bit field, and bit 15 of the ATT[0][n] bit field; i.e. a value of 10_B.

All segments are freely programmable with the following restrictions:-

- Segment-F is constrained to be Peripheral space
- Segment-D is constrained to be either cacheable or non-cacheable memory. Data fetches to the lower half segment and to the global address of the local data scratch memory are always non-cacheable irrespective of the programmed attributes.
- Segment-C is constrained to be either cacheable or non-cacheable memory. Code fetches to the lower half segment and to the global address of the local data scratch memory are always non-cacheable irrespective of the programmed attributes.
- Segment-A is constrained to be non-cacheable memory

Note: This register is ENDINIT protected.

PMA0
Physical Memory Attributes (F7E1 801C$_H$) Reset Value: C000 03FF

Field	Bits	Type	Description
ATT[1:0][15]	31, 15	r	Segment F_H physical memory attribute = 10_B. Segment F_H is constrained to always be peripheral space.

Field	Bits	Type	Description
ATT[1:0][14]	30, 14	rw	Segment E_H physical memory attribute.
ATT[1:0][13]	29, 13	rw	Segment D_H physical memory attribute = $0x_B$. Segment D_H is constrained to never be peripheral space
ATT[1:0][12]	28, 12	rw	Segment C_H physical memory attribute = $0x_B$. Segment C_H is constrained to never be peripheral space
ATT[1:0][11]	27, 11	rw	Segment B_H physical memory attribute.
ATT[1:0][10]	26, 10	r	Segment A_H physical memory attribute = 00_B. Segment A_H is constrained to be non-cached memory
ATT[1:0][9:0]	[25:16], [9:0]	rw	Segment 9_H - 0_H physical memory attributes.

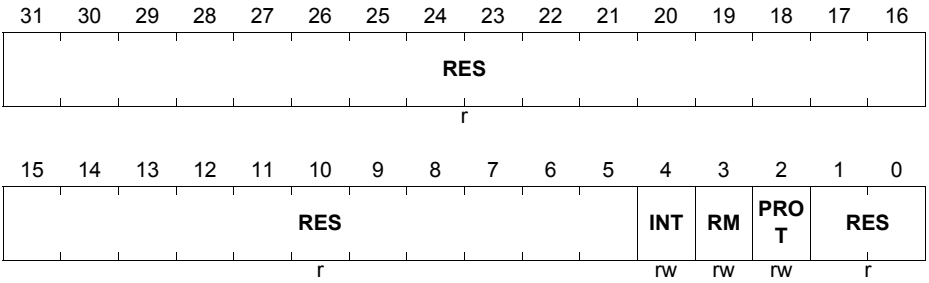
Table 2-3 ATT[1:0][n] Bit Field Encoding

ATT[1:0][n]	Segment Attributes
11	Reserved.
10	Peripheral Space.
01	Cacheable Memory.
00	Non-Cacheable Memory.

Compatibility Control Register

The Compatibility Control Register (COMPAT) is an implementation-specific CSFR which allows certain elements of backwards compatibility with TriCore 1.3.x behavior to be forced. The reset value of the COMPAT register ensures that backwards compatibility with TriCore 1.3 is enabled by default.

COMPAT
Compatibility Control Register (F7E1 9400$_H$) Reset Value: FFFF FFFF$_H$



Field	Bits	Type	Description
RES	[1:0]	r	**Reserved** Read as 1; should be written with 1.
PROT	2	rw	**Range Table to set mapping** 0_B Mapping enabled. 1_B Fixed mapping (TC1.3 behavior).
RM	3	rw	**Rounding mode compatibility** 0_B PSW.RM not restored by RET. 1_B PSW.RM restored by RET (TC1.3 behavior).
INT	4	r	**Interrupt Mode** 0_B Safe interrupt Operation, Software Acknowledge 1_B Standard Interrupt Operation, Hardware Acknowledge
RES	[31:5]	r	**Reserved** Read as 1; should be written with 1.

2.7 CPU General Purpose Registers

Figure 2-8 shows the General Purpose Registers (GPRs) of the TC1798.

2.8 CPU Memory Protection Registers

There are four Memory Protection Register Sets in the TC1798. The sets specify memory protection ranges and permissions for code and data. The PSW.PRS bit field determines which of these sets is currently in use by the CPU. The TC1.6 implements 16 data and 8 code range comparators. These may be flexibly shared amongst the of protection sets to provide a maximum of 8 data ranges and four code ranges per set. The Memory Protection Registers are Core Special Function Registers, they are described in detail in the TriCore Architecture Manual.

Table 2-5 Memory Protection Registers

Short Name	Description	Offset Address	Access Mode		Reset
			Read	Write	
DPR0_0L	Data Protection Range 0.0, Lower Bound Register	$C000_H$	U, SV, 32	SV, 32	Class 3 Reset $0000\ 0000_H$
DPR0_0U	Data Protection Range 0.0, Upper Bound Register	$C004_H$	U, SV, 32	SV, 32	Class 3 Reset $0000\ 0000_H$
DPR0_1L	Data Protection Range 0.1, Lower Bound Register	$C400_H$	U, SV, 32	SV, 32	Class 3 Reset $0000\ 0000_H$
DPR0_1U	Data Protection Range 0.1, Upper Bound Register	$C404_H$	U, SV, 32	SV, 32	Class 3 Reset $0000\ 0000_H$
DPR1_0L	Data Protection Range 1.0, Lower Bound Register	$C800_H$	U, SV, 32	SV, 32	Class 3 Reset $0000\ 0000_H$

2.9 Temporal Protection Registers

To Guard against task runtime overrun the TriCore1.6 implements a temporal protection system. This system consists of two independent decrementing counters arranged to generate a Temporal Asynchronous Error trap (TAE - Class-4, Tin-7) on decrement to zero. The Temporal Protection Registers are Core Special Function Registers, they are described in detail in the TriCore Architecture Manual.

Table 2-6 Temporal Protection System Registers

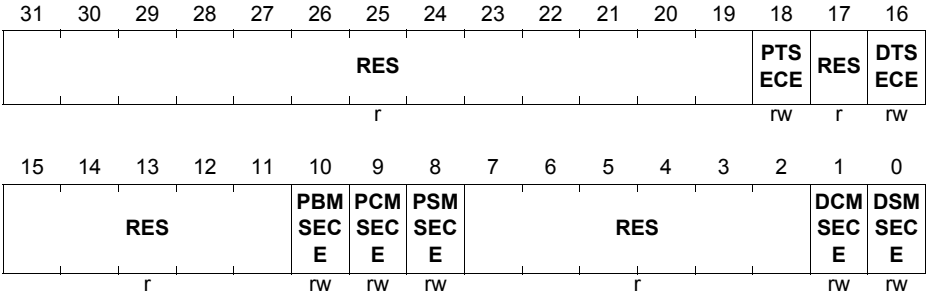
RES	[31:19]	r	**Reserved** Read as 0; should be written with 0.

Memory Integrity Error Control Register 2

The Memory Integrity Error Control Register 2 (MIECON2) allows software to control the handling of correctable memory integrity errors.

MIECON2
Memory Integrity Error Control Register 2
(F7E1 9048$_H$) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
DSMSECE	0	rw	**Data Scratch Memory Single Error Correction Enable** Enables single bit error correction for the DSPR Memories.
DCMSECE	1	rw	**Data Cache Memory Single Error Correction Enable** Enables single bit error correction for the Data Cache Memories.
RES	[7:2]	r	**Reserved**
PSMSECE	8	rw	**Program Scratch Memory Single Error Correction Enable** Enables single bit error correction for the Program Memories.
PCMSECE	9	rw	**Program Cache Memory Single Error Correction Enable** Enables single bit error correction for the Program Memories.

Field	Bits	Type	Description
PBMSECE	10	rw	**Program Bus Memory Single Error Correction Enable** Enables single bit error correction for the instructions fetched directly from the bus system.
RES	[15:11]	r	**Reserved**
DTSECE	16	rw	**Data Tag Single Error Correction Enable** Enables single bit error correction for the Data Tag
RES	17	r	**Reserved**
PTSECE	18	rw	**Program Tag Single Error Correction Enable** Enables single bit error correction for the Program Tag.
RES	[31:19]	r	**Reserved** Read as 0; should be written with 0.

Function

Although the xxIEE and xxSECE bits for a given memory type exist in different registers (MIECON and MIECON2 respectively) due to different protection requirements for these CSFR bits, the bits interact to perform the following general functions.

Table 2-9 Functions

xxSECE	xxIEE	Description
0	0	**No Memory Integrity Handling** All single and double-bit memory integrity errors ignored.
0	1	**Error Detection Mode** Single and double-bit errors treated as uncorrectable errors.
1	0	**SEC Only Mode** Single-bit errors corrected by ECC, double-bit errors ignored
1	1	**SECDED Mode** Single-bit errors corrected by ECC, double-bit errors treated as uncorrectable errors.

Program Integrity Error Information Registers

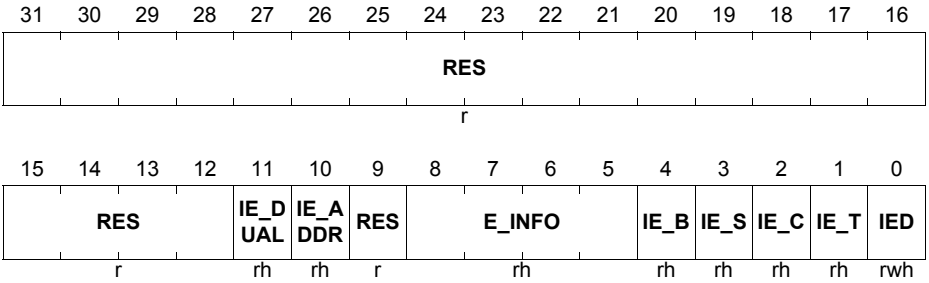
Two architecturally visible registers (PIETR, PIEAR) allow software to localise the source of the last detected uncorrectable program memory integrity error. These registers are updated when an uncorrectable program integrity error condition is detected and the PIETR.IED bit is zero. On update the PIETR.IED bit is set to one and remains set until cleared by software. Whilst PIETR.IED is set further hardware updates of PIETR and PIEAR are inhibited.

PIETR and PIEAR are updated on any uncorrectable program memory integrity error condition detected, either during a bus access or a CPU instruction pre-fetch. Since instruction pre-fetches are speculative, the PIETR and PIEAR registers may be updated without a corresponding PIE trap.

The Program Integrity Error Trap Register (PIETR) contains flags to support software in localising the source of the last detected uncorrectable program memory integrity error. Where an uncorrectable integrity error condition is detected during an instruction pre-fetch, the IE_S, IE_C and IE_T bits are updated to denote in which memory structure the error was detected, whilst BUS_ID and IE_B are cleared. Where the error is detected during an external bus access to a core memory, IE_B is set and BUS_ID updated to denote the master tag ID of the initiating bus master, whilst IE_S, IE_C and IE_T are cleared. If the error detected in the address the IE_ADDR bit is set. If the error detected is a dual bit error the IE_DUAL bit is set.

Program Integrity Error Trap Register (PIETR)

PIETR
Program Integrity Error Trap Register
(F7E1 9214$_H$) **Reset Value: 0000 0000$_H$**



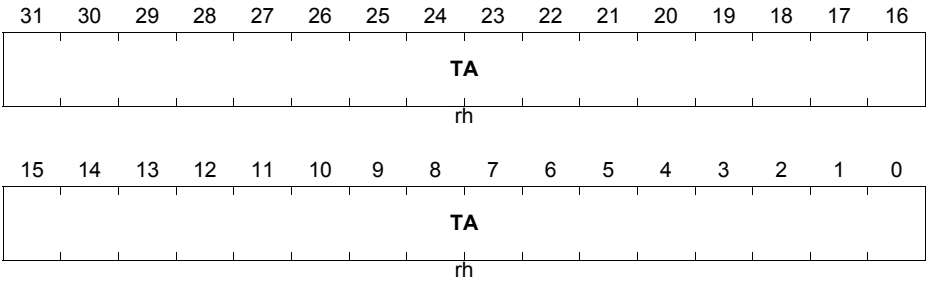
Field	Bits	Type	Description
IED	0	rwh	**Integrity Error Detected** Read Operation: 0_B No program integrity error condition occurred. 1_B Program integrity error condition detected. PIETR and PIEAR contents valid, further PIETR and PIEAR updates disabled. Write Operation: 0_B Clear IED bit, re-enable PIETR and PIEAR updates. 1_B No effect.
IE_T	1	rh	**Integrity Error - Tag Memory**
IE_C	2	rh	**Integrity Error - Cache Memory**
IE_S	3	rh	**Integrity Error - Scratchpad Memory**
IE_B	4	rh	**Integrity Error - Bus Access**
E_INFO	[8:5]	rh	**Error Information** If IE_B = 1 : Bus Master Tag ID of requesting master If IE_C = 1 : Cache way.
RES	9	r	**Reserved** Read as 0; should be written with 0.
IE_ADDR	10	r	**Integrity Error - Address Error Detected**
IE_DUAL	11	r	**Integrity Error - Dual Error Detected**

Field	Bits	Type	Description
RES	[31:12]	r	**Reserved** Read as 0; should be written with 0.

Program Integrity Error Address Register

This register contains the physical address accessed by the operation that encountered a uncorrectable program memory integrity error. This register is only updated if PIETR.IED is zero.

PIEAR
Program Integrity Error Address Register
(F7E1 9210$_H$) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
TA	[31:0]	rh	**Transaction Address** Physical address being accessed by operation that encountered program integrity error.

Data Integrity Error Information Registers

Two architecturally visible registers (DIETR, DIEAR) allow software to localise the source of the last detected uncorrectable data memory integrity error. These registers are updated when an uncorrectable data integrity error condition is detected and the DIETR.IED bit is zero. On update the DIETR.IED bit is set to one and remains set until cleared by software. Whilst DIETR.IED is set further hardware updates of DIETR and DIEAR are inhibited.

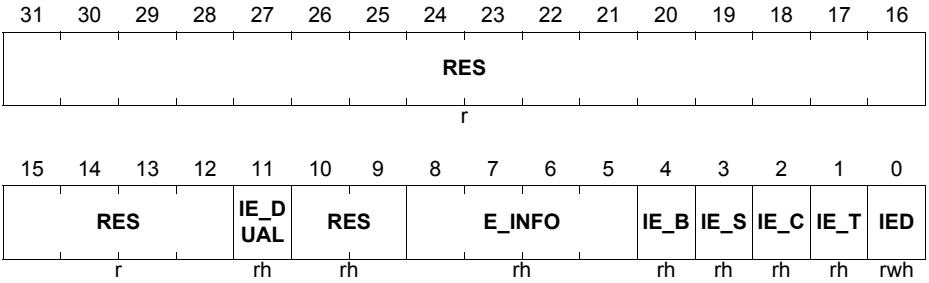
The Data Integrity Error Trap Register (DIETR) contains flags to support software in localising the source of the last detected uncorrectable data memory integrity error. Where an uncorrectable data memory integrity error condition is detected during a CPU Load/Store access, the IE_S, IE_C, IE_T and E_INFO fields are updated to denote where the error was detected and the nature of the DIE trap. whilst BUS_ID and IE_B are cleared. Where the error is detected during an external bus access to a core memory the IE_B is set and E_INFO updated to denote the master tag ID of the initiating bus master, whilst IE_S, IE_C, IE_T are cleared.

Whether a single or dual error is detected is indicated by the IE_DUAL bit. When a data integrity error is detected which causes an update of the DIE information registers and results in an asynchronous DIE trap the IED bit is set and further asynchronous DIE traps are disabled until DIETR.IED is cleared by software.

Data Integrity Error Trap Register (DIETR)

DIETR
Data Integrity Error Trap Register

(F7E1 9024$_H$) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
IED	0	rwh	**Integrity Error Detected** Read Operation: 0_B No data integrity error condition occurred. 1_B Data integrity error condition detected. DIETR and DIEAR contents valid, further DIETR and DIEAR updates disabled. Write Operation: 0_B Clear IED bit, re-enable DIETR and DIEAR update. 1_B No effect.
IE_T	1	rh	**Integrity Error - Tag Memory**
IE_C	2	rh	**Integrity Error - Cache Memory**
IE_S	3	rh	**Integrity Error - Scratchpad Memory**
IE_B	4	rh	**Integrity Error - Bus Access**
E_INFO	[8:5]	rh	**Error Information** If IE_B = 1 : Bus Master Tag ID of requesting master If IE_C = 1 : Cache way.
RES	[10:9]	r	**Reserved** Read as 0; should be written with 0.
IE_DUAL	11	rh	**IE_DUAL** Dual bit error detected.

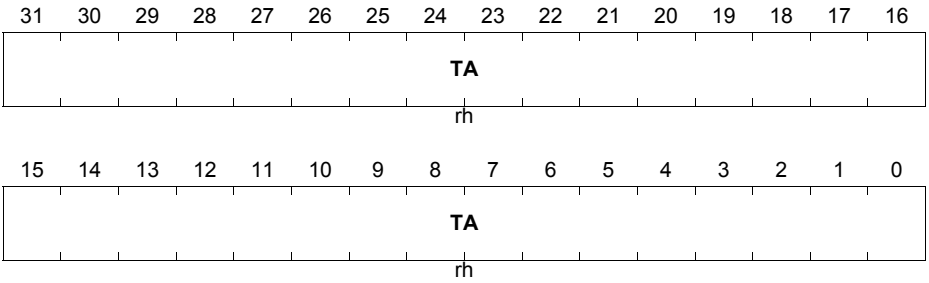
Field	Bits	Type	Description
RES	[31:12]	r	**Reserved** Read as 0; should be written with 0.

Data Integrity Error Address Register

This register contains the physical address accessed by the operation that encountered a uncorrectable data memory integrity error. This register is only updated if DIETR.IED is zero.

DIEAR
Data Integrity Error Address Register

(F7E1 9020$_H$) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
TA	[31:0]	rh	**Transaction Address** Physical address being accessed by operation that encountered data integrity error.

SIST (Software In-System) Test Support

The TriCore 1.6 core protects against memory integrity errors by ECC protection of the on-core memories. This has the side-effect of requiring memory blocks wider than the normal data access path to the memory. The additional ECC storage bits are not easily accessible via the existing data paths, causing problems where SIST based testing of the memories is required. The TriCore 1.6 core also includes embedded memory arrays, such as the tag memories, which are not ordinarily accessible by the usual CPU datapaths. In order to address this problem, the TriCore 1.6 core includes improved SIST support, allowing all on-core memory arrays to be accessed, both as a backup for MBIST based memory test and to allow the test and debug of the new fault tolerant memory systems.

The mapping of embedded memory arrays into the TriCore address space and the enabling of other SIST related features is controlled by the setting of bits within the SIST Mode Access Control Register (SMACON).

The embedded memory arrays are mapped into the program and data scratch areas (Segments C_H and D_H) of the address map by setting bits in the SMACON register. Program side embedded memories are mapped into the PSPR area and located in the address range $C01C0000_H$ - $C01FFFFF_H$.Data side embedded memories are mapped into the DSPR area and located in the address range $D01C0000_H$ - $D01FFFFF_H$. A memory that has been mapped into the scratch memory area using the SMACON register may not be accessed in its normal operational mode.

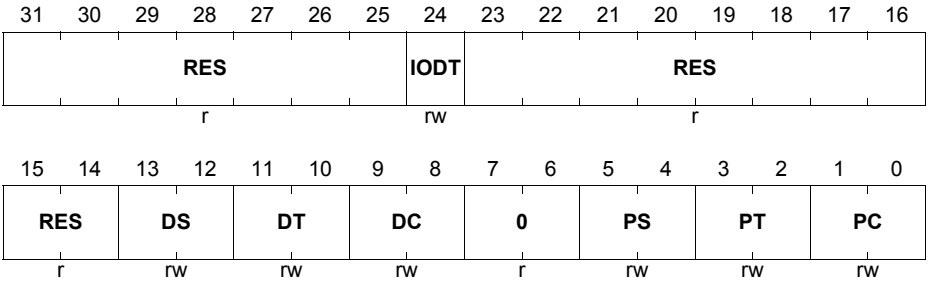
In general no bits of the SMACON register should be set during normal operation. The only exception to this is the mapping of cache to SRAM in hard real time systems in which cache operation is not desired. In such systems the cache memories may be mapped to SRAM for normal operation by setting the SMACON.PC and/or the SMACON.DC bits to “11”.

Note: When the Flash Read Protection (OTP protection) mechanism is active, the value of SMACON.PC is overridden and treated as 00_B 'normal operating mode'; however the field can still be read and written normally.

SIST Mode Access Control Register

SMACON
SIST Mode Access Control Register

(F7E1 900C$_H$) Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
PC	[1:0]	rw	**Instruction Cache Memory SIST mode access control** *Note: When the Flash Read Protection mechanism is active, the value of SMACON.PC is overridden and treated as 00_B 'normal operating mode'; however the field can still be read and written normally.* 00_B Normal Operation, No Mapping. 01_B Data Array Mapping, no error detection/correction. 10_B Check Array Mapping, no error detection/correction. 11_B Data Array Mapping, error detection/correction enabled.
PT	[3:2]	rw	**Program Tag Memory SIST mode access control** 00_B Normal Operation, No Mapping. 01_B Data Array Mapping, no error detection/correction. 10_B Check Array Mapping, no error detection/correction. 11_B Reserved.

Field	Bits	Type	Description
PS	[5:4]	rw	**Program Scratch Memory SIST mode access control** 00_B Normal Operation, No Mapping. 01_B Data Array Mapping, no error detection/correction. 10_B Check Array Mapping, no error detection/correction. 11_B Data Array Mapping, error detection/correction enabled.
RES	[7:6]	r	**Reserved** Read as 0; should be written with 0.
DC	[9:8]	rw	**Data Cache Memory SIST mode access control** 00_B Normal Operation, No Mapping. 01_B Data Array Mapping, no error detection/correction. 10_B Check Array Mapping, no error detection/correction. 11_B Data Array Mapping, error detection/correction enabled.
DT	[11:10]	rw	**Data Tag Memory SIST mode access control** 00_B Normal Operation, No Mapping. 01_B Data Array Mapping, no error detection/correction. 10_B Check Array Mapping, no error detection/correction. 11_B Reserved.
DS	[13:12]	rw	**Data Scratch Memory SIST mode access control** 00_B Normal Operation, No Mapping, Performance Optimised. 01_B Data Array Mapping, no error detection/correction. 10_B Check Array Mapping, no error detection/correction. 11_B Data Array Mapping, error detection/correction enabled.
RES	[23:14]	r	**Reserved** Read as 0; should be written with 0.

Field	Bits	Type	Description
IODT	24	rw	**In-Order Data Transactions** 0_B Normal operation, Non-dependent loads bypass stores. 1_B In-order operation, Loads always flush preceding stores, processor store buffer disabled.
RES	[31:25]	r	**Reserved** Read as 0; should be written with 0.

Control Fields

The control fields within the SMACON register allow individual control of the local memories. Each memory may be mapped to operate in a number of different modes.

Normal operation, No Mapping

No mapping of the memories is performed and normal operation is possible. Embedded memories not usually directly addressable are not accessible in the system address map. Performance optimisations are enabled such that loads may read from the physical memory or associated write buffers.

Data Array Mapping, no error detection/correction

The data array (only) of the memory is made visible in the address map. Writes to the memory will not affect the check bits. Error correction/detection for the memory is disabled. Performance optimisations are disabled such that memory accesses are guaranteed to be performed to the actual memory.

Check Array Mapping, no error detection/correction

The check bit array (only) of the memory is made visible in the address map. Writes to the memory will not affect the data bits. Error correction/detection for the memory is disabled. Performance optimisations are disabled such that memory accesses are guaranteed to be performed to the actual memory.

Data Array Mapping, error detection/correction enabled

The data array of the memory is made visible in the address map. Writes to the memory will update the check bits as per normal operation. Error correction/detection for the memory is enabled. Performance optimisations are disabled such that memory accesses are guaranteed to be performed to the actual memory.

2.12 CPU Slave Interface (CPS) Registers

The CPU Slave Interface (CPS) of the TriCore CPU directly accesses the interrupt service request registers in the CPU from the System Peripheral Bus. The CPS registers are described in detail in the TriCore Architecture Manual.

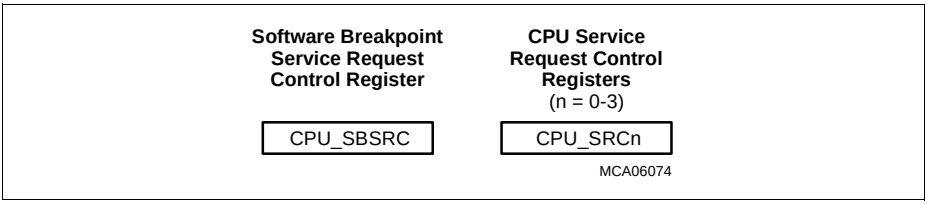


Figure 2-11 CPS Registers

Table 2-10 CPS Registers

Short Name	Description	Offset Address	Access Mode		Reset
			Read	Write	
CPU_SBSRC	CPU Software Breakpoint Service Request Control Register	$FFBC_H$	U, SV, 32	SV, 32	Class 3 Reset $0000\ 0000_H$
CPU_SRC3	CPU Service Request Control 3 Register	$FFF0_H$	U, SV, 32	SV, 32	Class 3 Reset $0000\ 0000_H$
CPU_SRC2	CPU Service Request Control 2 Register	$FFF4_H$	U, SV, 32	SV, 32	Class 3 Reset $0000\ 0000_H$
CPU_SRC1	CPU Service Request Control 1 Register	$FFF8_H$	U, SV, 32	SV, 32	Class 3 Reset $0000\ 0000_H$
CPU_SRC0	CPU Service Request Control 0 Register	$FFFC_H$	U, SV, 32	SV, 32	Class 3 Reset $0000\ 0000_H$

Note: The registers CPU_SBSRC and CPU_SRC[3:0] are not bit-addressable.

2.12.1 Register Descriptions

This registers have a specific implementation detail, the Type of Service Control (TOS) bit/bit field.

CPU Service Request Control Register

Note: The non-shaded areas in the register description define the implementation-specific bits/bit fields. The shaded areas are defined in the TriCore Architecture Manual.

CPU_SRCn (n = 0-3)
CPU Service Request Control Register n

(F7E0 FFFC$_H$-n*4) **Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0

w	w	rh	rw	r	rw	r		rw							

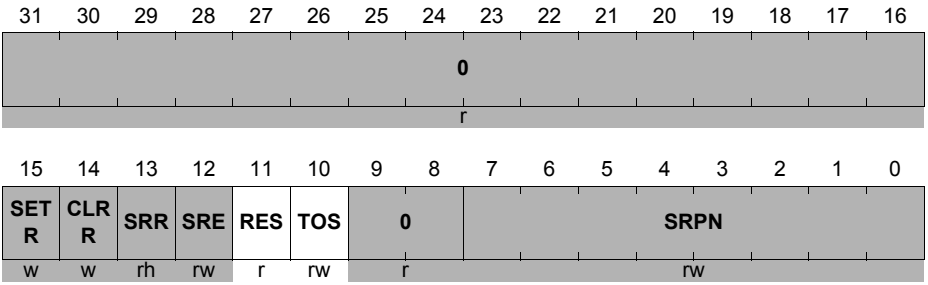
Field	Bits	Type	Description
TOS	10	rw	**Type of Service Control** 0_B Service Provider = CPU 1_B Service Provider = PCP2
RES	11	r	**Reserved** Read as 0; should be written with 0.

CPU Software Breakpoint Service Request Control Register

Note: The non-shaded areas in the register description define the implementation-specific bits/bit fields. The shaded areas are defined in the TriCore Architecture Manual.

CPU_SBSRC
CPU Software Breakpoint Service Request Control Register

(F7E0 FFBC$_H$) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
TOS	10	rw	**Type of Service Control** 0_B Service Provider = CPU 1_B Reserved
RES	11	r	**Reserved** Read as 0; should be written with 0.

2.13 Core Debug and Performance Counter Registers

The Core Debug and performance counter registers are available for debug purposes. For a complete description of all registers, refer to the TriCore Architecture Manual.

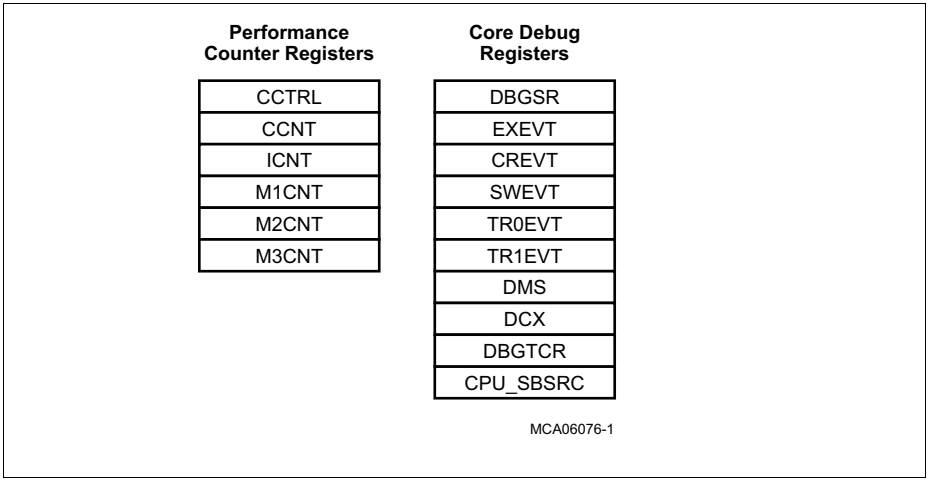


Figure 2-12 Core Debug Registers

Table 2-11 Core Debug and Performance Counter Registers

Short Name	Description	Offset Address	Access Mode		Reset
			Read	Write	
CCTRL	Counter Control Register	$FC00_H$	U, SV, 32	SV, 32	Class 1 Reset 0000 0000_H
CCNT	CPU Clock Count Register	$FC04_H$	U, SV, 32	SV, 32	Class 1 Reset 0000 0000_H
ICNT	Instruction Count Register	$FC08_H$	U, SV, 32	SV, 32	Class 1 Reset 0000 0000_H
M1CNT	Multi-Count Register 1	$FC0C_H$	U, SV, 32	SV, 32	Class 1 Reset 0000 0000_H

2.14 Implementation Specific Reset Values

This section summarizes the implementation specific reset values of the CPU registers not defined in this chapter.

Table 2-12 Implementation Specific Reset Values

Register	Address	Reset Value
PCXI	$F7E1\ FE00_H$	$0000\ 0000_H$
CPU_ID	$F7E1\ FE18_H$	$00C0\ C003_H$
FCX	$F7E1\ FE38_H$	$0000\ 0000_H$
LCX	$F7E1\ FE3C_H$	$0000\ 0000_H$
COMPAT	$F7E1\ 9400_H$	$FFFF\ FFFF_H$
ISP	$F7E1\ FE28_H$	$0000\ 0100_H$
BIV	$F7E1\ FE20_H$	$0000\ 0000_H$
BTV	$F7E1\ FE24_H$	$A000\ 0100_H$
FPU_ID	$F7E1\ A020_H$	$00C2\ C003_H$

2.15 CPU Instruction Timing

This section gives information on CPU instruction timing by execution unit. The Integer Pipeline and Load/Store Pipeline are always present, and the Floating Point Unit (FPU) is optional. The Load/Store unit implements the optional TLB instructions.

Definition of Terms:

- **Repeat Rate**

Assuming the same instruction is being issued sequentially, repeat is the minimum number of clock cycles between two consecutive issues. There may be additional delays described elsewhere due to internal pipeline effects when issuing a different subsequent instruction.

- **Result Latency**

The number of clock cycles from the cycle when the instruction is issued to the cycle when the result value is available to be used as an operand to a subsequent instruction or written into a GPR. Result latency is not meaningful for instructions that do not write a value into a GPR.

- **Address Latency**

The number of clocks cycles from the cycle when the instruction is issued to the cycle when the addressing mode updated value is available as an operand to a subsequent instruction or written into an Address Register.

- **Flow Latency**

The number of clock cycles from the cycle when the instruction is issued to the cycle when the next instruction (located at the target location or the next sequential instruction if the control change is conditional) is issued.

2.15.1 Integer-Pipeline Instructions

These are the Integer-Pipeline instruction timings for each instruction.

2.15.1.1 Simple Arithmetic Instruction Timings

Each instruction is single issued.

Table 2-13 Simple Arithmetic Instruction Timing

Instruction	Result Latency	Repeat Rate	Instruction	Result Latency	Repeat Rate
Integer Pipeline Arithmetic Instructions					
ABS	1	1	**MAX.H**	1	1
ABS.B	1	1	**MAX.HU**	1	1
ABS.H	1	1	**MAX.U**	1	1

SH.EQ	1	1	**SH.ORN.T**	1	1
SH.GE	1	1	**SH.XNOR.T**	1	1
SH.GE.U	1	1	**SH.XOR.T**	1	1
SH.H	1	1	**SHA**	1	1
SH.LT	1	1	**SHA.H**	1	1
SH.LT.U	1	1	**SHAS**	2	1

Table 2-13 Simple Arithmetic Instruction Timing (cont'd)

Instruction	Result Latency	Repeat Rate	Instruction	Result Latency	Repeat Rate
SH.NAND.T	1	1			
Coprocessor 0 Instructions					
BMERGE	2	1	**IXMIN**	2	1
BSPLIT	2	1	**UNPACK**	2	1
PARITY	2	1	**IXMAX**	2	1
PACK	2	1	**IXMAX.U**	2	1
IXMIN.U	2	1			
Integer Divide Instructions					
DVADJ	2	1	**DVSTEP**	6	4
DVINIT	2	1	**DVSTEP.U**	6	4
DVINIT.U	2	1	**DIV**	4-11	3-9
DVINIT.B	2	1	**DIV.U**	4-11	3-9
DVINIT.H	2	1			
DVINIT.BU	2	1			
DVINIT.HU	2	1			

The latency and repeat rate values listed for the DIV and DIV.U instructions are the minimum and maximum values.The algorithm used allows for early termination of the instruction once the full result is available.

2.15.1.2 Multiply Instruction Timings

Each instruction is single issued.

Table 2-14 Multiply Instruction Timing

Instruction	Result Latency	Repeat Rate	Instruction	Result Latency	Repeat Rate
MUL	2	1	**MUL.Q**	3	1
MUL.U	2	1	**MULM.H**	3	1
MULS	3	1	**MULR.H**	3	1
MULS.U	3	1	**MULR.Q**	3	1
MUL.H	3	1			

2.15.1.3 Multiply Accumulate (MAC) Instruction Timing

Each instruction is single issued.

Table 2-15 Multiply Accumulate Instruction Timing

Instruction	Result Latency	Repeat Rate	Instruction	Result Latency	Repeat Rate
MADD	3	1	**MSUB**	3	1
MADD.U	3	1	**MSUB.U**	3	1
MADDS	3	1	**MSUBS**	3	1
MADDS.U	3	1	**MSUBS.U**	3	1
MADD.H	3	1	**MSUB.H**	3	1
MADD.Q	3	1	**MSUB.Q**	3	1
MADDM.H	3	1	**MSUBM.H**	3	1
MADDMS.H	3	1	**MSUBMS.H**	3	1
MADDR.H	3	1	**MSUBR.H**	3	1
MADDR.Q	3	1	**MSUBR.Q**	3	1
MADDRS.H	3	1	**MSUBRS.H**	3	1
MADDRS.Q	3	1	**MSUBRS.Q**	3	1
MADDS.H	3	1	**MSUBS.H**	3	1
MADDS.Q	3	1	**MSUBS.Q**	3	1
MADDSU.H	3	1	**MSUBAD.H**	3	1
MADDSUM.H	3	1	**MSUBADM.H**	3	1
MADDSUMS.H	3	1	**MSUBADMS.H**	3	1
MADDSUR.H	3	1	**MSUBADR.H**	3	1
MADDSURS.H	3	1	**MSUBADRS.H**	3	1
MADDSUS.H	3	1	**MSUBADS.H**	3	1

For All MADD, MSUB and MUL type instructions the result latency is reduced to 1 for accumulator forwarding between similar instructions.

For MADD.Q, MADDS.Q, MSUB.Q, MSUBS.Q Instructions:

MADD.Q, MADDS.Q, MSUB.Q, MSUBS.Q	Result Latency	Repeat Rate
16 × 16	3	1
16 × 32	3	1
32 × 32	3	1

2.15.1.4 Control Flow Instruction Timing

Control flow instruction timing for TriCore1.6 is complicated by the use of branch target buffers and fetch FIFOs.

- Incorrectly predicted LS instructions incur a three cycle branch recovery penalty.
- Incorrectly predicted IP instructions incur a four cycle branch recovery penalty.
- Correctly predicted not taken breaches incur no penalty
- Correctly predicted taken branch incur a penalty of up to two cycles depending on the state of the fetch FIFOs and the branch target buffer.
- Loop instructions incur the same penalty as an LS conditional jump instruction.

Assumptions

- All target locations yield a full instruction in one access (i.e. not 16-bits of a 32-bit instruction).
- All code fetches take a single cycle.
- Timing is best case; no cache misses for context operations, no pending stores.

Table 2-16 Control flow timing

Prediction-Result	Flow Latency (LS, LP)	Repeat rate (LS,LP)	Flow Latency (IP)	Repeat Rate (IP)
Correct Not-Taken	1	1	1	1
Correct Taken	1-2	1-2	1-2	1-2
Incorrect Not-Taken	3	4	3	4
Incorrect Taken	3	4	3	4

2.15.2 Load-Store Pipeline Instructions

This section summarizes the Load-Store Pipeline instructions.

2.15.2.1 Address Arithmetic Timing

Each instruction is single issued.

Table 2-17 Address Arithmetic Instruction Timing

Instruction	Result Latency	Repeat Rate	Instruction	Result Latency	Repeat Rate
Load Store Arithmetic Instructions					
ADD.A	1	1	**GE.A**	1	1
ADDIH.A	1	1	**LT.A**	1	1
ADDSC.A	2	1	**NE.A**	1	1
ADDSC.AT	2	1	**NEZ.A**	1	1
EQ.A	1	1	**SUB.A**	1	1
EQZ.A	1	1	**NOP**	1	1
Trap and Interrupt Instructions					
DEBUG	–	1	**TRAPSV**[1)]	–	1
DISABLE	–	1	**TRAPV**[1)]	–	1
ENABLE	–	1	**RSTV**	–	1
RESTORE	–	1			
Move Instructions					
MFCR	2	1	**MOV.A**	1	1
MTCR	1	1	**MOV.AA**	1	1
MOVH.A	1	1	**MOV.D**	1	1
Sync Instructions					
DSYNC[2)]	–	1	**ISYNC**[3)]	–	1

1) Execution cycles when no TRAP is taken. The execution timing in the case of raising these TRAPs is the same as other TRAPs such as SYSCALL.

2) Repeat rate assumes that no shadow register writeback is pending, otherwise the repeat rate will depend upon the time for all delayed memory operation to occur.

3) Repeat rate assumes that code refetch takes a single cycle.

2.15.2.2 CSA Control Flow Instruction Timing

This section summarizes the timing of CSA Control Flow instructions.

- All targets yield a full instruction in one access (not 16-bits of a 32-bit instruction).
- All code fetches take a single cycle. Timing is best case; no cache misses for context operations, no pending stores.

Table 2-18 CSA Control Flow Instruction Timing

Instruction	Flow Latency	Repeat Rate	Instruction	Flow Latency	Repeat Rate
CALL	4-8	4-8	**SYSCALL**	4-8	4-8
CALLA	4-8	4-8	**SVLCX**	4-8	4-8
CALLI	4-8	4-8	**RSLCX**	4-8	4-8
RET	4-8	4-8	**RFE**	4-8	4-8
BISR	4-8	4-8	**RFM**	4-8	4-8
FCALL	1	1	**FCALLA**	1	1
FCALLI	1	1	**FRET**	1	1

Access to DSPR require 4 cycles, accesses to cached external memory require 8 cycles.

2.15.2.3 Load Instruction Timing

Load instructions can produce two results if they use the pre-increment, post-increment, circular or bit-reverse addressing modes. Hence, in those cases there are two latencies that must be specified, the result latency for the value loaded from memory and the address latency for using the updated address register result.

- Each instruction is single issued.
- The memory references is naturally aligned.
- The memory accessed takes a single cycle to return a data item.
- Timing is best case; no cache misses, no pending stores.

Table 2-19 Load Instruction Timing

Instruction	Address Latency	Result Latency	Repeat Rate	Instruction	Address Latency	Result Latency	Repeat Rate
Load Instructions							
LD.A	1	3	1	**LD.Q**	1	2	1
LD.B	1	2	1	**LD.W**	1	2	1
LD.BU	1	2	1	**LDLCX**	4-8	4-8	4

Table 2-19 Load Instruction Timing (cont'd)

Instruction	Address Latency	Result Latency	Repeat Rate	Instruction	Address Latency	Result Latency	Repeat Rate
LD.D	1	2	1	**LDUCX**	4-8	4-8	4
LD.DA	1	3	1	**SWAP.W**	2	3	2
LD.H	1	2	1	**LEA**[1)]	–	1	1
LD.HU	1	2	1				

1) The addressing mode returning an updated address is not relevant for this instruction.

2.15.2.4 Store Instruction Timing

Cache and Store instructions similar to Load instructions will have a result for the pre-increment, post-increment, circular or bit-reverse addressing modes, but do not produce a ‘memory’ result.

- Each instruction is single issued.
- The memory references is naturally aligned.
- The memory accessed takes a single cycle to accept a data item.
- Timing is best case; no cache misses, no pending stores.

Table 2-20 Cache and Store Instruction Timing

Instruction	Address Latency	Repeat Rate	Instruction	Address Latency	Repeat Rate
Cache Instructions					
CACHEA.I	1	1	**CACHEA.WI**[1)]	1	1
CACHEA.W[1)]	1	1	**CACHEI.W**	1	1
CACHEI.WI	1	1	**CACHEI.I**	1	1
Store Instructions					
ST.A	1	1	**ST.T**	1	2
ST.B	1	1	**ST.W**	1	1
ST.D	1	1	**STLCX**	1	4-8
ST.DA	1	1	**STUCX**	1	4-8
ST.H	1	1	**LDMST**	1	2
ST.Q	1	1			

1) Repeat rate assumes that no memory writeback operation occurs. Otherwise the repeat rate will depend upon the time for the castout buffers to clear.

2.15.3 Floating Point Pipeline Timing

These instructions are only valid if the optional Floating Point Unit is implemented.

Each instruction is single issued.

Table 2-21 Floating Point Instruction Timing

Instruction	Result Latency	Repeat Rate	Instruction	Result Latency	Repeat Rate
Floating Point Instructions

FTOUZ	2	1	**UTOF**	2	1

2.16 Program Memory Interface (PMI)

Figure 2-13 shows the block diagram of the Program Memory Interface (PMI) of the TC1798.

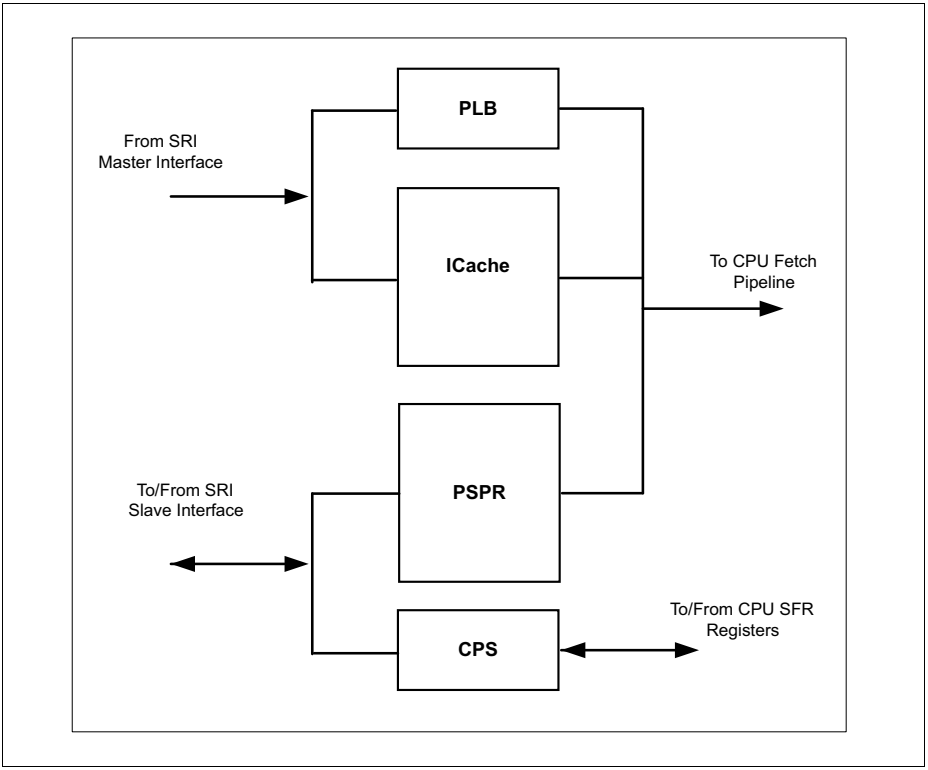

Figure 2-13 PMI Block Diagram

2.16.1 PMI Features

The Program Memory Interface (PMI) has the following features:

- 16 Kbyte Program Cache (ICACHE)
  - Four-way set associative cache
  - PLRU (Pseudo Least-Recently Used) replacement algorithm
  - Cache line size: 256 bits (4 double-words)
  - Validity granularity: One valid bit per cache line
  - ICACHE can be globally invalidated to provide support for software cache coherency (to be handled by the programmer)

  - ICACHE can be bypassed to provide a direct fetch from the CPU to on-chip and off-chip resources
  - ICACHE refill mechanism:
    Critical word first, line wrap around, streaming to CPU
- 32 Kbyte Program Scratchpad memory (PSPR)
- CPU interface
  - Supporting 64bit aligned fetches.
- CPU Slave interface (CPS)
- Shared Resource Interconnect Bus (SRI) Master Interface
- Shared Resource Interconnect Bus (SRI) Slave Interface to scratchpad RAM and CPS.
- All PMI SRAMs (PSPR, ICACHE, and cache tag SRAM) are ECC protected
  - ECC is calculated on address and data for the PSPR and ICACHE

2.16.2 Scratchpad RAM

The TC1798 contains 32 Kbyte of Program scratchpad RAM. Scratchpad RAM provides a fast, deterministic program fetch access from the CPU for use by performance critical code sequences.

- CPU program fetch accesses to scratchpad RAM are never cached in the instruction cache and are always directly targeted to the scratchpad RAM.

The CPU fetch interface will generate aligned accesses (64-bit), which will result in 64-bits of instruction being returned to the CPU.

Note that the CPU Fetch Unit can only read from the scratchpad RAM and can never write to it.

The scratchpad RAM may also be accessed from the SRI Slave interface by another bus master, such as the Data Memory Interface (DMI). The scratchpad RAM may be both read and written from the SRI. In the TC1798, the SRI Slave interface supports all SRI transaction types.

The scratchpad RAM is ECC protected across both address and data.

2.16.3 Instruction Cache

The TC1798 contains up to 16 Kbyte of Instruction Cache (ICACHE). The ICACHE is a four-way set-associative cache with a Pseudo Least-Recently-Used (PLRU) replacement algorithm. Each ICACHE line contains 256 bits of instruction along with a single associated valid bit and associated ECC bits.

CPU program fetch accesses which target a cacheable memory segment (and where the ICACHE is not bypassed) target the ICACHE. If the requested address and its associated instruction are found in the cache (Cache Hit), the instruction is passed to the CPU Fetch Unit without incurring any wait states. If the address is not found in the cache (Cache Miss), the PMI cache controller issues a cache refill sequence and wait states

are incurred whilst the cache line is refilled. The fetch request always returns an aligned 64bit packet to the CPU.

The Instruction cache is ECC protected on both address and data. The Instruction TAG Ram is ECC protected on data.

Instruction Cache Refill Sequence

Instruction Cache refills are performed using a critical double-word first strategy with cache line wrapping such that the refill size is always 4 double-words. ICACHE refills are always performed in 64-bit quantities. A refill sequence will always affect only one cache line. There is no prefetching of the next cache line.

ICACHE refills are therefore implemented using an SRI Burst Transfer 4 (BTR4) transfers. The Instruction Cache supports instruction streaming, meaning that it can deliver available instruction half-words to the CPU Fetch Unit whilst the refill operation is ongoing.

Instruction Cache Bypass

The Instruction Cache may be bypassed, under control of PCON0.PCBYP, to provide a direct instruction fetch path for the CPU Fetch Unit. The default value of PCON0.PCBYP is such that the ICACHE is bypassed after reset. ICACHE bypass should be disabled during initialization to enable the ICACHE.

Whilst ICACHE bypass is enabled, a fetch request by the CPU to a cacheable address will result in a forced cache miss, such that the cache controller issues a standard refill sequence and supplies instruction half-words to the CPU using instruction streaming, without updating the cache contents. Any valid cache lines within the ICACHE will remain valid and unchanged whilst the ICACHE is bypassed. As such, instruction fetch requests to cacheable addresses with ICACHE bypass enabled behave identically to instruction fetch requests to non-cacheable addresses.

Instruction Cache Invalidation

The PMI does not have automatic cache coherency support. Changes to the contents of memory areas external to the PMI that may have already been cached in the ICACHE are not detected. Software must provide the cache coherency in such a case. The PMI supports this via the cache invalidation function. The ICACHE contents may be globally invalidated by writing a ‘1’ to PCON1.PCINV. The ICACHE invalidation is performed over 128 cycles by a hardware state machine which cycles through the ICACHE entries marking each as invalid. During an invalidate sequence the CPU may continue to fetch instructions from non-cacheable memory. Any attempt to fetch instructions from a cacheable memory location during an invalidation sequence will result in the CPU stalling until the sequence completes. The status of the ICACHE invalidation sequence may be determined by reading the PCON1.PCINV bit.

2.16.4 Program Line Buffer

The PMI module contains a 256-bit Program Line Buffer (PLB). Program fetch requests to non-cacheable addresses (or to cacheable addresses with the cache in bypass) utilize the PLB as a single line cache. A single valid bit is associated with the PLB, denoting that the PLB contents are valid. As such all fetch requests resulting in an update of the PLB, whether to a cacheable address or not, are implemented as SRI Burst Transfer 4 (BTR4) transactions, with the critical double-word of the PLB line being fetched first size. The PLB may be invalidated by writing PCON1.PBINV.

The PLB is ECC protected on both address and data.

2.16.5 CPU Slave Interface (CPS)

The CPU Slave Interface provides access from the SRI bus to the core CSFR and SFR registers.

2.16.6 PMI Registers

Three control registers are control the operation of the Program Memory Interface. These registers and their bits are described in this section.

Table 2-22 PMI Registers

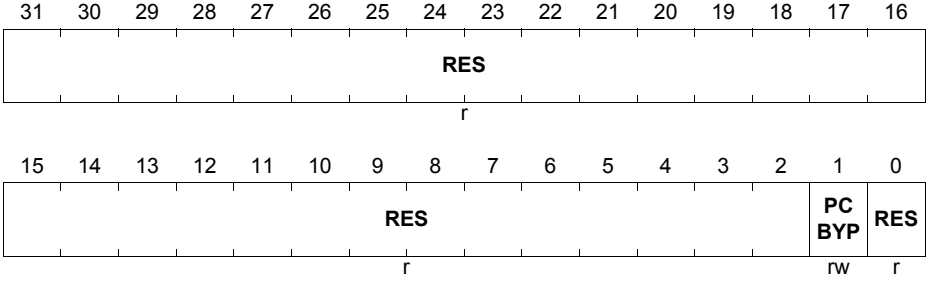
Short Name	Description	Offset Address	Access Mode		Reset
			Read	Write	
PCON0	PMI Control Register 0	$920C_H$	U, SV, 32	SV, 32	Class 3 Reset $0000\ 0002_H$
PCON1	PMI Control Register 1	9204_H	U, SV, 32	SV, 32	Class 3 Reset $0000\ 0000_H$
PCON2	PMI Control Register 2	9208_H	U, SV, 32	SV, E, 32	Class 3 Reset $0020\ 0010_H$
PMI_STR	PMI Synchronous Trap Register	9200_H	U, SV, 32	SV, 32	Class 3 Reset $0000\ 0000_H$

2.16.6.1 PMI Register Descriptions

PMI Control Register 0

PCON0
Program Memory Control Register 0

(F7E1 920C$_H$) **Reset Value: 0000 0002$_H$**

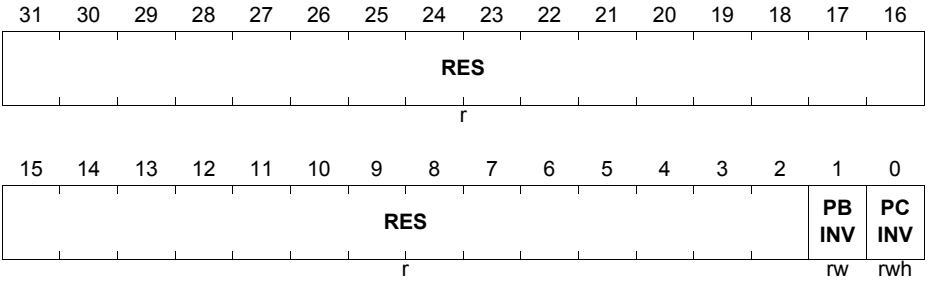


Field	Bits	Type	Description
RES	0	r	**Reserved** Read as 0; should be written with 0.
PCBYP	1	rw	**Instruction Cache Bypass** 0_B Cache enabled 1_B Cache bypassed (disabled)
RES	[31:2]	r	**Reserved** Read as 0; should be written with 0.

PMI Control Register 1

PCON1

Program Memory Control Register 1 (F7E1 9204$_H$) **Reset Value: 0000 0000$_H$**



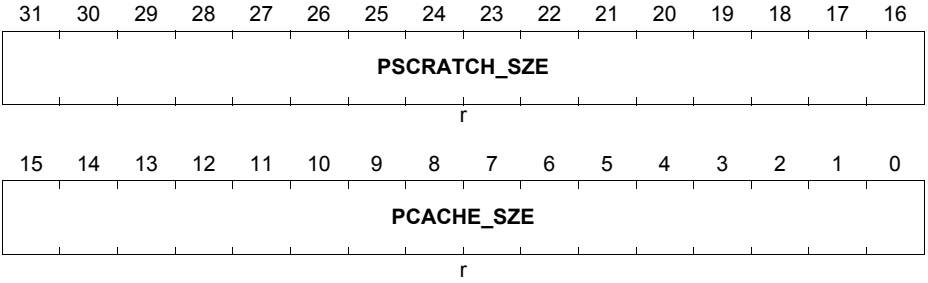
Field	Bits	Type	Description
PCINV	0	rwh	**Instruction Cache Invalidate** Write Operation: 0_B No effect. Normal instruction cache operation. 1_B Initiate invalidation of entire instruction cache. Read Operation: 0_B Normal operation. Instruction cache available. 1_B Instruction cache invalidation in progress. Instruction cache unavailable.
PBINV	1	rw	**Program Buffer Invalidate** Write Operation: 0_B No effect. Normal program line buffer operation. 1_B Invalidate the program line buffer. This field returns 0 when read.
RES	[31:2]	r	**Reserved** Read as 0; should be written with 0.

PMI Control Register 2

PCON2 contains size information for the Program memory system.

PCON2
Program Memory Control Register 2

(F7E1 9208$_H$) **Reset Value: 0020 0010$_H$**



Field	Bits	Type	Description
PCACHE_SZE	[15:0]	r	**Program Cache (ICACHE) Size** In KBytes
PSCRATCH_SZE	[31:16]	r	**Program Scratch Size** In KBytes

Program Memory Interface Synchronous Trap Register (PSTR)

PSTR contains synchronous trap information for the program memory system. The register is updated with trap information for PSE traps to aid the localisation of faults.

The register is only set whenever a trap is detected and the register has no bits already set. It is cleared by a CSFR write (independent of data value).

PSTR
Program Synchronous Trap Register
(F7E1 9200$_H$) **Reset Value: 0000 0000$_H$**

RES	[31:15]	r	**Reserved**

Fetch Range Error

A Fetch Range Error occurs whenever an access to the Program Scratch is outside the range of the SRAM.

Fetch Global Address Error

A Fetch Global Address Error occurs whenever an there is access to an address that cannot be translated to a valid global address.This will occur for accesses in the range D1000000 to D7FFFFFF

Fetch Bus Error

A Fetch bus error will be set whenever the SRI flags an error due a fetch from external memory. This will be set for both direct fetches from the bus and for cache refills.

Fetch Peripheral Error

A Fetch peripheral error will be flagged whenever a fetch is attempted to peripheral space.

Fetch MSIST Error

During SIST mode, a fetch from the PTAG will cause a PSE trap to occur.

2.17 Data Memory Interface (DMI)

This figure shows the block diagram of the Data Memory Interface (DMI) of the TC1798.

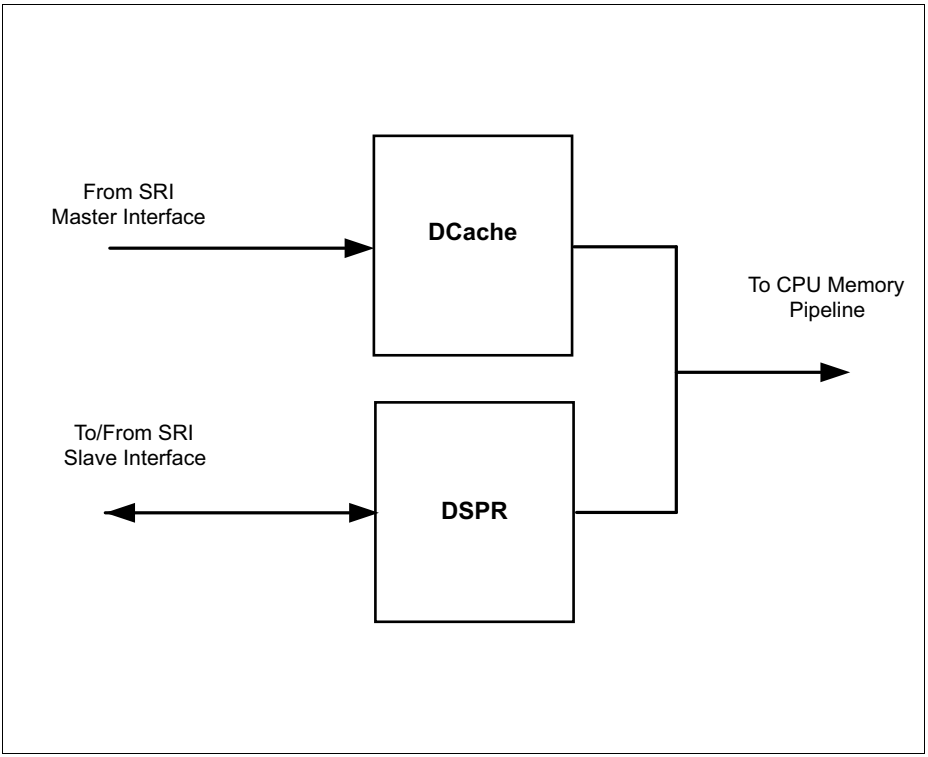

Figure 2-14 DMI Block Diagram

2.17.1 DMI Features

The Data Memory Interface (DMI) has the following features:

- 128 Kbyte Data Scratchpad Ram (DSPR)
  - Supporting unaligned access (16-bit aligned) with no penalty.
- 16 Kbyte Data Memory (DCACHE):
  - Four-way set associative cache, Pseudo least recently used (PLRU) replacement algorithm
  - Cache line size: 256 bits
  - Validity granularity: One valid bit per cache line
  - Write-back Cache: Writeback granularity: 256 bits
  - Refill mechanism: full cache line refill

- CPU interface
- Shared Resource Interface Bus (SRI) Master interface
- Shared Resource Interface (SRI) Slave interface to DSPR
-
- All DMI SRAMs (DSPR, DCACHE, and cache tag SRAM) are ECC protected

2.17.2 Data Scratchpad RAM (DSPR)

The TC1798 contains 128 Kbyte of DSPR. DSPR provides fast, deterministic data access to the CPU for use by performance critical code sequences.

The DSPR is organised as multiple memory “towers”. This organisation allow the CPU to access 64bits of data from any 16bit aligned address

The DSPR may also be accessed from the SRI Slave interface by another bus master, with both read and write transactions supported. The DSPR may be accessed by the SRI Slave interface using any SRI transaction type, including burst transfers. In accordance with the SRI protocol, accesses to the SRI Slave interface must be naturally aligned.

2.17.3 Data Cache

The TC1798 contains 16 KByte of Data Cache (DCache). The DCache is a four-way set-associative cache with a Pseudo Least-Recently-Used (PLRU) replacement algorithm. Each line contains 256 bits of data along with ECC bits. A single valid bit and a single dirty bit are associated with each line.

CPU data accesses to a cacheable memory segment target the DCache. If the requested address and its associated data are found in the cache (Cache Hit), the data is passed to/from the CPU Load-Store Unit without incurring any wait states. If the address is not found in the cache (Cache Miss), the DMI cache controller issues a cache refill sequence and wait states are incurred whilst the cache line is refilled. The CPU load-store interface will generate unaligned accesses (16-bit aligned), which will result in up to 64-bits of data being transferred to or from the CPU (for non-context operations). If the data access is made within a DCache line, no matter the alignment, and a cache hit is detected then the requested data is returned to the CPU in a single cycle. If the data access is made to the end of a DCache line, such that the requested data would span two DCache lines, a single wait cycle is incurred (if both cache lines are present in the cache, otherwise a refill sequence is required for the missing cache line(s)).

The TC1798 data cache is of the writeback type. When the CPU writes to a cacheable location the data is merged with the corresponding cache line and not written to main memory immediately. Associated with each cache line is a single ‘dirty’ bit, to denote that the data in the cache line has been modified. Whenever a CPU load-store access results in a cache miss, and each of the potential cache ways that could hold the requested cache line are valid, one of the cache lines is chosen for eviction based upon the PLRU replacement algorithm. The line selected for eviction is then checked to determine if it

has been modified using its dirty bit. If the line has not been modified the line is discarded and the refill sequence started immediately. If the line has been modified then the dirty data is first written back to main memory before the refill is initiated. Due to the single dirty bit per cache line, 256 bits of data will always be written back, resulting in a SRI Burst-4 Transfer (BTR4) transactions.

Data Cache refills always result in the full cache line being refilled, with the critical double-word of the DCache line being fetched first. A refill sequence will always affect only one cache line. There is no prefetching of the next cache line. Due to the uniform size of DCache refill sequences, such refills are always implemented using SRI Burst Transfer 4 (BTR4) transactions.

2.17.4 DMI Trap Generation

CPU data accesses to the DMI may encounter one of a number of potential error conditions, which result in one of the following trap conditions being reported by the DMI.

ALN Trap

An ALN trap is raised for the following conditions:

- An access whose effective address does not conform to the alignment rules
- An access where the length, size or index of a circular buffer is incorrect

Whenever an ALN trap occurs, the DSTR (Data Synchronous Trap Register) and the DEADD (Data Error Address Register) CSFRs are updated.

MEM Trap

A MEM trap is raised for the following conditions:

- An access whose effective address has a different segment to that of the base address (Segment Difference Error)
- An access whose effective address causes the data to span two segments (Segment Crossing Error)
- A memory address is used to access a CSFR area (CSFR Access Error)

Whenever a MEM trap occurs, the DSTR (Data Synchronous Trap Register) and the DEADD (Data Error Address Register) CSFRs are updated.

DSE Trap

A DSE trap is raised for the following conditions:

- An access outside the range of the DSPR (Scratch Range Error)
- An access to the lower half of segment C which cannot be translated into a global address, i.e. from C1000000 to C7FFFFFF (Global Address Error)
- An error on the bus for an external accesses due to a load (Load Bus Error)
- An error from the bus during a cache refill (Cache Refill Error)

- An error during a load whilst in SIST mode (Load MSIST Error)
- An error generated by the overlay system during a load.

Whenever a DSE trap occurs, the DSTR (Data Synchronous Trap Register) and the DEADD (Data Error Address Register) CSFRs are updated.

DAE Trap

A DAE trap is raised for the following conditions:

- An error on the bus for an external accesses due to a store (Store Bus Error)
- An error on the bus due to a cache writeback (Cache writeback Error)
- An error from the bus due to a cache flush (Cache Flush Error)
- An error due to a store whilst in SIST mode (Store MSIST Error)
- An error generated by the overlay system during a store.

Whenever a DAE trap occurs, the DATR (Data Synchronous Trap Register) and the DEADD (Data Error Address Register) CSFRs are updated.

Data Memory Protection Traps

Data memory protection traps (MPW, MPR, MPP, MPN) are raised by the memory protection system when a protection violation occurs. Whenever a data memory protection trap occurs the DSTR (Data synchronous trap register) and the DEADD (Data Error Address Register) are updated.

2.18 Memory Configuration

The TC1.6 memories are configured as follows:-

Table 2-23 Memory Configuration

Processor	Program Cache	Program Scratchpad	Data Cache	Data Scratchpad
TC1.6	16K Bytes	32 KBytes	16 KBytes	128 KBytes

The cache and tag memories may be mapped into the CPUs address space using the SMACON register. When mapped the locations of these memories is as follows.

The CACHEI.* instructions require a way and index value to be supplied in a valid address. The location of these bits in the 32bit address is as follows.

Table 2-24 Way and Index Location

Function	Address Bits
Way	[1:0]
Index	[11:5]

2.18.1 DMI Registers

Two control registers and three trap flag registers control the operation of the DMI. These registers and their bits are described in this section.

Table 2-25 DMI Registers

Short Name	Description	Offset Address	Access Mode		Reset
			Read	Write	
DCON0	DMI Control Register 0	9040_H	U, SV, 32	SV, E, 32	Class 3 Reset $0000\ 0002_H$
DCON2	DMI Control Register 2	9000_H	U, SV, 32	SV, E, 32	Class 3 Reset $0800\ 0010_H$
DSTR	DMI Synchronous Trap Flag Register	9010_H	U, SV, 32[1)]	SV, 32	Class 3 Reset $0000\ 0000_H$
DATR	DMI Asynchronous Trap Flag Register	9018_H	U, SV, 32[1)]	SV, 32	Class 3 Reset $0000\ 0000_H$
DEADD	DMI Data Error Address Register	$901C_H$	U, SV, 32	SV, 32	Class 3 Reset $0000\ 0000_H$

1) Writing these registers clears the contents independent of the data value.

.

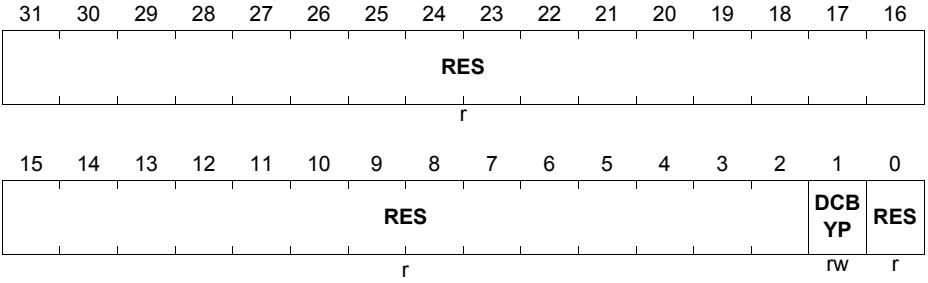
2.18.1.1 DMI Register Descriptions

Note: There is no DCON1 register in this implementation.

Data Memory Control Register 0 (DCON0)

The DCON0 register allows the Data cache to be bypassed.

DCON0
Data Memory Control Register (F7E1 9040$_H$) Reset Value: 0000 0002$_H$



Field	Bits	Type	Description
RES	0	-	**Reserved**
DCBYP	1	rw	**Data Cache Bypass** 0_B Cache enabled 1_B Cache Bypass (disabled)
RES	[31:2]	-	**Reserved**

Data Control Register 2 (DCON2)

DCON2 contains size information for the Data memory system.

DCON2

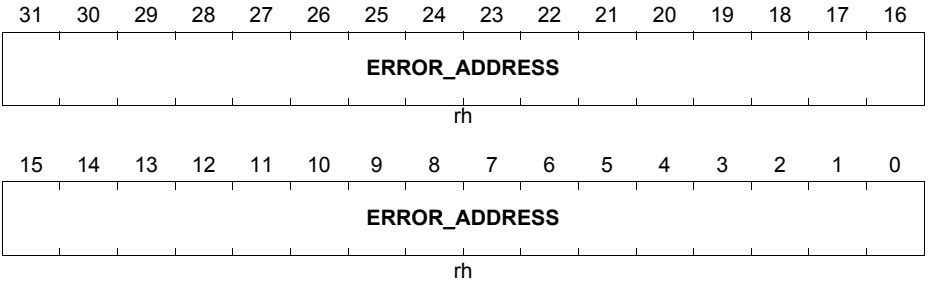
RES	[31:16]	r	**Reserved**

Data Error Address Register

DEADD contains trap address information for the Data memory system. The register is updated with trap information for MEM, ALN, DSE or DAE traps to aid the localisation of faults.

The register is only set whenever a trap is detected and either the DATR or DSTR registers have no bits already set.

DEADD
Data Error Address Register (F7E1 901C$_H$) Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
ERROR_ADDRESS	[31:0]	rh	**Error Address**

2.19 Safety Features

The TC1798 implements a number of safety concepts. As part of this the TriCore1.6 core implements the following features:-

- SRI Address Phase Error Injection
- SRI Data Phase Error Capture
- Safety Interrupt Acknowledge Decoupling

2.19.1 SRI Address Phase Error Injection

To allow the SRI address phase error detection system to be tested it is necessary to inject errors during the read phase of an SRI address transaction. This is done by selectively inverting individual bits of the SRI read or write phase ECC packet and is controlled using the SFAGEN register. The SFAGEN register contains two fields:- an enable (AE) and a bit flip (ADFLIP) field. When enabled the address ECC bits indicated by the flip field are inverted for the next SRI data read or write bus transaction performed by the DMI. Following the transaction the enable bit is cleared by hardware. This mechanism allows selected bits of the SRI address ECC to be corrupted for a single transaction.

2.19.2 SRI Data Phase Error Capture

Error information detected during the SRI read data phase as the result of a PMI fetch is captured in the SFERR0 and SFERR1 registers. Such an error will typically result in a PIE trap. On detection of an error the error information is captured and the SFERR0.E_VAL bit is set. No further error information is captured until this bit is cleared by software.

2.19.3 Safety Interrupt Acknowledge Decoupling

In standard operation a successfully requesting interrupt node is automatically acknowledged and cleared down by hardware. This is done as part of the interrupt entry sequence performed by the TriCore and before the start of the Interrupt Service Routine (ISR). An ISR is therefore unable to verify that the interrupt node corresponding to its level is active.

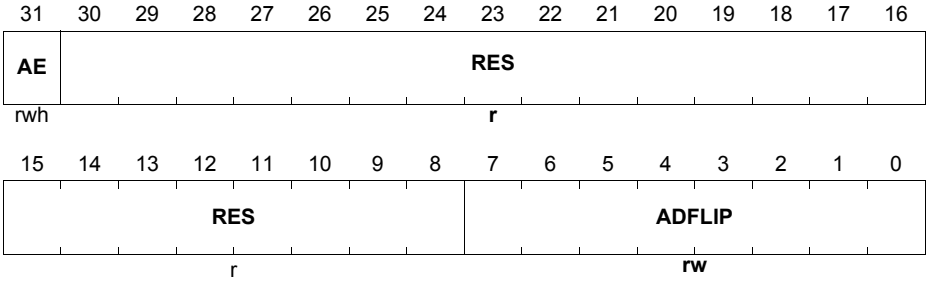
In safety systems such verification is desirable. The Tricore1.6 may be operated in a “Safe Interrupt” mode in which the acknowledgment and clearing of the requesting node is decoupled from the Interrupt entry sequence hence allowing an ISR to inspect the requesting node to verify correct operation. This mode is enabled by clearing the COMPAT.INT bit. The ISR is responsible for acknowledging and clearing down the interrupt node by clearing the SAFEINT.INT bit

2.19.4 Registers Implementing Safety Features

Safe Fetch Address Error Generation Register

The SFAGEN register controls the injection of SRI address phase errors from the DMI.

SFAGEN
Safe Fetch Address Error Generation Register ($F7E1\ 1030_H$) **Reset Value: $0000\ 000_H$**



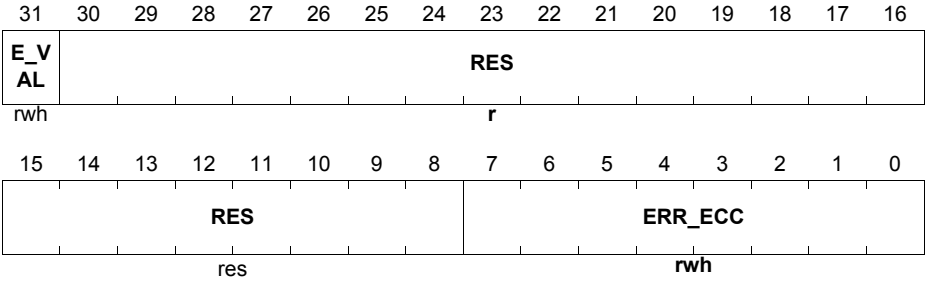
Field	Bits	Type	Description
ADFLIP	[7:0]	rw	**Address ECC bit flip** SRI address ECC Bits to be flipped on the next read or write transaction from the DMI when enabled by AE. 0_B No Flip 1_B Flip
RES	[30:8]	r	**Reserved**
AE	31	rwh	**Address Error Enable** Enabled the selective inverting of SRI address phase ECC packet bits defined by ADFLIP. This bit will be cleared by hardware after the next SRI read or write transaction from the DMI. 0_B Not Enabled 1_B Enabled

Safe Fetch Error Register 0

The SFERR0 register captures read data phase error information on safe fetch errors from the PMI.

SFERR0

Safe Fetch Error Register 0 **(F7E1 1000$_H$)** **Reset Value: 0000 000$_H$**

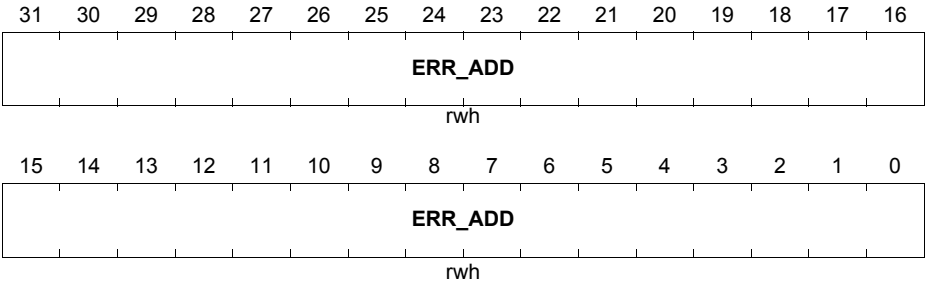


Field	Bits	Type	Description
ERR_ECC	[7:0]	rwh	**Error ECC** The ERR information of the erroneous SRI packet
RES	[30:8]	-	**Reserved**
E_VAL	31	rwh	**Error Valid** An error has been detected since the register was last cleared

Safe Fetch Error Register 1

SFERR1

Safe Fetch Error Register 1 **(F7E1 1004$_H$)** **Reset Value: 0000 000$_H$**

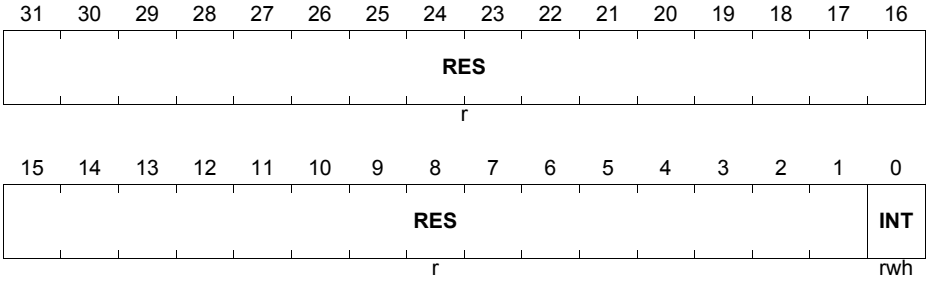


Field	Bits	Type	Description
ERR_ECC	[31:0]	rwh	**ERR_ADD** The Address of the erroneous SRI packet

Safe Interrupt register

In order to improve plausibility checks on Interrupt Service Routines (ISR) The acknowledgement of interrupts may be decoupled from interrupt entry. When interrupt entry occurs the SAFEINT.INT bit is set. The interrupt acknowledge is delayed until the register is written to zero.

SAFEINT
Safe Interrupt Register **(0xFe30)** **Reset value: 0000 0000$_H$**



Field	Bits	Type	Description
INT	0	rwh	**Interrupt Active** Read: 0 = Interrupt Inactive Read: 1 = Interrupt Active Write: 0 = Clear Safe Interrupt Write: 1 = No effect
RES	[31:1]	r	**Reserved**

3 System Control Unit (SCU)

The System Control Unit (SCU) of the TC1798 handles all system control tasks beside the debug related tasks which are controlled by the OCDS/Cerberus.

The SCU contains the following functional sub-blocks:

- Clock Control (see **Section 3.1**)
- Reset Operation (see **Section 3.2**)
- External Interface (see **Section 3.3**)
- Power Management (see **Section 3.4**)
- Software Boot Support (see **Section 3.5**)
- SRAM ECC Control (see **Section 3.6**)
- Die Temperature Measurement (see **Section 3.7**)
- Watchdog Timer (see **Section 3.8**)
- Emergency Stop Control (see **Section 3.9**)
- Interrupt Generation (see **Section 3.10**)
- NMI Trap Generation (see **Section 3.11**)
- SCU registers and Address map (see **Section 3.12**)
- SCU register overview table (see **Table 3-22**)

3.1 Clock System Overview

This section describes the TC1798 clock system. Topics covered include clock generation and the operation of clock circuitry.

The TC1798 clock system provides the following functions:

- Acquires and buffers incoming clock signals to create a master clock frequency
- Distributes in-phase synchronized clock signals throughout the TC1798's entire clock tree
- Divides the master clock frequency into lower frequencies required by the different modules for operation
- Reduces electromagnetic interference (EMI) by switching off unused modules

Figure 3-1 shows the structure of the TC1798 clock system. The master clock f_{PLL} is generated by the oscillator circuit and the PLL (phase-locked loop) unit (see **Section 3-2**).

The functionality of the control blocks shown in **Figure 3-1** varies depending on the functional unit being controlled. Some functional units such as the watchdog timer, are directly driven by the system clock. The implemented clock control register options are described for each module in the module chapter itself.

All clock control registers CLC and the fractional divider registers FDR are Endinit-protected.

Features of the TC1798 Clock System

- PLL operation for multiplying clock source by different factors
- Direct drive capability for direct clocking
- Comfortable state machine for secure switching between Freerunning Mode / Normal Mode and Prescaler Mode

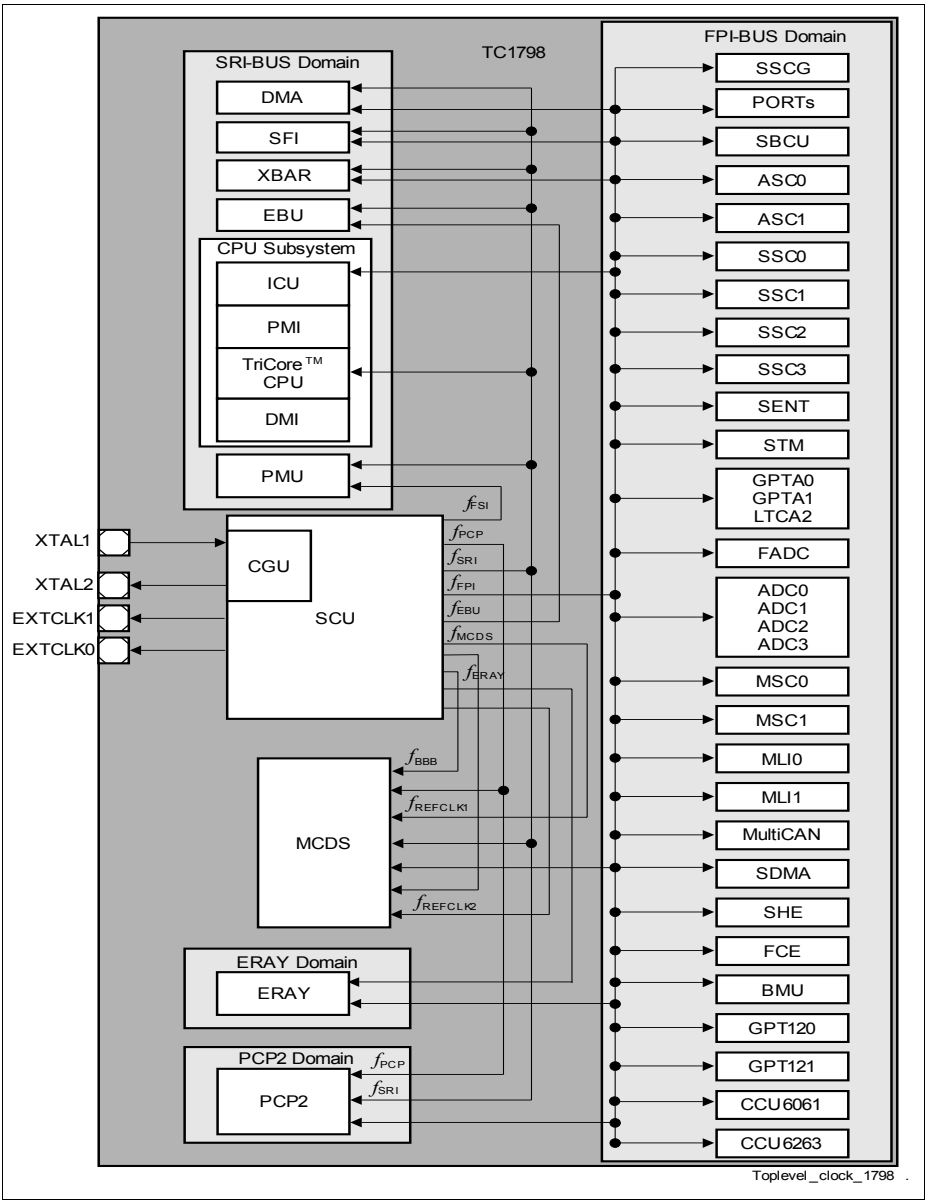


Figure 3-1 TC1798 Clocking System

3.1.1 Clock Generation Unit

The Clock Generation Unit (CGU) allows a very flexible clock generation for the TC1798. During user program execution the frequency can be programmed for an optimal ratio between performance and power consumption.

3.1.1.1 Overview

The CGU in the TC1798 consists of one oscillator circuit (OSC), two Phase-Locked Loop modules (PLL and PLL_ERAY) and a Clock Control Unit (CCU). The CGU can convert a low-frequency external clock signal to a high-speed internal clock.

The CGU provides clock signals for the different parts of the device that can be configured depending on the application needs within certain limits.

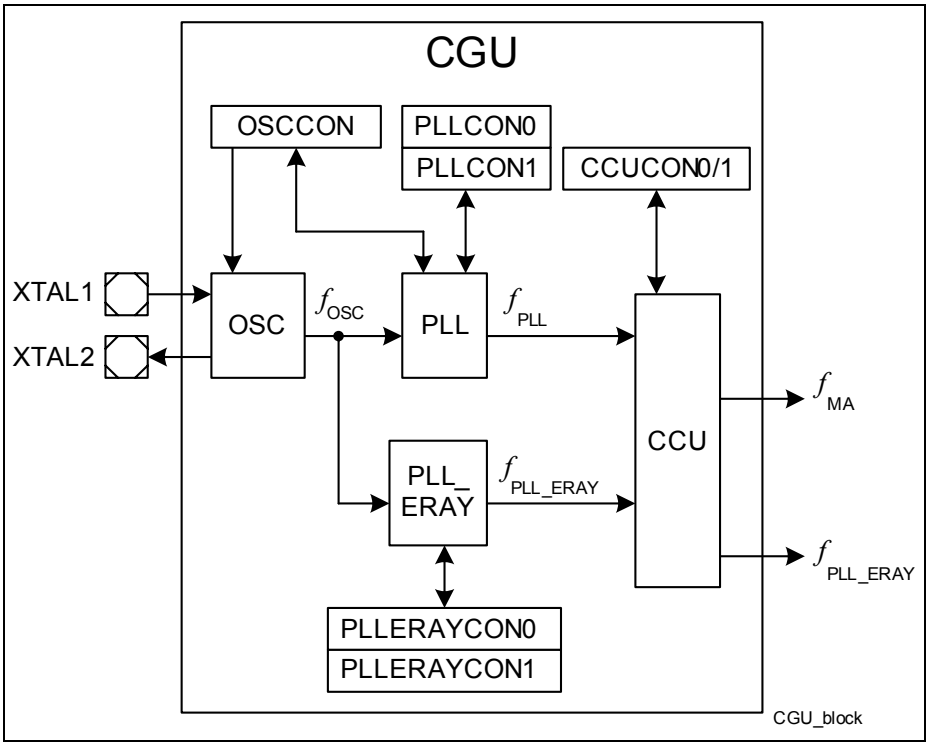

Figure 3-2 Clock Generation Unit Block Diagram

The following sections describe the different parts of the CGU.

3.1.1.2 Oscillator Circuit (OSC)

The oscillator circuit, a Pierce oscillator, is designed to work with both an external crystal / resonator or an external stable clock source, consists of an inverting amplifier with XTAL1 as input, and XTAL2 as output with an integrated feedback resistor.

External Input Clock Mode

When supplying the clock signal directly, not using an external crystal / ceramic resonator and bypassing the oscillator, the input frequency needs to be equal or greater than PLL VCO input frequency (the value is listed in the Data Sheet).

When using an external clock signal it must be connected to XTAL1. XTAL2 is left open (unconnected).

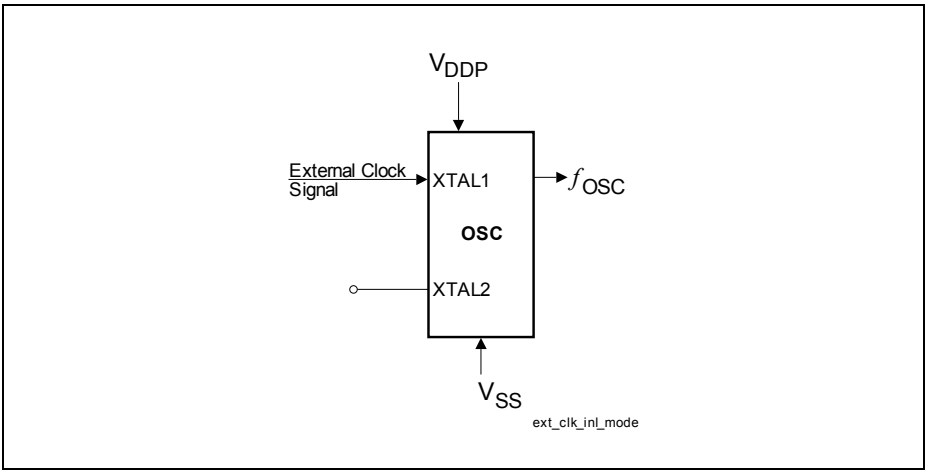

Figure 3-3 TC1798 Direct Clock Input

External Crystal / Ceramic Resonator Mode

Figure 3-4 shows the recommended external circuitries for both operating modes, External Crystal / Ceramic Resonator Mode with and without external components.

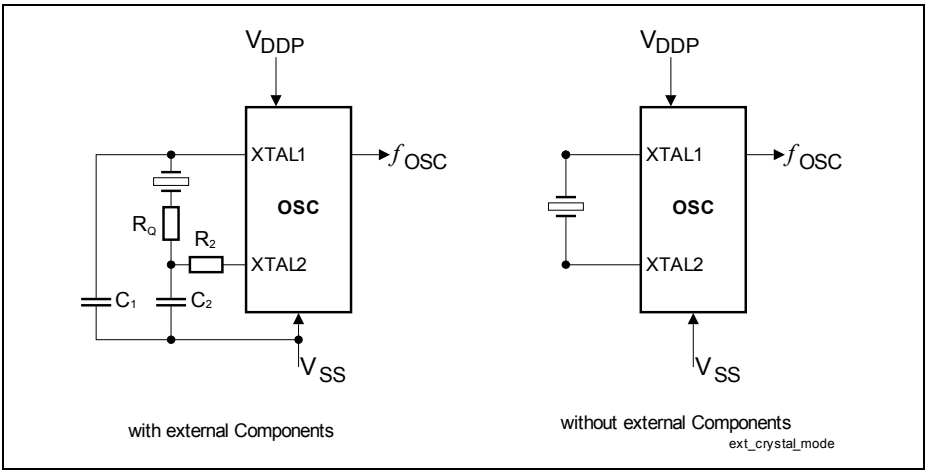

Figure 3-4 External Circuitry for Crystal / Ceramic Resonator operation

When using an external crystal / ceramic resonator, its frequency can be within the allowed range (the values are listed in the Data Sheet). An external oscillator load circuitry must be used, connected to both pins, XTAL1 and XTAL2. Additionally are necessary, two load capacitances C_1 and C_2, and depending on the crystal / ceramic resonator type, a series resistor R_2 to limit the current. A test resistor R_Q may be temporarily inserted to measure the oscillation allowance (negative resistance) of the oscillator circuitry. R_Q values are typically specified by the crystal / ceramic resonator vendor. The C_1 and C_2 values shown in the Data Sheet can be used as starting points for the negative resistance evaluation and for non-productive systems. The exact values and related operating range are dependent on the crystal / ceramic resonator frequency and have to be determined and optimized together with the crystal / ceramic resonator vendor using the negative resistance method. Oscillation measurement with the final target system is strongly recommended to verify the input amplitude at XTAL1 and to determine the actual oscillation allowance (margin negative resistance) for the oscillator-crystal / ceramic resonator system.

The oscillator can also be used in combination with a ceramic resonator. The final circuitry must be also verified by the resonator vendor.

Oscillator Run Detection

See .

3.1.1.3 Phase-Locked Loop (PLL) Module

The PLL can convert a low-frequency external clock signal to a high-speed internal clock for maximum performance. The PLL also has fail-safe logic that detects degenerate external clock behavior such as abnormal frequency deviations or a total loss of the external clock. It can execute emergency actions if it loses its lock on the external clock.

This module is a phase locked loop for integer frequency synthesis. It allows the use of input and output frequencies of a wide range by varying the different divider factors.

Features

- VCO lock detection
- 4-bit input divider **P:** (divide by PDIV+1)
- 7-bit feedback divider **N**: (multiply by NDIV+1)
- 7-bit output divider **K1 or K2:** (divide by either by K1DIV+1 or K2DIV+1)
- Oscillator Watchdog
  - Detecting too low input frequencies
  - Detecting too high input frequencies
  - Spike detection for the OSC input frequency
- Different operating modes
  - Prescaler Mode
  - Freerunning Mode
  - Normal Mode
- VCO Power Down
- Glitchless switching between both K-Dividers
- Glitchless switching between Normal Mode and Prescaler Mode
- Frequency Modulation
- Jitter reduction for modulation jitter

PLL Functional Description

The PLL consists of a Voltage Controlled Oscillator (VCO) with a feedback path. A divider in the feedback path (N-Divider) divides the VCO frequency down. The resulting frequency is then compared with the externally provided and divided frequency (P-Divider). The phase detection logic determines the difference between the two clocks and accordingly controls the frequency of the VCO (f_{VCO}). A PLL lock detection unit monitors and signals this condition. The phase detection logic continues to monitor the two clocks and adjusts the VCO clock if required. The PLL output clock f_{PLL} is derived from the VCO clock by the K2-Divider or from the oscillator clock and the K1-Divider.

The following figure shows the PLL block structure.

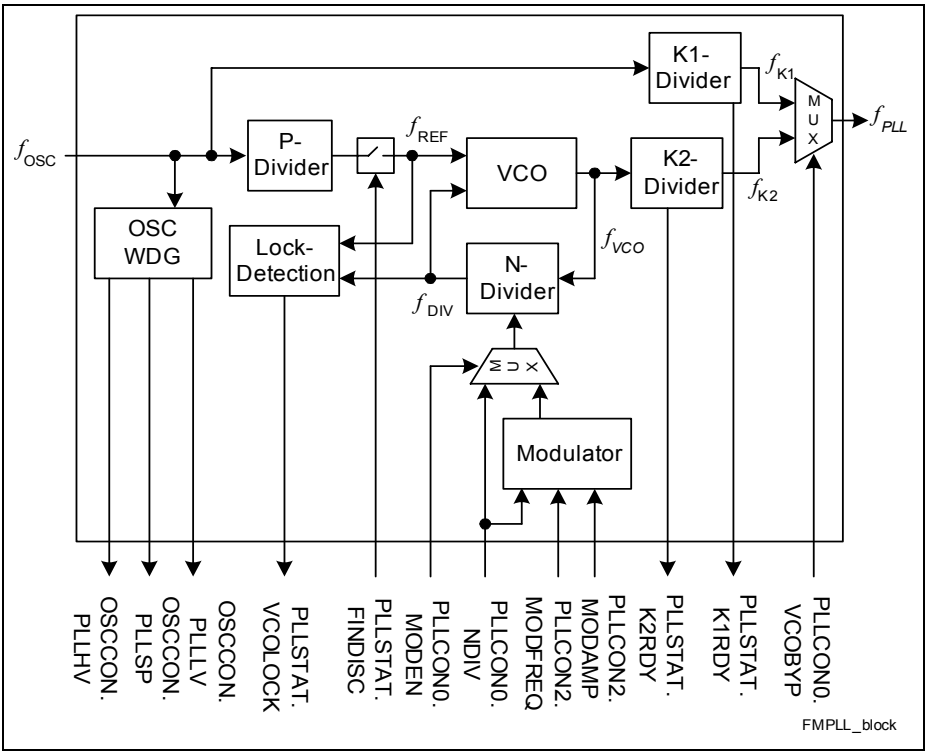

Figure 3-5 PLL Block Diagram

Clock Source Control

The PLL clock f_{PLL} is generated from f_{OSC} in one of three software selectable modes:

- Normal Mode
- Prescaler Mode
- Freerunning Mode

Normal Mode

In Normal Mode the input frequency f_{OSC} is divided down by a factor P, multiplied by a factor N and then divided down by a factor K2.

The output frequency is given by

(3.1)

$$f_{PLL} = \frac{N}{P \cdot K2} \cdot f_{OSC}$$

Prescaler Mode

In Prescaler Mode the reference frequency f_{OSC} is only divided down by a factor K1.

The output frequency is given by

$$f_{PLL} = \frac{f_{OSC}}{K1} \quad (3.2)$$

Freerunning Mode

In Freerunning Mode the base frequency output of the Voltage Controlled Oscillator (VCO) $f_{VCObase}$ is only divided down by a factor K2.

The output frequency is given by

$$f_{PLL} = \frac{f_{VCObase}}{K2} \quad (3.3)$$

Oscillator Watchdog (OSC_WDT)

The oscillator watchdog monitors the incoming clock frequency f_{OSC} from OSC. A stable and defined input frequency is a mandatory requirement for operation in both Prescaler Mode and Normal Mode. For operation in Freerunning Mode no f_{OSC} input frequency is required. Therefore this mode is selected automatically after each System Reset. In addition for the Normal Mode it is required that the input frequency f_{OSC} is in a certain frequency range to obtain a stabile master clock from the VCO part.

The expected input frequency is selected via the bit field OSCCON.OSCVAL. The OSC_WDT checks for too low frequencies and for too high frequencies.

The frequency that is monitored is f_{OSCREF} which is derived for f_{OSC}.

$$f_{OSCREF} = \frac{f_{OSC}}{OSCVAL + 1} \quad (3.4)$$

The divider value OSCCON.OSCVAL has to be selected in a way that f_{OSCREF} is 2.5 MHz.

Note: f_{OSCREF} has to be within the range of 2 MHz to 3 MHz and should be as close as possible to 2.5 MHz.

Before configuring the OSC_WDT function all the trap options should be disabled in order to avoid unintended traps. Thereafter the value of OSCCON.OSCVAL can be changed. Then the OSC_WDT should be reset by setting OSCCON.OSCRES. This requests the start of OSC_WDT monitoring with the new configuration. When the

expected positive monitoring results of OSCCON.PLLLV and / or OSCCON.PLLHV are set the input frequency is within the expected range. As setting OSCCON.OSCRES clears all three bits OSCCON.PLLSP, OSCCON.PLLLV, and OSCCON.PLLHV all three trap status flags will be set. Therefore all three flags should be cleared before the trap generation is enabled again. The trap disabling-clearing-enabling sequence should also be used if only bit OSCCON.OSCRES is set without any modification of OSCCON.OSCVAL.

Configuration and Operation of the Freerunning Mode

In Freerunning Mode, the PLL is running at its VCO base frequency and f_{PLL} is derived from f_{VCO} only by the K2-Divider.

The Freerunning Mode is entered after each System Reset.

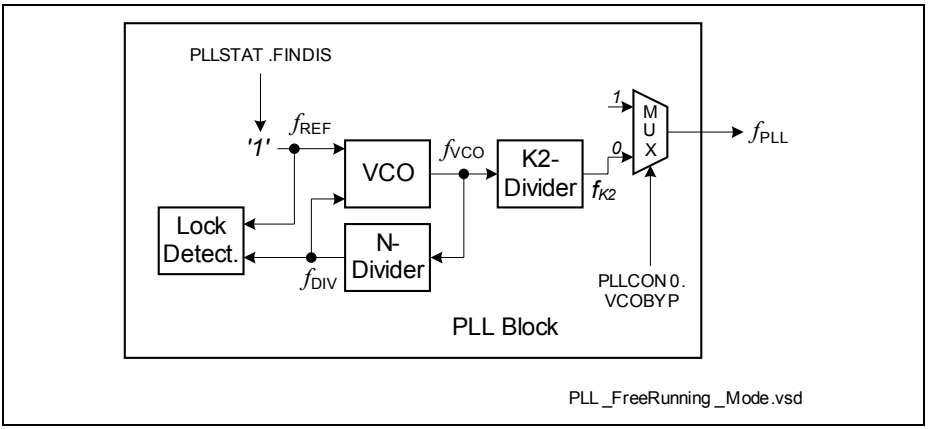

Figure 3-6 PLL Free-Running Mode Diagram

The output frequency is given by

$$f_{PLL} = \frac{f_{VCObase}}{K2} \quad (3.5)$$

The Freerunning Mode is selected by the following settings

- PLLCON0.VCOBYP = 0
- PLLCON0.SETFINDIS = 1

The Freerunning Mode is entered when

- PLLSTAT.FINDIS = 1
- AND
- PLLSTAT.VCOBYST = 0

Operation on the Freerunning Mode does not require an input clock frequency of f_{OSC}. The Freerunning Mode is automatically entered on a PLL VCO Loss-of-Lock event if bit PLLCON0.OSCDISCDIS is cleared. This mechanism allows a fail-safe operation of the PLL as in emergency cases still a clock is available.

The frequency of the Freerunning Mode $f_{VCObase}$ is listed in the Data Sheet.

Note: Changing the system operation frequency by changing the value of the K2-Divider has a direct coupling to the power consumption of the device. Therefore this has to be done carefully.

Depending on the selected divider value of the K2-Divider the duty cycle of the clock is selected. This can have an impact for the operation with an external communication interface. The duty cycles values for the different K2-divider values are defined in the Data Sheet.

Configuration and Operation of the Prescaler Mode

In Prescaler Mode, the PLL is running at the external frequency f_{OSC} and f_{PLL} is derived from f_{OSC} only by the K1-Divider.

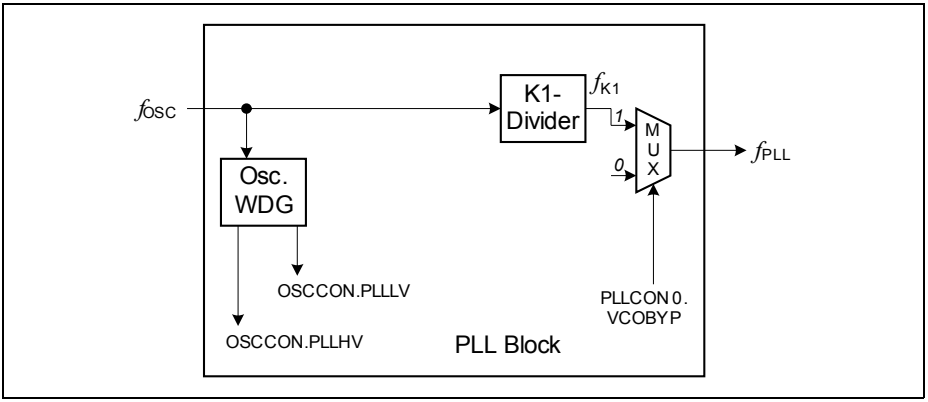

Figure 3-7 PLL Prescaler Mode Diagram

The output frequency is given by:

$$f_{PLL} = \frac{f_{OSC}}{K1} \quad (3.6)$$

The Prescaler Mode is selected by the following settings

- PLLCON0.VCOBYP = 1

The Prescaler Mode is entered when the following requirements are all together valid:

- PLLSTAT.VCOBYST = 1
- OSCCON.PLLLV = 1

Operation on the Prescaler Mode does require an input clock frequency of f_{OSC}. Therefore it is recommended to check and monitor if an input frequency f_{OSC} is available at all by checking OSCCON.PLLLV. For a better monitoring also the upper frequency can be monitored via OSCCON.PLLHV.

For the Prescaler Mode there are no requirements regarding the frequency of f_{OSC}.

The system operation frequency is controlled in the Prescaler Mode by the value of the K1-Divider. When the value of PLLCON1.K1DIV was changed the next update of this value should not be done before bit PLLSTAT.K1RDY is set.

Note: Changing the system operation frequency by changing the value of the K1-Divider has a direct coupling to the power consumption of the device. Therefore this has to be done carefully.

Depending on the selected divider value of the K1-Divider the duty cycle of the clock is selected. This can have an impact for the operation with an external communication interface. The duty cycles values for the different K1-divider values are defined in the Data Sheet.

The Prescaler Mode is requested from the Freerunning or Normal Mode by setting bit PLLCON.VCOBYP. The Prescaler Mode is entered when the status bit PLLSTAT.VCOBYST is set. Before the Prescaler Mode is requested the K1-Divider should be configured with a value generating a PLL output frequency f_{PLL} that matches the one generated by the Freerunning or Normal Mode as much as possible. In this way the frequency change resulting out of the mode change is reduced to a minimum.

The Prescaler Mode is requested to be left by clearing bit PLLCON.VCOBYP. The Prescaler Mode is left when the status bit PLLSTAT.VCOBYST is cleared.

Configuration and Operation of the Normal Mode

In Normal Mode, the PLL is running at the external frequency f_{OSC} and f_{PLL} is divided down by a factor P, multiplied by a factor N and then divided down by a factor K2.

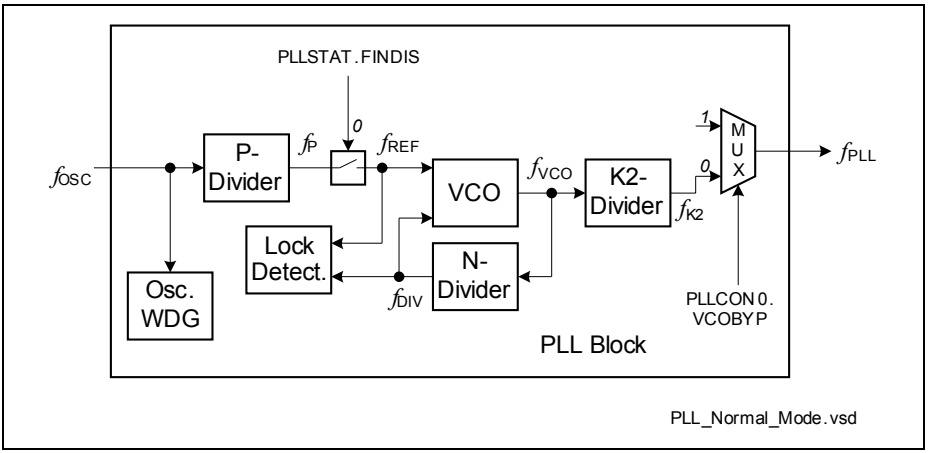

Figure 3-8 PLL Normal Mode Diagram

The output frequency is given by:

(3.7)

$$f_{PLL} = \frac{N}{P \cdot K2} \cdot f_{OSC}$$

The Normal Mode is selected by the following settings

- PLLCON0.VCOBYP = 0
- PLLCON0.CLRFINDIS = 1

The Normal Mode is entered when the following requirements are all together valid:

- PLLSTAT.FINDIS = 0
- PLLSTAT.VCOBYST = 0
- PLLSTAT.VCOLOCK = 1
- OSCCON.PLLLV = 1
- OSCCON.PLLHV = 1

For the Nomal Mode operation it is recommanded to clear bit PLLCON0.OSCDISCDIS.

Operation on the Normal Mode does require an input clock frequency of f_{OSC}. Therefore it is recommended to check and monitor if an input frequency f_{OSC} is available at all by checking OSCCON.PLLLV. For a better monitoring also the upper frequency can be monitored via OSCCON.PLLHV.

The system operation frequency is controlled in the Normal Mode by the values of the three dividers: P, N, and K2. A modification of the two dividers P and N has a direct influence to the VCO frequency and lead to a loss of the VCO Lock status. A modification

of the K2-divider has no impact on the VCO Lock status but still changes the PLL output frequency.

Note: Changing the system operation frequency by changing the value of the K2-Divider has a direct coupling to the power consumption of the device. Therefore this has to be done carefully.

When the frequency of the Normal Mode should be modified or entered the following sequence should be followed:

First the Prescaler Mode should be configured and entered. For more details see the Prescaler Mode.

The NMI trap generation for the VCO Lock should be disabled.

While the Prescaler Mode is used the Normal Mode can be configured and checked for a positive VCO Lock status. The first target frequency of the Normal Mode should be selected in a way that it matches or is only slightly higher as the one used in the Prescaler Mode. This avoids big changes in the system operation frequency and therefore power consumption when switching later from Prescaler Mode to Normal Mode. The P and N divider should be selected in the following way:

- Selecting P and N in a way that f_{VCO} is in the lower area of its allowed values leads to a slightly reduced power consumption but to a slightly increased jitter
- Selecting P and N in a way that f_{VCO} is in the upper area of its allowed values leads to a slightly increased power consumption but to a slightly reduced jitter

After the P, N, and K2 dividers are updated for the first configuration the indication of the VCO Lock status should be await (PLLSTAT.VCOLOCK = 1).

Note: It is recommended to reset the VCO Lock detection (PLLCON0.RESLD = 1) after the new values of the dividers are configured to get a defined VCO lock check time.

When this happens the switch from Prescaler Mode to Normal Mode can be done. Normal Mode is requested by clearing PLLCON.VCOBYP. The Normal Mode is entered when the status bit PLLSTAT.VCOBYST is cleared.

Now the Normal Mode is entered. The NMI status flag for the VCO Lock trap should be cleared and then enabled again. The intended PLL output target frequency can now be configured by changing only the K2-Divider.

Depending on the selected divider value of the K2-Divider the duty cycle of the clock is selected. This can have an impact for the operation with an external communication interface. The duty cycles values for the different K2-divider values are defined in the Data Sheet. This can result in multiple changes of the K2-Divider to avoid to big frequency changes. Between the update of two K2-Divider values 6 cycles of f_{PLL} should be waited.

PLL VCO Lock Detection

The PLL has a lock detection that supervises the VCO part of the PLL in order to differentiate between stable and instable VCO circuit behavior. The lock detector marks the VCO circuit and therefore the output f_{VCO} of the VCO as instable if the two inputs f_{REF} and f_{DIV} differ too much. Changes in one or both input frequencies below a level are not marked by a loss of lock because the VCO can handle such small changes without any problem for the system.

PLL VCO Loss-of-Lock Event

The PLL may become unlocked, caused by a break of the crystal or the external clock line. In such a case, an NMI trap is generated if the according NMI trap is enabled. Additionally, the OSC clock input f_{OSC} is disconnected from the PLL VCO to avoid unstable operation due to noise or sporadic clock pulses coming from the oscillator circuit. Without a clock input f_{OSC}, the PLL gradually slows down to its VCO base frequency and remains there. This automatic feature can be disabled by setting bit PLLCON0.OSCDISCDIS. If this bit is set the OSC clock remains connected to the VCO.

VCO Power Down Mode

The PLL offers a VCO Power Down Mode. This mode can be entered to save power within the PLL. The VCO Power Down Mode is entered by setting bit PLLCON0.VCOPWD. While the PLL is in VCO Power Down Mode only the Prescaler Mode is operable. Please note that selecting the VCO Power Down Mode does not automatically switch to the Prescaler Mode. So before the VCO Power Down Mode is entered the Prescaler Mode must be active.

PLL Power Down Mode

The PLL offers a Power Down Mode. This mode can be entered to save power if the PLL is not needed at all. The Power Down Mode is entered by setting bit PLLCON0.PLLPWD. While the PLL is in Power Down Mode no PLL output frequency is generated.

Frequency Modulation

If the PLL operates in Normal Mode the output frequency f_{PLL} can additionally be modified by a low-frequency modulation. A triangle waveform is generated and fed to a noiseshaper. The noiseshaper generate a stream of values for the N-divider that are used there to modify (modulate) the N-divider value. Due to the low pass function of the PLL (VCO part) non integer frequencies can be generated by switching fast enough between different values of the N-divider.

The modulation is enabled via bit PLLCON0.MODEN. The modulation itself is a triangle-shaped function with an amplitude that can be configured via bit field PLLCON2.MODAMP. Setting bit field MODAMP to zero disables the modulation synchronously. The modulation frequency itself is configurable by bit field PLLCON2.MODFREQ.

3.1.1.4 ERAY Phase-Locked Loop (PLL_ERAY) Module

The PLL_ERAY can convert a low-frequency external clock signal to a high-speed internal clock for maximum performance. The PLL_ERAY also has fail-safe logic that detects degenerate external clock behavior such as abnormal frequency deviations or a total loss of the external clock. It can execute emergency actions if it loses its lock on the external clock.

This module is a phase locked loop for integer frequency synthesis. It allows the use of input and output frequencies of a wide range by varying the different divider factors.

Features

- VCO lock detection
- 6-bit feedback divider **N**: (multiply by NDIV+1)
- 5-bit output divider **K1 or K2:** (divide by either by K1DIV+1 or K2DIV+1)
- Different operating modes
  - Prescaler Mode
  - Freerunning Mode
  - Normal Mode
- VCO Power Down (Sleep Mode)
- Glitchless switching between both K-Dividers
- Glitchless switching between Normal Mode and Prescaler Mode

PLL_ERAY Functional Description

The PLL_ERAY consists of a Voltage Controlled Oscillator (VCO) with a feedback path. A divider in the feedback path (N-Divider) divides the VCO frequency down. The resulting frequency is then compared with the externally provided frequency. The phase detection logic determines the difference between the two clocks and accordingly controls the frequency of the VCO (f_{VCO}). A PLL_ERAY lock detection unit monitors and signals this condition. The phase detection logic continues to monitor the two clocks and adjusts the VCO clock if required. The PLL_ERAY output clock f_{PLL_ERAY} is derived from the VCO clock by the K2-Divider or from the oscillator clock and the K1-Divider.

The following figure shows the PLL_ERAY block structure.

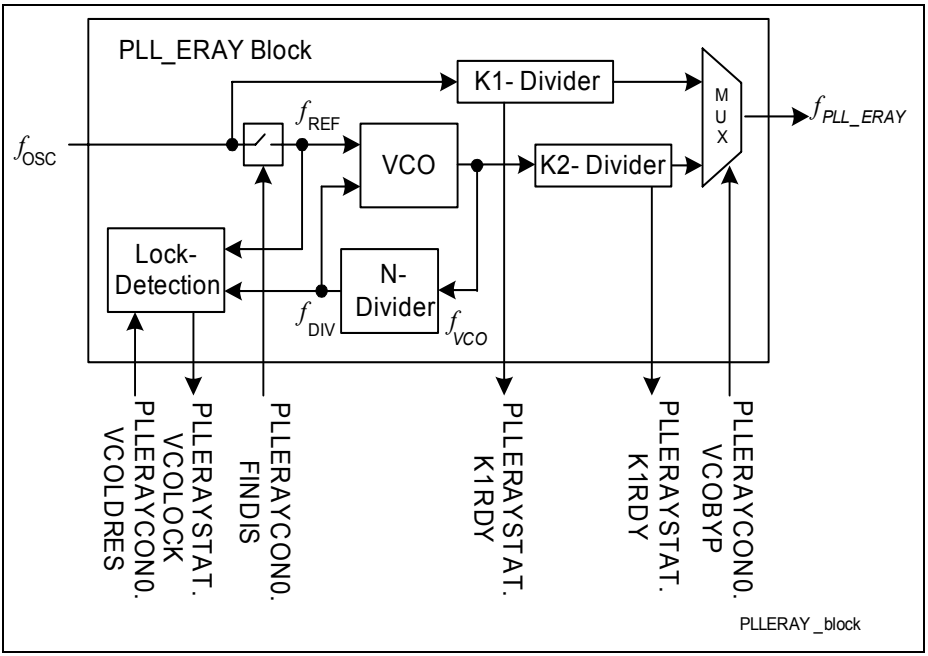

Figure 3-9 PLL_ERAY Block Diagram

Clock Source Control

The PLL_ERAY clock f_{PLL_ERAY} is generated from f_{OSC} in one of three software selectable modes:

- Bypassing N and both K dividers; this defines the Bypass Mode
- Normal Mode
- Prescaler Mode
- Freerunning Mode

Normal Mode

In Normal Mode the input frequency f_{OSC} is multiplied by a factor N and then divided down by a factor K2.

The output frequency is given by

(3.8)

$$f_{PLL} = \frac{N}{K2} \cdot f_{OSC}$$

Prescaler Mode

In Prescaler Mode the reference frequency f_{OSC} is only divided down by a factor K1.

The output frequency is given by

$$f_{PLL} = \frac{f_{OSC}}{K1} \quad (3.9)$$

Freerunning Mode

In Freerunning Mode the base frequency output of the Voltage Controlled Oscillator (VCO) $f_{VCObase}$ is only divided down by a factor K2.

The output frequency is given by

$$f_{PLL} = \frac{f_{VCObase}}{K2} \quad (3.10)$$

Configuration and Operation of the Freerunning Mode

In Freerunning Mode, the PLL_ERAY is running at its VCO base frequency and f_{PLL_ERAY} is derived from f_{VCO} only by the K2-Divider.

The Freerunning Mode is entered after each System Reset.

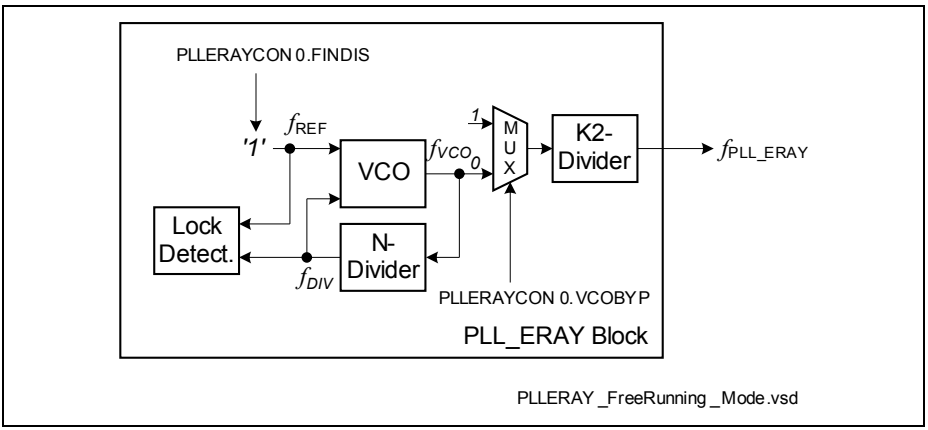

Figure 3-10 PLL_ERAY Free-Running Mode Diagram

The output frequency is given by

$$f_{PLL} = \frac{f_{VCObase}}{K2} \quad (3.11)$$

The Freerunning Mode is selected by the following settings

- PLLERAYCON0.VCOBYP = 0
- PLLERAYCON0.SETFINDIS = 1

The Freerunning Mode is entered when

- PLLERAYSTAT.FINDIS = 1
- AND
- PLLERAYSTAT.VCOBYST = 0

Operation on the Freerunning Mode does not require an input clock frequency of f_{OSC}. The Freerunning Mode is automatically entered on a PLL_ERAY VCO Loss-of-Lock event if bit PLLERAYCON0.OSCDISCDIS is cleared. This mechanism allows a fail-safe operation of the PLL_ERAY as in emergency cases still a clock is available.

The frequency of the Freerunning Mode $f_{VCObase}$ is listed in the Data Sheet.

Depending on the selected divider value of the K2-Divider the duty cycle of the clock is selected. This can have an impact for the operation with an external communication interface. The duty cycles values for the different K2-divider values are defined in the Data Sheet.

Configuration and Operation of the Prescaler Mode

In Prescaler Mode, the PLL_ERAY is running at the external frequency f_{OSC} and f_{PLL_ERAY} is derived from f_{OSC} only by the K1-Divider.

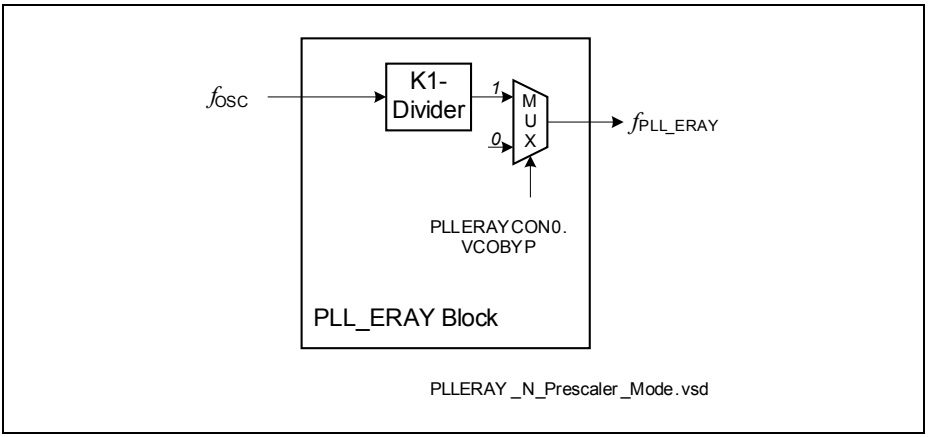

Figure 3-11 PLL_ERAY Prescaler Mode Diagram

The output frequency is given by:

(3.12)

$$f_{PLL} = \frac{f_{OSC}}{K1}$$

The Prescaler Mode is selected by the following settings

- PLLERAYCON0.VCOBYP = 1

The Prescaler Mode is entered when the following requirements are all together valid:

- PLLERAYSTAT.VCOBYST = 1
- OSCCON.PLLLV = 1

Operation on the Prescaler Mode does require an input clock frequency of f_{OSC}. Therefore it is recommended to check and monitor if an input frequency f_{OSC} is available at all by checking OSCCON.PLLLV. For a better monitoring also the upper frequency can be monitored via OSCCON.PLLHV.

For the Prescaler Mode there are no requirements regarding the frequency of f_{OSC}.

The system operation frequency is controlled in the Prescaler Mode by the value of the K1-Divider. When the value of PLLERAYCON1.K1DIV was changed the next update of this value should not be done before bit PLLERAYSTAT.K1RDY is set.

Depending on the selected divider value of the K1-Divider the duty cycle of the clock is selected. This can have an impact for the operation with an external communication interface. The duty cycles values for the different K1-divider values are defined in the Data Sheet.

The Prescaler Mode is requested from the Freerunning or Normal Mode by setting bit PLLERAYCON.VCOBYP. The Prescaler Mode is entered when the status bit PLLERAYSTAT.VCOBYST is set. Before the Prescaler Mode is requested the K1-Divider should be configured with a value generating a PLL_ERAY output frequency f_{PLL_ERAY} that matches the one generated by the Freerunning or Normal Mode as much as possible. In this way the frequency change resulting out of the mode change is reduced to a minimum.

The Prescaler Mode is requested to be left by clearing bit PLLERAYCON.VCOBYP. The Prescaler Mode is left when the status bit PLLERAYSTAT.VCOBYST is cleared.

Configuration and Operation of the Normal Mode

In Normal Mode, the PLL_ERAY is running at the external frequency f_{OSC} and f_{PLL_ERAY} is multiplied by a factor N and then divided down by a factor K2.

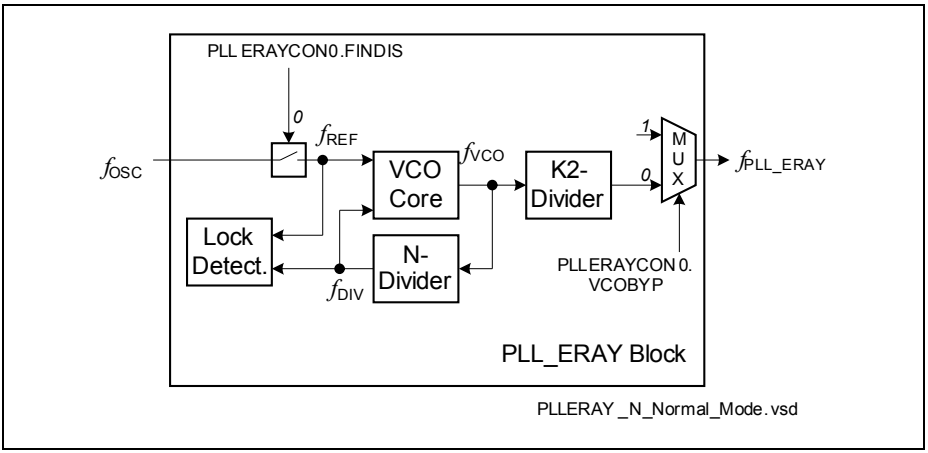

Figure 3-12 PLL_ERAY Normal Mode Diagram

The output frequency is given by:

(3.13)

$$f_{PLL} = \frac{N}{K2} \cdot f_{OSC}$$

The Normal Mode is selected by the following settings

- PLLERAYCON0.VCOBYP = 0
- PLLERAYCON0.CLRFINDIS = 1

The Normal Mode is entered when the following two requirements are all together valid:

- PLLERAYSTAT.FINDIS = 0

- PLLERAYSTAT.VCOBYST = 0
- PLLERAYSTAT.VCOLOCK = 1
- OSCCON.PLLLV = 1
- OSCCON.PLLHV = 1

Operation on the Normal Mode does require an input clock frequency of f_{OSC}. Therefore it is recommended to check and monitor if an input frequency f_{OSC} is available at all by checking OSCCON.PLLLV. For a better monitoring also the upper frequency can be monitored via OSCCON.PLLHV.

The system operation frequency is controlled in the Normal Mode by the values of the two dividers: N and K2. A modification of the divider N has a direct influence to the VCO frequency and lead to a loss of the VCO Lock status. A modification of the K2-divider has no impact on the VCO Lock status but still changes the PLL_ERAY output frequency.

When the frequency of the Normal Mode should be modified or entered the following sequence should be followed:

First the Prescaler Mode should be configured and entered. For more details see the Prescaler Mode.

The NMI trap generation for the VCO Lock should be disabled.

While the Prescaler Mode is used the Normal Mode can be configured and checked for a positive VCO Lock status. The first target frequency of the Normal Mode should be selected in a way that it matches or is only slightly higher as the one used in the Prescaler Mode. This avoids big changes in the system operation frequency and therefore power consumption when switching later from Prescaler Mode to Normal Mode. The N divider should be selected in the following way:

- Selecting N in a way that f_{VCO} is in the lower area of its allowed values leads to a slightly reduced power consumption but to a slightly increased jitter
- Selecting N in a way that f_{VCO} is in the upper area of its allowed values leads to a slightly increased power consumption but to a slightly reduced jitter

After the N and K2 dividers are updated for the first configuration the indication of the VCO Lock status should be await (PLLERAYSTAT.VCOLOCK = 1).

*Note: It is recommended to reset the VCO Lock detection (PLL*ERAY*CON0.RESLD = 1) after the new values of the dividers are configured to get a defined VCO lock check time.*

When this happens the switch from Prescaler Mode to Normal Mode can be done. Normal Mode is requested by clearing PLLERAYCON.VCOBYP. The Normal Mode is entered when the status bit PLLERAYSTAT.VCOBYST is cleared.

Now the Normal Mode is entered. The NMI status flag for the VCO Lock trap should be cleared and then enabled again. The intended PLL_ERAY output target frequency can not be configured by changing only the K2-Divider.

Depending on the selected divider value of the K2-Divider the duty cycle of the clock is selected. This can have an impact for the operation with an external communication interface. The duty cycles values for the different K2-divider values are defined in the Data Sheet. This can result in multiple changes of the K2-Divider to avoid to big frequency changes. Between the update of two K2-Divider values 6 cycles of f_{PLL_ERAY} should be waited.

PLL_ERAY VCO Lock Detection

The PLL_ERAY has a lock detection that supervises the VCO part of the PLL_ERAY in order to differentiate between stable and instable VCO circuit behavior. The lock detector marks the VCO circuit and therefore the output f_{VCO} of the VCO as instable if the two inputs f_{REF} and f_{DIV} differ too much. Changes in one or both input frequencies below a level are not marked by a loss of lock because the VCO can handle such small changes without any problem for the system.

PLL_ERAY VCO Loss-of-Lock Event

The PLL_ERAY may become unlocked, caused by a break of the crystal or the external clock line. In such a case, an NMI trap is generated if the according NMI trap is enabled. Additionally, the OSC clock input f_{OSC} is disconnected from the PLL_ERAY VCO to avoid unstable operation due to noise or sporadic clock pulses coming from the oscillator circuit. Without a clock input f_{OSC}, the PLL_ERAY gradually slows down to its VCO base frequency and remains there. This automatic feature can be disabled by setting bit PLLERAYCON0.OSCDISCDIS. If this bit is cleared the OSC clock remains connected to the VCO.

VCO Power Down Mode

The PLL_ERAY offers a VCO Power Down Mode. This mode can be entered to save power within the PLL_ERAY. The VCO Power Down Mode is entered by setting bit PLLCON0.VCOPWD. While the PLL_ERAY is in VCO Power Down Mode only the Prescaler Mode is operable. Please note that selecting the VCO Power Down Mode does not automatically switch to the Prescaler Mode. So before the VCO Power Down Mode is enter the Prescaler Mode must be active.

PLL_ERAY Power Down Mode

The PLL_ERAY offers a Power Down Mode. This mode can be entered to save power if the PLL_ERAY is not needed at all. The Power Down Mode is entered by setting bit PLLCON0.PLLPWD. While the PLL_ERAY is in Power Down Mode no PLL_ERAY output frequency is generated.

3.1.1.5 Clock Control Unit

The Clock Control Unit (CCU) receives the clock that is created by the two PLLs f_{PLL} and f_{PLL_ERAY}.

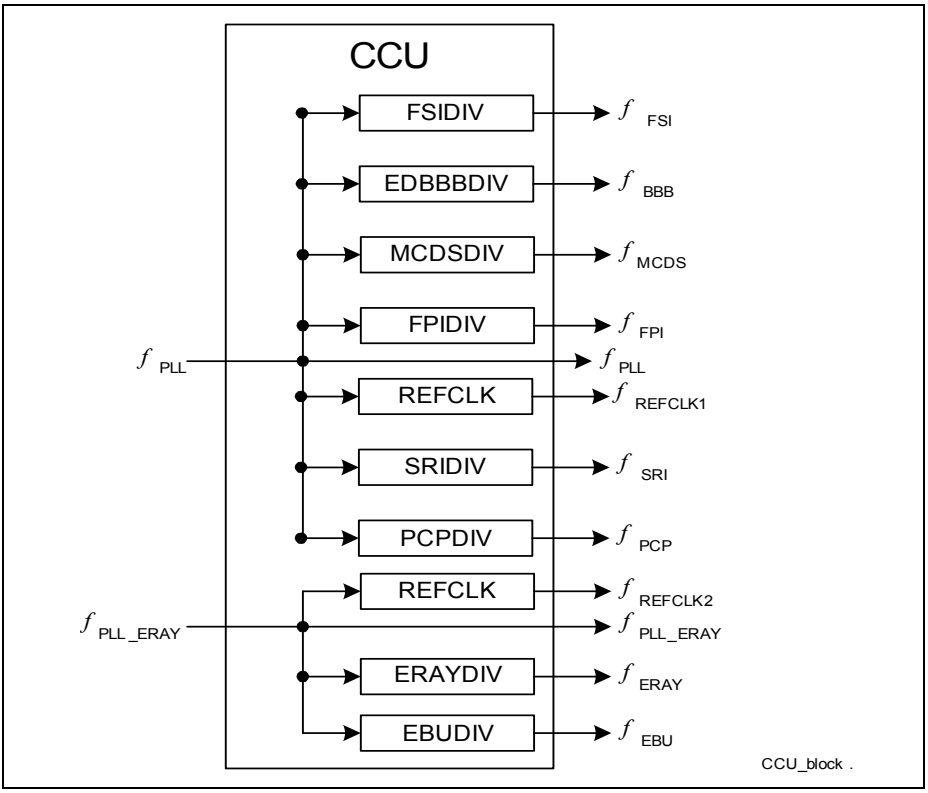

Figure 3-13 Clock Control Unit

The clocking system of the TC1798 consists of the Clock Control Unit (CCU) and the Clock Generation Unit.

There is also a fix reference clock REFCLK1 for the MCDS block which divides the master clock f_{PLL} by 24. This allows the MCDS to generate time stamps independent of the selected SRI-Bus and FPI-Bus clock speeds.

Clock Divider Limitations

The following table defines the allowed clock ratios for the application relevant clocks. The values given in the table define values for the bit fields of register CCUCON0.

Table 3-1 Allowed Clock Ratios

Register Name	Option 1	Option 2	Option 3	Option 4
SRIDIV	0	0	1	0
FSIDIV	0	1	3	1
PCPDIV	0	0	2	1
FPIDIV	0	1	5	3

Note: CCUCON1.EDBBBDIV and CCUCON1.MCDSDIV should always be set to SRI / CPU speed divided by two.

For changing the clock frequencies it is recommanded to follow the sequence described in **Figure 3-14**.

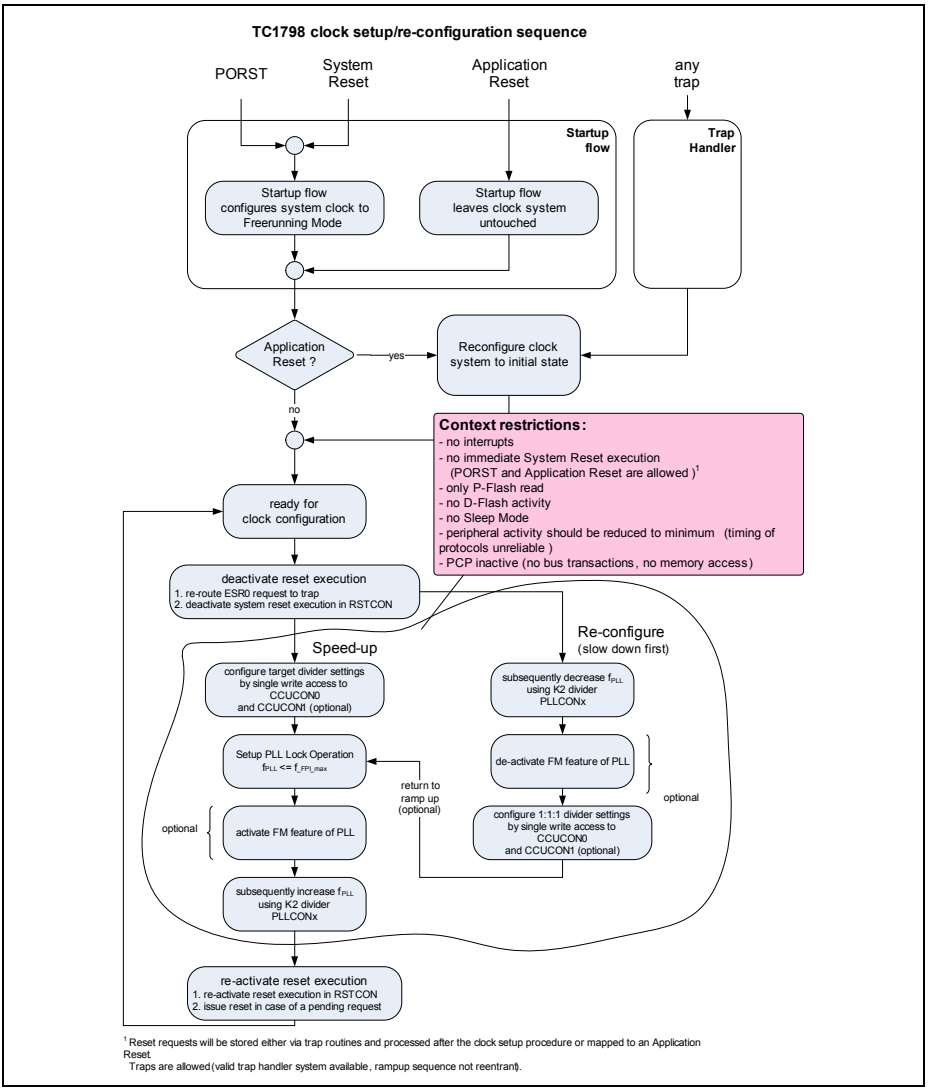

Figure 3-14 Clock changing Sequence

3.1.1.6 External Clock Output

Two external clock outputs are provided via pins EXTCLK0 and EXTCLK1. These external clocks can be enabled/disabled via bits EXTCON.EN0 for EXTCLK0 and

EXTCON.EN1 for EXTCLK1. Each of the clocks that defines a clock domain can individually be selected to be seen at pins EXTCLK0 or EXTCLK1, this is configured via bit field EXTCON.SEL0/1. Changing the content of bit field EXTCON.SEL0/1 can lead to spikes at pins EXTCLK0/1.

Note: Only the burst flash clock of the EBU is not included as the EBU provides a separate pin here.

Additionally a connection to the GPTA module is implemented to support the start-up control of an external crystal for the device clock generation. The first time before the master clock is generated based on a external crystal 1000 cycles of the crystal clock f_{OSC} should be waited before the clock control system is changed to External Crystal Mode. The 1000 cycles can be counted with the GPTA using f_{OSC} as count input for the counter.

Programmable Frequency Output for EXTCLK0

This section describes the external clock generation using the Fractional Divider.

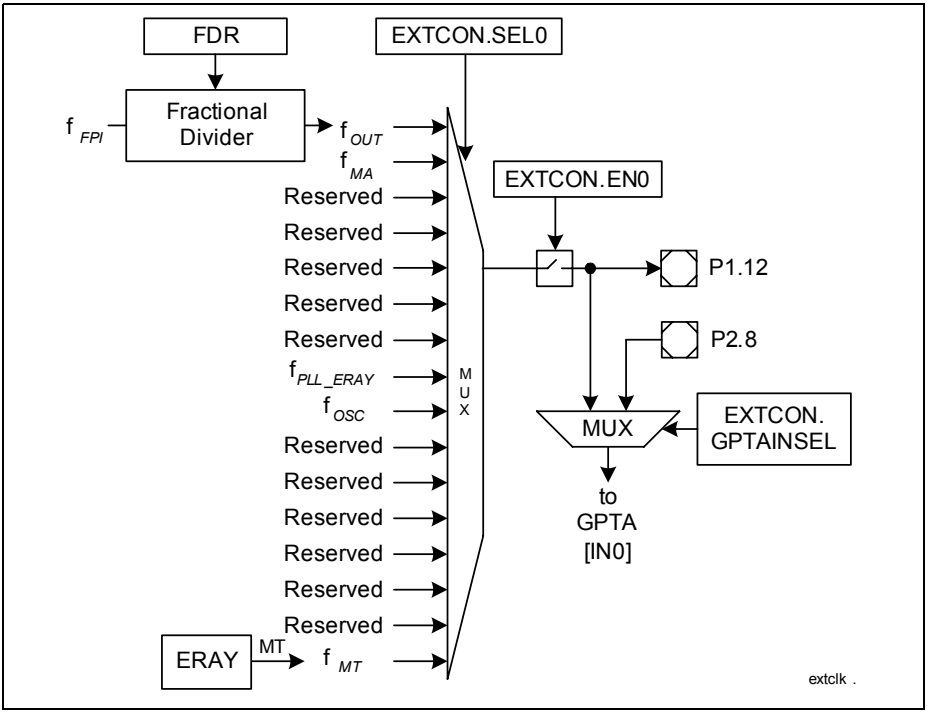

Figure 3-15 EXTCLK0 Generation

Overview

The fractional divider makes it possible to generate a external clock from the FPI-Bus clock using a programmable divider. The fractional divider divides the input clock f_{FPI} either by the factor 1/n or by a fraction of n/1024 for any value of n from 0 to 1023. This clock is thereafter divider additionally by a factor of two to guarantee a 50% duty cycle and outputs the clock, f_{OUT}. The fractional divider is controlled by the FDR register. **Figure 3-16** shows the fractional divider block diagram.

The adder logic of the fractional divider can be configured for two operating modes:

- Reload counter (addition of +1), generating an output clock pulse on counter overflow
- Adder that adds a STEP value to the RESULT value and generates an output clock pulse on counter overflow

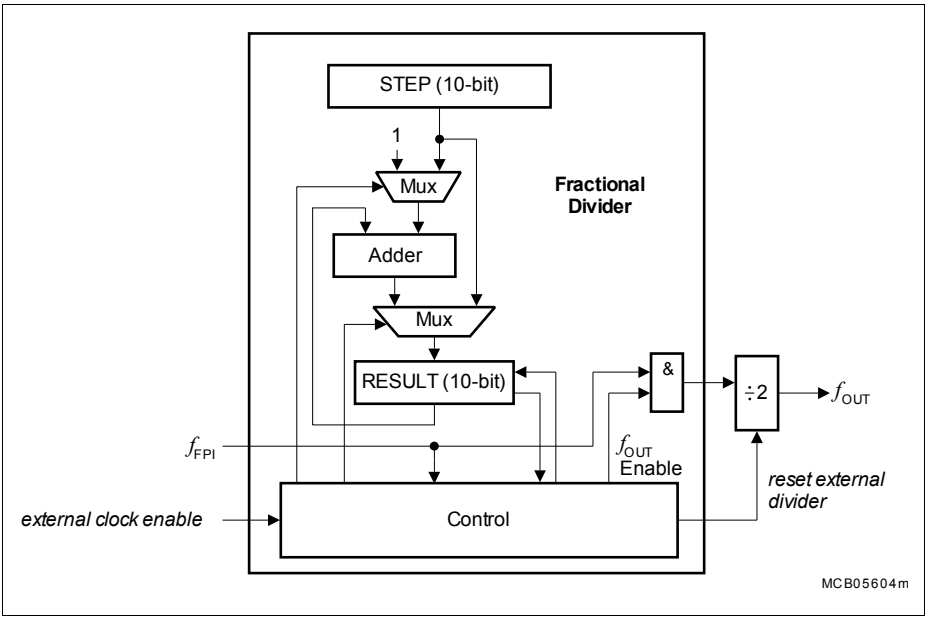

Figure 3-16 Fractional Divider Block Diagram

The adder logic of the fractional divider can be configured for two operating modes:

- **Normal Mode:** Reload counter (RESULT = RESULT + 1), generating an output clock pulse on counter overflow.
- **Fractional Divider Mode:** Adder that adds a STEP value to the RESULT value and generates an output clock pulse on counter overflow.

Fractional Divider Operating Modes

The fractional divider has two operating modes:

- Normal Divider Mode
- Fractional Divider Mode

Normal Divider Mode

In Normal Divider Mode (FDR.DM = 01_B), the fractional divider behaves as a reload counter (addition of +1) that generates an output clock pulse on the transition from $3FF_H$ to 000_H. FDR.RESULT represents the counter value and FDR.STEP determines the reload value.

The output frequencies in Normal Divider Mode are defined according to the following formulas:

$$f_{OUT} = \frac{f_{FPI} \times \frac{1}{n}}{2}, \text{ with n = 1024 - STEP} \quad (3.14)$$

In order to get $f_{OUT} = f_{FPI}/2$ STEP must be programmed with $3FF_H$.

Fractional Divider Mode

When the Fractional Divider Mode is selected (FDR.DM = 10_B), the output is derived from the input clock f_{FPI} by division of a fraction of n/1024 for any value of n from 0 to 1023 followed by the division of two. In general, the Fractional Divider Mode makes it possible to program the average output clock frequency with a higher accuracy than in Normal Divider Mode.

In Fractional Divider Mode, a pulse is generated depending on the result of the addition FDR.RESULT + FDR.STEP. If the addition leads to an overflow over $3FF_H$, a pulse is generated for the divider by two. Note that in Fractional Divider Mode the clock f_{OUT} can have a maximum period jitter of one f_{FPI} clock period.

The output frequencies in Fractional Divider Mode are defined according to the following formulas:

$$f_{OUT} = \frac{f_{FPI} \times \frac{n}{1024}}{2}, \text{ with n = 0-1023} \quad (3.15)$$

External Clock Enable

When the external clock generation with the fractional divider has been disabled by software (setting FDR.DISCLK = 1), the disable state can be exited (hardware controlled) when the External Clock Enable input = 1.

Programmable Frequency Output for EXTCLK1

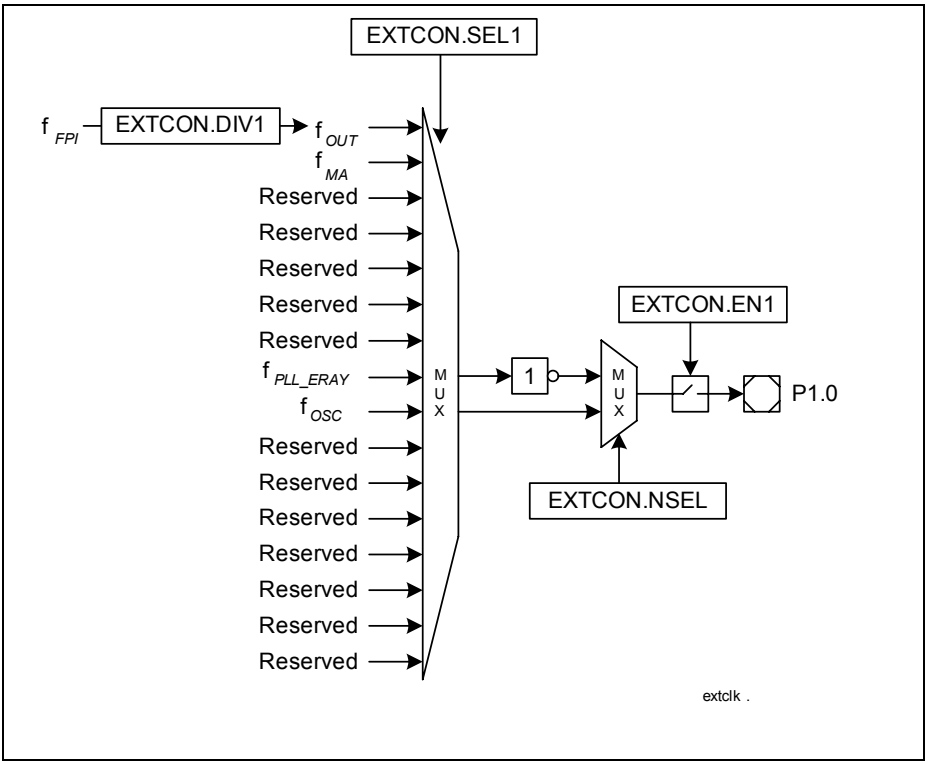

Figure 3-17 EXTCLK1 Generation

Clock f_{OUT} is generated via a counter, so the output frequency can be selected in small steps.

f_{OUT} always provides complete output periods.

Register EXTCON provides control over the output generation (frequency, activation).

3.1.1.7 CGU Registers

System Oscillator Register

This register controls the settings of OSC.

OSCCON
OSC Control Register **(010_H)** **Reset Value: 0000 021A$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0				X1D EN	X1D	PLL SP	PLL HV	0	MODE		GAINSEL		OSC RES	PLL LV	0
r				rw	rh	rh	rh	rw	rw		rh		w	rh	

Field	Bits	Type	Description
PLLLV	1	rh	**Oscillator for PLL Valid Low Status Bit** This bit indicates if the frequency output of OSC is usable for the VCO part of the PLL. This is checked by the Oscillator Watchdog of the PLL. 0_B The OSC frequency is not usable. Frequency f_{REF} is too low. 1_B The OSC frequency is usable
OSCRES	2	w	**Oscillator Watchdog Reset** 0_B The Oscillator Watchdog of the PLL is not cleared and remains active 1_B The Oscillator Watchdog of the PLL is cleared and restarted
GAINSEL	[4:3]	rw	**Oscillator Gain Selection** 00_B Reserved, do not use this combination 01_B The gain control is configured for frequencies from 8 MHz to 16 MHz 10_B The gain control is configured for frequencies from 8 MHz to 20 MHz 11_B The gain control is configured for frequencies from 8 MHz to 25 MHz

Field	Bits	Type	Description
MODE	[6:5]	rw	**Oscillator Mode** This bit field defines which mode can be used and if the oscillator entered the Power-Saving Mode or not. 00_B External Crystal Mode and External Input Clock Mode. The oscillator Power-Saving Mode is not entered. 01_B OSC is disabled. The oscillator Power-Saving Mode is not entered. 10_B External Input Clock Mode and the oscillator Power-Saving Mode is entered 11_B OSC is disabled. The oscillator Power-Saving Mode is entered.
PLLHV	8	rh	**Oscillator for PLL Valid High Status Bit** This bit indicates if the frequency output of OSC is usable for the VCO part of the PLL. This is checked by the Oscillator Watchdog of the PLL. 0_B The OSC frequency is not usable. Frequency f_{OSC} is too high. 1_B The OSC frequency is usable
PLLSP	9	rh	**Oscillator for PLL Valid Spike Status Bit** This bit indicates if the frequency output of OSC is usable for the VCO part of the PLL. This is checked by the Oscillator Watchdog of the PLL. 0_B The OSC frequency is not usable. Spikes are detected that disturb a locked operation 1_B The OSC frequency is usable
X1D	10	rh	**XTAL1 Data Value** This bit monitors the value (level) of pin XTAL1. If XTAL1 is not used as clock input it can be used as GPI pin. This bit is only updated if X1DEN is set.
X1DEN	11	rw	**XTAL1 Data Enable** 0_B Bit X1D is not updated 1_B Bit X1D can be updated

Field	Bits	Type	Description
OSCVAL	[20:16]	rw	**OSC Frequency Value** This bit field defines the divider value that generates the reference clock that is supervised by the oscillator watchdog. f_{OSC} is divided by OSCVAL + 1 in order to generate f_{OSCREF}.
0	7	rw	**Reserved** Should be written with 0.
0	0, [15:12], [31:21]	r	**Reserved** Read as 0; should be written with 0.

PLL Registers

These registers control the setting of the PLL.

PLLSTAT
PLL Status Register **(014_H)** **Reset Value: $0000\ 0038_H$**

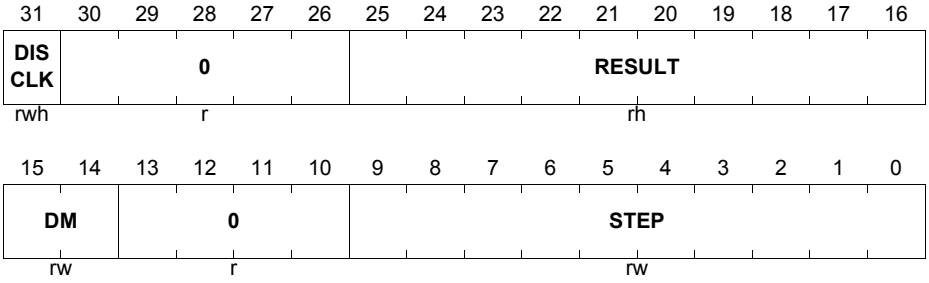
FDR
Fractional Divider Register **(038_H)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
STEP	[9:0]	rw	**Step Value** In Normal Divider Mode, STEP contains the reload value for RESULT. In Fractional Divider Mode, this bit field determines the 10-bit value that is added to RESULT with each input clock cycle.
DM	[15:14]	rw	**Divider Mode** This bit fields determines the functionality of the fractional divider block. 00_B Fractional divider is switched off; no output clock is generated. The Reset External Divider signal is 1. RESULT is not updated (default after System Reset). 01_B Normal Divider Mode selected. 10_B Fractional Divider Mode selected. 11_B Fractional divider is switched off; no output clock is generated. RESULT is not updated.
RESULT	[25:16]	rh	**Result Value** In Normal Divider Mode, RESULT acts as reload counter (addition +1). In Fractional Divider Mode, this bit field contains the result of the addition RESULT + STEP. If DM is written with 01_B or 10_B, RESULT is loaded with $3FF_H$.

Field	Bits	Type	Description
DISCLK	31	rwh	**Disable Clock** 0_B Clock generation of f_{OUT} is enabled according to the setting of bit field DM. 1_B Fractional divider is stopped. No change except when writing bit field DM. This bit is cleared when external clock enable input is asserted. In case of a conflict between hardware clear and software set of DISCLK, the software set wins. Any write or read-modify-write action leads to the described behavior. As a result, read-modify-write operations should be avoided.
0	[13:10], [30:26]	r	**Reserved** Read as 0; should be written with 0.

3.1.2 Module Clock Generation

The TC1798 on-chip modules have two registers for clock control:

- Clock Control Register CLC
- Fractional Divider Register FDR

The following sections describes the general functionality of CLC and FDR. The module-specific implementation details are described in the corresponding module chapters.

3.1.2.1 Clock Control Register CLC

All CLC registers have basically the same bit and bit field layout. However, not all CLC register functions are implemented for each peripheral module. **Table 3-2** defines in detail which bits and bit fields of the CLC registers are implemented for each clock control register.

The CLC register controls the generation of the peripheral module clock which is derived from the system clock. The following functions for the module are associated with the CLC register:

- Peripheral clock static on/off control
- Module clock behavior in Sleep Mode
- Operation during Suspend Mode
- Fast Shut-off Mode control

Module Enable/Disable Control

If a module is not used at all by an application, it can be completely shut off by setting bit DISR in its CLC register. For peripheral modules with a run mode clock divider field RMC, a second option to completely switch off the module is to set bit field RMC to 00_H. This also disables the module's operation.

The status bit DISS always indicates whether a module is currently switched off (DISS = 1) or switched on (DISS = 0).

Write operations to the non CLC registers of disabled modules are not allowed. However, the CLC of a disabled module can be written. An attempt to write to any of the other writable registers of a disabled module except CLC will cause the corresponding Bus Control Unit (BCU) to generate a bus error.

A read operation of registers of a disabled module is allowed and does not generate a bus error.

When a disabled module is switched on by writing an appropriate value to its MOD_CLC register (DISR = 0 and RMC (if implemented) > 0), status bit DISS changes from 1 to 0. During the phase in which the module becomes active, any write access to corresponding module registers (when DISS is still set) will generate a bus error. Therefore, when enabling a disabled module, application software should check after activation of the module once (read back of the CLC register) to find out whether DISS is already cleared, before a module register (including the CLC register) will be written to.

Sleep Mode Control

The EDIS bit in the CLC register controls whether or not a module is stopped during Sleep Mode. If EDIS is 0, a Sleep Mode request can be recognized by the module and, when received, its clock is shut off.

If EDIS is set to 1, a Sleep Mode request is disregarded by the module and the module continues its operation.

Suspend Mode Control

During emulation and debugging of TC1798 applications, the execution of an application program can be suspended. When an application is suspended, normal operation of the application's program is halted, and the TC1798 begins (or resumes) executing a special debug monitor program. If bit SPEN is set, the operation of the peripheral module is stopped when the Suspend Mode request is generated. If SPEN is cleared, the module does not react to the Suspend Mode request and continues its normal operation. This feature allows each peripheral module to be adapted to the unique requirements of the application being debugged. Setting SPEN bits is usually performed by a debugger.

This feature is necessary because application requirements typically determine whether on-chip modules should be stopped or left running when an application is suspended for debugging. For example, a peripheral unit that is controlling the motion of an external device through motors in most cases must not be stopped so as to prevent damage of the external device due to the loss of control through the peripheral. On the other hand, it makes sense to stop the system timer while the debugger is actively controlling the chip because it should only count the time when the user's application is running.

Note that it is never appropriate for application software to set the SPEN bit. The Suspend Mode should only be set by a debug software. To guard against application software accidently setting SPEN, bit SPEN is specially protected by the mask bit SBWE. The SPEN bit can only be written if, during the same write operation, SBWE is set, too. Application software should never set SBWE. In this way, user software can not accidentally alter the value of the SPEN bit that has been set by a debugger.

Entering Disabled Mode

Software can request that a peripheral unit be put into Disabled Mode by setting DISR. A module will also be put into Disabled Mode if the Sleep Mode is requested and the module is configured to allow Sleep Mode.

In Secure Shut-off Mode, a module first finishes any operation in progress, then proceeds with an orderly shut down. When all sub-components of the module are ready to be shut down, the module signals its clock control unit, that turns off the clock to this peripheral unit, that it is now ready for shut down. The status bit DISS is updated by the peripheral unit accordingly.

During emulation and debugging, it may be necessary to monitor the instantaneous state of the machine – including all or most of its modules – at the moment a software breakpoint is reached. In such cases, it may not be desired that the kernel of a module finish whatever transaction is in progress before stopping, because that might cause important states in this module to be lost. Fast Shut-off Mode, controlled by bit FSOE, is available for this situation.

If FSOE = 0, modules are stopped as described above. This is called Secure Shut-off Mode. The module is allowed to finish whatever operation is in progress. If Fast Shut-off Mode is selected (FSOE = 1), clock generation to the unit is stopped as soon as any outstanding bus operation is finished. The clock control unit does not wait until the module has finished its transaction. This option stops the unit's clock as fast as possible, and the state of the unit will be the closest possible to the time of the occurrence of the software breakpoint.

Note: In all TC1798 modules except MultiCAN and DMA, the only shut down operating mode that is available is the Fast Shut-off ModeTC1798, regardless of the state of the FSOE bit.

Whether Secure Shut-off Mode or Fast Shut-off Mode is required depends on the application, the needs of the debugger, and the type of unit. For example, the analog-to-digital converter might allow the converter to finish a running analog conversion before it can be suspended. Otherwise the conversion might be corrupted and a wrong value could be produced when Suspend Mode is exited and the unit is enabled again. This would affect further emulation and debugging of the application's program.

On the other hand, if a problem is observed to relate to the operation of the external analog-to-digital converter itself, it might be necessary to stop the unit as fast as possible in order to monitor its current instantaneous state. To do this, the Fast Shut-off Mode option would be selected. Although proper continuation of the application's program might not be possible after such a step, this would most likely not matter in such a case.

Note that it is never appropriate for application software to set the FSOE bit. Fast Shut-off Mode should only be set by debug software. To guard against application software accidently setting FSOE, bit FSOE is specially protected by the mask bit SBWE. The SPEN bit can only be written if, during the same write operation, SBWE is set, too. Application software should never set SBWE. In this way, user software can not accidentally alter the value of the FSOE bit. Note that this is the same guard mechanism used for the SPEN bit.

Module Clock Divider Control

Peripheral modules of the TC1798 can have a RMC control bit field in their CLC registers. This Run Mode Clock control bit field makes it possible to slow down the CLC clock via a programmable clock divider circuit.

A value of 00_H in RMC disables the clock signals to these modules (CLC clock is switched off). If RMC is not equal to 00_H, the clock for a module register (f_{CLC}) accesses is generated as

(3.16)

$$f_{CLC} = \frac{f_{FPI}}{RMC}$$

where RMC is the content of its CLC register RMC field with a range of 1 to 255. If RMC is not available in a CLC register, the CLC clock frequency f_{CLC} is always equal to the frequency of f_{FPI}.

Note: The number of module clock cycles (wait states) that are required for a "destructive read" access (means: flags/bits are set/cleared by a read access) to a module register of a peripheral unit depends on the selected CLC clock frequency.
Therefore, a slower CLC clock (selected via bit field RMC in the CLC register) may result in a longer read cycle access time on the FPI-Bus for peripheral units with "destructive read" access (e.g. the ASC).

Module Clock Register Implementations

Table 3-2 shows which of the CLC register bits/bit fields are implemented for each peripheral module in the TC1798 and which modules are equipped with a fractional divider.

Fractional Divider Operation

The fractional divider divides the input clock f_{CLC} either by the factor 1/n or by a fraction of n/1024 for any value of n from 0 to 1023, and outputs the clock signal, f_{MOD}. The fractional divider is controlled by the MOD_FDR register.

The fractional divider can be configured for two operating modes:

- **Normal Divider Mode:** Reload counter (RESULT = RESULT + 1), generating an output clock pulse on counter overflow.
- **Fractional Divider Mode:** Add a STEP value to the RESULT value and generates an output clock pulse on counter overflow.

Normal Divider Mode

In Normal Divider Mode (MOD_FDR.DM = 01_B), the fractional divider behaves as a reload counter (addition of +1) that generates an output clock pulse at f_{MOD} on the transition from $3FF_H$ to 000_H. MOD_FDR.RESULT represents the counter value and MOD_FDR.STEP determines the reload value.

The output frequencies in Normal Divider Mode are defined according to the following formulas:

$$f_{MOD} = f_{CLC} \times \frac{1}{n} \quad \text{, with n = 1024 - STEP} \tag{3.17}$$

Note: Each write to register FDR with bit field DM = 01_B or 10_B sets bit field RESULT to $3FF_H$.

In order to get $f_{MOD} = f_{CLC}$ MOD_FDR.STEP must be programmed with $3FF_H$. **Figure 3-18** shows the operation of the Normal Divider Mode with a reload value of MOD_FDR.STEP = $3FD_H$.

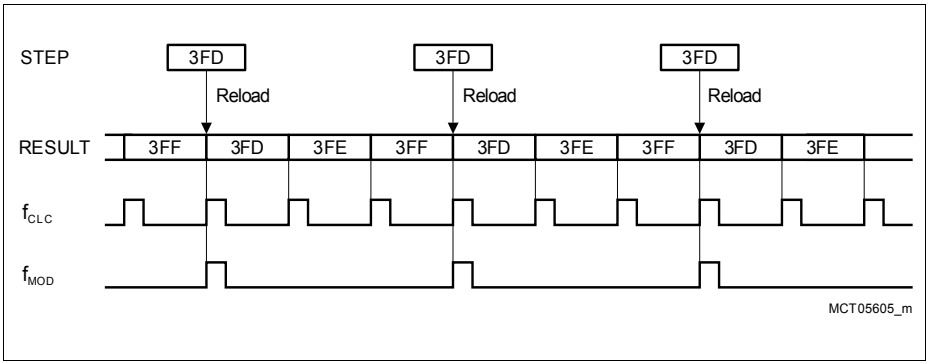

Figure 3-18 Normal Divider Mode

Fractional divider Mode

When the Fractional Divider Mode is selected (MOD_FDR.DM = 10_B), the module clock f_{MOD} is derived from the bus clock f_{CLC} by division of a fraction of n/1024 for any value of n from 0 to 1023. In general, the Fractional Divider Mode makes it possible to program the average module clock frequency with a higher accuracy than in Normal Divider Mode.

In Fractional Divider Mode, an clock pulse at f_{MOD} is generated depending on the result of the addition MOD_FDR.RESULT + MOD_FDR.STEP. If the addition leads to an overflow over $3FF_H$, a pulse is generated at f_{MOD}. Note that in Fractional Divider Mode the clock f_{MOD} can have a maximum period jitter of one f_{CLC} clock period.

The frequencies in Fractional Divider Mode are defined according to the following formula:

$$f_{MOD} = f_{CLC} \times \frac{n}{1024} \quad \text{, with n = 0-1023} \tag{3.18}$$

Note: Each write to register FDR with bit field DM = 01_B or 10_B sets bit field RESULT to $3FF_H$.

Suspend Mode

The operation of the fractional divider can be controlled by the Suspend Mode Request input. This input is activated in Suspend Mode by the on-chip debug control logic. In Suspend Mode, module registers are accessible for read and write actions, but other module internal functions are frozen.

The state of the Suspend Mode Request and Suspend Mode Acknowledge is latched in two status flags of register MOD_FDR, SUSREQ and SUSACK. Suspend Mode Request and (Suspend Mode Acknowledge or bit SM) must remain set both to maintain the Suspend Mode.

The Kernel Disable Request becomes always active when the Module Disable Request signal is activated, independently of the Suspend Mode settings in the fractional divider.

External Clock Enable

When the module clock generation has been disabled by software (setting MOD_FDR.DISCLK = 1), the disable state can be exited when the External Clock Enable input = 1. This feature is enabled when MOD_FDR.ENHW = 1.

Table 3-3 Fractional Divider Function Table

Mode	SC	DM	Result	f_{MOD}	Operation of Fractional Divider
Normal Mode	–	00_B	unchanged	inactive	switched off
		01_B	continuously updated	active	Normal Divider Mode
		10_B			Fractional Divider Mode

MSC0_FDR	Acknowledge depends on module state	from MultiCAN
MSC1_FDR	Acknowledge depends on module state	from MultiCAN
SSC0_FDR	Always immediately acknowledged; independently from module state	from MultiCAN
SSC1_FDR	Always immediately acknowledged; independently from module state	from MultiCAN
SSC2_FDR	Always immediately acknowledged; independently from module state	from MultiCAN
SSC3_FDR	Always immediately acknowledged; independently from module state	from MultiCAN
SENT_FDR	Always immediately acknowledged; independently from module state	from MultiCAN
SSCG0_FDR SSCG1_FDR SSCG2_FDR SSCG3_FDR	Always immediately acknowledged; independently from module state	from MultiCAN

1) This column shows whether a suspend acknowledge from a FDR controlled module depends on the module's state or not. If a suspend acknowledge depends from the module state, typically module operations such as serial transmissions are terminated before a suspend request is acknowledged back to the fractional divider. Note that bit FDR.SM must be cleared (granted suspend mode selected) when using the suspend mode acknowledge/grant functionality. If immediate suspend mode is selected (FDR.SM = 1), Suspend Mode is entered at once (if FDR.SC not equal 00_B) independently from the suspend acknowledge answer from the module.

2) This column shows whether the External Clock Enable input of a fractional divider is controlled by on-chip hardware (source module see comment) or not ("–").

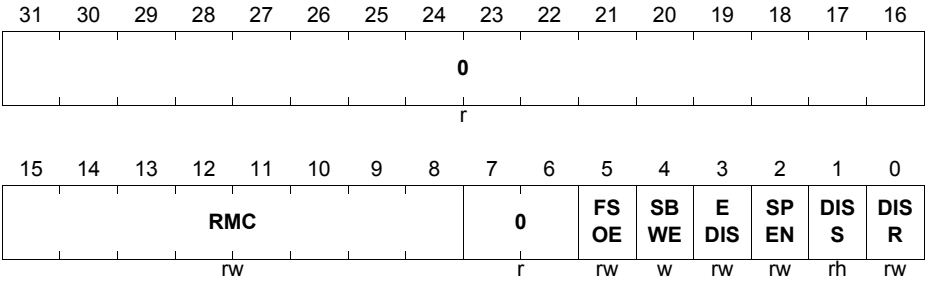
Clock Control Register **(00_H)** **Reset Value: Module-specific**



Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module. 0_B Module disable is not requested 1_B Module disable is requested
DISS	1	rh	**Module Disable Status Bit** Bit indicates the current status of the module 0_B Module is enabled 1_B Module is disabled If the RMC field is implemented and if it is 0, DISS is set automatically.
SPEN	2	rw	**Module Suspend Enable** Used for enabling the Suspend Mode. 0_B Module cannot be suspended (suspend is disabled) 1_B Module can be suspended (suspend is enabled) This bit can be written only if SBWE is set during the same write operation.
EDIS	3	rw	**Sleep Mode Enable Control** Used for module Sleep Mode control. 0_B Sleep Mode request is regarded. Module is enabled to go into Sleep Mode. 1_B Sleep Mode request is disregarded: Sleep Mode cannot be entered on a request.

Field	Bits	Type	Description
SBWE	4	w	**Module Suspend Bit Write Enable for OCDS** Determines whether SPEN and FSOE are write-protected. 0_B Bits SPEN and FSOE are write-protected 1_B Bits SPEN and FSOE are overwritten by respective value of SPEN or FSOE Reading this bit returns always 0.
FSOE	5	rw	**Fast Switch Off Enable** Used for fast clock switch-off in Suspend Mode. 0_B Clock switch-off in Suspend Mode via Disable Control Feature (Secure Clock Switch Off) selected 1_B Fast clock switch off in Suspend Mode selected This bit can be written only if SBWE is set during the same write operation.
RMC	[15:8]	rw	**8-Bit Clock Divider Value in RUN Mode** This is a maximum 8-bit divider value for clock f_{FPI}. If RMC is set to 0 the module is disabled.
0	7, 6, [31:16]	r	**Reserved** Read as 0; should be written with 0.

MOD_FDR
Fractional Divider Register **Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DISCLK	**ENHW**	**SUSREQ**	**SUSACK**	**0**		**RESULT**									
rwh	rw	rh	rh	r		rh									

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DM		**SC**		**SM**	**FDIS**	**STEP**									
rw		rw		rw	rw	rw									

Field	Bits	Type	Description
STEP	[9:0]	rw	**Step Value** In Normal Divider Mode, STEP contains the reload value for RESULT. In Fractional Divider Mode, this bit field determines the 10-bit value that is added to RESULT with each input clock cycle.
FDIS	10	rw	**Freeze Disable** This bit controls the freeze function for this module. 0_B Module operates on corrected clock, with reduced modulation jitter 1_B Module operates on uncorrected clock with full modulation jitter
SM	11	rw	**Suspend Mode** SM selects between granted or immediate Suspend Mode. 0_B Granted Suspend Mode selected 1_B Immediate Suspend Mode selected
SC	[13:12]	rw	**Suspend Control** This bit field determines the behavior of the fractional divider in Suspend Mode (bit SUSREQ and SUSACK set). 00_B Clock generation continues. 01_B Clock generation is stopped and the clock output signal is not generated. RESULT is not changed except when writing bit field DM with 01_B or 10_B. 10_B Clock generation is stopped and the clock output signal is not generated. RESULT is loaded with $3FF_H$. 11_B Same as SC = 10_B but signal Reset External Divider is 1 (independently of bit field DM).

Field	Bits	Type	Description
DM	[15:14]	rw	**Divider Mode** This bit fields determines the functionality of the fractional divider block. 00_B Fractional divider is switched off; no output clock is generated. The Reset External Divider signal is 1. RESULT is not updated. 01_B Normal Divider Mode selected. 10_B Fractional Divider Mode selected. 11_B Fractional divider is switched off; no output clock is generated. RESULT is not updated.
RESULT	[25:16]	rh	**Result Value** In Normal Divider Mode, RESULT acts as reload counter (addition +1). In Fractional Divider Mode, this bit field contains the result of the addition RESULT + STEP. If DM is written with 01_B or 10_B, RESULT is loaded with $3FF_H$.
SUSACK	28	rh	**Suspend Mode Acknowledge** 0_B Suspend Mode is not acknowledged. 1_B Suspend Mode is acknowledged. Suspend Mode is entered when SUSACK and SUSREQ are set.
SUSREQ	29	rh	**Suspend Mode Request** 0_B Suspend Mode is not requested. 1_B Suspend Mode is requested. Suspend Mode is entered when SUSREQ and SUSACK are set.
ENHW	30	rw	**Enable Hardware Clock Control** 0_B Bit DISCLK cannot be cleared by a high level of the External Clock Enable input 1_B Bit DISCLK is cleared while the External Clock Enable input is at high level.
DISCLK	31	rwh	**Disable Clock** 0_B Clock generation of f_{MOD} is enabled according to the setting of bit field DM. 1_B Fractional divider is stopped. Signal f_{MOD} becomes inactive. No change except when writing bit field DM.

Field	Bits	Type	Description
0	[27:26]	r	**Reserved** Read as 0; should be written with 0.

3.2 Reset Operation

This section describes the conditions under which the TC1798 will be reset and the reset operation configuration and control.

3.2.1 Overview

The following reset request triggers are available:

- 1 External power-on hardware reset request trigger; $\overline{\text{PORST}}$, (cold reset)
- 2 External System Request reset triggers; $\overline{\text{ESR0}}$, and $\overline{\text{ESR1}}$,(warm reset)
- Watchdog Timer (WDT) reset request trigger, (warm reset)
- Software reset (SW), (warm reset)
- Debug (OCDS) reset request trigger, (warm reset)
- Resets via the JTAG interface
- Flash Tuning Protection (TP) (warm reset)
- JTAG reset (special reset)

Note: The JTAG and OCDS resets are described in the OCDS chapter.

There are two basic types of reset request triggers:

- Trigger sources that do not depend on a clock, such as the $\overline{\text{PORST}}$. This trigger force the device into an asynchronous reset assertion independently of any clock. The activation of an asynchronous reset is asynchronous to the system clock, whereas its de-assertion is synchronized.
- Trigger sources that need a clock in order to be asserted, such as the input signals $\overline{\text{ESR0}}$,$\overline{\text{ESR1}}$, the WDT trigger, TP trigger, or the SW trigger.

Note: A $\overline{\text{PORST}}$ reset should only triggered for power related issue and not for pure functional purpose.

3.2.2 Reset Types

The following summary shows the different reset types.

- Power-on Reset:
  This reset leads to a initialization into a defined state of the complete system. This reset should only be requested on a real power-on event and can not by any non power related event.
  A Power-on Reset also generates a System Reset and an Application Reset.
- System Reset:
  This reset leads to a initialization into a defined state of the complete system without the following parts: reset control, power control.
  A System Reset also generates an Application Reset.
- Debug Reset:
  This reset leads to a initialization into a defined state of the complete debug system.

- Application Reset:
  This reset leads to a initialization into a defined state of the complete application system with the following parts: all peripherals, the CPU and partially the SCU and the flash memory.

3.2.3 Reset Sources Overview

The connection of the reset sources and the activated reset signals/domains are shown in Table 3-5.

Table 3-5 Effects of Resets for Reset Signal Activation

Reset Request Trigger	Application Reset	Debug Reset	System Reset
$\overline{\text{PORST}}$	Activated	Activated	Activated
$\overline{\text{ESR0}}$	Configurable	Not Activated	Configurable
$\overline{\text{ESR1}}$	Configurable	Not Activated	Configurable
WDT	Configurable	Not Activated	Configurable
SW	Configurable	Not Activated	Configurable
OCDS Reset	Not Activated	Activated	Not Activated
CBS_OJCONF.RSTCL0	Activated	Not Activated	Activated
CBS_OJCONF.RSTCL1	Not Activated	Activated	Not Activated
CBS_OJCONF.RSTCL3	Activated	Not Activated	Not Activated

3.2.4 Module Reset Behavior

Table 3-6 lists how the various functions of the TC1798 are affected through a reset depending on the reset type. A “X” means that this block has at least some register/bits that are affected by this reset.

Table 3-6 Effect of Reset on Device Functions

Module / Function	Application Reset	Debug Reset	System Reset	Power-on Reset
CPU Core	X	X	X	X
Peripherals (except SCU)	X	X	X	X
SCU	X	Not affected	X	X

Table 3-6 Effect of Reset on Device Functions (cont'd)

Module / Function		Application Reset	Debug Reset	System Reset	Power-on Reset
On-chip Static RAMs[1]	**OVRAM**	Not affected, reliable	Not affected, reliable	Affected, un-reliable	Affected, un-reliable
	DSPR	Not affected, reliable	Not affected, reliable	Affected, un-reliable	Affected, un-reliable
	DCACHE	Not affected, reliable	Not affected, reliable	Affected, un-reliable	Affected, un-reliable
	PSPR	Not affected, reliable	Not affected, reliable	Affected, un-reliable	Affected, un-reliable
	PRAM	Not affected, reliable	Not affected, reliable	Affected, un-reliable	Affected, un-reliable
	CMEM	Not affected, reliable	Not affected, reliable	Affected, un-reliable	Affected, un-reliable
	ICACHE	Not affected, reliable	Not affected, reliable	Affected, un-reliable	Affected, un-reliable
	LMU	Not affected, reliable	Not affected, reliable	Affected, un-reliable	Affected, un-reliable
Flash Memory		X [2]	Not affected, reliable	X	X
JTAG Interface		Not affected	Not affected	Not affected	Affected
OCDS		Not affected	X	Not affected	X
MCDS		Not affected	X	Not affected	X
Oscillators, PLL		Not affected	Not affected	X	X
Port Pins		X	Not affected	X	X
Pins ESRx		Not affected	Not affected	X	X

1) Reliable here means that also the redundancy is not affected by the reset.

2) Parts of the flash memory block are only reset by a class 0 reset. For more detail see the flash chapter.

3.2.5 General Reset Operation

A reset is generated if an enabled reset request trigger is asserted. Most reset request trigger can configured for the reset type that should initiated by it. No action (disabled) is one possible configuration and can be selected for a reset request trigger by setting the adequate bit field in a Reset Configuration Register to 00_B. The Debug Reset can only

be requested by dedicated reset request triggers and can not be selected via a Reset Configuration Register. For more information see also register RSTCON.

The duration of a reset is defined by two independent counters. One counter for the Power-on, System, and Application Reset types and one separate counter for the Debug Reset. A separate counter for the Debug Reset was implemented to allow a non-intrusive adaptation of the reset length to the debugger needs without modification of the application setting.

3.2.6 Reset State Machine

There is one central Reset State Machine (RSM) controlling the reset generation for the complete device beside the JTAG reset domain.

Note: The JTAG reset domain is controlled by the $\overline{TRST}$ pin.

The RSM is composed of a control block responsible for the operation flow, two counters with a reload register, and a distribution logic that controls the generation of the three dedicated resets.

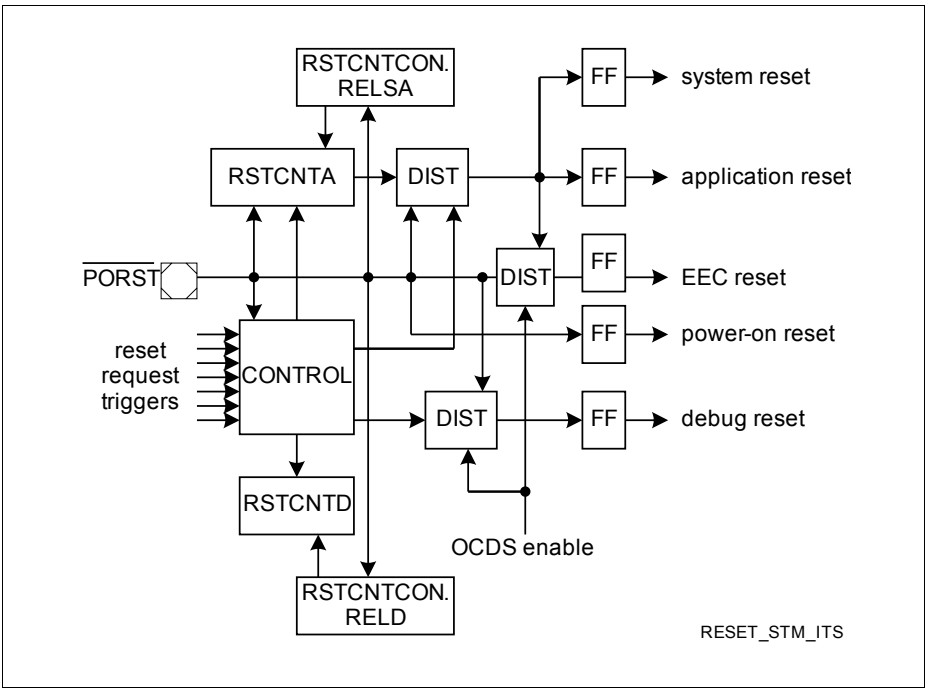


Figure 3-19 Reset State Machine Block Diagram

3.2.7 Reset Counters (RSTCNTA and RSTCNTD)

There are two reset counters implemented. RSTCNTA is the reset counter that controls the reset length for all non debug relevant resets (System Reset and Application Reset). RSTCNTD is the reset counter that controls the reset length for the Debug Reset.

The reset counters can be used for the following purposes:

- First to control the length of the internal resets.
- Second to configure the reset length in a way that the reset outputs via the ESRx pins match with the reset input requirements of external blocks connected with the reset outputs.

A reset counter RSTCNT is an 16-bit counter counting down from the reload value defined by RSTCNTCON.RELx (x = SA or D). The counter is started by the control block as soon as a reset request trigger condition becomes active (for more information see **Table 3-7** and **Table 3-8**). Whether the counter has to be started or not depends on the reset request trigger and whether the counter is already active or not. In case that the counter is inactive, not counting down, it is always started. While the counter is already active it depends on the reset of the new reset request trigger that was asserted anew if the counter is restarted or not. This behavior is summarized in **Table 3-7** and **Table 3-8**.

Table 3-7 Restart of RSTCNTA

Reset Active	New Reset Request			
	Power-on	System	Debug	Application
Power-on Reset	Restart	No Restart	No Restart	No Restart
System	Restart	No Restart	No Restart	No Restart
Application	Restart	Restart	No Restart	No Restart

Table 3-8 Restart of RSTCNTD

Reset Active	New Reset / Reset Type Request			
	Power-on	System	Debug	Application
Debug	Restart	No Restart	No Restart	No Restart

RSTCNTx ensures that a reset request trigger generates a reset of a minimum length which is configurable. But if a reset request trigger is asserted continuously longer than the counter needs for the complete count-down process the reset cannot be deasserted before the reset request trigger is also deasserted. Anyway the counter is not started again, instead the control block informs the distribution logic (DIST) that the reset still has to be asserted until the reset request trigger is deasserted.

The reset state of the control block is implemented such that the RSTCNTA is started and two reset types (System and Application) have to be asserted by the distribution logic.

The reset state of the control block is implemented such that the RSTCNTD is started and the Debug Reset has to be asserted by the distribution logic.

Note: The reset counter should not be configured with a value lower than 20_H due to the implementation.

3.2.8 De-assertion of a Reset

The reset is de-asserted when all of the following conditions are fulfilled.

- The reset counter has expired (reached zero)
- No reset request trigger that is configured to generate the same reset is currently asserted

3.2.8.1 Example1:

Reset request trigger A is asserted and leads to an Application Reset. If the reset request trigger is de-asserted before RSTCNTA reached zero the Application Reset is de-asserted when RSTCNTA reaches zero. If the reset request trigger is de-asserted after RSTCNTA reached zero the Application Reset is de-asserted when the reset request trigger is de-asserted.

3.2.8.2 Example2:

Reset request trigger A is asserted and leads to an Application Reset. Reset request trigger A is de-asserted before RSTCNTA reached zero. Reset request trigger B is asserted after reset request trigger A but before RSTCNTA reaches zero. Reset request trigger B is also configured to result in an Application Reset. If the reset request trigger B is de-asserted before RSTCNTA reached zero the Application Reset is de-asserted when RSTCNTA reaches zero. If the reset request trigger B is de-asserted after RSTCNTA reached zero the Application Reset is de-asserted when the reset request trigger B is de-asserted.

3.2.8.3 Example3:

Reset request trigger A is asserted and leads to a System Reset. Reset request trigger A is de-asserted before RSTCNTA reached zero. Reset request trigger B is asserted after reset request trigger A but before RSTCNTA reaches zero. Reset request trigger B is configured to result in an Application Reset. If the reset request trigger B is de-asserted before RSTCNTA reached zero the System and Application Resets are de-asserted when RSTCNTA reaches zero. If the reset request trigger B is de-asserted after

RSTCNTA reached zero the Application Reset is de-asserted when the reset request trigger B is de-asserted.

3.2.9 Reset Triggers

There are two types of reset triggers for the reset control logic:

- Triggers that lead to a specific reset
- Triggers that lead to a configurable reset

3.2.9.1 Specific Reset Triggers

These triggers lead to a predefined reset if the trigger is asserted. Additionally these triggers can not be enabled / disabled. All specific reset are listed in **Table 3-9**.

Table 3-9 Specific Reset Triggers

Reset Trigger	Reset Type Request
Debug (OCDS from Cerberus)	Debug Reset
Cerberus 0 (CB0)	System Reset
Cerberus 1 (CB1)	Debug Reset
Cerberus 3 (CB3)	Application Reset

3.2.9.2 Configurable Reset Triggers

These triggers lead to a selectable reset if the trigger is asserted. Additionally these triggers can be enabled / disabled. The behavior of the reset triggers action is defined by the configuration of the dedicated bit field for this trigger in register RSTCON.

3.2.10 Debug Specific Behavior

For safety reasons it is required by the debugger that if the OCDS system is disabled a Debug Reset is also asserted every time an Application Reset is asserted.

3.2.11 EEC Reset Specific Behavior

The complete EEC part is reset with the Power-on Reset. For safety reasons it is required by the debugger that if the OCDS system is disabled a EEC reset is also asserted every time an Application Reset is asserted.

3.2.12 Reset Controller Registers

3.2.12.1 Status Registers

After a reset has been executed, the Reset Status registers provide information on the source of the last reset(s). The reset status registers are updated upon each reset cycle. A reset cycle is finished when all resets are de-asserted. Within a reset cycle the status flags are used as sticky flags.

RSTSTAT
Reset Status Register

(050_H) **Reset Value: 0001 0001_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0										TP	CB3	CB1	CB0	OCDS	PORST
r										rh	rh	rh	rh	rh	rh

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0											SW	WDT	0	ESR1	ESR0
r											rh	rh	r	rh	rh

Field	Bits	Type	Description
ESR0	0	rh	**Reset Request Trigger Reset Status for ESR0** 0_B The last reset was not requested by this reset trigger 1_B The last reset was requested by this reset trigger *Note: This bit is set if the ESR0 pin is configured as open drain for output characteristics (IOCR.PC0 = 1101_H or 1110_H) and ESR0 is configured to generate a Reset (RSTCON.ESR0 = 01_B or 10_B) AND a reset is signaled by the ESR0 pin to the outside. That this bit is set under this condition can be avoided by either setting IOCR.PC0 = 1001_H or 1010_H or RSTCON.ESR0 = 00_B.*

Field	Bits	Type	Description
ESR1	1	rh	**Reset Request Trigger Reset Status for ESR1** 0_B The last reset was not requested by this reset trigger 1_B The last reset was requested by this reset trigger *Note: This bit is set if the ESR1 pin is configured as open drain for output characteristics (IOCR.PC1 = 1101_H or 1110_H) and ESR1 is configured to generate a Reset (RSTCON.ESR1 = 01_B or 10_B) AND a reset is signaled by the ESR1 pin to the outside. That this bit is set under this condition can be avoided by either setting IOCR.PC1 = 1001_H or 1010_H or RSTCON.ESR1 = 00_B.*
WDT	3	rh	**Reset Request Trigger Reset Status for WDT** 0_B The last reset was not requested by this reset trigger 1_B The last reset was requested by this reset trigger
SW	4	rh	**Reset Request Trigger Reset Status for SW** 0_B The last reset was not requested by this reset trigger 1_B The last reset was requested by this reset trigger
PORST	16	rh	**Reset Request Trigger Reset Status for PORST** 0_B The last reset was not requested by this reset trigger 1_B The last reset was requested by this reset trigger This bit is also set if the bits CB0, CB1, and CB3 are set in parallel.
OCDS	17	rh	**Reset Request Trigger Reset Status for OCDS** 0_B The last reset was not requested by this reset trigger 1_B The last reset was requested by this reset trigger

Field	Bits	Type	Description
CB0	18	rh	**Reset Request Trigger Reset Status for Cerberus System Reset** 0_B The last reset was not requested by this reset trigger 1_B The last reset was requested by this reset trigger
CB1	19	rh	**Reset Request Trigger Reset Status for Cerberus Debug Reset** 0_B The last reset was not requested by this reset trigger 1_B The last reset was requested by this reset trigger
CB3	20	rh	**Reset Request Trigger Reset Status for Cerberus Application Reset** 0_B The last reset was not requested by this reset trigger 1_B The last reset was requested by this reset trigger
TP	21	rh	**Reset Request Trigger Reset Status for TP** 0_B The last reset was not requested by this reset trigger 1_B The last reset was requested by this reset trigger
0	2, [15:5], [31:22]	r	**Reserved** Read as 0; should be written with 0.

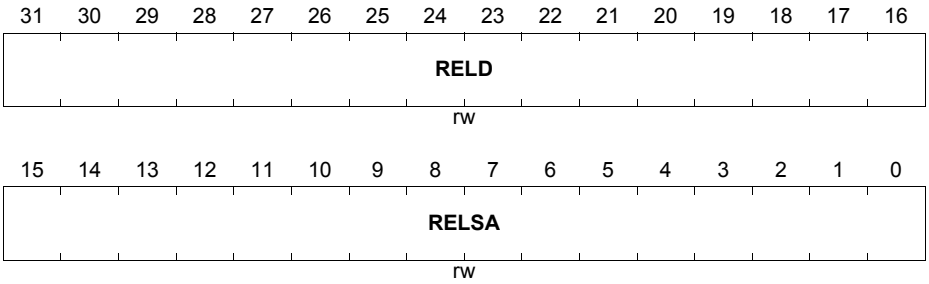
3.2.12.2 Configuration Registers

Reset Counter Control Register

This register controls the reset length settings for the three resets.

RSTCNTCON
Reset Counter Control Register

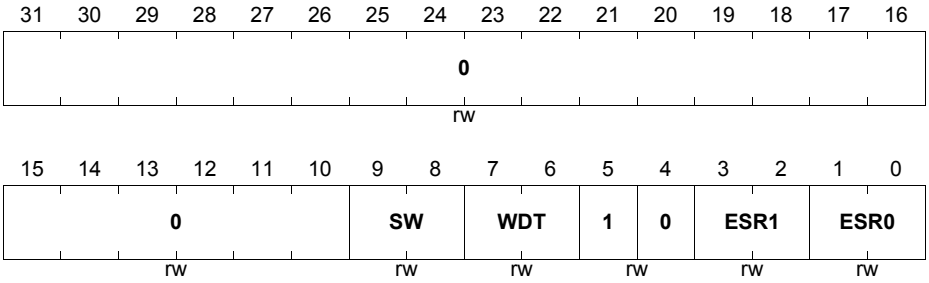
(054$_H$) Reset Value: 05BE 05BE$_H$



Field	Bits	Type	Description
RELSA	[15:0]	rw	**System Application Reset Counter Reload Value** This bit field defines the reload value of RSTCNTA. This value is always used when counter RSTCNTA is started.
RELD	[31:16]	rw	**Debug 1 Reset Counter Reload Value** This bit field defines the reload value of RSTCNTD. This value is always used when counter RSTCNTD is started.

RSTCON
Reset Configuration Register

(058$_H$) Reset Value: 0000 02A2$_H$

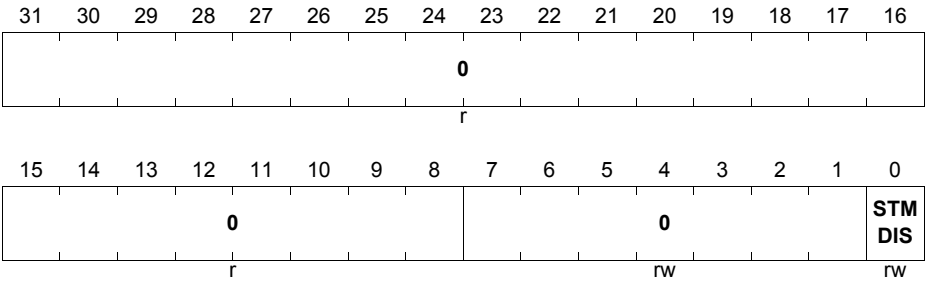


Field	Bits	Type	Description
ESR0	[1:0]	rw	**ESR0 Reset Request Trigger Reset Configuration** This bit field defines which reset is generated by a reset request trigger from ESR0 reset. 00_B No reset is generated for a trigger of ESR0 01_B A System Reset is generated for a trigger of ESR0 reset 10_B An Application Reset is generated for a trigger of ESR0 reset 11_B Reserved, do not use this combination
ESR1	[3:2]	rw	**ESR1 Reset Request Trigger Reset Configuration** This bit field defines which reset is generated by a reset request trigger from ESR1 reset. 00_B No reset is generated for a trigger of ESR1 01_B A System Reset is generated for a trigger of ESR1 reset 10_B An Application Reset is generated for a trigger of ESR1 reset 11_B Reserved, do not use this combination
WDT	[7:6]	rw	**WDT Reset Request Trigger Reset Configuration** This bit field defines which reset is generated by a reset request trigger from WDT reset. 00_B No reset is generated for a trigger of WDT 01_B A System Reset is generated for a trigger of WDT reset 10_B An Application Reset is generated for a trigger of WDT reset 11_B Reserved, do not use this combination
SW	[9:8]	rw	**SW Reset Request Trigger Reset Configuration** This bit field defines which reset is generated by a reset request trigger from software reset. 00_B No reset is generated for a trigger of software reset 01_B A System Reset is generated for a trigger of Software reset 10_B An Application Reset is generated for a trigger of Software reset 11_B Reserved, do not use this combination

Field	Bits	Type	Description
1	5	rw	**Reserved** Should be written with 1.
0	4, [31:10]	rw	**Reserved** Should be written with 0.

ARSTDIS
Application Reset Disable Register

(05C$_H$) **Reset Value: 0000 0000$_H$**



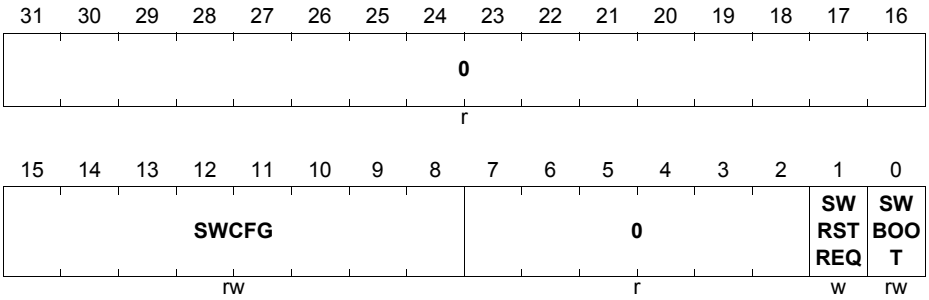
Field	Bits	Type	Description
STMDIS	0	rw	**STM Disable Reset** This bit field defines if an Application Reset leads to an reset for the STM. 0_B An Application Reset resets the STM 1_B An Application Reset has no effect for the STM
0	[7:1]	rw	**Reserved** Should be written with 0.
0	[31:8]	r	**Reserved** Read as 0; should be written with 0.

SW Reset Configuration Register

This register controls the SW Reset operation.

SWRSTCON
Software Reset Configuration Register

(060$_H$) Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
SWBOOT	0	rw	**Software Boot Configuration Selection** 0_B Bit field STSTAT.HWCFG is not updated with the content of SWCFG upon an Application Reset 1_B Bit field STSTAT.HWCFG is updated with the content of SWCFG upon an Application Reset
SWRSTREQ	1	w	**Software Reset Request** 0_B No SW Reset is requested 1_B A SW Reset request trigger is generated This bit is automatically cleared and read always as zero.
SWCFG	[15:8]	rw	**Software Boot Configuration** A software boot configuration different from the external applied hardware configuration can be specified with these bits. The configuration encoding is equal to the HWCFG encoding in register STSTAT.
0	[7:2], [31:16]	r	**Reserved** Read as 0; should be written with 0.

3.3 External Interface

The SCU provides interface pads for system purpose. Various functions are covered by these pins. Due to the different tasks some of the pads can not be shared with other functions but most of them can. The following functions are covered by the SCU controlled pads:

- Reset request triggers
- Reset indication
- Trap request triggers
- Interrupt request triggers
- Non SCU module triggers

The first three points are covered by the ESR pads and the last two points by the ERU pads.

3.3.1 External Service Requests ($\overline{\text{ESRx}}$)

The ESR pins can be used to trigger either a reset, a trap (NMI), as reset output, or as data pin.

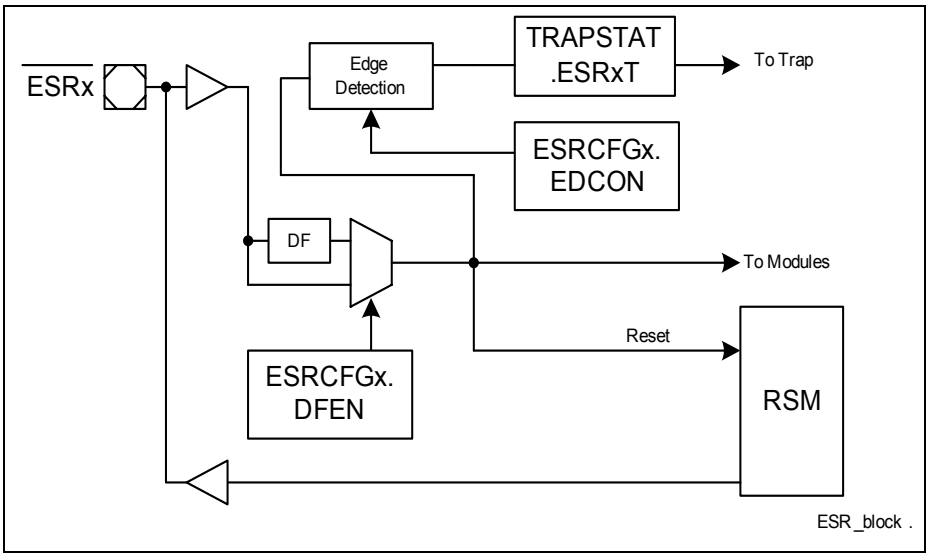


Figure 3-20 ESR Operation

3.3.1.1 $\overline{\text{ESRx}}$ as Reset Request Trigger

An $\overline{\text{ESR0}}$/$\overline{\text{ESR1}}$ reset request trigger leads to a System or Application Reset. The type of the reset can be configured via RSTCON.ESRx.

In order to be safely recognized $\overline{\text{ESR0}}$/$\overline{\text{ESR1}}$ has to be active for a minimum of 2 f_{FPI} clock cycles.

The input signal $\overline{\text{ESR0}}$/$\overline{\text{ESR1}}$ have digital filters (3-stage median filters), that can be disabled.

A 3-stage median filter samples with f_{FPI} three consecutive clock cycles and the output is defined by the majority of the three sampled values.

The behavior of all three $\overline{\text{ESR0}}$/$\overline{\text{ESR1}}$ pins can be configured by programming the registers ESRCFGn. The pad control functionality can be configured independently for each pin, comprising:

- A selection of the driver type (open-drain or push-pull)
- An enable function for the output driver (input and/or output capability)
- An enable function for the pull-up/down resistance

3.3.1.2 $\overline{\text{ESRx}}$ as Reset Output

The external pins $\overline{\text{ESR0}}$/$\overline{\text{ESR1}}$ can serve as an reset output (open drain) for the Application Reset.

Note: The reset output is only asserted for the duration the reset counter RSTCNTA is active. During a possible reset extension the reset output is not longer asserted.

If the pin $\overline{\text{ESR0}}$/$\overline{\text{ESR1}}$ is enabled as reset output and the input level is low while the output stage is disabled (indicating that it is still driven low externally), the reset circuitry holds the chip in reset until a high level is detected on $\overline{\text{ESR0}}$/$\overline{\text{ESR1}}$. The internal output stage drives a low level during reset only while RSTCNTA is active. It deactivates the output stage when the time defined by RSTCNTCON.RELSA has passed.

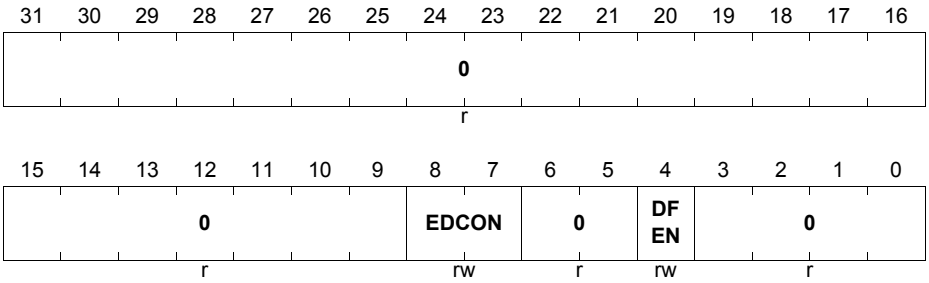
3.3.1.3 ESR Registers

ESRCFG0
ESR0 Configuration Register

(070_H) **Reset Value: $0000\ 0110_H$**

ESRCFG1
ESR1 Configuration Register

(074_H) **Reset Value: $0000\ 0090_H$**



Field	Bits	Type	Description
DFEN	4	rw	**Digital Filter Enable** This bit defines if the 3-stage median filter of the ESR0 is used or bypassed. 0_B The filter is bypassed 1_B The filter is used
EDCON	[8:7]	rw	**Edge Detection Control** This bit field defines the edges that lead to an ESR0 trigger of the synchronous path. 00_B No trigger is generated 01_B A trigger is generated upon a rising edge 10_B A trigger is generated upon a falling edge 11_B A trigger is generated upon a rising OR falling edge
0	[3:0], [6:5], [31:9]	r	**Reserved** Read as 0; should be written with 0.

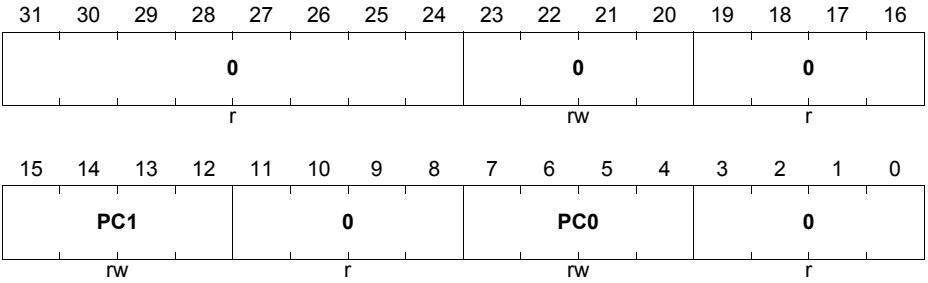
Input/Output Control Registers

The input/output control registers select the digital output and input driver functionality and characteristics of the pin. Direction (input or output), pull-up or pull-down devices for

inputs, and push-pull or open-drain functionality for outputs can be selected by the corresponding bit fields PCx (x = 0-1).

IOCR

Input/Output Control Register ($0A0_H$) Reset Value: $0020\ 10E0_H$



Field	Bits	Type	Description
PC0	[7:4]	rw	**Control for $\overline{\text{ESR0}}$ Pin** This bit field defines the $\overline{\text{ESR0}}$ pin functionality according to the coding table (see **Table 3-10**).
PC1	[15:12]	rw	**Control for $\overline{\text{ESR1}}$ Pin** This bit field defines the $\overline{\text{ESR1}}$ pin functionality according to the coding table (see **Table 3-11**).
0	[23:20]	rw	**Reserved** Have to be written with 0010_B.
0	[3:0], [11:8], [19:16], [31:24]	r	**Reserved** Read as 0; should be written with 0.

Pad Control Coding

Table 3-10 describes the coding of the PC0 bit field that determine the port line functionality.

Table 3-10 PC0 Coding

PC0[3:0]	I/O	Output Characteristics	Selected Pull-up/Pull-down/ Selected Output Function
$0X00_B$	Input is active and not inverted; Output is inactive		No input pull device connected
$0X01_B$			Input pull-down device connected
$0X10_B$			Input pull-up device connected
$0X11_B$			No input pull device connected
1000_B	Input is active and not inverted; Output is active	Push-pull	General-purpose Output
1001_B			Output drives a 0 for System Resets, a weak pull-up is active otherwise
1010_B			Output drives a 0 for Application Resets, a weak pull-up is active otherwise
1011_B			Reserved, do not use this combination
1100_B	the input is active and not inverted; Output is active	Open-drain	General-purpose Output
1101_B			Output drives a 0 for System Resets, a weak pull-up is active otherwise
1110_B			Output drives a 0 for Application Resets, a weak pull-up is active otherwise
1111_B			Reserved, do not use this combination

Pad Control Coding

Table 3-11 describes the coding of the PC1 bit field that determine the port line functionality.

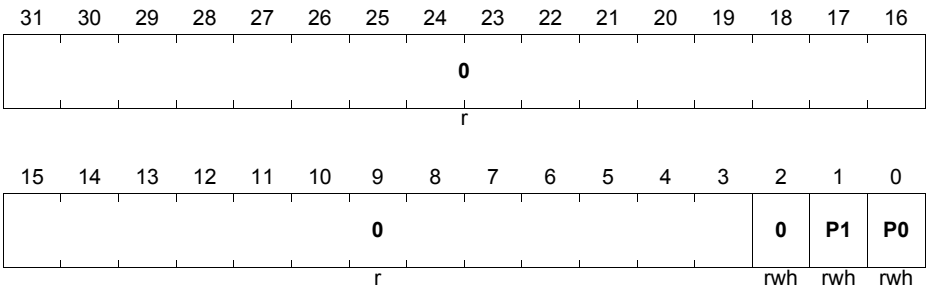
Table 3-11 PC1 Coding

PC1[3:0]	I/O	Output Characteristics	Selected Pull-up/Pull-down/ Selected Output Function
$0X00_B$	Input is active and not inverted; Output is inactive		No input pull device connected
$0X01_B$			Input pull-down device connected
$0X10_B$			Input pull-up device connected
$0X11_B$			No input pull device connected
1000_B	Input is active and not inverted; Output is active	Push-pull	General-purpose Output
1001_B			Output drives a 0 for System Resets, a 'Z' otherwise
1010_B			Output drives a 0 for Application Resets, a 'Z' otherwise
1011_B			Reserved, do not use this combination
1100_B	the input is active and not inverted; Output is active	Open-drain	General-purpose Output
1101_B			Output drives a 0 for System Resets, a 'Z' otherwise
1110_B			Output drives a 0 for Application Resets, a 'Z' otherwise
1111_B			Reserved, do not use this combination

Output Register

The output register determines the value of a GPIO pin when it is selected by IOCR as output. Writing a 0 to a OUT.Px (x = 0-1) bit position delivers a low level at the corresponding output pin. A high level is output when the corresponding bit is written with a 1. Note that each single bit or group of bits of OUT.Px can be set/cleared by writing appropriate values into the output modification register OMR.

OUT
Output Register **($0A4_H$)** **Reset Value: $0000\ 0000_H$**

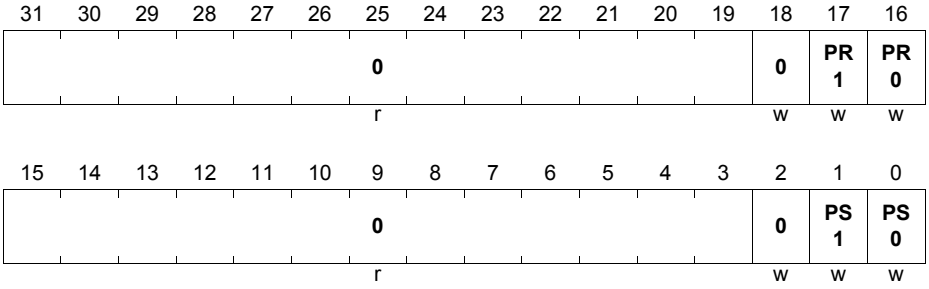


Field	Bits	Type	Description
Px **(x = 0-1)**	x	rwh	**Output Bit x** This bit determines the level at the output pin $\overline{ESR}$x if the output is selected as GPIO output. 0_B The output level of $\overline{ESR}$x is 0 1_B The output level of $\overline{ESR}$x is 1 Px can also be set/cleared by control bits of the OMR register.
0	2	rwh	**Reserved** Have to be written with 0.
0	[31:3]	r	**Reserved** Read as 0; should be written with 0.

Output Modification Register

The output modification register contains control bits that make it possible to individually set, clear, or toggle the logic state of a single pad by manipulating the output register.

OMR
Output Modification Register **($0A8_H$)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
PSx (x = 0-1)	x	w	**Set Bit x** Setting this bit will set or toggle the corresponding bit in the output register OUT. The function of this bit is shown in **Table 3-12**.
PRx (x = 0-1)	x + 16	w	**Clear Bit x** Setting this bit will clear or toggle the corresponding bit in the port output register OUT. The function of this bit is shown in **Table 3-12**.
0	2, 18	w	**Reserved** Read as 0; have to be written with 0.
0	[15:3], [31:19]	r	**Reserved** Read as 0; should be written with 0.

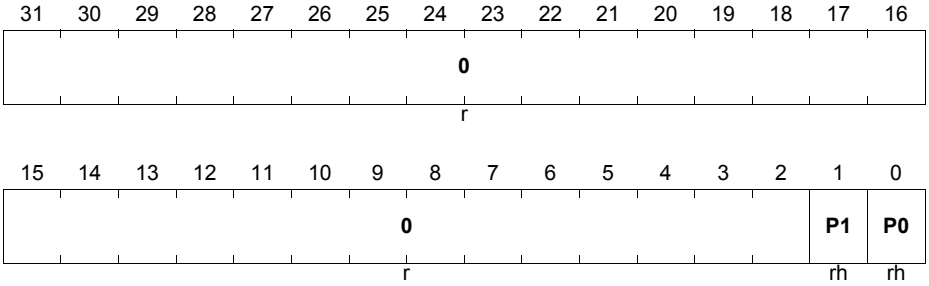
Table 3-12 Function of the Bits PRx and PSx

PRx	PSx	Function
0	0	Bit OUT.Px is not changed
0	1	Bit OUT.Px is set
1	0	Bit OUT.Px is cleared
1	1	Bit OUT.Px is toggled

Input Register

The logic level of a GPIO pin can be read via the read-only port input register IN. Reading the IN register always returns the current logical value at the GPIO pin independently whether the pin is selected as input or output.

IN
Input Register **($0AC_H$)** **Reset Value: $0000\ 000X_H$**



Field	Bits	Type	Description
Px **(x = 0-1)**	x	rh	**Input Bit x** This bit indicates the level at the input pin $\overline{ESR}$x. 0_B The input level of $\overline{ESR}$x is 0 1_B The input level of $\overline{ESR}$x is 1
0	[31:2]	r	**Reserved** Read as 0.

3.3.2 External Request Unit (ERU)

The External Request Unit (ERU) is a versatile event and pattern detection unit. Its major task is the **generation of interrupts based on selectable trigger events at different inputs**, e.g. to generate external interrupt requests if an edge occurs at an input pin. The detected events can also be used by other modules to trigger or to gate module-specific actions.

3.3.2.1 Introduction

The ERU of the TC1798 can be split in three main functional parts:

- 4 independent **Input Channels x** for input selection and conditioning of trigger or gating functions
- Event distribution: A **Connecting Matrix** defines the events of the Input Channel x that lead to a reaction of an Output Channel y.
- 4 independent **Output Channels y** for combination of events, definition of their effects and distribution to the system (interrupt generation, ...)

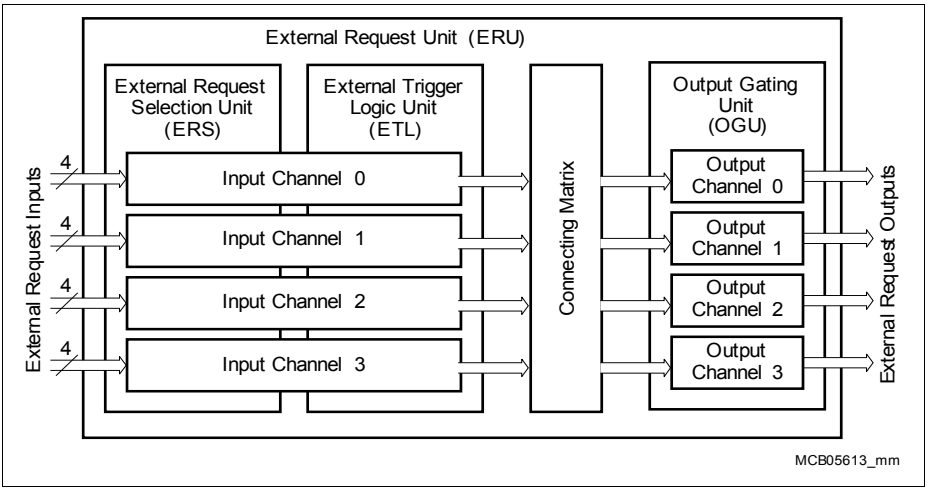


Figure 3-21 External Request Unit Overview

These tasks are handled by the following building blocks:

- An **External Request Select Unit (ERSx)** per Input Channel allows the selection of one input vector out of the 4 possible inputs available.
- An **Event Trigger Logic (ETLx)** per Input Channel allows the definition of the transition (edge selection, or by software) that lead to a trigger event and can also store this status. Here, the input levels of the selected signals are translated into

events (event detected = event flag becomes set, independent of the polarity of the original input signals).

- The **Connecting Matrix** distributes the events and status flags generated by the Input Channels to the Output Channels.
- An **Output Gating Unit (OGUy)** per Output Channel that combines the available trigger events and status information from the Input Channels. An event of one Input Channel can lead to reactions of several Output Channels, or also events of several Input Channels can be combined to a reaction of one Output Channel (pattern detection).
  Different types of reactions are possible, e.g. interrupt generation (based on signals ERU_IOUTy).

3.3.2.2 ERU Pin Connections

Figure 3-22 shows the ERU input connections.

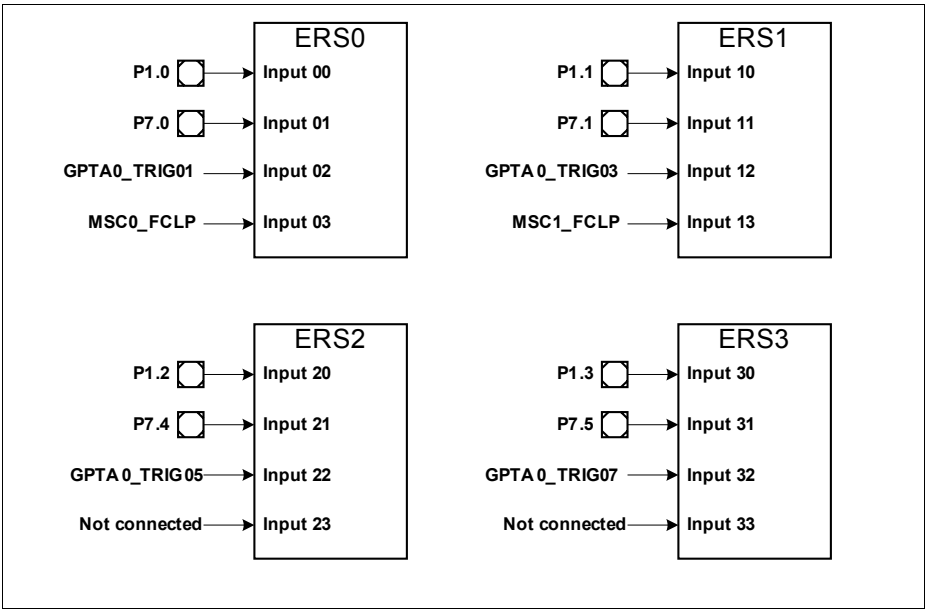

Figure 3-22 ERU Inputs Overview

The inputs to the ERU can be selected from a large number of input signals. While some of the inputs come directly from a pin, other inputs use signals from various peripheral modules.
Usually, such signals would be selected for an ERU function when the input function to the other module is not used otherwise, or the module is not used at all. However, it is also possible to select a input which is actually needed in the other module, and to use it also in the ERU to provide for certain trigger functions, eventually combined with other signals (e.g. to generate an interrupt trigger in case a start of frame is detected at a selected communication).

3.3.2.3 External Request Select Unit (ERS)

Each ERS combines four inputs to the one input signal of the respective input channel. Figure 3-23 shows the structure of this block.

In addition to the direct choice of either input Ax or Bx or their inverted values, the possible logical combinations for two selected inputs are a logical AND or a logical OR.

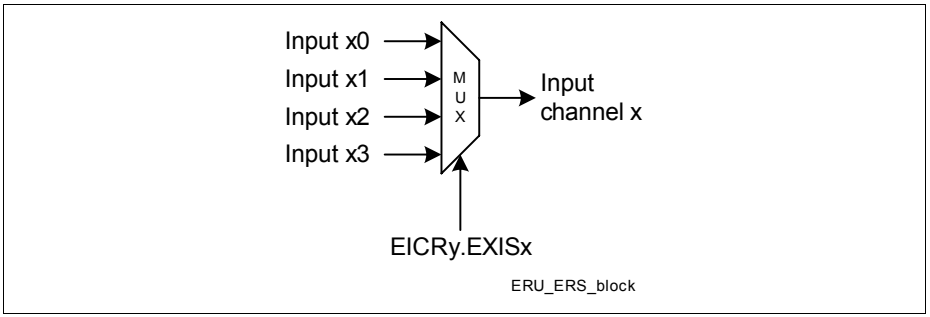

Figure 3-23 External Request Select Unit Overview

The ERS unit for channel x is controlled via bit field ERCIy.EXISx.

3.3.2.4 Event Trigger Logic (ETL)

For each Input Channel x, an event trigger logic ETLx derives a trigger event and a status from the input channel x delivered by the associated ERSx unit. Each ETLx is based on an edge detection block, where the detection of a rising or a falling edge can be individually enabled. Both edges lead to a trigger event if both enable bits are set (e.g. to handle a toggling input).
Each pair of the four ETL units has an associated EICRy register, that controls all options of an ETL (the register also holds control bits for the associated ERS unit pair, e.g. EICR0 to control ESR0 and ESR1 plus and ETL0 and ETL1).

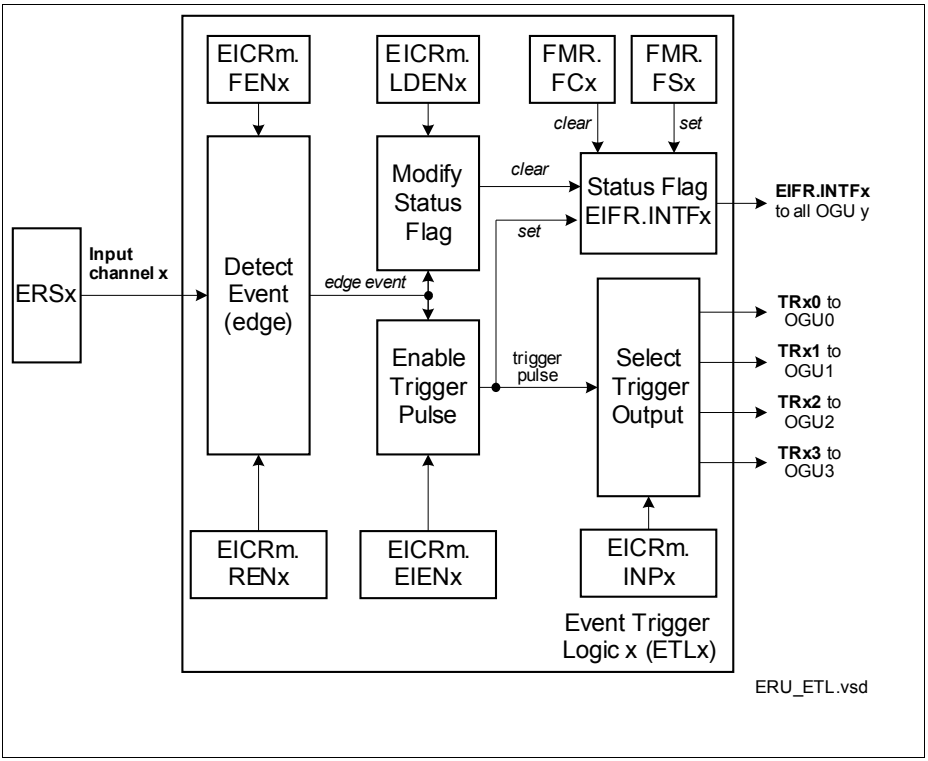

Figure 3-24 Event Trigger Logic Overview

When the selected event (edge) is detected, the status flag EIFR.INTFx becomes set. the status flag is cleared automatically if the “opposite” event is detected if enabled so via bit EICRy.LDENx = 1. For example, if only the falling edge detection is enabled to set the status flag, it is cleared when the rising edge is detected. In this mode, it can be used for pattern detection where the actual status of the input is important (enabling both edge detections is not useful in this mode).
The output of the status flag is connected to all following Output Gating Units (OGUz) in parallel (see **Figure 3-25**) to provide **pattern detection capability of all OGUz** units based on different or the same status flags.

In addition to the modification of the status flag, a trigger pulse output TRxz of ETLx can be enabled (by bit EICRy.EIENx) and selected to **trigger actions in one of the OGUz** units. The target OGUz for the trigger is selected by bit field EICRy.INPx.
The trigger becomes active when the selected edge event is detected, independently from the status flag EIFR.INTFx.

3.3.2.5 Connecting Matrix

The connecting matrix distributes the trigger signals (TRxy) and status signals (EIFR.INPFx) from the different ETLx units between the OGUy units. **Figure 3-25** provides a complete overview of the connections between the ETLx and the OGUz units.

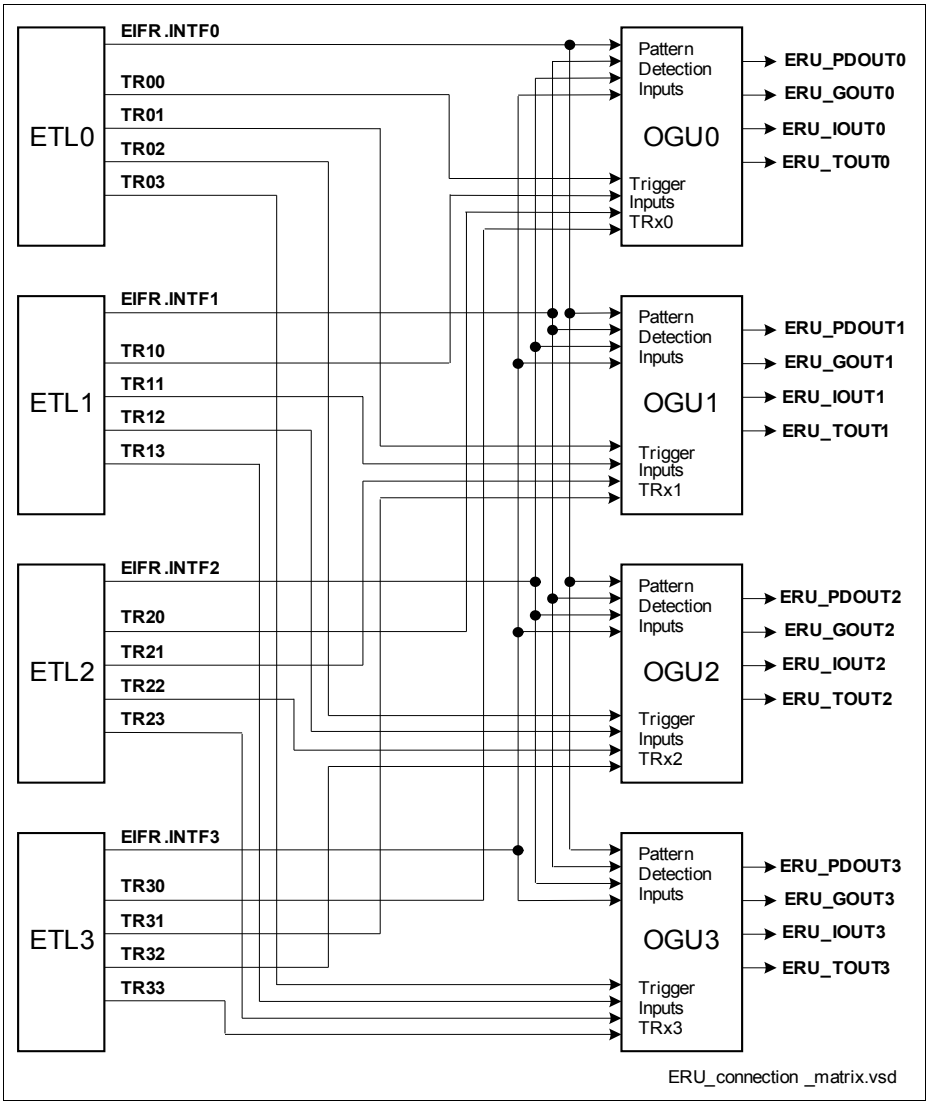

Figure 3-25 Connecting Matrix between ETLx and OGUy

3.3.2.6 Output Gating Unit (OGU)

Each OGUy unit combines the available trigger events and status flags from the Input Channels and distributes the results to the system. **Figure 3-26** illustrates the logic blocks within an OGUy unit. All functions of an OGUy unit are controlled by the associated IGCRm registers, one for each pair of output channels e.g. IGCR1 for OGU2 and OGU3. The function of an OGUy unit can be split into two parts:

- **Trigger combination**:
  All trigger signals TRxy from the Input Channels that are enabled and directed to OGUy and a pattern change event (if enabled) are logically OR-combined.
- **Pattern detection**:
  The status flags EIFR.INTFx of the Input Channels can be enabled to take part in the pattern detection. A pattern match is detected while all enabled status flags are set.

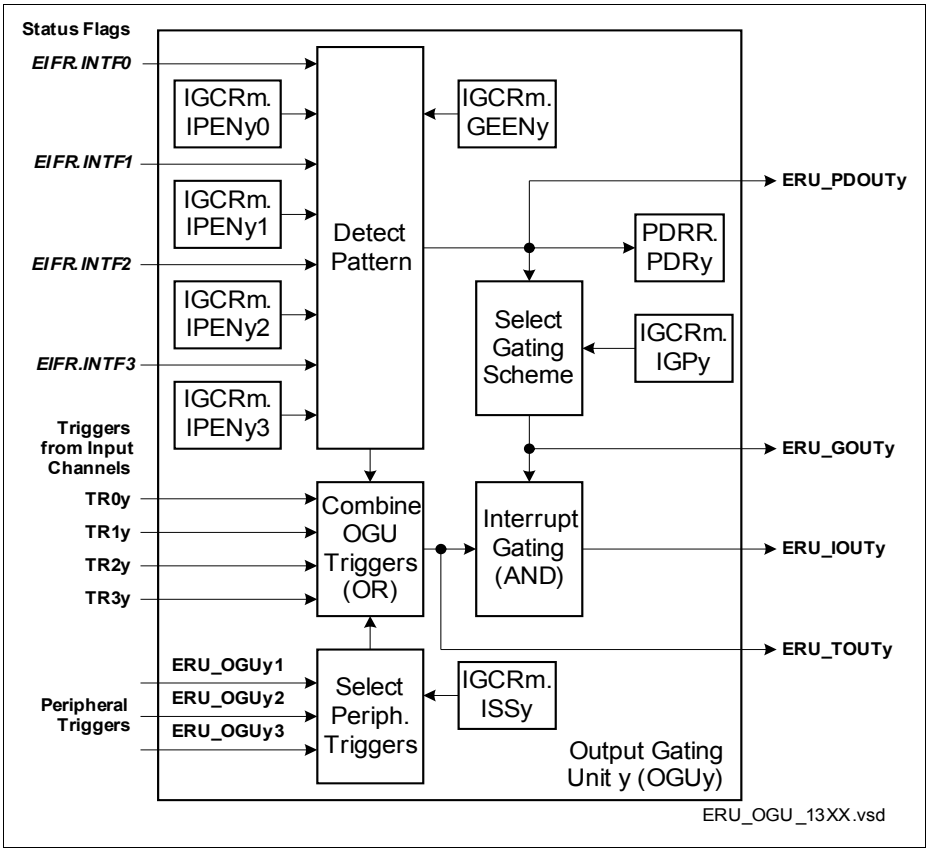

Figure 3-26 Output Gating Unit for Output Channel y

Each OGUy units generates 4 output signals that are distributed to the system.

- **ERU_PDOUTy** to directly output the pattern match information for gating purposes in other modules (pattern match = 1).
- **ERU_GOUTy** to output the pattern match or pattern miss information (inverted pattern match), or a permanent 0 or 1 under software control for gating purposes in other modules.
- **ERU_TOUTy** as combination of a peripheral trigger, a pattern detection result change event, or the ETLx trigger outputs TRxy to trigger actions in other modules.
- **ERU_IOUTy** as gated trigger output (ERU_GOUTy logical AND-combined with ERU_TOUTy) to trigger interrupts (e.g. the interrupt generation can be gated to allow interrupt activation during a certain time window).

Trigger Combination

The trigger combination logically OR-combines different trigger inputs to form a common trigger ERU_TOUTy. Possible trigger inputs are:

- In each ETLx unit of the **Input Channels**, the trigger output TRxy can be enabled and the trigger event can be directed to one of the OGUy units.
- One out of three **peripheral trigger** signals per OGUy can be selected as additional trigger source. These peripheral triggers are generated by on-chip peripheral modules, such as capture/compare or timer units. The selection is done by bit field EXOCONy.ISS.
- In the case that at least one **pattern detection** input is enabled (IGCRm.IPENxy) and a change of the pattern detection result from pattern match to pattern miss (or vice-versa) is detected, a trigger event is generated to indicate a pattern detection result event (if enabled by IGCRm.GEENy).

The trigger combination offers the possibility to program different trigger criteria for several input signals (independently for each Input Channel) or peripheral signals, and to combine their effects to a single output, e.g. to generate an interrupt or to start e.g. an ADC conversion. This combination capability allows the generation of an interrupt per OGU that can be triggered by several inputs (multitude of request sources -> one reaction).

The following table describes the peripheral trigger connections for the OGUy stages. The selection is defined by the bit fields ISS in registers **IGCR0** (for OGU0 and OGU1) and **IGCR1** (for OGU2 and OGU3).

Table 3-13 OGUy Peripheral Trigger Connections in TC1798

Input	from/to Module	I/O to OGUy	Can be used to/as
OGU0 Inputs			
ERU_ OGU01	CCU60_SR1	I	peripheral triggers for OGU0
ERU_ OGU02	Reserved	I	
ERU_ OGU03	Reserved	I

ERU_ OGU32	Reserved	I	
ERU_ OGU33	Reserved	I	

Pattern Detection

The pattern detection logic allows the combination of the status flags of all ETLx units. Each status flag can be individually included or excluded from the pattern detection for each OGUy, via control bits IGCRm.IPENxy. The pattern detection block outputs the following pattern detection results:

- **Pattern match** (PDRR.PDRy = 1 and ERU_PDOUTy = 1):
  A pattern match is indicated while all status flags that are included in the pattern detection are 1.
- **Pattern miss** (PDRR.PDRy = 0 and ERU_PDOUTy = 0):
  A pattern miss is indicated while at least one of the status flags that are included in the pattern detection is 0.

In addition, the pattern detection can deliver a trigger event if the pattern detection result changes from match to miss or vice-versa (if enabled by IGCRm.GEENy = 1). The pattern result change event is logically OR-combined with the other enabled trigger events to support interrupt generation or to trigger other module functions (e.g. in an ADC). The event is indicated when the pattern detection result changes and PDRR.PDRy becomes updated.

The interrupt generation in the OGUy is based on the trigger ERU_TOUTy that can be gated (masked) with the pattern detection result ERU_PDOUTy. This allows an automatic and reproducible generation of interrupts during a certain time window, where the request event is elaborated by the trigger combination block and the time window information (gating) is given by the pattern detection. For example, interrupts can be issued on a regular time base while a combination of input signals occurs (pattern detection based on ETLx status bits).

A programmable gating scheme introduces flexibility to adapt to application requirements and allows the generation of interrupt requests ERU_IOUTy under different conditions:

- **Pattern match** (IGCRm.IGPy = 10_B):
  An interrupt request is issued when a trigger event occurs while the pattern detection shows a pattern match.
- **Pattern miss** (IGCRm.IGPy = 11_B):
  An interrupt request is issued when the trigger event occurs while the pattern detection shows a pattern miss.
- **Independent** of pattern detection (IGCRm.IGPy = 01_B):
  In this mode, each occurring trigger event leads to an interrupt request. The pattern detection output can be used independently from the trigger combination for gating purposes of other peripherals (independent use of ERU_TOUTy and ERU_PDOUTy with interrupt requests on trigger events).
- **No interrupts** (IGCRm.IGPy = 00_B, default setting)
  In this mode, an occurring trigger event does not lead to an interrupt request. The pattern detection output can be used independently from the trigger combination for gating purposes of other peripherals (independent use of ERU_TOUTy and ERU_PDOUTy without interrupt requests on trigger events).

3.3.2.7 ERU Output Connections

This section describes the connections of the ERU output signals for gating or triggering other module functions, as well as the connections to the interrupt control registers.

Table 3-14 ERU Output Connections in TC1798

Output	from/to Module	I/O to OGUy	Can be used to/as
OGU0 Outputs

Field	Bits	Type	Description
IPEN0x (x = 0-3)	x	rw	**Interrupt Pattern Enable for Channel 0** Bit IPEN0x determines if the flag INTFx of channel x takes part in the pattern detection for the gating of the requests for the output signals GOUTy and IOUTy. 0_B The bit INTFx does not take part in the pattern detection 1_B The bit INTFx is taken into consideration for the pattern detection
ISS0	[9:8]	rw	**Internal Trigger Source Selection** This bit field defines which input is selected as peripheral trigger input for OGU0. The possible input signals are given in **Table 3-13**. 00_B The peripheral trigger function is disabled 01_B Input ERU_OGU01 is selected 10_B Input ERU_OGU02 is selected 11_B Input ERU_OGU03 is selected

Field	Bits	Type	Description
GEEN0	13	rw	**Generate Event Enable 0** Bit GEEN0 enables the generation of a trigger event for output channel 0 when the result of the pattern detection changes. When using this feature, a trigger (e.g. for an interrupt) is generated during the first clock cycle when a pattern is detected or when it is no longer detected. 0_B The trigger generation at a change of the pattern detection result is disabled 1_B The trigger generation at a change of the pattern detection result is enabled
ISS1	[25:24]	rw	**Internal Trigger Source Selection** This bit field defines which input is selected as peripheral trigger input for OGU1. The possible input signals are given in **Table 3-13**. 00_B The peripheral trigger function is disabled 01_B Input ERU_OGU11 is selected 10_B Input ERU_OGU12 is selected 11_B Input ERU_OGU13 is selected
IGP0	[15:14]	rw	**Interrupt Gating Pattern 0** Bit field IGP0 determines how the pattern detection influences the output lines GOUT0 and IOUT0. 00_B The detected pattern is not taken into account. An activation of IOUT0 is always possible due to a trigger event. 01_B The detected pattern is not taken into account. An activation of IOUT0 is not possible. 10_B The detected pattern is taken into account. An activation of IOUT0 is only possible due to a trigger event while the pattern is detected. 11_B The detected pattern is taken into account. An activation of IOUT0 is only possible due to a trigger event while the pattern is not detected.

Field	Bits	Type	Description
IPEN1x (x = 0-3)	16+x	rw	**Interrupt Pattern Enable for Channel 1** Bit IPEN1x determines if the flag INTFx of channel x takes part in the pattern detection for the gating of the requests for the output signals GOUTy and IOUTy. 0_B The bit INTFx does not take part in the pattern detection 1_B The bit INTFx is taken into consideration for the pattern detection
GEEN1	29	rw	**Generate Event Enable 1** Bit GEEN1 enables the generation of a trigger event for output channel 1 when the result of the pattern detection changes. When using this feature, a trigger (e.g. for an interrupt) is generated during the first clock cycle when a pattern is detected, or when it is no longer detected. 0_B The trigger generation at a change of the pattern detection result is disabled 1_B The trigger generation at a change of the pattern detection result is enabled
IGP1	[31:30]	rw	**Interrupt Gating Pattern 1** Bit field IGP1 determines how the pattern detection influences the output lines GOUT1 and IOUT1. 00_B The detected pattern is not taken into account. An activation of IOUT1 is always possible due to a trigger event. 01_B The detected pattern is not taken into account. An activation of IOUT1 is not possible. 10_B The detected pattern is taken into account. An activation of IOUT1 is only possible due to a trigger event while the pattern is detected. 11_B The detected pattern is taken into account. An activation of IOUT1 is only possible due to a trigger event while the pattern is not detected.
0	[7:4], [12:10], [23:20],[28:26]	r	**Reserved** Read as 0; should be written with 0.

IGCR1

Field	Bits	Type	Description
GEEN2	13	rw	**Generate Event Enable 2** Bit GEEN2 enables the generation of a trigger event for output channel 2 when the result of the pattern detection changes. When using this feature, a trigger (e.g. for an interrupt) is generated during the first clock cycle when a pattern is detected, or when it is no longer detected. 0_B The trigger generation at a change of the pattern detection result is disabled 1_B The trigger generation at a change of the pattern detection result is enabled
IGP2	[15:14]	rw	**Interrupt Gating Pattern 2** Bit field IGP2 determines how the pattern detection influences the output lines GOUT2 and IOUT2. 00_B The detected pattern is not taken into account. An activation of IOUT2 is always possible due to a trigger event. 01_B The detected pattern is not taken into account. An activation of IOUT2 is not possible. 10_B The detected pattern is taken into account. An activation of IOUT2 is only possible due to a trigger event while the pattern is detected. 11_B The detected pattern is taken into account. An activation of IOUT2 is only possible due to a trigger event while the pattern is not detected.
IPEN3x (x = 0-3)	16+x	rw	**Interrupt Pattern Enable for Channel 3** Bit IPEN3x determines if the flag INTFx of channel x takes part in the pattern detection for the gating of the requests for the output signals GOUTy and IOUTy. 0_B The bit INTFx does not take part in the pattern detection 1_B The bit INTFx is taken into consideration for the pattern detection

Field	Bits	Type	Description
ISS3	[25:24]	rw	**Internal Trigger Source Selection** This bit field defines which input is selected as peripheral trigger input for OGU13. The possible input signals are given in **Table 3-13**. 00_B The peripheral trigger function is disabled 01_B Input ERU_OGU31 is selected 10_B Input ERU_OGU32 is selected 11_B Input ERU_OGU33 is selected
GEEN3	29	rw	**Generate Event Enable 3** Bit GEEN3 enables the generation of a trigger event for output channel 3 when the result of the pattern detection changes. When using this feature, a trigger (e.g. for an interrupt) is generated during the first clock cycle when a pattern is detected, or when it is no longer detected. 0_B The trigger generation at a change of the pattern detection result is disabled 1_B The trigger generation at a change of the pattern detection result is enabled
IGP3	[31:30]	rw	**Interrupt Gating Pattern 3** Bit field IGP3 determines how the pattern detection influences the output lines GOUT3 and IOUT3. 00_B The detected pattern is not taken into account. An activation of IOUT3 is always possible due to a trigger event. 01_B The detected pattern is not taken into account. An activation of IOUT3 is not possible. 10_B The detected pattern is taken into account. An activation of IOUT3 is only possible due to a trigger event while the pattern is detected. 11_B The detected pattern is taken into account. An activation of IOUT3 is only possible due to a trigger event while the pattern is not detected.
0	[7:4], [12:10], [23:20], [28:26]	r	**Reserved** Read as 0; should be written with 0.

3.4 Power Management

This section describes the power management system of the TC1798. Topics covered here include the internal system interfaces, external interfaces, and the operations of the CPU and peripherals.

3.4.1 Power Management Overview

The TC1798 power-management system allows software to configure the various processing units so that they automatically adjust to draw the minimum necessary power for the application.

As shown in **Table 3-15**, there are three power management modes available:

- Run Mode
- Idle Mode
- Sleep Mode

Table 3-15 Power Management Mode Summary

Mode	Description
Run Mode	The system is fully operational. CPU and peripherals are enabled, as determined by software.
Idle Mode	The CPU is disabled, waiting for a condition to return it to Run Mode. Idle Mode can be entered by software when the processor has no active tasks to perform. Processor memory is accessible to peripherals. An Application Reset, Watchdog Timer event, an NMI trap, or any interrupt for the CPU will return the system to Run Mode.
Sleep Mode	Only those peripherals programmed to operate in Sleep Mode are active. The other peripheral module will be shut down. Interrupts for the CPU, a Watchdog Timer event, an NMI trap, or an Application Reset will return the system to Run Mode. Entering this state requires an orderly shut-down controlled by the Power Management State Machine.

The power-management modes provide flexible reduction of power consumption through a combination of techniques, including:

- Stopping the CPU
- Stopping other system components individually
- Clock-speed reduction of some peripheral components individually

The Power Management controls the power mode of all system components during Run Mode, Idle Mode, and Sleep Mode. This flexibility in power management provides minimum power consumption for any application.

In typical operation, Idle Mode and Sleep Mode may be entered and exited frequently during the run time of an application. For example, system software will typically cause

the CPU to enter Idle Mode each time it has to wait for an interrupt before continuing its tasks. In Sleep Mode and Idle Mode, wake-up is performed automatically when any interrupt is detected or if an NMI trap is activated.

3.4.2 Power Management Modes

This section describes in more detail the power management modes, their operations, and how power management modes are entered and exited. It also describes the behavior of TC1798 system components in all power management modes.

3.4.2.1 Idle Mode

The Idle Mode is requested by software when writing to register PMCSR.REQSLP = 01_B. The CPU finishes its current operation, sends an acknowledge to the Power Management, and then enters an inactive state in which the CPU and the DMI and PMI memory units are shut off.

Other system components that are able to write to register PMCSR can also request the Idle Mode. For example, the PCPDMA controller can request Idle Mode by writing to the PMCSR register.

During Idle Mode, memory accesses to the DMI and PMI cause these units to awaken automatically to handle the transactions. When memory transactions are complete, the DMI and PMI return to Idle Mode again.

The system will return to Run Mode through the occurrence of any of the following conditions:

- An interrupt is received from an interrupt source of the CPU
- An NMI trap request is received
- An Application Reset is generated

If any of these conditions arise, the TC1798 immediately awakens and returns to Run Mode. If it is awakened by a reset, the TC1798 system begins its reset sequence. If it is awakened by a Watchdog Timer overflow event, it executes the instruction following the one that was last executed before Idle Mode was entered. If it is awakened by an NMI or interrupt, the CPU will immediately vector to the appropriate handler.

3.4.2.2 Sleep Mode

The Sleep Mode is requested by software when writing to register PMCSR.REQSLP = 10_B.

Entering Sleep Mode

Sleep Mode is entered in two steps:

1. The CPU is put into Idle Mode as described in the previous section. When the Power Management receives the Idle acknowledge back from the CPU, it proceeds with the second step.
2. Each FPI Bus unit is requested to enter the Sleep Mode. The response of each FPI Bus unit to the sleep request is determined by its clock control register. These clock control registers must have been previously configured by software.

TC1798 State During Sleep Mode

Sleep Mode is disabled for a unit if MOD_CLC.EDIS is set. The sleep request is ignored in this case and the corresponding unit continues normal operation. If MOD_CLC.EDIS is cleared, Sleep Mode is enabled for this unit and the unit enters Sleep Mode. Two actions then occur:

- The unit finishes whatever bus transaction was in progress when the signal was received
- The unit functions are suspended

Depending on bit MOD_CLC.FSOE, the module is either immediately stopped (MOD_CLC.FSOE = 1), or the unit is allowed to finish ongoing operations (MOD_CLC.FSOE = 0) before the Sleep Mode is entered. For example, setting MOD_CLC.FSOE to 1 for a serial port will stop all actions in the serial port immediately when the sleep request is received. Ongoing transmissions or receptions will be aborted. If MOD_CLC.FSOE is cleared, ongoing transmissions or receptions will be completed, before Sleep Mode is entered. The purpose of setting MOD_CLC.FSOE = 1 is to allow a debugger to observe the internal state of a peripheral unit immediately.

Exiting Sleep Mode

The system will be returned to Run Mode by the same events that exit Idle Mode. The response of the CPU to being awakened is also the same as for Idle Mode. Peripheral units that have entered Sleep Mode will switch back to their selected Run Mode operation.

3.4.3 Power Management Control and Status Register, PMCSR

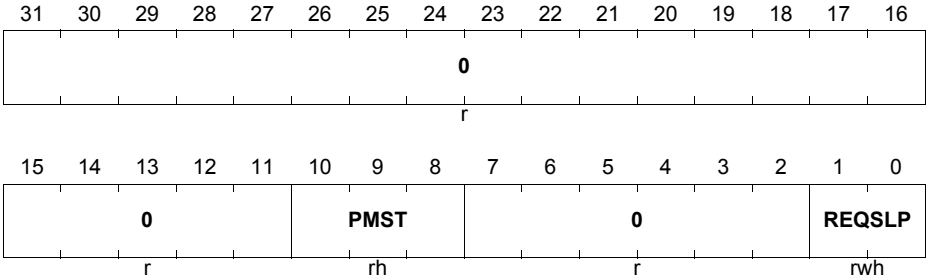
The set of registers used for power management is divided between central TC1798 components and peripheral components. The PMCSR register provides software control

and status information for the central part. There are individual clock control registers for peripheral components because the Sleep Mode behavior of each peripheral component is programmable. When entering Idle Mode and Sleep Mode, the Power Management directly controls TC1798 components such as the CPU, but indirectly controls peripheral components through their clock control registers.

PMCSR

Power Management Control and Status Register

($0B0_H$) **Reset Value: $0000\ 0100_H$**



Field	Bits	Type	Function
REQSLP	[1:0]	rwh	**Idle Mode and Sleep Mode Request** 00_B Normal Run Mode 01_B Request Idle Mode 10_B Request Sleep Mode 11_B Reserved; do not use this combination In Idle Mode or Sleep Mode, these bits are cleared in response to an interrupt for the CPU, or when bit 15 of the Watchdog Timer count register (the WDT_SR.TIM[15] bit) changes from 0 to 1.
PMST	[10:8]	rh	**Power Management Status** 000_B Waiting for PLL lock condition 001_B Normal Run Mode 010_B Idle Mode requested 011_B Idle Mode acknowledged 100_B Sleep Mode 101_B Reserved, do not use this combination 110_B Reserved, do not use this combination 111_B Reserved, do not use this combination

Field	Bits	Type	Function
0	[7:2], [31:11]	r	**Reserved** Read as 0; should be written with 0.

3.5 Software Boot Support

In order to determine the correct starting point of operation for the software a minimum of hardware support is required. As much as possible is done via software. Some decisions have to be done in hardware because they must be known before any software is operational.

For a startup operation there are two general cases that have to be handled:

- Differentiation between Test Mode and Normal Mode for each Power-on Reset event (see **Section 3.5.1**)
- Configuration of the boot option for each Application Reset event (see **Section 3.5.2**)

3.5.1 Configuration done with Start-up

With the device power-on some basic operating mode selection has to be made. The first decision that has to be made is if the device should operate in Test Mode or in Normal (Customer) Mode. The Test Mode is only for Infineon internal usage not for any customer and has nothing to do with debugging.

If the Normal Mode was selected the next decision is which debug interface type issued for debugging for this session (until the next power-on event).

Table 3-16 Normal Mode / Test Mode Input Selection

Field	Description
$\overline{\text{TEST}}$L	**Latched $\overline{\text{TEST}}$ Signal** 0 A Test Mode can be selected 1 Normal Mode is selected
$\overline{\text{TRST}}$L	**Latched $\overline{\text{TRST}}$ Signal** 0 The JTAG interface is active 1 The DAP interface is active

After these two decisions were made the detailed decision has to be made to define the real startup configuration. Most is made via the software and can be supported by some hardware selections depending on the startup configuration that should be selected.

3.5.2 Start-up Configuration Options

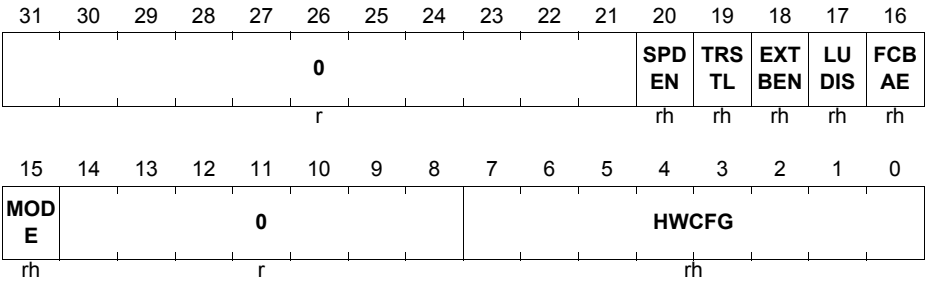
For the support of the start-up pins P0.0 to P0.7 are latched with the rising edge of the Application Reset and stored in register STSTAT.HWCFG. The update of bit field STSTAT.HWCFG with the latched value is only done if bit STSTAT.LUDIS is cleared. If bit STSTAT.LUDIS is set the value of STSTAT.HWCFG is not updated.

3.5.3 Start-up Registers

3.5.3.1 Start-up Status Register

Register STSTAT contains the information required by the boot software to identify the different start-up settings that can be selected.

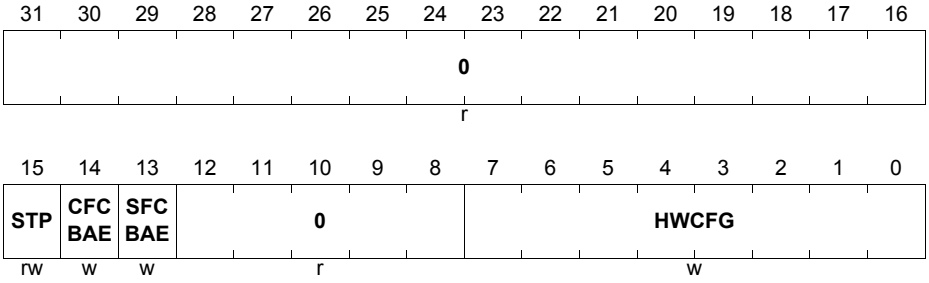
STSTAT
Start-up Status Register **($0C0_H$)** **Reset Value: 0008 80XX$_H$**



Field	Bits	Type	Description
HWCFG	[7:0]	rh	**Hardware Configuration Setting** This bit field contains the value that is used by the boot software. This bit field is updated in case of an Application Reset with the content by register SWRSTCON.SWCFG if bit SWRSTCON.SWBOOT AND RSTSTAT.SW are set. This bit field is updated in case of an Application Reset with the content of the latches of P0.0 to P.0.7 if bit SWRSTCON.SWBOOT OR RSTSTAT.SW are cleared and bit STSTAT.LUDIS is cleared. This bit field is left unchanged in case of an Application Reset and is not updated with the content of the latches of P0.0 to P.0.7 if bit SWRSTCON.SWBOOT OR RSTSTAT.SW are cleared and bit STSTAT.LUDIS is set. This bit field is updated with the value written to bit field STCON.HWCFG on a software write action.

Field	Bits	Type	Description
Mode	15	rh	**Mode** This bit indicates if the Test Mode is entered or not. 0_B A Test Mode can be selected 1_B Normal Mode is selected
FCBAE	16	rh	**Flash Config. Sector Access Enable** 0_B Flash config sector is not accessible. Instead the flash memory area is accessed. 1_B Flash config sector is accessible. The flash memory area can not be accessed. This bit can be cleared by setting bit STCON.CFCBAE. This bit can be set by setting bit STCON.SFCBAE.
LUDIS	17	rh	**Latch Update Disable** 0_B Bit field STSTAT.HWCFG is automatically updated with the latched value of pins P0.0 to P0.7 1_B Bit field STSTAT.HWCFG is not updated with the latched value of pins P0.0 to P0.7 This bit can be set by setting bit SYSCON.SETLUDIS.
EXTBEN	18	rh	**External Boot Enable** 0_B No Boot Configuration Value is fetched by the EBU 1_B A Boot Configuration Value is fetched by the EBU This bit can be set by setting bit SYSCON.SETEXTBEN.
TRSTL	19	rh	**TRSTL Status** This bit simply displays the value of TRSTL.
SPDEN	20	rh	**Single Pin DAP Mode Enable** 0_B Single Pin DAP Mode is disabled 1_B Single Pin DAP Mode is enabled
0	[14:8], [31:21]	r	**Reserved** Read as 0; should be written with 0.

STCON
Start-up Configuration Register (0C4$_H$) Reset Value: 0000 8000$_H$



Field	Bits	Type	Description
HWCFG	[7:0]	w	**Hardware Configuration Setting** Writing to this bit field updates bit field STSTAT.HWCFG. Reading this bit field returns zero.
SFCBAE	13	w	**Set Flash Config. Sector Access Enable** Setting this bit sets bit STSTAT.FCBAE. Reading this bit returns always a zero. *Note: This bit may not be set in parallel with bit CFCBAE.*
CFCBAE	14	w	**Clear Flash Config. Sector Access Enable** Setting this bit clears bit STCON.FCBAE. Reading this bit returns always a zero. *Note: This bit may not be set in parallel with bit SFCBAE.*
STP	15	rw	**Start-up Protection Setting** 0_B Start-up code is executed. Start-up protection is disabled. 1_B Start-up code protection is active This bit is also cleared by an Application Reset.
0	[12:8], [31:16]	r	**Reserved** Read as 0; should be written with 0.

3.6 ECC Error Handling

The on-chip RAM and flash modules check ECC information during read accesses and in case of an error a signal is generated. These signals are combined and trigger a trap.

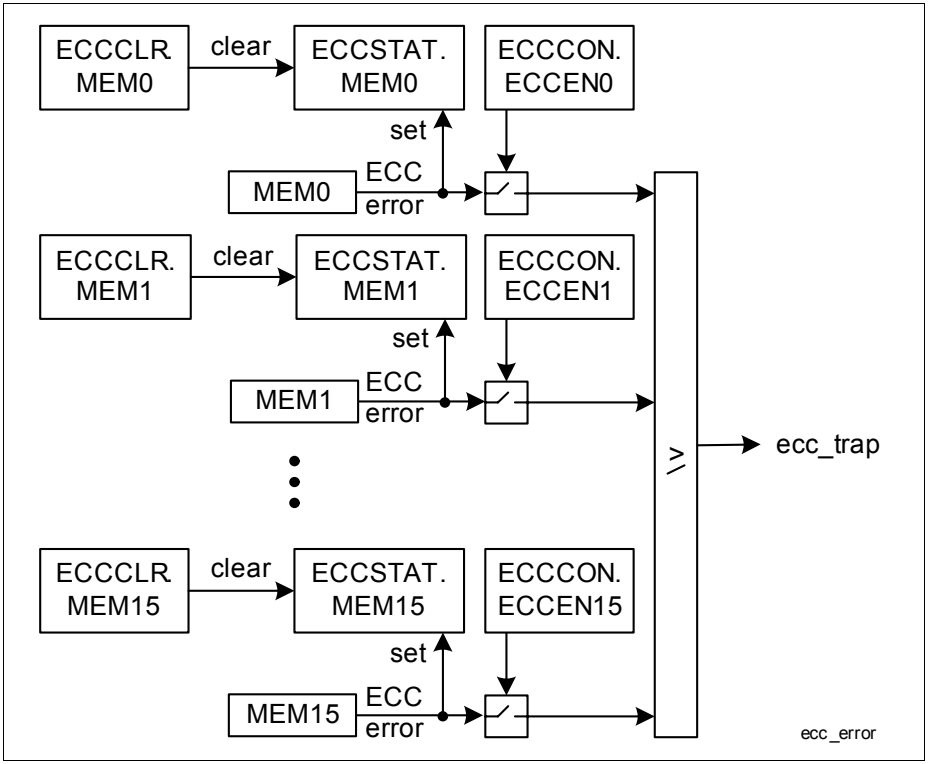


Figure 3-27 ECC Error Control Logic

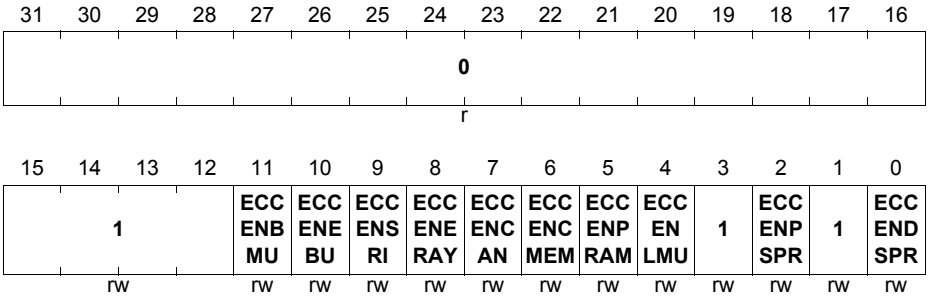
3.6.1 ECC Software Testing Support

This can be done for each module individually by simply disabling the ECC protection in the module change the content of a memory address enable ECC again and read the memory address again. For more information see the different module chapters.

3.6.2 ECC Registers

ECCCON
ECC Control Register **($0D0_H$)** **Reset Value: 0000 FFFF$_H$**



Field	Bits	Type	Description
ECCENDSPR	0	rw	**ECC Error Trap Enable for DSPR and DCACHE Memory** This bit determine whether a trap is requested if an uncorrected ECC error is detected in the DSPR / DCACHE memory. 0_B No ECC error trap trigger is requested 1_B A ECC error trap trigger is requested
ECCENPSPR	2	rw	**ECC Error Trap Enable for PDPR and ICACHE Memory** This bit determine whether a trap is requested if an uncorrected ECC error is detected in the PSPR / ICACHE memory. 0_B No ECC error trap trigger is requested 1_B A ECC error trap trigger is requested
ECCENLMU	4	rw	**ECC Error Trap Enable for LMU Memory** This bit determine whether a trap is requested if an uncorrected ECC error is detected in the LMU memory. 0_B No ECC error trap trigger is requested 1_B A ECC error trap trigger is requested

Field	Bits	Type	Description
ECCENPRAM	5	rw	**ECC Error Trap Enable for PCP PRAM** This bit determine whether a trap is requested if an uncorrected ECC error is detected in the PCP PRAM memory. 0_B No ECC error trap trigger is requested 1_B A ECC error trap trigger is requested
ECCENCMEM	6	rw	**ECC Error Trap Enable for PCP CMEM** This bit determine whether a trap is requested if an uncorrected ECC error is detected in the PCP CMEM memory. 0_B No ECC error trap trigger is requested 1_B A ECC error trap trigger is requested
ECCENCAN	7	rw	**ECC Error Trap Enable for CAN Memory** This bit determine whether a trap is requested if an uncorrected ECC error is detected in the CAN memory. 0_B No ECC error trap trigger is requested 1_B A ECC error trap trigger is requested
ECCENERAY	8	rw	**ECC Error Trap Enable for ERAY Memory** This bit determine whether a trap is requested if an uncorrected ECC error is detected in the ERAY memories. 0_B No ECC error trap trigger is requested 1_B A ECC error trap trigger is requested
ECCENSRI	9	rw	**ECC Error Trap Enable for SRI-Bus** This bit determine whether a trap is requested if an uncorrected ECC error is detected by the SRI-Bus protocol. 0_B No ECC error trap trigger is requested 1_B A ECC error trap trigger is requested
ECCENEBU	10	rw	**ECC Error Trap Enable for EBU** This bit determine whether a trap is requested if an uncorrected ECC error is detected by the EBU. 0_B No ECC error trap trigger is requested 1_B A ECC error trap trigger is requested

Field	Bits	Type	Description
ECCENBMU	11	rw	**ECC Error Trap Enable for BMU** This bit determine whether a trap is requested if an uncorrected ECC error is detected by the BMU. 0_B No ECC error trap trigger is requested 1_B A ECC error trap trigger is requested
1	1, 3, [15:12]	rw	**Reserved** Should be written with 1.
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

Note: Register ECCCON is Endinit-protected for write operations.

ECCSTAT
ECC Status Register **($0D4_H$)** **Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Bits	Type	Description
DSPR	0	w	**Clear DSPR and DCACHE EEC Error Status** 0_B No action 1_B Setting this bit clears bit EECSTAT.DSPR This bit always read as 0.
PSPR	2	w	**Clear PSPR and PCACHE EEC Error Status** 0_B No action 1_B Setting this bit clears bit EECSTAT.PSPR This bit always read as 0.
LMU	4	w	**Clear LMU Memory EEC Error Status** 0_B No action 1_B Setting this bit clears bit EECSTAT.LMU This bit always read as 0.

Field	Bits	Type	Description
PRAM	5	w	**Clear Parameter RAM Memory EEC Error Status** 0_B No action 1_B Setting this bit clears bit EECSTAT.PRAM This bit always read as 0.
CMEM	6	w	**Clear Parameter Code Memory EEC Error Status** 0_B No action 1_B Setting this bit clears bit EECSTAT.CMEM This bit always read as 0.
CAN	7	w	**Clear CAN Memory EEC Error Status** 0_B No action 1_B Setting this bit clears bit EECSTAT.CAN This bit always read as 0.
ERAY	8	w	**Clear ERAY Memory EEC Error Status** 0_B No action 1_B Setting this bit clears bit EECSTAT.ERAY This bit always read as 0.
SRI	9	w	**Clear SRI-Bus EEC Error Status** 0_B No action 1_B Setting this bit clears bit EECSTAT.SRI This bit always read as 0.
EBU	10	w	**Clear EBU EEC Error Status** 0_B No action 1_B Setting this bit clears bit EECSTAT.EBU This bit always read as 0.
BMU	11	w	**Clear BMU EEC Error Status** 0_B No action 1_B Setting this bit clears bit EECSTAT.BMU This bit always read as 0.
0	1, 3, [31:12]	r	**Reserved** Read as 0; should be written with 0.

3.7 Die Temperature Measurement

The Die Temperature Sensor (DTS) generates a measurement result that indicates directly the current temperature. The result of the measurement is displayed via bit field DTSSTAT.RESULT. In order to start one measurement bit DTSCON.START needs to be set.

The DTS has to be enabled before it can be used via bit DTSCON.PWD. When the DTS is powered after the start-up time of the DTS (defined in the Data Sheet) a temperature measurement can be started.

Note: If bit field DTSSTAT.RESULT is read before the first measurement was finished it will return 0x000.

When a measurement is started the result is available after the measurement time passed. If the DTS is ready to start a measurement can be checked via bit DTSSTAT.RDY. If a started measurement is finished or still in progress is indicated via the status bit DTSSTAT.BUSY. The measurement time is also defined in the Data Sheet.

In order to adjust production variations bit field DTSCON.CAL should be programmed with a predefined value. The value is located at address 0xD0000018 for the complete register DTSCON with bit DTSCON.PWD cleared.

Note: The first measurement after the DTS was powered delivers a result without calibration adjustment and should be ignored therefore.

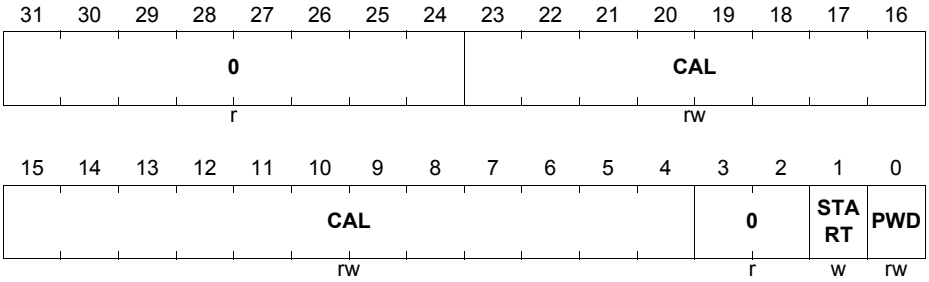
The formula to calculate the die temperature is defined in the Data Sheet.

Note: The maximum resolution is only achieved for a measurement that is part of multiple continuos measurements.

3.7.1 Die Temperature Sensor Register

DTSCON

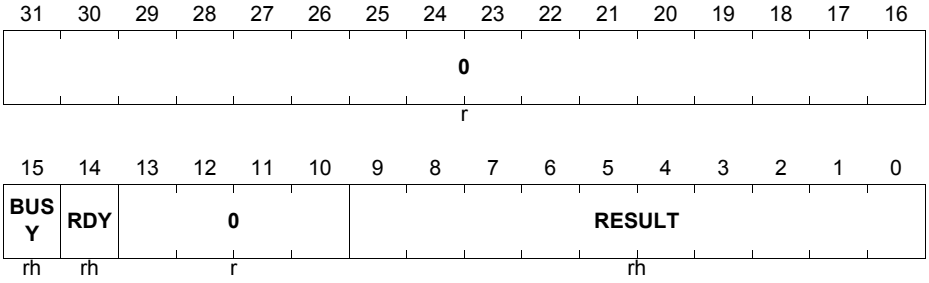
Die Temperature Sensor Control Register($0E4_H$) **Reset Value: $0000\ 0001_H$**



Field	Bits	Type	Description
PWD	0	rw	**Sensor Power Down** This bit defines the DTS power state. 0_B The DTS is powered 1_B The DTS is not powered
START	1	w	**Sensor Measurement Start** This bit starts a measurement of the DTS. 0_B No DTS measurement is started 1_B A DTS measurement is started If set this bit is automatically cleared. This bit always reads as zero.
CAL	[23:4]	rw	**Calibration Value** This bit field interfaces the calibration values to the DTS.
0	[3:2], [31:24]	r	**Reserved** Read as 0; should be written with 0.

DTSSTAT

Die Temperature Sensor Status Register($0E0_H$) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
RESULT	[9:0]	rh	**Result of the DTS Measurement** This bit field shows the result of the DTS measurement. The value given is directly related to the die temperature. Only the bit [9:2] have to be evaluated. The formula for mapping the result to a temperature will follow later.
RDY	14	rh	**Sensor Ready Status** This bit indicate the DTS is ready or not. 0_B The DTS is not ready 1_B The DTS is ready
BUSY	15	rh	**Sensor Busy Status** This bit indicate the DTS is currently busy or not. If the sensor is busy currently a measurement is running and the result should not be used. 0_B The DTS is not busy 1_B The DTS is busy *Note: This bit is updated 2 cycles after bit DTSCON.START is set.*
0	[13:10], [31:16]	r	**Reserved** Read as 0; should be written with 0.

3.8 Watchdog Timer

This section describes the TC1798 Watchdog Timer (WDT). Topics include an overview of the WDT function and descriptions of the registers, the password-protection scheme, accessing registers, modes, and initialization.

3.8.1 Watchdog Timer Overview

The WDT provides a highly reliable and secure way to detect and recover from software or hardware failure. The WDT helps to abort an accidental malfunction of the TC1798 in a user-specified time period. When enabled, the WDT can cause the TC1798 system to be reset if the WDT is not serviced within a user-programmable time period. The CPU must service the WDT within this time interval to prevent the WDT from causing a TC1798 System or Application Reset. Hence, routine service of the WDT confirms that the system is functioning properly.

In addition to this standard “Watchdog” function, the WDT incorporates the End-of-Initialization (Endinit) feature and monitors its modifications.

Because servicing the Watchdog and modifications of the ENDINIT bit are critical functions that must not be allowed in case of a system malfunction, a sophisticated scheme is implemented that requires a password and guard bits during accesses to the WDT control register. Any write access that does not deliver the correct password or the correct value for the guard bits is regarded as a malfunction of the system, and a Watchdog reset is requested. In addition, even after a valid access has been performed and the ENDINIT bit has been cleared to provide access to the critical registers, the Watchdog imposes a time limit for this access window. If bit ENDINIT has not been properly set again before this limit expires, the system is assumed to have malfunctioned, and a Watchdog reset is requested. These stringent requirements, although not guaranteed, nonetheless provide a high degree of assurance of the robustness of system operation.

A further enhancement in the TC1798’s WDT is its reset prewarning operation. Instead of immediately resetting the device on the detection of an error (the way that standard Watchdogs do), the WDT first issues a Non-Maskable Interrupt (NMI) to the CPU before finally resetting the device at a specified time period later.

3.8.2 Features of the Watchdog Timer

The main features of the WDT are summarized here.

- 16-bit Watchdog counter
- Selectable input frequency: $f_{FPI}/256$ or $f_{FPI}/16384$
- 16-bit user-definable reload value for normal Watchdog operation, fixed reload value for Time-Out and Prewarning Modes
- Incorporation of the ENDINIT bit and monitoring of its modifications

- Sophisticated Password Access mechanism with fixed and user-definable password fields
- Access Error Detection: Invalid password (during first access) or invalid guard bits (during second access) trigger the Watchdog reset generation
- Overflow Error Detection: An overflow of the counter triggers the Watchdog reset generation
- Watchdog function can be disabled; access protection and ENDINIT bit monitor function remain enabled
- Double Reset Detection

3.8.3 The Endinit Function

It is a prerequisite to understand the ENDINIT bit and its function for better understanding of the descriptions in the following sections. Hence, its function is explained first.

There are a number of registers in the TC1798 that are usually programmed only once during the initialization sequence of the application. Modification of such registers during normal application run can have a severe impact on the overall operation of modules or the entire system.

While the Supervisor Mode, that allows writes to registers only when it is active, provides a certain level of protection against unintentional modifications, it may not provide enough security for system-critical registers.

The TC1798 provides one more level of protection for such registers via the Endinit feature. This is a highly secure write-protection scheme that makes unintentional modifications of registers protected by this feature nearly impossible.

The Endinit feature consists of an ENDINIT bit incorporated in the WDT control register, WDT_CON0. Registers protected via Endinit determine whether or not writes are enabled. Writes are only enabled if bit ENDINIT = 0 AND Supervisor Mode is active. Write attempts if this condition is not true will be discarded and the register contents will not be modified in this case. The BCU controls the further operation following a discarded write access.

To get the highest level of security, this bit is incorporated in the highly secure access protection scheme implemented in the WDT. This is a complex procedure, that makes it nearly impossible for the ENDINIT bit to be modified unintentionally. In addition, the WDT monitors ENDINIT bit modifications by starting a time-out sequence each time software opens access to the critical registers through clearing bit ENDINIT. If the time out period ends before bit ENDINIT is set again, a malfunction of the software is assumed and a reset request is generated.

The access-protection scheme and the Endinit time-out operation of the WDT is described in the following sections. **Table 3-17** lists the registers that are protected via the Endinit feature in the TC1798.

Note: The clearing of the ENDINIT bit takes some time. Accesses to Endinit-protected registers after the clearing of the ENDINT bit must only be done when bit ENDINIT is really cleared. As a solution, WDT_CON0 (the register with the ENDINIT bit) should be read back once before Endinit-protected registers are accessed the first time after bit ENDINIT has been cleared.

Table 3-17 TC1798 Registers Protected via the Endinit Feature

Register Name	Description
mod_CLC	All clock control registers of the individual peripheral modules are Endinit-protected
mod_FDR	All clock fractional divider registers of the individual peripheral modules are Endinit-protected
BTV, BIV, ISP	Trap and interrupt vector table pointer as well as the interrupt stack pointer are Endinit-protected
MIECON **SMACON** **COMPAT**	CPU Control Registers
FLASH0_FCON **FLASH1_FCON** **FLASH0_RDWCFG0** **FLASH0_RDWCFG1** **FLASH0_RDWCFG2** **FLASH1_RDWCFG0** **FLASH1_RDWCFG1** **FLASH1_RDWCFG2** **FLASH0_MARP** **FLASH1_MARP** **FLASH0_ECCW** **FLASH1_ECCW** **FLASH0_ECCR** **FLASH1_ECCR**	Flash configuration registers
WDT_CON1	The Watchdog Timer Control Register 1, which controls the disabling and the input frequency of the Watchdog Timer, is Endinit-protected. In addition, its bits will only have an effect on the WDT when ENDINIT is properly set to 1 again.

Table 3-17 TC1798 Registers Protected via the Endinit Feature (cont'd)

Register Name	Description
SCU_OSCCON **SCU_PLLCON0** **SCU_PLLCON1** **SCU_CCUCON0** **FDR** **SCU_CCUCON1**	All clock control registers are protected
SCU_RSTCNTCON **SCU_RSTCON** **SCU_ARSTDIS** **SCU_SWRSTCON**	All reset control registers are protected
SCU_ESRCFG0 **SCU_ESRCFG1**	All ESR control registers are protected
SCU_EMSR	The emergency stop register
SCU_TRAPSET **SCU_TRAPDIS**	The trap set and disable register
SHE_MPRTS **SHE_MPRTE**	SHE memory protection
P17_PDISC **Px_ESR** **Px_PDR**	Port Control Registers
DMA_MExARR **DMA_MExAENR** **DMA_OCDSR** **DMA_SUSPMR**	DMA Control Registers
PCP_CS	PCP Control Registers
DMI_CON	DMI Control Registers

3.8.3.1 Password Access to WDT_CON0

A correct password must be written to register WDT_CON0 in order to unlock it for modifications. Software must either know the correct password in advance or compute it at runtime. The password required to unlock the register is formed by a combination of bits in registers WDT_CON0 and WDT_CON1, plus a number of guard bits. **Table 3-18** summarizes the requirements for the password.

Table 3-18 Password Access Bit Pattern Requirements

Bit Position	Required Value
0	Current state of bit WDT_CON0.ENDINIT
1	Fixed; must be written with 0
2	Current state of bit WDT_CON1.IR
3	Current state of bit WDT_CON1.DR
[7:4]	Fixed; must be written to 1111_B
[15:8]	Current value of user.definable password field WDT_CON0.PW
[31:16]	Current value of user-definable reload value, WDT_CON0REL

The password is designed such that it is not possible to just read the contents of a register and use this as the password. The password is never identical to the contents of WDT_CON0 or WDT_CON1, it is always required to modify the read value (at least bits 1 and [7:4]) to get the correct password. This prevents a malfunction from accidentally reading a WDT register's contents and writing it to WDT_CON0 as an unlocking password.

If the password matches the requirements, WDT_CON0 will be unlocked as soon as the Password Access is completed. The unlocked condition will be indicated by WDT_CON0.LCK = 0.

If an improper password value is written to WDT_CON0 during the Password Access, a Watchdog Access Error condition exists. Bit WDT_SR.AE is set and the Prewarning Mode is entered.

The user-definable password, WDT_CON0.PW, provides additional options for adjusting the password requirements to the application's needs. It can be used, for instance, to detect unexpected software loops, or to monitor the execution sequence of routines.

3.8.3.2 Modify Access to WDT_CON0

If WDT_CON0 is successfully unlocked, the following write access to WDT_CON0 can modify it. However, this access must also meet certain requirements in order to be accepted and regarded as valid. **Table 3-19** lists the required bit patterns. If the access does not follow these rules, a Watchdog Access Error condition is detected, bit WDT_SR.AE is set, and the Prewarning Mode is entered.

Table 3-19 Modify Access Bit Pattern Requirements

Bit Position	Value
0	User-definable; desired value for bit WDT_CON0.ENDINIT.
1	Fixed; must be written with 1.
2	Fixed; must be written with 0.
3	Fixed; must be written with 0.
[7:4]	Fixed; must be written with 1111_B.
[15:8]	User-definable; desired value of user-definable password field, WDT_CON0.PW.
[31:16]	User-definable; desired value of user-definable reload value, WDT_CON0.REL.

After the Modify Access has completed, WDT_CON0.LCK is set again, automatically re-locking WDT_CON0. Before the register can be modified again, a valid Password Access must be executed again.

3.8.3.3 Access to Endinit-Protected Registers

If some or all of the system's Endinit-protected registers must be changed during run time of an application, access can be re-opened. To do this, WDT_CON0 must first be unlocked with a Valid Password Access. In the subsequent Valid Modify Access, ENDINIT can be cleared. Access to Endinit-protected registers is now open again. However, when WDT_CON0 is unlocked, the WDT is automatically switched to Time-Out Mode. Thus, the access window is time-limited. Time-Out Mode is only terminated after ENDINIT has been set again, requiring another Valid Password and Valid Modify Access to WDT_CON0.

If the WDT is not used in an application and is therefore disabled (WDT_SR.DS = 1), the above described case is the only occasion when WDT_CON0 must be accessed again after the system is initialized. If there are no further changes to critical system registers needed, no further accesses to WDT_CON0, WDT_CON1, or WDT_SR are necessary. However, it is recommended that the WDT be used in an application for safety reasons.

For debugging support the Cerberus module can override the ENDINIT control to ease the debug flow. If bit CBS_OSTATE.ENIDIS is set the ENDINIT protection is disabled independent of the current status configured by the WDT. If CBS_OSTATE.ENIDIS is cleared the complete control is within the WDT.

3.8.4 Timer Operation

The timer is automatically active after an Application Reset. The 16-bit counter implementing the timer functionality is either triggered with f_{FPI} / 256 or f_{FPI} / 16384. The two possible counting rates are controlled via bit WDT_CON1.IR.

Determining WDT Periods

The WDT uses the FPI-Bus clock f_{FPI}. A clock divider in front of the WDT provides two output frequencies, f_{FPI} / 256 and f_{FPI} / 16384.

The general formula to calculate a Watchdog period is:

$$\text{period} = \frac{(2^{16} - \text{startvalue}) \cdot 256 \cdot 2^{(1-\text{IR}) \cdot 6}}{f_{FPI}} \quad (3.19)$$

The parameter start value represents the fixed value $FFFC_H$ for the calculation of the Time-Out Period, and the user-programmable reload value WDT_CON0.REL for the calculation of the Normal Period.

3.8.4.1 Timer Modes

The Watchdog Timer can operate in one of four different operating modes:

- Time-Out Mode
- Normal Mode
- Disable Mode
- Prewarning Mode

The following overview describes these modes and how the WDT changes from one mode to the other.

Time-Out Mode

The Time-Out Mode is entered after an Application Reset or when a valid Password Access to register WDT_CON0 is performed (see **Section 3.8.3.1**). The Time-Out Mode is indicated by bit WDT_SR.TO = 1. The timer is set to $FFFC_H$ and starts counting upwards. Time-Out Mode can only be exited properly by setting ENDINIT = 1 with a correct access sequence. If an improper access to the WDT is performed, or if the timer overflows before ENDINIT is set, a WDT_NMI is requested, and Prewarning Mode is entered.

A proper exit from Time-Out Mode can either be to the Normal or the Disable Mode, depending on the state of the disable request bit WDT_CON1.DR.

Normal Mode

In Normal Mode (DR = 0), the WDT operates in a standard Watchdog fashion. The timer is set to WDT_CON0.REL, and begins counting up. It has to be serviced before the counter overflows. Servicing is performed through a proper access sequence to the control register WDT_CON0. This enters the Time-Out Mode.

If the WDT is not serviced before the timer overflows, a system malfunction is assumed. Normal Mode is terminated, a WDT_NMI is requested, and Prewarning Mode is entered.

Disable Mode

Disable Mode is provided for applications which truly do not require the WDT function. It can be requested from Time-Out Mode when the disable request bit WDT_CON1.DR is set. The Disable Mode is entered when was requested AND bit WDT_CON0.ENDINIT is set. The timer is stopped in this mode. However, disabling the WDT only stops it from performing the standard Watchdog function, eliminating the need for timely service of the WDT. It does not disable Time-Out and Prewarning Mode. If an access to register WDT_CON0 is performed in Disable Mode, Time-Out Mode is entered if the access was valid, and Prewarning Mode is entered if the access was invalid. Thus, the ENDINIT monitor function as well as (a part of) the system malfunction detection will still be active.

Prewarning Mode

Prewarning Mode is entered always when a Watchdog error is detected. This can be due to an overflow of the timer in Normal or Time-Out Mode, or an invalid access to register WDT_CON0. Instead of immediately requesting a reset of the device, the WDT enables the system to enter a secure state by a prewarning before the reset occurs.

In Prewarning Mode, after having generated the NMI request, the WDT counts up from $FFFC_H$, and then generates a Watchdog reset request on the overflow. This reset request cannot be avoided in this mode; the WDT does not react anymore to accesses to its registers, nor will it change its state unless reset by an Application Reset. This is to prevent a malfunction from falsely terminating this mode, disabling the reset, and letting the device to continue to function improperly. Register WDT_CON0 can still be accessed by a valid Password Access.

Note: In Prewarning Mode, it is not required for the part to wait for the end of this mode and the reset. After having saved required state in the NMI routine, software can execute an Application Reset to shorten the time.

Note: The Prewarning Mode is only left by an application Reset and not only on the reset request. Therefore if bit field RSTCON.WDT is set to 00_B the Prewarning Mode is not left.

3.8.4.2 WDT Reset Behavior

WDT reset requests are generated for three cases:

- Invalid password access to register WDT_CON0
- Not finishing a password access before a timer overflow occurs in the Time-Out Mode
- Not serving the WDT before a timer overflow occurs in the Normal Mode

If a reset is generated on a WDT reset request and the kind of the reset can be configured via bit field RSTCON.WDT.

Note: The WDT itself is reset by any Application Reset.

Before a reset is requested the Prewarning Mode is entered, for more details see **Section 3.8.4.1**.

Double WDT Reset

If the Watchdog induced reset occurs twice, a severe system malfunction is assumed and the TC1798 is held in reset until a System Reset occurs. This prevents the device from being periodically reset if, for instance, connection to the external memory has been lost such that even system initialization could not be performed.

If the WDT is configured to request an Application Reset the second reset request will be permanently asserted resulting (without any change in the reset configuration) resulting in a permanent Application Reset. The information about the first WDT reset request is stored in an internal flag which is reset with the System Reset. This flag is set when the Prewarning Mode is finished and the reset request is generated. If a new reset is requested and the internal flag is already set a double reset event has occurred and a permanent request is generated. This internal flag is cleared by any System Reset or when bit WDT_CON1.CLRIRF is set AND bit WDT_CON0.ENDINIT is set too. Please note that a correct service of the WDT does not clear this internal flag. Bit WDT_CON1.CLRIRF can only be set when bit WDT_CON0.ENDINIT is cleared.

Note: It does not matter whether a reset was generated on a WDT reset request or if the reset configuration was changed between the two reset requests.

Note: If for any reason random code is executed bit field RSTCON.WDT can be updated unintentional. This can result that a WDT error does not lead to an reset. To avoid this after the SSW is finished this bit field should be checked and the ENDINIT protection enabled.

Servicing the Watchdog Timer

If the WDT is used in an application and is enabled (WDT_SR.DS = 0), it must be regularly serviced to prevent it from overflowing.

Service is performed in two steps. a Valid Password Access followed by a Valid Modify Access. The Valid Password Access to WDT_CON0 automatically switches the WDT to Time-Out Mode. Thus, the Modify Access must be performed before the Time-out expires or a System Reset will result.

During the next Modify Access, the strict requirement is that WDT_CON0.ENDINIT as well as bit 1 and bits [7:4] are written with 1, while bits [3:2] are written with 0.

Note: ENDINIT must be written with 1 to perform a proper service, even if it is already set to 1.

Changes to the reload value WDT_CON0.REL, or the user-definable password WDT_CON0.PW, are not required. However, changing WDT_CON0.PW is recommended so that software can monitor WDT service operations throughout the duration of an application program (see next section).

When WDT service is properly executed, Time-Out Mode is terminated, and the WDT switches back to its former mode of operation, and WDT service is complete.

3.8.4.3 WDT Operation During Power-Saving Modes

If the CPU is in Idle Mode or Sleep Mode, it cannot service the WDT because no software is running. Excluding the case where the system is running normally, a strategy for managing the WDT is needed while the CPU is in Idle or Sleep Mode. There are two ways to manage the WDT in these cases. First, the Watchdog can be disabled before idling the CPU. The disadvantage of this is that the system will no longer be monitored during the idle period.

A better approach to this problem relies upon a wake-up feature of the WDT. Whenever the CPU is put in Idle or Sleep Mode and the WDT is not disabled, it causes the CPU to be awakened at regular intervals. When the WDT changes its count value (WDT_SR.TIM) from $7FFF_H$ to 8000_H, the CPU is awakened and continues to execute the instruction following the instruction that was last executed before entering the Idle or Sleep Mode.

Note: Before switching into a non-running power-management mode, software should perform a Watchdog service sequence. At the Modify Access, the Watchdog reload value, WDT_CON0.REL, should be programmed such that the wake-up occurs after a period which best meets application requirements. The maximum period between two CPU wake-ups is one-half of the maximum WDT period.

3.8.4.4 Suspend Mode Support

In an enabled and active debug session the Watchdog functionality can lead to unintended resets. Therefore to avoid these resets the OCDS can control if the WDT is enabled or disabled (default after Application Reset) via bit CBS_OSTATE.WDTSUS if it is not already stopped.

Table 3-20 OCDS Behavior of WDT

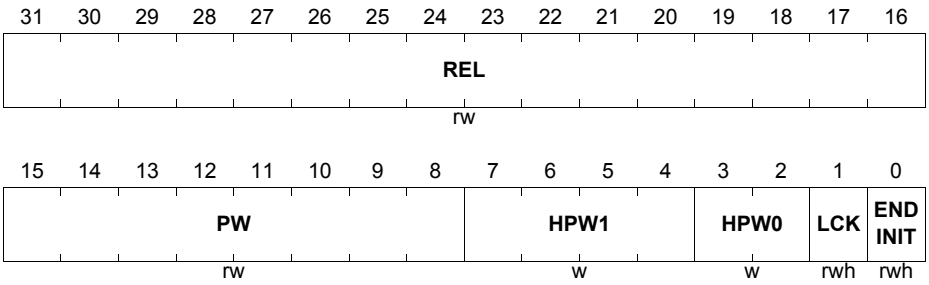
STCON.STP	WDT_SR.DS	CBS_OSTATE.OEN	CBS_OSTATE.SUS	CBS_MCDSSG.SOS	WDT Action
0	X	X	X	X	Stopped
1	1	X	X	X	Stopped
1	0	0	X	X	Running
1	0	1	0	X	Stopped
1	0	1	1	0	Running
1	0	1	1	1	Stopped

3.8.5 Watchdog Timer Registers

3.8.5.1 Watchdog Timer Control Register 0

Register WDT_CON0 manages Password Access to the Watchdog Timer. It also stores the timer reload value, a user-definable password field, a lock bit, and the End-of-Initialization (ENDINIT) control bit.

WDT_CON0
WDT Control Register 0 (F000 05F0$_H$) Reset Value: FFFC 0002$_H$



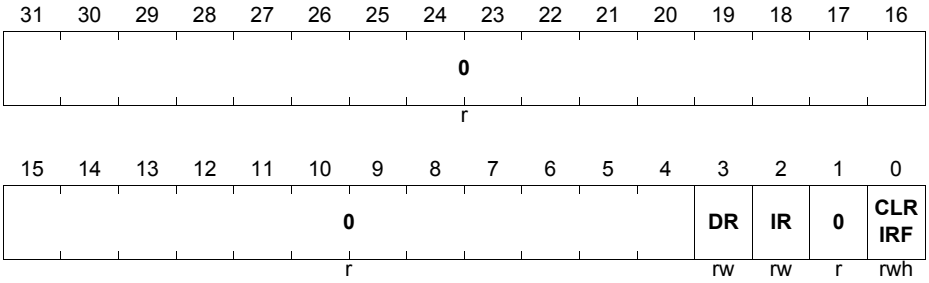
Field	Bits	Type	Description
ENDINIT	0	rwh	**End-of-Initialization Control Bit** 0_B Access to Endinit-protected registers is permitted (default after Application Reset) 1_B Access to Endinit-protected registers is not permitted

Field	Bits	Type	Description
LCK	1	rwh	**Lock Bit to Control Access to WDT_CON0** 0_B Register WDT_CON0 is unlocked 1_B Register WDT_CON0 is locked (default after Application Reset) The actual value of LCK is controlled by hardware. It is cleared after a valid Password Access to WDT_CON0, and automatically set again after a valid Modify Access to WDT_CON0. During a write to WDT_CON0, the value written to this bit is only used for the password-protection mechanism and is not stored. This bit must be cleared during a Password Access to WDT_CON0, and set during a Modify Access to WDT_CON0. That is, the inverted value read from LCK always must be written to itself.
HPW0	[3:2]	w	**Hardware Password 0** This bit field must be written with the value of the bits WDT_CON1.DR and WDT_CON1.IR during a Password Access. This bit field must be written with 0s during a Modify Access to WDT_CON0. When read, these bits always return 0.
HPW1	[7:4]	w	**Hardware Password 1** This bit field must be written with 1111_B during both Password Access and Modify Access to WDT_CON0. When read, these bits always return 0.
PW	[15:8]	rw	**User-Definable Password Field for Access to WDT_CON0** This bit field must be written with its current contents during a Password Access. It can be changed during a Modify Access to WDT_CON0.
REL	[31:16]	rw	**Reload Value for the WDT** If the Watchdog Timer is enabled and in Normal Timer Mode, it will start counting from this value after a correct Watchdog service. This bit field must be written with its current contents during a Password Access. It can be changed during a Modify Access to WDT_CON0 ($FFFC_H$ = default after Application Reset).

3.8.5.2 Watchdog Timer Control Register 1

WDT_CON1 manages operation of the WDT. It includes the disable request and frequency selection bits. It is ENDINIT-protected.

WDT_CON1
WDT Control Register 1 **(F000 05F4$_H$)** **Reset Value: 0000 0000$_H$**



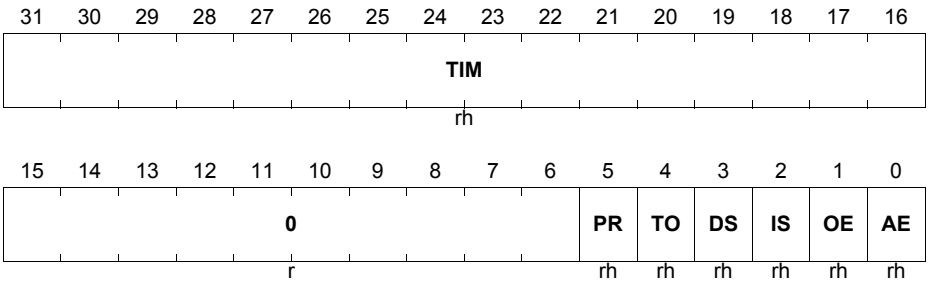
Field	Bits	Type	Description
CLRIRF	0	rwh	**Clear Internal Reset Flag** This bit is used to request a clear of the internal flag storing the information about the first WDT reset request. 0_B No action 1_B Request to clear the internal flag This bit can only be modified if WDT_CON0.ENDINIT is cleared. The internal flag is cleared when ENDINIT is set again. As long as ENDINIT is cleared, the internal flag is unchanged and controls the current past error status of the WDT. When ENDINIT is set again with a Valid Modify Access, the internal flag is cleared together with this bit.

Field	Bits	Type	Description
IR	2	rw	**Input Frequency Request Control Bit** 0_B Request to set input frequency to $f_{FPI}/16384$. 1_B Request to set input frequency to $f_{FPI}/256$. This bit can only be modified if WDT_CON0.ENDINIT is cleared. WDT_SR.IS is updated by this bit only when ENDINIT is set again. As long as ENDINIT is cleared, WDT_SR.IS controls the current input frequency of the Watchdog Timer. When ENDINIT is set again, WDT_SR.IS is updated with the state of IR.
DR	3	rw	**Disable Request Control Bit** 0_B Request to enable the WDT 1_B Request to disable the WDT This bit can only be modified if WDT_CON0.ENDINIT is cleared. WDT_SR.DS is updated when ENDINIT is set again. As long as ENDINIT is cleared, bit WDT_SR.DS controls the current enable/disable status of the WDT. When ENDINIT is set again with a Valid Modify Access, WDT_SR.DS is updated with the state of DR.
0	1, [31:4]	r	**Reserved** Read as 0; should be written with 0.

3.8.5.3 Watchdog Timer Status Register

Register WDT_SR shows the current state of the WDT. Status include bits indicating reset prewarning, Time-Out, enable/disable status, input clock status, and access error status.

WDT_SR
WDT Status Register **(F000 05F8$_H$)** **Reset Value: FFFC 0010$_H$**



Field	Bits	Type	Description
AE	0	rh	**Watchdog Access Error Status Flag** 0_B No Watchdog access error 1_B A Watchdog access error has occurred This bit is set when an illegal Password Access or Modify Access to register WDT_CON0 was attempted. This bit is only cleared when WDT_CON0.ENDINIT is set during a Valid Modify Access However, it is not possible to clear this bit if the WDT is in Prewarning Mode.
OE	1	rh	**Watchdog Overflow Error Status Flag** 0_B No Watchdog overflow error 1_B A Watchdog overflow error has occurred This bit is set when the WDT overflows from $FFFF_H$ to 0000_H. This bit is only cleared when WDT_CON0.ENDINIT is set to 1 during a Valid Modify Access. However, it is not possible to clear this bit if the WDT is in Prewarning Mode.
IS	2	rh	**Watchdog Input Clock Status Flag** 0_B The timer operation clock is f_{FPI}/16384 (default after Application Reset) 1_B The timer operation clock is f_{FPI}/256 This bit is updated with the state of bit WDT_CON1.IR after WDT_CON0.ENDINIT is written with 1 during a Valid Modify Access to register WDT_CON0.
DS	3	rh	**Watchdog Enable/Disable Status Flag** 0_B WDT is enabled (default after Application Reset) 1_B WDT is disabled This bit is updated with the state of bit WDT_CON1.DR after WDT_CON0.ENDINIT is set during a Valid Modify Access to register WDT_CON0.

Field	Bits	Type	Description
TO	4	rh	**Watchdog Time-Out Mode Flag** 0_B The Watchdog is not operating in Time-Out Mode 1_B The Watchdog is operating in Time-Out Mode (default after Application Reset) This bit is set when Time-Out Mode is entered. It is automatically cleared when Time-Out Mode is left.
PR	5	rh	**Watchdog Prewarning Mode Flag** 0_B The Watchdog is not operating in Prewarning Mode 1_B The Watchdog is operating in Prewarning Mode This bit is set when a Watchdog error is detected. The WDT has issued a trap trigger and is in Prewarning Mode. A reset of the chip occurs after the prewarning period has expired if it is enabled in bit field RSTCON.WDT.
TIM	[31:16]	rh	**Timer Value** Reflects the current content of the WDT.
0	[15:6]	r	**Reserved** Read as 0.

3.9 Emergency Stop Output Control

The emergency stop feature of the TC1798 allows for a fast emergency reaction on an external event without the intervention of software. In an emergency case, the outputs can be selectively put immediately to a well-defined logic state (for more information see the port chapter).

The emergency case is indicated by an emergency input signal with selectable polarity that has to be connected to input P9.10.

Figure 3-28 shows a diagram of the emergency stop input logic. This logic is controlled by the SCU Emergency Stop Register EMSR.

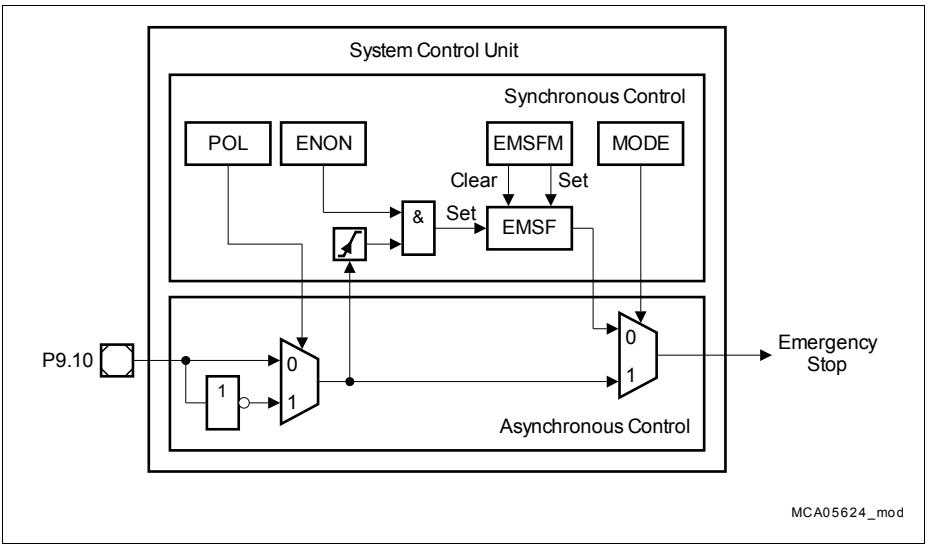


Figure 3-28 Emergency Stop Input Control

The emergency stop control logic for the ports can basically operate in two modes:

- Synchronous Mode (default after reset):
  Emergency case is activated by hardware and released by software.
- Asynchronous Mode:
  Emergency case is activated and released by hardware.

In Synchronous Mode (selected by EMSR.MODE = 0), the port signal is sampled for a inactive-to-active level transition, and an emergency stop flag EMSR.EMSF is set if the transition is detected. The setting of EMSR.EMSF activates the emergency stop signal. An emergency case can only be terminated by clearing EMSR.EMSF via software. The synchronous control logic is clocked by the system bus clock f_{FPI}. This results in a small delay between the port signal and emergency stop signal generation.

In Asynchronous Mode (selected by EMSR.MODE = 1), the occurrence of an active level at the port input immediately activates the emergency stop signal. Of course, a valid-to-invalid transition of the port input (emergency case is released) also immediately deactivates the emergency stop signal.

The EMSR.POL bit determines the active level of the input signal. The EMSR.MODE bit selects Synchronous or Asynchronous Mode for emergency stop signal generation.

3.9.1 Emergency Stop Register

The Emergency Stop Register EMSR contains control and status bits/flags of the emergency stop input logic.

EMSR
Emergency Stop Register **(100_H)** **Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r						w		r							rh

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0													ENON	MODE	POL
r													rw	rw	rw

Field	Bits	Type	Description
POL	0	rw	**Input Polarity** This bit determines the polarity of the input line. 0_B Input is high active 1_B Input is low active
MODE	1	rw	**Mode Selection** This bit determines the operating mode of the emergency stop signal. 0_B Synchronous Mode selected; emergency stop is derived from the state of flag EMSF 1_B Asynchronous Mode selected; emergency stop is directly derived from the state of the input signal
ENON	2	rw	**Enable ON** This bit enables the setting of flag EMSF by an inactive-to-active level transition of input signal. 0_B Setting of EMSF is disabled 1_B Setting of EMSF is enabled

Field	Bits	Type	Description
EMSF	16	rh	**Emergency Stop Flag** This bit indicates if an emergency stop condition has occurred. 0_B An emergency stop has not occurred 1_B An emergency stop has occurred and signal emergency stop becomes active (if MODE = 0)
EMSFM	[25:24]	w	**Emergency Stop Flag Modification** This bit field set or clear flag EMSF via software. 00_B EMSF remains unchanged 01_B EMSF becomes set 10_B EMSF becomes cleared 11_B EMSF remains unchanged EMSFM is always read as 00_B.
0	[15:3], [23:17], [31:26]	r	**Reserved** Read as 0; should be written with 0.

3.10 Interrupt Generation

The interrupt structure is shown in **Figure 3-29**. The interrupt request or the corresponding interrupt set bit (in register INTSET) can trigger the interrupt generation at the selected interrupt node x. The service request pulse is generated independently from the interrupt flag in register INTSTAT. The interrupt flag can be cleared by software by writing to the corresponding bit in register INTCLR.
If more than one interrupt source is connected to the same interrupt node pointer (in register INTNP), the requests are combined to one common line.

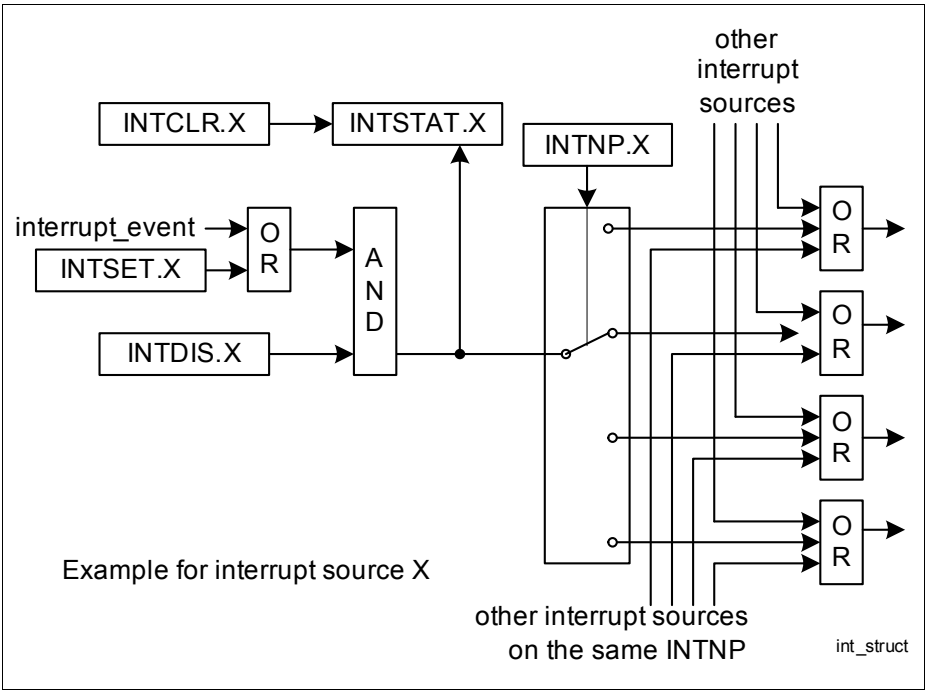

Figure 3-29 Interrupt Generation

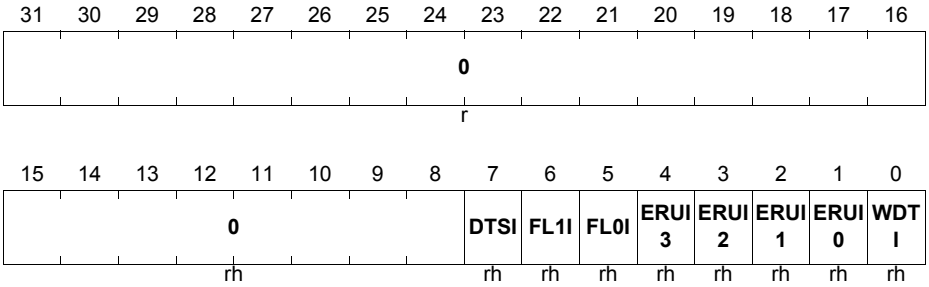
3.10.1 Interrupt Control Registers

INTSTAT
Interrupt Status Register **(110_H)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
WDTI	0	rh	**Watchdog Timer Interrupt Request Flag** This bit is set if the WDT Prewarning Mode is entered and bit is INTDIS.WDTI = 0. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLR.WDTI. This bit can be set by bit INTSET.WDTI.
ERUI0	1	rh	**ERU Channel 0 Interrupt Request Flag** This bit is set if the ERU channel 0 is active and bit is INTDIS.ERUI0 = 0. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLR.ERUI0. This bit can be set by bit INTSET.ERUI0.

Field	Bits	Type	Description
ERUI1	2	rh	**ERU Channel 1 Interrupt Request Flag** This bit is set if the ERU channel 1 is active and bit is INTDIS.ERUI1 = 0. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLR.ERUI1. This bit can be set by bit INTSET.ERUI1.
ERUI2	3	rh	**ERU Channel 2 Interrupt Request Flag** This bit is set if the ERU channel 2 is active and bit is INTDIS.ERUI2 = 0. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLR.ERUI2. This bit can be set by bit INTSET.ERUI2.
ERUI3	4	rh	**ERU Channel 3 Interrupt Request Flag** This bit is set if the ERU channel 3 is active and bit is INTDIS.ERUI3 = 0. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLR.ERUI3. This bit can be set by bit INTSET.ERUI3.
FL0I	5	rh	**Flash 0 Interrupt Request Flag** This bit is set if the Flash interrupt trigger is active and bit is INTDIS.FL0I = 0. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLR.FL0I. This bit can be set by bit INTSET.FL0I.

Field	Bits	Type	Description
FL1I	6	rh	**Flash 1 Interrupt Request Flag** This bit is set if the Flash interrupt trigger is active and bit is INTDIS.FL1I = 0. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLR.FL1I. This bit can be set by bit INTSET.FL1I.
DTSI	7	rh	**DTS Interrupt Request Flag** This bit is set if the DTS busy indication changes from 1_B to 0_B and bit is INTDIS.DTSI = 0. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLR.DTSI. This bit can be set by bit INTSET.DTSI.
0	[15:8]	rh	**Reserved** Read as 0. This bit can be cleared by bit INTCLR.[x]. This bit can be set by bit INTSET.[x]. *Note: x = 6, [13:8], 15.*
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

INTSET
Interrupt Set Register **(114_H)** **Reset Value: $0000\ 0000_H$**

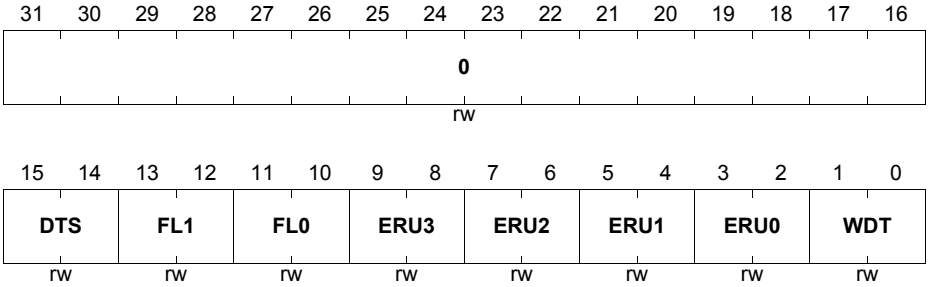
INTNP

Interrupt Node Pointer Register (120_H) Reset Value: $0000\ 0000_H$



Field	Bits	Type	Description
WDT	[1:0]	rw	**Interrupt Node Pointer for Interrupt WDT** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTAT.WDTI (if enabled by bit INTDIS.WDTI). 00_B Interrupt node 0 is selected 01_B Interrupt node 1 is selected 10_B Interrupt node 2 is selected 11_B Interrupt node 3 is selected
ERU0	[3:2]	rw	**Interrupt Node Pointer for Interrupt ERU0** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTAT.ERUI0 (if enabled by bit INTDIS.ERUI0). 00_B Interrupt node 0 is selected 01_B Interrupt node 1 is selected 10_B Interrupt node 2 is selected 11_B Interrupt node 3 is selected
ERU1	[5:4]	rw	**Interrupt Node Pointer for Interrupt ERU1** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTAT.ERUI1 (if enabled by bit INTDIS.ERUI1). 00_B Interrupt node 0 is selected 01_B Interrupt node 1 is selected 10_B Interrupt node 2 is selected 11_B Interrupt node 3 is selected

Field	Bits	Type	Description
ERU2	[7:6]	rw	**Interrupt Node Pointer for Interrupt ERU2** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTAT.ERUI2 (if enabled by bit INTDIS.ERUI2). 00_B Interrupt node 0 is selected 01_B Interrupt node 1 is selected 10_B Interrupt node 2 is selected 11_B Interrupt node 3 is selected
ERU3	[9:8]	rw	**Interrupt Node Pointer for Interrupt ERU3** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTAT.ERUI3 (if enabled by bit INTDIS.ERUI3). 00_B Interrupt node 0 is selected 01_B Interrupt node 1 is selected 10_B Interrupt node 2 is selected 11_B Interrupt node 3 is selected
FL0	[11:10]	rw	**Interrupt Node Pointer for Interrupt FL0** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTAT.FL0I (if enabled by bit INTDIS.FL0I). 00_B Interrupt node 0 is selected 01_B Interrupt node 1 is selected 10_B Interrupt node 2 is selected 11_B Interrupt node 3 is selected
FL1	[13:12]	rw	**Interrupt Node Pointer for Interrupt FL1** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTAT.FL1I (if enabled by bit INTDIS.FL1I). 00_B Interrupt node 0 is selected 01_B Interrupt node 1 is selected 10_B Interrupt node 2 is selected 11_B Interrupt node 3 is selected
DTS	[15:14]	rw	**Interrupt Node Pointer for Interrupt DTS** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTAT.DTSI (if enabled by bit INTDIS.DTSI). 00_B Interrupt node 0 is selected 01_B Interrupt node 1 is selected 10_B Interrupt node 2 is selected 11_B Interrupt node 3 is selected

Field	Bits	Type	Description
0	[31:16]	rw	**Reserved** Should be written with 0.

SRC0
Service Request Control 0 Register (1FC$_H$) Reset Value: 0000 0000$_H$
SRC1

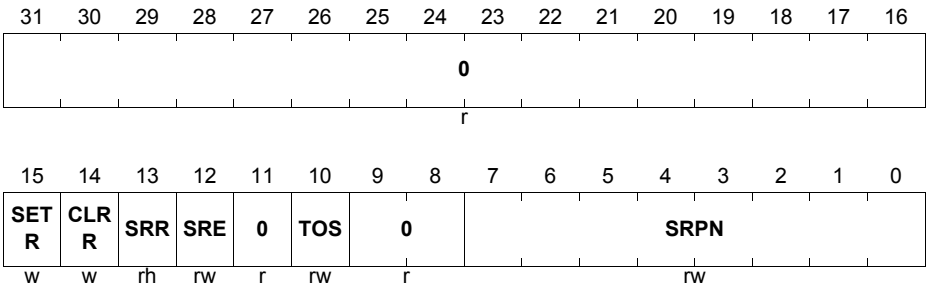
SRC2
Service Request Control 2 Register (1F4$_H$) Reset Value: 0000 0000$_H$
SRC3
Service Request Control 3 Register (1F0$_H$) Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
SRPN	[7:0]	rw	**Service Request Priority Number** 00_H Service request is never serviced 01_H Service request is on lowest priority ... FF_H Service request is on highest priority
TOS	10	rw	**Type of Service Control** 0_B CPU service is initiated 1_B PCP request is initiated
SRE	12	rw	**Service Request Enable** 0_B Service request is disabled 1_B Service request is enabled
SRR	13	rh	**Service Request Flag** 0_B No service request is pending 1_B A service request is pending

Field	Bits	Type	Description
CLRR	14	w	**Request Clear Bit** CLRR is required to clear SRR. 0_B No action 1_B Clear SRR; bit value is not stored; read always returns 0; no action if SETR is set also.
SETR	15	w	**Request Set Bit** SETR is required to set SRR. 0_B No action 1_B Set SRR; bit value is not stored; read always returns 0; no action if CLRR is set also.
0	[9:8], 11, [31:16]	r	**Reserved** Read as 0; should be written with 0.

3.11 NMI Trap Generation

The NMI trap structure is shown in **Figure 3-30**. The trap request trigger or the corresponding trap set bit (in register TRAPSET) can trigger the NMI trap generation. The trap flag can be cleared by software by writing to the corresponding bit in register TRAPCLR. A NMI request is only generated if the trap source was not disabled. Otherwise only the trap status flag is set but no NMI request is generated.

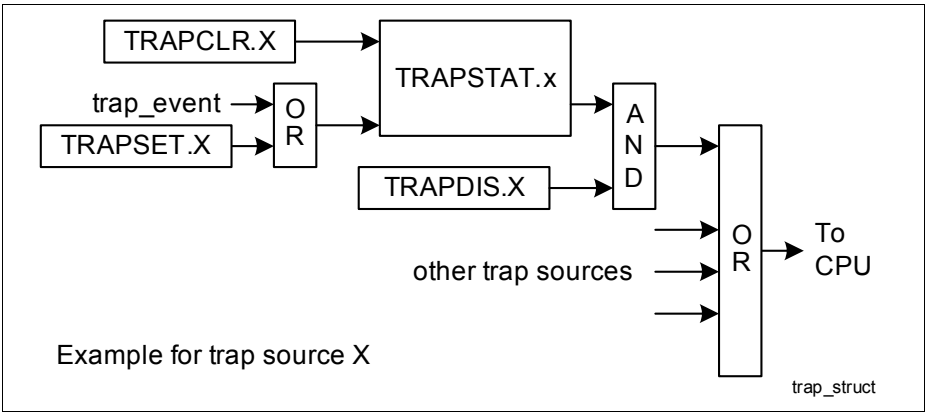


Figure 3-30 NMI Trap Generation

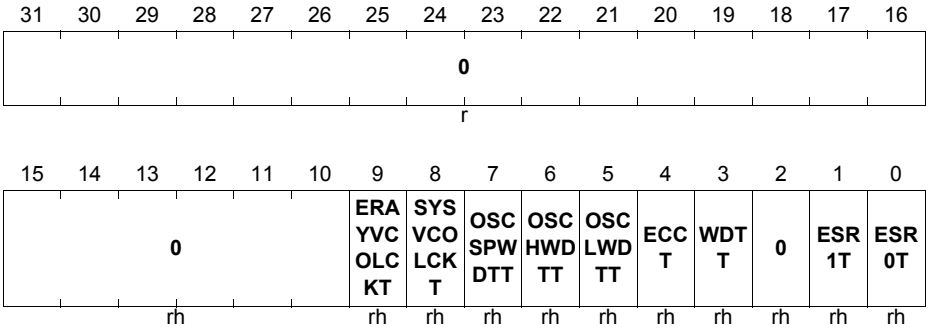
Handling NMI Traps

As an NMI trap is generated while the trap source is enable AND the trap status flag is set it is recommended to clear the trap status flag before the trap source is enabled. The trap status flag can be set before the trap source is enabled and simply enabling the trap source can result in unintended NMI traps. At the end of a NMI trap handing routine the trap status flag should be cleared.

3.11.1 Trap Control Registers

TRAPSTAT
Trap Status Register **(124_H)** **Reset Value: $0000\ 0100_H$**



Field	Bits	Type	Description
ESR0T	0	rh	**ESR0 Trap Request Flag** This bit is set if an ESR0 event is triggered and bit is TRAPDIS.ESR0T is cleared. 0_B No trap was requested since this bit was cleared the last time 1_B A trap was requested since this bit was cleared the last time This bit can be cleared by setting bit TRAPCLR.ESR0T. This bit can be set by setting bit TRAPSET.ESR0T.
ESR1T	1	rh	**ESR1 Trap Request Flag** This bit is set if an ESR1 event is triggered and bit is TRAPDIS.ESR1T is cleared. 0_B No trap was requested since this bit was cleared the last time 1_B A trap was requested since this bit was cleared the last time This bit can be cleared by setting bit TRAPCLR.ESR1T. This bit can be set by setting bit TRAPSET.ESR1T.

Field	Bits	Type	Description
WDTT	3	rh	**WDT Trap Request Flag** This bit is set if a WDT trap is indicated and bit is TRAPDIS.WDTT is cleared. 0_B No trap was requested since this bit was cleared the last time 1_B A trap was requested since this bit was cleared the last time This bit can be cleared by setting bit TRAPCLR.WDTT. This bit can be set by setting bit TRAPSET.WDTT.
ECCT	4	rh	**ECC Error Trap Request Flag** This bit is set if a memory ECC error is indicated and bit is TRAPDIS.ECCT is cleared. 0_B No trap was requested since this bit was cleared the last time 1_B A trap was requested since this bit was cleared the last time This bit can be cleared by setting bit TRAPCLR.ECCT. This bit can be set by setting bit TRAPSET.ECCT.
OSCLWDTT	5	rh	**OSCWDT Low Trap Request Flag** This bit is set if a oscillator WDT of the PLL detects a low event and bit is TRAPDIS.OSCLWDTT cleared. 0_B No trap was requested since this bit was cleared the last time 1_B A trap was requested since this bit was cleared the last time This bit can be cleared by setting bit TRAPCLR.OSCLWDTT. This bit can be set by setting bit TRAPSET.OSCLWDTT.

Field	Bits	Type	Description
OSCHWDTT	6	rh	**OSCWDT High Trap Request Flag** This bit is set if a oscillator WDT of the PLL detects a high event and bit is TRAPDIS.OSCHWDTT cleared. 0_B No trap was requested since this bit was cleared the last time 1_B A trap was requested since this bit was cleared the last time This bit can be cleared by setting bit TRAPCLR.OSCHWDTT. This bit can be set by setting bit TRAPSET.OSCHWDTT.
OSCSPWDTT	7	rh	**OSCWDT Spike Trap Request Flag** This bit is set if a oscillator WDT of the PLL detects a spike event and bit is TRAPDIS.OSCSPWDTT cleared. 0_B No trap was requested since this bit was cleared the last time 1_B A trap was requested since this bit was cleared the last time This bit can be cleared by setting bit TRAPCLR.OSCSPWDTT. This bit can be set by setting bit TRAPSET.OSCSPWDTT.
SYSVCOLCKT	8	rh	**SYSVCOWDT Trap Request Flag** This bit is set if a PLL VCO Loss-of-Lock event is triggered and bit is TRAPDIS.SYSVCOLCKT cleared. 0_B No trap was requested since this bit was cleared the last time 1_B A trap was requested since this bit was cleared the last time This bit can be cleared by setting bit TRAPCLR.SYSVCOLCKT. This bit can be set by setting bit TRAPSET.SYSVCOLCKT.

Field	Bits	Type	Description
ERAYVCOLCKT	9	rh	**ERAYVCOWDT Trap Request Flag** This bit is set if a PLL_ERAY VCO Loss-of Oscillator Lock event is triggered and bit is TRAPDIS.ERAYXVCOLCKT cleared. 0_B No trap was requested since this bit was cleared the last time 1_B A trap was requested since this bit was cleared the last time This bit can be cleared by setting bit TRAPCLR.ERAYVCOLCKT. This bit can be set by setting bit TRAPSET.ERAYVCOLCKT.
0	2, [15:10]	rh	**Reserved** Read as 0. This bit can be cleared by bit TRAPCLR.[x]. This bit can be set by bit TRAPSET.[x]. *Note: x = 2, [15:10].*
0	[31:16]	r	**Reserved** Read as 0.

TRAPSET
Trap Set Register **(128_H)** **Reset Value: 0000 0000$_H$**

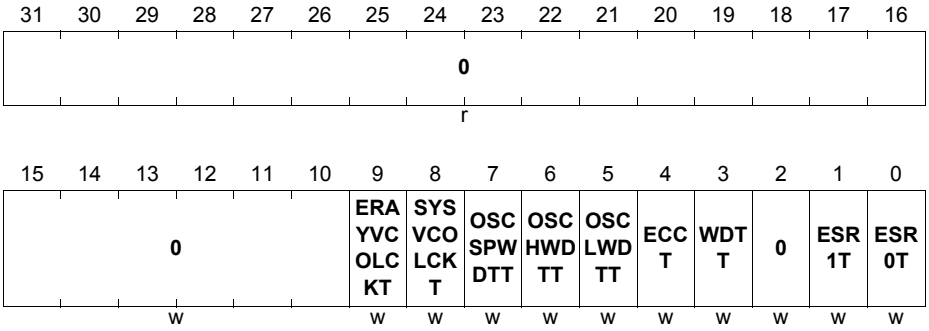
WDTT	3	w	**Set Trap Request Flag WDTT** Setting this bit set bit TRAPSTAT.WDTT. Clearing this bit has no effect. Reading this bit returns always zero.
ECCT	4	w	**Set Trap Request Flag ECCT** Setting this bit set bit TRAPSTAT.ECCT. Clearing this bit has no effect. Reading this bit returns always zero.
OSCLWDTT	5	w	**Set Trap Request Flag OSCLWDTT** Setting this bit set bit TRAPSTAT.OSCLWDTT. Clearing this bit has no effect. Reading this bit returns always zero.
OSCHWDTT	6	w	**Set Trap Request Flag OSCHWDTT** Setting this bit set bit TRAPSTAT.OSCHWDTT. Clearing this bit has no effect. Reading this bit returns always zero.
OSCSPWDTT	7	w	**Set Trap Request Flag OSCSPWDTT** Setting this bit set bit TRAPSTAT.OSCSPWDTT. Clearing this bit has no effect. Reading this bit returns always zero.
SYSVCOLCKT	8	w	**Set Trap Request Flag SYSVCOLCKT** Setting this bit set bit TRAPSTAT.SYSVCOLCKT. Clearing this bit has no effect. Reading this bit returns always zero.
ERAYVCOLCKT	9	w	**Set Trap Request Flag ERAYVCOLCKT** Setting this bit set bit TRAPSTAT.ERAYVCOLCKT. Clearing this bit has no effect. Reading this bit returns always zero.

Field	Bits	Type	Description
0	2, [15:10]	w	**Reserved** Read as 0; have to be written with 0.
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

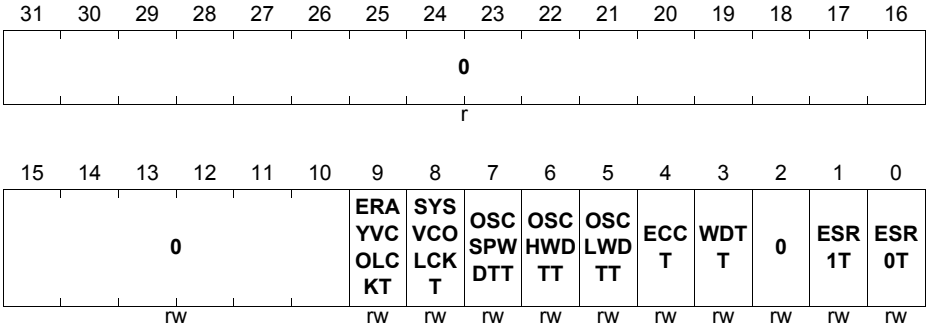
TRAPCLR
Trap Clear Register **($12C_H$)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
ESR0T	0	w	**Clear Trap Request Flag ESR0T** Setting this bit clears bit TRAPSTAT.ESR0T. Clearing this bit has no effect. Reading this bit returns always zero.
ESR1T	1	w	**Clear Trap Request Flag ESR1T** Setting this bit clears bit TRAPSTAT.ESR1T. Clearing this bit has no effect. Reading this bit returns always zero.
WDTT	3	w	**Clear Trap Request Flag WDTT** Setting this bit clears bit TRAPSTAT.WDTT. Clearing this bit has no effect. Reading this bit returns always zero.
ECCT	4	w	**Clear Trap Request Flag ECCT** Setting this bit clears bit TRAPSTAT.ECCT. Clearing this bit has no effect. Reading this bit returns always zero.

Field	Bits	Type	Description
OSCLWDTT	5	w	**Clear Trap Request Flag OSCLWDTT** Setting this bit clears bit TRAPSTAT.OSCLWDTT. Clearing this bit has no effect. Reading this bit returns always zero.
OSCHWDTT	6	w	**Clear Trap Request Flag OSCHWDTT** Setting this bit clears bit TRAPSTAT.OSCHWDTT. Clearing this bit has no effect. Reading this bit returns always zero.
OSCSPWDTT	7	w	**Clear Trap Request Flag OSCSPWDTT** Setting this bit clears bit TRAPSTAT.OSCSPWDTT. Clearing this bit has no effect. Reading this bit returns always zero.
SYSVCOLCKT	8	w	**Clear Trap Request Flag SYSVCOLCKT** Setting this bit clears bit TRAPSTAT.SYSVCOLCKT. Clearing this bit has no effect. Reading this bit returns always zero.
ERAYVCOLCKT	9	w	**Clear Trap Request Flag ERAYVCOLCKT** Setting this bit clears bit TRAPSTAT.ERAYVCOLCKT. Clearing this bit has no effect. Reading this bit returns always zero.
0	2, [15:10]	w	**Reserved** Read as 0; should be written with 0.
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

TRAPDIS
Trap Disable Register **(130_H)** **Reset Value: 0000 FFFF$_H$**



Field	Bits	Type	Description
ESR0T	0	rw	**Disable Trap Request ESR0T** 0_B A trap request can be generated for this source 1_B No trap request can be generated for this source
ESR1T	1	rw	**Disable Trap Request ESR1T** 0_B A trap request can be generated for this source 1_B No trap request can be generated for this source
WDTT	3	rw	**Disable Trap Request WDTT** 0_B A trap request can be generated for this source 1_B No trap request can be generated for this source
ECCT	4	rw	**Disable Trap Request ECCT** 0_B A trap request can be generated for this source 1_B No trap request can be generated for this source
OSCLWDTT	5	rw	**Disable Trap Request OSCLWDTT** 0_B A trap request can be generated for this source 1_B No trap request can be generated for this source

Field	Bits	Type	Description
OSCHWDTT	6	rw	**Disable Trap Request OSCHWDTT** 0_B A trap request can be generated for this source 1_B No trap request can be generated for this source
OSCSPWDTT	7	rw	**Disable Trap Request OSCSPWDTT** 0_B A trap request can be generated for this source 1_B No trap request can be generated for this source
SYSVCOLCKT	8	rw	**Disable Trap Request SYSVCOLCKT** 0_B A trap request can be generated for this source 1_B No trap request can be generated for this source
ERAYVCOLCKT	9	rw	**Disable Trap Request ERAYVCOLCKT** 0_B A trap request can be generated for this source 1_B No trap request can be generated for this source
0	2, [15:10]	rw	**Reserved** Have to be written with 1.
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

3.12 Miscellaneous System Control Register

This section collects different register that serve various system aspects.

3.12.1 GPTA Input IN1 Control

In the TC1798, the input line IN1 of the GPTA module can be used to measure the baud rate of an ASC0 or ASC1 receiver input signal with GPTA. This feature is controlled by SYSCON.GPTAIS.

Table 3-21 GPTA0/GPTA1/LTCA2 Input Line IN1 Connections

SYSCON.GPTAIS	GPTA0/GPTA1/LTCA2 Input IN1 Connected to
00_B	P2.9 / IN1 (default after Application Reset)
01_B	P5.0 / RXD0A
10_B	P6.8 / RXD0B
11_B	P6.10 / RXD1B

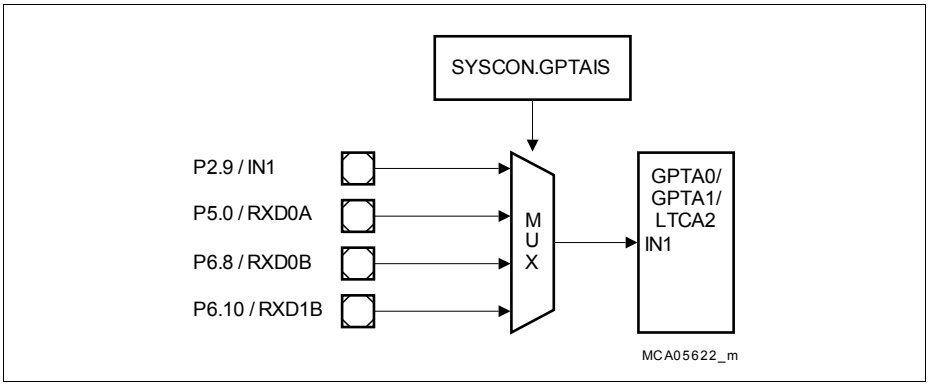


Figure 3-31 GPTA0/GPTA1/LTCA2 Input IN1 Control

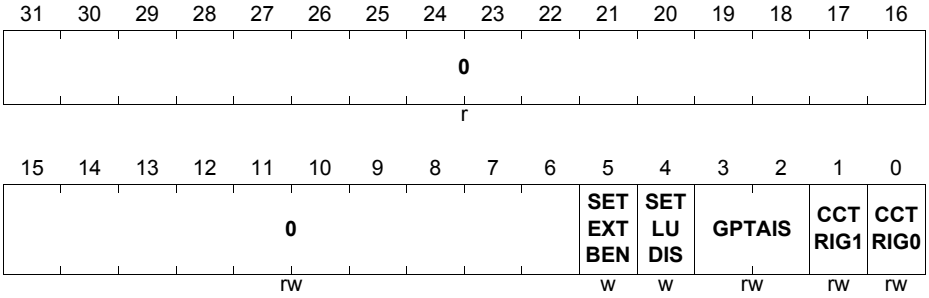
3.12.2 System Control Register

This register controls various functionality used by the SCU but that are located outside of the module. Additionally some functions for other modules are included.

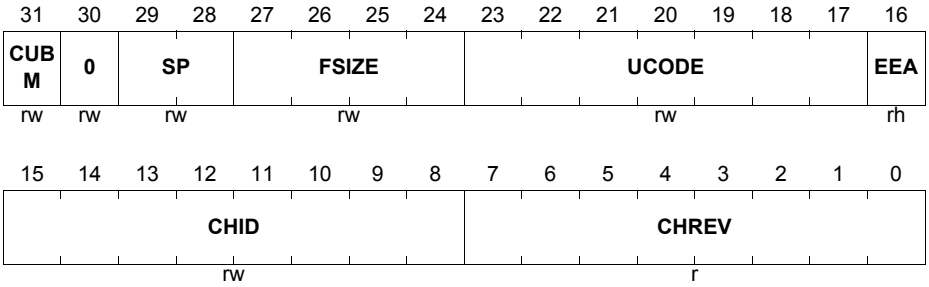
SYSCON
System Control Register **(040_H)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
CCTRIGx (x = 0-1)	x	rw	**Capture Compare Trigger x** This bit is used to trigger the Synchronous Start feature of the CAPCOMs in the system.
GPTAIS	[3:2]	rw	**GPTA Input Select** This bit field selects the input that is used for IN1 of the GPTA module. For more information see either Section 3.12.1 or the GPTA chapter. 00_B IN0 is selected 01_B IN1 is selected 10_B IN2 is selected 11_B IN3 is selected
SETLUDIS	4	w	**Set Latch Update Disable** Setting this bit sets bit STSTAT.LUDIS. Clearing this bit has no effect. This bit reads always as zero.
SETEXTBEN	5	w	**Set External Boot Enable** Setting this bit sets bit STSTAT.EXTBEN. Clearing this bit has no effect. This bit reads always as zero.
0	[15:6]	rw	**Reserved** Should be written with 0.
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

3.12.3 Identification Registers

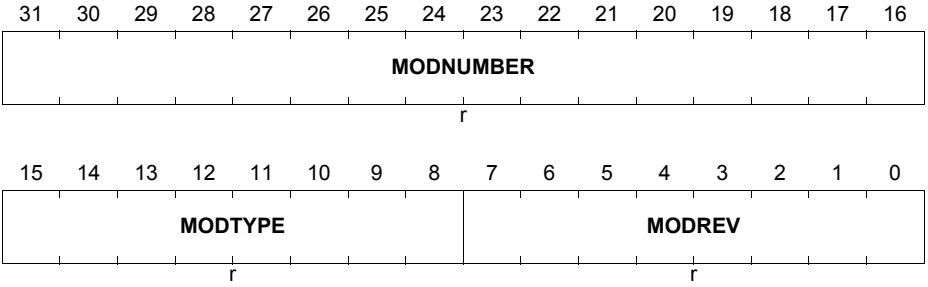
CHIPID
Chip Identification Register **(140_H)** **Reset Value: XXXX XXXX$_H$**



Field	Bits	Type	Description
CHREV	[7:0]	r	**Chip Revision Number** This bit field indicates the revision number of the TC1798 device. The value of this bit field is defined in the TC1798 Data Sheet.
CHID	[15:8]	rw	**Chip Identification Number** This bit field defines the product by a unique number. 98_H = 1798
EEA	16	rh	**Emulation Extension Available** Indicates if the emulation extension is available or not. 0_B EEC is not available 1_B EEC is available
UCODE	[23:17]	rw	**µCode Version** This bit field displays the Version x.y of the flash µCode.
FSIZE	[27:24]	rw	**Program Flash Size** this bit field indicates available program flash size for this device. Detailed information is shown in the Data Sheet.
SP	[29:28]	rw	**Speed** This bit field indicates the maximum allowed speed for the CPU of this device. Detailed information is shown in the Data Sheet.

Field	Bits	Type	Description
CUBM	31	rw	**Copper Bond Material** This bit indicates if copper was used for the bond wires. 0_B No copper was used 1_B Copper was used
0	30	rw	**Reserved** Have not to be written at all.

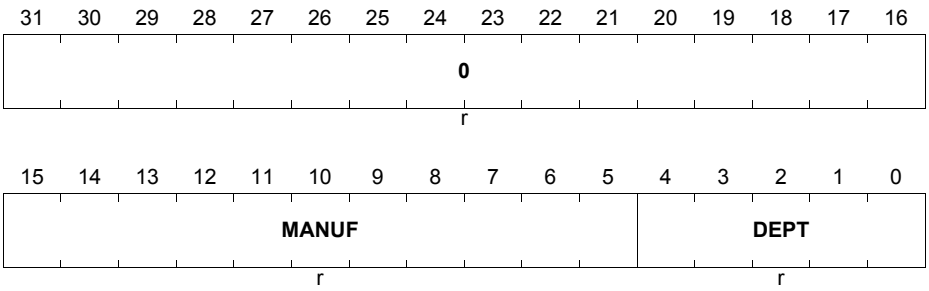
ID
Identification Register **(008_H)** **Reset Value: 0052 C0XX$_H$**



Field	Bits	Type	Description
MODREV	[7:0]	r	**Module Revision Number** This bit field indicates the revision number of the TC1798 module (01_H = first revision).
MODTYPE	[15:8]	r	**Module Type** This bit field is $C0_H$. It defines a 32-bit module
MODNUMBER	[31:16]	r	**Module Number** This bit field defines the module identification number.

MANID

Manufacturer Identification Register (144_H) **Reset Value: 0000 1820$_H$**



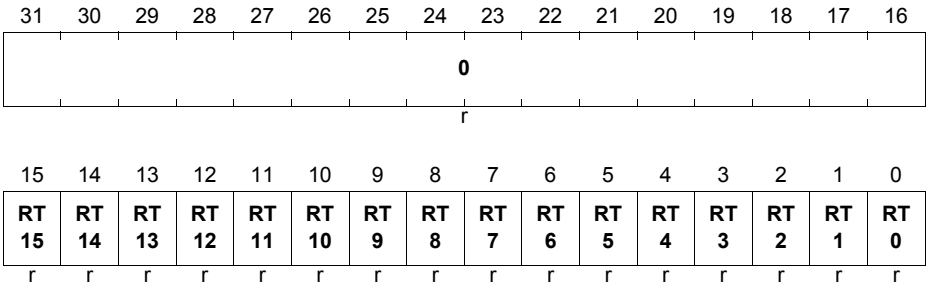
Field	Bits	Type	Description
DEPT	[4:0]	r	**Department Identification Number** = 00_H: indicates the Automotive & Industrial microcontroller department within Infineon Technologies.
MANUF	[15:5]	r	**Manufacturer Identification Number** This is a JEDEC normalized manufacturer code. MANUF = $C1_H$ stands for Infineon Technologies.
0	[31:16]	r	**Reserved** Read as 0.

The Redesign Tracing Register RTID provides a means of signalling minor redesigns that are not reflected in the CHIPID.CHREV bit field.

RTID

Redesign Tracing Identification Register

(148_H) **Reset Value: 0000 XXXX$_H$**



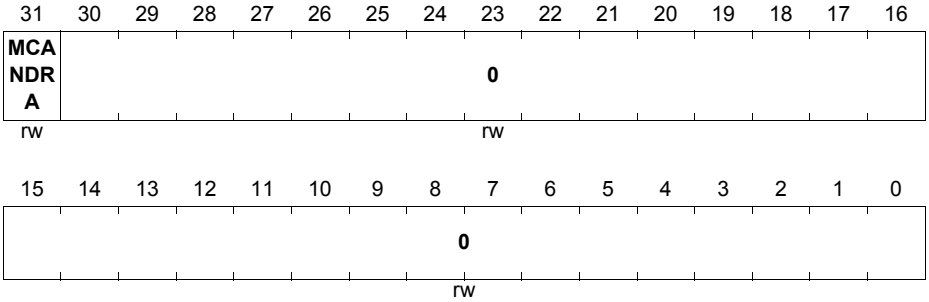
Field	Bits	Type	Description
RTx (x = 0-15)	x	r	**Redesign Trace Bit x** 0_B No change indicated 1_B A change has been made (without changing bit field CHIPID.CHREV). RTx can be used, e.g., for minor redesign stepping identification purposes.
0	[31:16]	r	**Reserved** Read as 0

Note: The RTID reset value for a major design step (without modifications) is 0000_H.

3.12.4 Memory Test Register

3.12.4.1 Register MEMTEST

MEMTEST
Memory Test Register **(160_H)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
MCANDRA	31	rw	**MCAN Direct RAM Access** 0_B Direct RAM access for the MCAN is not possible 1_B Direct RAM access for the MCAN is possible
0	[30:0]	r	**Reserved** Has to be written with 0.

3.12.5 SCU Kernel Registers

This section describes the kernel registers of the 32-bit SCU module. Most of 32-bit SCU kernel register names described in this section will be referenced in other parts of the TC1798 User´s Manual by the module name prefix “SCU_”.

SCU Kernel Register Overview

Table 3-22 Register Overview of SCU

Short Name	Long Name	Offset Addr.[1)]	Access Mode		Reset	Description See

4 On-Chip System Buses and Bus Bridges

The TC1798 has two independent on-chip buses:

- Shared Resource Interconnect (SRI)
- System Peripheral Bus (SPB)

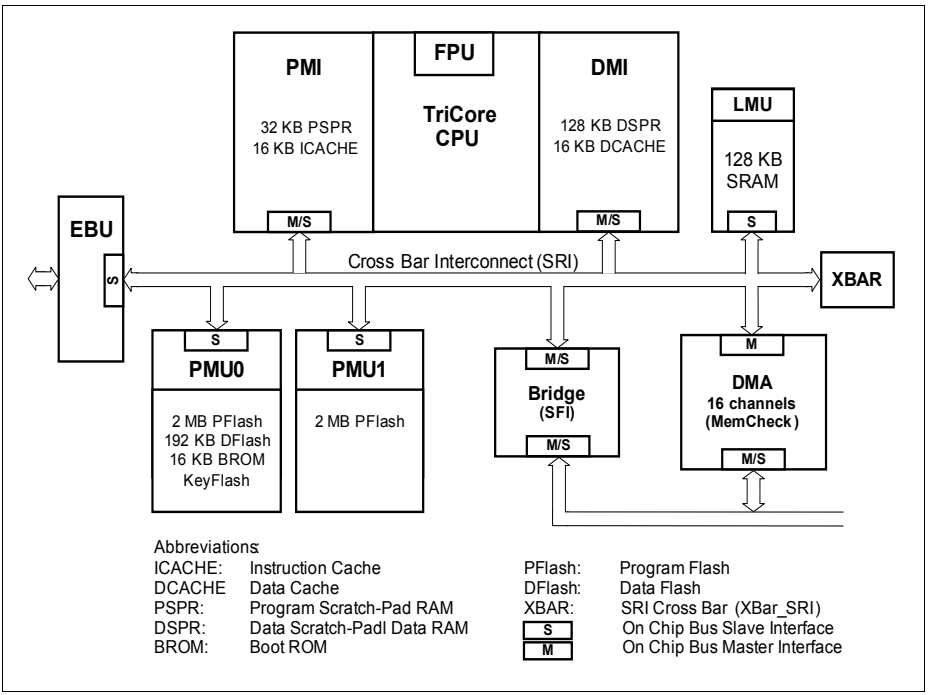

Figure 4-1 On Chip Buses in TC1798 Processor Subsystem

The SRI connects the TriCore CPU to its local resources for instruction fetches and data accesses.

The SPB is accessible by the CPU via the SRI to FPI Bridge (SFI).

4.1 What is new

Major differences of the TC1798 On Chip Bus System architecture compared to AudoF/AudoS and other TC1.3.x based products:

- The TC1798 is based on two on chip busses (SRI, SPB). The Local Memory Bus (LMB) was replaced by an Shared Resource Interconnect (SRI / SRI Crossbar, **Chapter 4.2**)
- The LBCU functionality is now covered by the SRI Crossbar (XBar_SRI)

- The LMB to FPI Bridge (LFI) was replaced by the SRI to FPI Bridge (SFI, **Chapter 4.3**)
- The SFI is fully transparent regarding address and master TAG ID
- The on chip bus architecture was adapted to the TC1.6 (CPS registers are now accessed via PMI SRI slave, additional LMU peripheral connected to SRI)
- The table On Chip Bus Master TAG Assignments was adapted (SDMA TAG added, LFI TAGs removed, **Page 4-103**)

4.2 SRI Crossbar (XBar_SRI)

4.2.1 Introduction

The Shared Resource Interconnection (SRI) is the new high speed system bus for TriCore1.6 CPU. The central module of the interconnect is the XBar_SRI which connects all components in one SRI system. The XBar_SRI handles, arbitrates and forwards the communication between all connected SRI-Master and SRI-Slave peripherals.

The XBar_SRI supports parallel transaction between different SRI-Master and SRI-Slave peripherals. It supports also pipelined requests from the SRI-Master interfaces and pipelined address phases to the connected SRI-Slave interfaces.

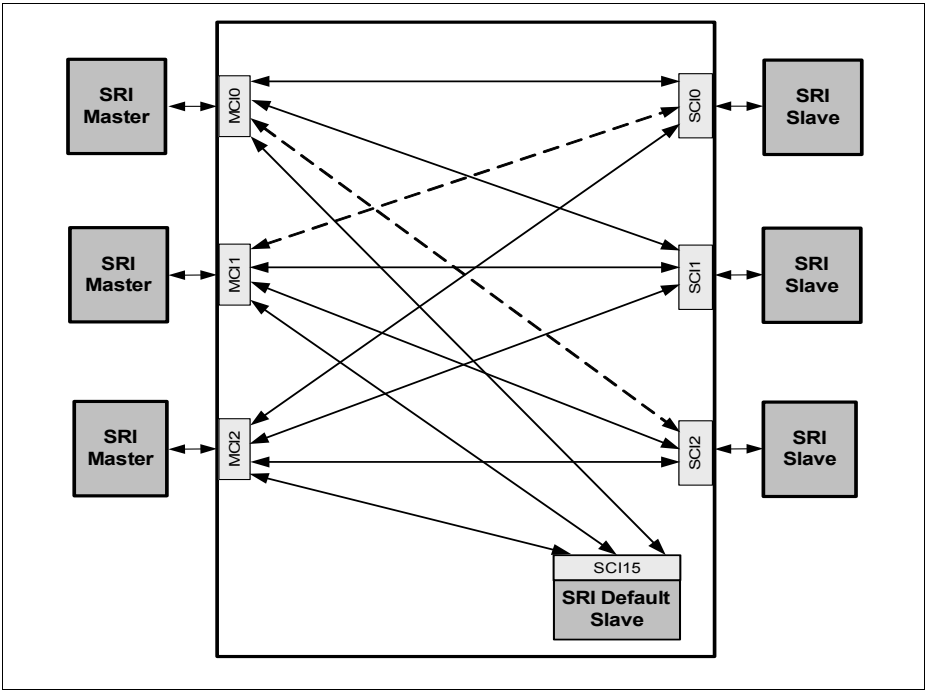

Figure 4-2 XBAR_SRI point to point connection scheme

The XBar_SRI provides SRI Slave Interfaces (SCIx) to connect SRI Slave modules and SRI Master Interfaces (MCIx) to connect SRI Master models to the XBar_SRI. The XBar_SRI includes an Default SRI Slave that provides access to the XBar_SRI control registers and that takes over all SRI transactions to address outside the connected SRI

Slave address ranges. The XBar_SRI includes also one Arbiter module per connected SRI slave module and the infrastructure for the enabled read/write data paths. Each connected SRI slave module as well as the default slave have an related arbiter module within the XBar_SRI.

Please note that only these SRI-Master <-> SRI-Slave connections are implemented that are required for the system functionality (example: connection between PMI Master and PMI Slave is not implemented, see also **Table 4-8**).

For performance optimization the XBar_SRI includes arbitration schemes that allows to configure SRI master priorities for each SRI slave individually (arbiter functionality). For debug support on system level the XBar_SRI includes debug support for SRI-Error and SRI-Transaction ID errors (local SRI slave module support in the related arbiter, global control in the Default Slave) .

Table 4-1 SRI Bus Terms

Term	Description
Agent	An SRI agent is any master or slave device which is connected to the SRI Bus.
Master	An SRI master device is an SRI agent which is able to initiate transactions on the SRI.
Slave	An SRI slave device is an SRI agent which is not able to initiate transactions on the SRI. It is only able to handle operations that are dedicated to it by SRI CrossBar (XBar_SRI).
XBar_SRI	The SRI CrossBar (XBar_SRI) provides the interconnects between connected Master and Slaves. The XBar_SRI includes arbitration mechanisms and debug capabilities. The XBar_SRI has 16 Master Connection Interfaces (MCI0 - MCI15) to connect SRI master devices to it and 15 Slave Connection Interfaces (SCI0 - SCI14) to connect SRI slave devices to it.
MCI	Each Master is connected via one Master Connection Interface (MCI x, x = 0 ...15). The XBar_SRI control registers include control and debug informations related to the Master Connection Interfaces MCI x (x = 0 ... 15).
SCI	Each Slave is connected via one Slave Connection Interface (SCI x, x = 0 ...14). The XBar_SRI control registers include control and debug informations related to the Slave Connection Interfaces SCI x (x = 0 ... 14). The XBar_SRI default slave is connected to SCI 15.

4.2.1.1 XBar_SRI Features

XBar_SRI feature overview:

- Single/Block Data Read Transaction Support (8/16/32/64 Bit)
- Single/Block Data Write Transactions Support (8/16/32/64 Bit)
- Read Modify Write Support
- Supports pipelined requests from SRI master peripherals
- Supports pipelined address phases to SRI slave peripherals
- Single arbiter module for each connected Slave device
- Arbitration priority scheme can be configured for each Slave device individually
- Flexible arbitration schemes (priority, two round robin groups, starvation prevention)
- Breakpoint signal generation based on SRI transactions (OCDS Level 1)
- Configurable MCDS trace interface
- Information integrity support for SRI address phase and read data path through the SRI interconnect.

4.2.2 SRI Transactions

Each SRI transaction consists of:

- one request phase
- one or multiple data phases if not finished with error acknowledge

Due to the point to point nature master/slave connections of the XBar a master that is requesting for access to one SIR slave peripheral is providing all transaction information in parallel with the request. This means that there are no separate on chip bus request and on chip bus address phases. An SRI request/address phase consists of:

- request signal
- lock signal (indicating a read modify write transaction)
- 32-bit address
- 4-bit SRI Op-Code (kind of single data or burst transaction)
- read/write signal (read, write or read modify transaction)
- supervisor mode signal
- Transaction ID (consists of a unique 6-bit Master TAG ID and a 2 bit running number increased for each new transaction of this master)
- 8-bit address phase ECC (covering all address phase signals with the exception of request and grant)
- one or multiple data phases if not finished with error acknowledge

After the request for a slave access was granted by the related XBar_SRI arbiter module, the transaction can be either finished with error acknowledge or with the read/write data phases as defined during the request/address phase.

Each data phase ends with the transmission of data phase informations including:

- Read or Write Transaction ID (must be equal to the related Transaction ID otherwise the address phase is invalid)

- 8-bit read/write data ECC (covering the 64-bit read/write data and the bits [23:3] of the related address.
- 64 bit read or write data. In case of an 8-bit, 16-bit or 32-bit read/write transaction the unused bits are filled with ´don't care´ data. The read/write data ECC covers the 64 data bits as transferred (incl. the possible don't care data).

4.2.3 SRI Op-Codes

The SRI Op-Code defines for a SRI transaction the number of data phases, the addressing mode in case of a multi beat transaction and valid bytes in case of a single data transaction.

Table 4-2 Operation Code Encoding

sri_opc[3:0]	Identifier	Description
0000	SDTB	Single Data Transfer Byte (8 bit)
0001	SDTH	Single Data Transfer Half-Word (16 bit)
0010	SDTW	Single Data Transfer Word (32 bit)
0011	SDTD	Single Data Transfer Double-Word (64 bit)
0100	-	Reserved
0101	-	Reserved
0110	-	Reserved
0111	-	Reserved
1000	BTR2	Block Transfer Request (2 transfers) Wrap Around Address Mode is used.
1001	BTR4	Block Transfer Request (4 transfers) Wrap Around Mode is used.
1010	BTRL2[1)]	Block Transfer Request (2 transfers) Linear Address Mode is used.
1011	BTRL4[1)]	Block Transfer Request (4 transfers) Linear Address Mode is used.
1100	-	Reserved
1101	-	Reserved
1110	-	Reserved
1111	-	Reserved

1) The SRI implementation in the TC1798 does not support bursts with linear addressing modes.

4.2.4 SRI Error Conditions

The sri_err_n signal is used by the slave during a transaction to signal the corresponding master that an error has happened which results in an immediate termination of the current transaction. Errors during transaction are tracked by the XBar_SRI and are signalled to via an interrupt and directly to the SMU.

Only the following error conditions are supported and recognized by SRI slaves:

- access level is incorrect (user/supervisor)
- unmapped address access from an SRI master[1)]
- unsupported op-code
- reserved op-code

An SRI error can be generated by the application SW e.g. with an access to a reserved address (see chapter Memory Map):

4.2.5 SRI Transaction ID Error Conditions

Transaction ID is an identifier connected to all phases of a transaction in order to make the transaction unique in the SRI system during the transactions live time.

The transaction ID is used by SRI masters and slaves to identify problems in the SRI system that results in data packets received by a master or slave that do not match the corresponding arbitration/address phase. If the read/write transaction identifier doesn't match with the previous send transaction identifier in the address phase, this is identified as a transaction ID error and tracked by the XBar_SRI.

In situations where at the data source side (master for write transactions, slave for read transactions) a data phase has to be invalidated (e.g. detection of an not correctable SRAM ECC error) and invalid transaction ID is send in order to invalidate the data phase.

An SRI Transaction ID error condition can be generated by injecting an non correctable error into one of the SRAMs (e.g. CPU Instruction Scratch Pad SRAM) and than reading the corrupted data by a CPU.

1) The accesses to unmapped slaves is checked by a default slave.

4.2.6 Operational Overview

This chapter describes the functionality of the XBar_SRI module in order to enable the user to configure the XBar_SRI control registers and to use the XBar_SRI debug resources.

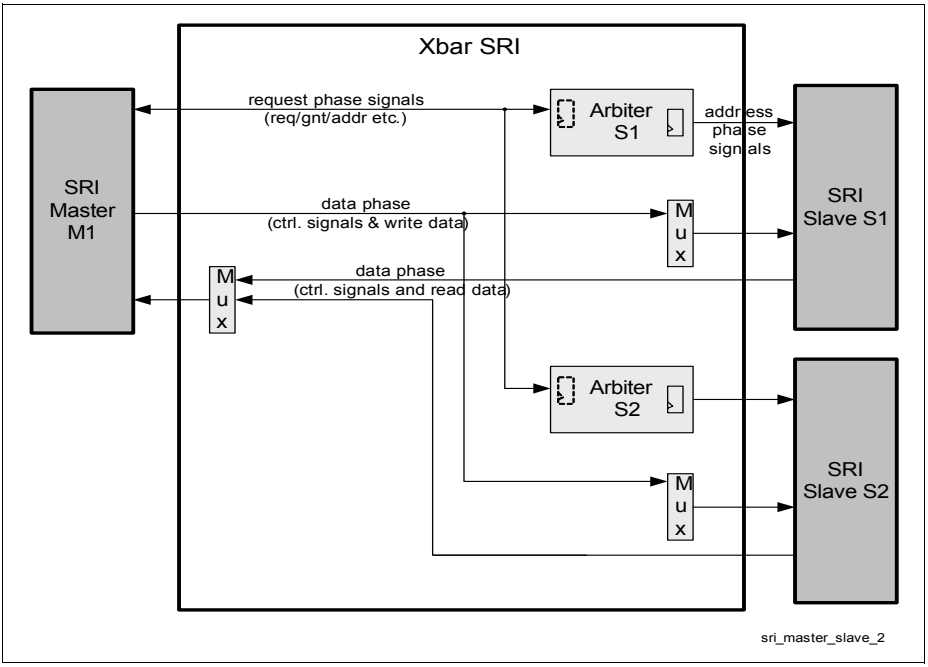

Figure 4-3 XBAR_SRI connections between SRI Master and SRI Slaves

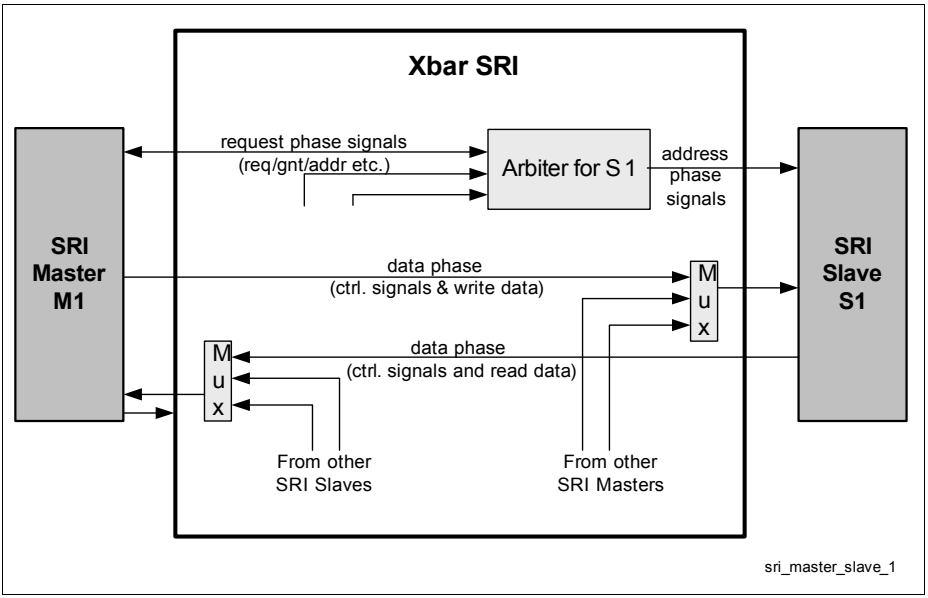

Figure 4-4 XBAR_SRI connections between SRI Slave and SRI Master modules

4.2.6.1 Functional Blocks

The XBar_SRI represents the highest level of the hierarchical SRI-Bus system. Since, it is closest to the TC1.6 core, peripherals critical to CPU performance can be attached to it.

The XBar_SRI module is partitioned into blocks for arbitration and data path control which are necessary for each XBar_SRI master- or slave interface and one block that covers the default slave - and debug functionality.

The XBar_SRI module can handle and process several transaction of different master in parallel if the masters requests different slaves.

XBar_SRI Master Connection Interface (MCI)

Each SRI master module in the system is mapped to one or more XBar_SRI Master Connection Interfaces (MCI). Each MCI is related within the XBAR_SRI module to a default arbitration priority and to register control bits and register control bit fields. So each SRI master in the system is mapped to an XBar_SRI internal default arbitration priority and to master related control register bits and bit fields via its MCI number (see also see also **Table 4-4** and **Table 4-6**).

XBar_SRI Slave Connection Interface (SCI)

Each SRI slave module in the system is mapped to one XBar_SRI Slave Connection Interfaces (SCIx). Each SCI is related within the XBAR_SRI module to one arbiter module with its arbiter module control register and to register control bits and register control bit fields related to this SCIx. So each SRI slave module in the system is mapped to an XBar_SRI internal arbiter module and to slave related control register bits and bit fields via its SCI number (see also see also **Table 4-7**).

XBar_SRI Arbiter

Each XBar_SRI slave connection interface is mapped to exactly one dedicated instantiation of the slave arbiter module in the XBar_SRI. This module includes all required functionality for the following tasks:

- Arbitration: the module includes all required functionality for the arbitration. This includes SRI address decoding, SRI request arbitration, SRI request starvation algorithm, SRI address phase generation and control registers for the priority of the connected master connection interfaces and an FSM to detect the end of the current SRI transaction.
- Debugging: the module tracks the SRI transactions to the dedicated slave connection interface for SRI errors. The transaction information of the first transaction where the SRI protocol error is captured in arbiter internal control registers.
  The module tracks the requests from all masters to detect starvation of masters in the arbitration rounds.
- Error signalling: The first SRI error or starvation error is signalled to the default slave module via two sideband signals.
- XBar_SRI control bus interface: the module has a slave interface to the XBar_SRI control bus. The slave arbiter decodes the address of each new control bus transaction and, if addressed, processes the read/write transaction to the module internal control registers.

Default Slave

The XBar_SRI default slave module is a XBar_SRI internal SRI slave module with its own, dedicated arbiter module inside the XBar_SRI. For accesses to the XBar_SRI control registers only SRI single data transactions of word size are supported. Any other op-code that is SRI protocol legal is not supported by the default slave module. Such transactions are acknowledged with an error by the default slave to the SIF_SRI. The default slave module includes all required functionality for the following tasks:

- As a SRI default slave, it deals with all transactions that are directed to a nonexisting slave in the SRI system as it is described in the SRI protocol. The purpose of the SRI default slave in that situation is to guarantee a defined behavior by terminating these SRI transactions with an error.

- The XBar_SRI default slave module is the SRI interface to all XBar_SRI internal diagnostic- and control registers.
- The XBar_SRI default slave module samples the mci_id_err_n and sci_id_err_n signals from all XBar_SRI master and slave connection interface modules. If the default slave module detects mci_id_err_n and sci_id_err_n pulses it generates an interrupt to the system. The sampling of each mci_id_err_n and sci_id_err_n signal from an arbiter can be disabled via the default slave interrupt control register IDINTEN.
- The XBar_SRI default slave module includes the interrupt node control structure and the corresponding control register.

4.2.7 Functional Overview

4.2.7.1 Arbitration Block

The arbiter has access to all arbitration-/address phase signals from the master connector interfaces he is enabled for, therefore he sees requests from all master connector interfaces in parallel.

In order to check if a master request is addressed to 'its' slave connector interface for the next transaction the arbiter checks if the address transmitted together with the request from the master matches with the allocated address area of this slave via address decoding. Due to the fact that a master can access any slave for a transaction all arbiters of the XBar_SRI are checking the requested address from a requesting master in parallel.

Due to the fact that multiple masters can request for one slave in parallel, each slave has to decode the addresses from all the master connector interfaces it is enabled for in parallel.

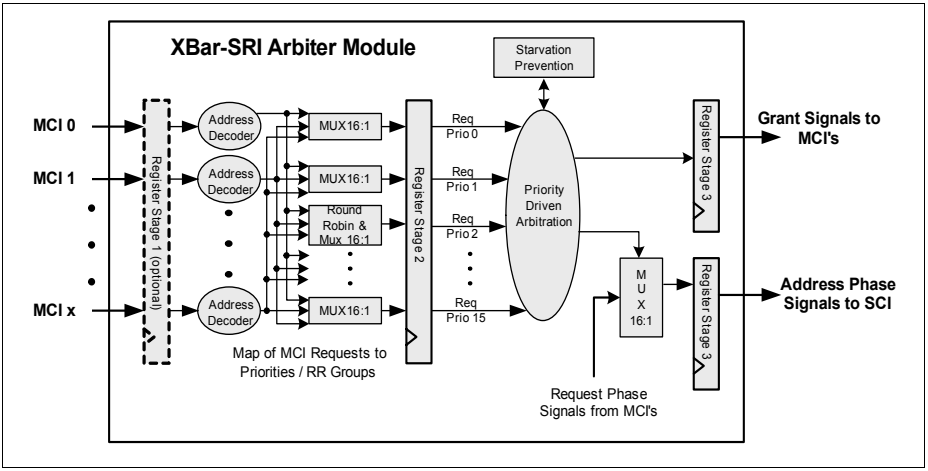

Figure 4-5 XBAR_SRI arbiter scheme

Address Map Checking

The arbiter performs the address comparison for all pending requests from the connected SRI master modules to its slave module in parallel.

Arbitration

A transaction request from a master that matches the address area of a slave connection interface takes part in the next arbitration cycle.

The arbitration is divided into two levels:

- priority driven arbitration
- arbitration within round robing groups (priority 2 and 8)

After reset each enabled master connector interface has a unique priority for the arbiters by default see (also see also **Table 4-4**). The priorities and the priority algorithm of the master connection interfaces can be programmed for each arbiter individually. The programming of the master priorities can be done by SRI read/write transaction via the default slave module.

The highest priority for an arbiter is 0 and the lowest is 15.

According to the transaction rules described in the SRI protocol specification the arbiter asserts the sri_gnt_x signal to grant the slave to this winning master.

In parallel - or after granting the master, the arbiter sends the address phase for the next transaction to the slave by propagating all necessary informations via the slave connection interface to the slave. The arbiter sends the address phase in parallel with the grant or delayed depending on the address phase pipeline status of the corresponding SRI slave.

For debug purposes, the arbiter samples all necessary transaction informations and provides them to the XBar_SRI default slave module if an SRI error happened and the protocol error feature was enabled.

Arbitration Algorithms

The arbiter related to a slave connection interface (SCI) can be connected to all master connection interfaces (MCI), see also **Chapter 4.2.8.3**. The priority of each MCI can be controlled via the arbiter priority registers (PRIOx). The priority of a master is defined by 4 bit field in the PRIOL / PRIOH register that is related to this master / its MCI number. This can be configured individually for each arbiter so the same master can be handled with different priorities for accesses to different slaves. After reset, each priority register has a default value, which means that each MCI has a unique default priority.

Please Note:

It must be ensured that two enabled masters don’t have the same priority, with the exception of priority 2 and priority 8 (round robin group priorities).

For changing the priorities during runtime (switching the priorities), all master connection interfaces that should be remapped have to be mapped to the round robin group priorities (2 / 8) before mapping them to their new priorities can be done. This will prevent situations where two masters have the same priority but not a round robin one.

Priority Driven Arbitration

The general arbitration algorithm is priority driven where priority 0 is the highest priority and 15 the lowest one. If multiple masters are requesting for one slave, the master with the highest priority will win the next arbitration round (see also 'starvation prevention').

Round Robin Groups

The arbiter arbitrates in general priority driven, where Priority 2 and priority 8 contain a second 'arbitration' layer. Both priorities can be used as round robin priorities for a group of max. 8 MCI's each. If only one master is mapped to a round robin group priority, the master's request will be treated as normal master request with the priority of the round robin group. If more than one master is mapped to the priority of a round robin group, the requests of the mapped masters will be handled by the round robin algorithm, the winning request of the round robin group arbitration has the priority of the round robin group within the priority driven arbitration.

After the winner of a round robin group is granted, the round robin group starts with a new arbitration round which means the requesting MCI's of the round robin group with the next highest MCI ID number will win the next round robin arbitration round. If there is no requesting MCI with a higher ID number in the round robin group, the algorithm will start with the MCI with the lowest MCI ID number that is mapped to the group, going to the next higher MCI ID number and so on.

Request Latency

If no other request is pending, a request from an MCI has a latency of 1 clock cycle, starting with the detection of the SRI master request on the bus, ending with the SRI grant to the requesting MCI and the SRI address phase to the addressed SCI.

Usually address decoding, round robin arbitration, priority driven arbitration and starvation prevention will be done in one clock cycle.

Table 4-3 XBar_SRI Request Latency

Clock Cycle Nr.:	Task(s)
0 (Default Slave)	sri_req_n is sampled at XBar_SRI MCI (Only valid for access to the XBar_SRI control registers)
1	address decoding, mapping of MCI's to priorities / round robin groups and starvation prevention. Round robin arbitrations, priority driven arbitration, mux request phase signals to the address phase registers masking sri_req_n from MCIx after granting the MCIx
2	sri_gnt_n to the requesting MCI, SRI address phase to SCI.

Grant -> New Request Latency (Request Dead Time)

After an MCI was granted, it takes 2 clock cycles before a new request from the same MCI will participate in a new arbitration round even when the SRI master has requested permanently. This request dead time is a result of the synchronous sri_req_n de-assertion and the XBar_SRI request latency.

Default MCI x Priorities after Reset

After Reset each Master has a default priority which is equal to the number of the Master Connection Interface (MCI x, x = 0 ... 15) it is connected to. MCI0 is configured with the highest priority and MCI15 with the lowest priority. **Table 4-4** shows the default priority of the MCI with the related coding in the **XBAR_PRIOLx (x = 3-6)** registers. After reset, the priority scheme of the MCIs can be re-configured via the **XBAR_PRIOLx (x = 3-6)** registers, for each SCI (accesses to the Slave connected to an SCI) individually.

Table 4-4 Default MCI Priority in the XBar_SRI Arbiters

Priority	Coding	Round Robin Group	Default Mapping:	Comments
0	0000	-	MCI 0	
1	0001	-	MCI 1	
2	0010	Yes, max 8 master	MCI 2	Maximal 8 MCI can be mapped to the priority 1 e.g. can have the prio ’0001’.
3	0011	-	MCI 3	
4	0100	-	MCI 4	
5	0101	-	MCI 5	
6	0110	-	MCI 6	
7	0111	-	MCI 7	
8	1000	Yes, max. 8 master	MCI 8	Maximal 8 MCI can be mapped to the priority 8 e.g. can have the prio ’1000’.
9	1001	-	MCI 9	
10	1010	-	MCI 10	
11	1011	-	MCI 11	
12	1100	-	MCI 12	
13	1101	-	MCI 13	
14	1110	-	MCI 14	
15	1111	-	MCI 15	

Starvation Prevention

Starvation can occur when masters with high priority continuously request a dedicated slave, preventing other masters with lower priority from getting access to this slave. To prevent such a situation, a starvation counter has been implemented in each arbiter. This mechanism allows the promotion of weak masters.

Each time the starvation counter in a slave module has and underflow, all pending requests to this arbiter will be entered in the arbiters request list. This even applies to all masters mapped to a round robin group.

Next time when the starvation counter has an underflow, the masters of this request list will be entered in the arbiters request promotion list if:

- The request was not granted during the last starvation period

The masters in that request promotion list will be the next to be granted independent of their priorities. The masters in the request promotion list will be granted one after the other, starting with the master which has the lowest MCI number in this list if there are more than one. The master promotion list has the highest priority within the arbiters main arbitration algorithm, therefore all masters in the promotion list will be granted before the arbiter switches back to its 'normal' arbitration. A master is removed from both lists when it is granted.

If several masters are mapped to a round robin priority, all masters of that round robin arbitration round will be entered in the request list/request promotion list when not granted.

The value controlling the counter period is programmable. After reset the starvation counter is disabled and has a value of zero. On a starvation counter underflow it is reloaded with the content of the arbiter control register ARBCON.SPC. An underflow occurs in the clock cycle when the counter tries to count down from zero.

The number of arbitration cycles a master must wait for the slave varies. But it's guaranteed to be no more than 2 $\times$ ARBCON.SPC until the master is promoted to the request promotion list.

Each time there is an underflow it is checked if there are any masters in the request promotion list that were not granted since the last underflow. This can happen if there are to many/to long transactions to be promoted compared to ARBCON.SPC value. In this case an error is generated via the xcb_sc_err_n signal to the default slave if the feature was enabled (bit ARBCONx.SCERREN set).

If currently a RMW transaction is processed the starvation counter is stopped before the next overflow. The starvation counter is released again after the address phase of the write part is generated or an error for the RMW transaction was received.

If currently a Read-Modify-Write (RMW) transaction is processed by the slave the starvation protection counter is stopped until this RMW is finished.

4.2.7.2 Default Slave

The default slave serves three features in the XBar_SRI implementation:

Control and Configuration Registers Interface

The XBar_SRI default slave module handles all read and write transactions to the debug- and control registers of the XBar_SRI. For this purpose, the default slave module has its own address space which must be mapped into the system address space by an address decoder, provided by the customer.

For a detailed description of the registers see **Chapter 4.2.9**.

Non Existing Addresses

The XBar_SRI internal default slave module has its own arbiter module.

If an SRI master sends a request with a non existing address[1)] to the XBar_SRI, the transaction will be directed to the default slave. The default slave finishes the transaction with error following the SRI protocol rules, which activates the error tracking mechanism of the arbiter. As a result of the error, the default slave module signals this incorrect behavior to the system by generating an interrupt.

A write from an SRI master to a non existing address on the System Peripheral Bus (SPB) will be handled by the Bus Control Unit on the SPB only. A read from an SRI master to a non existing address on the SPB will be handled by the by the Bus Control Unit on the SPB and also captured by the XBar_SRI arbiter as it will see the transaction as read transaction finished with Error Acknowledge.

Error Handling

If an arbiter detects an SRI protocol error during a transaction with a corresponding slave the involved arbiter samples all relevant information of the transaction in the arbiter internal diagnostic registers (ERRADDRx and ERRx) and signals this event via xcb_sri_err_n or xcb_sri_err_d_n sideband signal to the default slave module.

Note: The two error registers ERRx and ERRADDRx in each arbiter are updated with the content of the currently processed transaction in the data phase. The registers are only updated if they are not locked due to a pending protocol error and sri_ready_n was asserted in parallel with sri_err_n deasserted.

The error capture registers in the arbiter can't be changed until the interrupt was acknowledged to the slave arbiter module (set the ARBCON.INTACK) via the default slave.

1) non existing address = all Reserved address ranges described in the Memory Map chapter

The stored informations can be read from the default slave module with SRI single data read transactions, the acknowledge can be sent to the default slave via a write to a specific address.

This can result in a loss of interrupt data information of the same source beyond the first until the write was processed but as all SRI errors must be analyzed and fixed before the product will work, these kind of errors can be analyzed one after the other.

In case that a master or a slave signals an ID error to the XBar_SRI the default slave marks the source of the ID error by setting the according bit in register IDINTSAT if this feature was enabled for that specific master and/or slave interface.

As a result, the default slave generates an interrupt to the system.

Note: While a status bit for a error source is set in either the INTSAT or IDINTSAT register a new error from this particular source doesn't generate a new interrupt.

1. *Each participant in the SRI-Bus system has three interrupt sources; protocol errors, ID errors and time-out due to starvation. All error from the SRI-Bus components are combined in the single SRN of the XBar_SRI.*

Each arbiter has two 32 bit registers containing the error information. This registers are accessed as all other registers, via the default slave module.

The default slave module has one service request node (SRN) to start interrupts for detected SRI errors. Protocol errors, starvation errors as well as ID errors are handled together by this node.

4.2.7.3 SRI ECC Error Handling

The SRI protocol provides ECC protection for the:

- Address phase of an SRI transaction
- Read Data transmitted during read data phases

If an SRI slave detects an SRI address phase ECC error it finishes the transaction with SRI error acknowledge and does not further process it (see also **Chapter 4.2.7.4**).

It can happen that a data during a transaction shows an ECC error inside the data source peripheral (master during write, slave during read). Example: A burst read transaction from a memory slave peripheral where the second, third or forth data taken from the SRAM shows inside the slave/master an ECC error. In this situation a slave can finish a read transaction with error acknowledge (if the error is detected before the first data phase) or a slave / master can invalidate the related data phase with an invalid read / write transaction ID error (see also **Chapter 4.2.7.4**).

A master that detects an SRI read data ECC error is free to decide how it handles the situation:

- PMI and DMI: a bus error trap will be generated but only if and when a received 64 bit read data is really used by the CPU. This as PMI / DMI can read complete cache

lines (4x64 bit) where the critical 64 bit is used, the other 3 x 64 bit are speculative reads and might not be used by the CPU later.
- DMA: the DMA ignores read data ECC in this product. Background is that the SRI ECC was introduced for the safe instruction fetch path.
- SFI: the SFI SRI master ignores the read data ECC. Background is that the SRI ECC was introduced for the safe instruction fetch path.

Most of the SRI peripherals are signalling detected SRI ECC errors also to the SCU:

- PMI and DMI: detected SRI ECC errors are signalled to the SCU via the still available ECC error signals (to the SCU). More details (SRI Address Phase ECC Error or SRI ECC Read Data Error) can be found in the PMI / DMI control registers.
- EBU: signals detected SRI Address Phase ECC Errors to the SCU.
- LMU: signals detected SRI Address Phase ECC Errors to the SCU. More details (SRI Address Phase ECC Error or SRAM ECC Error) can be found in the LMU control registers.
- PMU and SFI SRI slave: no signalling of detected SRI Address Phase ECC Errors to the SCU.

4.2.7.4 Error Tracking Capability

The XBar_SRI tracks all SRI transactions for SRI protocol errors. Additionally it tracks informations about starvation errors and SRI transaction ID errors. This is done by all arbiters and the default slave in parallel as the XBar_SRI supports the processing of multiple transactions from master and slaves in parallel which can result in parallel events at different slave connector interfaces.

For this purpose, each arbiter has two error/debug registers where it samples the transaction informations of the transaction where the first protocol error happened.

Note: Protocol errors and debug trigger events can lock the error/debug registers. Only the first event of both sources can lock the registers. All other events are not captured with this two error/debug registers unless the lock was released in the meantime.

Further protocol errors will be ignored by an arbiter that has detected an protocol error until the tracking mechanism is re-activated via the arbiter internal control register. A detected protocol error or starvation error is signalled by the arbiter to the default slave module via two separate sideband signals for SRI- and starvation error. The default slave samples the sideband signals pulses in an error status register INTSAT. As each slave has its own sideband signals, the default slave has the information which arbiter has detected an SRI protocol or starvation error. Each error signal can be masked individually by control registers in the arbiter modules. All debug registers are accessible via the SRI-Bus interface of the default slave.

For transaction ID errors of write transactions the SCI propagates the sci_id_err_n signal via the sri_wr_tr_id_err signal from the slave to the default slave module. The default slave sets the assigned bit in register IDINTSAT.

For transaction ID error of read transactions the MCIs propagate the sri_id_err_n signal via the sri_rd_tr_id_err signal from the master to the default slave module. The default slave sets the assigned bit in register IDINTSAT.

Once an error was signalled from an arbiter or an MCI/SCI to the default slave, the default slave module sends an interrupt request to the system. The system can read out the error status registers in the default slave module to find out which arbiter(s) or master/slave have detected an error, then the system can start with more detailed diagnostics by reading out the error/debug registers in the arbiter for a protocol error. The error informations captured for an SRI protocol error allows the identification of the master via the sampled master tag ID and the final destination via the sampled target address. Additionally the arbiter samples the op-code and the sri_rd_n, sri_wr_n and sri_svm control signals of the transaction.

In addition to the SRI transaction information, the XBar_SRI captures sideband signal informations (**XBAR_ERRx (x = 0-6)**.MCI_SBS and **XBAR_ERRD**.MCI_SBS). In the TC1798 these sideband signals are used by the DMA SRI master interface to provide informations about the requestor of a transaction, in parallel to the SRI request phase. **Table 4-5** shows the encoding of the MCI_SBS bit field for the encoding of the TC1798.

Table 4-5 Encoding of ERRx.MCI_SBS in the TC1798

MCI_SBS[7:0]	Bit field encoding
MCI_SBS[2:0]	000_B DMA Channel 0 001_B DMA Channel 1 . . . 110_B DMA Channel 6 111_B DMA Channel 7 This bit field is only valid if MCI_SBS[7:3] shows the Move Engine 0 or Move Engine 1 encoding.
MCI_SBS[7:3]	00000_B Reserved 00001_B Move Engine 0 00010_B Move Engine 1 00011_B MLI 0 00100_B MLI 1 00101_B Cerberus Others -> Reserved

After reading all relevant error informations, the error/debug tracking mechanism can be reactivated.

4.2.7.5 Debug Trigger Event Generation (OCDS Level 1)

The goal is to generate breakpoints on selectable and configurable events in the SRI-Bus traffic. Inside the TriCore breakpoints are generated by the Cerberus module based in debug trigger event signals created by the several decentralized debug blocks in system.

The XBar_SRI module uses the xbar_brk_out_n signal for this purpose.

The generation of any debug trigger event signal has to be enabled by an asserted input signal ocds_enable. If this signal is deasserted no arbiter generate a debug trigger event independent of the selected configurations. The xbar_brk_out_n is driven with the default value in this case.

To enable the user to gain advantage of this feature in the needed way the debug event trigger selection and configuration is done via the three debug registers DBCON, DBADD and DBMADD and the three status registers DBSAT, ERR and ERRADDR.

All DBXXX registers reset only with the ocds_rst_n signal.

The register DBSAT collects all debug trigger events from all arbiters in the XBar_SRI module. When an arbiter generates a debug trigger event the according bit in register DBSAT is set. An arbiter signals a debug trigger event to the default slave via the xcb_db_evt_n signal.

The DBCON register defines the debug trigger event conditions for each arbiter individually. Several individual break conditions can be combined by enabling them in parallel. Possible break conditions are:

- Write transactions
  - If bit DBCON.WREN is set only transactions with an asserted sri_wr_n signal can generate a debug event.

Note: Only if DBCON.WREN and DBCON.RDEN are set together a RMW transaction generate a debug trigger event.

- Read transactions
  - If bit DBCON.RDEN is set only transactions with an asserted sri_rd_n signal can generate a debug event.

Note: Only if DBCON.WREN and DBCON.RDEN are set together a RMW transaction generate a debug trigger event.

- Supervisor mode transactions
  - If bit DBCON.SVMEN is set only transactions with an asserted sri_svm signal can generate a debug event.
- Transactions from a dedicated master
  - If bit DBCON.MASEN is set only transactions initiated by master DBCON.MASTER can generate a debug event.
- Transactions accessing a defined address area

– If bit DBCON.ADDEN is set only transactions accessing an address in the selected address area can generate a debug event. The selected address area is defined by the registers DBADD and DBMADD. Register DBADD defines one global 32-bit address that is compared with sri_addr[31:0] for all bits where DBMADDR is set to ’1’.

All enabled debug trigger conditions are combined by a logical AND.

Example: If DBCON.WREN and DBCON.SVMEN are set and all other enables are cleared a debug trigger event is only generated for a write transaction operating in the supervisor mode.

Additionally a debug trigger event is generated if DBCON.ERREN is set and an error occurs. Please note that an error occurs only when the generation for this source is enabled in the linked registers ARBCON or IDINTEN.

The result of the logical AND of the first five debug trigger event options is combined with the result of the error debug trigger event by a logical OR.

A debug event is signaled to the default slave. The default slave combines all XBar arbiter debug event signals with its own and generates the debug event signal that is sent to the Cerberus module.

The minimum length of debug event signal that is send out to the Cerberus module is adapted to the frequency of the Cerberus module. The debug event signal to the Cerberus will be asserted for as long as one at least one condition inside an XBar master module or the XBar default slave module is met at least.

Debug Trigger events inside the XBar_SRI are sampled in the register DBSAT. Additionally an interrupt can be generated for debug trigger events by the XBar_SRI.

When debug condition is reached in one of the XBar_SRI arbiter modules, informations of the transaction that matched to the debug condition is captured in the two error/debug capture registers ERRx and ERRADDRx. If the two registers are already locked due to an earlier action the capturing is not performed.

Writing to DBCON.REARM will rearm the feature, this also sets DBCON.ARM.

4.2.7.6 Interrupt and Debug Events of the XBar_SRI Module

There are some interactions between interrupt them self and debug events. In general due to the nature of the crossbar concept several interrupts from the same or a different source (arbiter, MCI or SCI) can occur. One interrupt could occur several times before a service request routine is initiate. Additionally can all interrupts occur in parallel to one or more debug trigger events.

All following examples assume a time interval without any acknowledge either from a service routine or a debug routine and all consecutive interrupts/events come from the same source.

Two Consecutive Protocol Errors

The first protocol error is captured as normal together with a generation of an interrupt to the system. The second protocol error is not captured as the two registers ERR and ERRADD are already locked and no interrupt is generated.

Two Consecutive Starvation Errors

The first starvation error generate an interrupt to the system. The second starvation error will not generate an interrupt to the system.

Two Consecutive Transaction ID Errors

The first transaction ID error generate an interrupt to the system. The second transaction ID error will not generate an interrupt to the system.

Two Consecutive Debug Trigger Events

The first debug trigger event is captured as normal together with a generation of debug trigger event signal to the system. The second debug trigger event is not captured as the two registers ERR and ERRADD are already locked and a debug trigger event signal is generated.

Protocol Error followed by a Debug Trigger Event

The first protocol error is captured as normal together with a generation of an interrupt to the system. The later debug trigger event is not captured as the two registers ERR and ERRADD are already locked and a debug trigger event signal is generated to the system.

Debug Trigger Event followed by a Protocol Error

The first debug trigger event is captured as normal together with a generation of debug trigger event signal to the system. The later protocol error is not captured as the two registers ERR and ERRADD are already locked and no interrupt is generated.

Starvation/Transaction ID Error followed by a Debug Trigger Event

The first starvation/transaction ID error generate an interrupt to the system. The later debug trigger event is captured to the two registers ERR and ERRADD and a debug trigger event signal is generated to the system.

Debug Trigger Event followed by a Starvation/Transaction ID Error

The first debug trigger event is captured as normal together with a generation of debug trigger event signal to the system. The later starvation/transaction ID error generates an interrupt to the system.

Releasing the Lock from registers ERR and ERRADD

If the ERR and ERRADD registers are locked only from one even only (protocol error or debug trigger event) the lock can be releasing by:

- Writing a one to ARBCONx.INTACK when the registers are locked by a protocol error
- Writing a one to DBCONx.REARM when the registers are locked by a debug trigger event

If both, a protocol error and a debug trigger event occurred since the lock was released the last time both locks have to be released

- Writing a one to DBCONx.REARM AND Writing and to ARBCONx.INTACK when the registers are locked by a debug trigger event AND a protocol error

4.2.8 Implementation of the Cross Bar (XBar_SRI) in the TC1798

This chapter describes the SRI Interconnect implementation in the TC1798. The knowledge of the specific implementation (e.g. the connection of the SRI master / slave devices to the Interconnect) is necessary in order to:

- map error informations to the connected slave devices
- define the arbitration scheme for accesses to the connected slave devices
- map XBar_SRI (arbiter) control registers to connected slave devices

This chapter includes three tables that are describing: the relationship (mapping) of

- the relationship (mapping) of TC1798 SRI master devices to the XBar_SRI Master Connection Interfaces MCI 0 - MCI 15 (**Table 4-6**)
- the relationship (mapping) of TC1798 SRI slave devices to the XBar_SRI Slave Connection Interfaces SCI 0 - SCI 15 (**Table 4-7**)
- the point to point connections between TC1798 SRI master and slave devices (**Table 4-8**)

4.2.8.1 Mapping of SRI Master Modules to XBar_SRI Master Interfaces

Table 4-6 shows the mapping of master devices to the XBar_SRI Master Interfaces (MCI 0 - MCI 15). Most of the XBar_SRI control registers are related to the XBar_SRI Slave Interfaces (SCI 0 - SCI 15) or the XBar_SRI Master Interfaces. Therefore it is important to know which TC1798 SRI master device relates to which XBar_SRI Slave Interface.

Example 1:

The XBar_SRI includes error registers where each MCI is represented with 1 bit, showing if during the transfers requested by the master devices connected to the MCI´s an error situation occurred (e.g. **XBAR_IDINTSAT**).

Example 2:

The XBar_SRI includes one arbiter module per connected SRI slave device. Each arbiter module includes a four bit field where the priority requests from connected MCI can be

defined. If the access priority of the DMI SRI master to one SRI slave device has to be changed, this can be done via the bit field related to MCI 4 in the arbiter control register related to this SRI slave (**XBAR_PRIOLx (x = 3-6)**, **XBAR_PRIOLD**).

Table 4-6 Mapping of TC1798 SRI master devices to MCI

XBar_SRI Master Connection Interface	Priority after Reset	Connected SRI master device
MCI 0	0	DMA SRI master interface, high priority
MCI 1	1	DMA SRI master interface, medium priority
MCI 2	2	DMA SRI master interface, low priority
MCI 3	3	SFI (PCP / SDMA access to SRI)
MCI 4	4	DMI
MCI 5	5	PMI
MCI 6 - MCI 15	6	-

4.2.8.2 Mapping of SRI Slave modules to XBar_SRI Slave Interfaces

Table 4-7 shows the mapping of slave modules to the XBar_SRI Slave Interfaces (SCI 0 - SCI 15). Most of the XBar_SRI control registers are related to the XBar_SRI Slave Interfaces (SCI 0 - SCI 15) or the XBar_SRI Master Interfaces. Therefore it is important to know which TC1798 SRI slave device relates to which XBar_SRI Slave Interface or arbiter module.

Example 1:

The XBar_SRI includes error registers where each SCI is represented with 1 bit, showing if during the transfers requested by the master devices connected to the MCI´s an error situation occurred (e.g. **XBAR_DBSAT**, **XBAR_IDINTSAT**, **XBAR_IDINTEN**).

Example 2:

The XBar_SRI includes one arbiter module per connected SRI slave device. Each arbiter module includes error capturing resources and breakpoint capabilities. These can be used e.g. to analyze accesses to the connected slave device that where answered with error acknowledge by the slave device (e.g. **XBAR_ERRx (x = 0-6)**, **XBAR_ERRADDRD**).

Table 4-7 Mapping of TC1798 SRI slave devices to SCI

XBar_SRI Slave Connection Interface (SCI)	Connected SRI master device
SCI 0	PMI (PSPR, PCache RAM)
SCI 1	DMI (DSPR, DCache RAM)
SCI 2	SFI (DMI access to devices on SPB)
SCI 3	PMU0
SCI 4	PMU1
SCI 5	LMU
SCI 6	EBU
SCI 7 - SCI 14	-
SCI 15	XBar_SRI Default Slave

4.2.8.3 TC1798 SRI Master / Slave Interconnection Matrix

Table 4-8 shows the SRI master to SRI Slave interconnects that are implemented in the TC1798. The not implemented SRI Master / Slave connections are redundant as they would not be used by the device and does therefore not restrict the functionality.

Table 4-8 TC1798 SRI Master / Slave Interconnection Matrix

XBar_SRI Master Connection Interface	DMA (MCI 0-2)	SFI (MCI 3)	DMI (MCI 4)	PMI (MCI 5)
PMI (SCI 0)	Yes	Yes	Yes	-
DMI (SCI 1)	Yes	Yes	-	Yes
SFI (SCI 2)	-	-	Yes	-
PMU0 (SCI 3)	Yes	Yes	Yes	Yes
PMU1 (SCI 4)	Yes	Yes	Yes	Yes
LMU (SCI 5)	Yes	Yes	Yes	Yes
EBU (SCI 6)	Yes	Yes	Yes	Yes
XBar_SRI (SCI 15)	Yes	Yes	Yes	Yes

4.2.8.4 Connection Master-Slave in XBar_SRI

As the SRI-Bus protocol is a point to point based bus implementation multiplexer inside the data paths in front of the MCIs and arbiter/SCIs are required (see **Figure 4-3** and **Figure 4-4**).

The write data path multiplexer in front of the SCIs are controlled by the related arbiter modules. The read data path multiplexers in front of the MCIs are controlled by all arbiters.

Master - and Slave side MUX

During an SRI transaction, the corresponding arbiter has to establish the data path connection from his slave connection interface to the corresponding master connection interface in order to enable the master to receive the SCI control signals , if it is a read transaction the read data, send by the slave.

4.2.9 SRI Crossbar Registers

Figure 4-6 and Table 4-9 are showing the address maps with all registers of the SRI Crossbar (XBar_SRI) module.

XBar_SRI Unit Register Overview

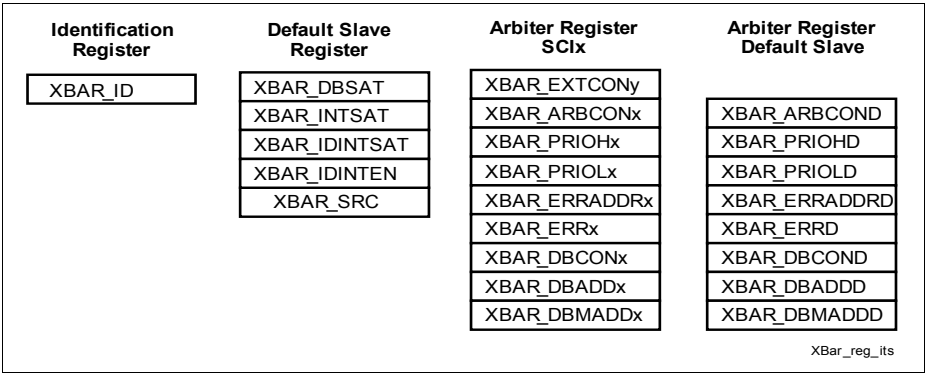

Figure 4-6 TC1798 Control Registers (x = 0 ... 6, y = 2)

Note: Addresses listed in column "Offset Address" of Table 4-9 are word (32-bit) addresses.

Note: XBar_SRI registers can be accessed only with SDTW (32 bit) transactions. 8, 16 bit and RMW transactions are not supported.

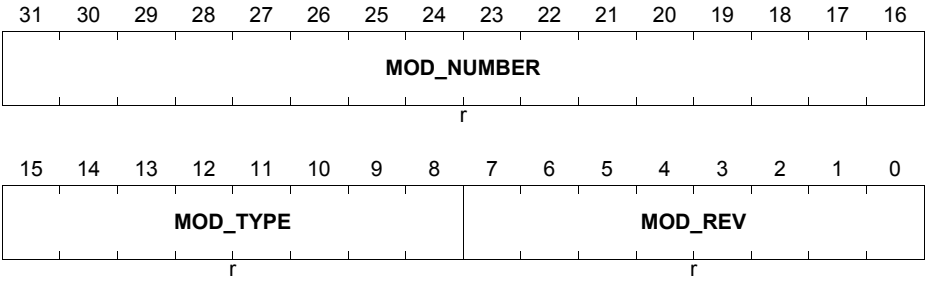
1) The absolute register address is calculated as follows:
Module Base Address (Table 4-10) + Offset Address (shown in this column)

2) This register is located inside the default slave

4.2.9.1 TC1798 Control Registers

The identification register allows the programmer version-tracking of the module. The table below shows the identification register which is implemented in the LBCU module.

XBAR_ID
Module Identification Register **(408_H)** **Reset Value: 0004 D0XX$_H$**



Field	Bits	Type	Description
MOD_REV	[7:0]	r	**Module Revision Number** This bit field defines the module revision number. The value of a module revision starts with 01_H (first revision).
MOD_TYPE	[15:8]	r	**Module Type** The bit field is set to $C0_H$ which defines the module as a 32-bit module.
MOD_NUMBER	[31:16]	r	**Module Number Value** This bit field defines a module identification number. The value for the LBCU module is $000F_H$.

XBAR_DBSAT

Debug Trigger Event Status Register ($40C_H$) **Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

ENSCID	15	rw	**Enable ID Error from Default Slave** 0_B No transaction ID error from the default slave is sampled 1_B A transaction ID error from the default slave is sampled
ENMCIn (n = 16-21)	n	rw	**Enable ID Error from MCIn** 0_B No transaction ID error from MCIn are sampled 1_B A transaction ID error from MCIn are sampled
0	[31:22], [14:7]	r	**Reserved** Read as 0; should be written with 0.

Note: Only the bits assigned to configured SCIs are implemented. Not implemented bits treated as reserved bits, read as ´0´, should be written with ´0´.

Note: Reset values for bits/bitfields coupled to masters or slaves that are not configured or enabled are zero.

XBAR_EXTCON2
External Control Register 2 **($0C0_H$)** **Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0							NOP DIS	RETRY_CNT				0			
rw							rw	rw				rw			

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MAXWS				0	NO RMW	NO DEL TR	0		FRE QDIS F	0	FRE QDIS S	WF WD	0		
rw				rw	rw	rw	rw		rw	rw	rw	rw	rw		

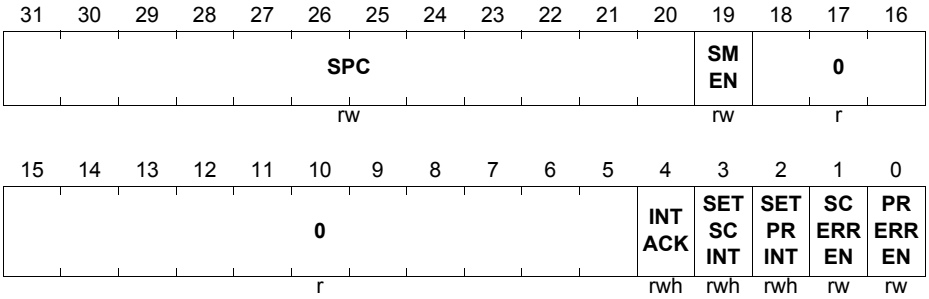
Field	Bits	Type	Description
WFWD	3	rw	**Wait for FPI Write Data** For FPI-Bus block write transfers the transaction request can be delayed until all write data arrived from the FPI-Bus in the SFI. As on thew FPI-Bus side very slow masters can resident SRI-Bus slaves can blocked for many SRI-Bus cycles if the write transaction is started with the first write data 0_B Write transactions on the SRI-Bus are requested with the first received write data from the FPI-Bus (default) 1_B Write transactions on the SRI-Bus are requested with the last received write data from the FPI-Bus
FREQDISS	4	rw	**Disable Fast Request Feature for SRI to FPI Transactions** 0_B Fast request feature is enabled (default) 1_B Fast request feature is disabled
FFREQS	5	rw	**Disable Fast Request Feature for SRI to FPI Transactions** 0_B Fast request feature is used normally (default) 1_B or all transaction automatically the fast request feature is used This bit is not used in TC1798 and is not connected to the SFI. Writing is possible and will change the bit nomal but has no impact to the SFI configuration

Field	Bits	Type	Description
FREQDISF	6	rw	**Disable Fast Request Feature for FPI to SRI Transactions** 0_B Fast request feature is enabled (default) 1_B Fast request feature is disabled
NODELTR	9	rw	**Control Signal for deferred transactions** 0_B Deferred Tranactions are generated (default) 1_B Deferred Tranactions are not generated
NORMW	10	rw	**Control Signal for deferred transactions** 0_B Deferred Tranactions are generated for RMW (default) 1_B Deferred Tranactions are not generated for RMW
MAX_WS	[19:13]	rw	**FPI-Bus Waitstait Retry Ratio** SIF-FPI retry after the programed value delayed transactions from the FPI-Bus. The value should be greater than 32, otherwise all transactions will be retired
RETRY_CNT	[23:20]	rw	**MIF_FPI Retry Idle Count** Number of clock cycles before MIF2_FPI repeats a transaction after a retry
NOPDIS	24	rw	**NOP-Inclusion Disable** 0_B NOP inclusion is used by SIF_FPI (default) 1_B NOP inclusion is disabled for SIF_FPI
0	[31:25], [19:16], 11, [8:7], 5, [2:0]	rw	**Reserved** Read as 0; should be written with 0.

Note: Only the bits assigned to configured SCIs are implemented. Not implemented bits treated as reserved bits, read as ´0´, should be written with ´0´.

Note: Reset values for bits/bitfields coupled to masters or slaves that are not configured or enabled are zero.

XBAR_ARBCONx (x = 0-6)
Arbiter Control Register x **(044_H+x*40_H)** **Reset Value: 0000 0003_H**
XBAR_ARBCOND
Arbiter Control Register D **(004_H)** **Reset Value: 0000 0003_H**



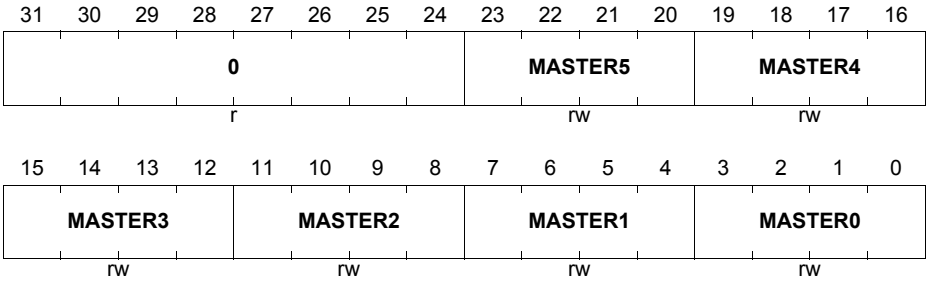
Field	Bits	Type	Description
PRERREN	0	rw	**SRI Protocol Error Enable** 0_B Protocol errors are not recognized and no information is captured. 1_B Protocol errors are recognized and information is captured.
SCERREN	1	rw	**SRI Starvation Error Enable** 0_B Starvation based errors are not recognized and no information is captured. 1_B Starvation based errors are recognized and information is captured.
SETPRINT	2	rwh	**Set SRI Protocol Interrupt** 0_B No protocol interrupt is generated 1_B A protocol interrupt is generated After the interrupt is generated by set the bit it's automatically cleared by the hardware
SETSCINT	3	rwh	**Set SRI Starvation Interrupt** 0_B No starvation interrupt is generated 1_B A starvation interrupt is generated After the interrupt is generated by set the bit it's automatically cleared by the hardware

Field	Bits	Type	Description
INTACK	4	rwh	**Interrupt Acknowledge** 0_B Default value 1_B An Error for this arbiter is pending. The ERRADDR and ERR registers are not updated for new errors. Writing a one to this bitfield while it's set have the following results: The error lock of registers ERRADDR and ERR are released and the register could be updated with the next interrupt request detected (see **Chapter 4.2.7.4**). In the cycle after the write action the hardware automatically clears the bit.
SMEN	19	rw	**Starvation Mode Enable** 0_B Starvation mode is disabled 1_B Starvation mode is enabled
SPC	[31:20]	rw	**Starvation Protection Counter Reload Value** The reload value defines the period for the starvation protection.
0	[18:5]	r	**Reserved** Read as 0; should be written with 0.

Note: Only the bits assigned to configured SCIs are implemented. Bits for non configured SCIs are treated as reserved bits.

Note: The ´D´ at ARBCOND stands for Default Slave.

XBAR_PRIOLx (x = 3-6)
Arbiter Priority Register x **($04C_H$+x*40_H)** **Reset Value: $0054\ 3210_H$**
XBAR_PRIOLD
Arbiter Priority Register D **($00C_H$)** **Reset Value: $0054\ 3210_H$**



Field	Bits	Type	Description
MASTER0	[3:0]	rw	**Master 0 Priority** (Priority of DMA High Priority access) This bitfield contains the master priority for the arbitration used by the arbiter of slave x. For each master a unique number for this slave has to be used. A lower number has a higher priority in the arbitration round than a higher one.
MASTER1	[7:4]	rw	**Master 1 Priority** (Priority of DMA Medium Priority access) This bitfield contains the master priority for the arbitration used by the arbiter of slave x. For each master a unique number for this slave has to be used. A lower number has a higher priority in the arbitration round than a higher one.
MASTER2	[11:8]	rw	**Master 2 Priority** (Priority of DMA Low Priority access) This bitfield contains the master priority for the arbitration used by the arbiter of slave x. For each master a unique number for this slave has to be used. A lower number has a higher priority in the arbitration round than a higher one.

Field	Bits	Type	Description
MASTER3	[15:12]	rw	**Master 3 Priority** (Priority of SFI access) This bitfield contains the master priority for the arbitration used by the arbiter of slave x. For each master a unique number for this slave has to be used. A lower number has a higher priority in the arbitration round than a higher one.
MASTER4	[19:16]	rw	**Master 4 Priority** (Priority of DMI access) This bitfield contains the master priority for the arbitration used by the arbiter of slave x. For each master a unique number for this slave has to be used. A lower number has a higher priority in the arbitration round than a higher one.
MASTER5	[23:20]	rw	**Master 5 Priority** (Priority of PMI access) This bitfield contains the master priority for the arbitration used by the arbiter of slave x. For each master a unique number for this slave has to be used. A lower number has a higher priority in the arbitration round than a higher one.
0	[31:24]	r	**Reserved** Read as 0; should be written with 0.

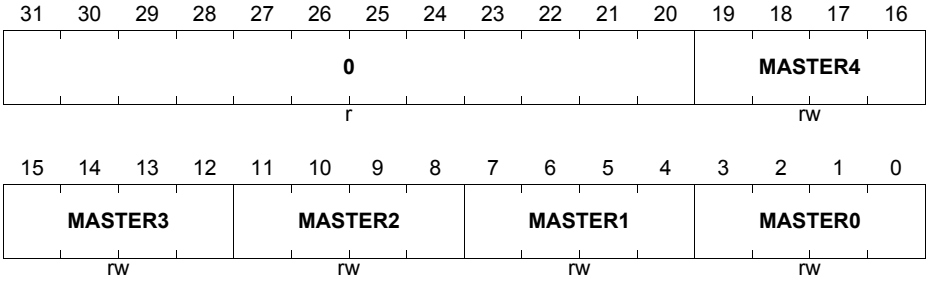
Note: Only the bits assigned to configured MCIs are implemented. Bits for non configured SCIs are treated as reserved bits.

Note: The ´D´ at XBAR_PRIOLD stands for Default Slave.

Note: Reset values for bits/bitfields coupled to masters or slaves that are not configured or enabled are zero.

XBAR_PRIOL0

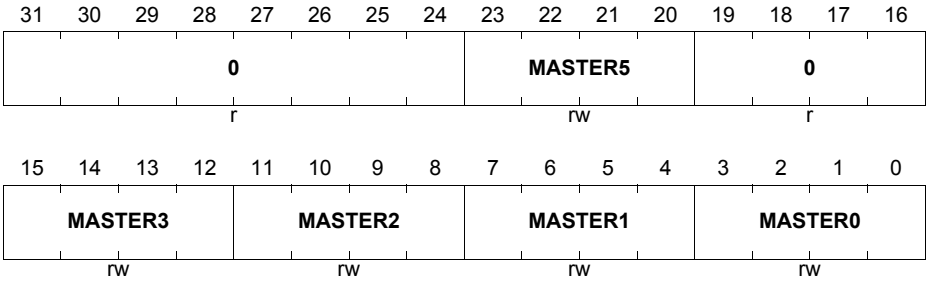
Arbiter Priority Register 0 **($04C_H$)** **Reset Value: $0004\ 3210_H$**



Field	Bits	Type	Description
MASTER0	[3:0]	rw	**Master 0 Priority** (Priority of DMA High Priority access) This bitfield contains the master priority for the arbitration used by the arbiter of slave x. For each master a unique number for this slave has to be used. A lower number has a higher priority in the arbitration round than a higher one.
MASTER1	[7:4]	rw	**Master 1 Priority** (Priority of DMA Medium Priority access) This bitfield contains the master priority for the arbitration used by the arbiter of slave x. For each master a unique number for this slave has to be used. A lower number has a higher priority in the arbitration round than a higher one.
MASTER2	[11:8]	rw	**Master 2 Priority** (Priority of DMA Low Priority access) This bitfield contains the master priority for the arbitration used by the arbiter of slave x. For each master a unique number for this slave has to be used. A lower number has a higher priority in the arbitration round than a higher one.

Field	Bits	Type	Description
MASTER3	[15:12]	rw	**Master 3 Priority** (Priority of SFI access) This bitfield contains the master priority for the arbitration used by the arbiter of slave x. For each master a unique number for this slave has to be used. A lower number has a higher priority in the arbitration round than a higher one.
MASTER4	[19:16]	rw	**Master 4 Priority** (Priority of DMI access) This bitfield contains the master priority for the arbitration used by the arbiter of slave x. For each master a unique number for this slave has to be used. A lower number has a higher priority in the arbitration round than a higher one.
0	[31:20]	r	**Reserved** Read as 0; should be written with 0.

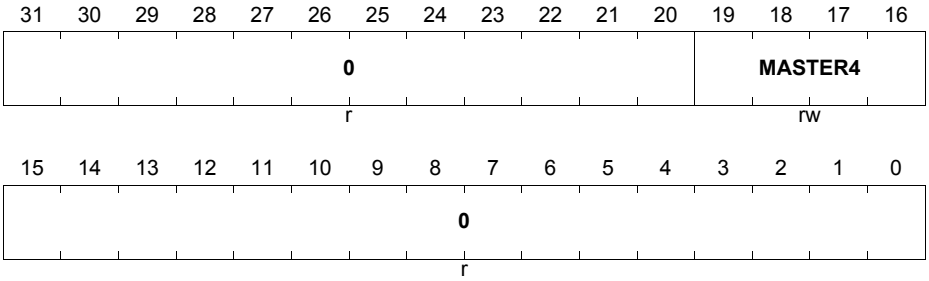
XBAR_PRIOL1
Arbiter Priority Register 1 **($08C_H$)** **Reset Value: $0050\ 3210_H$**



Field	Bits	Type	Description
MASTER0	[3:0]	rw	**Master 0 Priority** (Priority of DMA High Priority access) This bitfield contains the master priority for the arbitration used by the arbiter of slave x. For each master a unique number for this slave has to be used. A lower number has a higher priority in the arbitration round than a higher one.
MASTER1	[7:4]	rw	**Master 1 Priority** (Priority of DMA Medium Priority access) This bitfield contains the master priority for the arbitration used by the arbiter of slave x. For each master a unique number for this slave has to be used. A lower number has a higher priority in the arbitration round than a higher one.
MASTER2	[11:8]	rw	**Master 2 Priority** (Priority of DMA Low Priority access) This bitfield contains the master priority for the arbitration used by the arbiter of slave x. For each master a unique number for this slave has to be used. A lower number has a higher priority in the arbitration round than a higher one.
MASTER3	[15:12]	rw	**Master 3 Priority** (Priority of SFI access) This bitfield contains the master priority for the arbitration used by the arbiter of slave x. For each master a unique number for this slave has to be used. A lower number has a higher priority in the arbitration round than a higher one.

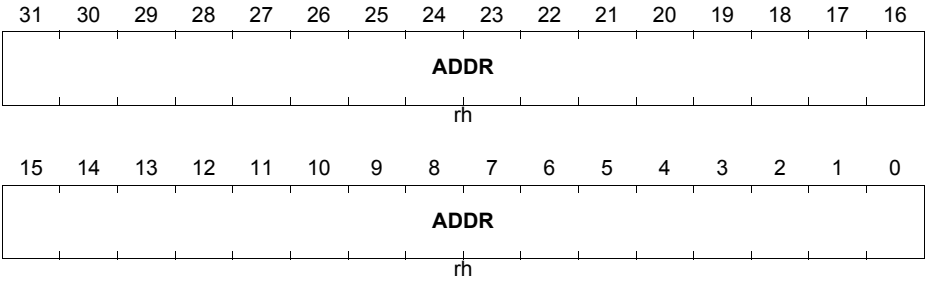
Field	Bits	Type	Description
MASTER5	[23:20]	rw	**Master 5 Priority** (Priority of PMI access) This bitfield contains the master priority for the arbitration used by the arbiter of slave x. For each master a unique number for this slave has to be used. A lower number has a higher priority in the arbitration round than a higher one.
0	[31:24], [19:16]	r	**Reserved** Read as 0; should be written with 0.

XBAR_PRIOL2
Arbiter Priority Register 2 **(0CC$_H$)** **Reset Value: 0004 0000$_H$**



Field	Bits	Type	Description
MASTER4	[19:16]	rw	**Master 4 Priority** (Priority of DMI access) This bitfield contains the master priority for the arbitration used by the arbiter of slave x. For each master a unique number for this slave has to be used. A lower number has a higher priority in the arbitration round than a higher one.
0	[31:20], [15:0]	r	**Reserved** Read as 0; should be written with 0.

XBAR_ERRADDRD
Error/Debug Address Capture Register D(010_H) **Reset Value: $0000\ 0000_H$**
XBAR_ERRADDR0
Error/Debug Address Capture Register 0(050_H) **Reset Value: $C000\ 0000_H$**
XBAR_ERRADDR1
Error/Debug Address Capture Register 1(090_H) **Reset Value: $D000\ 0000_H$**
XBAR_ERRADDR2
Error/Debug Address Capture Register 2($0D0_H$) **Reset Value: $F000\ 0000_H$**
XBAR_ERRADDRx (x = 3-6)
Error/Debug Address Capture Register x(050_H+x*40_H) **Reset Value: $8000\ 0000_H$**

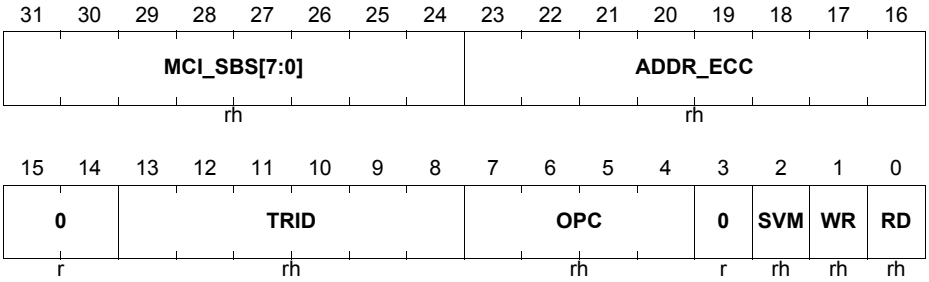


Field	Bits	Type	Description
ADDR	[31:0]	rh	**Transaction Address** This biffield contains the address of the erroneous transaction from the address phase

Note: The default value can differ from the one shown here because a constant can be used to reduce the number of compared bits in the arbitration if a slave occupies only a limited address area. For more details see the design specification of the XBar_SRI.

Note: The ´D´ at XBAR_ERRADDRD stands for Default Slave.

XBAR_ERRx (x = 0-6)
Error/Debug Capture Register x **(054_H+x*40_H)** **Reset Value: 0000 0000_H**
XBAR_ERRD
Error/Debug Capture Register D **(014_H)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
RD	0	rh	**Read Indication Status** 0_B The read indication SRI-Bus signal line was asserted 1_B The read indication SRI-Bus signal line was deasserted
WR	1	rh	**Write Indication Status** 0_B The write indication SRI-Bus signal line was asserted 1_B The write indication SRI-Bus signal line was deasserted
SVM	2	rh	**Supervisor Mode Indication Status** 0_B The supervisor mode indication SRI-Bus signal line was deasserted 1_B The supervisor mode indication SRI-Bus signal line was asserted
OPC	[7:4]	rh	**Operation Code** This bitfield contains the op-code of the erroneous transaction.

Field	Bits	Type	Description
TR_ID	[13:8]	rh	**Transaction ID** This bitfield contains the transaction ID of the erroneous transaction from the address phase. The Transaction ID is build out of an 4 bit unique TAG ID TR_ID[3:0] and a 2 bit running number TR_ID[5:4] (see also **Chapter 4.6**).
ADDR_ECC	[23:16]	rh	**SRI Address Phase Error Detection Information** This bitfield contains the Address Phase Error Detection Information of the erroneous transaction
MCI_SBS	[31:24]	rh	**MCI Sideband Signals [7:0]** This bitfield contains the MCI Sideband Signals [7:0] that are related to the address phase informations captured by the ERRD/ERRADDR registers. In the TC1798 the sideband signals are used by the DMA SRI master interface to provide information about the DMA requestor of a DMA transaction (for the encoding see **Table 4-5**).
0	[15:14], 3	r	**Reserved** Read as 0; should be written with 0

Note: The ´D´ at XBAR_ERRD stands for Default Slave.

XBAR_DBCONx (x = 0-6)
Debug Control Register x **(058_H+x*40_H)** **Reset Value: 0000 0000_H**
XBAR_DBCOND
Debug Control Register D **(018_H)** **Reset Value: 0000 0000_H**

4.3 Shared Resource Interconnect to FPI Bus Interface (SFI Bridge)

This section describes the basic functionality of the SFI Bridge.

4.3.1 Functional Overview

The SFI Bridge is a bi-directional bus bridge between the SRI Interconnect and the System Peripheral FPI Bus (SPB). The bridge supports all transactions types of both the SRI Bus and FPI Bus.

The bridge is transparent, this means that the address of a transaction and the master TAG of a bus master is forwarded to the other side of the bridge. Addresses are only changed by the bridge where it is required by the transaction conversion from the 64 bit SRI Interconnect to the 32 bit SPB.

In order to avoid deadlocks, priority is given to transactions initiated by the DMA on SPB or the PCP.

Bus Errors at Writes via the SFI Bridge

Write transactions are handled as posted writes. The SFI is able to buffer multiple posted writes. This means that a write operation from the SPB through the SFI Bridge to the SRI Interconnect can be finished on SPB and than generated on the SRI autonomously by the SFI. If this write operation results in a bus error on the SRI the Error information is not passed back to the SPB bus. This is also valid for transactions from SRI to SPB via SFI bridge. The bus error is detected by the on chip bus control logic of the target on chip bus system (BCU_FPI on the SPB, XBar_SRI on the SRI) which can generate an interrupt.

Note that this behavior occurs only at write operations via the SFI Bridge. It can also be triggered by an erroneous write cycle of a read-modify-write bus transaction.

4.4 System Peripheral Bus

The TC1798 has one on-chip FPI Bus:

- System Peripheral Bus (SPB)
  - System bus for on-chip peripherals

This section gives an overview of the on-chip FPI Bus. It describes its bus control units, the bus characteristics, bus arbitration, scheduling, prioritizing, error conditions, and debugging support.

4.4.1 Overview

The FPI Bus interconnects the on-chip peripheral functional units with the TC1798 processor subsystem.

The FPI Bus is designed to be quick to be acquired by on-chip functional units, and quick to transfer data. The low setup overhead of the FPI Bus access protocol guarantees fast FPI Bus acquisition, which is required for time-critical applications.

The FPI Bus is designed to sustain high transfer rates. For example, a peak transfer rate of up to 320 Mbyte/s can be achieved with the 32-bit data bus at 80 MHz bus clock. Multiple data transfers per bus arbitration cycle allow the FPI Bus to operate close to its peak bandwidth.

Additional features of the FPI Bus include:

- Optimized for high speed and high performance
- Support of multiple bus masters and pipelined transactions
- 32-bit wide address and data buses
- 8-, 16-, and 32-bit data transfers
- 64-, 128-, and 256-bit block transfers
- Central simple per-cycle arbitration
- Slave-controlled wait state insertion
- Support of atomic operations LDMST, ST.T and SWAP.W

The functional units of the TC1798 are connected to the FPI Bus via FPI Bus interfaces. An FPI Bus interfaces acts as bus agents, requesting bus transactions on behalf of their functional unit, or responding to bus transaction requests.

There are two types of bus agents:

- FPI Bus master agents can initiate FPI Bus transactions and can also act as slaves.
- Slave agents can only react and respond to FPI Bus transaction requests in order to read or write internal registers of slave modules as for example memories.

When an FPI Bus master attempts to initiate a transfer on the FPI Bus, it first signals a request for bus ownership to the bus control unit (SBCU). When bus ownership is granted by the SBCU, an FPI Bus read or write transaction is initiated. The unit targeted by the transaction becomes the FPI Bus slave, and responds with the requested action.

Some functional units operate only as slaves, while others can operate as either masters or slaves on the FPI Bus. In the TC1798, DMI and PMI (via the SFI Bridge), PCP, DMA (including Cerberus and MLI´s) and SDMA operate as FPI Bus masters. On-chip peripheral units are typically FPI Bus slaves.

FPI Bus arbitration is performed by the Bus Control Unit (SBCU) of the FPI Bus. In case of bus errors, the SBCU generates an interrupt request to the CPU and provides debugging information about the actual bus error to the CPU.

4.4.2 Bus Transaction Types

This section describes the SPB transaction types.

Single Transfers

Single transfers are byte, half-word, and word transactions that target any slave connected to SPB. Note that the SFI Bridge operates as an SPB master.

Block Transfers

Block transfers operate in principle in the same way as single transfers do, but one address phase is followed by multiple data phases. Block transfers can be composed of 2 word, 4 word, or 8 word transfers.

Note: In general, block transfers (2 word, 4 word, or 8 word) cannot be executed in the TC1798 with peripheral units that operate as FPI Bus slaves during an FPI Bus transaction.

Block transfers are initiated by the following CPU instructions: LD.D, LD.DA, MOV.D, ST.D and ST.DA. The BCOPY instruction of the PCP also initiates a block transfer transaction on the FPI Bus.

Atomic Transfers

Atomic transfers are generated by LDMST, ST.T and SWAP.W instructions that require two single transfers. The read and write transfer of an atomic transfer are always locked and cannot be interrupted by another bus masters. Atomic transfers are also referenced as read-modify-write transfers.

*Note: See also **Table 4-13** for available FPI Bus transfer types.*

4.4.3 Reaction of a Busy Slave

If an FPI Bus slave is busy at an incoming FPI Bus transaction request, it can delay the execution of the FPI Bus transaction. The requesting FPI Bus master releases the FPI Bus for one cycle after the FPI Bus transaction request, in order to allow the FPI Bus slave to indicate if it is ready to handle the requested FPI Bus transaction. This sequence is repeated as long as the slave indicates that it is busy.

Note: For the FPI Bus default master, the one cycle gap does not result in a performance loss because it is granted the FPI Bus in this cycle as default master if no other master requests the FPI Bus for some other reasons.

4.4.4 Address Alignment Rules

FPI Bus address generation is compliant with the following rules:

- Half-word transactions must have a half-word aligned address (A0 = 0). Half-word accesses on byte lanes 1 and 2 addresses are illegal.
- Word transactions must always have word-aligned addresses (A[1:0] = 00_B).
- Block transactions must always have block-type aligned addresses.

4.4.5 FPI Bus Basic Operations

This section describes some basic transactions on the FPI Bus.

The example in **Figure 4-7** shows the three cycles of an FPI Bus operation:

1. **Request/Grant Cycle:** The FPI Bus master attempts to perform a read or write transfer and requests for the FPI Bus. If the FPI Bus is available, it is granted in the same cycle by the FPI Bus controller.
2. **Address Cycle:** After the request/grant cycle, the master puts the address on the FPI Bus, and all FPI Bus slave devices check whether they are addressed for the following data cycle.
3. **Data Cycle:** In the data cycle, either the master puts write data on the FPI Bus which is read by the FPI Bus slave (write cycle) or vice versa (read cycle).

Transfers 2 and 3 show the conflict when two master try to use the FPI Bus and how the conflict is resolved. In the example, the FPI Bus master of transfer 2 has a higher priority than the FPI Bus master of transfer 3.

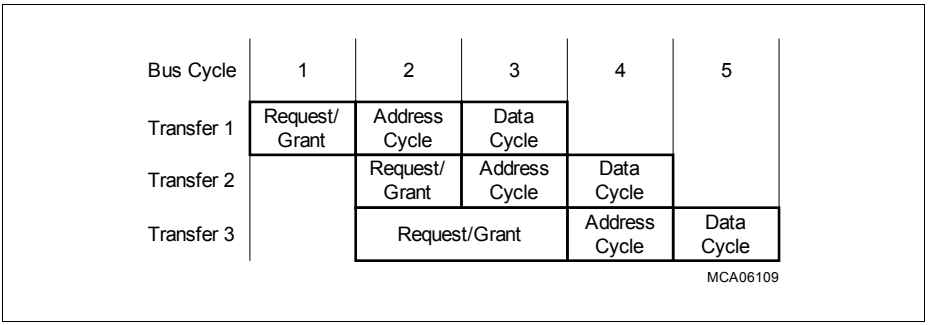

Figure 4-7 Basic FPI Bus Transactions

At a block transfer, the address cycle of a second transfer is extended until the data cycles of the block transfer are finished. In the example of **Figure 4-8**, transfer 1 is a block transfer, while transfer 2 is a single transfer.

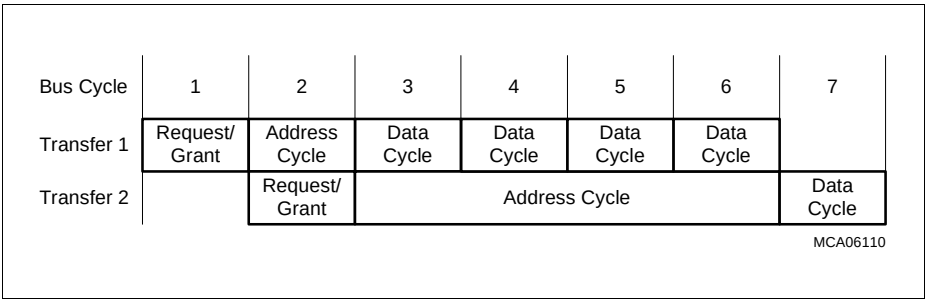

Figure 4-8 FPI Bus Block Transactions

4.5 FPI Bus Control Unit (SBCU)

The TC1798 incorporates one BCU for the SPB, called SBCU.

4.5.1 FPI Bus Arbitration

The arbitration unit of the BCU determines whether it is necessary to arbitrate for FPI Bus ownership, and, if so, which available bus requestor gets the FPI Bus for the next data transfer. During arbitration, the bus is granted to the requesting agent with the highest priority. If no request is pending, the bus is granted to a default master. If no bus master takes the bus, the BCU itself will drive the FPI Bus to prevent it from floating electrically.

4.5.1.1 Arbitration on the System Peripheral Bus

The TC1798 SPB has four bus agents that can become a SPB bus master (DMA, SFI, PCP, SDMA). Each agent is supplied an arbitration priority as shown in **Table 4-11**. DMA controller agent can be assigned to low, medium or high priority by software (via DMA Channel and OCDS control registers).

Table 4-11 Priority of TC1798 SPB Bus Agents

Priority	Agent	Comment
highest	Any bus requestor meeting the starvation protection criteria is assigned this priority	Highest priority, used only for starvation protection
	DMA, high priority	DMA requests from module: - OCDS high priority[1)] - DMA channel with high priority[2)]
	SDMA	
	Peripheral Control Processor (PCP)	Default master 0
	DMA, medium priority	DMA requests from module: - DMA channels with med. priority
	SFI Bridge	Default master 1
lowest	DMA, low priority	DMA requests from modules: - Cerberus low priority[1)] - DMA channels low priority[2)] - MLI

1) Priority of Cerberus transaction at the On Chip Busses is defined by the register bit IOCONF.FPI_PRIO. The register is defined in the OCDS chapter.

2) Priority of a DMA channel is defined by the corresponding CHCRmn.DMAPRIO bits. The registers are defined in the DMA chapter.

If there is no request from an SPB bus master, the SPB is granted to a default master (SFI Bridge or PCP) which has been at last the active master.

4.5.1.2 Starvation Prevention

Starvation prevention is a feature of the SBCU that can take care that even requesting low priority master agents will be granted after a period, where the period length can be controlled by SBCU control registers. Because the priority assignment of the SPB agents is fixed, it is possible that a lower-priority bus requestor may never be granted the bus if a higher-priority bus requestor continuously asks for, and receives, bus ownership. To protect against bus starvation of lower-priority masters, the starvation prevention mechanism of the SBCU will detect such cases and momentarily raise the priority of the lower-priority requestor to the highest priority (above all other priorities), thereby guaranteeing it access.

Starvation protection employs a counter that is decremented each time an arbitration is performed on the connected FPI bus. The counter is re-loaded with the starvation period value in the SBCU_CON.SPC bit field as long it is enabled SBCU_CON.SPE. When this counter is counted down to zero, for each active bus request a request flag is stored in the BCU. This flag is cleared automatically when a master is granted the bus.

When the next period is finished, an active request of a master from which the request flag was set, a starvation event happened. This master will now be set to the highest priority and will be granted service. If there are several masters to which this starvation condition applies, they are served in the order of their hard-wired priority ranking.

If a master that is processing its transaction under starvation condition is retried, its corresponding request flag is automatically again.

Starvation protection can be enabled and disabled through bit SBCU_CON.SPE. The sample period of the counter is programmed through bit field SBCU_CON.SPC. SPC should be set to a value at least greater than or equal to the number of masters. Its reset value is 40_H.

4.5.2 FPI Bus Error Handling

When an error occurs on an FPI Bus, its BCU captures and stores data about the erroneous condition and generates a service request if enabled to do so. The error conditions that force an error-capture are:

- Error Acknowledge: An FPI Bus slave responds with an error to a transaction.
- Un-implemented Address: No FPI Bus slave responds to a transaction request.
- Time-out: A slave does not respond to a transaction request within a certain time window. The number of bus clock cycles that can elapse until a bus time-out is generated is defined by bit field SBCU_CON.TOUT.

When a transaction causes an error, the address and data phase signals of the transaction causing the error are captured and stored in registers.

- The Error Address Capture Register (SBCU_EADD) stores the 32-bit FPI Bus address that has been captured during the erroneous FPI Bus transaction.

- The Error Data Capture Registers (SBCU_EDAT) stores the 32-bit FPI Bus data bus information that has been captured during the erroneous FPI Bus transaction.
- The Error Control Capture Register (SBCU_ECON) stores status information of the bus error event.

If more than one FPI Bus transaction generates a bus error, only the first bus error is captured. After a bus error has been captured, the capture mechanism must be released again by software.

If a write transaction from TriCore causes an error on the SPB, the originating master is not informed about this error as it is not an SPB master agent. With each bus error-capture event, a service request is generated, and an interrupt can be generated if enabled and configured in the corresponding service request register.

Interpreting the BCU Control Register Error Information

Although the address and data values captured in registers SBCU_EADD and SBCU_EDAT, respectively, are self-explanatory, the captured FPI Bus control information needs some more explanation.

Register SBCU_ECON captures the state of the read (RDN), write (WRN), Supervisor Mode (SVM), acknowledge (ACK), ready (RDY), abort (ABT), time-out (TOUT), bus master identification lines (TAG) and transaction operation code (OPC) lines of the FPI Bus.

The SVM signal is set to 1 for an access in Supervisor Mode and set to 0 for an access in User Mode. The time-out signal indicates if there was no response on the bus to an access, and the programmed time (via SBCU_TOUT) has elapsed. TOUT is set to 1 in this case. An acknowledge code has to be driven by the selected slave during each data cycle of an access. These codes are listed in **Table 4-12**.

Table 4-12 FPI Bus Acknowledge Codes

Code (ACK)	Description
00_B	NSC: No Special Condition.
01_B	SPT: Split Transaction (not used in the TC1798).
10_B	RTY: Retry. Slave can currently not respond to the access. Master needs to repeat the access later.
11_B	ERR: Bus Error, last data cycle is aborted.

Transactions on the FPI Bus are classified via a 4-bit operation code (see **Table 4-13**). Note that split transactions (OPC = 1000_B to 1110_B) are not used in the TC1798.

Table 4-13 FPI Bus Operation Codes (OPC)

OPC	Description
0000_B	Single Byte Transfer (8-bit)
0001_B	Single Half-Word Transfer (16-bit)
0010_B	Single Word Transfer (32-bit)
0100_B	2-Word Block Transfer
0101_B	4-Word Block Transfer
0110_B	8-Word Block Transfer
1111	No operation
0011_B, 0111_B, 1000_B - 1110_B	Reserved

4.5.3 BCU Debug Support

For debugging purposes, the BCU has the capability for breakpoint generation support. This OCDS debug capability is controlled by the Cerberus module and must be enabled by it (indicated by bit SBCU_DBCNTL.EO).

When BCU debug support has been enabled (EO = 1), any breakpoint request generated by the BCU to the Cerberus disarms the BCU breakpoint logic for further breakpoint requests. In order to rearm the BCU breakpoint logic again for the next breakpoint request generation, bit SBCU_DBCNTL.RA must be set. The status of the BCU breakpoint logic (armed or disarmed) is indicated by bit SBCU_DBCNTL.OA.

There are three types of trigger events:

- Address triggers
- Signal triggers
- Grant triggers

4.5.3.1 Address Triggers

The address debug trigger event conditions are defined by the contents of the SBCU_DBADR1, SBCU_DBADR2, and SBCU_DBCNTL registers. A wide range of possibilities arise for the creation of debug trigger events based on addresses. The following debug trigger events can be selected:

- Match on one signal address
- Match on one of two signal addresses
- Match on one address area
- Mismatch on one address area

Each pair of DBADRx registers and DBCNTL.ONAx bits determine one possible debug trigger event. The combination of these two possible debug trigger events defined by DBCNTL.CONCOM1 determine the address debug trigger event condition.

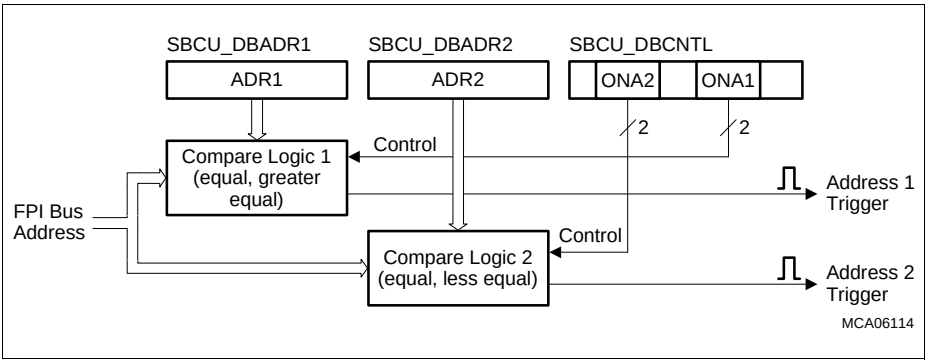

Figure 4-9 Address Trigger Generation

4.5.3.2 Signal Status Triggers

The signal status debug trigger event conditions are defined by the contents of the SBCU_DBBOS and SBCU_DBCNTL registers. Depending on the selected configuration a wide range of possibilities arise for the creation of a debug trigger event based on FPI Bus status signals. Possible combinations are:

- Match on a single signal status
- Match on a multiple signal status

With the multiple signal match conditions, all single signal match conditions are combined with a logical **AND** to the signal status debug trigger event signal. The selection whether or not a single match condition is selected can be enabled/disabled selectively for each condition via the SBCU_DBCNTL.ONBOSx bits.

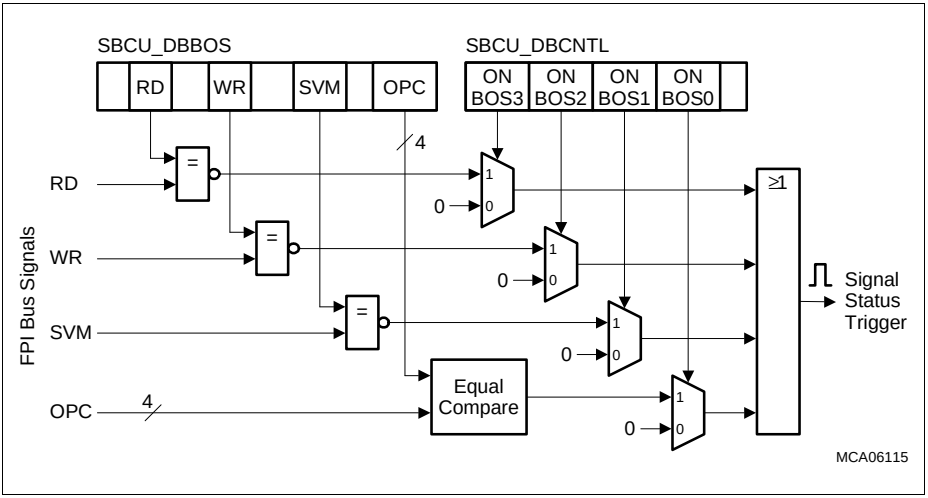

Figure 4-10 Signal Status Trigger Generation

4.5.3.3 Combination of Triggers

The combination of the four debug trigger signals to the single BCU breakpoint trigger event is defined via the bits CONCOM[2:0] of register SBCU_DBCNTL (see **Figure 4-11**). The two address triggers are combined to one address trigger that is further combined with signal status and grant trigger signals. A logical AND or OR combination can be selected for the BCU breakpoint trigger generation.

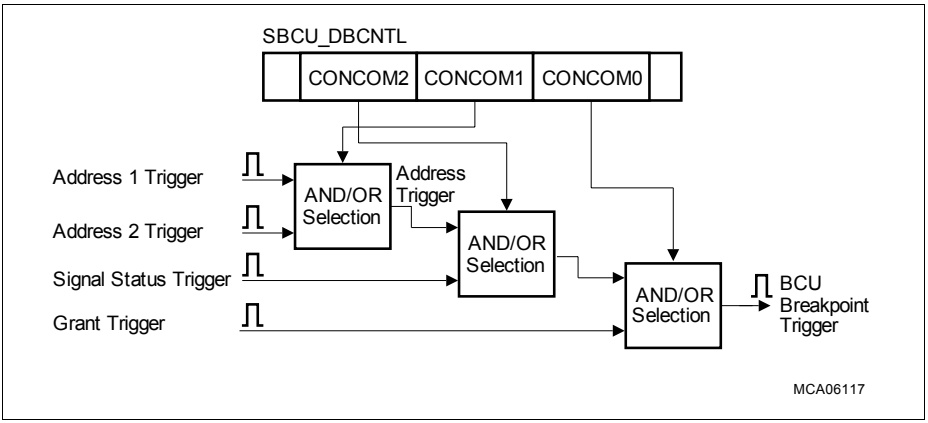

Figure 4-11 BCU Breakpoint Trigger Combination Logic

4.5.3.4 BCU Breakpoint Generation Examples

This section gives three examples of how BCU debug trigger events are programmed.

OCDS Debug Example 1

- Task: Generation of a BCU debug trigger event on any SPB write access to address 00002004_H or $000020A0_H$ by SPB master of the SFI Bridge or the PCP.

For this task, the following programming settings for the BCU breakpoint logic must be executed:

1. Writing SBCU_DBADR1 = 0000 2004_H
2. Writing SBCU_DBADR2 = 0000 $20A0_H$
3. Writing SBCU_DBCNTL = $C1115010_H$:
   a) ONBOS[3:0] = 1100_B means that no signal status trigger is generated (disabled) for a read signal match AND write signal match condition according to the settings of bits RD and WR in register SBCU_DBBOS. Debug trigger event generation for Supervisor Mode signal match and opcode signal match condition is disabled.
   b) ONA2 = 01_B means that the equal match condition for debug address 2 register is selected.

c) ONA1 = 01_B means that the equal match condition for debug address 1 register is selected.
d) ONG = 1 means that the grant debug trigger is enabled.
e) CONCOM[2:0] = 101_B means that the address trigger is created by address trigger 1 OR address trigger 2 (CONCOM1 = 0), and that the grant trigger is ANDed with the address trigger (CONCOM0 = 1), and that the signal status trigger is ANDed with the address trigger (CONCOM2 = 1).
f) RA = 1 means that the BCU breakpoint logic is rearmed.

4. Writing SBCU_DBGRNT = $FFFFFFD7_H$:
means that the grant trigger for the SPB master of the PCP and SFI Bridge is enabled.
5. Writing SBCU_DBBOS = 00001000_H:
means that the signal status trigger is generated on a write transfer and not on a read transfer.

OCDS Debug Example 2

- Task: generation of a BCU debug trigger event on any half-word access in User Mode to address area $01FFFFFF_H$ to $02FFFFFF_H$ by any master.

For this task, the following programming settings for the BCU breakpoint logic must be executed:

1. Writing SBCU_DBADR1 = $01FFFFFF_H$
2. Writing SBCU_DBADR2 = $02FFFFFF_H$
3. Writing SBCU_DBCNTL = 32206010_H:
a) ONBOS[3:0] = 0011_B means that the signal status trigger is disabled for a read or for write signal status match but enabled for Supervisor Mode match AND opcode match conditions according to the settings of bit SVM and bit field OPC in register SBCU_DBBOS.
b) ONA2 = 10_B means that the address 2 trigger is generated if the FPI Bus address is greater or equal to SBCU_DBADR2.
c) ONA1 = 10_B means that the address 1 trigger is generated if the FPI Bus address is greater or equal to SBCU_DBADR1.
d) ONG = 0 means that the grant debug trigger is disabled.
e) CONCOM[2:0] = 110_B means that the address trigger is created by address trigger 1 AND address trigger 2 (CONCOM1 = 1), and that the grant trigger is OR-ed with the address trigger (CONCOM0 = 0), and that the signal status trigger is AND-ed with the address trigger (CONCOM2 = 1).
f) RA = 1 means that the BCU breakpoint logic is rearmed.
4. Writing SBCU_DBGRNT = $FFFFFFFF_H$:
means that no grant trigger for SPB masters is selected (“don’t care” because also disabled by ONG = 0).

5. Writing SBCU_DBBOS = 00000001_H:
   means that the signal status trigger is generated for read (RD = 0) and write (WR = 0) half-word transfers (OPC = 0001_B) in User Mode (SVM = 0).

OCDS Debug Example 3

- Task: Generation of a BCU debug trigger event on any access into address area $01FFFFFF_H$ to $FFFFFFFF_H$ by the PCP.

For this task the following programming settings for the BCU breakpoint logic must be executed:

1. Writing SBCU_DBADR1 = $01FFFFFF_H$
2. Writing SBCU_DBADR2 = don't care
3. Writing SBCU_DBCNTL = 00215010_H:
   a) ONBOS[3:0] = 0000_B means that a signal status trigger is generated for all FPI Bus opcodes not equal to a "no operation" opcode.
   b) ONA2 = 00_B means that no address 2 trigger is generated.
   c) ONA1 = 10_B means that the address 1 trigger is generated if the FPI Bus address is greater or equal to SBCU_DBADR1.
   d) ONG = 1 means that the grant debug trigger is enabled.
   e) CONCOM[2:0] = 101_B means that the address trigger is created by address trigger 1 OR address trigger 2 (CONCOM1 = 0), and that the grant trigger is AND-ed with the address trigger (CONCOM0 = 1), and that the signal status trigger is ANDed with the address trigger (CONCOM2 = 1).
   f) RA = 1 means that the BCU breakpoint logic is rearmed.
4. Writing SBCU_DBGRNT = $FFFFFFF7_H$:
   means that the grant trigger for the SPB bus master of the PCP is enabled.
5. Writing SBCU_DBBOS is "don't care". No signal trigger for SVM, WR, or RD is generated.

4.5.4 System Bus Control Unit Registers

Figure 4-12 and Table 4-15 are showing the address maps with all registers of the System Bus Control Unit (SBCU) module.

SBCU Control Registers Overview

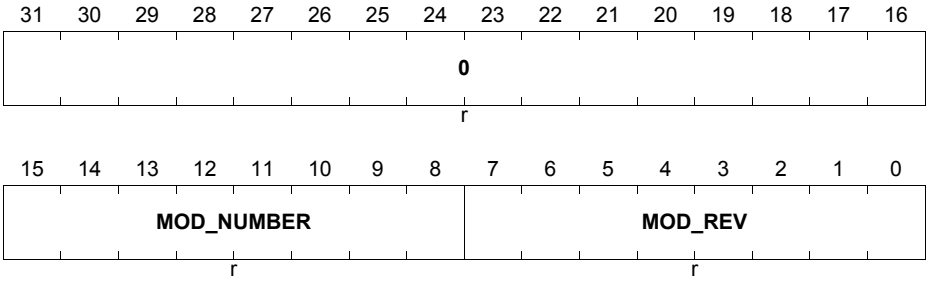
1) The absolute register address is calculated as follows:
Module Base Address (Table 4-14) + Offset Address (shown in this column)

4.5.4.1 SBCU ID Register Description

The identification register allows the programmer version-tracking of the module. The table below shows the identification register which is implemented in the SBCU module.

SBCU_ID
Module Identification Register **(008_H)** **Reset Value: 0000 6AXX$_H$**

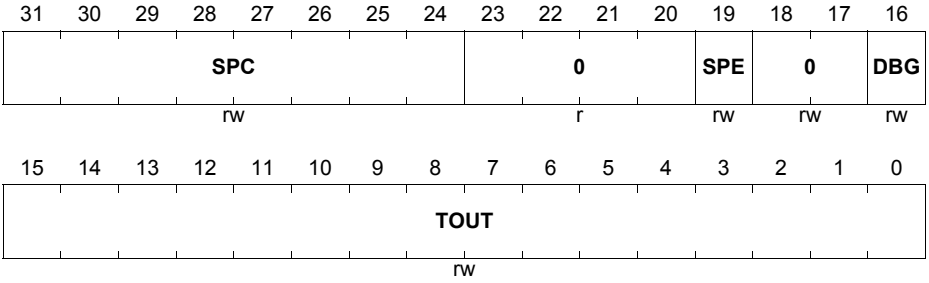


Field	Bits	Type	Description
MOD_REV	[7:0]	r	**Module Revision Number** This bit field defines the module revision number. The value of a module revision starts with 01_H (first revision).
MOD_NUMBER	[15:8]	r	**Module Number Value** This bit field defines a module identification number. The value for the LBCU module is 006AH.
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

4.5.4.2 SBCU Control Registers Descriptions

The SBCU Control Register controls the overall operation of the SBCU, including setting the starvation sample period, the bus time-out period, enabling starvation-protection mode, and error handling.

SBCU_CON
SBCU Control Register **(010_H)** **Reset Value: $4009\ FFFF_H$**



Field	Bits	Type	Description
TOUT	[15:0]	rw	**SBCU Bus Time-Out Value** The bit field determines the number of System Peripheral Bus time-out cycles. Default after reset is $FFFF_H$ (= 65536 bus cycles). Pls. Note: TOUT value must be >= 5.
DBG	16	rw	**SBCU Debug Trace Enable** 0_B SBCU debug trace disabled 1_B SBCU debug trace enabled (default after reset)
SPE	19	rw	**SBCU Starvation Protection Enable** 0_B SBCU starvation protection disabled 1_B SBCU starvation protection enabled (default after reset)
SPC	[31:24]	rw	**Starvation Period Control** Determines the sample period for the starvation counter. Must be larger than the number of masters. The reset value is 40_H.
0	[18:17], [23:20]	r	**Reserved** Read as 0; should be written with 0.

4.5.4.3 SBCU Error Registers Descriptions

The capture of bus error conditions is enabled by setting SBCU_CON.DBG to 1. In case of a bus error, information about the condition will then be stored in the SBCU error capture registers. The SBCU error capture registers can then be examined by software to determine the cause of the FPI Bus error.

If enabled and an FPI Bus error occurs, the SBCU_ECON register holds the captured FPI Bus control information and an error count of the number of bus errors. The SBCU_EADD register stores the captured FPI Bus address. The SBCU_EDAT register stores the captured FPI Bus data.

If the capture of FPI Bus error conditions is disabled (SBCU_CON.DBG = 0), the SBCU error capture registers remain untouched.

Note: The SBCU error capture registers store only the parameters of the first error. In case of multiple bus errors, an error counter SBCU_ECON.ERRCNT shows the number of bus errors since the first error occurred. An application reset clears this bit field to zero, but the counter can be set to any value through software. This counter is prevented from overflowing, so a value of 2^{16} - 1 indicates that at least this many errors have occurred, but there may have been more. After SBCU_ECON has been read, the SBCU_ECON, SBCU_EADD and SBCU_EDAT registers are re-enabled to trace FPI Bus error conditions.

SBCU_ECON
SBCU Error Control Capture Register (020_H) **Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
OPC				TAG				RDN	WRN	SVM	ACK		ABT	RDY	T OUT

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ERRCNT															
rwh															

Field	Bits	Type	Description
ERRCNT	[15:0]	rwh	**FPI Bus Error Counter** ERRCNT is incremented on every occurrence of an FPI Bus error. ERRCNT is reset to 0000_H after the SBCU_ECON register is read.[1)]
TOUT	16	rwh	**State of FPI Bus Time-Out Signal** This bit indicates the state of the time-out signal at an FBI Bus error. 0_B No time-out occurred 1_B Time-out has occurred
RDY	17	rwh	**State of FPI Bus Ready Signal** This bit indicates the state of the ready signal at an FBI Bus error. 0_B Wait state(s) have been inserted. Ready signal was active 1_B Ready signal was inactive
ABT	18	rwh	**State of FPI Bus Abort Signal** This bit indicates the state of the abort signal at an FBI Bus error. 0_B Master has aborted an FPI Bus transfer. Abort signal was active 1_B Abort signal was inactive
ACK	[20:19]	rwh	**State of FPI Bus Acknowledge Signals** This bit field indicates the acknowledge code that has been output by the selected slave at an FPI Bus error. Coding see **Table 4-12**.
SVM	21	rwh	**State of FPI Bus Supervisor Mode Signal** This bit indicates whether the FPI Bus error occurred in Supervisor Mode or in User Mode. 0_B Transfer was initiated in User Mode 1_B Transfer was initiated in Supervisor Mode
WRN	22	rwh	**State of FPI Bus Write Signal** This bit indicates whether the FPI Bus error occurred at a write cycle (see**Table 4-16**).
RDN	23	rwh	**State of FPI Bus Read Signal** This bit indicates whether the FPI Bus error occurred at a read cycle (see**Table 4-16**).

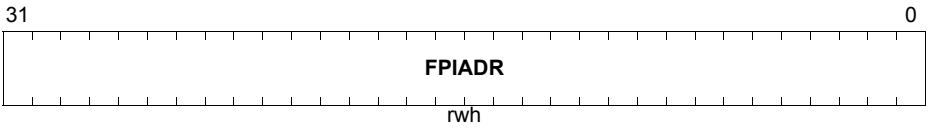
Field	Bits	Type	Description
TAG	[27:24]	rwh	**FPI Bus Master Tag Number Signals** This bit field indicates the FPI Bus master TAG number (definitions see **Table 4-17**).
OPC	[31:28]	rwh	**FPI Bus Operation Code Signals** The FPI Bus operation codes are defined in **Table 4-13**.

1) In the TC1798, aborted accesses to a 0 wait state SPB slave may also increment ERRCNT when the slave generates an error acknowledge.

Table 4-16 FPI Bus Read/Write Error Indication

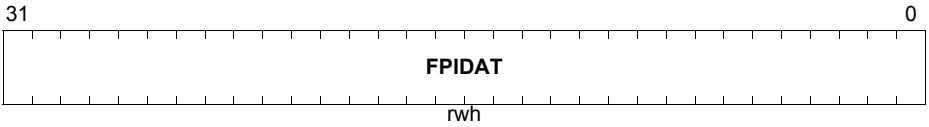
RD	WR	FPI Bus Cycle
0	0	FPI Bus error occurred at the read transfer of a read-modify-write transfer.
0	1	FPI Bus error occurred at a read cycle of a single transfer.
1	0	FPI Bus error occurred at a write cycle of a single transfer or at the write cycle of a read-modify-write transfer.
1	1	Does not occur.

SBCU_EADD
SBCU Error Address Capture Register (024_H) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
FPIADR	[31:0]	rwh	**Captured FPI Bus Address** This bit field holds the 32-bit FPI Bus address that has been captured at an FPI Bus error. Note that if multiple bus errors occurred, only the address of the first bus error is captured.

SBCU_EDAT
SBCU Error Data Capture Register (028$_H$) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
FPIDAT	[31:0]	rwh	**Captured FPI Bus Data** This bit field holds the 32-bit FPI Bus data that has been captured at an FPI Bus error. Note that if multiple bus errors occurred, only the data of the first bus error is captured.

4.5.4.4 SBCU OCDS Registers Descriptions

SBCU_DBCNTL
SBCU Debug Control Register **(030_H)** **Reset Value: 0000 7003$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ONBOS3	ONBOS2	ONBOS1	ONBOS0	0		ONA2		0		ONA1		0			ONG
rw	rw	rw	rw	r		rw		r		rw		r			rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	CONCOM2	CONCOM1	CONCOM0	0							RA	0		OA	EO
r	rw	rw	rw	r							w	r		r	r

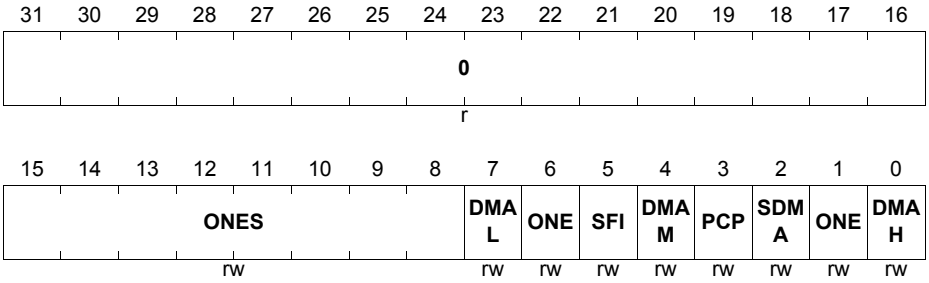
Field	Bits	Type	Description
EO	0	r	**Status of SBCU Debug Support Enable** This bit is controlled by the Cerberus and enables the SBCU debug support. 0_B SBCU debug support is disabled 1_B SBCU debug support is enabled (default after reset)
OA	1	r	**Status of SBCU Breakpoint Logic** 0_B The SBCU breakpoint logic is disarmed. Any further breakpoint activation is discarded 1_B The SBCU breakpoint logic is armed The OA bit is set by writing a 1 to bit RA. When OA is set, registers SBCU_DBGNTT, SBCU_DBADRT, and SBCU_DBBOST are reset.
RA	4	w	**Rearm SBCU Breakpoint Logic** Writing a 1 to this bit rearms SBCU breakpoint logic and sets bit OA = 1. RA is always reads as 0.

Field	Bits	Type	Description
CONCOM0	12	rw	**Grant and Address Trigger Relation** 0_B The grant phase trigger condition and the address trigger condition (see CONCOM1) are combined with a logical OR for further control 1_B The grant phase trigger condition and the address trigger condition (see CONCOM1) are combined with a logical AND for further control (see **Figure 4-11**)
CONCOM1	13	rw	**Address 1 and Address 2 Trigger Relation** 0_B Address 1 trigger condition and address 2 trigger condition are combined with a logical OR to the address trigger condition for further control 1_B Address 1 trigger condition and address 2 trigger condition are combined with a logical AND to the address trigger condition for further control (see **Figure 4-11**)
CONCOM2	14	rw	**Address and Signal Trigger Relation** 0_B Address trigger condition (see CONCOM1) and signal status trigger conditions are combined with a logical OR for further control 1_B Address phase trigger condition (see CONCOM1) and the signal status trigger conditions are combined with a logical AND for further control (see **Figure 4-11**)
ONG	16	rw	**Grant Trigger Enable** 0_B No grant debug event trigger is generated 1_B The grant debug event trigger is enabled and generated according the settings of register SBCU_DBGRNT (see **Figure 4-11**)
ONA1	[21:20]	rw	**Address 1 Trigger Control** 00_B No address 1 trigger is generated 01_B An address 1 trigger event is generated if the FPI Bus address is equal to SBCU_DBADR1 10_B An address 1 trigger event is generated if FPI Bus address is greater or equal to SBCU_DBADR1 11_B same as 00_B (See also **Figure 4-9**).

Field	Bits	Type	Description
ONA2	[25:24]	rw	**Address 2 Trigger Control** 00_B No address 2 trigger is generated 01_B An address 2 trigger event is generated if the FPI Bus address is equal to SBCU_DBADR2 10_B An address 2 trigger event is generated if FPI Bus address is greater or equal to SBCU_DBADR2 11_B same as 00_B See also **Figure 4-9**.
ONBOS0	28	rw	**Opcode Signal Status Trigger Condition** 0_B A signal status trigger is generated for all FPI Bus opcodes except a “no operation” opcode 1_B A signal status trigger is generated if the FPI Bus opcode matches the opcode as defined in DBBOS.OPC (see **Figure 4-10**)
ONBOS1	29	rw	**Supervisor Mode Signal Trigger Condition** 0_B The signal status trigger generation for the FPI Bus Supervisor Mode signal is disabled 1_B A signal status trigger is generated if the FPI Bus Supervisor Mode signal state is equal to the value of DBBOS.SVM (see **Figure 4-10**)
ONBOS2	30	rw	**Write Signal Trigger Condition** 0_B The signal status trigger generation for the FPI Bus write signal is disabled 1_B A signal status trigger is generated if the FPI Bus write signal state is equal to the value of DBBOS.WR (see **Figure 4-10**)
ONBOS3	31	rw	**Read Signal Trigger Condition** 0_B The signal status trigger generation for the FPI Bus read signal is disabled 1_B A signal status trigger is generated if the FPI Bus read signal state is equal to the value of DBBOS.RD (see **Figure 4-10**)

Field	Bits	Type	Description
0	[3:2], [11:5], 15, [19:17], [23:22], [27:26]	r	**Reserved** Read as 0; should be written with 0.

SBCU_DBGRNT
SBCU Debug Grant Mask Register (034_H) Reset Value: 0000 FFFF$_H$



Field	Bits	Type	Description
DMAH	0	rw	**Cerberus Grant Trigger Enable, High Priority**[1)] 0_B FPI Bus transactions with high-priority DMA as bus master are enabled for grant trigger event generation 1_B FPI Bus transactions with high-priority DMA as bus master are disabled for grant trigger event generation
SDMA	2	rw	**SDMA Grant Trigger Enable** 0_B FPI Bus transactions requested by the SDMA bus master are enabled for grant trigger event generation 1_B FPI Bus transactions requested by the SDMA bus master are disabled for grant trigger event generation

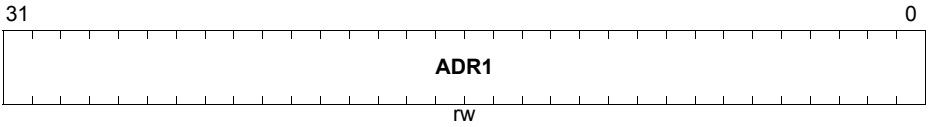
Field	Bits	Type	Description
PCP	3	rw	**PCP Grant Trigger Enable** 0_B FPI Bus transactions with PCP as bus master are enabled for grant trigger event generation 1_B FPI Bus transactions with PCP as bus master are disabled for grant trigger event generation
DMAM	4	rw	**DMA Grant Trigger Enable, Medium Priority**[2)] 0_B FPI Bus transactions with medium-priority DMA channels as bus master are enabled for grant trigger event generation 1_B FPI Bus transactions with medium-priority DMA channels as bus master are disabled for grant trigger event generation
SFI	5	rw	**SFI Bridge Grant Trigger Enable** 0_B FPI Bus transactions with SFI Bridge as bus master are enabled for grant trigger event generation 1_B FPI Bus transactions with SFI Bridge as bus master are disabled for grant trigger event generation
DMAL	7	rw	**DMA Grant Trigger Enable, Low Priority**[3)] 0_B FPI Bus transactions with low-priority DMA channels as bus master are enabled for grant trigger event generation 1_B FPI Bus transactions with low-priority DMA channels as bus master are disabled for grant trigger event generation
ONE, ONES	1, 6, [15:8]	rw	**Reserved** Read as 1 after reset; reading these bits will return the value last written.
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

1) Including DMA transactions from DMA channels with high priority and from Cerberus with high priority.

2) Including DMA transactions from DMA channels with medium priority.

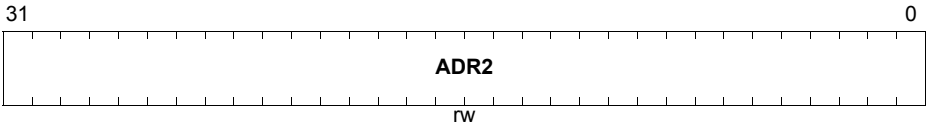
3) Including DMA transactions from DMA channels with low priority, MLI and from Cerberus with low priority.

SBCU_DBADR1
SBCU Debug Address 1 Register (038$_H$) Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
ADR1	[31:0]	rw	**Debug Trigger Address 1** This register contains the address for the address 1 trigger event generation.

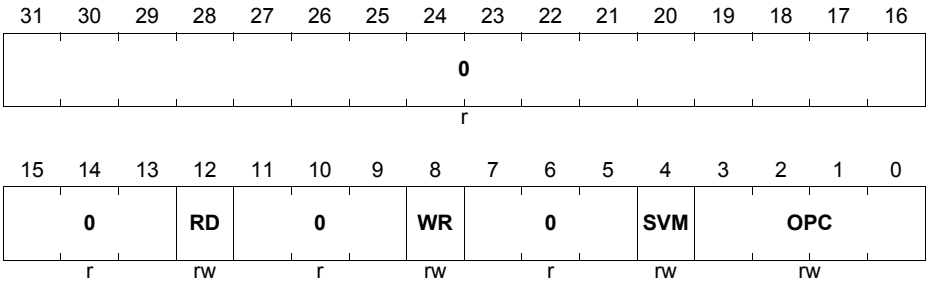
SBCU_DBADR2
SBCU Debug Address 2 Register (03C$_H$) Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
ADR2	[31:0]	rw	**Debug Trigger Address 2** This register contains the address for the address 2 trigger event generation.

SBCU_DBBOS
SBCU Debug Bus Operation Signals Register

(040$_H$) Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
OPC	[3:0]	rw	**Opcode for Signal Status Debug Trigger** This bit field determines the type (opcode) of an FPI Bus transaction for which a signal status debug trigger event is generated (if enabled by DBCNTL.ONBOS0 = 1). 0000_B Trigger on single byte transfer selected 0001_B Trigger on single half-word transfer selected 0010_B Trigger on single word transfer selected 0100_B Trigger on 2-word block transfer selected 0101_B Trigger on 4-word block transfer selected 0110_B Trigger on 8-word block transfer selected 1111_B Trigger on no operation selected Other bit combinations are reserved.
SVM	4	rw	**SVM Signal for Status Debug Trigger** This bit determines the mode of an FPI Bus transaction for which a signal status debug trigger event is generated (if enabled by DBCNTL.ONBOS1 = 1). 0_B Trigger on User Mode selected 1_B Trigger on Supervisor Mode selected

Field	Bits	Type	Description
WR	8	rw	**Write Signal for Status Debug Trigger** This bit determines the state of the $\overline{WR}$ signal of an FPI Bus transaction for which a signal status debug trigger event is generated (if enabled by DBCNTL.ONBOS2 = 1). 0_B Trigger on a single write transfer or write cycle of an atomic transfer selected 1_B No operation or read transaction selected
RD	12	rw	**Write Signal for Status Debug Trigger** This bit determines the state of the $\overline{RD}$ signal of an FPI Bus transaction for which a signal status debug trigger event is generated (if enabled by DBCNTL.ONBOS3 = 1). 0_B Trigger on a single read transfer or read cycle of an atomic transfer selected 1_B No operation or write transfer selected
0	[7:5], [11:9], [31:13]	r	**Reserved** Read as 0; should be written with 0.

SBCU_DBGNTT
SBCU Debug Trapped Master Register

(044_H) **Reset Value: 0000 FFFF$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r								rh	rh	rh	rh	rh	rh	r	rh

Field	Bits	Type	Description
DMAH	0	rh	**High-Priority DMA FPI Bus Master Status**[1)] This bit indicates whether the DMA with a high priority request was FPI Bus master when the break trigger event occurred. 0_B The high-priority DMA was not the FPI bus master. 1_B The high-priority DMA was the FPI Bus master.
SDMA	2	rh	**SDMA FPI Bus Master Status** This bit indicates whether the SDMA was FPI Bus master when the break trigger event occurred. 0_B The SDMA was not the FPI bus master. 1_B The SDMA was the FPI Bus master.
PCP	3	rh	**PCP FPI Bus Master Status** This bit indicates whether the PCP was FPI Bus master when the break trigger event occurred. 0_B The PCP was not an FPI bus master. 1_B The PCP was FPI bus master at the break trigger event.
DMAM	4	rh	**Medium-Priority DMA FPI Bus Master Status**[2)] This bit indicates whether the DMA with a medium priority request was FPI Bus master when the break trigger event occurred. 0_B The medium-priority DMA was not the FPI bus master. 1_B The medium-priority DMA was the FPI Bus master.
SFI	5	rh	**SFI Bridge FPI Bus Master Status** This bit indicates whether the SFI Bridge was FPI Bus master when the break trigger event occurred. 0_B The SFI Bridge was not an FPI Bus master. 1_B The SFI Bridge was FPI Bus master.

Field	Bits	Type	Description
DMAL	7	rh	**Low-Priority DMA FPI Bus Master Status**[3] This bit indicates whether the DMA with a low-priority request was the FPI Bus master when the break trigger event occurred. 0_B The low-priority DMA was not the FPI Bus master. 1_B The low-priority DMA was the FPI Bus master.
CHNR0y (y = 0-7)	16+y	rh	**DMA Channel Number Status** These bits indicate which DMA channel with number 0y was active when a DMA break trigger event occurred. 0_B DMA channel 0y was not active at a DMA break trigger event. 1_B DMA channel 0y was active at a DMA break trigger event.
ONE, ONES	1, 6, [15:8]	r	**Reserved** Read as 1; should be written with 0.
0	[31:24]	r	**Reserved** Read as 0; should be written with 0.

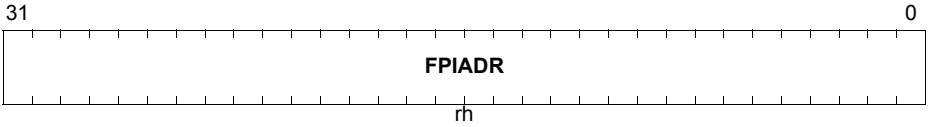
1) Including DMA transactions from DMA channels with high priority and from Cerberus with high priority.

2) Including DMA transactions from DMA channels with medium priority.

3) Including DMA transactions from DMA channels with low priority, MLI and from Cerberus with low priority.

SBCU_DBADRT
SBCU Debug Trapped Address Register

(048_H) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
FPIADR	[31:0]	rh	**FPI Bus Address Status** This register contains the FPI Bus address that was captured when the OCDS break trigger event occurred.

SBCU_DBBOST
SBCU Debug Trapped Bus Operation Signals Register
($04C_H$) **Reset Value: $0000\ 3180_H$**

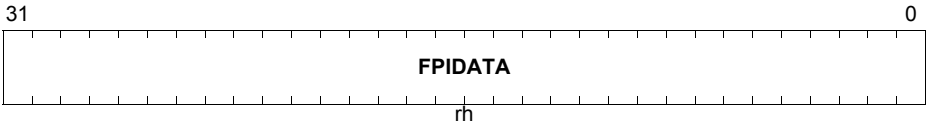
Field	Bits	Type	Description
FPIOPC	[3:0]	rh	**FPI Bus Opcode Status** This bit field indicates the type (opcode) of the FPI Bus transaction captured from the FPI Bus signal lines when the BCU break trigger event occurred. 0000_B Single byte transfer 0001_B Single half-word transfer 0010_B Single word transfer 0100_B 2-word block transfer 0101_B 4-word block transfer 0110_B 8-word block transfer 1111_B No operation Other bit combinations are reserved.
FPISVM	4	rh	**FPI Bus Supervisor Mode Status** This bit indicates the state of the Supervisor Mode signal captured from the FPI Bus signal lines when the BCU break trigger event occurred. 0_B User mode 1_B Supervisor mode

Field	Bits	Type	Description
FPIACK	[6:5]	rh	**FPI Bus Acknowledge Status** This bit field indicates the acknowledge signal status captured from the FPI Bus signal lines when the BCU break trigger event occurred. 00_B No special case 01_B Error 10_B Reserved 11_B Retry, slave did not respond
FPIRDY	7	rh	**FPI Bus Ready Status** This bit indicates the ready signal status captured from the FPI Bus signal lines when the BCU break trigger event occurred. 0_B Last cycle of transfer 1_B Not last cycle of transfer
FPIWR	8	rh	**FPI Bus Write Indication Status** This bit indicates the write signal status captured from the FPI Bus signal lines when the BCU break trigger event occurred. 0_B Single write transfer or write cycle of an atomic transfer 1_B No operation or read transfer
FPIRST	[10:9]	rh	**FPI Bus Reset Status** This bit field indicates the reset signal status captured from the FPI Bus signal lines when the BCU break trigger event occurred. 00_B Reset of all FPI Bus components 11_B No reset Others Reserved
FPIOPS	11	rh	**FPI Bus OCDS Suspend Status** This bit indicates the OCDS suspend signal status captured from the FPI Bus signal lines when the BCU break trigger event occurred. 0_B No OCDS suspend request is pending 1_B An OCDS suspend request is pending

Field	Bits	Type	Description
FPIRD	12	rh	**FPI Bus Read Indication Status** This bit indicates the read signal status captured from the FPI Bus signal lines when the BCU break trigger event occurred. 0_B Single read transfer or read cycle of an atomic transfer 1_B No operation or write transfer
FPIABORT	13	rh	**FPI Bus Abort Status** This bit indicates the abort signal status captured from the FPI Bus signal lines when the BCU break trigger event occurred. 0_B A transfer that has already started was aborted 1_B Normal operation
FPITOUT	14	rh	**FPI Bus Time-out Status** This bit indicates the time-out signal status captured from the FPI Bus signal lines when the BCU break trigger event occurred. 0_B Normal operation 1_B A time-out event was generated
FPITAG	[19:16]	rh	**FPI Bus Master TAG Status** This bit field indicates the master TAG captured from the FPI Bus signal lines when the BCU break trigger event occurred (see **Table 4-17**). The master TAG identifies the master of the transfer which generated BCU break trigger event.
0	15, [31:20]	rh	**Reserved** Read as 0; should be written with 0.

SBCU_DBDAT
SBCU Debug Data Status Register

(050_H) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
FPIDATA	[31:0]	rh	**FPI Bus Data Status** This register contains the FPI Bus data that was captured when the OCDS break trigger event occurred.

4.5.4.5 SBCU Service Request Control Register Description

In case of a bus error, the SBCU generates an interrupt request to the selected service provider (usually the CPU). This interrupt request is controlled through a standard service request control register.

SBCU_SRC
SBCU Service Request Control Register

($0FC_H$) **Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0	[9:8], 11, [31:16]	r	**Reserved** Read as 0; should be written with 0.

Note: Further details on interrupt handling and processing are described in the Interrupt Chapter of this TC1798 User´s Manual.

4.6 On Chip Bus Master TAG Assignments

Each master interface on the FPI Bus and on the SRI Bus is assigned to a 4-bit identification number, the master TAG number (see **Table 4-17**). This makes it possible for software debug and MCDS purposes to distinguish which master has performed the current transaction (see **"XBAR_ERRx (x = 0-6)" on Page 4-51**[1] and **"SBCU_DBADRT" on Page 4-97**).

Table 4-17 On Chip Bus Master TAG Assignments

TAG-Number	Module	Location	Description
0000_B	-	-	Reserved
0001_B	-	-	Reserved
0010_B	PMI	SRI	Program Memory Interface
0011_B	-	-	Reserved
0100_B	DMI	SRI	Data Memory Interface
0101_B	-	-	Reserved
0110_B	-	-	Reserved
0111_B	DMA	SRI	DMA Controller Master Interface on SRI
1000_B	SDMA	SPB	Safe DMA Controller Master Interface on SPB
1001_B	PCP	SPB	Control Processor
1010_B	DMA	SPB	DMA Controller Master Interface on SPB
1011_B	-	-	Reserved
1100_B	-	-	Reserved
1101_B	-	-	Reserved
1110_B	-	-	Reserved
1111_B	-	-	Reserved

1) Pls. note that the Transaction ID bit field in the register **"XBAR_ERRx (x = 0-6)" on Page 4-51** includes the TAG ID on the 4 MSB (TRID[3:0]).

5 Program Memory Unit (PMU)

The Program Memory Unit “PMU” is part of the processor subsystem. The PMUs control the Flash memory and the BootROM and connect these to the SRI bus system.

The devices of the AudoMax and Audo-S families have at least one Program Memory Unit. This is named “PMU0”. With increasing Flash memory more PMUs are added which are named “PMU1”, and so on. All PMUs are independent from each other.

Throughout this document a generic PMU is specified. The **Chapter 5.2** lists the configuration parameters of a PMU and their values in the TC1798. When PMU functionality depends on a parameter this is indicated in the text.

This chapter has the following structure:

- Generic feature list and block diagram (**Chapter 5.1**).
- PMU configuration of the TC1798 (**Chapter 5.2**).
- Functionality of the BootROM (**Chapter 5.3**).
- Functionality of the tuning protection (**Chapter 5.4**).
- Functionality of the Flash memory (**Chapter 5.5**).
- Register Set (**Chapter 5.6**).
- Application Hints (**Chapter 5.7**).

5.1 Generic Feature List

A PMU has dependent on its configuration the following features:

- BootROM (“BROM”).
- Up to 4 MBytes of Program Flash (“PFlash”).
- Up to 256 KByte of Data Flash (“DFlash”).
- Security Flash for SHE (“KeyFlash”).
- SRI slave interface for all assigned Flash memories and registers.
- Flash command control.
- Flash and BROM access control.
- Tuning Protection.
- Interface to security module SHE.

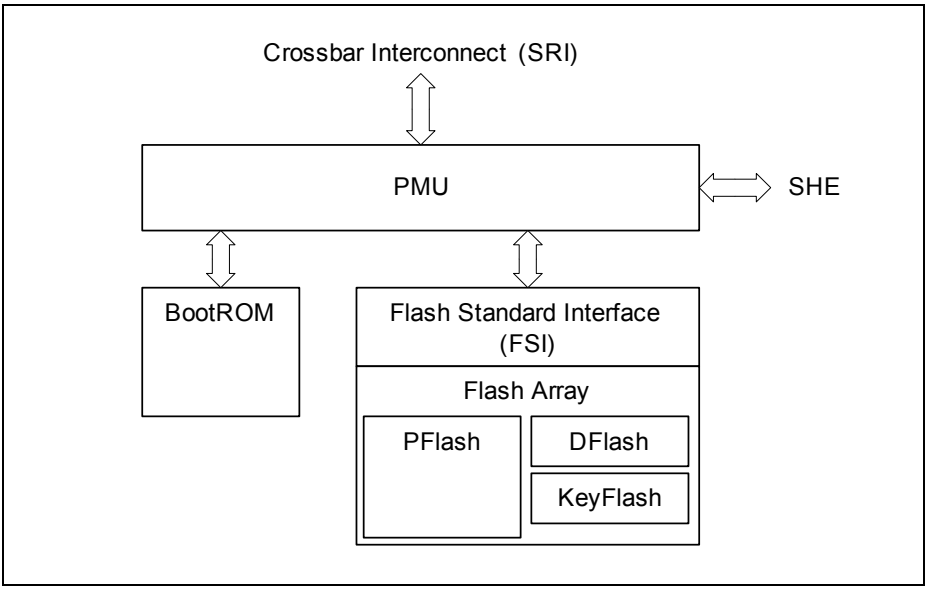

Figure 5-1 PMU Basic Block Diagram

5.2 PMU Configuration of TC1798

The following table defines the PMU configuration of TC1798.

Table 5-1 Configuration of PMU

Parameter	Value	Description
N_PMU	2	Number of PMUs
N_BROM0	1	Number of BROM in PMU0
S_BROM0	16 KByte	Size of the BROM in PMU0
AC_BROM0	8FFF C000$_H$	Base address of the BROM of PMU0 (cached)
AN_BROM0	AFFF C000$_H$	Base address of the BROM of PMU0 (non-cached)
N_PFlash0	1	Number of PFlash in PMU0
S_PFlash0	2 MByte	Size of the PFlash of PMU0
AC_PFlash0	8000 0000$_H$	Base address of the PFlash of PMU0 (cached)
AN_PFlash0	A000 0000$_H$	Base address of the PFlash of PMU0 (non-cached)

Table 5-1 Configuration of PMU (cont'd)

Parameter	Value	Description
AN_UCB0	A000 0000$_H$	Base address of the UCB area of PMU0 (non-cached)
N_DFlash0	1	Number of DFlash in PMU0
S_DFlash0	192 KByte	Size of the DFlash of PMU0
AN_DFlash0_B0	AF00 0000$_H$	Base address of bank 0 of DFlash of PMU0 (non-cached).
S_DFlash0_B0	96 KByte	Size of bank 0 of DFlash of PMU0.
AN_DFlash0_B1	AF08 0000$_H$	Base address of bank 1 of DFlash of PMU0 (non-cached)
S_DFlash0_B1	96 KByte	Size of bank 1 of DFlash of PMU0.
N_KeyFlash0	1	Number of KeyFlash in PMU0
N_RDB0	3	Number of PFlash read buffers in PMU0
N_BROM1	0	Number of BROM in PMU1
N_PFlash1	1	Number of PFlash in PMU1
S_PFlash1	2 MByte	Size of the PFlash of PMU1
AC_PFlash1	8080 0000$_H$	Base address of the PFlash of PMU1 (cached)
AN_PFlash1	A080 0000$_H$	Base address of the PFlash of PMU1 (non-cached)
AN_UCB1	A080 0000$_H$	Base address of the UCB area of PMU1 (non-cached)
N_DFlash1	0	Number of DFlash in PMU1
N_KeyFlash1	0	Number of KeyFlash in PMU1
N_RDB1	3	Number of PFlash read buffers in PMU1

5.2.1 Features of the BootROM

The BootROM contains firmware:

- Startup software "SSW": this software is executed at every reset.
- Test firmware: factory test routines for IFX purposes.

Additionally the BootROM and its control logic support the Tuning Protection.

5.2.2 Features of Program and Data Flash

Depending on the PMU configuration the following Flash features are implemented. Timing and reliability figures are just indicative. Binding data can be found in the “Data Sheet”.

Program Flash “PFlash”

- Consists of one bank.
- Commonly used for instructions and constant data.
- High throughput burst read based on a 256-bit Flash access.
- Application optimized sector structure with sectors ranging from 16 KBytes to 256 KBytes.
- Write protection separately configurable for groups of sectors.
- Hierarchical write protection control with 3 levels of which 2 are password based and 1 is a one-time programmable one.
- Password based read protection combined with write protection for the whole Flash.
- Separate configuration sector containing the protection configuration and IFX specific data.
- High throughput programming of a 256 byte page (see Data Sheet t_{PRP}).
- Erase time per sector: see Data Sheet t_{ERP}.
- All Flash operations initiated by command sequences as protection against unintended operation.
- Erase and program performed by a Flash specific control logic independent of the CPU.
- End of erase and program operations reported by interrupt.
- Dynamic correction of single-bit errors and detection of double-bit errors (“SEC-DED”).
- Error reporting by bus error, interrupts and status flags.
- “Safe read path” ensuring detection of transient and permanent errors.
- Margin reads for quality assurance.
- Delivery in the erased state.
- Configurable wait-state configuration of optimum read performance depending on FSI frequency (see Data Sheet WS_{PF}).
- Endurance and retention figures are documented in the Data Sheet separately for physical sectors (t_{RET}), logical sectors (t_{RETL}) and UCBs (t_{RTU}).
- Pad supply voltage used for program and erase.

Data Flash “DFlash”

As for PFlash but with the following differences:

- Consists of two banks.
- One sector per bank.
- Commonly used for EEPROM emulation (data storage at application run-time).

- Burst read is not supported.
- High throughput programming of a 128 byte page (see Data Sheet t_{PRD}).
- Erase time per sector: see Data Sheet t_{ERD}.
- Dynamic correction of single-bit and double-bit errors and detection of triple-bit errors (“DEC-TED”).
- The high endurance (see Data Sheet N_E) is granted under the condition of a robust EEPROM emulation algorithm (see **Chapter 5.7.3**).
- Configurable wait-state configuration of optimum read performance depending on FSI frequency (see Data Sheet WS_{DF}).

SHE KeyFlash

- Only usable by the SHE module (see corresponding chapter).
- The retention/endurance figure for keys is documented as t_{RETKF} in the Data Sheet.

5.3 BootROM

The content of the BROM is described in a separate chapter.

The BROM is readable and executable for user software but its functions shall only be executed when especially advised by IFX.

All write accesses to the BootROM are refused with a bus error.

In the SRI address range it is mapped to the following start addresses:

- AC_BROM0 (cached address range).
- AN_BROM0 (non-cached address range).

5.4 Tuning Protection

The special tuning protection support represents a security function provided additionally to Flash read/write/OTP protection.

For details on the tuning protection please contact your Infineon representative.

5.5 Flash

This chapter introduces the Flash memory of the TC1798. It is split into the following sections:

- Definition of terms (**Chapter 5.5.1**): what means “program”, “erase”, “sector”, “pages”, …
- Structure of a Flash module (**Chapter 5.5.2**): separation into “banks”, “sectors”, “word-lines”, “pages”, …
- Reading Flash (**Chapter 5.5.3**).
- Command sequences for Flash (**Chapter 5.5.4**): programming, erasing, handling protection.
- Flash protection (**Chapter 5.5.5**): read and write protection.
- Data integrity and safety (**Chapter 5.5.6**): ECC and margin checks.
- Interrupt and traps (**Chapter 5.5.7**).
- Reset and startup (**Chapter 5.5.8**).
- Power reduction by sleep and idle (**Chapter 5.5.9**).

5.5.1 Definition of Terms

The description of Flash memories uses a specific terminology for operations and the hierarchical structure.

Flash Operation Terms

- **Erasing**: The erased state of a Flash cell is logical ‘0’. Forcing a cell to this state is called “erasing”. Depending on the Flash area always complete physical sectors, logical sectors or word-lines are erased. All Flash cells in this area incur one “cycle” that counts for the “endurance”.
- **Programming**: The programmed state of a cell is logical ‘1’. Changing an erased Flash cell to this state is called “programming”. The 1-bits of a page are programmed concurrently.
- **Retention**: This is the time during which the data of a flash cell can be read reliably. The retention time is a statistical figure that depends on the operating conditions of the device (e.g. temperature profile) and is affected by operations on other Flash cells in the same word-line and physical sector. With an increasing number of program/erase cycles (see endurance) the retention is lowered.
- **Endurance**: As described above the data retention is reduced with an increasing number of program/erase cycles. The maximum number of program/erase cycles of each Flash cell is called “endurance”. As said for the retention it is a statistical figure that depends on operating conditions and the use of the flash cells and not to forget on the required quality level. The endurance is documented in the data sheet separately for PFlash physical sectors, PFlash logical sectors, UCBs, DFlash and SHE keys.

Flash Structure Terms

- **Flash Module**: A PMU contains one “Flash module” with its own operation control logic.
- **Bank**: A “Flash module” contains separate “banks”, one for PFlash and two for DFlash. “Banks” support concurrent operations (read, program, erase) with some limitations due to common logic (see **Chapter 5.5.4.4**).
- **Physical Sector**: A Flash “bank” consists of “physical sectors” ranging from 64 KBytes to 256 KBytes. The Flash cells of different “physical sectors” are isolated from each other. Therefore cycling Flash cells in one physical sectors does not affect the retention of Flash cells in other physical sectors. A “physical sector” is the largest erase unit.
- **Logical Sector**: A “logical sector” is a group of word-lines of one physical sector. They can be erased with a single operation but other Flash cells in the same physical sector are slightly disturbed.
- **Sector**: The plain term “sector” means “logical sector” when a physical sector is divided in such, else it means the complete physical sector.
- **User Configuration Block “UCB”**: A “UCB” is a specific logical sector contained in the configuration sector. It contains the protection settings and other data configured by the user. The “UCBs” are the only part of the configuration sector that can be programmed and erased by the user.
- **Configuration Sector**: The “configuration sector” is a separate physical sector of the PFlash. Because of its protection relevant content it is not directly accessible to the user.
- **KeyFlash**: The KeyFlash is used by SHE for storage of keys. It is a separate range of physical sectors in the DFlash bank only accessible to the SHE module.
- **Word-Line**: A “word-line” consists of two pages, an even one and an odd one. In the PFlash area a word-line contains aligned 512 bytes and in the DFlash area 256 bytes.
- **Page**: A “page” is a part of a word-line that is programmed at once. In PFlash a page is an aligned group of 256 bytes and in DFlash 128 bytes.

5.5.2 Flash Structure

The PMU contains the following Flash banks. The offset address of each sector is relative to the base address of its bank which is given in **Table 5-1**. In devices of the same family the Flash banks keep the same base address.

Derived devices (see data sheet) can have less Flash memory. The PFlash bank shrinks by cutting-off higher numbered physical sectors. The DFlash banks shrink by reducing the size of their (single) sectors.

PFlash

All offset addresses based on Ax_PFlashx (see **Table 5-1**). All sectors from S9 on have a size of 256 KByte.

Table 5-2 Sector Structure of PFlash

Sector	Phys. Sector	Size	Offset Address
S0	PS0	16 KB	$00'0000_H$
S1		16 KB	$00'4000_H$
S2		16 KB	$00'8000_H$
S3		16 KB	$00'C000_H$
S4	PS4	16 KB	$01'0000_H$
S5		16 KB	$01'4000_H$
S6		16 KB	$01'8000_H$
S7		16 KB	$01'C000_H$
S8	–	128 KB	$02'0000_H$
S9	–	256 KB	$04'0000_H$
S10	–	256 KB	$08'0000_H$
S11	–	256 KB	$0C'0000_H$
S12	–	256 KB	$10'0000_H$
S13	–	256 KB	$14'0000_H$
S14	–	256 KB	$18'0000_H$
S15	–	256 KB	$1C'0000_H$

DFlash

All offset addresses are based on AN_DFlashx_B0 (see **Table 5-1**).

Table 5-3 Sector Structure of DFlash Bank 0

Sector	Size	Offset Address
DS0	S_DFlashX_B0	$00'0000_H$

All offset addresses are based on AN_DFlashx_B1 (see **Table 5-1**).

Table 5-4 Sector Structure of DFlash Bank 1

Sector	Size	Offset Address
DS1	S_DFlashX_B1	$00'0000_H$

The DFlash contains also the SHE KeyFlash. It can be only used by the SHE module.

UCB

All offset addresses are based on AN_UCBx (see **Table 5-1**). As explained before the UCBx are logical sectors.

Table 5-5 Structure of UCB Area

Sector	Size	Offset Address
UCB0	1 KB	$00'0000_H$
UCB1	1 KB	$00'0400_H$
UCB2	1 KB	$00'0800_H$

5.5.3 Flash Read Access

Flash banks that are active and in read mode can be directly read as ROM.

The wait cycles for the Flash access must be configured as defined in the data sheet or in the chapter “Electrical Parameters”.

The PFlash allows SRI bursts BTR4 and BTR2 and single transfers.

The Tricore uses BTR4 for code fetches from the cached address range in order to fill one cache line. Code fetches from the non-cached area are also performed with BTR4. Data reads from the cached range are performed with BTR4. Data reads from the non-cached address range are performed with single transfers.

The DFlash allows only single transfers. Therefore they are only accessible in the non-cached address range and Tricore can’t fetch instructions from them.

Read accesses from Flash can be blocked by the read protection (see **Chapter 5.5.5**).

Read accesses to the DFlash can be blocked by SHE operations (see **Chapter 5.5.4.4** and **SEMA** on **Page 5-49**).

ECC errors can be detected and corrected (see **Chapter 5.5.6**).

Read Buffers

The PMU contains N_RDBx read buffers. Each of these read buffers is assigned by configuration (see **Chapter 5.6.2.3**) to one bus master. Additionally all read data passes

through a pipeline stage in the FSI called “global read buffer”. The read buffers can be filled with a single PFlash read which delivers 256 data bits.

Read accesses to the DFlash are always serviced by reading the Flash. Buffer hits are not supported.

5.5.4 Flash Operations

The Flash memory knows operations for reading, changing data (program/erase) and handling protection settings. This section and the following describe only the features as such. How to use them is described in the application notes (**Chapter 5.7**).

5.5.4.1 Modes of Operation

A Flash module can be in one of the following states:

- Active (normal) mode.
- Sleep mode (see **Chapter 5.5.8**).

In sleep mode write and read accesses to all Flash ranges of this PMU are refused with a bus error.

When the Flash module is in normal mode each Flash bank can be separately in one of these modes:

- Read mode.
- Command mode.

In read mode a Flash bank can be read and command sequences are interpreted. In read mode a Flash bank can additionally enter page mode which enables it to receive data for programming.

In command mode an operation is performed. During its execution the Flash bank reports BUSY in FSR. In this mode read accesses to this Flash bank are refused with a bus error. At the end of an operation the Flash bank returns to read mode and BUSY is cleared. Only operations with a significant duration (shown in the command documentation) set BUSY.

Register read and write accesses are not affected by these modes.

5.5.4.2 Command Sequences

All Flash operations except read are performed with command sequences. When a Flash bank is in read mode or page mode all write accesses to its reserved address range are interpreted as command cycle belonging to a command sequence. Write accesses to a busy bank cause SQER.

Command sequences consist of 1 to 6 command cycles. The command interpreter checks that a command cycle is correct in the current state of command interpretation. Else a SQER is reported.

When the command sequence is accepted the last command cycle finishes read mode and the Flash bank transitions into command mode.

These write accesses must be single transfers (thus they should address the non-cached address range).

All write accesses transferring write data shall address the Flash bank that will execute the program operation. This Flash bank must be in page mode.

All write accesses of one command sequence must address the same Flash bank.

Command sequences can be blocked by the Flash reservation semaphore (see **Chapter 5.5.4.4** and **SEMA** on **Page 5-49**).

Generally when the command interpreter detects an error it reports a sequence error by setting FSR.SQER. Then the command interpreter is reset and a page mode is left. The next command cycle must be the 1st cycle of a command sequence. The only exception is “Enter Page Mode” when a bank is already in page mode (see below).

5.5.4.3 Command Sequence Definitions

The command sequence descriptions use the following nomenclature (symbolic assembly language):

ST addr, data: Symbolic representation of a command cycle moving “data” to “addr”.

The parameter “addr” can be one of the following:

- **$CCCC_H$**: The “addr” must point into the bank that performs the operation. The last 16 address bits must match $CCCC_H$. It is recommended to use as address the base address of the bank incremented by $CCCC_H$.
- **PA**: Absolute start address of the Flash page.
- **UCPA**: Absolute start address of a user configuration block page.
- **SA**: Absolute start address of a Flash sector. Allowed are the PFlash sectors Sx.
- **PSA**: Absolute start address of a physical sector. Allowed are the PFlash physical sectors PSx and the DFlash sectors DSx.
- **UCBA**: Absolute start address of a user configuration block.

The parameter “data” can be one of the following:

- **WD**: 64-bit or 32-bit write data to be loaded into the page assembly buffer.
- **xxYY**: 8-bit write data as part of a command cycle. Only the byte “YY” is used for command interpretation. The higher order bytes “xx” are ignored.
  - **xx5y**: Specific case for “YY”. The “y” can be “0_H” for selecting the PFlash bank or “D_H” to select the DFlash banks.
- **UL**: User protection level ($xxx0_H$ or $xxx1_H$ for user levels 0 and 1).
- **PWx**: 32-bit password.

When using for command cycles 64-bit transfers the “data” is expected in the correct 32-bit word as indicated by the address “addr”.

Command Sequence Overview Table

The **Table 5-6** summarizes all commands sequences. The following sections describe each command sequence in detail.

Table 5-6 Command Sequences for Flash Control

Command Sequence		1. Cycle	2. Cycle	3. Cycle	4. Cycle	5. Cycle	6. Cycle
Reset to Read	Address Data	.5554 ..xx**F0**					
Enter Page Mode	Address Data	.5554 ..xx**5y**					
Load Page	Address Data	.55F0 **WD**					
Write Page	Address Data	.5554 ..xx**AA**	.AAA8 ..xx**55**	.5554 ..xx**A0**	**PA** ..xx**AA**		
Write UC Page	Address Data	.5554 ..xx**AA**	.AAA8 ..xx**55**	.5554 ..xx**C0**	**UCPA** ..xx**AA**		
Erase Sector	Address Data	.5554 ..xx**AA**	.AAA8 ..xx**55**	.5554 ..xx**80**	.5554 ..xx**AA**	.AAA8 ..xx**55**	**SA** ..xx**30**
Erase Phys Sector	Address Data	.5554 ..xx**AA**	.AAA8 ..xx**55**	.5554 ..xx**80**	.5554 ..xx**AA**	.AAA8 ..xx**55**	**SA** ..xx**40**
Erase UC Block	Address Data	.5554 ..xx**AA**	.AAA8 ..xx**55**	.5554 ..xx**80**	.5554 ..xx**AA**	.AAA8 ..xx**55**	**UCBA** ..xx**C0**
Disable Write Protection	Address Data	.5554 ..xx**AA**	.AAA8 ..xx**55**	.553C **UL**	.AAA8 **PW 0**	.AAA8 **PW 1**	.5558 ..xx**05**
Disable Read Protection	Address Data	.5554 ..xx**AA**	.AAA8 ..xx**55**	.553C ..xx**00**	.AAA8 **PW 0**	.AAA8 **PW 1**	.5558 ..xx**08**
Resume Protection	Address Data	.5554 ..xx**5E**					
Clear Status	Address Data	.5554 ..xx**F5**					

Reset to Read

Calling:

- ST 5554_H, xx$F0_H$

Function:

This function resets the command interpreter to its initial state (i.e. the next command cycle must be the 1st cycle of a sequence). A page mode is aborted.

This command is the only that is accepted without SQER when the command interpreter has already received command cycles of a different sequence but is still not in command

mode. Thus “Reset to Read” can cancel every command sequence before its last command cycle has been received.

The error flags of **FSR** (PFOPER, DFOPER, SQER, PROER, DFSBER, DFCBER, PFDBER, PFMBER, ORIER, VER) and the **XFSR** are cleared. The flags can be also cleared in the status registers without command sequence.

If any Flash bank is busy this command is executed but the flag SQER is set.

Enter Page Mode

Calling:

- ST 5554_H, $xx5y_H$

Function:

The PFlash or the addressed DFlash bank enter page mode. The selection of the PFlash assembly buffer (256 bytes) or the DFlash assembly buffer (128 bytes) is additionally done by the parameter “y_H”.

The write pointer of the page assembly buffer is set to 0, its previous content is maintained.

The page mode is signalled by the flag PAGEx in the FSR separately for PFlash and DFlash.

If a new “Enter Page Mode” command sequence is received while any Flash bank is already in page mode SQER is set but this sequence is correctly executed (i.e. in this case the command interpreter is not reset).

Load Page

Calling:

- ST $55F0_H$, WD (Note: offset $55F4_H$ is used for the higher order 32-bit transfers).

Function:

Loads the data “WD” into the page assembly buffer and increments the write pointer to the next position[1)].

All WD transfers for one page must have the same width (either all 32-bit or all 64-bit). Else the transfer is refused with SQER.

The addressed bank must be in page mode, else SQER is issued.

If “Load Page” is called more often than necessary for filling the page SQER is issued and if configured an interrupt is triggered. The overflow data is discarded. The page mode is not left.

1) More specifically: after “Load Page” has transferred 64 bits (i.e. two command with 32-bit WD or one command with one 64-bit WD) the ECC is calculated and the result is transferred to the assembly buffer.

Write Page

Calling:

- ST 5554_H, $xxAA_H$
- ST $AAA8_H$, $xx55_H$
- ST 5554_H, $xxA0_H$
- ST PA, $xxAA_H$

Function:

This function starts the programming process for one page with the data transferred previously by “Load Page” commands. Upon entering command mode the page mode is finished (indicated by clearing the corresponding PAGE flag) and the BUSY flag of the bank is set.

This command is refused with SQER when the addressed Flash bank is not in page mode.

SQER is also issued when PA addresses an unavailable Flash range or when PA does not point to a legal page start address.

If after “Enter Page Mode” too few data or no data was transferred to the assembly buffer with “Load Page” then “Write Page” programs the page but sets SQER. The missing data is programmed with the previous content of the assembly buffer.

When the page “PA” is located in a sector with active write protection or the Flash module has an active global read protection the execution fails and PROER is set.

Write User Configuration Page

Calling:

- ST 5554_H, $xxAA_H$
- ST $AAA8_H$, $xx55_H$
- ST 5554_H, $xxC0_H$
- ST UCPA, $xxAA_H$

Function:

As for “Write Page”, except that the page “UCPA” is located in a user configuration block. This changes the Flash module’s protection configuration.

When the page “UCPA” is located in an UCB with active write protection or the Flash module has an active global read protection the execution fails and PROER is set.

When UCPA is not the start address of a page in a valid UCB the command fails with SQER.

Erase Sector

Calling:

- ST 5554_H, $xxAA_H$

- ST $AAA8_H$, $xx55_H$
- ST 5554_H, $xx80_H$
- ST 5554_H, $xxAA_H$
- ST $AAA8_H$, $xx55_H$
- ST SA, $xx30_H$

Function:

The sector “SA” is erased.

SQER is returned when SA does not point to the base address of a correct sector (as specified at the beginning of this section) or to an unavailable sector.

When SA has an active write protection or the Flash module has an active global read protection the execution fails and PROER is set.

Erase Physical Sector

Calling:

- ST 5554_H, $xxAA_H$
- ST $AAA8_H$, $xx55_H$
- ST 5554_H, $xx80_H$
- ST 5554_H, $xxAA_H$
- ST $AAA8_H$, $xx55_H$
- ST PSA, $xx40_H$

Function:

The physical sector “PSA” is erased.

SQER is returned when PSA does not point to the base address of a correct sector (as specified at the beginning of this section) or an unavailable sector.

When PSA has an active write protection or the Flash module has an active global read protection the execution fails and PROER is set.

Erase User Configuration Block

Calling:

- ST 5554_H, $xxAA_H$
- ST $AAA8_H$, $xx55_H$
- ST 5554_H, $xx80_H$
- ST 5554_H, $xxAA_H$
- ST $AAA8_H$, $xx55_H$
- ST UCBA, $xxC0_H$

Function:

The addressed user configuration block “UCB” is erased.

When the UCB has an active write protection or the Flash module has an active global read protection the execution fails and PROER is set.

The command fails with SQER when UCBA is not the start address of a valid UCB.

Disable Sector Write Protection

Calling:

- ST 5554_H, $xxAA_H$
- ST $AAA8_H$, $xx55_H$
- ST $553C_H$, UL
- ST $AAA8_H$, PW0
- ST $AAA8_H$, PW1
- ST 5558_H, $xx05_H$

Function:

The sector write protection belonging to user level “UL” is temporarily disabled by setting FSR.WPRODIS when the passwords PW0 and PW1 match their configured values in the corresponding UCB.

The command fails by setting PROER when any of PW0 and PW1 does not match. In this case until the next application reset all further calls of “Disable Sector Write Protection” and “Disable Read Protection” fail with PROER independent of the supplied password.

Disable Read Protection

Calling:

- ST 5554_H, $xxAA_H$
- ST $AAA8_H$, $xx55_H$
- ST $553C_H$, $xx00_H$
- ST $AAA8_H$, PW0
- ST $AAA8_H$, PW1
- ST 5558_H, $xx08_H$

Function:

The Flash module read protection including the derived module wide write protection are temporarily disabled by setting FSR.RPRODIS when the passwords PW0 and PW1 match their configured values in the UCB0.

The command fails by setting PROER when any of PW0 and PW1 does not match. In this case until the next application reset all further calls of “Disable Sector Write Protection” and “Disable Read Protection” fail with PROER independent of the supplied password.

Resume Protection

Calling:

- ST 5554_H, $xx5E_H$

Function:

This command clears all FSR.WPRODISx and the FSR.RPRODIS effectively enabling again the Flash protection as it was configured.

A FSR.WPRODISx is not cleared when corresponding UCBx is not in the “confirmed” state (see **Chapter 5.5.5.3**).

Clear Status

Calling:

- ST 5554_H, $xxF5_H$

Function:

The flags FSR.PROG and FSR.ERASE and the error flags of **FSR** (PFOPER, DFOPER, SQER, PROER, DFSBER, DFCBER, PFDBER, PFMBER, ORIER, VER) and **XFSR** are cleared. These flags can be also cleared in the status registers without command sequence.

When any Flash bank is busy this command fails by setting additionally SQER.

5.5.4.4 Concurrent Operations

Each PMU of a device is independent of the other. Therefore they can be operated concurrently without limitation. Thus also Flash operations in different PMUs can be performed concurrently.

The Flash banks of one Flash module use common resources in Flash and in the PMU. Therefore the concurrent operations are restricted. These are the general rules:

- When the PFlash is not busy reads of all not-busy banks are allowed. This includes margin reads (**Chapter 5.5.6.2**).
- When the PFlash is busy read accesses to DFlash banks shall not be performed but do not cause a bus error.
- Read accesses to busy banks return generally a bus error.
- When any Flash bank is busy with programming the command sequence “Enter Page Mode” must not be executed. The results are unpredictable. Thus at most one programming process can be active.

The following table shows an overview of the allowed combinations. It uses the abbreviations:

- R: Read. Including margin reads (see **Chapter 5.5.6.2**).
- P: Program.
- E: Erase.

- SHE: DFlash reserved for the SHE module.

A ‘/’ indicates that both operations are allowed and ‘–’ that no operation is allowed.

Please note that even if a table row contains more than one “R” the PMU performs only one Flash read access at a time. The table indicates which reads are possible.

Table 5-7 Concurrent Flash Processes

PFlash	DFlash0	DFlash1	Comment
R	R	R	
P/E	–	–	Read of DFlash not supported but does not return a bus error.
R	P/E	R	
R	R	P/E	
R	P	E	When erase started first: “erase suspend”, when program started first: “delayed erase”.
R	E	P	
R	SHE		SHE reserves complete DFlash and prohibits all command sequences.

In all other cases not contained in the table command sequences are forbidden when any Flash bank is busy. This is not automatically prevented by hardware!

The “erase suspend” feature: For EEPROM emulation “Enter Page Mode”, “Load Page” and “Write Page” are accepted for a DFlash page when the other DFlash bank is busy with an erase operation. Suspending the erase operation does typically not exceed t_{FL_ErSusp}. After that the programming is performed and finally the erase operation is automatically resumed.

The “delayed erase” feature: when on one DFlash bank a programming is ongoing an “Erase Sector” or “Erase Physical Sector” sequence is accepted by the PMU. It sets immediately busy but internally the execution of the erase process starts after the programming has finished.

5.5.5 Flash Protection

The Flash memory can be read and write protected. The protection is configured by programming the user configuration blocks “UCB”.

Advice how to use the Flash protection can be found in **Chapter 5.7.5**. This chapter contains only the terse facts.

The SHE module offers a separate possibility to protect Flash content from unauthorized modification or use.

5.5.5.1 Effective Flash Read Protection

The effectiveness of Flash read protection is selected per master. A read access to PFlash or DFlash fails with bus error under the following conditions:

- Tricore PMI (code fetch): FCON.DCF and FCON.RPA.
- Tricore DMI (data read): FCON.DDF and FCON.RPA.
- DMA, SDMA and their submasters: (FCON.DDF and FCON.RPA) or FCON.DDFDMA.
- PCP: (FCON.DDF and FCON.RPA) or FCON.DDFPCP.
- SHE: (FCON.DDF and FCON.RPA) or FCON.DDFSHE.

The read protection bit FCON.RPA is determined during startup by the protection configuration of UCB0. It can be temporarily modified by the command sequences “Disable Read Protection” and “Resume Protection” which modify FSR.RPRODIS. FCON.RPA is determined by the following equation:

- FCON.RPA = PROCON0.RPRO and not FSR.RPRODIS.

The SHE module has always full access to its KeyFlash.

The bits FCON.DDFx and FCON.DCFx are initialized by the startup software depending on the configured protection and the startup mode. They can also be directly modified by the user software under conditions noted in the description of **FCON**.

5.5.5.2 Effective Flash Write Protection

A range of Flash can be write protected by several means:

- The complete PFlash and optionally the complete DFlash can be write protected by the read protection.
- Groups of sectors of PFlash can be write-protected by three different “users”, i.e. UCBs:
  - UCB0: Write protection that can be disabled with the password of UCB0.
  - UCB1: Write protection that can be disabled with the password of UCB1.
  - UCB2: Write protection that can not be disabled anymore (ROM or OTP function: “one-time programmable”).

The write protection is effective independent of the master.

An active write protection causes the program and erase command sequences to fail with a PROER. This was described in the command sequence documentation (**Chapter 5.5.4.3**).

A range “x” (i.e. a group of sectors, see **PROCON0**) of the PFlash is write protected if any of the following conditions is true:

- FCON.RPA
- PROCON2.SxROM
- PROCON0.SxL and not(FSR.WPRODIS0)
- PROCON1.SxL and not(PROCON0.SxL) and not(FSR.WPRODIS1)

Thus with the password of UCB0 the write protection of sectors protected by user 0 and user 1 can be disabled, however with the password of UCB1 only those sectors that are only protected by user 1. The write protection of user 2 (OTP) can be obviously not disabled. The global write protection caused by the read protection can be disabled as described above by using the password of UCB0 to disable the read protection.

The DFlash is write protected if any of the following conditions is true:

- FCON.RPA and not(PROCON0.DFEXPRO).

Thus the DFEXPRO bit can be used to exclude the DFlash from an otherwise global write protection.

5.5.5.3 Configuring Flash Protection in the UCB

As indicated above the effective protection is determined by the content of the PROCON0–2 registers. These are loaded during startup from the UCB0–2. Each UCB comprises 1 KByte of Flash organized in 4 UC pages of 256 bytes. The UCBs have the following structure:

Table 5-8 UCB Content

UC Page	Bytes	UCB0	UCB1	UCB2
0	0–3	PROCON0	PROCON1	PROCON2
	4–7	SHEBOOT0	SHEBOOT1	SHEBOOT2
	8–11	PROCON0 (copy)	PROCON1 (copy)	PROCON2 (copy)
	12–15	SHEBOOT0 (copy)	SHEBOOT1 (copy)	SHEBOOT2 (copy)
	16–19	PW0 of User 0	PW0 of User 1	unused
	20–23	PW1 of User 0	PW1 of User 1	unused
	24–27	PW0 of User 0 (copy)	PW0 of User 1 (copy)	unused
	28–31	PW1 of User 0 (copy)	PW1 of User 1 (copy)	unused
1	unused	unused	unused	unused
2	0–3	confirmation code	confirmation code	confirmation code
	8–11	confirmation code (copy)	confirmation code (copy)	confirmation code (copy)
	other	unused	unused	unused
3	unused	unused	unused	unused

If the confirmation code field is programmed with 8AFE 15C3$_H$ the UCB content is “confirmed” otherwise it is “unconfirmed”. The status flags FSR.PROIN, FSR.RPROIN and FSR.WPROIN0–2 indicate this confirmation state:

- FSR.PROIN: set when any UCB is in the confirmed state.
- FSR.RPROIN: set when PROCON0.RPRO is ‘1’ and the UCB0 is in “confirmed” state.
- FSR.WPROIN0–2: set when their UCB0–2 is in “confirmed” state.

An UCB can be erased with the command “Erase User Configuration Block”. An UCB page can be programmed with the command “Write User Configuration Page”. These commands fail with PROER when the UCB is write-protected.

An UCB is write-protected if:

- UCB0: (FSR.RPROIN and not FSR.RPRODIS) or (FSR.WPROIN0 and not FSR.WPRODIS0)
- UCB1: FSR.WPROIN1 and not FSR.WPRODIS1.
- UCB2: FSR.WPROIN2

So when the UCB2 is in the “confirmed” state its protection can not be changed anymore. Therefore this realizes a one-time programmable protection.

5.5.5.4 System Wide Effects of Flash Protection

An active Flash read protection needs to be respected in the complete system.

The SSW checks if the Flash read protection is active in any PMU, if yes:

- If the selected boot mode executes from internal PFlash.
  - The SSW clears the DCF, DDF and the DDFx.
  - The SSW leaves the debug interface locked (OSTATE.IF_LCK stays 1).
- If the selected boot mode does not execute from internal PFlash:
  - The SSW either leaves DCF and DDF set or actively sets them again in each PMU after evaluating the configuration sector.
  - Additionally the master individual DDFx flags (DDFDMA, DDFPCP, and DDFSHE) are set.
  - The debug interface is unlocked.

If the read protection is inactive in all PMUs the DCF, DDF and DDFx flags are cleared by the SSW and the debug interface is unlocked.

Only depending on the Flash read protection of PMU0 are:

- If the read protection of PMU0 is active the CPU allows only one write access to PMI_CON2 effectively allowing only one instruction cache configuration change. The field PC of the register SMACON which affects the instruction cache is ignored and the value 00_B is used.

Full Flash analysis of an FAR device is only possible when the customer has removed all installed protections or delivers the necessary passwords with the device. As the removal of an OTP protection in UCB2 is not possible the OTP protection inevitably limits analysis capabilities.

5.5.6 Data Integrity and Safety

The data in Flash is stored with error correcting codes “ECC” in order to protect against data corruption. The healthiness of Flash data can be checked with margin checks.

5.5.6.1 ECC

The data in Flash is stored with ECC codes. These are automatically generated when the data is programmed. When data is read these codes are evaluated. Depending on the Flash bank different algorithms with different error correction capabilities are used:

- Data in PFlash uses an ECC code with SEC-DED (Single Error Correction, Double Error Detection) capabilities. Each block of 64 data bits is accompanied with 8 ECC bits.
  Two different algorithms can be selected:
  – Standard ECC as used in previous product generations (default).
  – “Safety ECC” or “Address ECC”: this algorithm calculates the ECC not only over the data bits but additionally over address bits.
- Data in DFlash uses an ECC code with DEC-TED (Double Error Correction, Triple Error Detection) capabilities. Each block of 64 data bits is accompanied with 16 ECC bits.

The selection of the standard PFlash ECC or the “Address ECC” for generation and evaluation is done by the register bit FCON.ADDECC. This is set by the startup software depending on the PROCON0.ADDECC but can also be modified by software.

Standard PFlash ECC

In the standard PFlash ECC the 8-bit ECC value is calculated over 64 data bits. An erased data block (all bits ‘0’) has an ECC value of 00_H. Therefore an erased sector is free of ECC errors. A data block with all bits ‘1’ has an ECC value of FF_H.

The ECC is automatically generated when programming the PFlash when this is not disabled with ECCW.PECENCDIS.

The ECC is automatically evaluated when reading data.

This algorithm has the following capabilities:

- Single-bit error:
  – Is noted in FSR.PFSBER.
  – Data and ECC value are corrected if this is not disabled with ECCR.PECDECDIS.
  – Interrupt is triggered if enabled with FCON.PFSBERM.
- Double-bit error:
  – Is noted in FSR.PFDBER.
  – Is noted in XFSR.PFDBER.
  – Causes a bus error if not disabled by MARP.TRAPDIS.
  – Interrupt is triggered if enabled with FCON.PFDBERM.

Address errors are not detected.

Safety PFlash ECC

The standard ECC can not detect addressing errors, i.e. delivery of a correct data block from an incorrect address. The SRI bus ensures that addressing errors are detected between master and PMU. But addressing errors in the PMU and Flash can not be detected. This missing capability is added by the “Address ECC”.

An 8-bit ECC value is calculated over 64 data bit and the address bits 23:3.

The detection and correction features of the standard ECC are kept as described above.

Additionally the PMU can detect single-bit address corruptions:

- It is noted in FSR.PFDBER[1].
- It is noted in XFSR.PFADER.
- Causes a bus error if not disabled by MARP.TRAPDIS.
- Interrupt is triggered if enabled with FCON.PFDBERM.

As side effect of this ECC algorithm an erased sector (containing 0 data and 0 ECC) can not be read without detecting ECC errors. Thus when this algorithm is enabled data must be programmed before the Flash range may be read.

DFlash ECC

In the DFlash a 16-bit ECC value is calculated over 64 data bits. An erased data block has an ECC value 0000_H. Therefore an erased sector is free of ECC errors. A data block with all bits ‘1’ has an ECC value of $FFFF_H$.

The algorithm has the following capabilities:

- Single-bit error and double-bit error:
  - Is noted in FSR.DFCBER.
  - Data and ECC value are corrected if this is not disabled with ECCR.DECDECDIS.
  - Interrupt is triggered if enabled with FCON.DFCBERM.
- Triple-bit error:
  - Is noted in FSR.DFMBER.
  - Causes a bus error if not disabled by MARD.TRAPDIS.
  - Interrupt is triggered if enabled with FCON.DFMBERM.

Address errors are not detected.

5.5.6.2 Margin Checks

The Flash memory offers a “margin check feature”: the limit which defines if a Flash cell is read as logic ‘0’ or logic ‘1’ can be shifted. This is controlled by the registers **MARP** and **MARD**.

1) This bit is set because it is used in the FSR to notify uncorrectable errors.

The margin selection of PFlash and DFlash is independent. The margin selected with MARD is effective for the complete DFlash.

After changing the read margin at least $t_{FL\_MarginDel}$ have to be waited before reading the affected Flash module.

5.5.7 Interrupts and Traps

Generally the PMU reports fatal errors by issuing a bus error which is translated by the CPU into a trap (PMI sets PSE trap and DMI the DSE trap).

This is a list of conditions for reporting a bus error:

- Uncorrectable ECC error (if not disabled by MARP or MARD).
- Write access to read-only register.
- Not allowed write access to protected register (e.g. SV or ENDINIT).
- Not allowed Flash read access with active read protection.
- Read access to not available Flash memory.
- Read-modify-write access to the Flash memory.
- Read accesses to a busy Flash bank.
- Read accesses to a Flash bank reserved by SHE.

Furthermore selected events can trigger interrupts. The service request node is documented in the SCU. It is controlled by the SCU registers INTSET, INTCLR, INTDIS, INTNP, and INTSTAT. The selection of the events for interrupt triggering is done by **FCON**.

The following events can trigger an interrupt when enabled:

- End of busy: any transition of any of PBUSY, D0BUSY or D1BUSY from ‘1’ to ‘0’ triggers the interrupt (program and erase sequences, wake-up).
- Operational error: see OPER flag.
- Verify error: see VER flag.
- Protection error: see PROER flag.
- Sequence error: see SQER flag.
- Correctable bit-error: read access delivered corrected data.
- Uncorrectable bit-error: read access had an uncorrectable bit error.

The event that triggered the interrupt can be determined from the FSR register.

An interrupt event it also triggered when the event appears again and the corresponding status flag is still set.

5.5.8 Reset and Startup

All PMU and Flash functionality is reset with the application reset with the exception of the register bits: FSR.PROG, FSR.ERASE, FSR.PFOPER, FSR.DFOPER. These bits are reset with the power-on reset.

During Flash startup the logical sectors are checked for an over-erased state (caused by an aborted sector erase) which could prevent read access to all logical sectors of the same physical sector. This feature is configured with **PROCON1** and further described in **Chapter 5.7.8.3**.

During startup after each reset the protection setting is installed from the UCBs. If a protection field has a double-bit error its copy is used. This is indicated by setting FSR.ORIER. If a copy has also a double-bit error the startup software does not enter the user code.

5.5.9 Power Reduction

The Flash module can enter sleep mode to reduce its power consumption. The sleep request can have two sources:

- Global sleep mode requested by the SCU (see “Power Management”). Only executed by the Flash when FCON.ESLDIS = 0.
- Programming ‘1’ to the bit FCON.SLEEP.

After receiving a sleep request the Flash starts the ramp down when the Flash becomes idle, i.e. none of the banks is in command mode and no reads are executed anymore. An ongoing read burst is finished completely. During ramp down to sleep mode all FSR.BUSYx are set.

The sleep mode is indicated in FSR.SLM. The FSR.BUSYx stay set.

The Flash module can be woken up by releasing the sleep request. It enters read mode again after t_{WU}. During the wake-up phase the FSR.BUSYx are set.

Note: It is not recommended to use the SCU controlled sleep mode with FCON.ESLDIS = 0. Because software had to ensure that upon wake-up the Flash is only read after it has returned to read mode. Earlier reads cause bus errors! Therefore the reset value of FCON.ESLDIS is 1.

Note: Requesting sleep mode does not disable automatically an enabled end-of-busy interrupt. When requesting sleep mode during an ongoing Flash operation with enabled end-of-busy interrupt, the operation finishes, the interrupt is issued and then the Flash enters sleep mode. However this end-of-busy interrupt will wake-up the CPU again.

An additional power reduction feature is enabled by setting FCON.IDLE. In this case the PFlash read path is switched off when no read access is pending and the read buffers are filled. System performance is slightly reduced because a flash line hit can not be exploited.

5.6 Register Set

The register set consists of some general PMU registers which are partly only implemented for PMU0 because they control its specific functionality (**Chapter 5.6.1**). The other registers control Flash functionality (**Chapter 5.6.2**). Register fields related to DFlash, KeyFlash and SHE are implemented also when these Flash banks or functionalities are not available but they are without function.

The register access conditions use the following abbreviations:

- "U": Access permitted in User Mode 0 or 1 (applicable to write and read).
- "SV": Access permitted in Supervisor Mode (applicable to write and read).
- "E": ENDINIT protected write. "E" means a write access is only allowed before ENDINIT or after disabling this protection with a password as described in the SCU chapter.
- "–" or "BE": Access not permitted.

The PMU and Flash use the following combinations (see **Table 5-10** and **Table 5-12**):

- U, SV: access always allowed (i.e. in user mode or supervisor mode).
- BE: access never allowed, causing a bus error.
- SV, E: access only in supervisor mode with disabled ENDINIT protection.

All accesses prevented due to these restrictions fail with a bus error.

Also accesses to unoccupied register addresses fail with a bus error.

Note: It is convention to use short register names (e.g. "FCON") in the chapter that defines these registers. In all other chapters and in the development tools long register names are used that are a concatenation of the module instance (e.g. "PMU0" or "FLASH0"), an underscore and the short register name, i.e. "FLASH0_FCON". This document uses for clarification also mostly the long names.

5.6.1 PMU Registers

Non-Flash related registers for the PMU. They have the prefix "PMUx_".

Table 5-9 Registers Address Space

Module	Base Address	End Address	Note
PMU0	$F800\ 0500_H$	$F800\ 052B_H$	
PMU1	$F800\ 0600_H$	$F800\ 062B_H$	

Table 5-10 Registers Overview

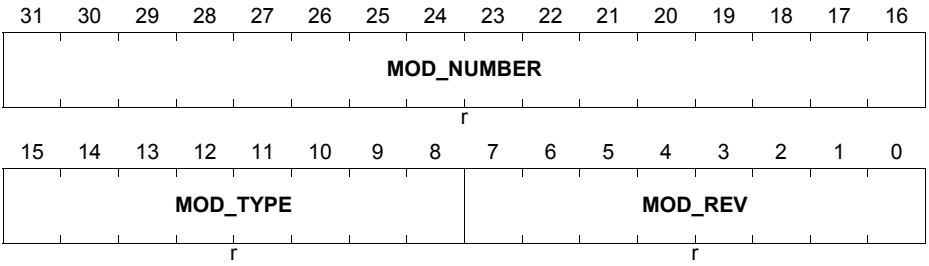
Short Name	Description	Offset Addr.[1]	Access Mode		Reset Class	Page Number
			Read	Write		
ID	Module Identification	08_H	U, SV	BE	3	5-28

1) The absolute register address is calculated as follows:
Module Base Address (Table 5-9) + Offset Address (shown in this column)

5.6.1.1 PMU Identification

The PMU_ID register identifies the PMU and its version.

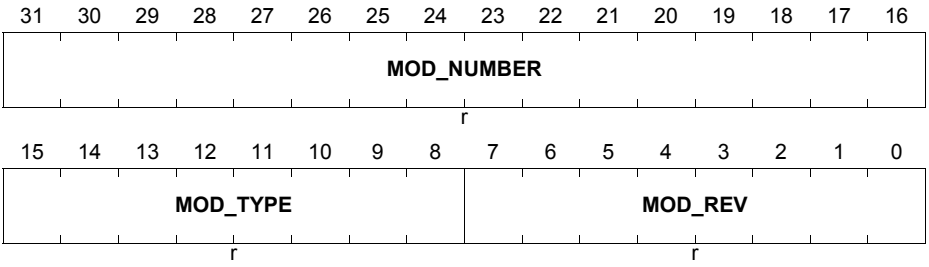
PMU0_ID
PMU0 Identification Register (F800 0508$_H$) Reset Value: 0081 C0XX$_H$



Field	Bits	Type	Description
MOD_REV	[7:0]	r	**Module Revision Number** MOD_REV defines the module revision number. The value of a module revision starts with 01_H (first rev.).
MOD_TYPE	[15:8]	r	**Module Type** This bit field is $C0_H$. It defines the module as a 32-bit module.
MOD_NUMBER	[31:16]	r	**Module Number Value** This bit field defines the module identification number for PMU0.

PMU1_ID

PMU1 Identification Register (F800 0608$_H$) Reset Value: 0082 C0XX$_H$



Field	Bits	Type	Description
MOD_REV	[7:0]	r	**Module Revision Number** MOD_REV defines the module revision number. The value of a module revision starts with 01$_H$ (first rev.).
MOD_TYPE	[15:8]	r	**Module Type** This bit field is C0$_H$. It defines the module as a 32-bit module.
MOD_NUMBER	[31:16]	r	**Module Number Value** This bit field defines the module identification number for PMU1.

5.6.2 Flash Registers

The absolute address of a Flash register is calculated by the base address from Table 5-11 plus the offset address of this register from Table 5-12.

Table 5-11 Registers Address Space

Module	Base Address	End Address	Note
FLASH0	F800 1000$_H$	F800 23FF$_H$	Flash registers of PMU0
FLASH1	F800 3000$_H$	F800 43FF$_H$	Flash registers of PMU1

Table 5-12 Registers Overview

Short Name	Description	Offset Addr.[1]	Access Mode		Reset Class	Page Number
			Read	Write		
ID	Flash Module Identification Register	1008$_H$	U, SV	BE	3	5-47
FSR	Flash Status Register	1010$_H$	U, SV	U, SV	3 [2]	5-32
FCON	Flash Configuration Register	1014$_H$	U, SV	SV, E	3	5-41
MARP	Margin Control Register PFLASH	1018$_H$	U, SV	SV, E	3	5-50
MARD	Margin Control Register DFLASH	101C$_H$	U, SV	U, SV	3	5-51
PROCON0	Flash Protection Config. User 0	1020$_H$	U, SV	BE	3	5-52
PROCON1	Flash Protection Config. User 1	1024$_H$	U, SV	BE	3	5-55
PROCON2	Flash Protection Config. User 2	1028$_H$	U, SV	BE	3	5-58

SEMA	Flash Access Semaphore	1030$_H$	U, SV	U, SV	3	5-49
SHEBOOT0	SHE Secure Boot Configuration 0	1034$_H$	U, SV	BE	3	5-62
SHEBOOT1	SHE Secure Boot Configuration 1	1038$_H$	U, SV	BE	3	5-62

Table 5-12 Registers Overview (cont'd)

Short Name	Description	Offset Addr.[1]	Access Mode		Reset Class	Page Number
			Read	Write		
SHEBOOT2	SHE Secure Boot Configuration 2	$103C_H$	U, SV	BE	3	5-62
RDBCFG0	Read Buffer Configuration 0	1040_H	U, SV	SV, E	3	5-46
RDBCFG1	Read Buffer Configuration 1	1044_H	U, SV	SV, E	3	5-46
RDBCFG2	Read Buffer Configuration 2	1048_H	U, SV	SV, E	3	5-46
ECCW	ECC Write Register	$10E0_H$	U, SV	SV, E	3	5-60
ECCR	ECC Read Register	$10E4_H$	U, SV	SV, E	3	5-61

1) The absolute register address is calculated as follows:
Module Base Address (Table 5-11) + Offset Address (shown in this column)

2) Some bits are not reset with the application reset but only with the power-on reset.

5.6.2.1 Flash Status

The Flash Status Register FSR reflects the overall status of the Flash module after Reset and after reception of the different commands.

The error flags and the two status flags (PROG, ERASE) are affected by the "Clear Status" command. The error flags are also cleared with the "Reset to Read" command.

Some error flags are marked as writable. These flags can be cleared by writing a '1' to this bit.

Flash Status Register

FSR
Flash Status Register **(1010_H)** **Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rh	rh	rwh	rwh	rh	rh	rh	rh

Field	Bits	Type	Description
PBUSY	0	rh	**Program Flash Busy** [1)] HW-controlled status flag. 0_B PFlash ready, not busy; PFlash in read mode. 1_B PFlash busy; PFlash not in read mode. Indication of busy state of PFlash because of active execution of program or erase operation; PFlash busy state is also indicated during Flash startup after reset or in sleep mode; while in busy state, the PFlash is not in read mode.
FABUSY	1	rh	**Flash Array Busy**[1)] Internal busy flag for testing purposes. Must be ignored by application software. This may only use PBUSY, D0BUSY and D1BUSY.
D0BUSY	2	rh	**Data Flash Bank 0 Busy**[1)] HW-controlled status flag. 0_B DFlash0 ready, not busy; DFlash0 in read mode. 1_B DFlash0 busy; DFlash0 not in read mode. Indication of busy state of DFlash bank 0 because of active execution of program or erase operation; DFlash0 busy state is also indicated during Flash startup after reset or in sleep mode; while in busy state the DFlash0 is not in read mode.

Field	Bits	Type	Description
D1BUSY	3	rh	**Data Flash Bank 1 Busy**[1)] HW-controlled status flag. 0_B DFlash1 ready, not busy; DFlash1 in read mode. 1_B DFlash1 busy; DFlash1 not in read mode. Indication of busy state of DFlash bank 1 because of active execution of program or erase operation; DFlash1 busy state is also indicated during Flash startup after reset or in sleep mode; while in busy state the DFlash0 is not in read mode.
PROG	4	rwh	**Programming State** [2)3)] HW-controlled status flag. 0_B There is no program operation requested or in progress or just finished. 1_B Programming operation (write page) requested (from FIM) or in action or finished. Set with last cycle of Write Page command sequence, cleared with Clear Status command (if not busy) or with power-on reset. If one BUSY flag is coincidently set, PROG indicates the type of busy state. If xOPER is coincidently set, PROG indicates the type of erroneous operation. Otherwise, PROG indicates, that operation is still requested or finished. Can be also cleared by writing ‘1’ to it.
ERASE	5	rwh	**Erase State**[2)3)] HW-controlled status flag. 0_B There is no erase operation requested or in progress or just finished 1_B Erase operation requested (from FIM) or in action or finished. Set with last cycle of Erase command sequence, cleared with Clear Status command (if not busy) or with power-on reset. Indications are analogous to PROG flag. Can be also cleared by writing ‘1’ to it.

Field	Bits	Type	Description
PFPAGE	6	rh	**Program Flash in Page Mode** [1)4)] HW-controlled status flag. 0_B Program Flash not in page mode 1_B Program Flash in page mode; assembly buffer of PFlash (256 byte) is in use (being filled up) Set with Enter Page Mode for PFlash, cleared with Write Page command *Note: Concurrent page and read modes are allowed*
DFPAGE	7	rh	**Data Flash in Page Mode**[1)4)] HW-controlled status flag. 0_B Data Flash not in page mode 1_B Data Flash in page mode; assembly buffer of DFlash (128 byte) is in use (being filled up) Set with Enter Page Mode for DFlash, cleared with Write Page command. *Note: Concurrent page and read modes are allowed*
PFOPER	8	rwh	**Program Flash Operation Error**[2)3)4)] 0_B No operation error reported by Program Flash 1_B Flash array operation aborted, because of a Flash array failure, e.g. an ECC error in microcode. This bit is not cleared with application reset, but with power-on reset. Registered status bit; must be cleared per command or by writing ‘1’.
DFOPER	9	rwh	**Data Flash Operation Error**[2)3)4)] Function analogous to Program Flash OPER
SQER	10	rwh	**Command Sequence Error**[1)2)4)] 0_B No sequence error 1_B Command state machine operation unsuccessful because of improper address or command sequence. A sequence error is not indicated if the Reset to Read command aborts a command sequence. Registered status bit; must be cleared per command or by writing ‘1’.

Field	Bits	Type	Description
PROER	11	rwh	**Protection Error**[1)2)4)] 0_B No protection error 1_B Protection error. A Protection Error is reported e.g. because of a not allowed command, for example an Erase or Write Page command addressing a locked sector, or because of wrong password(s) in a protected command sequence such as “Disable Read Protection” Registered status bit; must be cleared per command or by writing ‘1’.
PFSBER	12	rwh	**PFlash Single-Bit Error and Correction**[1)2)4)] 0_B No Single-Bit Error detected during read access to PFlash 1_B Single-Bit Error detected and corrected The error is set when in a 256-bit block read from Flash at least one 64-bit block contained a single-bit error. This is independent of cached/non-cached addressing. Registered status bit; must be cleared per command or by writing ‘1’.
DFCBER	13	rwh	**DFlash Correctable Bit Error and Correction**[1)2)4)] 0_B No Correctable Bit Error detected during read access to DFlash. 1_B Correctable Bit Error detected and corrected. Registered status bit; must be cleared per command or by writing ‘1’.
PFDBER	14	rwh	**PFlash Double-Bit Error**[1)2)4)] 0_B No Double-Bit Error or Address Error detected during read access to PFlash 1_B Double-Bit Error or Address Error detected in PFlash The error is set when in a 256-bit block read from Flash at least one 64-bit block contained a double-bit error. This is independent of cached/non-cached addressing. Registered status bit; must be cleared per command or by writing ‘1’.

Field	Bits	Type	Description
DFMBER	15	rwh	**DFlash Multi-Bit Error**[1)2)4)] 0_B No uncorrectable Multi-Bit Error detected during read access to DFlash 1_B Uncorrectable Multi-Bit Error detected in DFlash Registered status bit; must be cleared per command or by writing '1'.
PROIN	16	rh	**Protection Installed** 0_B No protection is installed 1_B Read or/and write protection for one or more users is configured and correctly confirmed in the User Configuration Block(s). HW-controlled status flag
RPROIN	18	rh	**Read Protection Installed** 0_B No read protection installed 1_B Read protection and global write protection (with or without Data Flash) is configured and correctly confirmed in the User Configuration Block 0. Supported only for the master user (user zero). HW-controlled status flag
RPRODIS	19	rh	**Read Protection Disable State** [1)5)] 0_B Read protection (if installed) is not disabled 1_B Read and global write protection is temporarily disabled. Flash read with instructions from other memory, as well as program or erase on not separately write protected sectors is possible. HW-controlled status flag
WPROIN0	21	rh	**Sector Write Protection Installed for User 0** 0_B No write protection installed for user 0 1_B Sector write protection for user 0 is configured and correctly confirmed in the User Configuration Block 0. HW-controlled status flag

Field	Bits	Type	Description
WPROIN1	22	rh	**Sector Write Protection Installed for User 1** 0_B No write protection installed for user 1 1_B Sector write protection for user 1 is configured and correctly confirmed in the User Configuration Block 1. HW-controlled status flag
WPROIN2	23	rh	**Sector OTP Protection Installed for User 2** 0_B No OTP write protection installed for user 2 1_B Sector OTP write protection with ROM functionality is configured and correctly confirmed in the UCB2. The protection is locked for ever. HW-controlled status flag
WPRODIS0	25	rh	**Sector Write Protection Disabled for User 0**[1)5)] 0_B All protected sectors of user 0 are locked if write protection is installed 1_B All write-protected sectors of user 0 are temporarily unlocked, if not coincidently locked by user 2 or via read protection. Hierarchical protection control: User-0 sectors are also unlocked, if coincidently protected by user 1. But not vice versa. HW-controlled status flag
WPRODIS1	26	rh	**Sector Write Protection Disabled for User 1**[1)5)] 0_B All protected sectors of user 1 are locked if write protection is installed 1_B All write-protected sectors of user 1 are temporarily unlocked, if not coincidently locked by user 0 or user 2 or via read protection. HW-controlled status flag
SLM	28	rh	**Flash Sleep Mode**[1)] HW-controlled status flag. Indication of Flash sleep mode taken because of global or individual sleep request; additionally indicates when the Flash is in shut down mode. 0_B Flash not in sleep mode 1_B Flash is in sleep or shut down mode

Field	Bits	Type	Description
ORIER	30	rh	**Original Error**[1)2)4)] 0_B No original error detected during startup. 1_B Original data replaced by its copy.
VER	31	rwh	**Verify Error**[1)2)4)] 0_B The page is correctly programmed or the sector correctly erased. All programmed or erased bits have full expected quality. 1_B A program verify error or an erase verify error has been detected. Full quality (retention time) of all programmed (“1”) or erased (“0”) bits cannot be guaranteed. See **Chapter 5.7.7.1** and **Chapter 5.7.7.2** for proper reaction. This flag is set when either PFlash, D0Flash, or D1Flash reported VER. Registered status bit; must be cleared per command or writing ‘1’.
0	17,20, 24, 27, 29	r	**Reserved** Read zero, no write

1) Cleared with application reset (class 3 reset)
2) Cleared with command “Clear Status”
3) Cleared with power-on reset (PORST)
4) Cleared with command “Reset to Read”
5) Cleared with command “Resume Protection”

Note: The xBUSY flags as well as the protection flags cannot be cleared with the “Clear Status” command or with the “Reset to Read” command. These flags are controlled by HW.

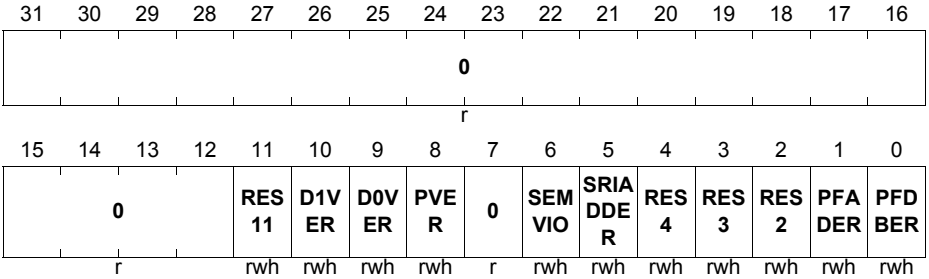
*Note: The reset value above is indicated after correct execution of Flash startup. Additionally, errors are possible after startup (see **Chapter 5.7.7.2**).*

Extended Flash Status Register

The extended Flash status contains additional information about error conditions.

All bits can be cleared by writing a ‘1’ to it. Additionally the complete register is cleared by the command sequences “Reset to Read” and “Clear Status”.

XFSR
Extended Flash Status Register (102C$_H$) Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
PFDBER	0	rwh	**PFlash DBER** A DBER was noted when decoding the ECC of data read from PFlash. The error is set when in a 256-bit block read from Flash at least one 64-bit block contained a double-bit error. This is independent of cached/non-cached addressing.
PFADER	1	rwh	**PFlash Address ECC Error** An address ECC error was noted when decoding the address ECC of data read from PFlash. The error is set when in a 256-bit block read from Flash at least one 64-bit block contained an address ECC error. This is independent of cached/non-cached addressing.
RES2	2	rwh	**Reserved** Status information for internal use.
RES3	3	rwh	**Reserved** Status information for internal use.
RES4	4	rwh	**Reserved** Status information for internal use.
SRIADDERR	5	rwh	**SRI Bus Address ECC Error** This flag is set when the PMU detects an ECC error in the address phase bus transaction on the SRI bus.

Field	Bits	Type	Description
SEMVIO	6	rwh	**Semaphore Violation** When the Flash is reserved by the SHE module command cycles received by any other master set this bit.
PVER	8	rwh	**PFlash Verify Error** A VER was reported during a PFlash operation (see VER in FSR).
D0VER	9	rwh	**D0Flash Verify Error** A VER was reported during a D0Flash operation (see VER in FSR).
D1VER	10	rwh	**D1Flash Verify Error** A VER was reported during a D1Flash operation (see VER in FSR).
RES11	11	rwh	**Reserved** Status information for internal use.
0	[31:12], 7	r	**Reserved;** always read as 0; should be written with 0.

5.6.2.2 Flash Configuration Control

The Flash Configuration Register FCON reflects and controls the following general Flash configuration functions:

- Number of wait states for Flash accesses.
- Indication of installed and active read protection.
- Instruction and data access control for read protection.
- Interrupt mask bits.
- Power reduction and shut down control.

FCON
Flash Configuration Register (1014_H) Reset value: $0007\ 4F08_H$[1)]

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

1) After Flash startup and execution of the startup SW in BootROM (after firmware exit), the initial value is $000X\ 4F08_H$. The initial value of ADDECC depends on PROCON0.ADDECC.

Field	Bits	Type	Description
WSPFLASH	[3:0]	rw	**Wait States for read access to PFlash** This bitfield defines the number of wait states in number of FSI clock cycles (see SCU chapter CCUCON0), which are used for an initial read access to the Program Flash memory area. 0000_B PFlash access with one wait state 0001_B PFlash access with one wait state 0010_B PFlash access with two wait states 0011_B PFlash access with three wait states 0100_B PFlash access with four wait states 0101_B PFlash access with five wait states 0110_B PFlash access with six wait states 0111_B PFlash access with seven wait states. .... PFlash access with eight up to fourteen wait states. 1111_B PFlash access with fifteen wait states.
WSECPF	4	rw	**Wait State for Error Correction of PFlash** 0_B No additional wait state for error correction 1_B One additional wait state for error correction during read access to Program Flash. If enabled, this wait state is only used for the first transfer of a burst transfer. Set this bit only when requested by Infineon.

Field	Bits	Type	Description
WSDFLASH	[11:8]	rw	**Wait States for read access to DFlash** This bitfield defines the number of wait states in number of FSI clock cycles (see SCU chapter CCUCON0), which are used for a read access to the Data Flash memory area. 0000_B DFlash access with one wait state 0001_B DFlash access with one wait state 0010_B DFlash access with two wait states 0011_B DFlash access with three wait states 0100_B DFlash access with four wait states 0101_B DFlash access with five wait states 0110_B DFlash access with six wait states 0111_B DFlash access with seven wait states. 1000_B DFlash access with eight wait states. .... DFlash access with nine up to fourteen wait states. 1111_B DFlash access with fifteen wait states.
WSECDF	12	rw	**Wait State for Error Correction of DFlash** 0_B No additional wait state for error correction 1_B One additional wait state for error correction during read access to Data Flash Set this bit only when requested by Infineon.
IDLE	13	rw	**Dynamic Flash Idle** 0_B Normal/standard Flash read operation 1_B Dynamic idle of Program Flash enabled for power saving; static prefetching disabled *Note: In Data Flash, dynamic idle is always enabled (prefetching not supported).*
ESLDIS	14	rw	**External Sleep Request Disable** 0_B External sleep request signal input is enabled 1_B Externally requested Flash sleep is disabled The ‘external’ signal input is connected with a global power-down/sleep request signal from SCU.
SLEEP	15	rw	**Flash SLEEP** 0_B Normal state or wake-up 1_B Flash sleep mode is requested, Wake-up from sleep is started with clearing of the SLEEP-bit.

Field	Bits	Type	Description
RPA	16	rh	**Read Protection Activated** This bit monitors the status of the Flash-internal read protection. This bit can only be ‘0’ when read protection is not installed or while the read protection is temporarily disabled with password sequence. 0_B The Flash-internal read protection is not activated. Bits DCF, DDF are not taken into account. Bits DCF, DDFx can be cleared 1_B The Flash-internal read protection is activated. Bits DCF, DDF are enabled and evaluated.
DCF	17	rwh	**Disable Code Fetch from Flash Memory** This bit enables/disables the code fetch from the internal Flash memory area. Once set, this bit can only be cleared when RPA=’0’. This bit is automatically set with reset and is cleared during startup, if no RP installed, and during startup (BootROM SW) in case of internal start out of Flash. 0_B Code fetching from the Flash memory area is allowed. 1_B Code fetching from the Flash memory area is not allowed. This bit is not taken into account while RPA=’0’.
DDF	18	rwh	**Disable Any Data Fetch from Flash** This bit enables/disables the data read access to the Flash memory area (Program Flash and Data Flash). Once set, this bit can only be cleared when RPA=’0’. This bit is automatically set with reset and is cleared during startup, if no RP installed, and during startup (BootROM SW) in case of internal start out of Flash. 0_B Data read access to the Flash memory area is allowed. 1_B Data read access to the Flash memory area is not allowed. This bit is not taken into account while RPA=’0’.

Field	Bits	Type	Description
DDFDMA	20	rw	**Disable Data Fetch from DMA Controller** This bit enables/disables the data read access to PFlash and DFlash memory from the DMA controller, the SDMA controller and other bus masters that access the SRI bus via the DMA peripheral interfaces — these are, dependent on the device: Cerberus, MLI and Memcheck. Once set, this bit can only be cleared when RPA='0'. 0_B The data read access by the DMA, SDMA controller and its peripheral interfaces to the Flash memory area is allowed. 1_B The data read access to the Flash memory area is not allowed for the DMA, SDMA controller and its peripheral interfaces.
DDFPCP	21	rw	**Disable Data Fetch from PCP Controller** This bit enables/disables the data read access to PFlash and DFlash memory via the LFI bridge from PCP controller. Once set, this bit can only be cleared when RPA='0'. 0_B The data read access by the PCP controller to the Flash memory area is allowed. 1_B The data read access to the Flash memory area is not allowed for the PCP controller.
DDFSHE	22	rw	**Disable Data Fetch from SHE Module** This bit enables/disables the data read access to PFlash and DFlash memory via the LFI bridge from the SHE module. Once set, this bit can only be cleared when RPA='0'. 0_B The data read access by the SHE module to the Flash memory area is allowed. 1_B The data read access to the Flash memory area is not allowed for the SHE module.
ADDECC	23	rw	**Address ECC in PFlash** This bit selects if the data in PFlash is written and read with an ECC code that is calculated over address bits (see **Chapter 5.5.6**). 0_B Standard ECC is used. 1_B Address ECC is used. **Attention: this bit must not be changed while accessing Flash (reading, programming, erasing).**

Field	Bits	Type	Description
VOPERM	24	rw	**Verify and Operation Error Interrupt Mask** 0_B Interrupt not enabled 1_B Flash interrupt because of Verify Error or Operation Error in Flash array (FSI) is enabled
SQERM	25	rw	**Command Sequence Error Interrupt Mask** 0_B Interrupt not enabled 1_B Flash interrupt because of Sequence Error is enabled
PROERM	26	rw	**Protection Error Interrupt Mask** 0_B Interrupt not enabled 1_B Flash interrupt because of Protection Error is enabled
PFSBERM	27	rw	**PFlash Single-Bit Error Interrupt Mask** 0_B No Single-Bit Error interrupt enabled 1_B Single-Bit Error interrupt enabled for PFlash
DFCBERM	28	rw	**DFlash Correctable Bit Error Interrupt Mask** 0_B No Correctable Bit Error interrupt enabled 1_B Correctable Bit Error interrupt enabled for DFlash
PFDBERM	29	rw	**PFlash Double-Bit Error Interrupt Mask** 0_B Double-Bit Error interrupt for PFlash not enabled 1_B Double-Bit Error interrupt for PFlash enabled. Especially intended for margin check
DFMBERM	30	rw	**DFlash Multi-Bit Error Interrupt Mask** 0_B Multi-Bit Error interrupt for DFlash not enabled 1_B Multi-Bit Error interrupt for DFlash enabled. Especially intended for margin check
EOBM	31	rw	**End of Busy Interrupt Mask** 0_B Interrupt not enabled 1_B EOB interrupt is enabled
0	[7:5], 19	r	**Reserved** Read/write zero

Note: The default numbers of wait states represent the slow cases. This is a general proceeding and additionally opens the possibility to execute higher frequencies without changing the configuration.

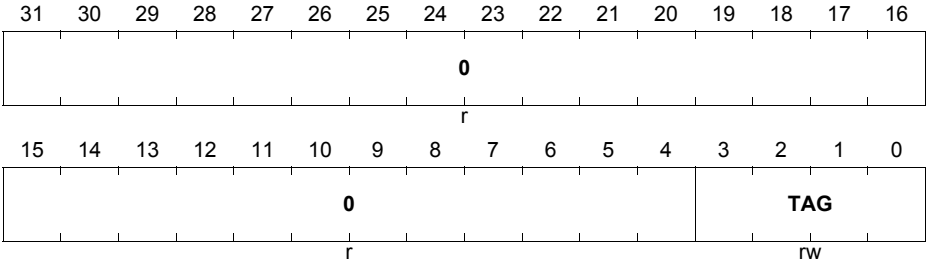
Note: After reset and execution of BootROM startup SW, the read protection control bits are coded as follows:
DDF, DCF, RPA = "110": No read protection installed
DDF, DCF, RPA = "001": Read protection installed; start in internal Flash
DDF, DCF, RPA = "111": Read protection installed; start not in internal Flash.

5.6.2.3 Flash Read Buffer Configuration

The RDBCFG0–2 registers define the assignment of read buffers to masters. The functionality of the read buffers is described in **Chapter 5.5.3**.

It is forbidden to assign more than one read buffer to the same master. The resulting behavior is unpredictable.

RDBCFG0
Read Buffer Cfg 0 **(1040_H)** **Reset Value: $0000\ 0002_H$**
RDBCFG1
Read Buffer Cfg 1 **(1044_H)** **Reset Value: $0000\ 0004_H$**
RDBCFG2
Read Buffer Cfg 2 **(1048_H)** **Reset Value: $0000\ 000D_H$**



Field	Bits	Type	Description
TAG	[3:0]	rw	**Master Tag** This read buffer is assigned to the master with SRI tag = TAG.
0	[31:4]	r	**Reserved** Write 0, read 0.

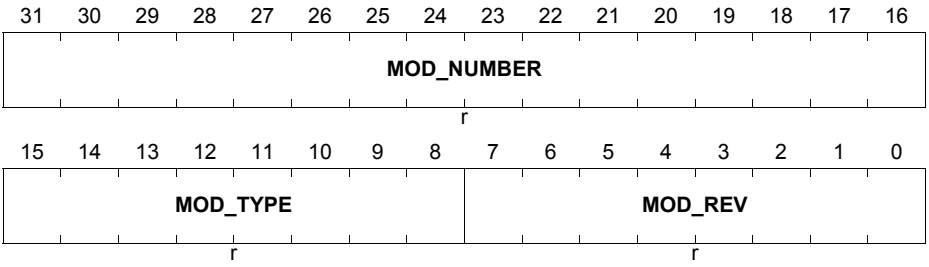
5.6.2.4 Flash Identification Register

The register identifies the Flash module which can have a different version from the PMU.

Flash0 Identification

FLASH0_ID

Flash Module Identification Register (1008_H) **Reset Value: 0083 C0XX$_H$**



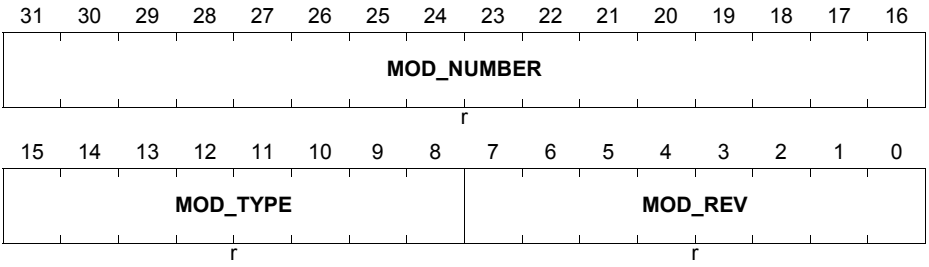
Field	Bits	Type	Description
MOD_REV	[7:0]	r	**Module Revision Number** MOD_REV defines the module revision number. The value of a module revision starts with 01_H (first revision).
MOD_TYPE	[15:8]	r	**Module Type** This bit field is $C0_H$. It defines the module as a 32-bit module.
MOD_NUMBER	[31:16]	r	**Module Number Value** This bit field defines a module identification number. For the TC1798 Flash0 this number is 0083_H.

Flash1 Identification

The second Flash array (Flash1) controlled by PMU1 can have a different feature set from the Flash0 at PMU0, e.g. it typically does not contain a DFlash. Therefore it has another ID number than the Flash0 array.

FLASH1_ID

Flash Module Identification Register (1008_H) **Reset Value: 0084 C0XX$_H$**



Field	Bits	Type	Description
MOD_REV	[7:0]	r	**Module Revision Number** MOD_REV defines the module revision number. The value of a module revision starts with 01_H (first revision).
MOD_TYPE	[15:8]	r	**Module Type** This bit field is $C0_H$. It defines the module as a 32-bit module.
MOD_NUMBER	[31:16]	r	**Module Number Value** This bit field defines a module identification number. For the TC1798 Flash1 this number is 0084_H.

5.6.2.5 Flash Reservation Semaphore

The Flash banks use common resources which limits the concurrency of Flash processes (see **Chapter 5.5.4.4**). This is especially an issue when the SHE module and a Flash EEPROM emulation driver both need access to the DFlash. The Flash user interface is not suitable for multi-master operation. Therefore this semaphore enables different masters or SW threads to reserve the Flash interface.

The bit “SHE” can be set and cleared exclusively by the SHE module using a separate communication path. This is done by the SHE module when it executes commands that need Flash access.

The bits Sx can be set by writing a ‘1’ to this bit. No bit is changed to ‘1’ when already SHE or any Sx is ‘1’ or if the write access contains more than one ‘1’-bit in the Sx positions.

A bit can be cleared by writing a ‘1’ to the corresponding clear bit SxC.

When the SHE bit is set:

- Command cycles are only accepted from the SHE module. All others are rejected with a bus error and set XFSR.SEMVIO.
- Read accesses from DFlash and KeyFlash by any other bus master than SHE fail with a bus error.
- Command cycles addressing the PFlash fail with SQER.
- Further protections (especially of registers) are not activated. The application is responsible to configure the Flash so that it can be operated by the SHE module. This is not security risk because the SHE module verifies all operations.

When an other Sx bit is set the SHE module can not request Flash access. The Sx bits do not affect the hardware operation any further. Flash drivers can use them to organize competing Flash accesses.

This register is also existing in PMU1 and higher. In these the bit SHE is not connected to the SHE module and stays always at ‘0’.

SEMA
Flash Access Semaphore **(1030_H)** **Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

w	rwh	w	rwh	w	rwh	w	rwh	w	rwh	w	rwh	w	rwh	r	rh

Field	Bits	Type	Description
SHE	0	rh	**SHE Semaphore** If set only the SHE module has full Flash access (see **Chapter 5.5.4.4**)
Sx (x=1-7)	2*x	rwh	**Semaphore x** This bit can be written to ‘1’ if no other Sx or the SHE bit is ‘1’. This bit can be cleared by writing a ‘1’ to the corresponding SxC.
SxC (x=1-7)	2*x+1	w	**Semaphore x Clear** Writing a ‘1’ clears the corresponding Sx. Read 0.

Field	Bits	Type	Description
0	[31:16], 1	r	**Reserved** Write 0, read 0.

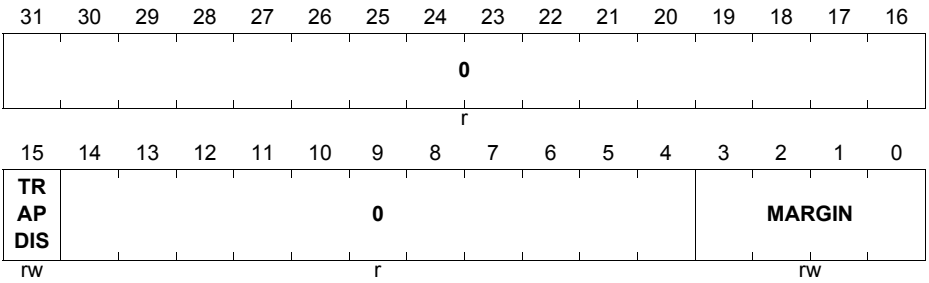
5.6.2.6 Margin Check Control

Note: Although double-bit error traps are disabled with reset, the traps are enabled by the startup SW (firmware) in Boot ROM before Boot ROM exit.

Margin Check Control PFlash

MARP

Margin Control Register PFLASH (1018$_H$) **Reset Value: 0000 8000$_H$**



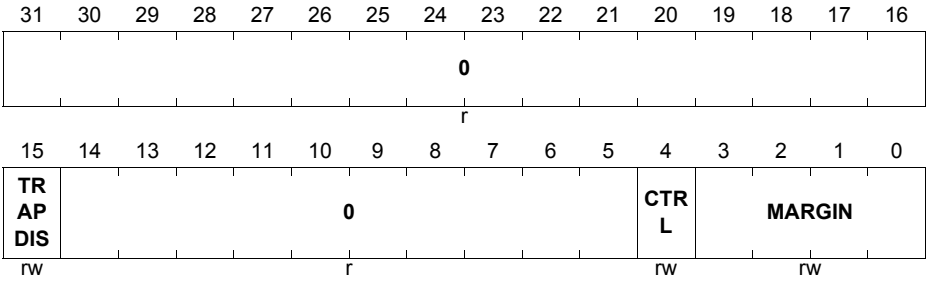
Field	Bits	Type	Description
MARGIN	[3:0]	rw	**PFLASH Margin Selection** 0000_B **Default**, Standard (default) margin. 0001_B **Tight0**, Tight margin for 0 (low) level. Suboptimal 0-bits are read as 1s. 0100_B **Tight1**, Tight margin for 1 (high) level. Suboptimal 1-bits are read as 0s. – Reserved.
TRAPDIS	15	rw	**PFLASH Double-Bit Error Trap Disable** 0_B If a double-bit error occurs in PFLASH, a bus error trap is generated[1]. 1_B The double-bit error trap is disabled. Shall be used only during margin check
0	[14:4], [31:16]	r	**Reserved;** always read as 0; should be written with 0.

1) After Boot ROM exit, double-bit error traps are enabled (TRAPDIS = 0).

Margin Check Control DFlash

MARD

Margin Control Register DFLASH (101C$_H$) **Reset Value: 0000 8000$_H$**



Field	Bits	Type	Description
MARGIN	[3:0]	rw	**DFLASH Margin Selection** 0000$_B$ **Default**, Standard (default) margin. 0001$_B$ **Tight0**, Tight margin for 0 (low) level. Suboptimal 0-bits are read as 1s. 0100$_B$ **Tight1**, Tight margin for 1 (high) level. Suboptimal 1-bits are read as 0s. – Reserved.
CTRL	4	rw	**Margin Control Enable** 0_B The active read margin for both DFLASH banks is determined by MARGIN. 1_B Both DFlash banks are read with standard (default) margin independently of MARGIN.
TRAPDIS	15	rw	**DFLASH Multiple-Bit Error Trap Disable** 0_B If an uncorrectable multi-bit error occurs in DFLASH, a bus error trap is generated[1]. 1_B The multi-bit error trap is disabled. Shall be used only during margin check
0	[14:5], [31:16]	r	**Reserved;** always read as 0; should be written with 0.

1) After Boot ROM exit, multi-bit error traps are enabled (TRAPDIS = 0).

5.6.2.7 Protection Configuration Indication

The configuration of read/write/OTP protection is indicated with registers PROCON0, PROCON1 and PROCON2, thus separately for every user, and it is generally indicated in the status register FSR.

The three PROCONx registers are read-only registers. They are defined as follows:

Protection Configuration for User 0

PROCON0
Flash Protection Config. User 0 (1020_H) Reset Value: 0000 0000_H

DATM	30	rh	**Disable ATM** This bit indicates if the ATM “Application Test Mode” is disabled or not. 0_B ATM is enabled. 1_B ATM is disabled. This bit is only used in PMU0.
RES31	31	rh	**Reserved** Deliver the corresponding content of UCB2.
RES	[29:17]	rh	**Reserved** Deliver the corresponding content of UCB2.

5.6.2.8 Flash ECC Access

ECC Write Register

The Error Correction Code Write register ECCW contains bits for disabling the ECC encoding separately for PFlash and DFlash.

When disabling the ECC encoding for PFlash with PECENCDIS = ‘1’ the 8-bit ECC code for the next 64-bit data block transferred from PMU to the Flash assembly buffer is taken from ECCW.WCODEL.

When disabling the ECC encoding for DFlash with DECENCDIS = ‘1’ the 16-bit ECC code for the next 64-bit data block transferred from PMU to the Flash assembly buffer is taken from ECCW.WCODEH (bits 15:8) and ECCW.WCODEL (bits 7:0).

Because of internal dependencies only one of PECENCDIS or DECENCDIS may be set to ‘1’.

ECCW
ECC Write Register **($10E0_H$)** **Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PECENCDIS	DECENCDIS	0													
rw	rw	r													

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
WCODEH								WCODEL							
rw								rw							

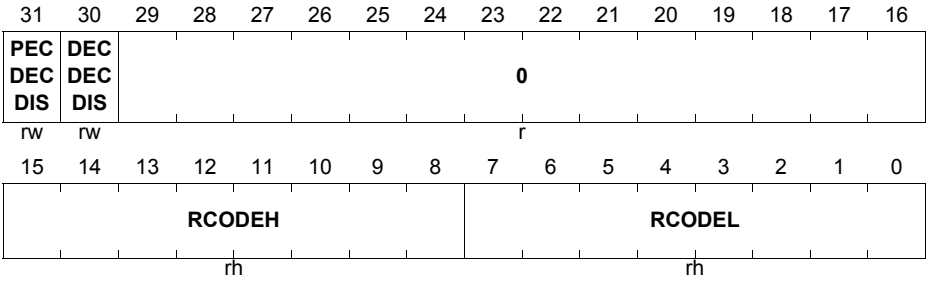
Field	Bits	Type	Description
WCODEL	[7:0]	rw	**Error Correction Write Code Low** 8-bit ECC code for the current 64-bit write buffer to be written into the assembly buffer instead of generated ECC.
WCODEH	[15:8]	rw	**Error Correction Write Code High** 8-bit ECC code for the current 64-bit write buffer to be written into the assembly buffer instead of generated ECC.
DECENCDIS	30	rw	**DFlash ECC Encoding Disable** 0_B The ECC code is automatically calculated. 1_B The ECC code is taken from WCODEH and WCODEL.
PECENCDIS	31	rw	**PFlash ECC Encoding Disable** 0_B The ECC code is automatically calculated. 1_B The ECC code is taken from WCODEL.
0	[29:16]	r	**Reserved;** always read as 0.

ECC Read Register

The Error Correction Code Read register ECCR allows to disable the ECC correction. The ECC decoding (i.e. the error detection) is not influenced. If necessary the trap generation has to be separately disabled by MARP.TRAPDIS and MARD.TRAPDIS. Further on this register allows to read the uncorrected ECC code.

The ECC code of the last read access is stored in ECCR.RCODEx. For PFlash reads the 8-bit ECC code is stored in ECCR.RCODEL and for DFlash the 16-bit ECC code is stored in ECCR.RCODEH and ECCR.RCODEL.

ECCR
ECC Read Register **($10E4_H$)** **Reset value: $0000\ 0000_H$**

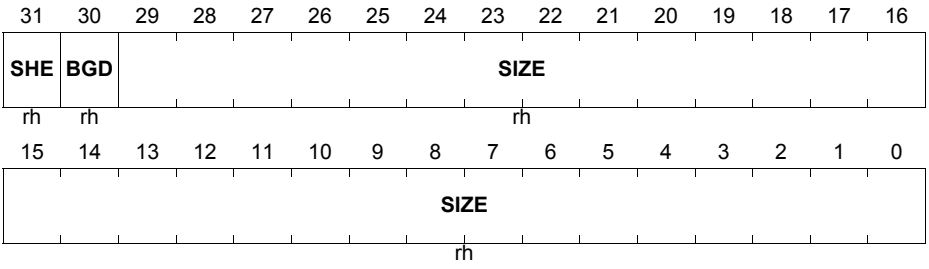


Field	Bits	Type	Description
RCODEL	[7:0]	rh	**Error Correction Read Code Low** 8-Bit ECC code, read from the Flash read buffer with last data read operation. For PFlash this is the complete ECC value. For DFlash this is the lower half of the 16-bit ECC value.
RCODEH	[15:8]	rh	**Error Correction Read Code High** 8-Bit ECC code, read from the Flash read buffer with last data read operation. Unused for PFlash reads. For DFlash this is the upper half of the 16-bit ECC value.
DECDECDIS	30	rw	**DFlash ECC Decoding Disable** 0_B ECC correction for DFlash enabled. 1_B ECC correction for DFlash disabled.
PECDECDIS	31	rw	**PFlash ECC Decoding Disable** 0_B ECC correction for PFlash enabled. 1_B ECC correction for PFlash disabled.
0	[29:16]	r	**Reserved;** always read as 0.

5.6.2.9 SHE Secure Internal Flash Boot

The SHEBOOT0–2 registers supply the bytes 4–7 of the user configuration blocks 0–2. As documented in the SHE chapter these fields can be used to configure a secure boot from internal Flash.

SHEBOOTx (x=0-2)
SHE Secure Boot Cfg **(1034_H+4*x)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
SHE	31	rh	**Secure Boot Enable** As documented in the SHE chapter this bit enables the secure boot from internal Flash with SIZE taken as size of the boot loader.
BGD	30	rh	**Background Secure Boot** As documented in the SHE chapter the secure boot can be performed in background or foreground. 0_B **FGD**, Foreground secure boot. 1_B **BGD**, Background secure boot.
SIZE	[29:0]	rh	**SHE Bootloader Size** Byte length of the SHE bootloader.

5.7 Application Hints

The following application hints should support the user in using the PMU and Flash optimally.

5.7.1 Changes with Respect to Audo-NG and Audo-F

The following changes of the PMU with respect to Audo-NG and Audo-F products are highlighted:

- Changed bus interface from LMB to SRI.
- No bus “retry” anymore in case of reading busy flash banks. Always a bus error is triggered.
- The wait-state settings in FCON don’t relate to the bus clock as in Audo-F (i.e. the LMB clock) but to the FSI clock. This clock has its own divider from the PLL clock which needs to be configured in SCU_CCUCON0.FSIDIV. It must be configured to have a relation f_{SRI}/f_{FSI} or 2/1 or 1/1.
- Enhanced Flash read buffer concept with master specific read buffers.
- The OVRAM and the EMEM were moved to a different module “LMU”.
- Support of SHE
  - Software handling Flash memory should negotiate Flash access with SHE module using the SEMA semaphore.
  - Different content of UCBs supporting SHE secure boot function. New SHEBOOTx registers.
  - DDFSHE flag in FCON.
  - Handling key storage for SHE in additional private sectors of the DFlash.
- Configuration of ALSE with UCB1: possibility to disable ALSE for selected logical sectors.
- DFEXPRO set independent of RPROIN.
- TP: changed address RTPWT. Changed configuration. See separate documentation.
- Programming and reading data with disabled ECC generation and correction allows customers to program data with invalid ECC.
- Error flags in FSR can be selectively cleared to enable easier flag handling for concurrent operations.
- New extended status register XSFR.
- Reorganization of PROCONs due to extended memory range.
- Changed base addresses of all Flash modules.
- DEC-TED ECC algorithm in DFlash.
- Address ECC and normal SEC-DED ECC in PFlash.
  Attention: this feature can cause incompatibility of Audo-NG/F Flash drivers with this device.

5.7.2 Performing Flash Operations

This section offers advice for programming command sequences.

General Advice

- Code that performs PFlash programming or erasing must not be executed from the same PFlash.
- The command cycles shall address the non-cached address range of the Flash (otherwise the data may stay in the cache or could be received by the PMU in an incorrect order).
- The non-cached Flash range is not regarded as peripheral address space by the TriCore. This means that a read (notably reading the FSR for checking the flags) placed behind the last command cycle write in program order might be executed before this last write.
  The FSR flags PAGE, PROG, ERASE can be used to ensure that polling for a cleared BUSY starts only after the command was accepted by the PMU.
  Additionally it is recommended to place a “DSYNC” instruction between a command sequence and read accesses to depending data including affected registers.
- The caches (data cache in DMI “DCache” and instruction cache in PMI “ICACHE”) as well as the data line buffer in the DMI “DLB” are not automatically invalidated nor updated after changing Flash content by erasing or programming. It is therefore recommended to either invalidate them actively or read the Flash content via the non-cached address range. Otherwise old data might be delivered from these buffers.
  The DMI cache and line buffer can be invalidated by writing OVC_OCON.DCINVAL to ‘1’. The ICACHE can be invalidated by writing PCON1.PCINV to ‘1’. All buffers are invalidated by a reset.
- The PMU and Flash work with the SRI and FSI clocks. When changing the divider values of these clocks in SCU_CCUCON0 the following rules apply:
  – The only allowed PMU/Flash “operation” when switching is reading from Flash memory. Programming or erasing the Flash is forbidden.
  – It must be ensured that before, during and after the divider change the configured number of Flash wait-cycles is sufficient for the selected clock frequency. Remember that the wait-cycles are counted with f_{FSI}.

Sequence for Programming

The following sequence is the most defensive one for programming a page. It is however acceptable to skip some checks because the programmed data should be verified anyhow afterwards:

- “Clear Status” to clear flags.
- “Enter Page Mode”.
- DSYNC.
- Wait until FSR.xFPAGE = ‘1’ or fail if FSR.SQER = ‘1’ or FSR.PROER = ‘1’.

- Repeat “Load Page” until the page is filled.
- “Write Page”.
- DSYNC.
- Wait until FSR.PROG = ‘1’ or fail if FSR.SQER = ‘1’ or FSR.PROER = ‘1’.
- Wait until FSR.xBUSY = ‘0’ or enable the interrupt.
  – While FSR.xBUSY is ‘1’ the flags FSR.xFOPER can be checked for ‘1’ as abort criterion to protect against hardware failures causing BUSY to stay ‘1’.
- Check for FSR.VER flag (see handling advice in **Chapter 5.7.7.1**).
- Fail if FSR.xFOPER = ‘1’.
- Check programmed content, evaluate FSR.xDBER and possibly count single-bit errors.
- Clear error flags and FSR.PROG either with “Clear Status” or by directly writing to FSR.

Sequence for Erasing

The following sequence is the most defensive one for erasing a sector. It is however acceptable to skip some checks because the programmed data should be verified anyhow after programming:

- “Clear Status” to clear flags.
- “Erase Sector”.
- DSYNC.
- Wait until FSR.ERASE = ‘1’ or fail if FSR.SQER = ‘1’ or FSR.PROER = ‘1’.
- Wait until FSR.xBUSY = ‘0’ or enable the interrupt.
  – While FSR.xBUSY is ‘1’ the flags FSR.xFOPER can be checked for ‘1’ as abort criterion to protect against hardware failures causing BUSY to stay ‘1’.
- Check for FSR.VER flag (see handling advice in **Chapter 5.7.7.1**).
- Fail if FSR.xFOPER = ‘1’.
- Clear error flags and FSR.ERASE either with “Clear Status” or by directly writing to FSR.

Concurrent Use of D0Flash and D1Flash

The DFlash supports concurrent operations, notably programming in one bank and erasing in the second bank (see **Chapter 5.5.4.4**). This feature was already available in previous product generations Audo-NG and Audo-F. In these product generations the Flash driver faced some challenges because error flags were not separated for each bank and flags could not be easily cleared while an operation was ongoing. With this product generation flag handling for concurrent operations was significantly enhanced.

The following depicts the flow for a programming routine on D0Flash which can be executed while an erase is already ongoing in D1Flash:

- “Enter Page Mode”
- DSYNC.

- Wait until FSR.DFPAGE = ‘1’ or fail if FSR.SQER = ‘1’ or FSR.PROER = ‘1’ (development time check).
- Repeat “Load Page” until the page is filled.
- “Write Page”.
- DSYNC.
- Wait until FSR.PROG = ‘1’ or fail if FSR.SQER = ‘1’ or FSR.PROER = ‘1’ (development time check).
- Wait until FSR.D0BUSY = ‘0’ or enable the interrupt.
  – While FSR.D0BUSY is ‘1’ the flags FSR.DFOPER can be checked for ‘1’ as abort criterion to protect against hardware failures causing BUSY to stay ‘1’.
- Check for XFSR.D0VER (see handling advice in **Chapter 5.7.7.1**). Clear flag by writing XFSR.D0VER = ‘1’.
- Fail if FSR.DFOPER = ‘1’ (could have been caused by programming or erasing).
- Check programmed content and evaluate FSR.DFMBER. Clear flag by writing FSR.DFMBER = ‘1’.
- Clear FSR.PROG by directly writing to FSR.

ENDINIT Register Protection

As described in **Chapter 5.6** many registers are write protected. The write protection “E” is changed by an SPB write access. The user should be aware that this SPB write access changing the protection and preceding or following SRI accesses to registers affected by this protection can incur different system delays. Thus they may not become effective in program order. As remedy it is recommended to read back the protection register (WDT_CON0) before performing the depending SRI accesses.

5.7.3 EEPROM Emulation With DFlash

The term “EEPROM emulation” designates an algorithm with the following features:

- It increases the effective endurance by spreading the EEPROM write accesses over a larger range of Flash memory.
- It ensures that all Flash cells incur a similar number of cycles independent of the update frequency of the EEPROM data (“wear levelling”).
- It manages the allocation of EEPROM data to Flash ranges so that stale data can be erased.

As the DFlash of the TC1798 contains 2 sectors (one in each bank) and only complete sectors can be erased all EEPROM emulation algorithms follow the same general idea:

- The EEPROM writes are performed in one sector, the “active” one. The other sector stays erased.
- The data is stored so that several writes of the same EEPROM address can be performed in one DFlash sector. The position of the latest data version and the original EEPROM address can be determined from the address in Flash and

additional administrative data (e.g. all data is pushed to a stack and the pushed data contains the EEPROM address).
- At a certain sector fill level a sector switch is performed. This moves all active data to the erased sector. After that the active sector is erased and the other sector becomes the active one.

One specific requirement for an EEPROM emulation algorithm is the resistance against aborts during its operation. In any case the algorithm must be able after device startup to recover without data loss, determine the active sector and resume operation.

In many applications even resistance against aborted Flash processes (program, erase) is needed. See details in **Chapter 5.7.8.2**.

5.7.3.1 Robust EEPROM Emulation

A key requirement for an EEPROM emulation algorithm is the reliability of the stored data. The DFlash with its DEC-TED ECC algorithm protects perfectly against bit or bit-line oriented failures. However word-line oriented failures need to be handled by the EEPROM emulation algorithm.

The following hints shall be followed to achieve highest possible robustness:

- Before programming a page save the content of the other page on the same word-line in SRAM.
- Program the new page and compare the content of this page and of the saved page with their reference data. This can be done with normal read margins. Ignore correctable errors and the VER flag.
- If the data comparison fails program this page and the saved content of the other page to a different word-line.
- This procedure can be repeated if the data comparison fails again. The number of repetitions should be limited (e.g. to 3) in case the programming fails because of out-of-spec operating conditions.
- Word-line oriented fails can also have the effect that the affected word-lines can not be erased anymore (other word-lines stay fully functional). A robust EEPROM emulation is immune against such word-lines (e.g. by identifying old data by version counters).

For the TC1798 this robust EEPROM algorithm is required for the usage of the DFlash.

Due to the specificity of each application the appropriate usage and implementation of these measures (together with the more elaborate VER handling) must be chosen according to the context of the application.

5.7.4 Performance Considerations

This section contains advice for optimizing the performance of Flash accesses.

DFlash Performance

The features of the DFlash were optimized for the requirements of an EEPROM emulation. As side effect the access time is significantly higher as in the PFlash. Additionally it can't be read with burst accesses. Therefore it is not recommended to use the DFlash directly memory mapped in the application. In its typical use scenario the active EEPROM data is retrieved from the DFlash once during application startup and is copied to SRAM from where it is used by the application. Further read accesses are only done by the emulation driver when performing updates.

Read Buffers

As described in **Chapter 5.5.3** the PMU contains a set of configurable read buffers. Each of them is assigned to one bus master. It is filled by pre-fetching an incremental following address. For optimum performance a read buffer should be assigned to each master with a high number of PFlash reads.

After reset one read buffer is assigned to the SHE module for optimum performance of the secure boot. When the SHE module is not needed or after finishing the secure boot it is advisable to change this buffer tag depending on application needs (e.g. DMA).

As the pre-fetching is done with increasing addresses reading PFlash ranges with decreasing addresses (e.g. reading an array from a high index to low indices) doesn't benefit from the read buffers.

5.7.5 Handling Flash Protection

Failing to use the Flash protection correctly can on one hand lock the device forever, even damage it or on the other hand leave the protection ineffective.

Effective Use of Flash Protection

For an effective IP protection the Flash read protection must be activated. As described in **Chapter 5.5.5.4** this ensures system wide that the Flash cannot be read from external or changed without authorization.

With the default setting of PROCON0.DFEXPRO (= '0') an active Flash read protection causes a global write protection of PFlash and DFlash in this PMU. Thus for programming the DFlash at application run-time the read protection would have to be disabled with the correct password. This means the password needs to be installed in the Flash.

By programming DFEXPRO to '1' the DFlash is excluded from the global write protection. Now the application can program the DFlash without disabling the read protection and the password doesn't need to be known to the application.

Attention: Full Flash analysis of an FAR device is only possible when the customer has removed all installed protections or delivers the necessary passwords with the device.

As the removal of an OTP protection in UCB2 is not possible the OTP protection inevitably limits analysis capabilities.

Changing UCBs

The protection installation is modified by erasing and programming the UCBs (see **Chapter 5.5.5.3**). These operations need to be performed with care as described in the following.

Aborting an “Erase UC Block” operation (e.g. due to reset or power failure) must be avoided at all means. As an UCB is a logical sector of the configuration sector an aborted erase can affect readability of the complete configuration sector content. With an unreadable configuration sector the device is unusable. An automatic repair (as for the logical sectors, see **Chapter 5.7.8.3**) is not implemented.

For the same reason the allowed number of program/erase cycles of the UCBs must not be exceeded. Over-cycling the UCBs can disturb data in the configuration sector which finally leads to an unusable device.

The installation of the protection and its confirmation on different pages of the UCB offers the possibility to check the installation before programming the confirmation. First the protection needs to be programmed, then an application reset must be triggered to trigger the reading of the UCBs by the PMU and after that the protection can be verified (e.g. “Disable … Protection” to check the password and by checking PROCONs, SHEBOOTs and FCON). The application reset is inevitable because the PMU reads the UCBs only during the startup phase.

5.7.6 Cooperation with SHE

As described in **Chapter 5.5.4.4** the SHE module stores its keys in the KeyFlash. As this KeyFlash has common resources with the PFlash and DFlash the SHE module blocks the DFlash (completely) and the PFlash (only program/erase) by setting its semaphore bit SHE_SEMA.SHE when it accesses the KeyFlash.

Therefore in all applications supporting SHE functionality the Flash drivers should cooperate with the SHE module by setting an other SHE_SEMA bit before doing a program/erase access to PFlash or DFlash and before reading the DFlash. After finishing their access they have to release the semaphore bit again to enable the SHE module access to its KeyFlash.

When Flash drivers don’t set the semaphore bit it might happen that their command sequences are disturbed due to an interception by the SHE module.

When Flash driver don’t release their semaphore bit in time they can prevent the SHE module from performing key updates.

Please note that the SHE subroutines SHE::LOAD_KEY and SHE::DEBUG_AUTHORIZATION call “Clear Status” before programming the keys, effectively clearing FSR. But SHE never calls “Clear Status” when finishing a subroutine

(either reading keys or programming keys). Thus errors reported by a SHE subroutine can be analyzed by reading FSR.

5.7.7 Handling Errors

The earlier sections described shortly the functionality of “error indicating” bits in the flash status registers **FSR** and **XFSR**. This section elaborates on this with more in-depth explanation of the error conditions and recommendations how these should be handled by customer software.

5.7.7.1 Handling Errors During Operation

This first part handles error conditions occurring during operation (i.e. after issuing command sequences) and the second part (**Section 5.7.7.2**) error conditions detected during startup.

SQER “Sequence Error”

Fault conditions:

- Improper command cycle address or data, i.e. incorrect command sequence.
- Write access to busy Flash bank.
- New “Enter Page” in Page Mode.
- “Load Page” and not in Page Mode.
- “Load Page” results in buffer overflow.
- “Load Page” with mixed 32/64 transfers.
- First “Load Page” addresses 2. word.
- “Write Page” with buffer underflow.
- “Write Page” and not in Page Mode.
- “Write Page” to unavailable Flash range.
- Command sequence with address not pointing to a legal start address (e.g. page, UCB or sector).
- Byte transfer to password or data.
- “Erase Sector” command to DFlash.
- Erase UCB with wrong UCBA.

New state:

Read mode is entered with following exceptions:

- “Enter Page” in Page Mode re-enters Page Mode.
- “Write Page” with buffer underflow is executed.
- After “Load Page” causing a buffer overflow the Page Mode is not left, a following “Write Page” is executed.

Proposed handling by software:

Usually this bit is only set due to a bug in the software. Therefore in development code the responsible error tracer should be notified. In production code this error will not occur. It is however possible to clear this flag with “Clear Status” or “Reset to Read” and simply issue the corrected command sequence again.

PFOPER/DFOPER “Operation Error”

Fault conditions:

ECC double-bit error detected in Flash microcode SRAM during a program or erase operation in PFlash or DFlash. This can be a transient event due to alpha-particles or illegal operating conditions or it is a permanent error due to a hardware defect. This situation will practically not occur.

Attention: these bits can also be set during startup (see **Chapter 5.7.7.2**).

New state:

The Flash operation is aborted, the BUSY flag is cleared and read mode is entered. It is however possible that an ECC failure in the Flash SRAM prevents the BUSY flag from being cleared.

Proposed handling by software:

The flag should be cleared with “Clear Status”. The last operation can be determined from the PROG and ERASE flags[1)]. In case of an erase operation the affected physical sector must be assumed to be in an invalid state, in case of a program operation only the affected page. Other physical sectors can still be read. New program or erase commands must not be issued before the next reset.

Consequently a reset must be performed (please note that an application reset is sufficient but it does not automatically clear the PFOPER/DFOPER flags). This performs a new Flash startup with initialization of the microcode SRAM. The application must determine from the context which operation failed and react accordingly. Mostly erasing the addressed sector and re-programming its data is most appropriate. If a “Program Page” command was affected and the sector can not be erased (e.g. in Flash EEPROM emulation) the word-line could be invalidated if needed by marking it with all-one data and the data could be programmed to another empty word-line.

Only in case of a defective microcode SRAM the next program or erase operation will incur again this error.

As protection against an endless BUSY a Flash driver can check for PFOPER/DFOPER during Flash operation.

1) Only when both DFlash banks were busy, one with program and the other with erase the affected bank and operation can not be determined.

Note: Although this error indicates a failed operation it is possible to ignore it and rely on a data verification step to determine if the Flash memory has correct data. Before re-programming the Flash the flow must ensure that a new reset is applied.

*Note: Even when the flag is ignored it is recommended to clear it. Otherwise all following operations — including "sleep" — could trigger an interrupt even when they are successful (see **Chapter 5.5.7**, interrupt because of operational error).*

PROER "Protection Error"

Fault conditions:

- Password failure.
- Erase/Write to protected sector.
- Erase UCB and protection active.
- Write UC-Page to protected UCB.

Attention: a protection violation can even occur when a protection was not explicitly installed by the user. This is the case when the Flash startup detects an error and starts the user software with read-only Flash (see **Chapter 5.7.7.2**). Trying to change the Flash memory will then cause a PROER.

New state:

Read mode is entered. The protection violating command is not executed.

Proposed handling by software:

Usually this bit is only set during runtime due to a bug in the software. In case of a password failure a reset must be performed in the other cases the flag can be cleared with "Clear Status" or "Reset to Read". After that the corrected sequence can be executed.

VER "Verification Error"

Fault conditions:

This flag is a warning indication and not an error. It is set when a program or erase operation was completed but with a suboptimal result. This bit is already set when only a single bit is left over-erased or weakly programmed which would be corrected by the ECC anyhow.

However excessive VER occurrence can be caused by operating the Flash out of the specified limits, e.g. incorrect voltage or temperature. A VER after programming can also be caused by programming a page whose sector was not erased correctly (e.g. aborted erase due to power failure).

Under correct operating conditions a VER after programming will practically not occur. A VER after erasing is not unusual.

Attention: this bit can also be set during startup (see **Chapter 5.7.7.2**).

New state:

No state change. Just the bit is set.

Proposed handling by software:

This bit can be ignored. It should be cleared with “Clear Status” or “Reset to Read”. In-spec operation of the Flash memory must be ensured.

If the application allows (timing and data logistics), a more elaborate procedure can be used to get rid of the VER situation:

- VER after program: erase the sector and program the data again. This is only recommended when there are more than 3 program VERs in the same sector. When programming the DFlash in field (EEPROM emulation) ignoring program VER is normally the best solution because its most likely cause are violated operating conditions. Take care that never a sector is programmed in which the erase was aborted. In the EEPROM emulation the algorithm must ensure this e.g. by programming a marker after finishing successfully the erase.
- VER after erase: the erase operation can be repeated until VER disappears. Repeating the erase more than 3 times consecutively for the same sector is not recommended. After that it is better to ignore the VER, program the data and check its readability. Again for EEPROM emulation its most likely cause are violated operating conditions. Therefore it is recommended to repeat the erase at most once or ignore it altogether.

For optimizing the quality of Flash programming see the following section about handling single-bit ECC errors.

*Note: Even when this flag is ignored it is recommended to clear it. Otherwise all following operations — including “sleep” — could trigger an interrupt even when they are successful (see **Chapter 5.5.7**, interrupt because of verify error).*

PFSBER/DFSBER “Single-Bit Error”

Fault conditions:

When reading data or fetching code from PFlash or DFlash the ECC evaluation detected a single-bit error (“SBE”) which was corrected.

This flag is a warning indication and not an error. A certain amount of single-bit errors must be expected because of known physical effects.

New state:

No state change. Just the bit is set.

Proposed handling by software:

This flag can be used to analyze the state of the Flash memory. During normal operation it should be ignored. In order to count single-bit errors it must be cleared by “Clear Status” or “Reset to Read” after each occurrence[1)].

Usually it is sufficient after programming data to compare the programmed data with its reference values ignoring the SBE bits. When there is a comparison error the sector is erased and programmed again.

When programming the PFlash (end-of-line programming or SW updates) customers can further reduce the probability of future read errors by performing the following check after programming:

- Change the read margin to “high margin 0”.
- Verify the data and count the number of SBEs.
- When the number of SBEs exceeds a certain limit (e.g. 10 in 2 MByte) the affected sectors could be erased and programmed again.
- Repeat the check for “high margin 1”.
- Each sector should be reprogrammed at most once, afterwards SBEs can be ignored.

In case of EEPROM emulation using DFlash the verification of programmed data should be done with the normal read level and SBEs should be ignored. Further advice can be found in **Chapter 5.7.3**.

5.7.7.2 Handling Errors During Startup

The FSR flags are not only used to inform about the success of Flash command sequences but they are also used to inform (1) the startup software and (2) the user software about special situations incurred during startup. In order to react on this information these flags must be evaluated after reset before performing any flag clearing sequence as “Clear Status” or “Reset to Read”.

The following two levels of situations are separated:

- Fatal level: the user software is not started. A WDT reset is performed.
- Error level: the user software is started but the Flash memory must not be programmed or erased.
- Warning level: the user software is started but a warning is issued.

Fatal Level (WDT Reset)

These error conditions are evaluated by the startup software which decides that the Flash is not operable and thus waits for a WDT reset. The application sees only a longer startup time followed by a WDT reset.

The reason for a failed Flash startup can be a hardware error or damaged configuration data.

1) Further advice: the ECC error flags of the PFlash in **FSR** and **XFSR** represent the errors found in an aligned block of 256 bits independent of the read data width of the CPU. This is also independent of the addressed range (cached or non-cached). Thus errors can’t be counted exactly.

Error Level (Flash Read-Only)

In this condition the user software is started but the Flash memory must not be programmed or erased. If writability of the Flash is mandatory the user software itself has to perform a reset.

Flash microcode error:

FSR bits set: PFOPER and DFOPER.

The user software is started normally but the Flash must not be programmed or erased. Please note that programming or erasing is not blocked by hardware. Issuing program or erase sequences despite this condition is forbidden.

Warning Level

These conditions inform the user software about an internally corrected or past error condition.

Logical sector corrected:

FSR bits set: VER.

The Flash detected that a logical sector erase was apparently aborted by reset or power failure. In order to maintain readability of the other logical sectors the Flash tried to repair this state. The aborted erase operation must be repeated. See also **“Recovery From Aborted Logical Sector Erase (“ALSE”)” on Page 5-78**.

Leftover OPER:

FSR bits set: PFOPER or/and DFOPER.

The OPER flags are only cleared by the command sequence “Clear Status” or with a power-on reset. After any other reset a OPER flag can still be set when the user software is started.

Single-bit error in protection:

FSR bits set: PFSBER.

An corrected ECC single-bit error was detected during installation of the protection.

5.7.8 Resets During Flash Operation

A reset or power failure during an ongoing Flash operation (i.e. program or erase) must be considered as violation of stable operating conditions. However the Flash was designed to prevent damage to non-addressed Flash ranges when the reset is applied as defined in the data sheet. The exceptions are erasing logical sectors and UCBs. Aborting an erase process of a logical sector can leave the complete physical sector unreadable. An automatic recovery mechanism is implemented (see **Chapter 5.7.8.3**). When an UCB erase is aborted the complete Flash can become unusable. There is no recovery implemented because UCBs are usually only erased in a controlled environment. The addressed Flash range is left in an undefined state.

5.7.8.1 General Advice

When an erase operation is aborted the addressed logical or physical sector can contain any data. It can even be in a state that doesn't allow this range to be programmed.

When a page programming operation is aborted the page can still appear as erased (but contain slightly programmed bits), it can appear as being correctly programmed (but the data has a lowered retention) or the page contains garbage data. It is also possible that the read data is instable so that depending on the operating conditions different data is read.

For the detection of an aborted Flash process the flags FSR.PROG and FSR.ERASE could be used as indicator but only when the reset was an application reset. Power-on resets can not be determined from any flags. It is not possible to detect an aborted operation simply by reading the Flash range. Even the margin reads don't offer a reliable indication.

When erasing or programming the PFlash usually an external instance can notice the reset and simply restart the operation by erasing the Flash range and programming it again.

5.7.8.2 Advice for EEPROM Emulation

However for the case of EEPROM emulation in the DFlash this external instance is not existing. A common solution is detecting an abort by performing two operations in sequence and determine after reset from the correctness of the second the completeness of the first operation.

E.g. after erasing a DFlash sector a page is programmed. After reset the existence of this page proves that the erase process was performed completely.

The detection of aborted programming processes can be handled similarly. After programming a block of data an additional page is programmed as marker. When after reset the block of data is readable and the marker is existent it is ensured that the block of data was programmed without interruption.

Because often very small amounts of data need to be programmed in EEPROM emulation not always a complete page can be spent as marker. The following recipe allows to reduce the marker size to 8 bytes. This recipe violates the rule that a page may be programmed only once. This violation is only allowed for this purpose (EEPROM emulation with DFlash) and only when the algorithm is robust against disturbed pages (see **Chapter 5.7.3**) by repeating a programming step when it detects a failure.

Robust programming of a page of data with an 8 byte marker:

1. After reset program preferably always first to an even page ("Target Page").
2. If the Other Page on the same word-line contains active data save it to SRAM (the page can become disturbed because of the 4 programming operations per word-line).

3. Program the data to the Target Page (marker bytes of step 5 left as ‘0’).
4. Perform strict check of the Target Page and Other Page (see below).
5. Program 8 byte marker to Target Page (data bytes of step 3 left as ‘0’).
6. Perform strict check of the Target Page and Other Page.
7. In case of any error of the strict check go to the next word-line and program the saved data and the target data again following the same steps.
8. Ensure that the algorithm doesn’t repeat unlimited in case of a violation of operating conditions.

Strict checking of programmed data:

1. Ignore correctable errors and the VER flag.
2. Switch to tight margin 0.
3. If the data (check the complete page) is not equal to the expected data report an error.
4. If an uncorrectable error is detected report an error.

After reset the algorithm has to check the last programmed page if it was programmed completely:

1. Read with normal read level. Ignore single-bit errors.
2. Read 8-byte marker and check for double-bit error.
3. Read data part and verify its consistency (e.g. by evaluating a CRC). Check for double-bit error.
4. If the data part is defective don’t use it (e.g. by invalidating the page).
5. If the data part is ok:
   a) If the marker is erased the data part could have been programmed incompletely. Therefore the data part should not be used or alternatively it could be programmed again to a following page.
   b) If the marker contains incorrect data the data part was most likely programmed correctly but the marker was programmed incompletely. The page could be used as is or alternatively the data could be programmed again to a following page.
   c) If the marker is ok the data part was programmed completely and has the full retention. However this is not ensured for the marker part itself. Therefore the algorithm must be robust against the case that the marker becomes unreadable later.

In very specific cases it is allowed to repair data left from an aborted programming operation: if the algorithm can detect that an abort occurred and the algorithm knows which data must be present in the page it is possible to simply redo the programming by programming the same data again. However the previous methods which “jump” over incorrect data are preferred.

5.7.8.3 Recovery From Aborted Logical Sector Erase (“ALSE”)

When while erasing one of the logical sectors in PFlash a power failure occurs or a reset is triggered the aborted erase process might leave the complete physical sector

unreadable. As often the logical sectors contain important boot code the application might not start anymore. Thus the recommended step to repeat the aborted erase after startup can not be realized.

The FSI implements two recovery algorithms. The selection between the two is done with the SPREC bit (“Soft-Programming Recovery”), i.e. bit 0 of byte 2 in the UCB1 (see **“Configuring Flash Protection in the UCB” on Page 5-21**).

In both cases the algorithm checks first the sectors PS0 and PS4 for an over-erased state. When this is detected the bit FSR.VER is set to inform the application (see **Chapter 5.7.7.2**). After that the algorithm tries to repair this state:

- The default algorithm is selected with SPREC = 0. The over-erased logical sector is searched. When finding one this algorithm programs it shortly with all-one data. The other logical sectors become readable again.
  At least theoretically (especially when operating the device outside of the allowed operating conditions) this algorithm could destroy valid data: when an over-erased logical sector is reported incorrectly during normal startup without a preceding sector erase the data of a logical sector would be overwritten with all-one.
- An alternative algorithm is selected when SPREC = 1. This algorithm searches also for the over-erased logical sector as before. For repair a smarter but more time consuming algorithm is performed. The affected logical sector is not overwritten with all-one but only the over-erased 0-bits are slightly programmed so that they become normal 0-bits again. Under all circumstances this algorithm can not destroy any data but when a lot of data has to be repaired the flash startup time can be increased to t_{FL_SPREC}.

In case this feature is not needed (e.g. because the Alternate Boot Mode “ABM” is used) the execution of the recovery algorithm can be disabled for selected logical sectors with the field “ALSEDIS” of **PROCON1**.

Note: If not disabled the ALSE recovery algorithm is triggered by every reset. However in case of an application reset at high clock frequencies the algorithm “SPREC=1” might not finish before the watchdog is triggered. This can cause a device hang-up. A power-on reset (which switches to a slower clock during startup) lets the repair algorithm finish and the device boot successfully again.

Attention: The ALSE repair algorithm was designed to recover the device after a reset during erase in PFlash caused by an accidental loss of power. Any other possible cause of resets must be prevented by the customer.

5.7.9 ECC

For special applications the ECC features need to be considered.

Using Address ECC

The address ECC is a vital part of the safe fetch path needed for safety applications. The difference between standard ECC and address (“safety”) ECC is explained in Chapter 5.5.6.1.

The calculation of the safety ECC is done over data bits and the address bits 23:3. As side effect erased PFlash ranges or PFlash ranges programmed with the standard ECC will be read with ECC errors.

Thus the installation of an application using the safety ECC should be done as follows:

- By default the devices starts with the standard ECC enabled.
- The Flash loader can enabled the safety ECC by setting FCON.ADDECC.
- From this point on the data is programmed with the safety ECC to the PFlash. Erased ranges can not be verified anymore.
- A sector should be programmed completely to ensure that it can be read without ECC errors.
- In order to configure the safety ECC as standard for the next startup the UCB0 shall be programmed so that PROCON0.ADDECC is set to ‘1’.

Attention: Changing FCON.ADDECC while accessing the Flash (reading, programming, erasing) is forbidden and can cause unpredictable behavior.

Creating Incorrect ECC

In safety applications error detection features are usually verified at each startup. In order to verify the detection logic for ECC double-bit errors an address in PFlash needs to be programmed with such an error.

This can be done by programming a page twice. The data and the calculated ECC bits of both programming steps are effectively or-ed in the Flash because only the 1-bits are programmed. With the knowledge of the ECC calculation the data of the first and second programming step can be chosen to create a page containing a double-bit error. Programming a page twice is allowed if the other page of this word-line is not programmed because then the word-line is programmed only two times.

In the TC1798 the customer can disable automatic ECC generation with ECCW.PECENCDIS. With this feature and with the knowledge of the ECC calculation a page with a double-bit ECC error can be programmed with just one programming step.

Ready-to-use programming routines for the creation of double-bit errors are part of the IFX safety software “SafeTcore”.

6 Local Memory Unit (LMU)

The Local Memory Unit is an SRI peripheral providing access to volatile memory resources. It's primary purpose is to provide 128 kbytes of local memory for general purpose usage but it will also provide access to the separate block of emulation and debug memory (EMEM) provided in the Emulation Devices.

6.1 Feature List

An overview of the features implemented in the LMU follows:

- 128 kbytes of SRAM
  - organised as 64 bit words
  - support for byte, half word and word accesses as well as double-word and burst accesses
- Interface to the EMEM of the ED device.
- OLDA region support.

6.2 Local Memory

The local memory can be used for code execution, data storage or overlay memory. The address range of the memory is 90000000_H to $9001FFFF_H$. As well as being accessed via cached (segment 9_H), the memory can be accessed via non-cached (segment B_H) memory addresses.

The memory implements memory integrity checking for error detection and correction. This means that the memory must be initialised before reads are attempted with the integrity checking enabled to avoid generating spurious data corruption errors. Initialising before enabling the memory integrity logic allows the local memory to support initialisation using word (32 bit) or smaller writes as well as 64 bit writes. The memory integrity checking is enabled using the **LMU_MEMCON.DED_EN** bitfield. After a class 3 reset, this is disabled (0_B).

If memory integrity checking is enabled, a read access which fails the integrity check will be terminated with an SRI error condition. This behaviour can be changed by setting the **LMU_MEMCON.ERRDIS** bit to 1_B. If the bit is set then an SRI error will not occur.

An ECC error will also be reportedto the SCU. The SCU will use this signal for error indication and triggering of an NMI trap (if enabled). Errors will also be flagged using the status bit **DBERR** in the **LMU_MEMCON** register. These bits are set when an error condition occurs and can be cleared by a valid write of 0_B to the bit location. This behaviour is not altered by the setting of **LMU_MEMCON.ERRDIS**.

Note that if multiple accesses are occurring to the LMU, it is possible that a write access to clear the error status will be pipelined behind another access which triggers a new error. In this case, the error will be flagged to the SCU but not reported in the **LMU_MEMCON** register.

If the **LMU_MEMCON.DED_EN** bitfield is set to 0_B after an error has occurred but before and **DBERR** flags has been cleared, then the error flag will remain set to allow software to determine the source of the ECC error.

Local memory performance will be the same as, or better than, the performance of the embedded flash. This applies to both the initial latency of the first word returned and also the incremental latency for each word in the same cache line fetched.

If the CPU access can't be handled by the local memory (e.g. an unsupported SRI opcode has been received), an SRI bus error is reported by the LMU. This will cause a DSE trap.

Some bitfields of the **LMU_MEMCON** register are protected by **LMU_MEMCON.PMIC** bit. If the data written to the register has the bitfield set to 0_B, no change will be made to bit 23_D to 9_D of the register regardless of the data written to these fields.

6.3 Emulation Memory (EMEM)

In the Emulation Device , an Emulation Memory (EMEM) of 768 kbytes is provided, which can be used for either calibration via overlay of non-volatile memory or OLDA (see **Chapter 6.4** below). The address range of the memory is $9F000000_H$ to $9F0BFFFF_H$ (which is identical for all EMEM sizes in the derivatives). As well as the cached addresses (segment 9_H), noncached address (segment B_H) accesses can be used for EMEM accesses via the LMU.

The Emulation Memory interface is a 64-bit wide memory interface that controls the CPU-accesses to the Emulation Memory in the Emulation Device. All widths of write accesses are supported (byte, halfword, word, double-word).

CPU-controlled Load-Modify-Store accesses (with LDMST instruction) are supported as separate read and write instructions not as an atomic operation.

In the production device, the EMEM interface is always disabled. A CPU read access from the Emulation Memory region causes a DSE trap by returning an SRI bus error. If the Emulation Memory region read access is initiated by a SPB master (e.g. PCP), additionally a SPB error interrupt can be generated.

By default, write accesses to the Emulation Memory by any master cause an SRI bus error trap in the production device.

In the Emulation Device, a SRI bus error is returned by the LMU if a read access can't be handled by the EMEM, for example, when the CPU accesses a trace memory tile in EMEM. In this case, the EMEM access is aborted by the LMU.

Write accesses which cannot be handled by the EMEM will fail silently as the write access is completed on the SRI bus before being passed to the EMEM. Therefore any error condition encountered by the EMEM will occur after the SRI access has completed.

The LMU contains a read buffer which is used during EMEM accesses. The contents of the buffer will be used if a subsequent read access overlaps the address range of the

data stored in the buffer. Coherency with the EMEM contents is not maintained. If the address stored in the read buffer has been modified in EMEM by another master on the backbone bus, then invalid data will be returned from the read buffer if the address is then read again via the LMU.

6.4 Online Data Acquisition (OLDA) and its Overlay

Calibration is additionally supported by an OLDA memory range of up to 32 Kbyte, which is a virtual memory and physically only available, if it is redirected (by the overlay feature of the processor) to internal or external physical memory or to the EMEM in the Emulation Device.

If OLDA support is enabled in the LMU, direct write accesses (without redirection) to the OLDA range are not really executed, and they do not generate a bus error trap[1)]. If OLDA support is not enabled, write accesses will generate a bus error trap. OLDA support is enabled by setting LMU_MEMCON.OLDAEN to 1_B.

Read accesses to the OLDA range generate a bus error trap, if not redirected to a physically available overlay block. Successful accesses to the OLDA memory range will only take place when the accesses are redirected to real, physical memory.

The base address of the virtual OLDA memory range is A/8FE7 0000_H, the end address is A/8FE7 $7FFF_H$. Accesses to the OLDA range are also supported in cached address space.

Note: In OTARx registers, any target address can be selected for redirection, thus also addresses in the OLDA range. However, the handling of direct accesses to the OLDA range is completely controlled in the LMU.

6.5 Clock Control

The LMU contains a clock control register, **LMU_CLC**, which allows the LMU to be put into a power saving mode.

If LMU_CLC.DISR is set then the LMU will be disabled and all accesses will be errored unless they are addressed to a register.

1) Write accesses to a cached memory address will trigger a read to fill the cache line before the data is written to the cache. This read will trigger a bus error.

6.6 LMU Registers

The LMU registers are mapped into a 256 byte address space which allows for 64 registers. Accesses to unused register space will cause an SRI bus error.

Table 6-1 Registers Address Space

Module	Base Address	End Address	Note
LMU	F870 0800$_H$	F870 08FF$_H$	All registers are endinit protected and are accessible in Supervisor mode only

Table 6-2 Registers Overview

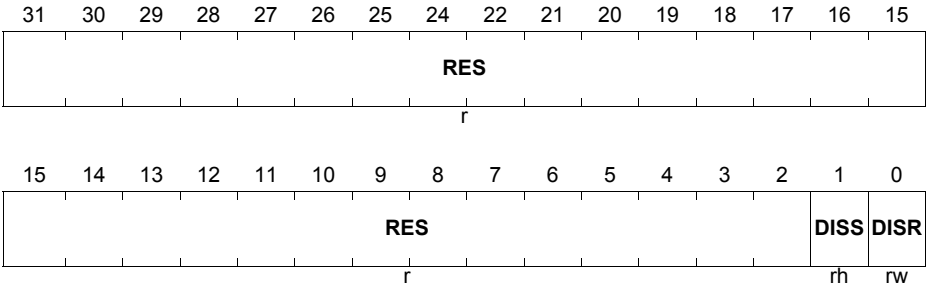
Short Name	Description	Offset Addr.[1]	Access Mode		Reset Class	Page Number
			Read	Write		
LMU_CLC	LMU Clock Control	0$_H$	SV,BE,32	SV,E,BE,32	3	6-5
LMU_MEMCON	LMU Memory Control	4$_H$	SV,BE,32	SV,E,BE,32	3	6-6
LMU_MODID	LMU Module ID	8$_H$	SV, BE,32	R,BE	3	6-9

1) The absolute register address is calculated as follows:
Module Base Address (Table 6-1) + Offset Address (shown in this column)

LMU Clock Control Register

LMU_CLC

LMU Clock Control Register **(000_H)** **Reset Value: 0000 0000_H**

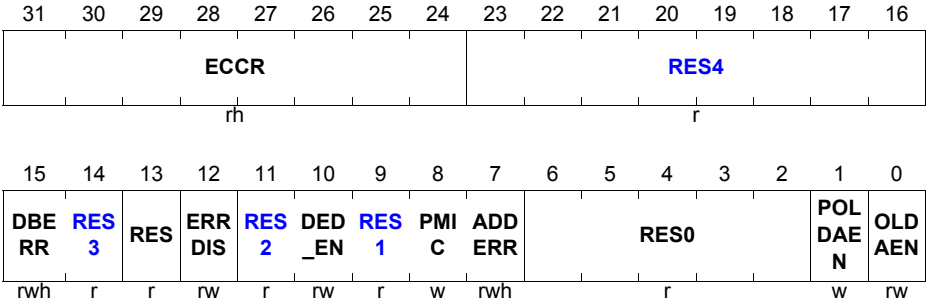


Field	Bits	Type	Description
DISR	0	rw	**LMU Disable Request Bit** This bit is used for enable/disable control of the LMU. 0_B LMU disable is not requested 1_B LMU disable is requested
DISS	1	rh	**LMU Disable Status Bit** Current state of LMU. 0_B LMU is enabled (default after reset) 1_B LMU is disabled
RES	31:2	r	**Reserved**

LMU Memory Control Register

Provides Control of the memory integrity error checking, error signalling to the SCU and error injection for ECC logic test. Also control of the OLDA function. The register is cleared by a Class 3 reset.

LMU_MEMCON
LMU Memory Control Register (004$_H$) Reset Value: 0000 0800$_H$



Field	Bits	Type	Description
OLDAEN	0	rw	**Online Data Acquisition Enabled** This bit is used to control trap generation for write accesses to the OLDA address range. 0_B Trap generation on write access to OLDA memory range is enabled 1_B No trap generated on write access to OLDA memory range.
POLDAEN	1	w	**Protection Bit for OLDAEN** 0_B Bit Protection: Bit OLDAEN remains unchanged after LMU_MEMCON write. 1_B OLDAEN can be changed by current write to LMU_MEMCON
RES0	6:2	r	**Reserved** Read and write 0_B

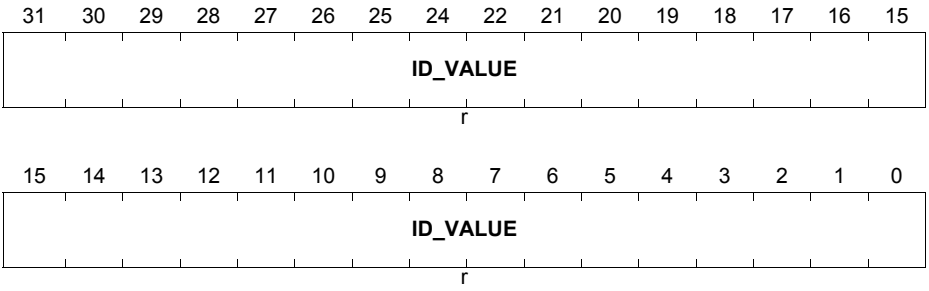
Field	Bits	Type	Description
ADDERR	7	rwh	**SRI Address Phase ECC Error** Flag set by hardware when the SRI interface detects an ECC error on an incoming transaction. This bit is cleared by writing 0_B but cannot be set by software. 0_B No error has occurred 1_B An ECC error has been observed on an SRI transaction addressed to the LMU
PMIC	8	w	**Protection Bit for Memory Integrity Control Bits** Will always return 0_B when read 0_B Bit Protection: Bits 23 to 9 remain unchanged after LMU_MEMCON write. 1_B Bits 23 to 9 will be updated by the current write to LMU_MEMCON
RES1	9	r	**Reserved** read as 0_B. Must be written as 0_B
DED_EN	10	rw	**Memory Integrity Dual Error Detection Enable** 0_B ECC errors in local memory read data do not cause an error indication (interrupt, bus trap, error bits). 1_B ECC errors are enabled. Memory errors are flagged to the SCU.
RES2	11	r	**Reserved** read as 1_B. Must be written as 1_B
ERRDIS	12	rw	**ECC Error Disable** When set SRI bus errors caused by ECC errors in data read from the SRAM will be disabled 0_B Normal behaviour. SRI error will occur on SRAM ECC errors if DED_EN is set. Default after reset 1_B Test Mode. SRI errors will not be generated on an SRAM ECC error. This does not affect the generation of interrupts.
RES	13	r	**Reserved**
RES3	14	r	**Reserved** Read as 0_B

Field	Bits	Type	Description
DBERR	15	rwh	**Double Bit Error Status** This bit set when a double bit error has occurred when reading from the local memory. The bit is cleared by writing 0_B. Writing 1_B has no effect. 0_B read access did not have a double bit error 1_B read access did have a double bit error
RES4	23:16	r	**Reserved** Read as 00_H, must be written as 00_H
ECCR	31:24	rh	**ECC Code for Last Read Access** This field contains the ECC code retrieved from the local memory with the last read access.

LMU Module ID Register

LMU_MODID

LMU Module ID Register **(008_H)** **Reset Value: $0088\ C001_H$**



Field	Bits	Type	Description
ID_VALUE	31:0	r	**Module Identification Value**

7 Data Access Overlay (OVC)

The data overlay functionality provides the capability to redirect data accesses by the TriCore to program memory (internal Program Flash or external memory) to the LMU SRAM, or to the Emulation Memory in Emulation Device ED, or to the external memory. This functionality makes it possible, for example, to modify the application's test and calibration parameters (which are typically stored in the program memory) during run time of a program. Note that read and write data accesses from/to program memory are redirected.

Attention: As the address translation is implemented in the DMI it is only effective for data accesses by the TriCore. Instruction fetches by the TriCore or accesses by any other master (including the debug interface) are not affected!

Note: The external memory can be used as overlay memory only in selected devices. Please contact Infineon sales representative for more information.

Summary of Features and Functions

- 16 overlay ranges ("blocks") configurable for Program Flash and external memory;
- Support redirection to Overlay memory located in:
  - Local Memory (LMU)
  - Emulation Memory (Emulation Device only)
  - External EBU Space (selected devices only)
- Support of up to 2 MB overlay memory address range;
- Overlay block size from 32 byte to 128 Kbyte;
- Support of Online Data Acquisition into range of up to 32 KB and of its overlay;
- Overlay memory and block size selected individually for every overlay block;
- All prepared overlay blocks can be enabled with only one register write access;
- Programmable flush (invalidate) control for data cache in DMI.

7.1 Basic Overlay Control

Per overlay block, there are three possibilities for redirection of the original data address, redirection to the LMU SRAM, redirection to the external memory and redirection to the Emulation Memory EMEM, if the chip includes the Emulation Extension Control EEC for an Emulation Device. In all cases, the same overlay mechanism is used.

The basic overlay scheme is shown in **Figure 7-1**.

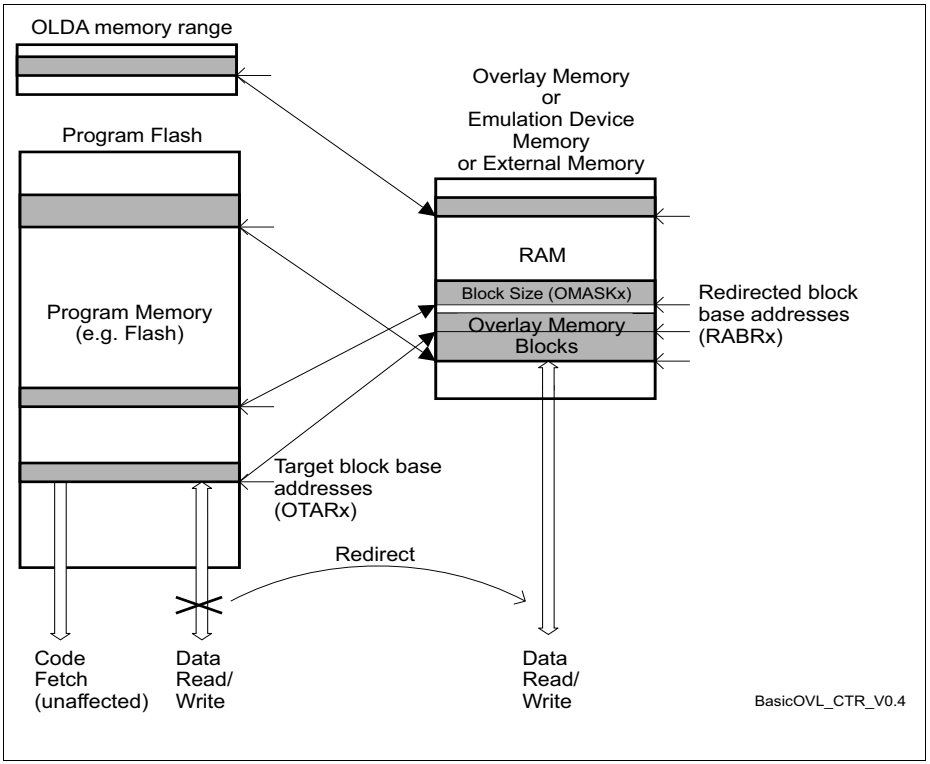


Figure 7-1 Redirection of Data Accesses to/from Code Memory to Overlay Memory

In the TC1798, the target memory (Program Flash, external memory or OLDA range, see **Chapter 7.4.1**) can be divided into a maximum of sixteen memory blocks for redirection into an overlay memory. The base address in target and overlay memory as well as the block size of each overlay block can be individually selected. The possible sizes of overlay blocks depend on the selected overlay memory: Blocks in the internal LMU SRAM are smaller than overlay blocks in EMEM or external memory. All overlay blocks can be enabled concurrently with one register access. In addition, the data cache may be flushed.

The operation of the address translation process is described in **Figure 7-2**, shown for redirection into the LMU SRAM.

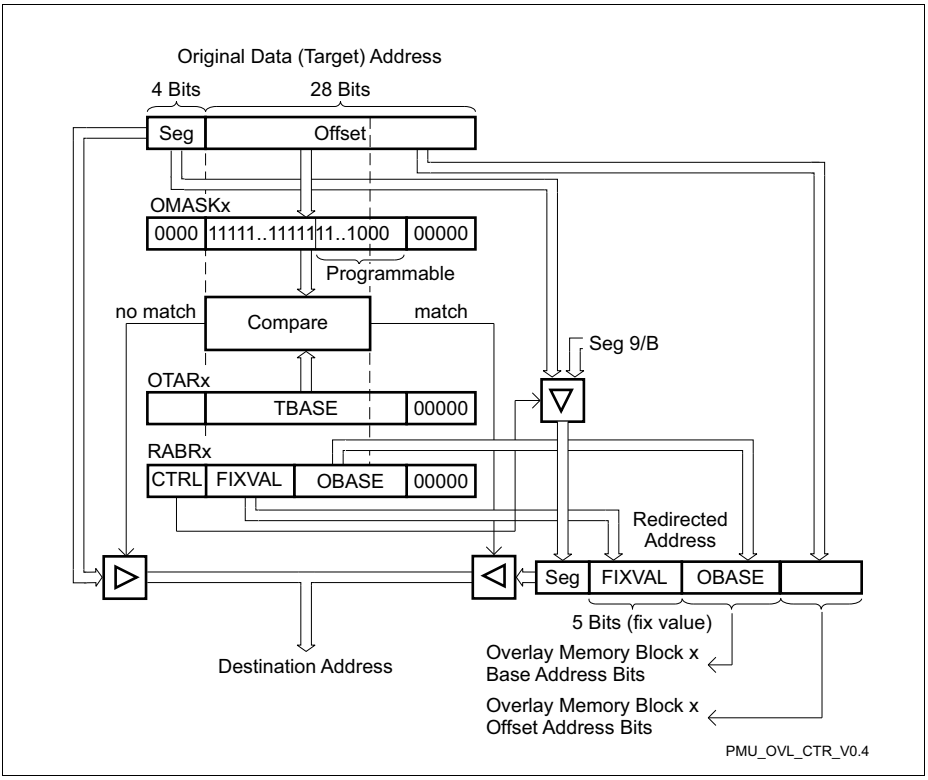

Figure 7-2 Address Translation Process

In each enabled overlay block control logic, three registers hold the information to control the overlay functionality:

- The overlay target address in the Overlay Target Address Register OTARx, which determines the base address of the program or OLDA memory data block x to be redirected.
- The base address of the LMU SRAM, external memory or EMEM (if emulation Device) in the Redirected Address Base Register RABRx, and the related enable and control bits.
- A mask in the Overlay Mask Register OMASKx, defining the size of the block, the address bits to be checked for an address match, and which bits are used from the redirected address base and which from the original data address.

The size of the overlay memory blocks can be 2^n x 32 bytes, with n = 0 to 12. This gives the block size range from 32 bytes to 128 Kbytes. The start address of the block can be an integer multiple of the programmed block size (natural page boundary).

If the data segment address is A_H or 8_H, the segment offset of the original data address is compared with the target base addresses of all overlay blocks which are enabled in RABRx. This bit-wise comparison is qualified by the content of the mask, ignoring the address bits that form the offset into the overlaid block.

If there is no match, the original data address is taken to perform the access.

If there is a match (see **Figure 7-2**):

- The four segment address bits (A_H or 8_H) are either taken directly from the data address (for external overlay memory) or changed to B_H and 9_H, respectively (for internal and emulation overlay memory).
- The most significant part of the segment offset, that addresses the base address of the overlay memory, is set to predefined values according to the address map (fixed bits in registers RABRx).
- The part of the target block address, that corresponds to the overlay block base address, is replaced by the respective overlay block base address bits (bits OBASE in RABRx, where the corresponding mask bits OMASK in registers OMASKx are set to “1”).
- The address is completed by the original offset into the block; the number of bits used are determined by the bits set to “0” in the mask OMASK.

7.2 Online Data Acquisition (OLDA) and its Overlay

Calibration is additionally supported by an OLDA memory range of up to 32 Kbyte, which is a virtual memory and physically only available, if it is redirected (as described above) to the internal or external overlay memory or to the EMEM in Emulation Device. If OLDA is enabled in PMU, direct write accesses (without redirection) to the OLDA range are not really executed, and they do not generate a bus error trap. This trap suppression works only for accesses to the non-cached range. Read accesses to the OLDA range generate a bus error trap, if not redirected to a physically available overlay block.

The base address of the virtual OLDA memory range is A/8FE7 0000_H, the end address is A/8FE7 $7FFF_H$. Accesses to the OLDA range are also supported in cached address space but there the bus error trap for write accesses is not suppressed.

Note: In OTARx registers, any target address can be selected for redirection, thus also addresses in the OLDA range. However, the handling of direct accesses to the OLDA range is completely controlled in the PMU.

7.3 Enable Control of Overlay Blocks

For basic control of overlay execution, the OCON register is provided with following functionality:

- 16 enable bits (SHOVENx), one for every overlay block configuration, to support concurrent and parallel switching of up to 16 overlay ranges (blocks); shadow

functionality to the single enable bits in the 16 block control registers (RABRx) provide compatibility to enable-control in TC1766/96.
- One common overlay start bit (OVSTRT) to enable all prepared (enabled) overlay configurations by writing all shadow enable bits into the 16 block control registers in parallel (write-only bit); stop-function if all-zeros are written.
- One control flag (DCINVAL), to be set by the CPU or Cerberus, to flush (invalidate) the (clean) data cache lines in the DMI (write-only bit).
- One common overlay stop (OVSTP) bit to disable all overlay configurations in the 16 block control registers (write-only bit), without changing the configuration
- One overlay configured status bit (OVCONF), which may be set when overlay registers are configured by the Cerberus via JTAG interface, and which may be cleared by the CPU after common overlay start (re-direction of all enabled overlay blocks).

The control flag in the high byte of the Overlay Control Register OCON (see **Page 7-14**) is implemented with additional protection bit, supporting write access to OCON by different users without violation of such control bit which shall remain unchanged. Additionally, byte protection is possible by support of byte write accesses to OCON.

7.4 Target and Overlay Memories

In the following, the possible target and overlay memories are described. Address range of 2 MB is supported for the overlay memories. The LMU SRAM and the interface to the Emulation Memory EMEM are located in the LMU module.

7.4.1 Target Memories

Any data read or write access to the segments 8_H and A_H is checked for a valid overlay target address, using all 16 OTARx registers concurrently for comparison (if they are enabled for overlay execution). Since the OTARx registers are writable, any data memory within the segments 8_H and A_H may be used for redirection to an overlay memory. Thus, the following memories can be selected as target memories:

- Program Flash
- Data Flash
- The (virtual) OLDA memory range
- The external memory.

7.4.2 Internal Overlay Memory

The internal LMU SRAM is available in both the Production Device and the Emulation Device. The LMU SRAM is selected for overlay redirection, if the bits IEMS and EXOMS in the block-related RABRx register are zero. The base address of the LMU SRAM is B/9000 0000_H (non-cached/cached space). During address translation, the upper 9 address bits are set to $B/90_H0_B$, respectively.

7.4.3 Emulation Overlay Memory

The EMEM can only be selected for overlay blocks, if the chip is an Emulation Device ED. The Emulation Memory EMEM is selected for overlay execution, if the block-related RABRx bits IEMS=1 and EXOMS=0. The base address of the Emulation Memory is B/9F00 0000_H. During address translation, the upper 9 address bits are set to BF_H0_B (non-cached) or to $9F_H0_B$ (cached space).

7.4.4 External Overlay Memory

If an external memory is available in the Emulation Device system, it can also be used for calibration via program memory or OLDA overlay. The overlay blocks can be located in the external memory only in selected devices.The External Memory is selected for overlay execution, if the block-related RABRx bit EXOMS=1 (IEMS value is ignored). The base address of the Emulation Memory is A/8300 0000_H. During address translation, the upper 9 address bits are set to $A3_H0_B$ (non-cached) or to 83_H0_B (cached space).

7.5 Change of Overlay Parameters and Overlay Start

When changing the overlay parameters of a block or when switching a block from one overlay memory to another overlay memory, it must be ensured that the respective OVEN bit in register RABRx is reset, before the block parameters are set properly, and then the overlay block is enabled again. Otherwise, unintended access redirections may occur.

It is especially supported to enable (start) all prepared overlay blocks concurrently, when using the shadow mechanism for the OVEN bits in the one OCON register instead of the single OVEN bits in the different RABRx registers (see **Chapter 7.3**). With this function it is possible to switch directly from one set of overlay blocks to another set of overlay blocks, without any restriction concerning the block-specific use of (available) overlay memories.

Note: The Overlay Control does not prevent configuring the translation logic incorrectly so that memory accesses are translated to not implemented or forbidden memory ranges.

7.6 Concurrent Matches and Access Performance

Concurrent matches in more than one enabled overlay block are not supported. When an address matches two, or more, of the enabled overlay blocks, an exception is raised and the memory access is not performed. A load operation with multiple matches on overlay ranges, raises a Data Access Synchronous Error (DSE) trap, and a store operation raises Data Access Asynchronous Error (DAE) trap. In such case, relevant trap information registers: Data Synchronous Trap Register (DSTR), Data

Asynchronous Trap Register (DATR), and Data Error Address Register (DEADD) are updated, see DMI Registers chapter for more information.

The dynamic address translation for redirection to the overlay memory is executed without performance penalty.

7.7 Overlay Control Registers

Figure 7-3 shows all the overlay control registers associated with control of the overlay memory blocks.

Overlay Control Registers Overview

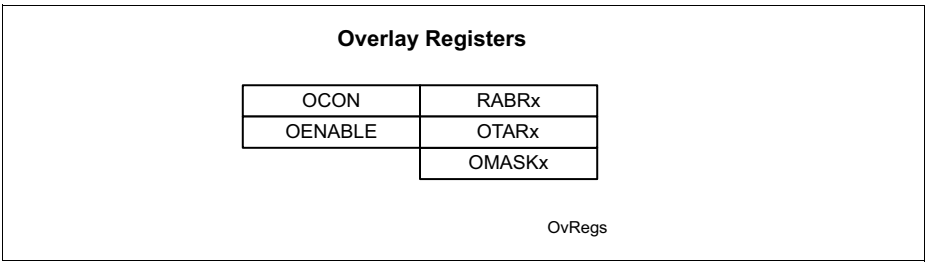

Figure 7-3 Overlay Control Registers

The address space for the overlay control registers is as follows:

Table 7-1 Registers Address Space of OVC Registers

Module	Base Address	End Address	Note
OVC	F87F FB00$_H$	F87F FBFF$_H$	

Table 7-2 Registers Overview

Register[1] Short Name	Register Long Name	Offset Address	Access Mode[2]		Description see
			Read	Write	
RABRx	Redirected Address Base Register x (x = 0-15)	0020$_H$ + x * C$_H$	U, SV, 32	SV, 32	Page 7-9
OTARx	Overlay Target Address Register x (x = 0-15)	0024$_H$ + x * C$_H$	U, SV, 32	SV, 32	Page 7-11

Table 7-2 Registers Overview (cont'd)

Register[1] Short Name	Register Long Name	Offset Address	Access Mode[2]		Description see
			Read	Write	
OMASKx	Overlay Mask Register x (x = 0-15)	0028_H + x ∗ C_H	U, SV, 32	SV, 32	Page 7-12
OCON	Overlay Control Register	$00E0_H$	U, SV, 32	SV, 32	Page 7-14
OENABLE	Overlay Enable Register	$00E8_H$	U, SV, 32	SV, E, 32	Page 7-16

1) The OVC register short names are extended with the module name prefix "OVC_".

2) Symbol U: Access permitted in User Mode 0 or 1
Symbol SV: Access permitted in Supervisor Mode
Symbol E: Endinit-protected register
Symbol 32: Only 32-bit word access is permitted

Note: Accesses to free/not used register addresses within the OVC address space are not executed and not serviced with a bus error trap.

Register Descriptions

For each of the 16 overlay memory blocks (indicated by index x), three registers control the overlay operation and the memory selection:

- The Redirected Address Base Register RABRx, which holds the base address of the overlay memory to be used (with fixed address bits) and of the overlay memory block within the overlay memory, and some control bits.
- The Overlay Target Address Register OTARx, which holds the base address of the memory block in internal Flash, in external memory or in the OLDA memory being overlaid (and being compared with original data address).
- The Overlay Mask Register OMASKx, which determines which bits (from RABRx) are used for the base address (of overlay memory and block) and which bits (of original data address) are directly used as offset within the block (remaining unchanged).

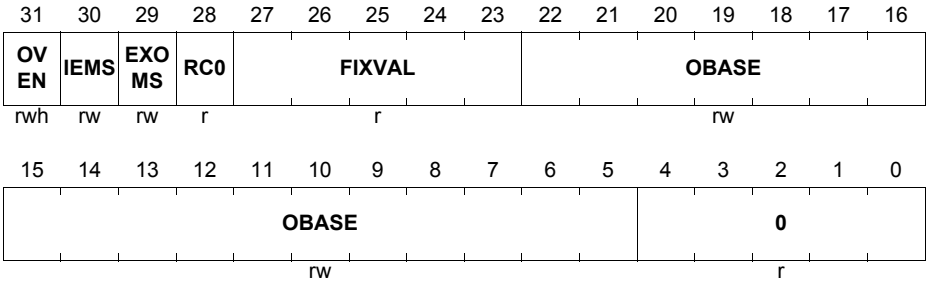
Additionally, for general overlay control the registers OCON and OENABLE are provided.

All overlay block and control registers are reset to their default values with the application reset. A special debug reset is not considered.

The RABRx register is defined as follows:

RABRx (x=0-15)
Redirected Address Base Register x

(20_H+x*C_H) **Reset Value: 0000 0000_H**



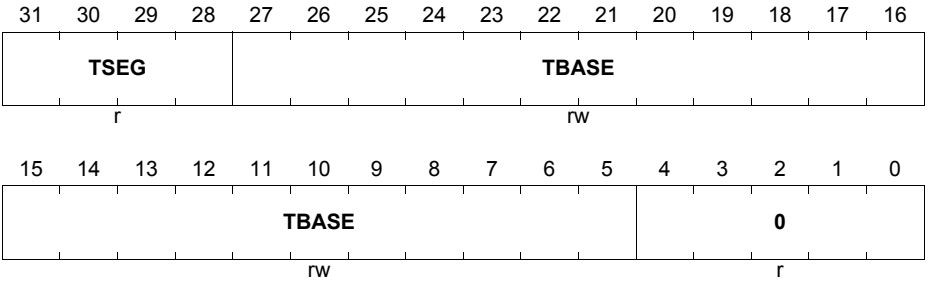
Field	Bits	Type	Description
OBASE	[22:5]	rw	**Overlay Block Base Address** This bit field holds the base address of the overlay memory block in the overlay memory.
FIXVAL	[27:23]	r	**Fixed Value** Base address of the selected overlay memory within segment. 00000_B LMU SRAM base address (when EXOMS=0 and IEMS = 0) 11110_B EMEM base address (when EXOMS=0 and IEMS = 1) 00110_B EMEM base address (when EXOMS=1) All other values are reserved. Should be written with the same value.
RC0	28	r	**Reserved Control Bit** Reserved for future control expansions. Read returns 0. Must be written with 0.

Field	Bits	Type	Description
EXOMS	29	rw	**External Overlay Memory Select** If set, the external memory is used as overlay memory. This is only available in selected devices. 0_B Overlay memory of block x type is selected by IEMS. 1_B Overlay memory of block x is the external memory.
IEMS	30	rw	**Internal or Emulation/External Memory Select** If EXOMS is not set, IEMS selects the type of the overlay memory. If EXOMS is set, IEMS value is ignored. 0_B Internal LMU SRAM is selected as overlay memory. 1_B Emulation Memory EMEM is selected as overlay memory. IEMS must be written with zero in production device.
OVEN	31	rwh	**Overlay Enabled** This bit controls whether or not the overlay function of overlay block x is enabled. 0_B Overlay function of block x is disabled. 1_B Overlay function of block x is enabled. This bit can also be changed via its shadow bit in the OCON register.
0	[4:0]	r	**Fixed Value** Read as 0; should be written with 0.

The Overlay Target Address Register OTARx is defined as follows:

OTARx (x=0-15)
Overlay Target Address Register x

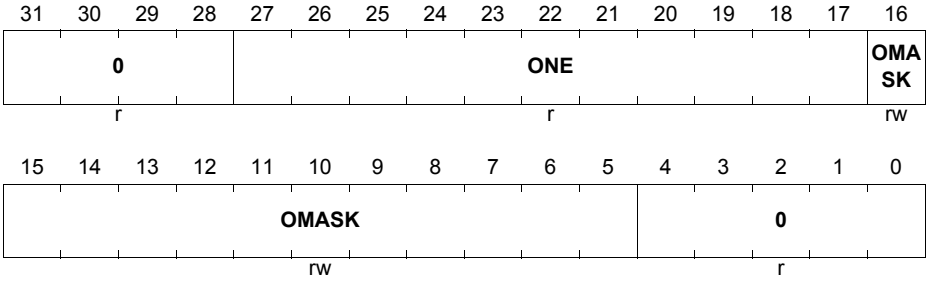
(24_H+x*C_H) **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
TBASE	[27:5]	rw	**Target Base** This field holds the base address of the overlay memory block in the target memory (Program Flash or OLDA memory or external memory). For each TBASE bit: If the corresponding bit in OMASK register is set to one TBASE bit value is used in the address match. If the corresponding bit in OMASK register is set to zero TBASE bit value is ignored.
TSEG	[31:28]	r	**Target Segment (reserved)** This bit field is reserved for future use, to select a segment. In TC1798 implementation, any access to segments 8_H, or A_H will be checked for a valid base address. Returns 0 if read; should be written with 0.
0	[4:0]	r	**Reserved** Reads as 0; should be written with 0.

The Overlay Mask Register OMASKx determines the size of the overlay memory block x (by the number of least significant zero's). It also determines which address bits will participate in the address compare for the block base address (all high-order one's), and in case of address match which bits are taken from RABRx (as many high order bits as defined in OMASKx for address compare) and which bits are used from the original data address as offset within the block (all low order bits related to zero values in OMASKx).

OMASKx (x=0-15)
Overlay Mask Register x **(28_H+x*C_H)** **Reset Value: 0FFF FFE0$_H$**



Field	Bits	Type	Description
OMASK	[16:5]	rw	**Overlay Address Mask** This bitfield determines the overlay block size and the bits used for address comparison and translation. 000000000000_B, 128 Kbyte block size 100000000000_B, 64 Kbyte block size 110000000000_B, 32 Kbyte block size [...] 111111111110_B64 byte block size 111111111111_B32 byte block size "Zero" bits determine the corresponding address bits which are not used in the address comparison and thus determine the block size; corresponding final address bits are derived from the original data address. "One" bits determine the corresponding address bits which are used for the address comparison; corresponding final address bits are derived from RABRx register in case of address match.

Field	Bits	Type	Description
ONE	[27:17]	r	**Fixed “1” Values** Corresponding address bits are participating in the address comparison. Corresponding final address bits are taken from RABRx.
0	[4:0], [31:28]	r	**Fixed “0” Values** Corresponding address bits are not used in the address comparison. Corresponding final address bits are taken from the original data address.

The Overlay Control Register OCON is defined as follows:

OCON
Overlay Control Register **($00E0_H$)** **Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0	0	0	0	0	0	POVCONF	OVCONF	0	0	0	0	0	DCINVAL	OVSTP	OVSTRT
r	r	r	r	r	r	w	rw	r	r	r	r	r	w	w	w

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SHOVENx															
rw															

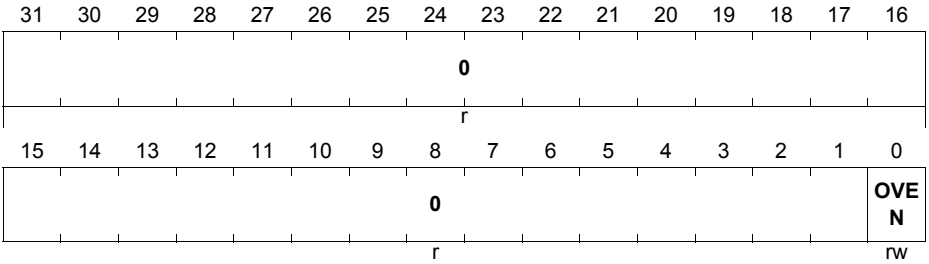
Field	Bits	Type	Description
SHOVENx (x=0-15)	x	rw	**Shadow Overlay Enable x** 0_B Overlay block x is disabled with next OVSTRT 1_B Overlay block x is enabled with next OVSTRT For each of the 16 overlay blocks (indicated by index x), one enable (disable) bit is provided.
OVSTRT	16	w	**Overlay Start** 0_B No action 1_B All 16 shadow overlay enable bits SHOVEN ar loaded into the related OVEN bits in RABRx registers in parallel. Related to the SHOVEN bits state, the overlay blocks are concurrently enabled or disabled. Return 0 if read.
OVSTP	17	w	**Overlay Stop** 0_B No action 1_B All 16 OVEN bits in RABRx registers are cleared in parallel independently of the SHOVEN bits and without changing the SHOVEN bits. Return 0 if read.

Field	Bits	Type	Description
DCINVAL	18	w	**Data Cache Invalidate** No function in devices without data cache in Tricore. 0_B No action 1_B Data Cache Lines in DMI are invalidated (flushed). *Note: Per write modified cache lines are not invalidated.*[1)] Return 0 if read.
OVCONF	24	rw	**Overlay Configured** Overlay configured status bit 0_B Overlay is not configured or it has been already started by CPU 1_B Overlay block control registers are configured and ready for overlay start This bit may be used as handshake bit between a debug device (via JTAG interface and Cerberus) and the CPU.
POVCONF	25	w	**Protection Bit for OVCONF** 0_B Bit protection: Bit OVCONF remains unchanged with register OCON write 1_B OVCONF can be changed with actual write access to register OCON This bit enables OVCONF-write during OCON write. Return 0 if read.
0	[23:19], [31:26]	r	**Reserved** Read/write 0.

1) Because the data cache is a writeback cache (not a writethrough cache; therefore saving of modified data in cache has to be performed by the user) it is highly recommended to use only non-cached accesses for overlaid (redirected) accesses to the target memory (normally the Program Flash), if write accesses are involved.

The Overlay Enable Register OENABLE is defined as follows:

OENABLE
Overlay Enable Register **($00E8_H$)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
OVEN	0	rw	**Overlay Enable** 0_B OVC is disabled. All Overlay redirections are disabled. 1_B OVC is enabled.
0	[31:1]	r	**Reserved** Read/write 0.

This register is Endinit-protected.

8 BootROM Content

TC1798 BootROM from user point of view consists of two parts:

- Startup Software (short name SSW);
- Software modules implementing additional functions (Bootstrap Loaders).

8.1 Startup Software

The Startup Software is the first software executed after a chip reset. This means, the first value loaded into the Program Counter register PC points to first address inside BootROM - the SSW entry-point.

The Startup Software contains procedures to initialize the device depending on:

- values applied to external (configuration-) pins;
- the type of event which has triggered the SSW-execution (the last reset event);
- information previously stored into the Flash Configuration Sector;
- the current state of special bits/fields in dedicated register/memory locations.

The SSW also calls - in case - other firmware modules.

8.1.1 Boot Options Summary

This chapter summarizes the TC1798 startup configurations.

Internal Start

In this basic startup mode, the first user instruction is fetched from the Internal Program Flash of the device.

Bootloader Modes

Different Bootstrap Loader routines are used in these modes to download code/data into the Program Scratchpad Memory PSPR.

Alternate Boot Modes

In these modes, program code is started from user-defined address but only if at least one of the two check-conditions is satisfied. If both the conditions are false - a Bootstrap Loader routine is started to download the code into the device, this code is afterwards started by the SSW.

Secure Booting

This startup option is only supported in devices having Secure Hardware Extension (SHE) implemented and available for the user.

When selected, Secure Booting implements an extension of the startup procedure in Internal start and Alternate Boot Modes, using SHE to check the user code.

8.1.2 Startup Software Main Flow

In next Chapters, the SSW functionality is specified, during different execution-steps (refer to **Figure 8-1**) and upon various configuration settings.

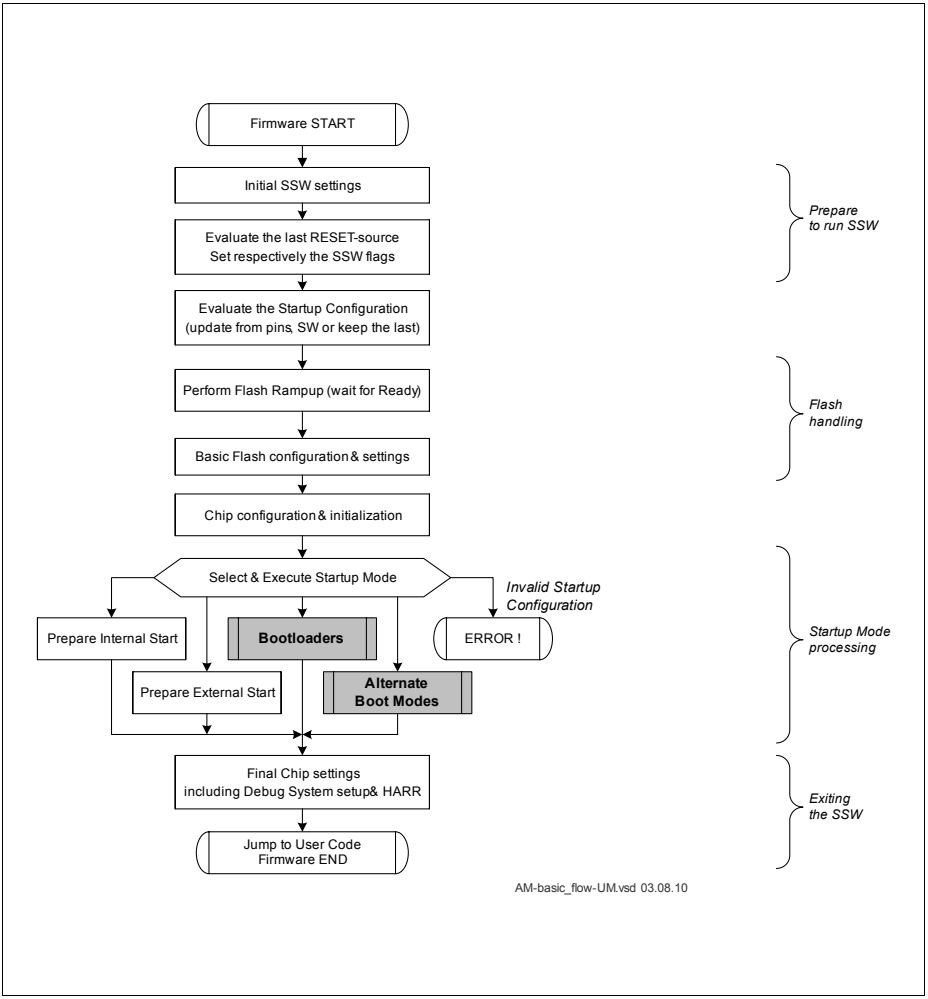


Figure 8-1 TC1798 Firmware: SSW main flow

8.1.2.1 Entering the Startup Software

The first SSW instruction is fetched after any reset from address AFFF'C000$_H$ in BootROM.

8.1.2.2 Initial Handling of the Startup Configuration

The SSW determines which startup mode to execute based on the configuration coded in SCU_STSTAT.HWCFG bit field.

The value in this bit field can be updated in different ways:

1. with values latched at the configuration pins P0[7:0] upon the rising reset-edge
   This happens when SCU_STSTAT.LUDIS=0, therefore after any system (class 0) reset, and after other resets - depending on LUDIS bit.
2. with values from SCU_SWRSTCON.SWCFG bit field
   This happens upon Software reset - triggered by writing 1 to SCU_SWRSTCON.SWRSTREQ - if at the same time Software Boot Configuration is selected - SCU_SWRSTCON.SWBOOT=1.

Due to the way HWCFG-bit field is handled by TC1798 hardware, at this point of its flow the SSW does not need to do some special processing regarding the startup configuration. besides of setting SSW-internal flag:

- "Reset Configuration Updated" flag
  – is set to 1 if
    - the last reset has been a software-reset with software-configuration
      ((SCU_RSTSTAT.SW=1) AND (SCU_SWRSTCON.SWBOOT=1))
  – if the last reset is of a type NOT stated in a)
    - the flag is set to the inverted value of SCU_STSTAT.LUDIS bit

8.1.2.3 Flash Rampup

The Flash Rampup is automatically started after every reset by hardware (refer to PMU Chapter, Program and Data Flash). Therefore the SSW does not initiate the Rampup but only observes the flags in Flash SFRs and reacts accordingly.

The Flash Rampup is further handled by the SSW. Basically the Flash "Busy" status is checked as the section below describes.

If after the time-out the Flash is still "Busy", then:

- "Flash Rampup" error-code is created
- the Flash is put into sleep mode
- a jump to the SSW Error-processing routine is performed

Flash Rampup

Flash "Busy" status is continuously checked but no longer than for a defined time-out. Once all of the Flash Array Banks are "Ready" (PBUSY=0), the startup procedure

continues immediately. As far as the Rampup duration varies from device to device and upon operational conditions, the overall startup time respectively will be slightly different.

8.1.2.4 Basic Device Settings

The target of this functional module is to initialize several TC1798-registers with the values, which will be first seen by the user - or generally available - after exiting the SSW.

Following device resources are initialized here:

- JTAG Device Identification register (JTAGID.JTAG_ID)
- Unique Chip ID - it is written by the SSW at the beginning of DSPR - 4 Words starting at $D000'0000_H$.

8.1.2.5 Select and Prepare Startup Modes

TC1798 User Startup Configurations and modes are summarized in **Table 8-1**.

Table 8-1 Startup Modes supported in TC1798

HWCFG[7:0]	Startup Mode	Pins used
11xxxxxx$_B$	Internal Start from Flash	2
011xxxxx$_B$	Internal Start from Flash	3
010xxxxx$_B$	Bootstrap Loader Mode, Generic Bootloader at CAN pins	3
10101xxx$_B$	Bootstrap Loader Mode, ASC Bootloader	5
10100xxx$_B$	Alternate Boot Mode (ABM),ASC Bootloader on fail	5
1011xxxx$_B$	Alternate Boot Mode, Generic Bootloader at CAN pins on fail	4
1000xxxx$_B$	Alternate Boot Mode, Generic Bootloader at CAN pins on fail	4
1001C1Ax$_B$ [1)]	External Alternate Boot Modes	7
0010E1Ax$_B$ [1)]	External Start Modes	7
0001xxxx$_B$	Reserved	7
000011xx$_B$	Reserved	6

1) C bit - Pins used for bootloading: 0 - ASC (ASC bootloader);1 - CAN (Generic bootloader)
A bit - EBU Arbitration Mode: 0 - Participant; 1 - Arbiter (previously referred as “External Master”)
E bit - EBU Configuration: 0 - Default; 1 - Automatic

The SSW evaluates the configuration in SCU_STSTAT.HWCFG and device-start is prepared in accordance to the mode currently selected.

Basically, the User Start Address is prepared in STADD, as well as additional functions are executed in case - like Bootstrap Loaders and Alternate Boot.

Internal Start

This is the basic TC1798 type of operation in which the user code is started out of the Internal Flash Memory.

The User Start Address STADD is set to the beginning of Internal Flash Memory Module at address A000'0000$_H$.

External Starts

The User Start Address STADD is set to address A300'0000$_H$ in external EBU space.

Bootstrap Loader Modes

The selected Bootstrap Loader (these routines are described in **Chapter 8.2**) is executed only if the SSW-flag "Reset Configuration Updated" is set (refer to **Chapter 8.1.2.2**). This is to avoid multiple executions of the Bootstrap Loader and to start directly the code already downloaded after some - intended to be "application only" - reset events, for example after a Watchdog Timer reset which has been configured as class 3 reset.

The supported Bootloader selections are:

- ASC Bootloader - ASC communication protocol via ASC pins
- Generic Bootloader via CAN pins - the communication protocol is automatically selected by the SSW between ASC and CAN

After downloading (in case) the code, the User Start Address STADD is set to the beginning of Program Scratchpad RAM at C000'0000$_H$.

Alternate Boot Modes

There are variety of such modes in TC1798, whereas the differences are in:

1. where the Headers and (in case being available) the application code is located
   a) in Internal Flash Memory
   b) in External Memory
2. which Bootloader to execute upon an error in ABM Header
   a) ASC Bootloader
   b) Generic Bootloader at CAN pins

The SSW flow in these modes is:

- evaluate the startup configuration to decide where are the Headers located
- check the Headers - refer to the description in **Chapter 8.1.3.1** - and react accordingly:
  – if the check is OK for one of the Headers - set the User Start Address STADD to the respective value from this correct header (STADABMx) and continue

– if the Header-checks fail - start a Bootloader (ASC/Generic) corresponding to the startup configuration. After downloading the code, the User Start Address STADD is set to the beginning of Program Scratchpad RAM at $C000'0000_H$.

Secure Booting is possible in Alternate Start mode - see below.

Secure Boot option handling

If SHE-module is available - Secure Booting is supported for the device. In such a case the SSW performs additional steps in different startup modes, as below described.

- in **Internal Start** mode:

1. check the SHE-bit sequentially in SHEBOOT2, SHEBOOT0 and SHEBOOT1 registers
   a) if all the bits are zero - Secure Booting is not requested, then:
      -call SHE_NON_SECURE_BOOT procedure
      -continue SSW (executing Internal Start)
   b) if bit SHE=1 is found in a SHEBOOTx register - continue with 2.
2. read SIZE from the respective bitfield in SHEBOOTx register
3. call SHE_SECURE_BOOT procedure with parameters BL_START=STADD ($A000'0000_H$) and BL_SIZE=SHEBOOTx.SIZE
4. check the BGD-bit tn the respective SHEBOOTx register (with SHE=1)
   a) if SHEBOOTx.BGD=1 (background secure boot is selected) - continue SSW with user code start without waiting for SHE-operation finished
   b) if SHEBOOTx.BGD=0 (not background secure boot is selected) - wait until SHE_SECURE_BOOT procedure is finished

- in **External and Bootstrap Loader** modes:

Call SHE_NON_SECURE_BOOT procedure.

- in **Alternate Boot** modes:

There are two cases regarding SHE-handling in Alternate Boot Mode

1. if one of the Header-checks with CRC passed -Secure Boot procedure is executed to check the user code by SHE
2. if both the Header-checks with CRC failed - Bootstrap Loader mode is started and SHE_NON_SECURE_BOOT procedure called there.

8.1.2.6 Final Chip Settings

The last device configuration steps performed by the SSW include:

Unique Chip ID Installation

The Unique Chip ID represents a 16-Byte value which is written by the SSW after any reset at the beginning of DSPR - starting from address $D000'0000_H$.

Calibration Data Installation

The Calibration Data (for DTS as well as placeholder for future extensions) represents a 128-Byte value which is written after power-on reset by the SSW into DSPR starting from address $D000'0018_H$.

Flash Protection Control

The SSW processing on Flash protection differs upon the startup mode currently selected:

1. in modes where the user code is started from Internal Flash - Internal start, Internal ABM with CRC OK:
   a) if Read Protection is NOT activated (FCON.RPA=0):
      - SSW enables all the specific (DMA, PCP, Debug) Data Fetches from Flash
      - no SSW action is needed regarding Code and Data Fetches from Flash - they are generally enabled by hardware.
   b) if Read Protection is Activated (FCON.RPA=1):
      - SSW enables Code Fetch from Flash;
      - SSW enables Data Fetch from Flash in general as well as in particular for DMA (FCON.DDFDMA=0) and PCP;
      - SSW disables Data Fetch from Flash for the Debug Controller.
2. in modes where the user code is not started from Internal Flash - all Bootstrap Loader modes, all ABM modes after the CRC fails:
   a) if Read Protection is NOT activated (FCON.RPA=0) - the same functionality as upon a start from Internal Flash - refer to 1.a) above;
   b) if Read Protection is activated (FCON.RPA=1):
      - SSW disables all Code and Data Fetches from Flash
      - SSW disables all the specific (DMA, PCP, Debug) Data Fetches from Flash.

At the end of this module, accesses to Configuration Sector Data are disabled.

Debug System handling

As first point of this processing, the SSW internal flag Unlock Debug Interface is set, with exception of the following case only:

- Internal start with active Flash protection

In any other case, debugging is no security risk as far as either the protection is not activated or reading from Flash is not possible.

Next, Halt after Reset is prepared if requested. Besides a Halt itself is no security risk - even the system is stopped but a channel (communication/debug) is still needed to access internal resources - this feature is configured and enabled only if the SSW-flag “Unlock Debug IF” is set.

The SSW processing here is as follows:

- check either external (debug) access to the device will be generally granted (SSW_Internal_flag=1)
  – if Not -> exit this procedure
- check either Halt After Reset is requested (OSTATE.HARR=1)
  – if Not -> exit this procedure
- configure a Break After Make breakpoint at the last SSW instruction
  – write the respective address into Code Segment Protection Lower Bound register MPR_CPR0_0L
  – configure signal assertion from Memory Protection System to Core Debug Controller upon instruction fetch access match with MPR_CPR0_0L (write MPR_CPM0.BL0=1)
  – configure debug action in Trigger Event 0 control register TR0EVT as follows:
    - Halt on break - EVTA := 010_B
    - Break After Make - BBM := 0
    - Suspend output active - SUSP := 1
- enable On-Chip Debug Support system.

*Note: The final debug-related operation - unlocking (in case) the debug interface - is performed later - refer to **Chapter 8.1.2.7**.*

8.1.2.7 Ending the SSW and Starting the User Code

The last steps executed by the SSW are:

- activate the Startup Protection
  - as a result, the Watchdog Timer starts to run
- if the Debug Interface is to be unlocked (SSW_Unlock_DIF=1):
  – perform a write to OEC with IF_LCK=0 and IF_LCK_P=1 (protection bit). With this operation OSTATE.IF_LCK gets reset to 0 and the debug interface is unlocked - the IOClient (Cerberus) is allowed to enter RW Mode and therefore can access potentially all the system resources.
- restore default content of registers modified by SSW
- jump to the first User Instruction at address STADD.

8.1.3 Specific SSW Features

Below some specific procedures are described, which are used at several places during the SSW flow. The definition is given separately here for a more readable form of the complete document.

8.1.3.1 Header Check in Alternate Boot Modes

The Alternate Boot Modes (ABM) in TC1798 are intended to start program code already available at arbitrary user-defined address if a check-condition is satisfied. If the check-condition fails - a Bootstrap Loader routine is invoked in accordance to the current startup mode.

The address of the code to be started together with all information needed to verify the check-condition are contained in dedicated memory areas named Headers.

The address of the code to be started together with all information needed to verify the check-condition are contained in dedicated memory areas named Headers. The Headers can be located in Internal Flash memory of the device, whereas the locations are defined:

- Header 0 - Base address A001'FFE0$_H$; End address A001'FFFF$_H$
- Header 1 - Base address A000'FFE0$_H$; End address A000'FFFF$_H$

If External starts are also supported as Startup Configurations, respectively so-call External Alternate Boot Modes are defined. In such a case, the Headers are located in External EBU address space as follows:

- Header 0, External - Base address A300'FFE0$_H$; End address A300'FFFF$_H$
- Header 1, External - Base address A308'FFE0$_H$; End address A308'FFFF$_H$

Note: In all the External ABM, the SSW first tries to fetch the configuration word as check for availability of an external memory. If this fetch fails to return valid data - the situation is considered as error in the Header and a bootloader is started.

In Alternate Boot Mode of TC1798 two Headers are defined - Header 0 and Header 1 (referred as ABM.HD0 and ABM.HD1), the user code can be started from:

- up to two different addresses - if Secure Booting is not selected
- one only address - if Secure Boot option is activated.

The Headers are 32 Bytes long, containing information in accordance to **Table 8-2**.

Table 8-2 ABM Header Structure

Offset Addr.	Size Byte	Field Name	Description
00_H	4	STADABM	User Code Start Address
04_H	4	ABMHDID	ABM Header ID (Confirmation code): Standard ID = DEAD $BEEF_H$ (STDHID) Secure ID = CODE 0000_H (SECHID) 1) Background ID = CODE 0001_H (BSECHID) 1)
08_H	4	ChkStart 2)	Memory Range to be checked - Start Address
$0C_H$	4	ChkEnd 3)	Memory Range to be checked - End Address
10_H	4	CRCrange	Check Result for the Memory Range
14_H	4	$\overline{\text{CRCrange}}$	Inverted Check Result for the Memory Range
18_H	4	CRChead	Check Result for the ABM Header (offset 00H..17H)
$1C_H$	4	$\overline{\text{CRChead}}$	Inverted Check Result for the ABM Header

1) Only in Header 0

2) Address of the first word to be checked.

3) Address of the last word to be checked.

Header 0 is checked first, if failed and Secure Booting is not selected - Header 1 is checked next. Where the check gives OK, the full start address is taken from the respective Header field STADABMx (index x=0,1 for Header 0,1).

The validation procedure executes CRC calculation based on a 32-bit polynomial:

$$f(x) = x^{32}+x^{26}+x^{23}+x^{22}+x^{16}+x^{12}+x^{11}+x^{10}+x^8+x^7+x^5+x^4+x^2+x+1 \quad (8.1)$$

If Secure Booting is activated and the CRC calculation pass - the user code is also checked by SHE module.

The check procedure is as follows:

1. check the ABM Header ID (ABMHID) at offsets $04_H..07_H$:
   a) if ABMHDID=STDHID or SECHID or BSECHID - continue with 2.
   b) else - exit the check-procedure for this Header with Error.
2. calculate the CRC of the first 24 Bytes from the ABM Header (refer to **Table 8-2**) - process the fields STADABM...CRCRange at offsets $00_H...17_H$
   a) compare the result with the CRChead value (offset 18_H)
      - if OK - continue with 2.b)
      - if Not - exit the check-procedure for this Header with Error.
   b) inverse the result value and compare with $\overline{\text{CRChead}}$ (offset $1C_H$)
      - if OK - continue with 3.
      - if Not - exit the check-procedure for this Header with Error.

3. calculate the CRC over the memory address range ChkStart...ChkEnd (start- and end- addresses taken from offsets 08_H and $0C_H$ respectively)
   a) compare the result with the CRCrange value (offset 10_H)
      - if OK - continue with 3. b)
      - if Not - exit the check-procedure for this Header with Error.
   b) inverse the result value and compare with $\overline{\text{CRCrange}}$ (offset 14_H)
      - if OK - continue with 4.
      - if Not - exit the check-procedure for this Header with Error.
4. check the ABM Header ID (ABMHID) at offsets $04_H..07_H$:
   a) if ABMHDID=STDHID - continue SSW to start the user-code from STADABMx address.
   b) if ABMHDID=SECHID or BSECHID - continue with 5.
   c) else - exit the check-procedure for this Header with Error.
5. check are the requested memory addresses correct:
   a) both ChkEnd and ChkStart must be between A000 0000_H and A11F $FFFF_H$ or between 8000 0000_H and 811F $FFFF_H$ (cached or not-cached area) occupying only addresses reserved for PFlash and not overlapping a RAM or External area
   b) ChkStart must be aligned to 128 Byte (i.e. the 7 LS bit = zero)
      - if both the conditions are met - continue with 6.
      - if Not - exit the check-procedure for this Header with Error.
6. check with which Header ID the procedure passed till this point:
   a) if ABMHDID=BSECHID selecting background secure boot - continue SSW, Secure Boot will be triggered later by SSW
   b) if ABMHDID=SECHID selecting secure boot not background - then:
      - start secure boot and wait until finished
      - continue SSW to start the user-code from STADABMx address.

Note: As seen from the above definitions, both in Secure and in Standard ABM modes only error in Header or wrong CRC prevents starting the used code.
The result from code-check done by SHE is not relevant for the user code start but affects the further SHE behavior.

In case the check procedure is exited with error:

- if Header 0 is currently processed - restart the procedure from 1. using Header 1
- else - jump either to ASC- or to Generic- (CAN pins) Bootloader according to the startup mode currently configured in HWCFG.

8.1.4 Startup Errors Handling

There are a number of check-points during the Startup Software execution where Errors can be raised (refer to the SSW block-diagrams). The processing upon an Error is as follows:

- an Exit-code according to the error is stored into CBS_COMDATA register (refer to **Table 8-3**
- the Watchdog Timer Reset is configured to class 3
- all code- and data- fetches from Flash are disabled
- access to the Flash Config sector is disabled
- startup protection is activated, which activation starts the Watchdog Timer
- the debug interface is unlocked
- an endless loop is executed (jump to itself)

As far as the Watchdog Timer is already enabled, the endless loop is aborted by a WDT reset which triggers a new SSW-execution. If this new startup fails again, the following error-processing will lead to the same endless loop. Respectively, a second WDT reset will occur being already a locked reset, which can be aborted only by a next power-on sequence.

Table 8-3 Errors reported by the TC1798 SSW

Coding in d12/COMDATA	Description
00000001_H	Bootcode wrongly called after exiting startup mode
00000002_H	Flash error during rampup
00000003_H	Error in Flash Configuration sector
00000004_H	Invalid Startup mode selected
00000008_H	MultiCAN module not available but CAN Bootloader selected
00000018_H	CAN0 node not available (due to ATM) but CAN Bootloader selected
00000009_H	ASC module not available but ASC Bootloader selected
00000010_H	Error in BootROM
00000011_H	
00000012_H	Error in SHE module
00000013_H	Error in ERAY module during initialization (no XTAL clock)
$0000004x_H$	Trap of Class x (0..7) raised during SSW

8.2 Bootstrap Loaders

These routines provide mechanisms to load an user program via selected interface by moving code into Program Scratchpad RAM. The loaded code is started after exiting the BootROM.

Two interfaces can be utilized for downloading in TC1798 - ASC and CAN. Besides two separate procedures are supporting any of these interfaces/protocols, they have a common first part. In other words, there is one entry-point **bl_entry** for all bootloader procedures.

8.2.1 Common Procedures for all Bootloaders

The first such a common procedure is to reconfigure the clock system in case the last reset is a Power-on. This reconfiguration switches from the initial PLL Freerunning mode (VCO base frequency) to Prescaler Mode with F_{FPI}:F_{OSC}=1:2.

Therefore the FPI-peripherals (including MultiCAN and ASC modules) run at half the frequency of an external crystal which must be connected between XTAL1/XTAL2 pins if a Bootloader mode will be selected upon Power-on. This 1:2 relation must be taken into account when selecting the host speed for downloading. For example, when using the MultiCAN bootstrap loader F_{OSC} should be greater or equal to 20 MHz for a baud rate of 1 Mbit/s.

Attention: This clock-switch to external oscillator upon Power-on is overwritten by a switch back to PLL freerunning mode at the end of SSW .
Therefore if it is desired after downloading to continue communication with the same baudrate, the user code must first reinstall:
- PLL prescaler mode (SCU_PLLCON0.VCOBYP:=0) and
- K1 divider 1:1 (SCU_PLLCON1.KDIV:=00_H).

Upon any other reset but not power-on, the clock configuration - respectively the system frequency - remains the same as previously selected.

Next, depending on the Bootloader-type currently configured in HWCFG a pin is selected as receive-data input (RxD) which will be evaluated on the following step. Note, that still no further pin-configuration is done here - e.g. no assignment to a specific (ASC/CAN) module functionality - but only the pin input-value is directly checked in this procedure.

The procedure waits to receive a low-level pulse at RxD and measures its duration - the time between the falling and rising edges - into the BL_meas work variable.

Then, the SSW checks the startup configuration in HWCFG:

- upon ASC Bootloader Mode - a jump to the respective routine (**Chapter 8.2.2**) is directly executed
- upon Generic Bootloader Mode - the type of interface (ASC/CAN) currently used must be detected by the SSW. For this the RxD pin is checked until:

– low level is found there - then a jump to **CAN Bootstrap Loader**will be executed; **OR**
– no edge is found for a time 6 time longer than the value in BL_meas - then **ASC Bootstrap loader** will be executed.

This interface-detection procedure is based on the following principles:

- an ASC-Bootloader Host sends one only start Byte and then waits for a response from the target system
- a CAN-Bootloader Host sends a complete frame, whereas no more than 5 consecutive bits can be sent having equal logical levels - i.e. after two consecutive edges for a given time dT, in any case another edge must follow within the next time-frame of 6*dT.

8.2.2 ASC Bootstrap loader

The ASC Bootloading routine implements the following steps:

- RxD/TxD pins configuration is done in accordance to the TC1798 definitions, as well as depending either the routine is invoked upon “ASC Bootloader”-startup mode (ASC-only pins are used) or following an ASC-protocol detection upon “Generic Bootloader”-mode (CAN/ASC-shared pins are used but configured to ASC module)
- baudrate calculation is done based on the value already captured
- ASC0 is initialized (without enabling the receiver) to the baudrate as determined, 8 data and 1 stop bit
- acknowledge byte $D5_H$ is sent to the host indicating the device is ready to accept a data transfer
- after the acknowledge byte is transmitted, the receiver is enabled
- the bootloader enters a loop waiting to receive exactly 128 bytes which are stored as 32 words in Program Scratchpad RAM starting from address $C000'0000_H$

Once 128 bytes are received, the SSW starts the user code from address $C000'0000_H$.

8.2.3 CAN Bootstrap Loader

The CAN bootstrap loader transfers program code/data via node 0 of the MultiCAN module into the Program Scratchpad RAM. Data is transferred from the external host to the TC1798 using eight-byte data frames. The number of data frames to be received is programmable and determined by the 16-bit data message count value DMSGC.

The communication between TC1798 and external host is based on the following three CAN standard frames:

- Initialization frame - sent by the external host to the TC1798
- Acknowledge frame - sent by the TC1798 to the external host
- Data frame(s) - sent by the external host to the TC1798

The initialization frame is used in the TC1798 for baud rate detection. After a successful baud rate detection is reported to the external host by sending the acknowledge frame, data is transmitted using data frames.

Initialization Phase

The first task is to determine the CAN baud rate at which the external host is communicating. This task requires the external host to send initialization frames continuously to the TC1798. The first two data bytes of the initialization frame include a 2-byte baud rate detection pattern (5555_H), an 11-bit (2-byte) identifier ACKID for the acknowledge frame, a 16-bit data message count value DMSGC, and an 11-bit (2-byte) identifier DMSGID to be used by the data frame(s).

The CAN baud rate is determined by analyzing the received baud rate detection pattern (5555_H) and the baud rate registers of the MultiCAN module are set accordingly. The TC1798 is now ready to receive CAN frames with the baud rate of the external host.

Acknowledge Phase

In the acknowledge phase, the bootstrap loader waits until it receives the next correctly recognized initialization frame from the external host, and acknowledges this frame by generating a dominant bit in its ACK slot. Afterwards, the bootstrap loader transmits an acknowledge frame back to the external host, indicating that it is now ready to receive data frames. The acknowledge frame uses the message identifier ACKID that has been received with the initialization frame.

Data Transmission Phase

In the data transmission phase, data frames are sent by the external host and received by the TC1798. The data frames use the 11-bit data message identifier DMSGID that has been sent with the initialization frame. Eight data bytes are transmitted with each data frame. The first data byte is stored in Program Scratchpad RAM starting from address $C000'0000_H$. Consecutive data bytes are stored at incrementing addresses.

Both communication partners evaluate the data message count DMSGC until the requested number of CAN data frames has been transmitted.

After the reception of the last CAN data frame, the SSW starts the user code from address $C000'0000_H$.

8.3 Additional information and usage hints

The information below is provided to help the customer to use properly the functionality of TC1798 startup software.

8.3.1 Conditions upon user code start

After SSW, the user code execution starts upon the following basic conditions within TC1798:

- system clock
  - after power-on/PORST: PLL in freerunning mode, 16.66 MHz system frequency (nominal)

*Note: When in Bootloader mode - keep in mind the Attention-note at the beginning of **Chapter 8.2.1** (**Common Procedures for all Bootloaders**)!*

  - otherwise: as previously configured - no change due to the bootcode
- interrupts and traps
  - all maskable interrupts are disabled by ICR.IE=0
  - all NMI-traps are disabled in SCU_TRAPDIS
- Watchdog-Timer - running in time-out mode

8.3.2 RAMs Handling

No RAM initialization is performed by the Startup Software in TC1798.

Attention: In regard to TC1798 RAMs after startup the user must consider:

- if ECC will be enabled for a RAM module - correct initial content of this memory must be assured
- upon application software start, error detection is disabled in all memories

8.3.3 Influencing the next SSW-execution

By writing 1 to SYSCON.SETLUDIS (no protection), the user software will prevent automatic update of SCU_STSTAT.HWCFG upon the next application reset.

If such setting is active when a Bootstrap Loader mode is configured in STSTAT.HWCFG bitfield, after the next application reset the Bootloader routine will not be executed but directly the application-code will be started from SPRAM.

The LUDIS=1 setting will have effect until a system/power-on reset which will force the SYSCON register to its reset value with LUDIS=0. Therefore, upon system/power-on reset the startup HW-configuration (SCU_STSTAT.HWCFG) is always updated from pins.

8.3.4 TC1798 registers modified by SSW

TC1798 SSW modifies some registers against their reset value - refer to **Table 8-4**.

Table 8-4 TC1798 registers modified by SSW

Register	Value	Comments
SCU_STSTAT[18], [7:0]	EXTBEN, HWCFG	According to the current start-up mode
SCU_STCON[15]	1	Start-up protection activated
ERAY_SEDCON	$0000\ 0000_H$	SED disabled in ERAY RAMs
ERAY_DEDCON	$0000\ 0000_H$	DED disabled in ERAY RAMs
ERAY_CLC	$0000\ 0003_H$	ERAY module disabled
FLASHx_MARP[15], FLASH0_MARD[15]	0	Flash double-bit error traps enabled
FLASHx_FCON [22:17]	000000_B 111111_B	If Flash is not protected or Internal start mode If Flash is protected and not Internal start mode
CBS_OEC[17]	1	If Flash is not protected or Internal start mode

Additionally to the above, registers can be affected by dynamic conditions/events during SSW execution:

1. ASC/CAN configuration (clock settings, pin usage etc.) registers in BSL modes - depending on the start-up configuration and baudrate.
   The settings in these registers allow user software generally to continue using the same interface (ASC/CAN) after downloading - for this, keep attention to the note at **Page 8-13**.
2. PLLSTAT, TRAPSTAT registers - flag(s) can be set due to event/exception(s) during boot phase like loss-of-lock upon power-on and system reset.
   This is not critical for the application because the traps are generally disabled (in SCU_TRAPDIS) after any reset.

9 Memory Maps

This chapter gives an overview of the TC1798 memory map, and describes the address locations and access possibilities for the units, memories, and reserved areas as “seen” from the two different on-chip buses’ point of view.

The TC1798 has the following memories

- Program Memory Unit (PMU) with
  - 4 Mbyte of Program Flash Memory (PFLASH)
  - 192 Kbyte of Data Flash Memory (DFLASH)
  - 16 Kbyte of Boot ROM (BROM)
- Program Memory Interface (PMI)
  - 32 Kbyte of Instruction Scratch-Pad SRAM (PSPR)[1)]
  - 16 Kbyte of Instruction Cache (ICACHE)[2)]
- Data Memory Interface (DMI)
  - 128 Kbyte of Data Scratch-Pad SRAM (DSPR)[1)]
  - 16 Kbyte of Data Cache (DCACHE)[2)]
- Local Memory Unit (LMU)
  - 128 Kbyte of SRAM (LMURAM)[1)]
- PCP memory
  - 32 Kbyte of PCP Code Memory (CMEM)[1)]
  - 16 Kbyte of PCP Data Memory (PRAM)[1)]

Furthermore, the TC1798 has two on-chip buses:

- System Peripheral Bus (SPB)
- Shared Resource Interconnect (SRI)

Note: After PORST the ECC (single bit) correction is enabled, signalling of corrected ECC errors is disabled, signalling of detected non-correctable ECC errors is enabled.

1) Before used by the application, the memory has to be initialized by customer SW by overwriting it one time

2) When mapping Cache SRAM into the memory map and accessing as normal SRAM: the memory has to be initialized by customer SW before using it as normal SRAM by overwriting it one time

9.1 What is new

The target for the AudoMax devices memory map is to keep it compatible to AudoNG and AudoFuture wherever it is possible. This means to keep memory space/flash segment start addresses and peripheral control register address spaces where they where mapped to in AudoNG and AudoFuture.

Major differences of the TC1798 Memory Map compared to AudoFuture, TC1784 and TC1387:

- General:
  - Flash sizes, SRAM sizes and module instances adapted to the TC1798 requirements
  - Adaptation of the system address map to the TC1.6 requirements
  - Some modules shifted (start address / segment)
- Segment 8 / A:
  - PMU1 PFlash start address shifted
  - External EBU Space start address shifted, size reduced to 192 MB
  - OVRAM removed, LMU sram to be used as overlay memory instead
  - Emulation memory was shifted into segment 9 / B.
- Segment 8:
  - DFlash removed from segment 8
- Segment 9:
  - Added LMU SRAM
  - Added Emulation memory
- Segment A:
  - DFlash Bank0/1 start address shifted, size of DFlash Bank 0/1 increased
  - Address ranges for SHE KeyFlash Banks 0/1 added
- Segment B:
  - Added LMU SRAM
  - Added Emulation memory
- Segment C:
  - Segment is reserved for TC1.6 PMI SRAMs (Program Scratch Pad SRAM, ICache[1)] SRAM, PTAG SRAM[1)], image of Program Scratch Pad, PTAG[1)] and ICache SRAMs)
- Segment D:
  - Removed External EBU Space
  - Segment is reserved for TC1.6 DMI SRAMs (Data Scratch Pad SRAM, DCache[1)] and DTAG SRAMs[1)], image of Data Scratch Pad, DTAG[1)] and DCache SRAMs)
- Segment C / D:
  - Renamed SPRAM to PSPR (Program Scratch Pad SRAM)
  - Renamed LDRAM to DSPR (Data Scratch Pad SRAM)

1) Mapping of Cache and TAG SRAMs into the memory map is controlled by CPU register SMACON.

  - Lower half of segment C / D is fixed non-cached bahiour
  - Physical Memory Attributes (PMA) of upper half can be defined now via TC1.6 control registers (cached, non-cached)
- Segment E:
  - Reserved. There is no FPI->CPU bus address translation any more in SRI/TC1.6 systems.
- Segment F:
  - Shifted SSC0, SSC1, SSC2 to keep SSC3 and the SSC Guardian together
  - Lower part of the segment F reserved for FPI peripheral control registers, upper part reserved for SRI peripheral control registers
  - Added SSC2 / SSC3 module
  - Added SSC Guardian instances SSCG01 and SSCG21
  - Added Port16 and Port17 modules
  - Added ADC3 kernel
  - Added SDMA (Safe DMA module)
  - Added Bus Monitor Unit (BMU)
  - Removed LMBH, LFI and TC1.3 PMI/DMI registers
  - Added XBar_SRI module
  - Added LMU module
  - Added Flexible CRC Engine (FCE)
  - Added Secure Hardware Extension module (SHE)
  - Replaced TC1.3 against TC1.6 register ranges

9.2 How to Read the Address Maps

The bus-specific address maps describe how the different bus master devices react on accesses to on-chip memories and modules, and which address ranges are valid or invalid for the corresponding buses.

The FPI Bus address map shows the system addresses from the point of view of the SPB master agents. SPB master agents are PCP2 and is the DMA[1)].

The SRI address map shows the system addresses from the point of view of the SRI master agents. SRI master agents are PMI, DMI and DMA[1)].

The SFI is a bi-directional bridge between SRI and SPB and therefore not mentioned here as SRI or SPB master in the Address Map. The SFI is fully transparent and does not include an address translation mechanism.

1) DMA including: DMA Move Engines and module connected to the DMA Peripheral Interface like MLI modules.

Table 9-1 defines the acronyms and other terms that are used in the address maps (Table 9-2 and Table 9-3).

Table 9-1 Definition of Acronyms and Terms

Term	Description
…BE	Means “Bus error” generation.
…BET	Means “Bus error & trap” generation.
SPBBE	A bus access is terminated with a bus error on the SPB.
SPBBET	A bus access is terminated with a bus error on the SPB and a DSE trap (read access) or DAE trap (write access).
SRIBE	A bus access is terminated with a bus error on the SRI.
SRIBET	A bus access is terminated with a bus error on the SRI and a DSE trap (read access) or DAE trap (write access).
access	A bus access is allowed and is executed.
ignore	A bus access is ignored and is not executed. No bus error is generated.
trap	A DSE trap (read access) or DAE trap (write access) is generated.
32	Only 32-bit word bus accesses are permitted to that register/address range.
nE	A bus access generates no bus error, although the bus access points to an undefined address or address range. This is valid e.g. for CPU accesses (MTCR/MFCR) to undefined addresses in the CSFR range.

9.3 Contents of the Segments

This section summarizes the contents of the segments.

Segments 0-7

These segments are reserved segments in the TC1798.

Segment 8

This memory segment allows cacheable access to PFlash, External EBU Space, BROM.

Accesses from the DMA Move Engines, Cerberus or MLI to this segment are processed by the DMA SRI master interface on the SRI Bus.

Segment 9

This memory segment allows cacheable access to LMU SRAM and EMEM (Emulation Device only).

Segment 10

This memory segment allows non-cacheable access to PFlash, DFlash, External EBU Space, BROM.

From the DMA point of view, Move Engine, Cerberus and MLI accesses to this segment are processed by the DMA SRI master interface on the SRI Bus.

Segment 11

This memory segment allows non cacheable access to LMU SRAM and EMEM (Emulation Device only).

Segment 12

This memory segment allows access to the Program Scratch Pad SRAM (PSPR), PTAG SRAM and the Program Cache (ICache).

ICache and PTAG SRAM can be only accessed if the Program Cache is disabled[1)].

The attribute of this segment (cached / non-cached) can be partially configured[1)].

Segment 13

This memory segment allows access to the Data Scratch Pad SRAM (DSPR), DTAG SRAM and the Data Cache (DCache).

DCache and DTAG SRAM can be only accessed if the Data Cache is disabled[1)].

1) see CPU chapter, register SMACON, for details.

The attribute of this segment (cached / non-cached) can be partially configured.

Segment 14

This memory segment is reserved in the TC1798.

Segment 15

This memory segment allows accesses to all SFRs, CSFRs, the PCP memories and the MLI transfer windows.

Access from DMA Move Engines, Cerberus and MLI to the lower 128 MB of this segment are processed by the DMA FPI master interface on the SPB Bus, to the upper 128 MB of this segment by the DMA SRI master interface on the SRI Bus.

9.4 Address Map of the On Chip Bus System

This chapter describes the system address map as it is seen from the SRI and SPB bus masters PMI, DMI, PCP, DMA, SDMA, SHE, MLI and Cerberus.

9.4.1 Segments 0 to 14

Table 9-2 shows the address map of segments 0 to 14.

Table 9-2 On Chip Bus Address Map of Segment 0 to 14

Segment	Address Range	Size	Description	Access Type	
				Read[1]	Write[2]
0-7	$0000\ 0000_H$ - $0000\ 0007_H$	8 byte	Reserved (virtual address space)	SPBBE	SPBBE
	$0000\ 0008_H$ - $7FFF\ FFFF_H$	8×256 Mbyte		SPBBE	SPBBE
8	$8000\ 0000_H$ - $801F\ FFFF_H$	2 Mbyte	Program Flash 0 (PFLASH0)	access	access[2]
	$8020\ 0000_H$ - $803F\ FFFF_H$	2 Mbyte	Reserved	SRIBE	SRIBE
	$8040\ 0000_H$ - $807F\ FFFF_H$	-	Reserved	SRIBE & SPBBE	SRIBE
	$8080\ 0000_H$ - $809F\ FFFF_H$	2 Mbyte	Program Flash 1 (PFLASH1)	access	access[2]
	$80A0\ 0000_H$ - $80FF\ FFFF_H$	-	Reserved	SRIBE	SRIBE
	$8100\ 0000_H$ - $82FF\ FFFF_H$	-	Reserved	SRIBE	SRIBE
	$8300\ 0000_H$ - $8EFF\ FFFF_H$	192 Mbyte	External EBU Space	access	access
	$8F00\ 0000_H$ - $8F1F\ FFFF_H$	-	Reserved	SRIBE	SRIBE
	$8F20\ 0000_H$ - $8FE6\ FFFF_H$	-	Reserved	SRIBE	SRIBE
	$8FE7\ 0000_H$ - $8FE7\ 7FFF_H$	32 Kbyte	Online Data Acquisition (OLDA)	SRIBE	access[3] / SRIBE
	$8FE7\ 8000_H$ - $8FFF\ BFFF_H$	-	Reserved	SRIBE	SRIBE

Table 9-2 On Chip Bus Address Map of Segment 0 to 14 (cont'd)

Segment	Address Range	Size	Description	Access Type	
				Read[1)]	Write[2)]
	$8FFF\ C000_H$ - $8FFF\ FFFF_H$	16 Kbyte	Boot ROM (BROM)	access	SRIBE
9	$9000\ 0000_H$ - $9001\ FFFF_H$	128 Kbyte	LMU SRAM	access	access
	$9002\ 0000_H$ - $9EFF\ FFFF_H$	-	Reserved	SRIBE	SRIBE
	$9F00\ 0000_H$ - $9F0B\ FFFF_H$	768 Kbyte	Reserved for TC1798 Emulation Device Memory (EMEM)	SRIBE	SRIBE
	$9F0C\ 0000_H$ - $9FFF\ FFFF_H$	-	Reserved	SRIBE	SRIBE
10	$A000\ 0000_H$ - $A01F\ FFFF_H$	2 Mbyte	Program Flash 0 (PFLASH0)	access	access[2)]
	$A020\ 0000_H$ - $A03F\ FFFF_H$	-	Reserved	SRIBE	SRIBE
	$A040\ 0000_H$ - $A07F\ FFFF_H$	-	Reserved	SRIBE	SRIBE
	$A080\ 0000_H$ - $A09F\ FFFF_H$	2 Mbyte	Program Flash 1 (PFLASH1)	access	access[2)]
	$A0A0\ 0000_H$ - $A0FF\ FFFF_H$	-	Reserved	SRIBE	SRIBE
	$A100\ 0000_H$ - $A2FF\ FFFF_H$	-	Reserved	SRIBE	SRIBE
	$A300\ 0000_H$ - $AEFF\ FFFF_H$	192 Mbyte	External EBU Space	access	access
	$AF00\ 0000_H$ - $AF01\ 7FFF_H$	96 Kbyte	Data Flash (DFLASH) Bank 0	access	access[2)]
	$AF01\ 8000_H$ - $AF07\ FFFF_H$	-	Reserved	SRIBE	SRIBE
	$AF08\ 0000_H$ - $AF09\ 7FFF_H$	96 Kbyte	Data Flash (DFLASH) Bank 1	access	access[2)]
	$AF09\ 8000_H$ - $AF0F\ FFFF_H$	-	Reserved	SRIBE	SRIBE

Table 9-2 On Chip Bus Address Map of Segment 0 to 14 (cont'd)

Segment	Address Range	Size	Description	Access Type	
				Read[1]	Write[2]
	AF10 0000$_H$ - AF1F FFFF$_H$	~ 1 MByte	Reserved	SRIBE	SRIBE
	AF20 0000$_H$ - AF20 1FFF$_H$	-	Reserved	SRIBE	access[2]SRIBE
	AF20 2000$_H$ - AF20 3FFF$_H$	-	Reserved	SRIBE	SRIBE
	AF20 4000$_H$ - AF2F FFFF$_H$	-	Reserved	SRIBE	SRIBE
	AF30 0000$_H$ - AFE6 FFFF$_H$	-	Reserved	SRIBE	SRIBE
	AFE7 0000$_H$ - AFE7 7FFF$_H$	32 Kbyte	Online Data Acquisition (OLDA)	SRIBE	access[3] / SRIBE
	AFE7 8000$_H$ - AFFF BFFF$_H$	-	Reserved	SRIBE	SRIBE
	AFFF C000$_H$ - AFFF FFFF$_H$	16 Kbyte	Boot ROM (BROM)	access	SRIBE
11	B000 0000$_H$ - B001 FFFF$_H$	128 Kbyte	LMU SRAM	access	access
	B002 0000$_H$ - BEFF FFFF$_H$	-	Reserved	SRIBE	SRIBE
	BF00 0000$_H$ - BF0B FFFF$_H$	768 Kbyte	Reserved for TC1798 Emulation Device Memory (EMEM)	SRIBE	SRIBE

14	$E000\ 0000_H$ - $EFFF\ FFFF_H$	-	Reserved	SRIBE	SRIBE
15	$F000\ 0000_H$ - $FFFF\ FFFF_H$	256 Mbyte	see **Table 9-3**		

1) A read transaction through the SRI to FPI bridge that is terminated with Bus Error will result in Bus Errors on SRI and FPI (valid for transactions from FPI to SRI and SRI to FPI)

2) Write access to Flash resources are handled by the PMU module (Flash command sequence, see PMU chapter for details)

3) Online Data Acquisition address space can be disabled/enabled via PMU control register bit LMU_MEMCON.OLDAEN. CPU access to OLDA address space via segment 8 (cached) results in SRIBE independent of the LMU_MEMCON.OLDAEN bit setting.

4) ICache/DCache SRAMs (and the corresponding TAG SRAMs) can be only accessed when mapped into the address space (ICache / DCache disabled, see CPU chapter for details)via 32 bit access and only with 64 bit aligned address.

5) TAG SRAMs are not meant to be used as general SRAMS and can be accessed only with single data access and only with 64 bit aligned address. Mapping of TAG SRAMs in the address map can be used as additional option for memory testing.

9.4.2 Segment 15

Table 9-3 shows the address map of segment 15 as seen from the SRI and SPB bus masters PMI, DMI, PCP, SHE, DMA, SDMA and OCDS.

Please note that Table 9-3 describes the mapping of modules to segment F. The details of the module address ranges can be found in the module chapters register overview.

Table 9-3 On Chip Bus Address Map of Segment 15

Unit	Address Range	Size	Access Type	
			Read	Write

9.5 Memory Module Access Restrictions

Table 9-4 describes which type of accesses are possible to the different memories in the TC1798.

Table 9-4 Possible Memory Accesses[1)]

Memory		Bit	Byte		Half-word		Word		Double-word	
		rmw	r	w	r	w	r	w	r	w
PMI[2)]	PSPR	y	y	y	y	y	y	y	y	y
	PTAG[3)]	-	-	-	-	-	y	y	-	y
	PCACHE	y	y	y	y	y	y	y	y	y
DMI[2)]	DSPR	y	y	y	y	y	y	y	y	y
	DTAG[3)]	-	-	-	-	-	y	y	-	-
	DCACHE	y	y	y	y	y	y	y	y	y
LMU[2)]	LMURAM	y	y	y	y	y	y	y	y	y
PMU	BROM	–	y	–	y	–	y	–	y	–
	PFLASH	–	y	–	y	–	y	y	y	y
	DFLASH	–	y	–	y	–	y	y	y	y
PCP[4)]	CMEM	y	–	–	–	–	y	y	y	y
	PRAM	y	–	–	–	–	y	y	y	y
BMU[4)]	BMURAM	–	–	–	–	–	y	y	y	y

1) ´y´ means: supported. ´-´ means: not supported

2) The module also supports SRI 2-Word and 4-Word Block read and write accesses.

3) TAG SRAMs are not meant to be used as general SRAMS and can be accessed only via 32 bit single data access and only with 64 bit aligned address. Mapping of TAG SRAMs in the address map can be used as additional option for memory testing.

4) The module also supports FPI/SPB 4-Word and 8-Word Block read and write accesses.

9.6 Side Effects from Modules to Data Scratch Pad SRAM (DSPR)

Please note that the DSPR is also used by Boot routine and can be used by the CPU for system tasks:

- the Boot routine copies some devices informations during the startup into the DSPR (see chapter ´BootROM Content´)
- DSPR can be used as context save area (for details see chapter ´CPU Subsystem´)

10 General Purpose I/O Ports and Peripheral I/O Lines (Ports)

The TC1798 has 252 digital General Purpose Input/Output (GPIO) port lines which are connected to the on-chip peripheral units. They are divided into:

Table 10-1 Ports Overview

Port	Pins	Base Address	End Address	Note
P0	16	F000 0C00$_H$	F000 0CFF$_H$	+hwcfg, +E-Ray, EMSTOP, CCU6/GPT12
P1	16	F000 0D00$_H$	F000 0DFF$_H$	EMSTOP, CCU6/GPT12

The External Bus Interface (EBU) has its own set of dedicated signal lines. Further details are described in the port-specific sections of this chapter.

10.1 Basic Port Operation

Figure 10-1 is a general block diagram of a TC1798 GPIO port slice.

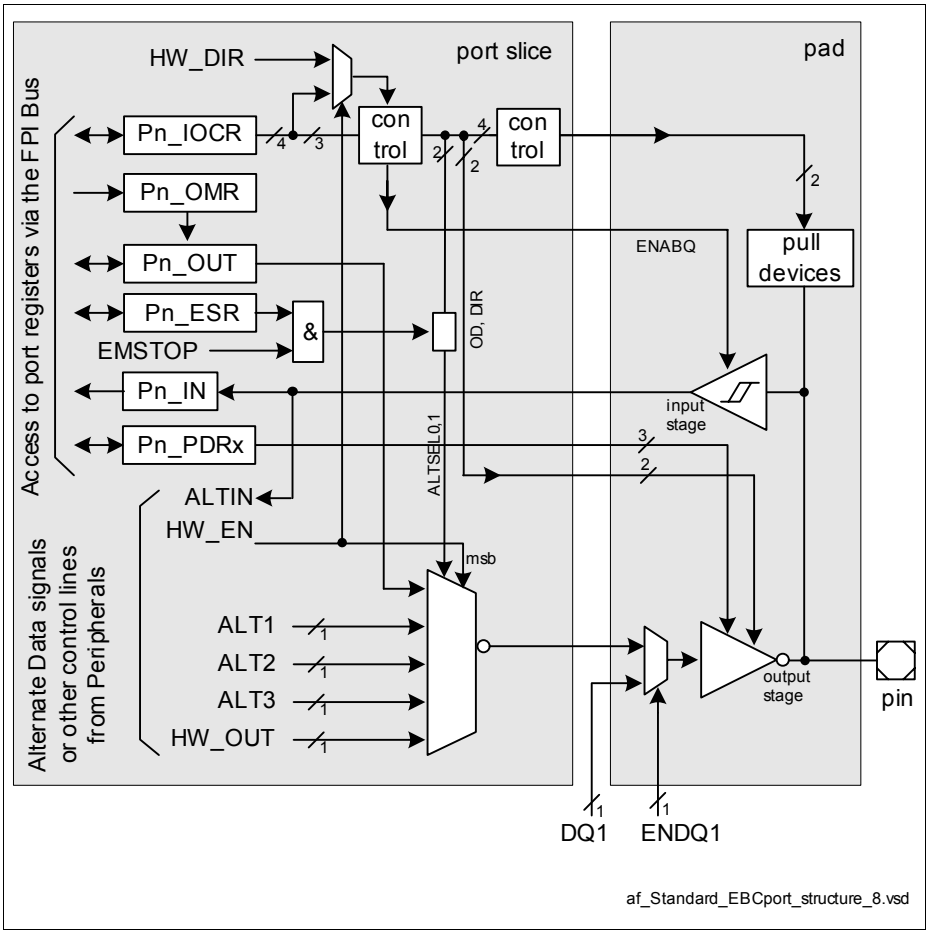

Figure 10-1 General Structure of a Port Pin

Each port line has a number of control and data bits, enabling very flexible usage of the line. Each port pin (except Port 10) can be configured for input or output operation. In input mode (default after reset), the output driver is switched off (high-impedance). The actual voltage level present at the port pin is translated into a logical 0 or 1 via a Schmitt-Trigger device and can be read via the read-only register Pn_IN. An input signal can also be connected directly to the various inputs of the peripheral units (AltDataIn). The

function of the input line from the pin to the input register Pn_IN and to AltDataIn is independent of whether the port pin operates as input or output. This means that when the port is in output mode, the level of the pin can be read by software via Pn_IN or a peripheral can use the pin level as an input.

In output mode, the output driver is activated and drives the value supplied through the multiplexer to the port pin. Switching between input and output mode is accomplished through the Pn_IOCR register, which enables or disables the output driver. If a peripheral unit uses a GPIO port line as a bi-directional I/O line, register Pn_IOCR has to be written for input or output selection. The Pn_IOCR register further controls the driver type of the output driver, and determines whether an internal weak pull-up or pull-down device is alternatively connected to the pin when used as an input. This offers additional advantages in an application.

The output multiplexer in front of the output driver selects the signal source for the GPIO line when used as output. If the pin is used as general-purpose output, the multiplexer is switched by software (Pn_IOCR register) to the Output Data Register Pn_OUT. Software can set or clear the bit in Pn_OUT, and therefore it can directly influence the state of the port pin. If the on-chip peripheral units use the pin for output signals, the alternate output lines ALT1 to ALT3 can be switched via the multiplexer to the output driver. The data written into the output register Pn_OUT by software can be used as input data to an on-chip peripheral. This enables, for example, peripheral tests via software without external circuitry.

When selected as general-purpose output line, the logic state of each port pin can be changed individually by programming the pin-related bits in the Output Modification Register Pn_OMR. The bits in Pn_OMR make it possible to set, reset, toggle, or leave the bits in the Pn_OUT register unchanged.

When selected as general-purpose output line, the actual logic level at the pin can be examined through reading Pn_IN and compared against the applied output level (either applied through software via the output register Pn_OUT, or via an alternate output function of a peripheral unit). This can be used to detect some electrical failures at the pin caused through external circuitry. In addition, software-supported arbitration schemes can be implemented in this way using the open-drain configuration and an external wired-And circuitry. Collisions on the external communication lines can be detected when a high level (1) is output, but a low level (0) is seen when reading the pin value via the input register Pn_IN.

All GPIO lines of the TC1798 that are used by the GPTA modules (GPTA0, GPTA1, LTCA2) have an emergency stop logic. This logic makes it possible to individually disconnect GPTA outputs from the driving GPTA module outputs and to put them onto a well defined logic state in an emergency case. In en emergency case, the content of the port output register Pn_OUT is driven at the output pin instead of the GPTA module output. The Emergency Stop Register Pn_EMR determines whether a GPTA output is enabled or disabled in an emergency case.

10.2 Description Scheme for the Port IO Functions

The following two general building block can be used to describe each GPIO pin:

Table 10-2 Port x Input/Output Functions

Port Pin	I/O	Select	Connected Signal(s)	From / to Module
Px.y	Input		Signal(s)	module(s)
	Output	GPIO	Signal	module
		ALT1	Signal	module
		ALT2	Signal	module
		ALT3	Signal	module
	HW_DIR	HW_Out	Signal	module; group En

or:

Table 10-3 Port x Functions

Port Pin	I/O	Pin Functionality	Associated Reg./ I/O Line	Port I/O Control Select.	
				Reg./Bit Field	Value
Px.y	I	GPIOt	Px_IN.Py	Px_IOCRz. PC0	$0XXX_B$
	O	GPIO	Px_OUT.Py		$1X00_B$
					$1X01_B$
					$1X10_B$
					$1X11_B$
	HW_DIR	module; group En	Signal		HW_DIR

- HW_DIR:
  The type Alternate Direction signal which is needed if HW_En is active:
  – Out -always output
    DIRx - the pins in one port having the same DIRx (x=0, 1, 2, ...), are controlled as a group by a dedicated HW_DIR signal.
    SDIR- Single DIR- the pin is controlled by its own, dedicated, single HW_DIR signal.
- grouping indicates if the respective pin is controlled by hardware:

  - ENx - the pins in one port having the same ENx (x=0, 1, 2, ...), are controlled as a group by a dedicated HW_EN signal.
  - SEN - Single EN - the pin is controlled by its own, dedicated, single HW_EN signal
- Digital port slices with HW_DIR defined are the ports described in **Figure 10-1**.

Note: HW_EN signal has higher priority then Emergency Stop. Emergency Stop is functional when the pins are set in the GPIO mode.

Note: HW_DIR signal, output case, switches the pad to push-pull output state.
HW_DIR signal, input case, switches the pad to the input state with pull-up/down setting as defined by the IOCR register.

10.3 Port Register Description

The individual control and data bits of each GPIO port are implemented in a number of registers. The registers are used to configure and use the port as general-purpose I/O or alternate function input/output. For some ports, not all registers are implemented. The availability of the registers in the specific ports is described in **Table 10-10** on **Page 10-28** up to **Table 10-28** on **Page 10-87**.

Note: All port-registers have control bits implemented in groups of four (a nibble), starting from the bit position 0. If a port is do not fit to multiple of four without rest, or starts with a bit number other than zero, then some control bits remain unused. These bits behave as standard read-write bits, but do not have any function. The registers of not implemented groups of bits starting on the position 0 are implemented, but do not have any function. For example, Port 6 contains control registers and bitfields for the first nibble P6.0 to P6.3, although there are no such pins physically implemented. The not implemented bits appear in the boundary-scan chain, although they do not have an external connection.

10.3.1 Port Input/Output Control Registers

The port input/output control registers select the digital output and input driver functionality and characteristics of a GPIO port pin. Port direction (input or output), pull-up or pull-down devices for inputs, and push-pull or open-drain functionality for outputs can be selected by the corresponding bit fields PCx (x = 0-15). Each 32-bit wide port input/output control register controls four GPIO port lines:

Register Pn_IOCR0 controls the Pn.[3:0] port lines
Register Pn_IOCR4 controls the Pn.[7:4] port lines
Register Pn_IOCR8 controls the Pn.[11:8] port lines
Register Pn_IOCR12 controls the Pn.[15:12] port lines

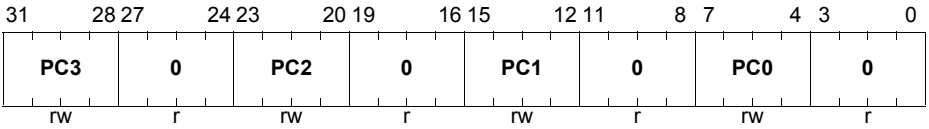
The diagrams below show the register layouts of the port input/output control registers with the PCx bit fields. One PCx bit field controls exactly one port line Pn.x.

Pn_IOCR0 (n=0-1)
Port n Input/Output Control Register 0
($F000\ 0C10_H + n*100_H$) **Reset Value: $2020\ 2020_H$**

Pn_IOCR0 (n=3-11)
Port n Input/Output Control Register 0
($F000\ 0C10_H + n*100_H$) **Reset Value: $2020\ 2020_H$**

Pn_IOCR0 (n=12-16)
Port n Input/Output Control Register 0
($F02F\ F410_H + n*100_H$) **Reset Value: $2020\ 2020_H$**

P18_IOCR0
Port 18 Input/Output Control Register 0
(10_H) **Reset Value: $2020\ 2020_H$**

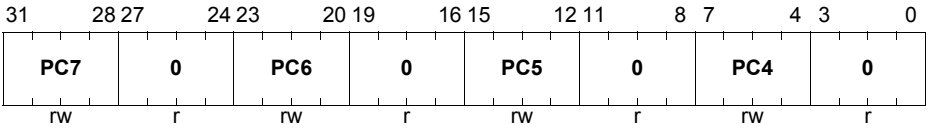


Field	Bits	Type	Description
PC0, PC1, PC2, PC3	[7:4], [15:12], [23:20], [31:28]	rw	**Port Control for Port n Pin 0 to 3** This bit field determines the Port n line x functionality (x = 0-3) according to the coding table (see **Table 10-7**).
0	[3:0], [11:8], [19:16], [27:24]	r	**Reserved** Read as 0; should be written with 0.

Pn_IOCR4 (n=0-11)
Port n Input/Output Control Register 4
(F000 0C14$_H$ + n*100$_H$) **Reset Value: 2020 2020$_H$**

Pn_IOCR4 (n=12-16)
Port n Input/Output Control Register 4
(F02F F414$_H$ + n*100$_H$) **Reset Value: 2020 2020$_H$**

P18_IOCR4
Port 18 Input/Output Control Register 4
(14$_H$) **Reset Value: 2020 2020$_H$**



Field	Bits	Type	Description
PC4, PC5, PC6, PC7	[7:4], [15:12], [23:20], [31:28]	rw	**Port Control for Port n Pin 4 to 7** This bit field determines the Port n line x functionality (x = 4-7) according to the coding table (see **Table 10-7**).
0	[3:0], [11:8], [19:16], [27:24]	r	**Reserved** Read as 0; should be written with 0.

Pn_IOCR8 (n=0-6)
Port n Input/Output Control Register 8
(F000 0C18$_H$ + n*100$_H$) **Reset Value: 2020 2020$_H$**

P9_IOCR8
Port 9 Input/Output Control Register 8
(18$_H$) **Reset Value: 2020 2020$_H$**

P11_IOCR8

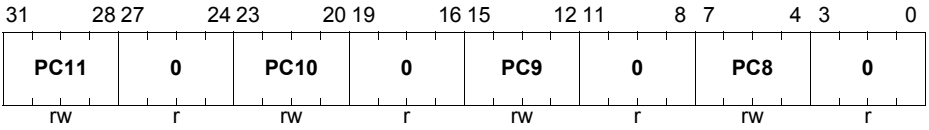
Pn_IOCR8 (n=13-15)
Port n Input/Output Control Register 8
(F02F F418$_H$ + n*100$_H$) **Reset Value: 2020 2020$_H$**

P16_IOCR8
Port 16 Input/Output Control Register 8
(18$_H$) **Reset Value: 2020 2020$_H$**

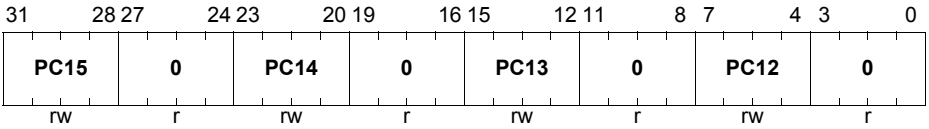


Field	Bits	Type	Description
PC8, PC9, PC10, PC11	[7:4], [15:12], [23:20], [31:28]	rw	**Port Control for Port n Pin 8 to 11** This bit field determines the Port n line x functionality (x = 8-11) according to the coding table (see **Table 10-7**).
0	[3:0], [11:8], [19:16], [27:24]	r	**Reserved** Read as 0; should be written with 0.

Pn_IOCR12 (n=0-6)
Port n Input/Output Control Register 12
(F000 0C1C$_H$ + n*100$_H$) **Reset Value: 2020 2020$_H$**

P11_IOCR12
Port 11 Input/Output Control Register 12
(1C$_H$) **Reset Value: 2020 2020$_H$**

Pn_IOCR12 (n=13-15)
Port n Input/Output Control Register 12
(F02F F41C$_H$ + n*100$_H$) **Reset Value: 2020 2020$_H$**



Field	Bits	Type	Description
PC12, PC13, PC14, PC15	[7:4], [15:12], [23:20], [31:28]	rw	**Port Control for Port n Pin 12 to 15** This bit field determines the Port n line x functionality (x = 12-15) according to the coding table (see Table 10-7).
0	[3:0], [11:8], [19:16], [27:24]	r	**Reserved** Read as 0; should be written with 0.

Depending on the GPIO port functionality (number of GPIO lines of a port), not all of the port input/output control registers are implemented.

The structure with one control bit field for each port pin located in different register bytes offers the possibility to configure the port pin functionality of a single pin with byte-oriented accesses without accessing the other PCx bit fields.

Port Control Coding

Table 10-7 describes the coding of the PCx bit fields that determine the port line functionality. Port 4 has a different PCx coding than the other ports (in input mode, no pull devices can be connected).

Table 10-7 PCx Coding

PCx[3:0]	I/O	Output Characteristics	Selected Pull-up / Pull-down / Selected Output Function
$0X00_B$	Input	–	No input pull device connected
$0X01_B$			Input pull-down device connected
$0X10_B$			Input pull-up device connected[1)]
$0X11_B$			No input pull device connected
1000_B	Output	Push-pull	General-purpose output
1001_B			Alternate output function 1
1010_B			Alternate output function 2
1011_B			Alternate output function 3
1100_B		Open-drain	General-purpose output
1101_B			Alternate output function 1
1110_B			Alternate output function 2
1111_B			Alternate output function 3

1) This is the default pull-up state after reset.

10.3.2 Pad Driver Mode Register

Overview

The pad structure of the TC1798 GPIO lines offers the possibility to select the output driver strength and the slew rate. These two parameters are controlled by the bit fields in the pad driver mode registers Pn_PDR0/1, independently from input/output and pull-up/pull-down control functionality as programmed in the Pn_IOCR register. Pn_PDR0 and Pn_PDR1 registers are assigned to each port.

The GPIO pads classes are:

- Class A1 pins (low speed 3.3V LVTTL outputs)
- Class A1+ pins (medium speed 3.3V LVTTL outputs)
- Class A2 pins (high speed 3.3V LVTTL outputs. e.g. for serial outputs)

The assignment of each port pin to one of these pad classes is shown in the port configuration figures. Further details about pad driver classes that are available in the TC1798 are summarized in the “Electrical Specification” chapter.

Depending on the assigned pad class, the 3-bit wide pad driver mode selection bit fields PDx in the pad driver mode registers Pn_PDR make it possible to select the port line functionality as shown in **Table 10-8**. Note that the pad driver mode registers are specific for each port. Therefore, the Pn_PDR layout is described for each port in the port-specific sections.

Class A1 pins make it possible to select between medium and weak output drivers. Class A1+ pins make it possible to select between strong/medium/weak output drivers. Class A2 pins make it possible to select between strong/medium/weak output drivers. Class B pins make it possible to select between strong/medium/weak output drivers, however class B pins with a PDx configured to an other value than 000_B have the behavior of class A2 pins. In the case of strong driver type, the signal transition edge can be additionally selected as sharp/medium/soft.

Table 10-8 Pad Driver Mode Selection

Pad Class	PDx.2	PDx.1	PDx.0	Functionality
A1	X	X	0	Medium driver
			1	Weak driver
A1+	0	X	0	Strong driver soft edge
	0	X	1	Strong driver slow edge
	1	X	0	Medium driver
	1	X	1	Weak driver

Table 10-8 Pad Driver Mode Selection (cont'd)

Pad Class	PDx.2	PDx.1	PDx.0	Functionality
A2 / B	0	0	0	Strong driver, sharp edge
	0	0	1	Strong driver, medium edge
	0	1	0	Strong driver, soft edge
	0	1	1	Strong driver, sharp - edge
	1	0	0	Medium driver
	1	0	1	Medium driver
	1	1	0	Strong driver, medium - edge
	1	1	1	Weak driver

Note: TC1798 Data Sheet describes the DC characteristics of all pad classes.

Pad Driver Mode Registers

This is the general description of the PDR registers. Each port contains its own specific PDR registers, described additionally at each port, that can contain between one and eight PDx fields for PDR0 and PDR1 registers, respectively. Each field controls 1 pin. For coding of PDx, see **Page 10-16**.

Pn_PDR0 (n=0-1)

10.3.3 Pin Function Decision Control Register

Pin Function Decision Control Register

The pad structure of the TC1798 GPIO lines offers the possibility to select the digital SENT input or analog ADC input functionalities at Port 17.This feature can be controlled by individual bits in the P17_PDISC, independently from input/output and pull-up/pull-down control functionality as programmed in the Pn_IOCR register.

P17_PDISC
Port 17 Pin Function Decision Control Register(60_H) **Reset Value: FFFF $FFFF_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
PDISx (x = 0-15)	x	rw	**Pad Disable for Port n Pin x** This bit disables the port pad. 0_B Pad Pn.x is enabled. 1_B Pad Pn.x is disabled.
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

10.3.4 Port Output Register

The port output register determines the value of a GPIO pin when it is selected by Pn_IOCRx as output. Writing a 0 to a Pn_OUT.Px (x = 0-15) bit position delivers a low level at the corresponding output pin. A high level is output when the corresponding bit is written with a 1. Note that the bits of Pn_OUT.Px can be individually set/reset by writing appropriate values into the port output modification register Pn_OMR.

Pn_OUT (n=0-11)
Port n Output Register **($F000\ 0C00_H + n*100_H$)** **Reset Value: $0000\ 0000_H$**
Pn_OUT (n=12-16)
Port n Output Register **($F02F\ F400_H + n*100_H$)** **Reset Value: $0000\ 0000_H$**
P18_OUT
Port 18 Output Register **(00_H)** **Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh

Field	Bits	Type	Description
Px **(x = 0-15)**	x	rwh	**Port n Output Bit x** This bit determines the level at the output pin Pn.x if the output is selected as GPIO output. 0_B The output level of Pn.x is 0. 1_B The output level of Pn.x is 1. Pn.x can also be set/reset by control bits of the Pn_OMR register.
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

Note: Only Port 0, 1, 3, 4, 5, 11, 13, 14, 15and 17 are 16-bit wide ports. The Pn_OUT registers of the other ports have a reduced number of Px bits (see Pn_OUT register descriptions in the corresponding port sections).

10.3.5 Port Output Modification Register

The port output modification register contains control bits that make it possible to individually set, reset, or toggle the logic state of a single port line by manipulating the output register.

Pn_OMR (n=0-11)
Port n Output Modification Register (F000 0C04$_H$ + n*100$_H$) Reset Value: 0000 0000$_H$
Pn_OMR (n=12-16)
Port n Output Modification Register (F02F F404$_H$ + n*100$_H$) Reset Value: 0000 0000$_H$
P18_OMR
Port 18 Output Modification Register (04$_H$) Reset Value: 0000 0000$_H$

w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Field	Bits	Type	Description
PSx (x = 0-15)	x	w	**Port n Set Bit x** Setting this bit will set or toggle the corresponding bit in the port output register Pn_OUT. The function of this bit is shown in **Table 10-9**.
PRx (x = 0-15)	x + 16	w	**Port n Reset Bit x** Setting this bit will reset or toggle the corresponding bit in the port output register Pn_OUT. The function of this bit is shown in **Table 10-9**.

Note: Register Pn_OMR is virtual and does not contain any flip-flop. A read action delivers the value of 0. One 8 or 16-bits write behaves as a 32-bit write padded with zeros.

Table 10-9 Function of the Bits PRx and PSx

PRx	PSx	Function
0	0	Bit Pn_OUT.Px is not changed.
0	1	Bit Pn_OUT.Px is set.
1	0	Bit Pn_OUT.Px is reset.
1	1	Bit Pn_OUT.Px is toggled.

10.3.6 Emergency Stop Register

All GPIO lines which are used by the GPTA modules (GPTA0, GPTA1, LTCA2) have an emergency stop logic implemented (see **Figure 10-1**). These GPTA related GPIO lines are:

- P0.[7:0], P1.[15:8], P2.[15:8], P3.[15:0], P4.[15:0], P5.[15:0], P8.[7:0], P9.[7:0], P13.[15:0], and P14.[15:0]

Each of these GPIO lines has its own emergency stop enable bit ENx that is located in the emergency stop register Pn_ESR of Port n. If the emergency stop signal becomes active, one of two states can be selected:

- Emergency stop function disabled (ENx = 0):
  A GPTA output line remains connected to the GPTA module (alternate function).
- Emergency stop function enabled (ENx = 1):
  A GPTA output line is disconnected from the GPTA module (alternate function) and connected to the corresponding bit of the Pn_OUT output register (the content of the corresponding PCx bit fields in register Pn_IOCR is discarded).

Pn_ESR (n=0-5)
Port n Emergency Stop Register ($F000\ 0C50_H + n*100_H$) Reset Value: $0000\ 0000_H$
Pn_ESR (n=8-9)
Port n Emergency Stop Register ($F000\ 0C50_H + n*100_H$) Reset Value: $0000\ 0000_H$
Pn_ESR (n=13-14)
Port n Emergency Stop Register ($F02F\ F450_H + n*100_H$) Reset Value: $0000\ 0000_H$

Field	Bits	Type	Description
ENx (x = 0-15)	x	rw	**Emergency Stop Enable for Port n Pin x** This bit enables the emergency stop function for GPIO lines used as GPTA outputs. If the emergency stop condition is met and enabled, the output selection is automatically switched from alternate (GPTA output) function to GPIO output function. 0_B Emergency stop function for Pn.x is disabled. 1_B Emergency stop function for Pn.x is enabled.
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

Note: Ports 3, 4, 5, 13, and 14 are 16-bit wide ports entirely used by the GPTA modules. The Pn_ESR registers of the other ports have a reduced number of bits (see Pn_ESR register descriptions in the corresponding port sections).

10.3.7 Port Input Register

The logic level of a GPIO pin can be read via the read-only port input register Pn_IN. Reading the Pn_IN register allways returns the current logical value at the GPIO pin independently whether the pin is selected as input or output.

Pn_IN (n=0-11)
Port n Input Register **(F000 0C24$_H$ + n*100$_H$)** **Reset Value: 0000 XXXX$_H$**
Pn_IN (n=12-16)
Port n Input Register **(F02F F424$_H$ + n*100$_H$)** **Reset Value: 0000 XXXX$_H$**
Pn_IN (n=17-18)
Port n Input Register **(F02F F424$_H$ + n*100$_H$)** **Reset Value: 0000 XXXX$_H$**

Field	Bits	Type	Description
Px **(x = 0-15)**	x	rh	**Port n Input Bit x** This bit indicates the level at the input pinPn.x. 0_B The input level of Pn.x is 0. 1_B The input level of Pn.x is 1.
0	[31:16]	r	**Reserved** Read as 0.

Note: Only Port 0, 1, 3, 4, 5, 11, 13, 14, 15and 17 are 16-bit wide ports. The Pn_IN registers of the other ports have a reduced number of Px bits (see Pn_IN register descriptions in the corresponding port sections).

10.4 Port 0

This section describes the Port 0 functionality in detail.

10.4.1 Port 0 Configuration

Port 0 is a general-purpose 16-bit bi-directional port. It serves as GPIO lines without secondary functions.

Table 10-10 summarizes the I/O control selection functions of each Port 0 line.

10.4.2 Port 0 Function Table

Table 10-10 summarizes the I/O control selection functions of each Port 0 line.

Table 10-10 Port 0 Functions

10.4.3 Port 0 Registers

The following registers are available on Port 0:

Table 10-11 Port 0 Registers

Register Short Name	Register Long Name	Offset[1] Address	Description see
P0_OUT	Port 0 Output Register	0000_H	Page 10-21
P0_OMR	Port 0 Output Modification Register	0004_H	Page 10-22
P0_IOCR0	Port 0 Input/Output Control Register 0	0010_H	Page 10-11
P0_IOCR4	Port 0 Input/Output Control Register 4	0014_H	Page 10-12
P0_IOCR8	Port 0 Input/Output Control Register 8	0018_H	Page 10-13
P0_IOCR12	Port 0 Input/Output Control Register 12	$001C_H$	Page 10-14
P0_IN	Port 0 Input Register	0024_H	Page 10-25
P0_PDR0	Port 0 Pad Driver Mode 0 Register	0040_H	Page 10-18
P0_PDR1	Port 0 Pad Driver Mode 1 Register	0044_H	Page 10-19
P0_ESR	Port 0 Emergency Stop Register	0050_H	Page 10-24

1) The absolute addresses are calculated by adding the offset address to the module base address (see Table 10-4)

10.4.3.1 Port 0 Emergency Stop Register

The basic P0_ESR register functionality is described on Page 10-24. At Port 0, only port lines P0.[7:0] have GPTA outputs. Therefore, the P0_ESR bits EN[15:8] are not implemented. They are always read as 0 and should be written with 0.

10.5 Port 1

This section describes the Port 1 functionality in detail.

10.5.1 Port 1 Configuration

Port 1 is a 16-bit bi-directional general-purpose I/O port that can be alternatively used for the MLI0 I/O lines or for the external trigger inputs REQ[3:0] of the CPU. Furthermore, the system clock output SYSCLK is provided at Port 1.

10.5.2 Port 1 Function Table

Table 10-12 summarizes the I/O control selection functions of each Port 1 line.

Table 10-12 Port 1 Functions

10.5.3 Port 1 Registers

The following registers are available on Port 1:

Table 10-13 Port 1 Registers

Register Short Name	Register Long Name	Offset[1] Address	Description see
P1_OUT	Port 1 Output Register	0000_H	Page 10-21
P1_OMR	Port 1 Output Modification Register	0004_H	Page 10-22
P1_IOCR0	Port 1 Input/Output Control Register 0	0010_H	Page 10-11
P1_IOCR4	Port 1 Input/Output Control Register 4	0014_H	Page 10-12
P1_IOCR8	Port 1 Input/Output Control Register 8	0018_H	Page 10-13
P1_IOCR12	Port 1 Input/Output Control Register 12	$001C_H$	Page 10-14
P1_IN	Port 1 Input Register	0024_H	Page 10-25
P1_PDR0	Port 1 Pad Driver Mode 0 Register	0040_H	Page 10-18
P1_PDR1	Port 1 Pad Driver Mode 1 Register	0044_H	Page 10-19
P1_ESR	Port 1 Emergency Stop Register	0050_H	Page 10-24

1) The absolute addresses are calculated by adding the offset address to the module base address (see Table 10-4)

10.5.3.1 Port 1 Emergency Stop Register

The basic P1_ESR register functionality is described on **Page 10-24**. At Port 1, only port lines P1.[15:8] have GPTA outputs. Therefore, the P1_ESR bits EN[7:0] are not implemented. They are always read as 0 and should be written with 0.

10.6 Port 2

This section describes the Port 2 functionality in detail.

10.6.1 Port 2 Configuration

Port 2 is a 14-bit bi-directional general-purpose I/O port that can be used either for the SSC0/SSC1 chip select output lines or for MSC0/MSC1 or GPTA0/GPTA1/LTCA2 I/O lines.

10.6.2 Port 2 Function Table

Table 10-14 summarizes the I/O control selection functions of each Port 2 line.

Table 10-14 Port 2 Functions

Port Pin	I/O	Pin Functionality	Associated Reg./ I/O Line	Port I/O Control Select.	
				Reg./Bit Field	Value
P2.2	I	General-purpose input	P2_IN.P2	P2_IOCR0.PC2	$0XXX_B$

10.6.3 Port 2 Registers

The following registers are available on Port 2:

Table 10-15 Port 2 Registers

Register Short Name	Register Long Name	Offset[1] Address	Description see
P2_OUT	Port 2 Output Register	0000_H	below[2]
P2_OMR	Port 2 Output Modification Register	0004_H	
P2_IOCR0	Port 2 Input/Output Control Register 0	0010_H	Page 10-45[2]
P2_IOCR4	Port 2 Input/Output Control Register 4	0014_H	Page 10-12
P2_IOCR8	Port 2 Input/Output Control Register 8	0018_H	Page 10-13
P2_IOCR12	Port 2 Input/Output Control Register 12	$001C_H$	Page 10-14
P2_IN	Port 2 Input Register	0024_H	Page 10-45[2]
P2_PDR0	Port 2 Pad Driver Mode 0 Register	0040_H	Page 10-46
P2_PDR1	Port 2 Pad Driver Mode 1 Register	0044_H	Page 10-19
P2_ESR	Port 2 Emergency Stop Register	0050_H	Page 10-46[2]

1) The absolute addresses are calculated by adding the offset address to the module base address (see Table 10-4)

2) These registers are listed and noted here in the Port 2 section because they differ from the general port register description given in Section 10.3.

10.6.3.1 Port 2 Output Register

The basic P2_OUT register functionality is described on Page 10-21. Port lines P2.[1:0] are not connected to port lines. Therefore, reading the P2_OUT bits P[1:0] returns the value that was last written (0 after reset). These bits can be also set/reset by the corresponding P2_OMR bits.

10.6.3.2 Port 2 Output Modification Register

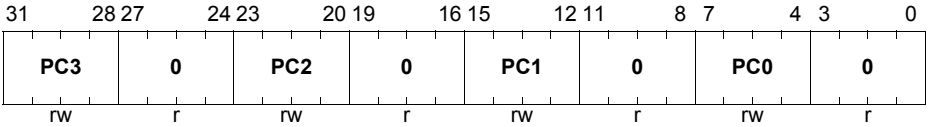
The basic P2_OMR register functionality is described on Page 10-22. However, port lines P2.0 and P2.1 are not available. Therefore, the P2_OMR bits PS[1:0] and PR[1:0] have no direct effect on port lines but only on register bits P2_OUT.P[1:0].

10.6.3.3 Port 2 Input/Output Control Register 0

Port lines P2.0 and P2.1 are not available. Therefore, the PC0 and PC1 bit fields in register P2_IOCR0 are not connected to any port lines.

P2_IOCR0
Port 2 Input/Output Control Register 0

(10_H) **Reset Value: 2020 2020_H**



Field	Bits	Type	Description
PC0, PC1	[7:4], [15:12]	rw	**Reserved** Read as 0010_B after reset; returns value that was written.
PC2	[23:20]	rw	**Port Control for Port 2.2** (coding see **Table 10-7** on **Page 10-15**)
PC3	[31:28]	rw	**Port Control for Port 2.3** (coding see **Table 10-7** on **Page 10-15**)
0	[3:0], [11:8], [19:16], [27:24]	r	**Reserved** Read as 0; should be written with 0.

10.6.3.4 Port 2 Input Register

The basic P2_IN register functionality is described on **Page 10-25**. However, port lines P2.0 and P2.1 are not available. Therefore, bits P0 and P1 in register P2_IN are always read as 0.

10.6.3.5 Port 2 Pad Driver Mode 0 Register

The basic P2_PDR0 register functionality is described on Page 10-18. However, port lines P2.0 and P2.1 are not available.

P2_PDR0
Port 2 Pad Driver Mode 0 Register (40_H) Reset Value: 0000 0000$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0	PD7			0	PD6			0	PD5			0	PD4		
r	rw			r	rw			r	rw			r	rw		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	PD3			0	PD2			0	PD1			0	PD0		
r	rw			r	rw			r	rw			r	rw		

Field	Bits	Type	Description
PD0	[2:0]	rw	**Reserved** Read as 000_B after reset; returns value that was written.
PD1	[6:4]	rw	**Reserved** Read as 000_B after reset; returns value that was written.
PD2	[10:8]	rw	**Pad Driver Mode for P2.2**
PD3	[14:12]	rw	**Pad Driver Mode for P2.3**
PD4	[18:16]	rw	**Pad Driver Mode for P2.4**
PD5	[22:20]	rw	**Pad Driver Mode for P2.5**
PD6	[26:24]	rw	**Pad Driver Mode for P2.6**
PD7	[30:28]	rw	**Pad Driver Mode for P2.7**
0	3, 7, 11, 15, 19, 23, 27, 31	r	**Reserved** Read as 0; should be written with 0.

10.6.3.6 Port 2 Emergency Stop Register

The basic P2_ESR register functionality is described on Page 10-24. At Port 2, only port lines P2.[15:8] are connected to GPTA I/O lines. Therefore, only these port lines of Port 2

can be controlled for the emergency stop function. The P2_ESR bits EN[7:0] are not implemented. They are always read as 0 and should be written with 0.

10.7 Port 3

This section describes the Port 3 functionality in detail.

10.7.1 Port 3 Configuration

Port 3 is a 16-bit bi-directional general-purpose I/O port that can be used for the GPTA0/GPTA1/LTCA2 I/O lines.

10.7.2 Port 3 Function Table

Table 10-16 summarizes the I/O control selection functions of each Port 3 line.

Table 10-16 Port 3 Functions

Port Pin	I/O	Pin Functionality	Associated Reg./ I/O Line	Port I/O Control Select.	
				Reg./Bit Field	Value
P3.0	I	General-purpose input	P3_IN.P0	P3_IOCR0.PC0	$0XXX_B$

1) The absolute addresses are calculated by adding the offset address to the module base address (see Table 10-4)

10.8 Port 4

This section describes the Port 4 functionality in detail.

10.8.1 Port 4 Configuration

Port 4 is a 16-bit bi-directional general-purpose I/O port that can be used for the GPTA0/GPTA1/LTCA2 I/O lines.

10.8.2 Port 4 Function Table

Table 10-18 summarizes the I/O control selection functions of each Port 4 line.

Table 10-18 Port 4 Functions

Port Pin	I/O	Pin Functionality	Associated Reg./ I/O Line	Port I/O Control Select.	
				Reg./Bit Field	Value
P4.0	I	General-purpose input	P4_IN.P0	P4_IOCR0.PC0	$0XXX_B$
		GPTA0/GPTA1/LTCA2 input	IN24		
		SSC2 input A (Slave Mode)	MRST2A

10.8.3 Port 4 Registers

The following registers are available on Port 4:

Table 10-19 Port 4 Registers

Register Short Name	Register Long Name	Offset[1] Address	Description see
P4_OUT	Port 4 Output Register	0000_H	Page 10-21
P4_OMR	Port 4 Output Modification Register	0004_H	Page 10-22
P4_IOCR0	Port 4 Input/Output Control Register 0	0010_H	Page 10-11
P4_IOCR4	Port 4 Input/Output Control Register 4	0014_H	Page 10-12
P4_IOCR8	Port 4 Input/Output Control Register 8	0018_H	Page 10-13
P4_IOCR12	Port 4 Input/Output Control Register 12	$001C_H$	Page 10-14
P4_IN	Port 4 Input Register	0024_H	Page 10-25
P4_PDR0	Port 4 Pad Driver Mode 0 Register	0040_H	Page 10-18
P4_PDR1	Port 4 Pad Driver Mode 1 Register	0044_H	Page 10-19
P4_ESR	Port 4 Emergency Stop Register	0050_H	Page 10-24

1) The absolute addresses are calculated by adding the offset address to the module base address (see Table 10-4)

10.9 Port 5

Port 5 is an 16-bit GPIO port. Pins associated to it be used in two ways:

- as a CMOS Port where each pin outputs one signal, as any other port (only exception - no open drain mode available), and
- as an output LVDS port where a pin pair (two pins) outputs one differential MSC signal.

The switching between the two modes is done via the PDR registers.

The swithcing between Input/Ouput and Pull-Up/Pull-Down control is done via the IOCR register.

Attention: In the LVDS mode the IOCR.PCx bit field of each pin of the LVDS pair must be programed as output, that is $1xxx_B$.

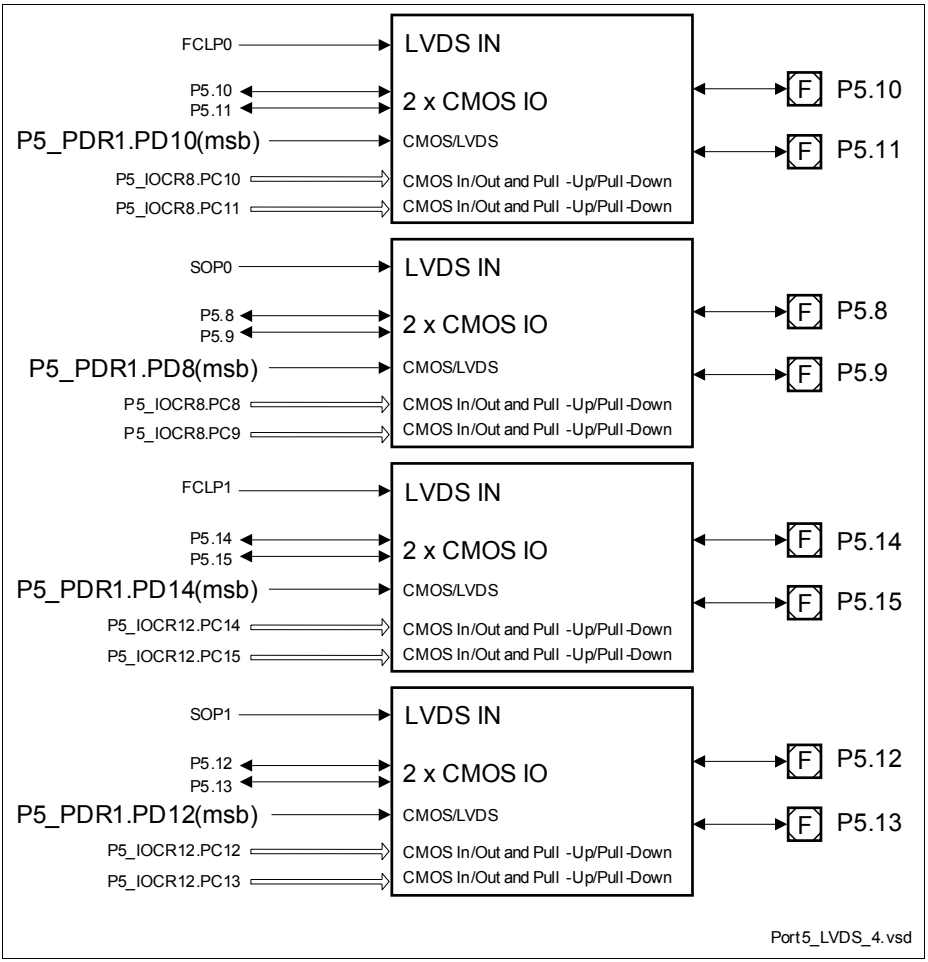

Figure 10-3 Port 5 Pad Connections

10.9.1 Port 5 Configuration

Port 5 is an bi-directional general-purpose I/O port which can be used for the ASC0/ASC1, MSC0/MSC1, or MLI0 interface I/O lines.

10.9.2 Port 5 Function Table

Table 10-20 summarizes the I/O control selection functions of each Port 5 line.

Table 10-20 Port 5 Functions

Port Pin	I/O	Pin Functionality	Associated Reg./ I/O Line	Port I/O Control Select.	
				Reg./Bit Field	Value
P5.0	I	General-purpose input	P5_IN.P0	P5_IOCR0.PC0	$0XXX_B$
		ASC0 input	RXD0A		
		GPT120	T6EUDA

10.9.3 Port 5 Registers

The following registers are available on Port 5:

Table 10-21 Port 5 Registers

Register Short Name	Register Long Name	Offset[1] Address	Description see
P5_OUT	Port 5 Output Register	0000_H	below[2]
P5_OMR	Port 5 Output Modification Register	0004_H	
P5_IOCR0	Port 5 Input/Output Control Register 0	0010_H	Page 10-11
P5_IOCR4	Port 5 Input/Output Control Register 4	0014_H	Page 10-13
P5_IOCR8	Port 5 Input/Output Control Register 8	0018_H	Page 10-13
P5_IOCR12	Port 5 Input/Output Control Register 12	$001C_H$	Page 10-13
P5_IN	Port 5 Input Register	0024_H	below[2]
P5_PDR0	Port 5 Pad Driver Mode 0 Register	0040_H	Page 10-18
P5_PDR1	Port 5 Pad Driver Mode 1 Register	0044_H	Page 10-19
P5_ESR	Port 5 Emergency Stop Register	0050_H	Page 10-24

1) The absolute addresses are calculated by adding the offset address to the module base address (see Table 10-4)

2) These registers are noted here in the Port 5 section because they differ from the general port register description given in Section 10.3.

10.9.3.1 Port 5 Output Register

The basic P5_OUT register functionality is described on Page 10-21.

10.9.3.2 Port 5 Output Modification Register

The basic P5_OMR register functionality is described on Page 10-22.

10.9.3.3 Port 5 Input Register

The basic P5_IN register functionality is described on Page 10-25.

10.9.3.4 Port 5 Emergency Stop Register

The basic P5_ESR register functionality is described on Page 10-24. At Port 5, all port lines P5.[15:0] have GPTA outputs and correspondent ESR lines.

10.10 Port 6

This section describes the Port 6 functionality in detail.

10.10.1 Port 6 Configuration

Port 6 is a 12-bit bi-directional general-purpose I/O port which can be used for the SSC1, ASC0/ASC1, or for the MultiCAN controller I/O lines.

10.10.2 Port 6 Function Table

Table 10-22 summarizes the I/O control selection functions of each Port 6 line.

Table 10-22 Port 6 Functions

Port Pin	I/O	Pin Functionality	Associated Reg./ I/O Line	Port I/O Control Select.	
				Reg./Bit Field	Value
P6.4	I	General-purpose input	P6_IN.P4	P6_IOCR4.PC4	$0XXX_B$
		SSC1 input (slave mode)	MTSR1		
		SSC Guardian 1 Master Receive Input (Master Mode)	MRSTG1		
	O	General-purpose output	P6_OUT.P4		$1X00_B$
		SSC1 output (master mode)	MTSR1		$1X01_B$
		Reserved	–		$1X10_B$

10.10.3 Port 6 Registers

The following registers are available on Port 6:

Table 10-23 Port 6 Registers

Register Short Name	Register Long Name	Offset[1] Address	Description see
P6_OUT	Port 6 Output Register	0000_H	below[2]
P6_OMR	Port 6 Output Modification Register	0004_H	
P6_IOCR4	Port 6 Input/Output Control Register 4	0014_H	Page 10-12
P6_IOCR8	Port 6 Input/Output Control Register 8	0018_H	Page 10-13
P6_IOCR12	Port 6 Input/Output Control Register 12	$001C_H$	Page 10-14
P6_IN	Port 6 Input Register	0024_H	below[2]
P6_PDR0	Port 6 Pad Driver Mode 0 Register	0040_H	Page 10-76
P6_PDR1	Port 6 Pad Driver Mode 1 Register	0044_H	Page 10-19

1) The absolute addresses are calculated by adding the offset address to the module base address (see Table 10-4)

2) These registers are listed and noted here in the Port 6 section because they differ from the general port register description given in Section 10.3.

10.10.3.1 Port 6 Output Register

The basic P6_OUT register functionality is described on Page 10-21. Port lines P6.[3:0] are not connected to port lines. Therefore, reading the P6_OUT bits P[3:0] returns the value that was last written (0 after reset). These bits can be also set/reset by the corresponding P6_OMR bits.

10.10.3.2 Port 6 Output Modification Register

The basic P6_OMR register functionality is described on Page 10-22. Port lines P6.[3:0] are not available. Therefore, they are not implemented. These bits should always be written with 0.

10.10.3.3 Port 6 Input Register

The basic P6_IN register functionality is described on Page 10-25. Port lines P6.[3:0] are not available. Therefore, the P6_IN bits P[3:0] are always read as 0.

10.10.3.4 Port 6 Pad Driver Mode 0 Register

The basic P6_PDR0 register functionality is described on Page 10-18. However, port lines P6.[3:0] are not available.

P6_PDR0
Port 6 Pad Driver Mode 0 Register (40_H) Reset Value: 0000 0000$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0		**PD7**		**0**		**PD6**		**0**		**PD5**		**0**		**PD4**	
r		rw		r		rw		r		rw		r		rw	

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0		**PD3**		**0**		**PD2**		**0**		**PD1**		**0**		**PD0**	
r		rw		r		rw		r		rw		r		rw	

Field	Bits	Type	Description
PD0	[2:0]	rw	**Reserved** Read as 000_B after reset; returns value that was written.
PD1	[6:4]	rw	**Reserved** Read as 000_B after reset; returns value that was written.
PD2	[10:8]	rw	**Reserved** Read as 000_B after reset; returns value that was written.
PD3	[14:12]	rw	**Reserved** Read as 000_B after reset; returns value that was written.
PD4	[18:16]	rw	**Pad Driver Mode for P6.4**
PD5	[22:20]	rw	**Pad Driver Mode for P6.5**
PD6	[26:24]	rw	**Pad Driver Mode for P6.6**
PD7	[30:28]	rw	**Pad Driver Mode for P6.7**
0	3, 7, 11, 15, 19, 23, 27, 31	r	**Reserved** Read as 0; should be written with 0.

10.11 Port 7

This section describes the Port 7 functionality in detail.

10.11.1 Port 7 Configuration

Port 7 is an 8-bit bi-directional general-purpose I/O port that can be used for the external trigger input lines REQ[7:4] or for the ADC0/ADC1 external multiplexer control output lines.

10.11.2 Port 7 Function Table

Table 10-24 summarizes the I/O control selection functions of each Port 7 line.

Table 10-24 Port 7 Functions

Port Pin	I/O	Pin Functionality	Associated Reg./ I/O Line	Port I/O Control Select.	
				Reg./Bit Field	Value

10.11.3 Port 7 Registers

The following registers are available on Port 7:

Table 10-25 Port 7 Registers

Register Short Name	Register Long Name	Offset[1] Address	Description see
P7_OUT	Port 7 Output Register	0000_H	below[2]
P7_OMR	Port 7 Output Modification Register	0004_H	
P7_IOCR0	Port 7 Input/Output Control Register 0	0010_H	Page 10-11
P7_IOCR4	Port 7 Input/Output Control Register 4	0014_H	Page 10-12
P7_IN	Port 7 Input Register	0024_H	below[2]
P7_PDR0	Port 7 Pad Driver Mode 0 Register	0040_H	Page 10-18

1) The absolute addresses are calculated by adding the offset address to the module base address (see Table 10-4)

2) These registers are listed and noted here in the Port 7 section because they differ from the general port register description given in Section 10.3.

10.11.3.1 Port 7 Output Register

The basic P7_OUT register functionality is described on Page 10-21. Port lines P7.[15:8] are not available. Therefore, the P7_OUT bits P[15:8] should be written with 0, and are always read as 0.

10.11.3.2 Port 7 Output Modification Register

The basic P7_OMR register functionality is described on Page 10-22. Port lines P7.[15:8] are not available. Therefore, the P7_OMR bits PS[15:8] and PR[15:8] are not implemented. These bits should always be written with 0.

10.11.3.3 Port 7 Input Register

The basic P7_IN register functionality is described on Page 10-25. Port lines P7.[15:8] are not available. Therefore, the P7_IN bits P[15:8] are always read as 0.

10.12 Port 8

This section describes the Port 8 functionality in detail.

10.12.1 Port 8 Configuration

Port 8 is an 8-bit bi-directional general-purpose I/O port which can be used for the MLI1 interface lines or for the GPTA0/GPTA1 I/O lines.

10.12.2 Port 8 Function Table

Table 10-26 summarizes the I/O control selection functions of each Port 8 line.

Table 10-26 Port 8 Functions

Port Pin	I/O	Pin Functionality	Associated Reg./ I/O Line	Port I/O Control Select.	
				Reg./Bit Field	Value

		CCU61	COUT61		$1X10_B$
		GPT121	T6OUT		$1X11_B$

1) The PCx should not be configured as push-pull. Only open-drain mode is applicable.

10.12.3 Port 8 Register

The following registers are available on Port 8:

Table 10-27 Port 8 Registers

Register Short Name	Register Long Name	Offset[1] Address	Description see
P8_OUT	Port 8 Output Register	0000_H	below[2]
P8_OMR	Port 8 Output Modification Register	0004_H	
P8_IOCR0	Port 8 Input/Output Control Register 0	0010_H	Page 10-11
P8_IOCR4	Port 8 Input/Output Control Register 4	0014_H	Page 10-12
P8_IN	Port 8 Input Register	0024_H	below[2]
P8_PDR0	Port 8 Pad Driver Mode 0 Register	0040_H	Page 10-18
P8_ESR	Port 8 Emergency Stop Register	0050_H	below[2]

1) The absolute addresses are calculated by adding the offset address to the module base address (see Table 10-4)

2) These registers are listed here in the Port 8 section because they differ from the general port register description given in Section 10.3.

10.12.3.1 Port 8 Output Register

The basic P8_OUT register functionality is described on Page 10-21. Port lines P8.[15:8] are not available. Therefore, the P8_OUT bits P[15:8] should be written with 0 and are always read as 0.

10.12.3.2 Port 8 Output Modification Register

The basic P8_OMR register functionality is described on Page 10-22. Port lines P8.[15:8] are not available. Therefore, the P8_OMR bits PS[15:8] and PR[15:8] are not implemented. These bits should always be written with 0.

10.12.3.3 Port 8 Input Register

The basic P8_IN register functionality is described on Page 10-25. Port lines P8.[15:8] are not available. Therefore, the P8_IN bits P[15:8] are always read as 0.

10.12.3.4 Port 8 Emergency Stop Register

The basic P8_ESR register functionality is described on Page 10-24. At Port 8, only port lines P8.[7:0] are implemented. Therefore, the P8_ESR bits EN[15:8] are not implemented. They are always read as 0 and should be written with 0.

10.13 Port 9

This section describes the Port 9 functionality in detail.

10.13.1 Port 9 Configuration

Port 9 is a 15-bit bi-directional general-purpose I/O port which can be used for the MSC0/MSC1 interface output lines or for the GPTA0/GPTA1 I/O lines.

10.13.2 Port 9 Function Table

Table 10-28 summarizes the I/O control selection functions of each Port 9 line.

Table 10-28 Port 9 Functions

Port Pin	I/O	Pin Functionality	Associated Reg./ I/O Line	Port I/O Control Select.	
				Reg./Bit Field	Value
P9.0	I	General-purpose input	P9_IN.P0	P9_IOCR0.PC0	$0XXX_B$
		GPTA0/GPTA1 input	IN48		
	O	General-purpose output	P9_OUT.P0		$1X00_B$

1) The PCx should not be configured as push-pull. Only open-drain mode is applicable.

10.13.3 Port 9 Registers

The following registers are available on Port 9:

Table 10-29 Port 9 Registers

Register Short Name	Register Long Name	Offset[1] Address	Description see
P9_OUT	Port 9 Output Register	0000_H	below[2]
P9_OMR	Port 9 Output Modification Register	0004_H	
P9_IOCR0	Port 9 Input/Output Control Register 0	0010_H	Page 10-11
P9_IOCR4	Port 9 Input/Output Control Register 4	0014_H	Page 10-12
P9_IOCR8	Port 9 Input/Output Control Register 8	0018_H	Page 10-13
P9_IOCR12	Port 9 Input/Output Control Register 12	$001C_H$	Page 10-93[2]
P9_IN	Port 9 Input Register	0024_H	Page 10-93[2]
P9_PDR0	Port 9 Pad Driver Mode 0 Register	0040_H	Page 10-18
P9_PDR1	Port 9 Pad Driver Mode 1 Register	0044_H	Page 10-94
P9_ESR	Port 9 Emergency Stop Register	0050_H	Page 10-95[2]

1) The absolute addresses are calculated by adding the offset address to the module base address (see Table 10-4)

2) These registers are listed and noted here in the Port 9 section because they differ from the general port register description given in Section 10.3.

10.13.3.1 Port 9 Output Register

The basic P9_OUT register functionality is described on Page 10-21. Port line P9.15 is not available. Therefore, the P9_OUT bit 15 should be written with 0 and is always read as 0.

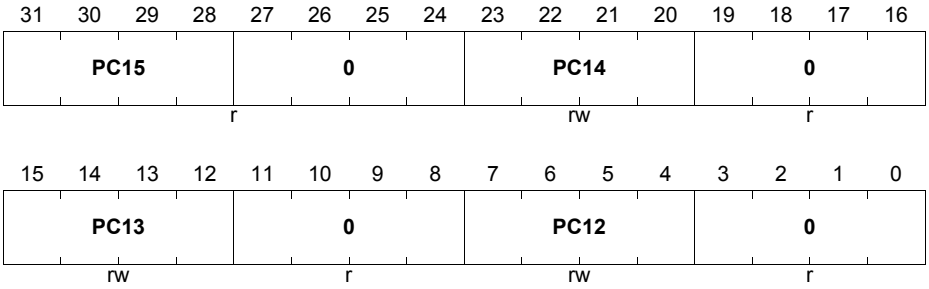
10.13.3.2 Port 9 Output Modification Register

The basic P9_OMR register functionality is described on Page 10-22. Port line P9.15 is not available. Therefore, the P9_OMR bits PS15 and PR15 are not implemented. These bits should always be written with 0.

10.13.3.3 Port 9 Input/Output Control Register 8

P9_IOCR12
Port 9 Input/Output Control Register 12

($1C_H$) **Reset Value: 2020 2020_H**



Field	Bits	Type	Description
PC12	[7:4]	rw	**Port Control for P9.12** This bit field determines the P9.12 functionality.
PC13	[15:12]	rw	**Port Control for P9.13** This bit field determines the P9.13 functionality.
PC14	[23:20]	rw	**Port Control for P9.14** This bit field determines the P9.14 functionality.
PC15	[31:28]	rw	**Reserved** Read as 0010_B after reset; returns value that was written.
0	[3:0], [11:8], [19:16], [27:24]	r	**Reserved** Read as 0; should be written with 0.

10.13.3.4 Port 9 Input Register

The basic P9_IN register functionality is described on **Page 10-25**. Port line P9.15 is not available. Therefore, the P9_IN bit P9.15 is always read as 0.

10.13.3.5 Port 9 Pad Driver Mode 1 Register

The basic P9_PDR1 register functionality is described on Page 10-18. However, port lines P9.15 is not available. Therefore, bit fields PD7 in P9_PDR1 is always read as 0 and should be written with 0.

10.13.3.6 Port 9 Pad Driver Mode 1 Register

The basic P9_PDR1 register functionality is described on Page 10-18. However, port lines P9.15 is not available.

P9_PDR1
Port 9 Pad Driver Mode 1 Register (44_H) Reset Value: 0000 0000_H

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0	PD15			0	PD14			0	PD13			0	PD12		
r	rw			r	rw			r	rw			r	rw		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	PD11			0	PD10			0	PD9			0	PD8		
r	rw			r	rw			r	rw			r	rw		

Field	Bits	Type	Description
PD8	[2:0]	rw	**Pad Driver Mode for P9.8**
PD9	[6:4]	rw	**Pad Driver Mode for P9.9**
PD10	[10:8]	rw	**Pad Driver Mode for P9.10**
PD11	[14:12]	rw	**Pad Driver Mode for P9.11**
PD12	[18:16]	rw	**Pad Driver Mode for P9.12**
PD13	[22:20]	rw	**Pad Driver Mode for P9.13**
PD14	[26:24]	rw	**Pad Driver Mode for P9.14**
PD15	[30:28]	rw	**Reserved** Read as 000_B after reset; returns value that was written.
0	3, 7, 11, 15, 19, 23, 27, 31	r	**Reserved** Read as 0; should be written with 0.

10.13.3.7 Port 9 Emergency Stop Register

The basic P9_ESR register functionality is described on Page 10-24. At Port 9, only port lines P9.[7:0] have GPTA outputs. Therefore, the P9_ESR bits EN[15:8] are not implemented. They are always read as 0 and should be written with 0.

10.14 Port 10

This section describes the Port 10 functionality in detail.

10.14.1 Port 10 Configuration

Port 10 is a 6-bit port.

10.14.2 Port 10 Function Table

Table 10-26 summarizes the I/O control selection functions of each line.

Table 10-30 Port 10 Functions

Port Pin	I/O	Pin Functionality	Associated Reg./I/O Line	Port I/O Control Select.	
				Reg./Bit Field	Value
P10.0	I	General-purpose input	P10_IN.P0	P10_IOCR0 .PC0	$0XXX_B$

		SSC0 Input, slave mode	MTSR0		
		SSC Guardian 0 Master Receive Input (Master Mode)	MRSTG0		
	O	General-purpose output	–		$1X00_B$
		SSC0 Output, master mode	MTSR0		$1X01_B$
		Reserved	–		$1X10_B$
		Reserved[1)]	–		$1X11_B$

Table 10-30 Port 10 Functions (cont'd)

Port Pin	I/O	Pin Functionality	Associated Reg./I/O Line	Port I/O Control Select.	
				Reg./Bit Field	Value
P10.2	I	General-purpose input	P10_IN.P2	P10_IOCR0 .PC2	$0XXX_B$
		SSC0 Input	$\overline{SLSI0}$		
	O	General-purpose output	P10_OUT.P2		$1X00_B$
		Reserved	–		$1X01_B$
		Reserved	–		$1X10_B$
		Reserved	–		$1X11_B$
P10.3	I	General-purpose input	P10_IN.P3	P10_IOCR0 .PC3	$0XXX_B$
		SSC0 Input	SCLK0		
	O	General-purpose output	P10_OUT.P3		$1X00_B$
		SSC0 Output	SCLK0		$1X01_B$
		Reserved	–		$1X10_B$
		Reserved	–		$1X11_B$
P10.4	I	General-purpose input	P10_IN.P4	P10_IOCR4 .PC4	$0XXX_B$
	O	General-purpose output	P10_OUT.P4		$1X00_B$
		SSC0 Output	SLSO0		$1X01_B$
		Reserved	–		$1X10_B$
		Reserved	–		$1X11_B$
P10.5	I	General-purpose input	P10_IN.P5	P10_IOCR4 .PC5	$0XXX_B$
	O	General-purpose output	P10_OUT.P5		$1X00_B$
		SSC0 Output	SLSO1		$1X01_B$
		Reserved	–		$1X10_B$
		Reserved	–		$1X11_B$

1) The port I/O control values P10_IOCRx.Py that are assigned to this reserved alternate output control selection should not be used.

10.14.3 Port 10 Registers

The following registers are available on Port 10:

Table 10-31 Port 10 Registers

Register Short Name	Register Long Name	Offset Address[1)]	Description see
P10_OUT	Port 10 Output Register	0000_H	Page 10-98
P10_OMR	Port 10 Output Modification Register	0004_H	Page 10-98
P10_IOCR0	Port 10 Input/Output Control Register 0	0010_H	Page 10-11
P10_IOCR4	Port 10 Input/Output Control Register 4	0014_H	Page 10-99[2)]
P10_IN	Port 10 Input Register	0024_H	Page 10-99[2)]
P10_PDR0	Port 10 Pad Driver Mode 0 Register	0040_H	Page 10-100

1) The absolute addresses are calculated by adding the offset address to the module base address (see Table 10-4)

2) This register is listed here in the Port 10 section because it differs from the general port register description given in Section 10.3.

Note: Register P10_IN makes it possible to read the actual logic levels of the Port 10 inputs.

10.14.3.1 Port 10 Output Register

The basic P10_OUT register functionality is described on Page 10-21. Port lines P10.[15:6] are not connected to port lines. Therefore, reading the P10_OUT bits P[15:6] returns the value that was last written (0 after reset). These bits can be also set/reset by the corresponding P10_OMR bits.

10.14.3.2 Port 10 Output Modification Register

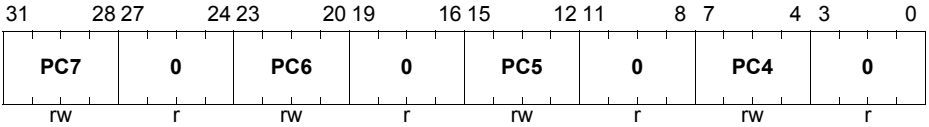
The basic P10_OMR register functionality is described on Page 10-22. However, port lines P10.[15:6] are not available. Therefore, the P10_OMR bits PS[15:6] and PR[15:6] have no direct effect on port lines but only on register bits P10_OUT.P[15:6].

10.14.3.3 Port 10 Input/Output Control Register 4

Port lines P10.[15:6] are not available. Therefore, the PC6 and PC7 bit fields in register P10_IOCR4 are not connected to any port lines.

P10_IOCR4
Port 10 Input/Output Control Register 4

(14_H) **Reset Value: 2020 2020_H**



Field	Bits	Type	Description
PC4	[7:4]	rw	**Port Control for Port 10.4** (coding see **Table 10-7** on **Page 10-15**)
PC5	[15:12]	rw	**Port Control for Port 10.5** (coding see **Table 10-7** on **Page 10-15**)
PC6, PC7	[23:20], [31:28]	rw	**Reserved** Read as 0010_B after reset; returns value that was written.
0	[3:0], [11:8], [19:16], [27:24]	r	**Reserved** Read as 0; should be written with 0.

10.14.3.4 Port 10 Input Register

The basic P10_IN register functionality is described on **Page 10-25**. Port lines P10.[15:6] are not available. Therefore, the P10_IN bits P[15:6] are always read as 0.

10.14.3.5 Port 10 Pad Driver Mode 0 Register

The basic P10_PDR0 register functionality is described on Page 10-18. However, port lines P10.[15:6] are not available.

P10_PDR0
Port 10 Pad Driver Mode 0 Register (40$_H$) **Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r	rw			r	rw			r	rw			r	rw		

Field	Bits	Type	Description
PD0	[2:0]	rw	**Pad Driver Mode for P10.0**
PD1	[6:4]	rw	**Pad Driver Mode for P10.1**
PD2	[10:8]	rw	**Pad Driver Mode for P10.2**
PD3	[14:12]	rw	**Pad Driver Mode for P10.3**
PD4	[18:16]	rw	**Pad Driver Mode for P10.4**
PD5	[22:20]	rw	**Pad Driver Mode for P10.5**
PD6	[26:24]	rw	**Reserved** Read as 000_B after reset; returns value that was written.
PD7	[30:28]	rw	**Reserved** Read as 000_B after reset; returns value that was written.
0	3, 7, 11, 15, 19, 23, 27, 31	r	**Reserved** Read as 0; should be written with 0.

10.15 Port 11

This section describes the Port 11 functionality in detail.

10.15.1 Port 11 Configuration

Port 11 is a general-purpose 16-bit bi-directional port. It serves as GPIO lines without secondary functions.

Table 10-10 summarizes the I/O control selection functions of each Port 11 line.

10.15.2 Port 11 Function Table

Table 10-10 summarizes the I/O control selection functions of each Port 11 line.

Table 10-32 Port 11 Functions

P11_PDR1	Port 11 Pad Driver Mode 1 Register	0044_H	Page 10-19

1) The absolute addresses are calculated by adding the offset address to the module base address (see Table 10-4)

10.16 Port 12

This section describes the Port 12 functionality in detail.

10.16.1 Port 12 Configuration

Port 12 is an 8-bit bi-directional general-purpose I/O port.

10.16.2 Port 12 Function Table

Table 10-26 summarizes the I/O control selection functions of each Port 12 line.

Table 10-34 Port 12 Functions

Port Pin	I/O	Pin Functionality	Associated Reg./I/O Line	Port I/O Control Select.	
				Reg./Bit Field	Value

1) The port I/O control values P12_IOCRx.Py that are assigned to this reserved alternate output control selection should not be used.

10.16.3 Port 12 Registers

The following registers are available on Port 12:

Table 10-35 Port 12 Registers

Register Short Name	Register Long Name	Offset[1] Address	Description see
P12_OUT	Port 12 Output Register	0000_H	below[2]
P12_OMR	Port 12 Output Modification Register	0004_H	
P12_IOCR0	Port 12 Input/Output Control Register 0	0010_H	Page 10-11
P12_IOCR4	Port 12 Input/Output Control Register 4	0014_H	Page 10-12
P12_IN	Port 12 Input Register	0024_H	below[2]
P12_PDR0	Port 12 Pad Driver Mode 0 Register	0040_H	Page 10-18

1) The absolute addresses are calculated by adding the offset address to the module base address (see Table 10-4)

2) These registers are listed here in the Port 12 section because they differ from the general port register description given in Section 10.3.

10.16.3.1 Port 12 Output Register

The basic P12_OUT register functionality is described on Page 10-21. Port lines P12.[15:8] are not available. Therefore, the P12_OUT bits P[15:8] should be written with 0 and are always read as 0.

10.16.3.2 Port 12 Output Modification Register

The basic P12_OMR register functionality is described on Page 10-22. Port lines P12.[15:8] are not available. Therefore, the P12_OMR bits PS[15:8] and PR[15:8] are not implemented. These bits should always be written with 0.

10.16.3.3 Port 12 Input Register

The basic P12_IN register functionality is described on Page 10-25. Port lines P12.[15:8] are not available. Therefore, the P12_IN bits P[15:8] are always read as 0.

10.17 Port 13

This section describes the Port 13 functionality in detail.

10.17.1 Port 13 Configuration

Port 13 is a general-purpose 16-bit bi-directional port. It serves as GPIO lines without secondary functions.

Table 10-10 summarizes the I/O control selection functions of each Port 0 line.

10.17.2 Port 13 Function Table

Table 10-10 summarizes the I/O control selection functions of each Port 13 line.

Table 10-36 Port 13 Functions

Port Pin	I/O	Pin Functionality	Associated Reg./ I/O Line	Port I/O Control Select.

P13_PDR1	Port 13 Pad Driver Mode 1 Register	0044_H	Page 10-19
P13_ESR	Port 13 Emergency Stop Register	0050_H	Page 10-24

1) The absolute addresses are calculated by adding the offset address to the module base address (see Table 10-4)

10.17.3.1 Port 13 Emergency Stop Register

The basic P13_ESR register functionality is described on Page 10-24. At Port 13, all port lines P13.[15:0] have GPTA outputs and correspondent ESR lines.

10.18 Port 14

This section describes the Port 14 functionality in detail.

10.18.1 Port 14 Configuration

Port 14 is a general-purpose 16-bit bi-directional port. It serves as GPIO lines without secondary functions.

Table 10-10 summarizes the I/O control selection functions of each Port 14 line.

10.18.2 Port 14 Function Table

Table 10-10 summarizes the I/O control selection functions of each Port 14 line.

Table 10-38 Port 14 Functions

10.18.3 Port 14 Registers

The following registers are available on Port 14:

Table 10-39 Port 14 Registers

Register Short Name	Register Long Name	Offset[1] Address	Description see
P14_OUT	Port 14 Output Register	0000_H	Page 10-21
P14_OMR	Port 14 Output Modification Register	0004_H	Page 10-22
P14_IOCR0	Port 14 Input/Output Control Register 0	0010_H	Page 10-11
P14_IOCR4	Port 14 Input/Output Control Register 4	0014_H	Page 10-12
P14_IOCR8	Port 14 Input/Output Control Register 8	0018_H	Page 10-13
P14_IOCR12	Port 14 Input/Output Control Register 12	$001C_H$	Page 10-14
P14_IN	Port 14 Input Register	0024_H	Page 10-25
P14_PDR0	Port 14 Pad Driver Mode 0 Register	0040_H	Page 10-18
P14_PDR1	Port 14 Pad Driver Mode 1 Register	0044_H	Page 10-18
P14_ESR	Port 14 Emergency Stop Register	0050_H	Page 10-24

1) The absolute addresses are calculated by adding the offset address to the module base address (see Table 10-4)

10.18.3.1 Port 14 Emergency Stop Register

The basic P14_ESR register functionality is described on Page 10-24. At Port 14, all port lines P14.[15:0] have GPTA outputs and correspondent ESR lines.

10.19 Port 15

This section describes the Port 15 functionality in detail.

10.19.1 Port 15 Configuration

Port 15 is a general-purpose 16-bit bi-directional port. It serves as GPIO lines without secondary functions.

Table 10-10 summarizes the I/O control selection functions of each Port 15 line.

10.19.2 Port 15 Function Table

Table 10-10 summarizes the I/O control selection functions of each Port 0 line.

Table 10-40 Port 15 Functions

P15_PDR1	Port 15 Pad Driver Mode 1 Register	0044_H	Page 10-19

1) The absolute addresses are calculated by adding the offset address to the module base address (see Table 10-4)

10.20 Port 16

This section describes the Port 16 functionality in detail.

10.20.1 Port 16 Configuration

Port 16 is an 13-bit bi-directional general-purpose I/O port which can be used for the EBU I/O lines.

10.20.2 Port 16 Function Table

Table 10-26 summarizes the I/O control selection functions of each Port 16 line.

Table 10-42 Port 16 Functions

Port Pin	I/O	Pin Functionality	Associated Reg./I/O Line	Port I/O Control Select.

10.20.3 Port 16 Registers

The following registers are available on Port 16:

Table 10-43 Port 16 Registers

Register Short Name	Register Long Name	Offset[1] Address	Description see
P16_OUT	Port 16 Output Register	0000_H	below[2]
P16_OMR	Port 16 Output Modification Register	0004_H	below[2]
P16_IOCR0	Port 16 Input/Output Control Register 0	0010_H	Page 10-11
P16_IOCR4	Port 16 Input/Output Control Register 4	0014_H	Page 10-13
P16_IOCR8	Port 16 Input/Output Control Register 8	0018_H	Page 10-13
P16_IOCR12	Port 16 Input/Output Control Register 12	$001C_H$	Page 10-138[2]
P16_IN	Port 16 Input Register	0024_H	below[2]
P16_PDR0	Port 16 Pad Driver Mode 0 Register	0040_H	Page 10-18
P16_PDR1	Port 16 Pad Driver Mode 1 Register	0044_H	Page 10-140[2]

1) The absolute addresses are calculated by adding the offset address to the module base address (see Table 10-4)

2) These registers are listed here in the Port 16 section because they differ from the general port register description given in Section 10.3.

10.20.3.1 Port 16 Output Register

The basic P16_OUT register functionality is described on Page 10-21. Port lines P16.[15:13] are not available. Therefore, the P16_OUT bits P[15:13] should be written with 0 and are always read as 0.

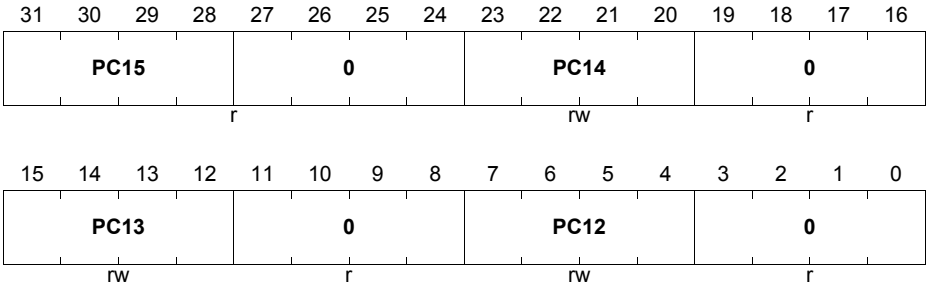
10.20.3.2 Port 16 Output Modification Register

The basic P16_OMR register functionality is described on Page 10-22. Port lines P16.[15:13] are not available. Therefore, the P16_OMR bits PS[15:13] and PR[15:13] are not implemented. These bits should always be written with 0.

10.20.3.3 Port 16 Input/Output Control Register 12

P16_IOCR12
Port 16 Input/Output Control Register 12

($1C_H$) **Reset Value: 2020 2020_H**



Field	Bits	Type	Description
PC12	[7:4]	rw	**Port Control for P16.12** This bit field determines the P16.12 functionality.
PC13	[15:12]	rw	**Reserved** Read as 0010_B after reset; returns value that was written.
PC14	[23:20]	rw	**Reserved** Read as 0010_B after reset; returns value that was written.
PC15	[31:28]	rw	**Reserved** Read as 0010_B after reset; returns value that was written.
0	[3:0], [11:8], [19:16], [27:24]	r	**Reserved** Read as 0; should be written with 0.

10.20.3.4 Port 16 Input Register

The basic P16_IN register functionality is described on **Page 10-25**. Port lines P16.[15:13] are not available. Therefore, the P16_IN bits P16.[15:13] are always read as 0.

10.20.3.5 Port 16 Emergency Stop Register

The P16_ESR register is not implemented. Nevertheless, access to its address 0xF0300450 does not generate a Bus Error.

10.20.3.6 Port 16 Pad Driver Mode 1 Register

The basic P16_PDR1 register functionality is described on Page 10-18. However, port lines P16[15:13] are not available.

P16_PDR1

10.21 Port 17

This section describes the Port 17 functionality in detail.

10.21.1 Port 17 Configuration

Port 17 is a 16-bit input port.

Table 10-44 summarizes the input control selection functions of each Port 17 line.

10.21.2 Port 17 Function Table

Table 10-44 summarizes the input control selection functions of each Port 17 line.

Table 10-44 Port 17 Functions

Port Pin	I/O	Pin Functionality	Associated Reg./ Input Line	Port Functionality Control Select	
				Reg./Bit Field	Value
P17.0	I	ADC Analog Input	AN8	P17_PDISC.PDIS0	1_B
		SENT Digital Input	SENT0		0_B
P17.1	I	ADC Analog Input	AN9	P17_PDISC.PDIS1	1_B
		SENT Digital Input	SENT1		0_B
P17.2	I	ADC Analog Input	AN10	P17_PDISC.PDIS2	1_B
		SENT Digital Input	SENT2		0_B
P17.3	I	ADC Analog Input	AN11	P17_PDISC.PDIS3	1_B
		SENT Digital Input	SENT3		0_B
P17.4	I	ADC Analog Input	AN12	P17_PDISC.PDIS4	1_B
		SENT Digital Input	SENT4		0_B
P17.5	I	ADC Analog Input	AN13	P17_PDISC.PDIS5	1_B
		SENT Digital Input	SENT5		0_B
P17.6	I	ADC Analog Input	AN14	P17_PDISC.PDIS6	1_B
		SENT Digital Input	SENT6		0_B
P17.7	I	ADC Analog Input	AN15	P17_PDISC.PDIS7	1_B
		SENT Digital Input	SENT7		0_B
P17.8	I	ADC Analog Input	AN36	P17_PDISC.PDIS8	1_B
		SENT Digital Input	SENT0		0_B
P17.9	I	ADC Analog Input	AN37	P17_PDISC.PDIS9	1_B
		SENT Digital Input	SENT1		0_B
P17.10	I	ADC Analog Input	AN38	P17_PDISC.PDIS10	1_B
		SENT Digital Input	SENT2		0_B
P17.11	I	ADC Analog Input	AN39	P17_PDISC.PDIS11	1_B
		SENT Digital Input	SENT3		0_B
P17.12	I	ADC Analog Input	AN40	P17_PDISC.PDIS12	1_B
		SENT Digital Input	SENT4		0_B

Table 10-44 Port 17 Functions (cont'd)

Port Pin	I/O	Pin Functionality	Associated Reg./ Input Line	Port Functionality Control Select	
				Reg./Bit Field	Value
P17.13	I	ADC Analog Input	AN41	P17_PDISC.PDIS13	1_B
		SENT Digital Input	SENT5		0_B

10.21.3 Port 17 Registers

The following registers are available on Port 17:

Table 10-45 Port 17 Registers

Register Short Name	Register Long Name	Offset[1] Address	Description see
P17_IOCR0	Port 17 Input/Output Control Register 0	0010_H	Page 10-145[2]
P17_IOCR4	Port 17 Input/Output Control Register 4	0014_H	Page 10-145[2]
P17_IOCR8	Port 17 Input/Output Control Register 8	0018_H	Page 10-145[2]
P17_IOCR12	Port 17 Input/Output Control Register 12	$001C_H$	Page 10-145[2]
P17_IN	Port 17 Input Register	0024_H	Page 10-25
P17_PDISC	Port 17 Pin Function Decision Control Register	0060_H	Page 10-148[2]

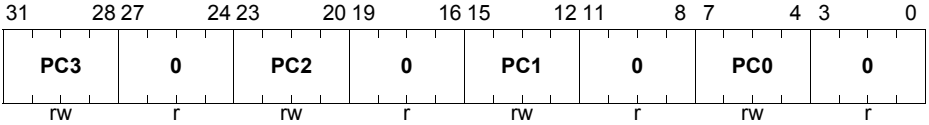
1) The absolute addresses are calculated by adding the offset address to the module base address (see Table 10-4)

2) These registers are listed here in the Port 17 section because they differ from the general port register description given in Section 10.3.

10.21.4 Port 17 Input/Output Control Registers

P17_IOCR0
Port 17 Input/Output Control Register 0

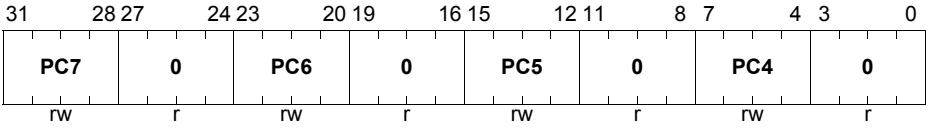
(10_H) **Reset Value: 2020 2020_H**



Field	Bits	Type	Description
PC0, PC1, PC2, PC3	[7:4], [15:12], [23:20], [31:28]	rw	**Port Control for Port n Pin x** This bit field defines the Port n line x functionality according to **Table 10-46**.
0	[3:0], [11:8], [19:16], [27:24]	r	**Reserved** Read as 0; should be written with 0.

P17_IOCR4
Port 17 Input/Output Control Register 4

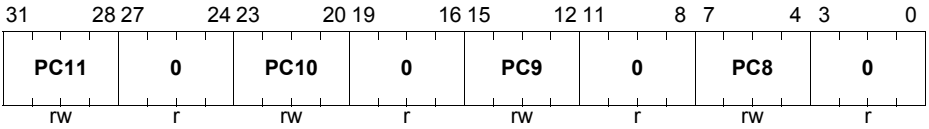
(14_H) **Reset Value: 2020 2020_H**



Field	Bits	Type	Description
PC4, PC5, PC6, PC7	[7:4], [15:12], [23:20], [31:28]	rw	**Port Control for Port n Pin x** This bit field defines the Port n line x functionality according to **Table 10-46**.
0	[3:0], [11:8], [19:16], [27:24]	r	**Reserved** Read as 0; should be written with 0.

P17_IOCR8
Port 17 Input/Output Control Register 8

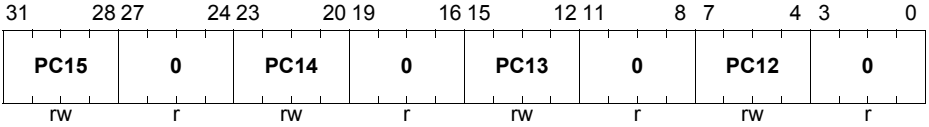
(18_H) **Reset Value: 2020 2020_H**



Field	Bits	Type	Description
PC8, PC9, PC10, PC11	[7:4], [15:12], [23:20], [31:28]	rw	**Port Control for Port n Pin x** This bit field defines the Port n line x functionality according to **Table 10-46**.
0	[3:0], [11:8], [19:16], [27:24]	r	**Reserved** Read as 0; should be written with 0.

P17_IOCR12
Port 17 Input/Output Control Register 12

($1C_H$) **Reset Value: 2020 2020_H**



Field	Bits	Type	Description
PC12, PC13, PC14, PC15	[7:4], [15:12], [23:20], [31:28]	rw	**Port Control for Port n Pin x** This bit field defines the Port n line x functionality according to **Table 10-46**.
0	[3:0], [11:8], [19:16], [27:24]	r	**Reserved** Read as 0; should be written with 0.

Table 10-46 PCx Coding for Port 17

PCx[3:0]	I/O	Output Characteristics	Selected Pull-up / Pull-down / Selected Output Function
$0X00_B$	Input	–	No input pull device connected
$0X01_B$			Input pull-down device connected
$0X10_B$			Input pull-up device connected[1)]
$0X11_B$			No input pull device connected

1) This is the default pull-up state after reset.

10.21.5 Port 17 Pin Function Decision Control Register

P17_PDISC

Port 17 Pin Function Decision Control Register(60_H) **Reset Value: FFFF FFFF$_H$**

Field	Bits	Type	Description
PDIS0	0	rw	**Pad Disable for Port 17 Pin 0** This bit disables or enables the pad. The disabled (default) state of the pad selects the ADC analog input. Upon enabling, the functionality switches to the SENT digital input. 0_B Pad is enabled, SENT digital input 0. 1_B Pad is disabled, ADC analog input 8.
PDIS1	1	rw	**Pad Disable for Port 17 Pin 1** This bit disables or enables the pad. The disabled (default) state of the pad selects the ADC analog input. Upon enabling, the functionality switches to the SENT digital input. 0_B Pad is enabled, SENT digital input 1. 1_B Pad is disabled, ADC analog input 9.
PDIS2	2	rw	**Pad Disable for Port 17 Pin 2** This bit disables or enables the pad. The disabled (default) state of the pad selects the ADC analog input. Upon enabling, the functionality switches to the SENT digital input. 0_B Pad is enabled, SENT digital input 2. 1_B Pad is disabled, ADC analog input 10.

Field	Bits	Type	Description
PDIS3	3	rw	**Pad Disable for Port 17 Pin 3** This bit disables or enables the pad. The disabled (default) state of the pad selects the ADC analog input. Upon enabling, the functionality switches to the SENT digital input. 0_B Pad is enabled, SENT digital input 3. 1_B Pad is disabled, ADC analog input 11.
PDIS4	4	rw	**Pad Disable for Port 17 Pin 4** This bit disables or enables the pad. The disabled (default) state of the pad selects the ADC analog input. Upon enabling, the functionality switches to the SENT digital input. 0_B Pad is enabled, SENT digital input 4. 1_B Pad is disabled, ADC analog input 12.
PDIS5	5	rw	**Pad Disable for Port 17 Pin 5** This bit disables or enables the pad. The disabled (default) state of the pad selects the ADC analog input. Upon enabling, the functionality switches to the SENT digital input. 0_B Pad is enabled, SENT digital input 5. 1_B Pad is disabled, ADC analog input 13.
PDIS6	6	rw	**Pad Disable for Port 17 Pin 6** This bit disables or enables the pad. The disabled (default) state of the pad selects the ADC analog input. Upon enabling, the functionality switches to the SENT digital input. 0_B Pad is enabled, SENT digital input 6. 1_B Pad is disabled, ADC analog input 14.
PDIS7	7	rw	**Pad Disable for Port 17 Pin 7** This bit disables or enables the pad. The disabled (default) state of the pad selects the ADC analog input. Upon enabling, the functionality switches to the SENT digital input. 0_B Pad is enabled, SENT digital input 7. 1_B Pad is disabled, ADC analog input 15.

Field	Bits	Type	Description
PDIS8	8	rw	**Pad Disable for Port 17 Pin 8** This bit disables or enables the pad. The disabled (default) state of the pad selects the ADC analog input. Upon enabling, the functionality switches to the SENT digital input. 0_B Pad is enabled, SENT digital input 0. 1_B Pad is disabled, ADC analog input 36.
PDIS9	9	rw	**Pad Disable for Port 17 Pin 9** This bit disables or enables the pad. The disabled (default) state of the pad selects the ADC analog input. Upon enabling, the functionality switches to the SENT digital input. 0_B Pad is enabled, SENT digital input 1. 1_B Pad is disabled, ADC analog input 37.
PDIS10	10	rw	**Pad Disable for Port 17 Pin 10** This bit disables or enables the pad. The disabled (default) state of the pad selects the ADC analog input. Upon enabling, the functionality switches to the SENT digital input. 0_B Pad is enabled, SENT digital input 2. 1_B Pad is disabled, ADC analog input 38.
PDIS11	11	rw	**Pad Disable for Port 17 Pin 11** This bit disables or enables the pad. The disabled (default) state of the pad selects the ADC analog input. Upon enabling, the functionality switches to the SENT digital input. 0_B Pad is enabled, SENT digital input 3. 1_B Pad is disabled, ADC analog input 39.
PDIS12	12	rw	**Pad Disable for Port 17 Pin 12** This bit disables or enables the pad. The disabled (default) state of the pad selects the ADC analog input. Upon enabling, the functionality switches to the SENT digital input. 0_B Pad is enabled, SENT digital input 4. 1_B Pad is disabled, ADC analog input 40.

Field	Bits	Type	Description
PDIS13	13	rw	**Pad Disable for Port 17 Pin 13** This bit disables or enables the pad. The disabled (default) state of the pad selects the ADC analog input. Upon enabling, the functionality switches to the SENT digital input. 0_B Pad is enabled, SENT digital input 5. 1_B Pad is disabled, ADC analog input 41.
PDIS14	14	rw	**Pad Disable for Port 17 Pin 14** This bit disables or enables the pad. The disabled (default) state of the pad selects the ADC analog input. Upon enabling, the functionality switches to the SENT digital input. 0_B Pad is enabled, SENT digital input 6. 1_B Pad is disabled, ADC analog input 42.
PDIS15	15	rw	**Pad Disable for Port 17 Pin 15** This bit disables or enables the pad. The disabled (default) state of the pad selects the ADC analog input. Upon enabling, the functionality switches to the SENT digital input. 0_B Pad is enabled, SENT digital input 7. 1_B Pad is disabled, ADC analog input 43.
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

10.22 Port 18

This section describes the Port 18 functionality in detail.

10.22.1 Port 18 Configuration

Port 18 is a general-purpose 8-bit bi-directional port.

Table 10-47 summarizes the I/O control selection functions of each Port 18 line.

10.22.2 Port 18 Function Table

Table 10-47 summarizes the I/O control selection functions of each Port 18 line.

Table 10-47 Port 18 Functions

Port Pin	I/O	Pin Functionality	Associated Reg./ I/O Line	Port I/O Control Select.	
				Reg./Bit Field	Value

10.22.3 Port 18 Registers

The following registers are available on Port 18 :

Table 10-48 Port 18 Registers

Register Short Name	Register Long Name	Offset[1] Address	Description see
P18_OUT	Port 0 Output Register	0000_H	Page 10-155[2]
P18_OMR	Port 0 Output Modification Register	0004_H	Page 10-155[2]
P18_IOCR0	Port 0 Input/Output Control Register 0	0010_H	Page 10-11
P18_IOCR4	Port 0 Input/Output Control Register 4	0014_H	Page 10-12
P18_IN	Port 0 Input Register	0024_H	Page 10-155[2]
P18_PDR0	Port 0 Pad Driver Mode 0 Register	0040_H	Page 10-18

1) The absolute addresses are calculated by adding the offset address to the module base address (see Table 10-4)

2) These registers are listed here in the Port 18 section because they differ from the general port register description given in Section 10.3.

10.22.3.1 Port 18 Output Register

The basic P18_OUT register functionality is described on Page 10-21. Port lines P18.[15:8] are not available. Therefore, the P18_OUT bits P[15:8] should be written with 0 and are always read as 0.

10.22.3.2 Port 18 Output Modification Register

The basic P18_OMR register functionality is described on Page 10-22. Port lines P18.[15:8] are not available. Therefore, the P18_OMR bits PS[15:8] and PR[15:8] are not implemented. These bits should always be written with 0.

10.22.3.3 Port 18 Input Register

The basic P18_IN register functionality is described on Page 10-25. Port lines P18.[15:8] are not available. Therefore, the P18_IN bits P18.[15:8] are always read as 0.

10.22.3.4 Port 18 Emergency Stop Register

The P18_ESR register is not implemented. Nevertheless, access to its address 0xF0300650 does not generate a Bus Error.

11 Peripheral Control Processor (PCP)

This chapter describes the Peripheral Control Processor (PCP), its architecture, programming model, registers, and instructions. The TC1798's PCP is an enhanced version of the TC1767's and TC1797's PCP peripheral control processor, which is an enhanced version of the TC1766's and TC1796's PCP, which is, in turn, an enhanced version of TC1775's PCP.

Section 11.2 of this chapter describes the TC1798's PCP in general. TC1798 implementation-specific details are described in **Section 11.22**.

11.1 PCP Feature/Enhancement History List

The following table lists all PCP enhancements sequentially, for all versions of the PCP. The table will therefore list enhancements that may not apply to the PCP version included in TC1798.

Table 11-1 PCP Feature/Enhancement History List

Version	Enhancement
TC1775	First released version of PCP
TC1766, TC1796	• Optimised Context switching • Support for nested interrupts • Enhanced instruction set • Enhanced instruction execution speed • Enhanced interrupt queueing
TC1767, TC1797	• Enhanced PCP core to support higher clock frequencies • Multiple clock ratios PCP:FPI 1:1 and 2:1 • Adaption of PCP Trace Interface to PAL-MCDS • Implementation of Parity
TC1387, TC1784, TC1798, TC172x Only enhancements in this row and above are included in TC1798	• Support for High Integrity Operation (see **Chapter 11.2.1**). – Programmable ENDINIT write protection for all Registers. – Programmable write protection for CMEM. – Programmable write protection for PRAM. – Programmable limit of FPI addresses than can be written by the PCP. • Implementation of ECC (replacing Parity) • Various Errata fixes.

11.1.1 Switchable Core Clock Ratio

For shorter interrupt latency, shorter uninterruptible task time and increased computing power the PCP is improved to allow operation with a core clock that is faster than the FPI clock (of the FPI Bus to which the PCP is connected). The available clocking ratios (f_{FPI}/f_{PCP}) are 1:1 and 1:2. The clock is controlled and generated in the SCU. The PCP has separate clock inputs for the core and for the FPI-bus related circuits.

11.2 Peripheral Control Processor Overview

The PCP in the TC1798 performs tasks that would normally be performed by the combination of a DMA controller and its supporting CPU interrupt service routines in a traditional computer system. It could easily be considered as the host processor's first line of defence as an interrupt-handling engine. The PCP can unload the CPU from having to service time-critical interrupts. This provides many benefits, including:

- Avoiding large interrupt-driven task context-switching latencies in the host processor
- Reducing the cost of interrupts in terms of processor register and memory overhead
- Improving the responsiveness of interrupt service routines to data-capture and data-transfer operations
- Easing the implementation of multitasking operating systems.

The PCP has an architecture that efficiently supports DMA-type transactions to and from arbitrary devices and memory addresses within the TC1798 and also has reasonable stand-alone computational capabilities.

11.2.1 High Integrity Operation

The PCP can be used in High Integrity Systems to perform various system critical tasks. It follows that, when using the PCP for this function, a fundamental requirement is that the operation of the software running on the PCP must be robust against interference by an external agent (e.g. TriCore). Otherwise a system failure outside PCP could impact the operation of the PCP which might, in turn, cause the system critical task (running on the PCP) to fail.

This concept of immunity is further extended such the PCP can be configured to operate with a number of "Protected" channel programs. These channels are protected not only against failure of external agents but also against software failures in other "Unprotected" channel programs running on the PCP itself.

For High Integrity Systems it is also necessary to prevent the PCP from generating unwanted FPI writes to critical locations in the event of a PCP software malfunction. For this reason a programmable Memory Protection feature is provided to control (in hardware) the address range that can be written to by the PCP.

11.3 PCP Architecture

The PCP is made up of several modular blocks as follows. Please refer to **Figure 11-1**.

- PCP Processor Core
- Code Memory (CMEM)
- Parameter Memory (PRAM)
- PCP Interrupt Control Unit (PICU)
- PCP Service Request Nodes (PSRN)
- System bus interface to the Flexible Peripheral Interface (FPI Bus)

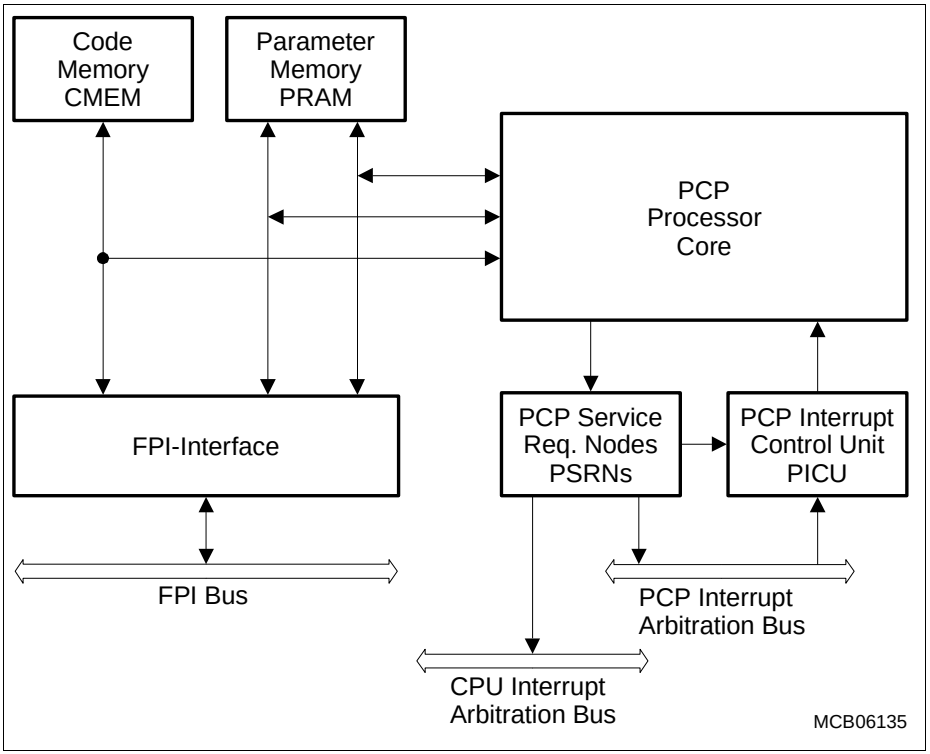

Figure 11-1 PCP Block Diagram

11.3.1 PCP Processor

The PCP Processor is the main engine of the PCP. It contains an instruction pipeline, a set of GPRs, an arithmetic/logic unit (ALU), as well as control and status registers and logic. Its instruction set is optimized especially for the tasks it has to perform. **Table 11-2** provides an overview of the PCP instruction set.

The PCP Processor Core receives service requests from peripherals or other modules in the system via its PCP Interrupt Control Unit (PICU) and executes a channel program (see **Page 11-8**) selected via the priority number of each service request. It first restores the channel program's context from the PRAM and then starts to execute the channel program's instructions stored in the Code Memory (CMEM). Upon an exit condition, it terminates the channel program and saves its context into PRAM. It is then ready to receive the next service request.

The PCP Processor Core is capable of suspending execution of a Channel Program on receipt of a service request with a higher priority than the channel currently being executed. The Core will automatically resume processing of the original Channel Program once the higher-priority request (or requests) has been processed. A channel that has been suspended in this way is termed as "Suspended Channel".

The PCP is fully interrupt-driven, meaning it is only activated through service requests; there is no main program running in the background as with a conventional processor.

Table 11-2 PCP Instruction Set Overview

Instruction Group	Description
DMA Primitives	Efficient DMA channel implementation
Load/Store	Transfer data between PRAM or FPI memory and the GPRs, as well as move or exchange values between registers
Arithmetic	Add, subtract, compare and complement
Divide/Multiply	Divide and multiply
Logical	And, Or, Exclusive Or, Negate
Shift	Shift right or left, rotate right or left, prioritize
Bit Manipulation	Set, clear, insert, and test bits
Flow Control	Jump conditionally, jump long, exit
Miscellaneous	No operation, Debug

11.3.2 PCP Code Memory

The Code Memory (CMEM) of the PCP holds the channel programs, consisting of PCP instructions. All instructions of the PCP are 16 bits long; thus, the PCP accesses its CMEM in 16-bit (half-word) quantities. With the 16-bit Program Counter (PC) of the PCP, a maximum of 64 K instructions can be addressed. This results in a maximum size of the PCP code memory of 128 Kbytes. The actual type (Flash, ROM, SRAM, etc.) and size of the code memory is implementation-specific; see **Page 11-157** for the implemented type and size of the code memory in the TC1798.

The PCP CMEM is viewed from the FPI Bus as a 32-bit wide memory, that must be accessed with 32-bit (word) accesses, and is addressed with byte addresses. Thus, care has to be taken when calculating PCP instruction FPI addresses. See **Page 11-57** for details.

Note: The PCP has a "Harvard" architecture and therefore cannot directly access the CMEM other than reading instructions from it. It is recommended that the PCP should not access CMEM via the FPI Bus.

11.3.2.1 CMEM Protection

To allow the PCP to handle system critical tasks it is necessary to ensure that the PCP can operate properly regardless of a failure in another part of the system or the PCP itself. This means that it is necessary to protect the content of the CMEM from such failures.

CMEM content can only be modified via the FPI. Protection of CMEM therefore consists of prevention of unwanted FPI writes to CMEM.

The normal model of PCP operation is that the program code (i.e. CMEM) is loaded at system initialization and remains unchanged for the duration of operation of the system. Thus a simple locking scheme is provided to prevent any write to CMEM once the content has been loaded during initialization. When CMEM has been loaded (at system initialization) the memory can be locked such that all incoming FPI write accesses are issued with an error response and the CMEM content will remain unmodified.

Regardless of protection the entire CMEM remains readable via FPI.

This function is controlled by the **PCP_CPROT** register (see **Page 11-86**).

11.3.3 PCP Parameter RAM

The PCP Parameter RAM (PRAM) is the local holding place for each channel program's context, and for general data storage. It is also an area that the PCP and the host processor or other FPI Bus masters can use to communicate and share data.

While a portion of the PRAM is always implicitly used for the Context Save Areas (CSAs) of the channel programs (see **Chapter 11.4.2.2**), the remaining area can be used for channel-specific or general data storage. A programmable 8-bit Data Pointer (DPTR),

concatenated with a 6-bit offset, is provided for arbitrary access to the PRAM. The effective address is a 14-bit word address, allowing a PRAM size of up to 64 Kbytes. The actual type (SRAM, DRAM, etc.) and size of the parameter RAM is implementation-specific; see **Page 11-157** for the implemented size of the PRAM in this derivative.

Both the PCP and FPI Bus masters address the PRAM as 32-bit words. There is no concept of half-word or byte accesses to PRAM. FPI Bus masters must, however, use byte addresses in order to access the PRAM. As for the CMEM, care has to be taken when calculating PRAM FPI addresses. See **Page 11-57** for details.

11.3.3.1 PRAM Protection

To allow the PCP to handle system critical tasks it is necessary to ensure that the PCP can operate properly regardless of a failure in another part of the system or the PCP itself. This means that it is necessary to protect all or part of the content of the PRAM from such failures.

All or part of PRAM can be protected from FPI writes using the **PCP_PPROT** register (see **Page 11-87**). This register also allows a region of PRAM to be selected which can only be used by Protected PCP channel programs.

11.3.4 FPI Bus Interface

The PCP can access all peripheral units on the FPI Bus and other resources through the FPI Bus interface. The PCP can become an FPI Bus slave, so that other FPI Bus master may access CMEM and PRAM and the control and status registers in the PCP.

The CMEM and PRAM blocks are visible to FPI Bus masters as a block of memory on the FPI Bus. If an FPI Bus master accesses CMEM or PRAM memory concurrently with the PCP, the external FPI Bus master is given precedence over the PCP to avoid deadlocks. The PCP access is stalled for several cycles until the FPI Bus master has completed its access. If an FPI Bus master performs an atomic read-modify-write access to a PCP memory block, any concurrent PCP access to that block is stalled for the duration of the atomic operation.

11.3.5 PCP Interrupt Control Unit and Service Request Nodes

The PCP is activated in response to an interrupt request programmed for PCP service in one of the Service Request Nodes (SRNs) of the system (nodes associated with a peripheral, the CPU, external interrupts, etc.). The PCP Interrupt Control Unit (PICU) determines the request with the currently highest priority and routes the request together with its priority number to the PCP Processor Core. It also acknowledges the requesting source when the PCP starts the service of this interrupt.

The PCP itself can generate service requests to either the CPU or itself through a number of PCP Service Request Nodes (PSRNs). The PSRNs are also used to store all information required by the PCP Processor Core to allow the later restart of a channel

program when it is suspended in favor of a higher-priority Service Request. Please refer to **Section 11.6.3** for more detailed information on the operation of these nodes.

11.4 PCP Programming Model

The PCP programming model can be viewed as a set of autonomous programs, or tasks, called channel programs, that share the processing resources of the PCP. Channel programs may be short and simple, or very complex; but they can coexist persistently within the PCP.

From the programming point of view, the individual parts of a channel program are its instruction sequence in the CMEM and its context in the PRAM. It uses the instruction set and the GPRs (R0 - R7) of the PCP Processor Core to perform the necessary operations, and to communicate with the various resources of the on-chip and off-chip system depending on its task in the application.

These parts of the programming model are discussed in the following sections (with the obvious exception of the system environment outside of the scope of the PCP).

11.4.1 General Purpose Register Set of the PCP

The program-accessible register file of the PCP is composed of eight 32-bit General Purpose Registers (GPRs). These registers are all accessible by PCP programs directly as part of the PCP instruction set. Source and destination registers must be specified in most instructions. These registers are referenced to in this document as Rn or R[n], where n is in the range 0 to 7.

Table 11-3 Directly Accessible Registers

Register	Implicit Use	Description
R0	Accumulator	Implicit target for some arithmetic and logical instructions
R1	–	32-bit general-use register
R2	Return Address	32-bit general-use register
R3	–	32-bit general-use register
R4	SRC (Source)	Source Pointer for BCOPY/COPY instructions
R5	DST (Destination)	Destination Pointer for BCOPY/COPY instruction
R6	CPPN/SRPN/ TOS/CNT1	CNT1: Transfer Count for COPY TOS: Type-of-Service SRPN: 8-bit field used for posting interrupt on EXIT instruction CPPN: Current PCP Priority Number
R7	DPTR/Flags	PRAM Data Pointer (DPTR) and Status Flags

R7 is the only one of the eight registers that may not be used as a full GPR. The most significant 16 bits of R7 may not be written, and will always read back as 0. However, no error will occur when writing to the most significant 16 bits.

Note: The GPRs of the PCP are not memory-mapped into the overall address space. They can only be directly accessed through PCP instructions. The contents of all or some of the registers are part of a channel program's context stored in the PRAM between executions of the channel program. This context is then accessible from outside the PCP.

11.4.1.1 Register R0

R0 is used as an implicit operand destination for some instructions. These are detailed in the individual instruction descriptions.

11.4.1.2 Registers R1, R2, and R3

R1, R2, and R3 are general-use registers. It is recommended that, by convention, R2 should be used as a return address register when call and return program structures are used.

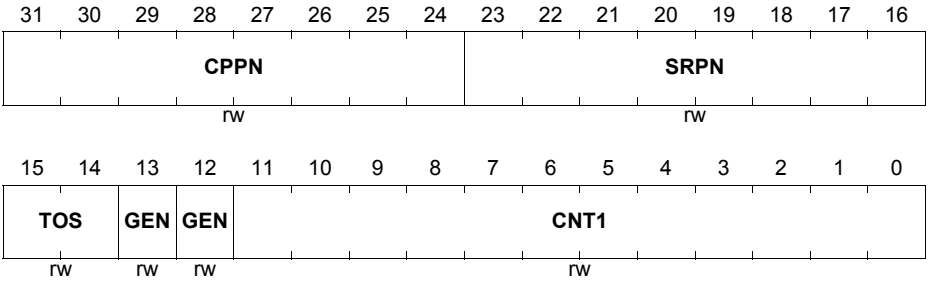
11.4.1.3 Registers R4 and R5

Registers R4 and R5 are also general-use registers. However, the BCOPY/COPY instructions implicitly use R4 and R5 as full 32-bit address pointers (R4 is used as the source address and R5 as the destination address). As the BCOPY/COPY instructions use these registers to maintain the address pointers, either or both R4 and R5 values may or may not be modified by the BCOPY/COPY instructions, depending on the options used in the instructions.

11.4.1.4 Register R6

Register R6 may also be used as a general-use register. Again however, there are some instructions that use fields within R6. If the COPY or EXIT instructions are used, then the field R6.CNT1 can optionally be used implicitly as a counter. If an EXIT instruction is used that causes an interrupt, R6.SRPN and R6.TOS must be configured properly prior to execution of the EXIT. If interrupt priority management is used, then R6.CPPN must be set to the priority level at which the channel shall run at its next invocation, before the EXIT is executed. The fields for R6 are shown below.

PCP Register R6 **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
CPPN	[31:24]	rw	**General-use/PCP Priority Number Posted to PICU**
SRPN	[23:16]	rw	**General-use/Service Request Priority Number for EXIT Interrupt**
TOS	[15:14]	rw	**General-use/Type-of-Service for EXIT Interrupt** Upper bit of TOS is always forced to 0 when transferred into the PCP SRNs, regardless of the value specified in R6[15].
GEN	13	rw	**General-use**
GEN	12	rw	**General-use**
CNT1	[11:0]	rw	**General-use/Outer Loop count for COPY Instruction or EXIT Instruction**

11.4.1.5 Register R7

Register R7 is an exception with respect to the other registers in that not all bits within the register can be written, and the implicit use of the remaining bits virtually excludes the use of R7 as a GPR. R7 serves similar purposes as those in the Program Status Word found in traditional processors.

R7 holds the flag bits, a channel enable/disable control bit, and the PRAM Data Pointer (DPTR). The upper 16 bits of R7 are reserved.

Most instructions of the PCP update the flags (CN1Z, V, C, N, Z) in R7 according to the result of their operation. See **Table 11-15** on **Page 11-134** for details on the flag updates of the individual instructions. The values of the flag bits in R7 maintain their state until another instruction that updates their state is executed.

Note: Implicit updates to the flags caused by instruction take precedence over any bits that are explicitly moved to R7. For example, if a MOV instruction is used to place $0000FF07_H$ in R7, then the bit positions for the C (carry), Z (zero) and N (negative) flags are being written with 1. The MOV instruction, however, implicitly updates the Z and N flag bits in R7 as a result of its operation. Because the number is not negative, and not zero, it will update the Z and N flags to 0. As a result, the value left in R7 after the MOV is complete will be $0000FF04_H$ (i.e C = 1, Z = 0, N = 0). It is recommended that only SET and CLR instructions should be used to explicitly modify flags in R7.

The Data Pointer, R7.DPTR, is the means of accessing PRAM variables programmatically. It points to a 64-word PRAM segment that may be addressed by instructions that can use the PRAM for source or destination operands (xx.P and xx.PI instructions). The 8 bits of the DPTR are concatenated with a 6-bit offset value (either specified in the instruction as an immediate value or contained in one of the registers) to give a 14-bit (word) address. A program is able to update the DPTR value dynamically, in order to index more than 64 words of PRAM.

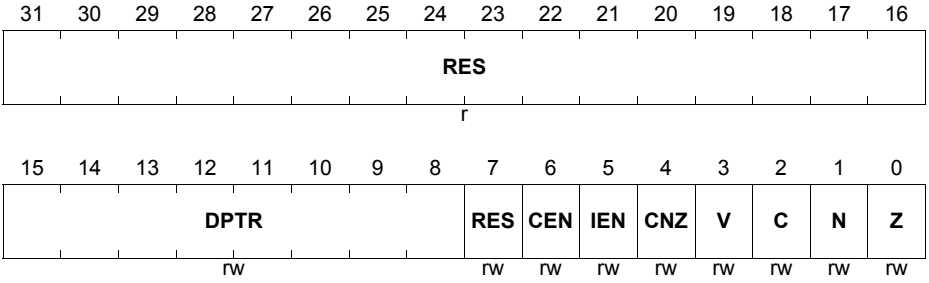
Note: Care must be taken when updating R7.DPTR to ensure that other bits within R7 (e.g. R7.CEN) are not inadvertently corrupted.

The channel enable control bit, R7.CEN, allows the enabling or disabling of specific channel programs. If an interrupt request is received for a channel that is disabled an error exit is forced, and an error interrupt to the CPU is activated.

The interrupt enable control bit, R7.IEN, allows the enabling or disabling of channel interruption on a channel to channel basis. When R7.IEN is 0, the channel will continue its execution regardless of the priority of any new service requests. When R7.IEN is 1, and conditions allow, the channel will be suspended on receipt of a higher-priority service request.

*Note: See **Section 11.21.3.1** regarding the use of R7.IEN.*

PCP Register R7 **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
RES	[31:16]	r	**Reserved** read as 0; should be written with 0.
DPTR	[15:8]	rw	**Data Pointer Segment Address for PRAM accesses**
RES	7	rw	**Reserved** should always be written with 0.
CEN	6	rw	**Channel Enable Control Bit**
IEN	5	rw	**Interrupt Enable** 0_B Channel is not interruptible 1_B Channel can be suspended in favor of a higher-priority service request
CNZ	4	rw	**Outer Loop Counter 1 Zero Flag**
V	3	rw	**Overflow**
C	2	rw	**Carry**
N	1	rw	**Negative**
Z	0	rw	**Zero**

11.4.2 Contexts and Context Models

After initialization, the instruction sequence of a PCP channel program is permanently stored (i.e. usually at least as long as the application is running) in the CMEM, and data parameters are held in the PRAM. These will remain stored regardless of whether a particular channel program is currently idle or is executing (although, of course, the value of data variables in the PRAM might be modified by the PCP or external FPI Bus masters). The contents of the GPRs of the PCP (used as address pointers, data variables, intermediate results, etc.) however, are usually only valid for a given channel program as long as it is executing. If another channel program is executed, the channel program will re-use the GPRs according to its needs.

Thus, the state of the GPRs of a channel program (termed the “Context” of the channel) needs to be preserved while a channel program is not being executed. The content of the registers needs to be saved when execution of a channel program finishes, and needs to be restored before execution starts again.

The PCP implements automatic handling of these context save and restore operations. On termination of a channel program, the state of all or some of the GPRs is automatically copied to a defined area in the PRAM (Context Save). If the same channel program is re-activated, the contents of the registers are restored by copying the values from the same defined PRAM area into the appropriate registers (Context Restore).

The defined area in the PRAM for the context save and restore operations is called the CSA. Each channel program has its own individual, predefined region in the CSA. When a service request is accepted by the PCP, the service request priority number (SRPN) associated with the request is used to select the channel program and its respective CSA region.

11.4.2.1 Context Models

A Context Model is a means of selecting whether some or all of the registers are saved and restored when a context switch occurs. In order to serve different application needs in terms of PRAM space usage, the PCP offers a choice between three different Context Models:

- Full Context Model: Eight Registers (8 × 32-bit words) are saved/restored per channel.
- Small Context Model: Four Registers (4 × 32-bit words) are saved/restored per channel.
- Minimum Context Model: Two Registers (2 × 32-bit words) are saved/restored.

As illustrated in **Figure 11-2**, the contents of R0 through R7 constitute the Full Context of a channel program. A Small Context consists of R4 through R7. Use of the Small Context Model allows for correct operation of DMA channels, as well as channels which are not required to save large amounts of data in their contexts between invocations. A Minimum Context saves and restores only R6 and R7.

To distinguish the actual register contents from the copies stored in the PRAM context regions, the term CRx is used throughout the rest of this document to refer to the register values in the context regions. Registers R6 and R7 are always handled in a special way during context save and restore operations, this is described in detail in **Section 11.4.2.3**.

The Context Model is selected via bit field (PCP_CS.CS), this is a global setting (i.e. the selected Context Model is used for all channels). Once a context model has been selected (during PCP configuration) and the PCP has been started the PCP must continue to use that Context Model. Attempting to change the Context Model in use during PCP operation will lead to invalid context restore operations which will in turn lead to invalid PCP operation.

In the case of Small and Minimum Context Models, the unsaved and un-restored registers (shaded in **Figure 11-2**) can be thought of as global registers that any channel program can use or change, or reference as constants – for example as base address pointers (see **Section 11.20.2** for more detail).

*Note: Special care must be taken when using Minimum or Small Context Model with nested interrupts (see **Page 11-151**).*

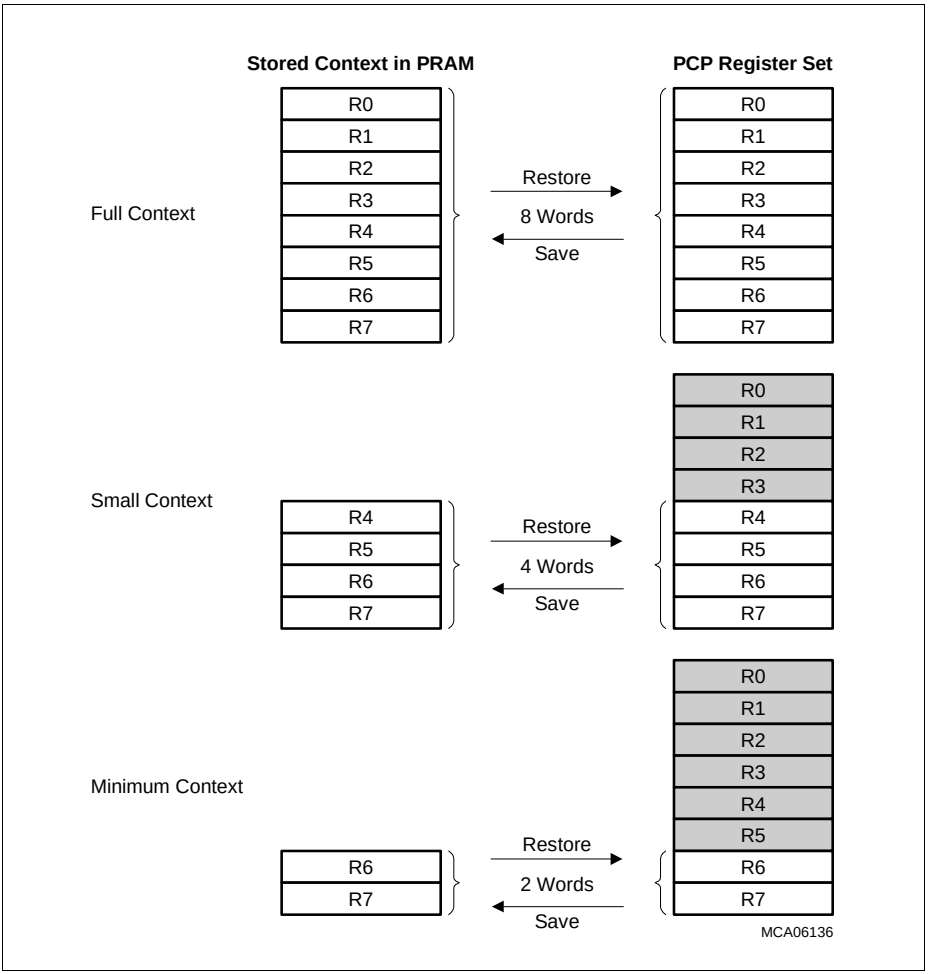


Figure 11-2 PCP Context Models

11.4.2.2 Context Save Area

The Context Save Area (CSA) is a region in PRAM reserved for storing the contexts for all channel programs (while any particular channel is not executing). Each channel's context is stored in a region of the CSA based on the channel number. The channel number is equal to the priority number (SRPN) of the service request. The PCP uses this number to calculate the start address of the context of the associated channel program. The size of a context is determined by the Context Model that the PCP has been initialized to use. As all channels use the same context size, the PRAM address (word address) of the context for a particular channel is simply calculated by multiplying the channel number by the number of registers in the context (8 for Full Context, 4 for Small Context and 2 for Minimum Context). **Figure 11-3** shows the resulting PRAM layout, and from this it can be seen that changing the Context Model also changes the base address for all regions within the CSA. Thus, the chosen Context Model may only be set when the PCP is initialized, and may not be changed during operation.

The CSA in the PRAM starts at address 00_H and grows upward. It is partitioned into equally sized regions, where the size of these regions is determined by the selected Context Model. The priority number (SRPN) of a service request is used to access the appropriate context region for the associated channel program. Since a request with an SRPN of 00_H is not considered as valid request in the TriCore Architecture, the bottom region (context region 0) of the CSA is never used for an actual context.

The total size of the CSA depends on the Context Model and the number of service request numbers used in a given system. Each priority number used in a service request node which can activate interrupts to the PCP must be represented through a dedicated context region in the PRAM. The highest address range in the PRAM used for a context region is determined by the highest priority number presented to the PCP with a service request.

The range of usable priority numbers is further determined by the size of the implemented PRAM and by the space required for other variables and global data located in the PRAM. See **Page 11-157** for the implemented size of the PRAM in the TC1798. As an example, a PRAM of 2 Kbytes, solely used for the CSA, can store up to 255 Minimum Contexts, allowing the highest SRPN used for a PCP service request to be 255 (remember, an SRPN of 0 and an associated context region is never used; the valid SRPNs and the context and channel numbers range from 1 to 255). With a Small Context Model, 127 contexts can be stored, resulting in 127 being the highest usable SRPN in this configuration. Finally, a Full Context Model allows 63 context areas, with 63 being the highest usable SRPN. Interrupt requests to the PCP with priority numbers that would cause loading of a context from outside the available PRAM area must not be generated. Invalid PCP operation will result should this situation be allowed to occur. The PCP can be optionally configured such that if an interrupt request is received that would cause loading of a context from outside the available PRAM area then an error exit is forced, and an error interrupt to the CPU is activated (see **Page 11-44**).

If portions of the PRAM are used for other variables and global data, the space available for the CSA and the range of valid SRPNs is reduced by the memory space required for this data. For best utilization of PRAM, it is advisable to have the CSA grow upwards as a contiguous area without any “holes”, meaning that all SRPNs in the range 1 … max. are actually used to place interrupt requests on the PCP. Unused regions within the CSA (that is, the unused region at the base of the CSA and any context regions associated with unused channels) cannot be used for general variable storage.

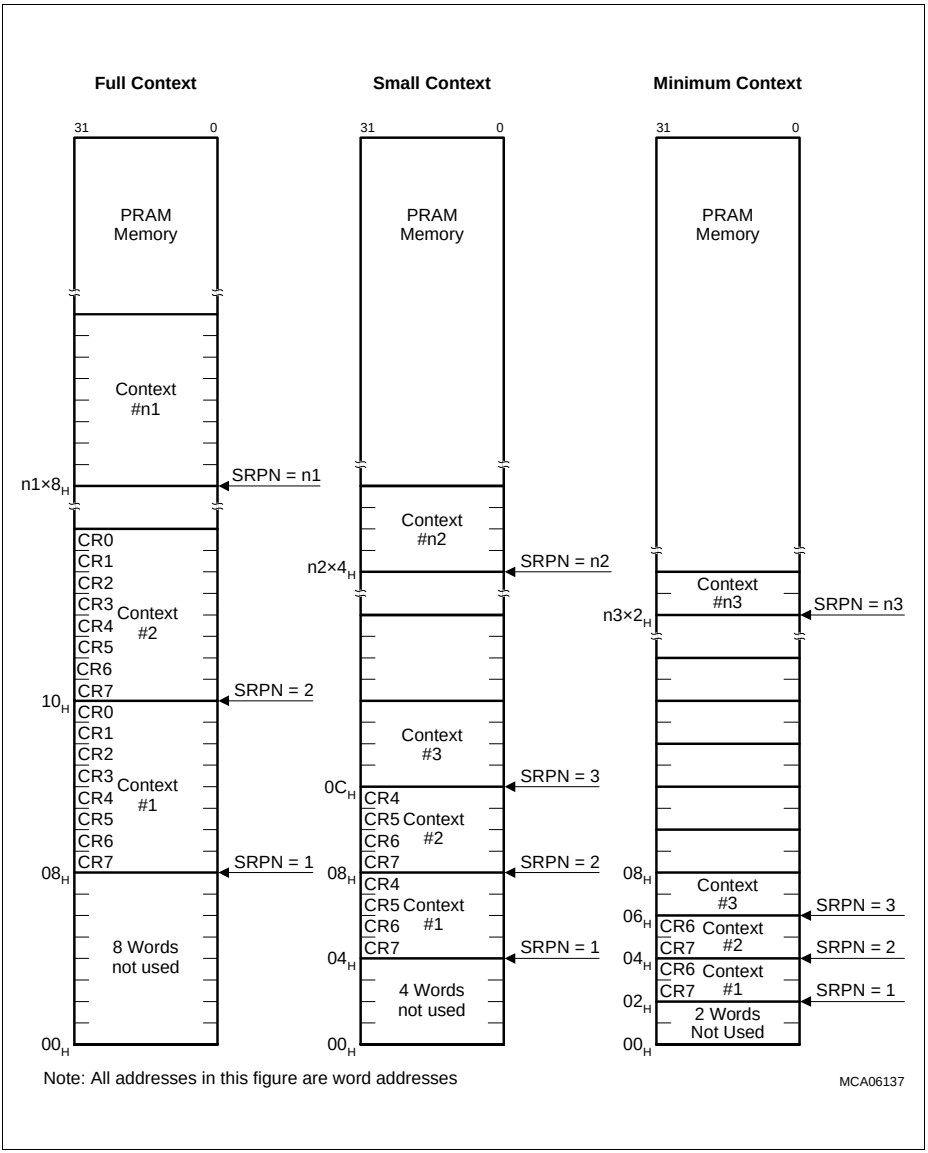

Figure 11-3 Context Storage in PRAM

When choosing the Context Model for a given application, the following considerations can be helpful. When choosing the Small or the Minimum Context Models, save and restore operations for registers not handled in the automatic context operations can still be handled through explicit load and store instructions under control of the user. This may be advantageous for applications in which the majority of the channels do not need the Full Context, and only some would require more context to be saved. In this case, a Smaller Context Model can be used, and the channels which would require more register to be saved/restored would do this via explicit load and store instructions. This is especially advantageous if the channel program can be designed such that the initial real-time response operations can be executed using only the registers which have been automatically restored. Then, as the timing requirements of the service are relaxed, further register contents can be restored from PRAM through regular load instructions. Of course, the contents of these registers needs to be explicitly saved, through regular store instructions, before the exit of the channel program.

Note: Special care must be exercised when using Minimum or Small Context Models in conjunction with nested interrupts (see **Page 11-151***).*

The criteria for choosing the Context Model are listed in the following:

- Size of PRAM implemented in a given derivative
- Amount of channels (= SRPNs) that need to be used in a system
- Amount of PRAM used for general variables and global's
- Amount of context (register content) which need to be saved and restored quickly by most of the most important channels

While registers R0 through R5 are always restored in a normal manner (according to the context size), registers R6 and R7 merit discussion regarding context restore operations. The memory location CR7 in a context region is used to hold two different pieces of information: The lower part of register R7, and the PC value of the channel. Similarly, the memory location CR6 in a context region can also be used to hold two different pieces of information: The value to be restored to register R6, and the Operating Priority (CPPN) value of the channel. This leads to the Restore/Save operations described in the following two sections.

11.4.2.3 Context Restore Operation for CR6 and CR7

The operation of R6 and R7 context restore varies according to whether the channel program that is starting is a "new" channel program (i.e. a channel program that is starting in response to the receipt of a new service request) or is a "suspended" channel program (i.e. a channel program that is re-starting after being suspended in favor of a higher-priority channel program). In addition, when a "new" channel program is starting, the context restore operation depends on the channel start mode that has been selected (see **Page 11-27**).

Channel Resume Mode

Figure 11-4 illustrates the operation of a context restore for a “new” channel program when Channel Resume Mode has been selected (see Page 11-28). The PC is loaded from CR7[31:16], and the lower half of R7 is loaded from CR7[15:0]. The operating priority of the channel is taken from CR6[31:24] and all of R6 is loaded from CR6.

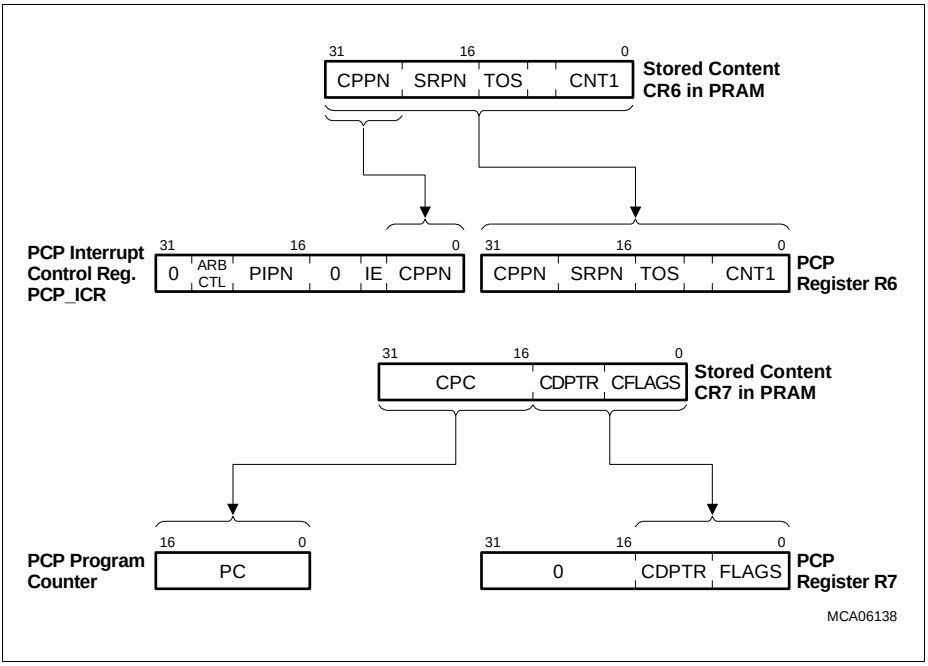

Figure 11-4 Context Restore: Channel Start in “Channel Resume Mode”

Channel Restart Mode

Figure 11-5 illustrates the operation of a context restore for a “new” channel program when Channel Restart Mode has been selected (see Page 11-27). The PC is loaded with the channel entry table address, and the lower half of R7 is loaded from CR7[15:0]. The upper half of CR6 is discarded. The operating priority of the channel is taken from CR6[31:24] and all of R6 is loaded from CR6.

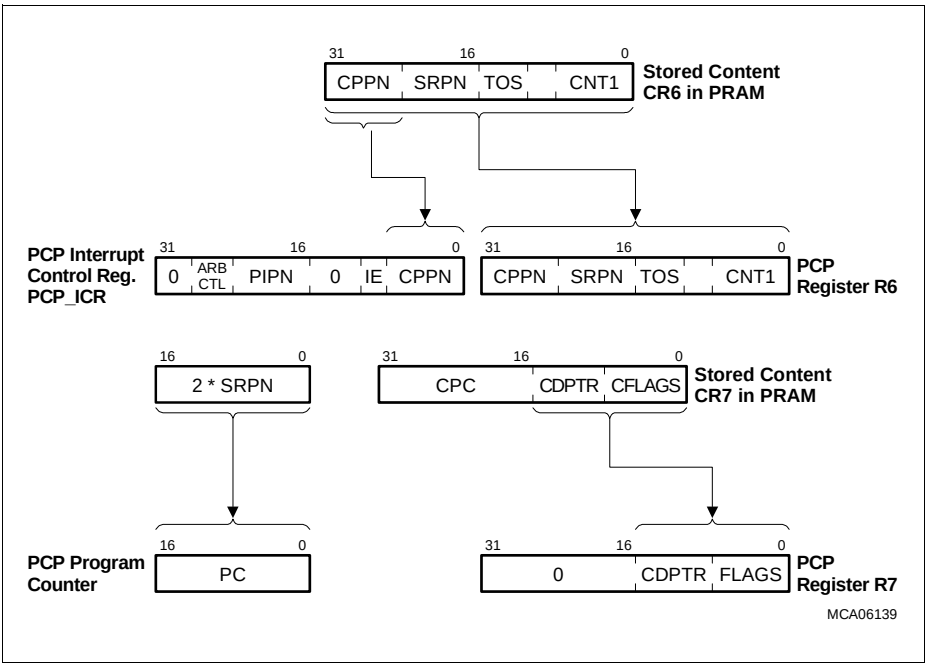

Figure 11-5 Context Restore: Channel Start in Channel Restart Mode

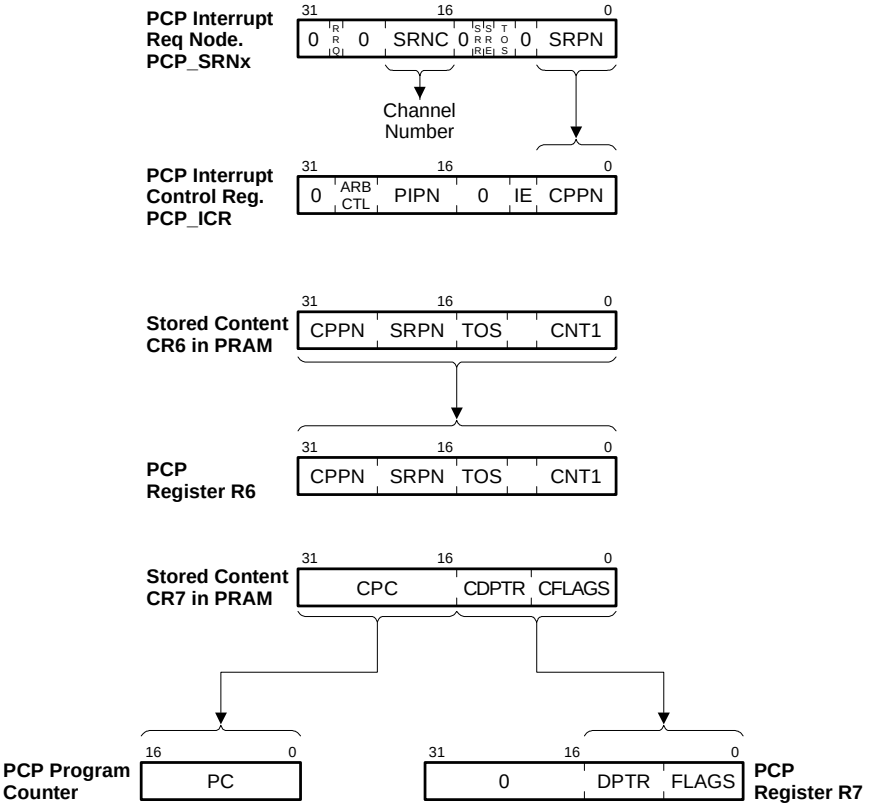
Suspended Channel Restart

Figure 11-6 illustrates the operation of a context restore for a “suspended” channel program. The PC is loaded from CR7[31:16] (regardless of the Channel Start Mode), and the lower half of R7 is loaded from CR7[15:0]. All of R6 is loaded from CR6. The figure also shows how the operating priority of the channel (PCP_IR.CPPN) is restored from the Service Request Node that was used to store the Suspended Interrupt Request (see Page 11-96).



Note: During a context restore for a suspended channel the PCP_SRCNx.SRNC field (n = 9, 10, 11) is used to determine the channel number.

MCA06140

Figure 11-6 Context Restore: Suspended Channel Restart

11.4.2.4 Context Save Operation for CR6 and CR7

The operation of R6 and R7 context save varies according to whether the save operation is the result of a channel exit condition, or whether the channel is being suspended in favor of a higher-priority channel program.

Channel Resume Mode

Figure 11-7 illustrates the operation of a context save for a channel exit when Channel Resume Mode has been selected. The value written to CR7 is created by concatenating the 16-bit PC value with the lower 16 bits of R7. CR6 is written with the value taken from R6.

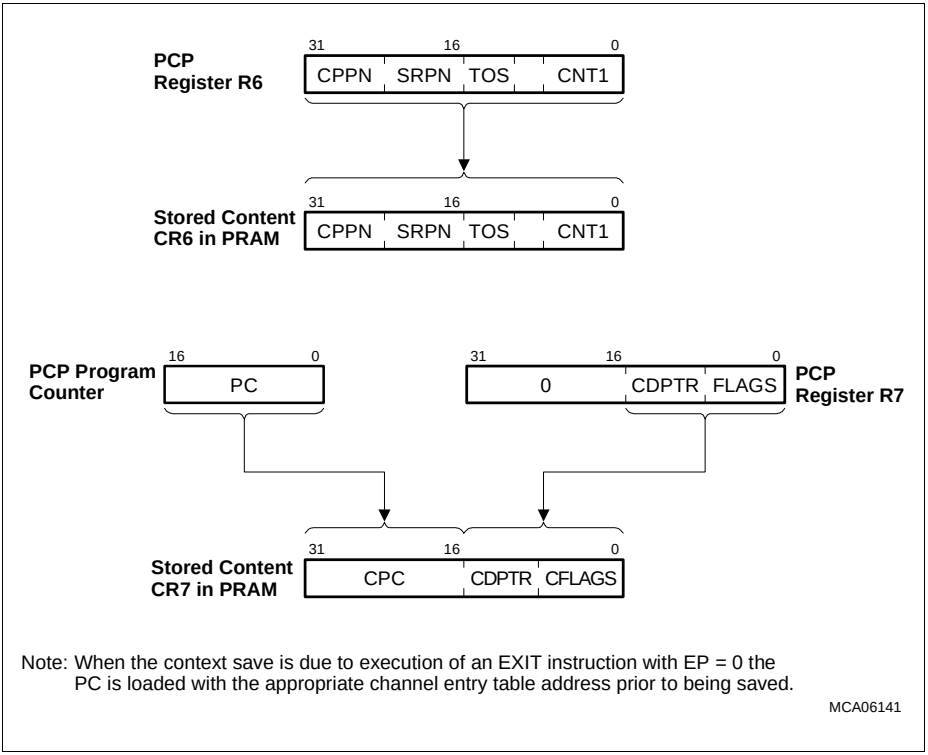


Figure 11-7 Context Save: Channel Exit in Channel Resume Mode

Channel Restart Mode

Figure 11-8 illustrates the operation of a context save for a channel exit when Channel Restart Mode has been selected. This is the same as for Channel Resume mode except that the PC value is discarded, and the appropriate Channel Entry Table address is written to CR7[31:16].

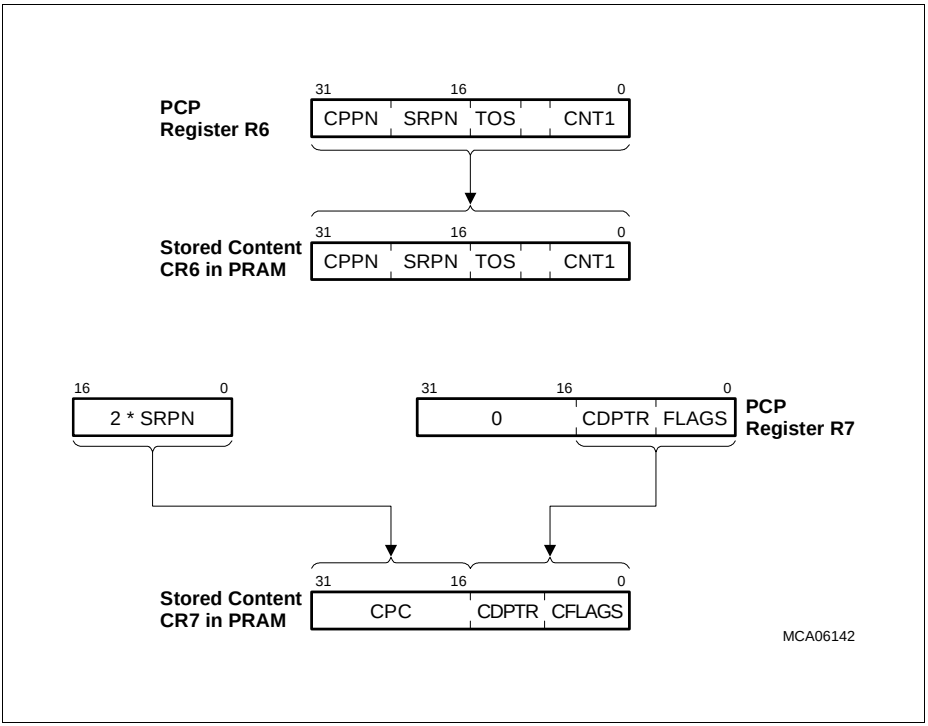

Figure 11-8 Context Save: Channel Exit in Channel Restart Mode

Channel Suspend

Figure 11-9 illustrates the operation of a context save for a channel that is being suspended. This is the same as for Channel Resume mode except that an interrupt request is created to allow the channel to be restarted at a later time. This restore operation utilizes one of three specially extended SRNs (see Page 11-96) to store the interrupt request. The information stored as part of the interrupt request is the channel number (SRPN), and the operating priority (CPPN) with which the channel was operating prior to being suspended. This operation in conjunction with the suspended channel restore operation shown in Figure 11-6 allows the temporary suspension of a channel in favor of a higher-priority channel.

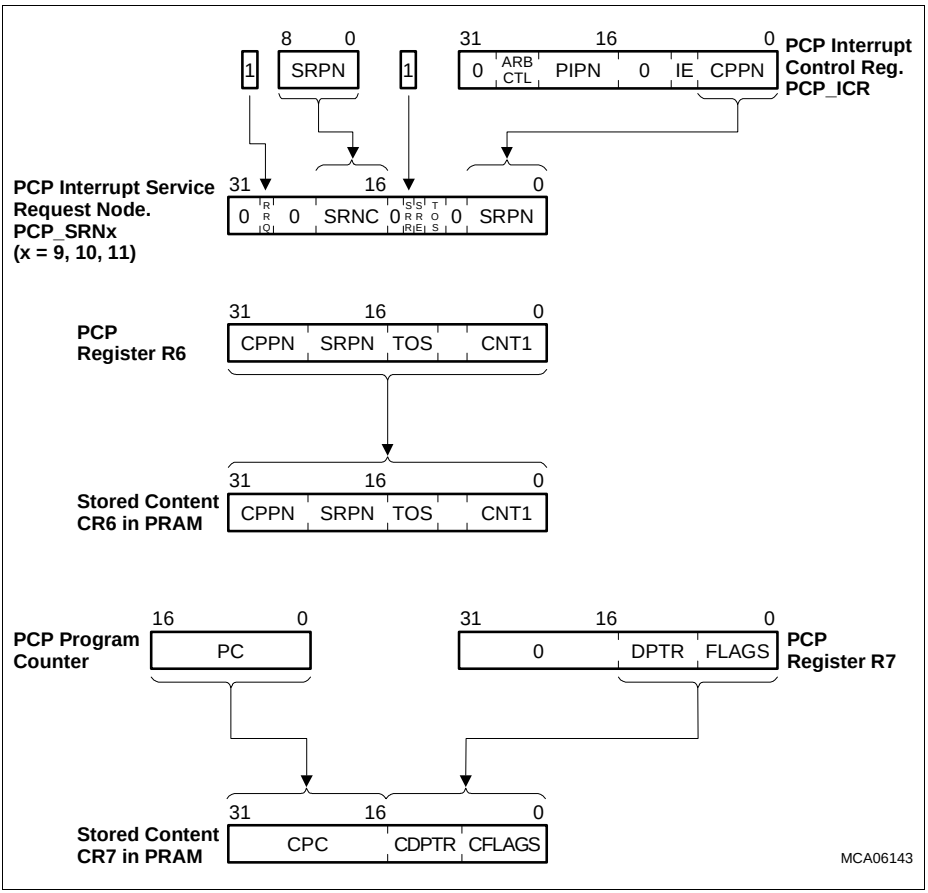

Figure 11-9 Context Save: Channel Suspend

11.4.2.5 Initialization of the Contexts

The programmer is responsible for configuring each channel program's context before commencing operation. Because this must be done by writing to the PCP across the FPI Bus, it is important to understand exactly where each channel program's context is from the FPI Bus perspective (see **Page 11-58** for details).

11.4.2.6 Context Save Optimization

The PCP has an optimized context-switching strategy consisting of optimization of both context load and store. During a context load in which the channel that is starting is also the last channel that the PCP was running then the PCP GPRs already contain the values appropriate to the channel. In this case there is no need to reload the context (i.e. the PCP can immediately continue operation at the appropriate point in the code without having to perform a context load). During a Context Store (i.e. the PCP exits a channel as a result of EXIT or DEBUG instructions or exits in response to a higher-priority channel interrupt), only those registers that have been updated (i.e. written to) since the context was loaded are saved to the CSA.

11.4.3 Channel Programs

The PCP CMEM is used to store the instruction sequences, the channel programs, for each of the PCP channels. The individual channel programs for the individual PCP service requests can usually be viewed as independent and separate programs. There is no background program defined and running for the PCP in TC1798 as there would be with traditional processors.

When the PCP receives a service request for a specific channel program, it needs to determine exactly which channel program to activate and where to start its execution. To accommodate different application needs, the PCP architecture allows the selection of two different entry methods into the channel programs:

- Channel Restart Mode
- Channel Resume Mode

Channel Restart Mode forces the PCP to begin each channel program from a known fixed point in the CMEM that is related to the interrupt number. At the entry point related to the interrupt number in question, there will typically be a jump instruction which vectors the PCP to the main body of the channel program. This is identical to the traditional interrupt vector jump table. In Channel Restart Mode, channel code execution will always start at the same address in the interrupt entry table each time the channel is requested.

Channel Resume Mode allows the PCP to begin execution at the PC address restored as part of the channel program context. This mode allows code to be contiguous and start at any arbitrary address. It also allows for the implementation of interrupt-driven state machines, and even the sharing of code across multiple programs with different context.

The selection of one of the two modes is a global PCP setting, that is, it applies to all channels. Selection is made via the PCP_CS.RCB bit in the PCP configuration register PCP_CS (see **Page 11-69**).

11.4.3.1 Channel Restart Mode

Channel Restart Mode is selected with PCP_CS.RCB = 1. In this mode, the PCP views the CMEM as being partitioned into an interrupt entry table at the beginning of the CMEM, and a general code storage area above this table.

The interrupt entry table consists of two instruction slots (2×16-bit) for each channel. When a PCP service request is received, the PCP calculates the start PC for the requested channel by a simple equation based on the SRPN of that request (PC = $2 \times$ SRPN). It then executes the instruction found on that address. If more than two instructions are required for the operation of the channel program, then one of the instructions within the interrupt entry table must be a jump to the remainder of the channel's code. The PCP executes the channel's code until an exit condition or higher-priority interrupt is detected.

It is recommended that all EXIT instructions for all channels should use the EP = 0 setting when the PCP is operated in Channel Restart Mode (see **Page 11-115**).

Note that when Channel Restart Mode is in use a Channel Entry Table must be provided with a valid entry for every channel being used. **Figure 11-10** shows an example of CMEM organization when Channel Restart Mode has been selected. Failure to provide a valid entry for all channels that are in use will lead to invalid PCP operation.

11.4.3.2 Channel Resume Mode

Channel Resume Mode is selected with PCP_CS.RCB = 0. In this mode, the user can arbitrarily determine the address at which the channel program will be started the next time it is invoked. For this purpose, the PC is saved and restored as part of the context of a PCP channel.

Additional flexibility is available when Channel Resume Mode is globally selected by configuring each EXIT instruction to determine the channel start address to be used on the next invocation of a channel (see **Page 11-115**). When the EP = 0 setting is used, the PC value saved in the channel's context (saved in CPC) is the address of the appropriate location in the channel entry table. This forces the channel to start at the appropriate location in the interrupt entry table at next invocation. When the EP = 1 setting is used, the PC value saved in the channel's context is the address of the instruction immediately following the EXIT instruction. The use of the EP = x setting with the EXIT instruction allows the mixture of channels that use a Channel Restart strategy with others using a Channel Resume strategy, and also allows individual channels to use either strategy as appropriate on different invocations.

Note: A valid entry within a Channel Entry Table must be provided for every channel that uses an EXIT instruction with the EP = 0 setting when Channel Resume Mode has been selected. Failure to provide a valid entry for such channels will lead to invalid PCP operation.

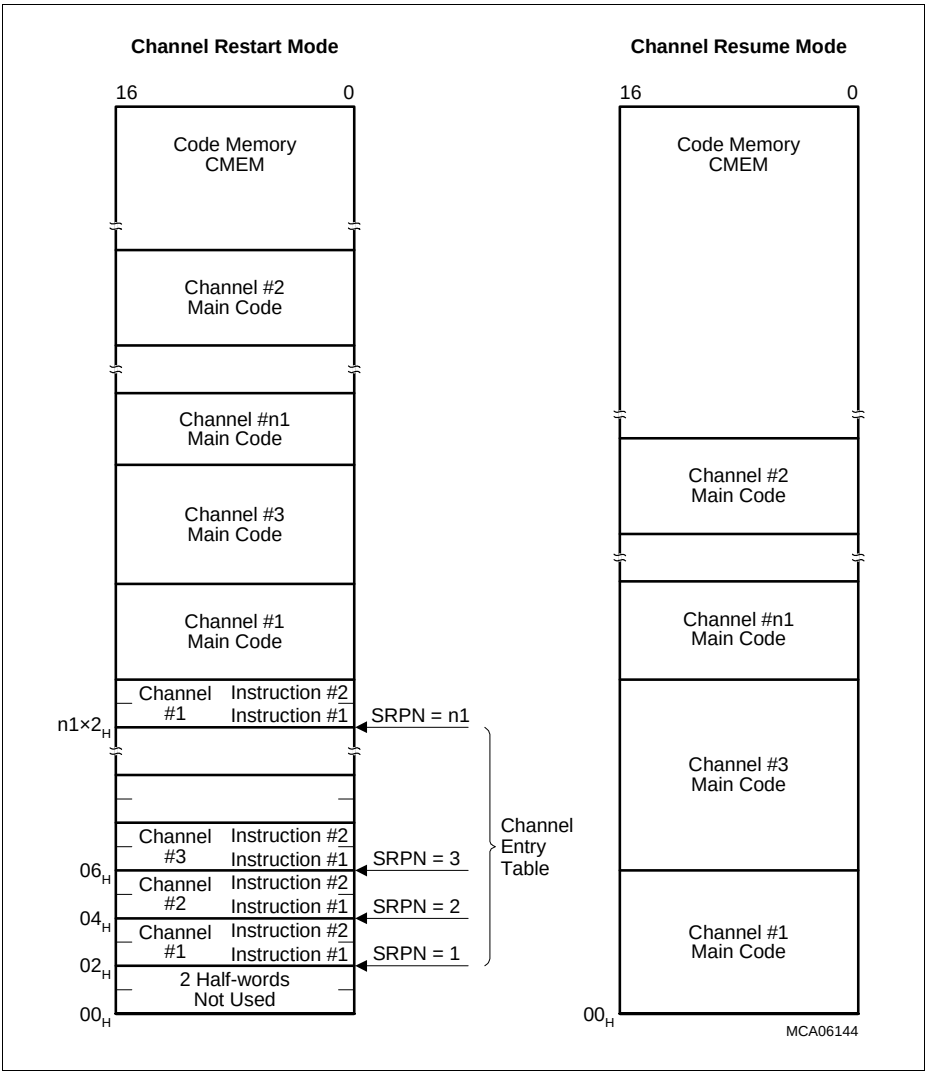

Figure 11-10 Examples of Code Memory Organization for Channel Restart and Channel Resume Modes

Note: The CMEM address offsets in the above figure are shown as PCP instruction (half-word) offsets. To obtain FPI address offsets (byte offset) multiply each offset by two.

11.5 PCP Operation

This section describes how to initialize the PCP, how to invoke a channel program, and the general operation of the PCP.

11.5.1 PCP Initialization

The PCP is placed in a quiescent state when the TC1798 is first powered-on or reset. Before a channel program can be enabled, the PCP as a whole must be initialized by some other FPI Bus master, typically the CPU. Initialization steps include:

- Configure global PCP registers.
  - Initialize PCP Control and Status Register (with PCP_CS.EN = 0).
  - Configure interrupt system via PCP_ICR.
- Load channel programs into the CMEM.
- Load initial context (if/as required) of channel programs in PRAM (R0 - R7 for Maximum context, R4 - R7 for Small Context, R6 - R7 for Minimum Context). Only those registers in each channel whose initial content is required on first invocation of the channel need to be loaded. This may need to include the initial PC, depending on the value of PCP_CS.RCB.
- Clear R7 in the context for unused channels.
- Enable PCP operation PCP_CS.EN = 1.

Now, the PCP is able to begin accepting interrupts and executing channel programs.

11.5.2 Channel Invocation and Context Restore Operation

A channel program is started when one or other of the following conditions occurs:

- The current round of PCP interrupt arbitration results in a winning interrupt number (SRPN) and the PCP is currently quiescent (has exited the previous channel and stored the context for that channel).
- The current round of PCP interrupt arbitration results in a winning interrupt number (SRPN) that has to be greater than the current channel priority (SRPN > CPPN), if suitable Service Request Node space is available in the PSRN to store a suspended interrupt request and the current channel allows interrupts (R7.IEN = 1). See also **Page 11-35**).

When this happens the winning SRPN becomes the current interrupt, and a context restore operation occurs before the new channel program can begin operation, as follows:

- The context of the channel (= winning SRPN) is restored from PRAM into the GPRs from the appropriate address within the CSA. Depending on the value of PCP_CS.CS, a Full, Small, or Minimum Context restore is performed.
- The new priority level of the PCP is taken from R6.CPPN field and is written to PCP_ICR.CPPN. This value can be useful during debugging, as the CPPN of the currently executing or last-executed channel program can be read from PCP_ICR.

After the channel program starts, the value of R6 may be changed without altering the value of the effective CPPN, because updates to the value of R6.CPPN have no effect until the next invocation of the channel program.

- If the R7.CEN bit is clear (0), then an error has occurred because a disabled channel program has been invoked, the PCP_ES.DCR bit is set to flag the error, and the channel program performs an error exit (see Page 11-31).
- If the R7.CEN bit is set (1), then code execution begins at the value of the restored PC or at the address of the interrupt routine in the Channel Entry Table, depending on the value of PCP_CS.RCB.

Special care needs to be taken regarding the number of clock cycles required to switch context when the last state of the PCP before channel exit was execution of channel “N” (SRPN = “N”), and the current service request is also SRPN = “N”. In this case, the PCP Processor Core should not load the context (as the PCP GPRs already contain the correct content), but continue operation from the current point and state (noting that the PC value should be set to the appropriate channel entry point if PCP_CS.RCB = 1).

11.5.3 Channel Exit and Context Save Operation

The context of a channel program must be saved when it terminates. Three events can cause the termination of a channel program:

- Execution of the EXIT instruction (normal termination)
- Occurrence of an error
- Execution of the DEBUG instruction (channel termination is optional). The DEBUG instruction must only be used in DEBUG mode; otherwise an “Illegal Operation” (IOP) error will be generated

These channel termination possibilities are described in the next sections.

11.5.3.1 Normal Exit

Under normal circumstances, a channel program finishes by executing an EXIT instruction. This instruction has several setting fields that allow the user to specify a number of optional actions to be performed during the channel exit sequence (see Page 11-115). These optional actions are:

- Decrement counter CNT1
- Set the start PC for the next channel invocation to the next instruction address (Channel Resume) or to the channel entry address (Channel Restart)
- Disable further invocations of this channel
- Generate an interrupt request to the CPU or to the PCP itself

When the EXIT instruction is executed, the following sequence occurs:

- If EC = 1 is specified Counter R6.CNT1 is decremented and the CN1Z flag is updated.

- If ST = 1 is specified bit R7.CEN (Channel Enable) is cleared (i.e. the channel is disabled).
- If EP = 0 is specified **or** PCP_CS.RCB = 1 (Channel Restart Mode has been selected), the PCP program counter to be saved to context location CR7.PC is set to the appropriate channel entry table address. If EP = 1 is specified **and** PCP_CS.RCB = 1 (Channel Resume Mode has been selected), the PCP program counter to be saved to context location CR7.PC is set to the address of the instruction immediately following the EXIT instruction.
- If INT = 1 is specified **and** the specified condition cc_B is True, then an interrupt request is raised according to the SRPN value held in R6.SRPN. The interrupt is asserted via one of the PCP_SRCx registers, where x is determined by the combination of the value of R6.TOS and the list of free entries. This allows the conditional creation of a service request to the CPU or PCP with the SRPN value indicated in register R6.SRPN.
- The channel program's context (including all register modifications caused within this EXIT sequence) is saved to the appropriate region in the PRAM Context Save Area. Depending on the value of PCP_CS.CS, either a Full, Small, or Minimum Context save is used.

Special care needs to be taken to optimize the number of clock cycles required to perform a Context Save. During a Context Save, the PCP Processor Core needs only to save those registers that have been written since the last Context Restore was performed.

Note: Particular attention must be paid to the values of R6 and R7 prior to execution of the EXIT instruction. When posting an interrupt request, the user must ensure that R6.SRPN and R6.TOS contain the correct values to generate the required interrupt request. When using the Outer Loop Counter (CNT1), the user must ensure that the value in R6.CNT1 will provide the required function. When using interrupt priority management, the user must ensure that R6.CPPN contains the interrupt priority with which the channel is to run on next invocation. If the channel is to be subsequently re-invoked, the user must ensure that the Channel Enable Bit (R7.CEN) is set.

11.5.3.2 Error Condition Channel Exit

PCP error conditions can occur for a variety of reasons (e.g. an invalid operation code was executed by a channel program, or an FPI Bus error occurred). When an error condition occurs, the PCP Error Status Register (PCP_ES) is updated to reflect the error, and the channel program is aborted. The error exit sequence is as follows:

- The channel enable bit R7.CEN is cleared. This means the channel program will be unable to restart until another FPI Bus master has re-configured the channel program's stored context to set CR7.CEN to 1 again.

- The PC of the instruction that was executing when the error occurred is stored in PCP_ES.EPC.
- The number of the channel program that was executing when the error occurred is stored in PCP_ES.EPN.
- The error type is set in the appropriate field of register PCP_ES.
- The context is saved back to the PRAM CSA. Depending on the chosen context size (PCP_ES.CS) a Full, Small, or Minimum Context save is performed.
- If the error condition was not due to an FPI Bus error or a DEBUG instruction, then an interrupt request to the CPU is generated with the priority number stored in register PCP_CS.ESR.

The repetitive posting of PCP error interrupts will not cause an overwhelming number of interrupts to the CPU. In this situation, the PCP's CPU service request queue (see **Page 11-35**) will quickly fill, and force the PCP to stall until the CPU can resolve the situation.

Note: An error condition (other than an FPI Bus error) will result in an interrupt being sent to the CPU. The interrupt routine that responds to this interrupt must be capable of dealing with the cause as recorded in PCP_ES, and it must be able to restore the channel program to operation. The minimum required to restart the channel program is to set the context value of CR7.CEN = 1.

11.5.3.3 Debug Exit

If the DEBUG instruction is programmed to stop the channel program execution (SDB = 1 has been specified), the PCP performs an exit sequence that is very similar to the error exit sequence, with the exception that no interrupt request to the CPU is generated. This sequence is:

- If RTA = 0, then the channel enable bit R7.CEN is cleared. This means the channel program will be unable to restart until another FPI Bus master has re-configured the channel program's stored context to set CR7.CEN to 1 again. Otherwise, the R7.CEN bit remains unchanged, and the PC is decremented (such that it points to the DEBUG instruction)
- If EDA = 1, a break-point event is generated
- If DAC = 1, then the PCP_CS.EN bit is cleared. This means that the PCP will not execute any further channel programs until the PCP_CS.EN bit is set by another FPI Bus master
- The address of the DEBUG instruction (i.e. the current PC) is stored in register PCP_ES.PC
- The current channel number is stored in register PCP_ES.PN

The execution of the current channel program is stopped at the point of the DEBUG instruction. This instruction only disables the current channel; the PCP will continue to operate, accepting service requests for other channels as they arise.

Note: The DEBUG instruction must be only used in DEBUG mode; otherwise an "Illegal Operation" (IOP) error will be generated.

11.6 PCP Interrupt Operation

The PICU and the PSRNs (PCP_SRC[11:0]) are similar to the CPU's ICU and all other SRNs in the system. They do, however, have some special characteristics, which are described in the following sections. **Figure 11-11** shows an overview of the PCP interrupt scheme.

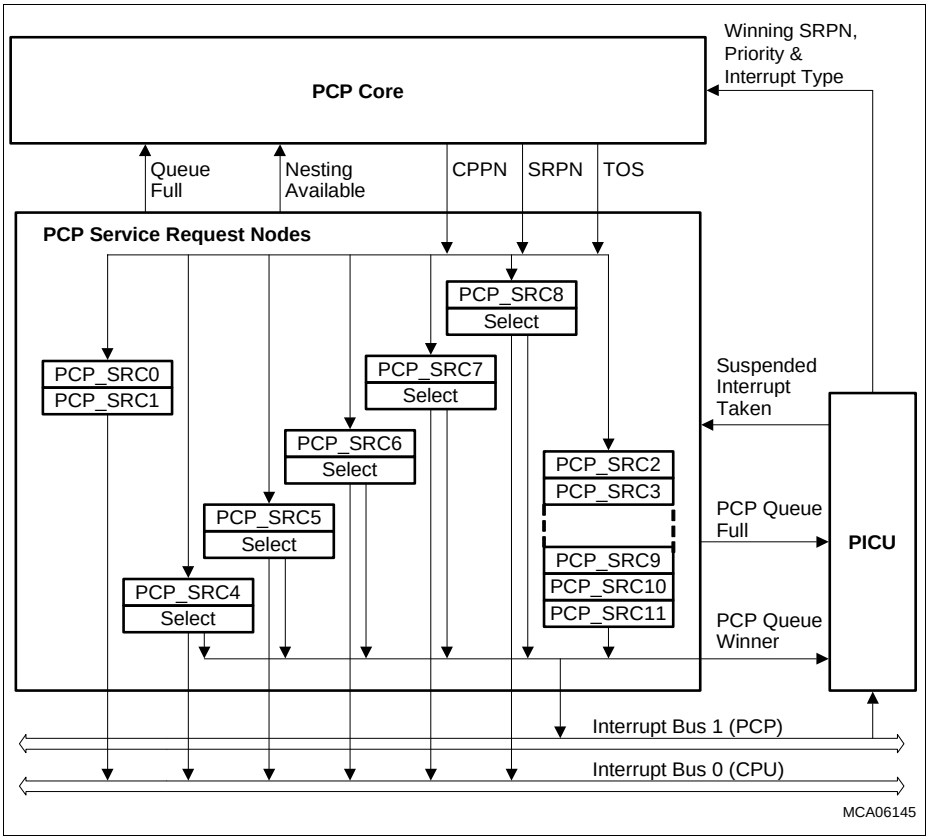

Figure 11-11 PCP Interrupt Block Diagram

11.6.1 Issuing Service Requests to CPU or PCP

The PCP may use one of two mechanisms to raise an interrupt request to the CPU or itself. The first, and most inefficient, method for a PCP channel program is to issue service requests by performing an FPI Bus write operation to an external service request node (SRN). Alternately, the PCP can raise a service request using one of its own internal SRNs. An interrupt can only be generated by the PCP via an internal SRN when executing an EXIT instruction, or when an error condition occurs. In the following descriptions, PCP service requests triggered through an EXIT instruction or the occurrence of an error are called “implicit” PCP service requests to distinguish them from the “explicit” way of generating a service request through an FPI Bus write to a service request node external to the PCP.

11.6.2 PCP Interrupt Control Unit

The PICU operates in a similar manner to the ICU of the CPU. The PICU manages the PCP service request arbitration bus, and handles the communication of service requests and priority numbers to and from the PCP kernel. The PCP_ICR register is provided to control and monitor the arbitration process.

When one or more service requests to the PCP are activated, the PICU performs an arbitration round to determine the request with the highest priority. It then places the priority number of this “winning” service request into the PIPN field of register PCP_ICR, and generates a service request to the PCP kernel.

If the PCP kernel is currently busy processing a channel program, the new request is left pending until the current channel program has finished.

When the PCP kernel is ready to accept a new service request, it calculates the context start address from the Pending Interrupt Priority Number, PIPN, stored in register ICR, and begins with the context restore. It notifies the PICU of the acceptance of this request, and in turn the PICU acknowledges the winner of the last arbitration round. This service request node then resets its Service Request Flag, SRR.

There is one special condition in which the PICU operates differently from the way that the CPU Interrupt Control Unit operates. This special operation is described on **Page 11-38**.

The PCP interrupt arbitration can be adapted to the application’s needs and characteristics through controls in register PCP_ICR. Bit field PCP_ICR.PARBCYC controls the number of arbitration cycles per arbitration round (one through four cycles), while bit PCP_ICR.PONECYC controls whether one arbitration cycle equals one or two system (FPI Bus) clock cycles.

11.6.3 PCP Service Request Nodes

The PCP contains twelve service request nodes, including twelve service request control registers, PCP_SRC0 to PCP_SRC11, which are provided for implicit PCP service

requests. The service request control registers differ from standard SRC registers in that they are fully controlled by the PCP kernel; they are read-only registers during PCP operation. The user cannot generate interrupts by writing to them.

The twelve service request nodes are split into four groups.

- The first group, containing registers PCP_SRC0 and PCP_SRC1, handles implicit PCP service requests targeted to the CPU. The Type-of-Service control fields, TOS, of these registers are hard-wired to 00_B, directing the requests to the CPU.
- The second group, registers PCP_SRC2 and PCP_SRC3, handles the service requests targeted to the PCP itself. The respective TOS field of these registers are hard-wired to 01_B, directing the requests to the PCP.
- The third group, containing registers PCP_SRC4 to PCP_SRC8, have programmable TOS fields which allow these registers to be assigned (at configuration time) to any of the available interrupt buses.
- The fourth group, containing registers PCP_SRC9, PCP_SRC10 and PCP_SRC11, are an extended version of a standard Service Request Node. These handle service requests targeted to the PCP itself, including service requests representing a suspended interrupt. The respective TOS field of these registers are hard-wired to 01_B, directing the requests to the PCP.

The service request enable bits, SRE, of the PCP_SRCx registers are hard-wired to 1, meaning these service requests are always enabled.

Note: The number of interrupt buses is device-dependent. Programming a PCP_SRCx register (x = 4 to 8) with a TOS value representing a non-available interrupt bus (10_B or 11_B in the TC1798) will disable Service Request Node x.

The actual service request flag and the service request priority number of the PCP_SRCx registers are updated by the PCP when it generates an implicit service request. The way this is performed is described in the following section.

The service request nodes in each of the groups described above are implemented as queues with the appropriate number of entries. When the PCP generates an implicit service request, it places the request into the next available free entry of the appropriate queue rather than writing it into a specific register. Queue management logic automatically ensures proper handling of the queue. If all entries of a queue are filled with pending service requests, the queue management reports this condition to the PCP kernel via a “queue full” signal.

In the following descriptions, the terms “CPU Queue” and “PCP Queue” are used to refer to the queues in the two groups of PCP service request nodes.

11.6.4 Issuing PCP Service Requests

The PCP can issue implicit service requests on the execution of an EXIT instruction, when suspending a channel, or when an error occurs during a channel program execution. While the service request generation for the EXIT instruction is optional, a

service request is always generated when a channel is suspended or an error occurs. Further differences between these three mechanisms are detailed in the following sections.

11.6.4.1 Service Request on EXIT Instruction

An implicit PCP service request is issued when the INT field of the EXIT instruction is set to 1 and the specified condition code, cc_B, of this instruction is true. Such a service request can be issued to any of the available interrupt buses, depending on the programmed value in the TOS field of register R6. The PCP examines the TOS field in register R6 and issues a service request to the appropriate queue of the service request nodes. Along with this request, it passes the service request priority number stored in the SRPN field of register R6 to the queue. If the queue has a free entry left, the service request flag, SRR, of the associated service request register, PCP_SRCx, will be set, and the service request priority number will be written to the SRPN field of the SRC register. Please see **Page 11-38** for the case where there is no free entry in the queue.

Because the desired service request is programmed through the TOS and SRPN fields in register R6, each channel program can issue its individual service request. Note that this register needs to be programmed properly if a service request is to be generated by the EXIT instruction.

11.6.4.2 Service Request on Suspension of Interrupt

An implicit PCP service request is issued when the PCP suspends execution of the ongoing channel program in favor of a service request with a higher priority. Such a service request is always issued to the PCP's own interrupt bus and is stored in one of the three extended Service Request Nodes (PCP_SCR9, PCP_SRC10, PCP_SRC11). Along with this request, it passes the current channel operating priority (CPPN) as an SRPN and also the channel number (the original SRPN). The service request flag, SRR, and the Restart Request flag, RRQ, of the associated service request register, PCP_SRCx, will be set, the Operating Priority will be written to the SRPN field, and the channel number will be written to the SRNC field of the SRC register.

Use of the Operating Priority as the SRPN for resumption of the channel program ensures that during subsequent arbitration rounds the PCP will resume execution of the suspended channel program at the appropriate time.

The PCP treats an interrupt request with the RRQ bit set in a special fashion. In this case the PCP clears the interrupt request bit in the appropriate internal Service Request Node but does not issue an interrupt acknowledge to any external nodes. This prevents the unwanted clearing of external service requests with an SRPN that matches the priority of a suspended channel.

Note: The PCP will only suspend channel operation when there are two or more free SRNs with the appropriate TOS value for the PCP, and one of the free SRNs is an

Extended Service Request Node. This allows for the posting of an interrupt request to the PCP on exit from the new channel program.

11.6.4.3 Service Request on Error

While a service request triggered through an EXIT instruction is optional and can be issued either to the CPU or to the PCP itself, a service request due to an error condition will always be automatically issued and will always be directed to the CPU. The PCP issues a service request to the CPU queue of the service request nodes. Along with this request, it passes the SRPN stored in the ESR field of register PCP_CS to the queue. If the queue has a free entry left, the SRR flag of the associated service request register, PCP_SRCx, will be set, and the SRPN will be written to the SRPN field of the SRC register. See next section for the case where there is no free entry in the queue (queue full).

Due to the fact that the priority number is stored in the global control register PCP_CS, all channel programs share the same service request routine in case of an error. The exact cause of the error and the channel number of the program that was executed when the error occurred can be determined through examination of the contents of the Error/Debug Status Register, PCP_ES.

11.6.4.4 Queue Full Operation

Queuing the implicit service requests typically allows the PCP to continue with the next service request without stalling. The depth of the queue and the number of channel programs using them determines the stall rate. Depending on the selected service provider (via R6.TOS in case of an EXIT interrupt or always to the CPU in case of an error interrupt), the request is routed to a free entry in the appropriate queue.

If no free entries are available in a queue at the time the PCP wants to post a request to that queue, the PCP is forced to stall until an entry becomes clear. This ensures that the PCP does not lose any interrupts. An entry in a queue becomes free when its SRR flag, is cleared through an acknowledge from the PICU (that is, the CPU or PCP, as appropriate, has started to service this request).

One special case needs to be resolved for the PCP-related queue through special operation of the PICU. Consider the case in which the PCP queue is full, meaning registers PCP_SRC2, PCP_SRC3 and PCP_SRC9 to PCP_SRC11 are already loaded with pending service requests to the PCP. If the PCP kernel now needed to post an additional service request into that queue, a deadlock situation would be generated: The PCP would stall, since there is not a free entry in the PCP queue in which to place the request. In turn, as the PCP is stalled, it cannot accept new service requests and so the PCP service request queue cannot be emptied. This would result in a deadlock of the PCP.

To avoid such a deadlock, the PICU performs a special arbitration round as soon as the PCP queue becomes full. In this arbitration round, only the service request nodes assigned to the PCP queue are allowed to participate; all service requests from nodes external to the PCP are excluded, regardless of whether their priorities are higher or lower than those of the PCP queue. In this way, it is guaranteed that one entry in the PCP queue gets serviced, freeing one slot in the queue.

The PCP programmer needs to carefully consider this special operation. It ensures that deadlocks are avoided, but it implies that if too many PCP channel programs post service requests to the PCP (self-interrupt), the PCP will have to service these rather than outside interrupt sources. Depending on the priority given to these requests, this could undermine an otherwise appropriate use of the interrupt priority scheme. It is recommended that the system be designed such that in most cases, high-priority numbers can be assigned to these self-interrupts, so that they can win normal arbitration rounds, avoiding the situation where the PCP queue becomes full.

Note: If the CPU queue is full, the PCP can continue to operate until it needs to post another service request to the CPU queue.

11.7 PRAM Protection

To allow the PCP to handle system critical tasks it is necessary to ensure that the PCP can operate properly regardless of a failure in another part of the system or the PCP itself. this means that it is necessary to protect all or part of the content of the PRAM from such failures.

By default, after reset, the PRAM can be considered to be a single memory space writeable both by FPI Masters and by instructions executed by the PCP itself. However the PCP contains a programmable protection scheme allowing the definition of up to four memory regions with different protection from FPI PRAM writes and internally generated PRAM writes. This is illustrated in **Figure 11-12** below:-

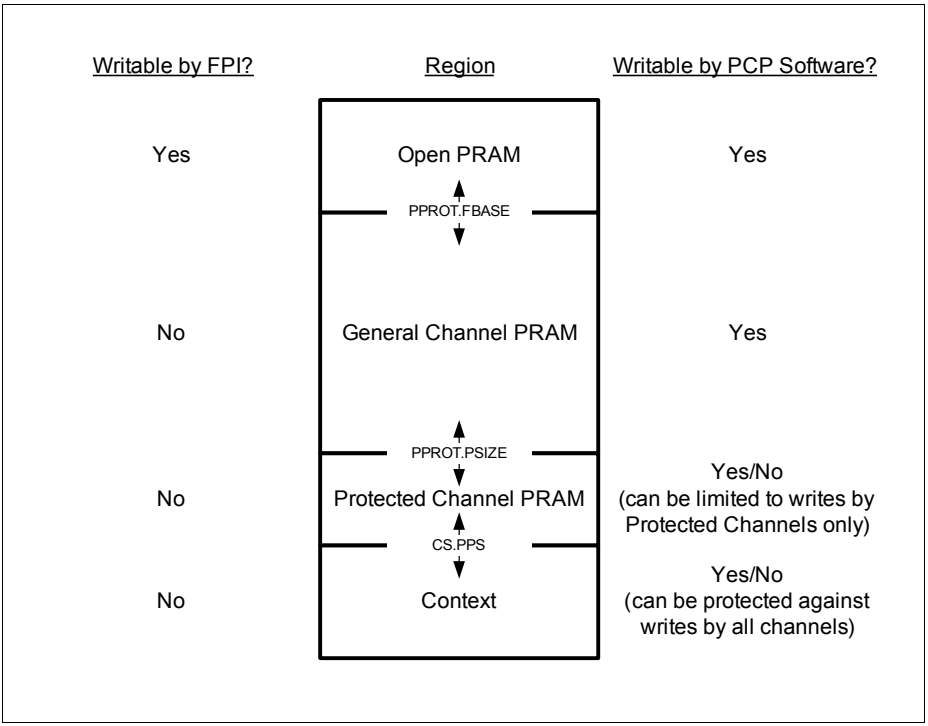

Figure 11-12 PRAM Regions

*Note: **Figure 11-12** shows a typical configuration that might be used. Configuration is sufficiently flexible, however, that all of, none of, or any combination of the above regions can be implemented and that the region boundaries can be set with a granularity of at least 256 bytes.*

While **Figure 11-12** shows four regions, in reality the protection scheme can be seen from two viewpoints:-

- Protection from FPI writes (see **Section 11.7.1**).
- Protection from internally generated PRAM writes (see **Section 11.7.2**).

Protection of PRAM is provided to allow running of system critical tasks on the PCP. Protection means that such tasks can be made immune from failures outside of the PCP or indeed from software failures in non-critical tasks running on the PCP itself.

PRAM protection is based around the concept of “Protected” and “Unprotected” Channel Programs. A “Protected” channel program is one that is running a critical system task and is termed “Protected” since it (and any other Protected Channel Programs) have

write access to an area of PRAM that cannot be modified by an Unprotected Channel Program.

Determination of whether a channel is Protected or Unprotected is performed by examination of the channel number against a programmable threshold (programmed via PCP_PPROT.PTHRES). In addition to the threshold the user can select (via PCP_PPROT.PCAT) whether Channel Programs above (and including the threshold) are Protected or whether Channel Programs below (and including the threshold) are Protected.

11.7.1 Protection of PRAM against FPI Writes

The PRAM FPI protection function is provided so that once the PRAM has been loaded (typically at system initialization) the PRAM can be partially or totally protected against FPI write accesses. This function is controlled by the PCP_PPROT register (**“PRAM Protection Register, PCP_PPROT” on Page 11-87**).

When the protection function is enabled (via PCP_PPROT.EN) any incoming FPI write access outside a defined PRAM address range (defined by PCP_PPROT.FBASE) is issued with an error response and the PRAM content remains unmodified.

The address range can be select such that an “Open Window” of PRAM (based at the top of PRAM) remains available for incoming FPI write accesses. The “Open Window” is provided as PRAM is often used for implementation of a “mail-box” to allow communication between the PCP and other on-chip cores.

Regardless of the enabling of write protection the entire PRAM content remains readable via FPI.

Note: The PCP internal PRAM write instructions (i.e. instructions that modify the PRAM content) are unaffected by this protection.

11.7.2 Protection of PRAM against Internally Generated PRAM Writes

Protection of PRAM against internal writes is performed via two regions:-

- Context Save Region
- Protected Channel PRAM

11.7.2.1 Context Save Region Protection

The Context Save Region can be protected by the PRAM Partitioning Scheme (see **“PCP Control and Status Register, PCP_CS” on Page 11-69**). This protection is enabled via PCP_CS.PPE and the size of the context area being protected is defined by PCP_CS.PPS. When enabled the context region is protected from writes by any Channel Program (i.e. regardless of whether Protected or Unprotected).

Note: This scheme also limits the number of Channel Programs that can be invoked.

Note: FPI PRAM write accesses to PRAM are unaffected by this protection.

11.7.2.2 Protected Channel PRAM Protection

To ensure that an Unprotected Channel Program cannot corrupt the PRAM assigned to a protected channel program it is necessary to protect the PRAM space used by the protected channels from instruction executed by non-protected channels. The PCP provides a protection scheme which prevents corruption of a programmable range of locations at the base of PRAM by writes generated by a non-protected channel. This region is termed the “Protected Channel PRAM”. Protection is enabled via PPROT.ENI and the size of the protected region is controlled by PPROT.PSIZE. This function is controlled by the PCP_PPROT register (**“PRAM Protection Register, PCP_PPROT” on Page 11-87**).

Whenever a Unprotected Channel Program executes a PRAM write instruction (and protection is enabled) the target address will be examined to determine whether it lies within the Protected Channel PRAM region. If the address lies within the region then the PRAM write will not take place and the PCP will exit the channel with an IOP (Illegal Operation) error.

Note: FPI PRAM write accesses to PRAM are unaffected by this protection.

11.8 FPI Interface

The PCP operates both as an FPI Master and an FPI Slave.

11.8.1 Operation as an FPI Master

The PCP generates FPI read and write transactions in response to execution of PCP FPI instructions. The PCP can generate Byte, Half-word and Word single transactions and bursts of length two, four and eight. All FPI transactions are generated in Supervisor Mode.

For High Integrity Systems it is necessary to prevent the PCP from generating unwanted FPI writes to critical locations in the event of a PCP malfunction. To address this problem a Memory Protection feature is provided to control the address range that can be written to by the PCP. The scheme is based around a user definable FPI address window. Along with defining the window base address and size the user can select whether:-

- Writes are allowed only to addresses that are within the window (Limit).
- Writes are allowed only to addresses that are outside the window (Exclude).

Whenever the PCP executes an FPI instruction that will result in an FPI write accesses the destination address is checked to ensure that it is to an allowed address. If a write access is to an address that is not allowed then the write will not take place and the PCP will exit the channel with an IOP (Illegal Operation) error.

This function is controlled by the **PCP_FWWIN** register (see **Page 11-91**).

11.8.2 Operation as an FPI Slave

The PCP is visible to FPI Masters as a 256 Kbyte R/W block of memory on the System Bus. The PCP must be accessed only with word (32 bit) accesses. Accessing an unassigned address (i.e. an address outside the range of Control & Status Registers, PRAM and CMEM) will generate an FPI bus error. All PCP locations can be read in either User or Supervisor Modes. All writes must be performed in Supervisor Mode. Attempting to write to any PCP location in User Mode will generate an FPI error. Some Control and Status Registers are ENDINIT protected.

There are some additional user selectable FPI write protection options to support High Integrity operation:-

- Some/all Control and Status registers can be programmed to be ENDINIT protected.
- CMEM can be programmed to be read only.
- PRAM can be programmed to be partially or wholly read-only.

11.9 PCP Error Handling

The PCP contains a number of fail-safe mechanisms to ensure that error conditions are handled gracefully and predictably. In addition to providing an extra level of system robustness suitable for high integrity and safety-critical systems, these mechanisms can often ease the task of finding programming errors during the development process. Whenever an error is detected, the channel program that was executing exits and the PCP_ES register is updated with information to allow determination of the error that occurred, the instruction address, and the channel program that was executing when the error occurred (see **Page 11-32**).

11.9.1 PRAM Protection Violation

PRAM can be considered as being split into a number of distinct areas (see **Section 11.7**).

The default configuration of the PCP allows the PCP to use PRAM as a single area. While this default configuration allows complete flexibility regarding the use of PRAM, this flexibility also introduces the possibility of invalid PCP operation as a result of the following issues:

- Any channel program is allowed to write to any PRAM location (including any location in the CSA). This means that a channel program may be inadvertently programmed to corrupt the context save region or PRAM storage belonging to another channel, causing invalid operation of the corrupted channel when it next executes.
- Generation of an interrupt request to the PCP with a priority number that would cause loading of a context from outside the CSA will cause the spurious execution of a channel program with an invalid context loaded from outside the CSA.

11.9.1.1 Enforced PRAM Partitioning

The lowest of the PRAM areas is the CSA (see **Page 11-16**) which is used for storing context information for each active channel while the channel program is not actually executing.

To avoid spurious PCP operation as a result of programming errors, the PCP can be optionally configured via the global PCP control and status register (PCP_CS) to enforce strict partitioning of PRAM between the CSA and the remainder of PRAM. PRAM partitioning is selected by programming PCP_CS.PPE = 1 and the size of the CSA in use is selected via the PCP_CS.PPS bit field (see **Page 11-69**). When PRAM partitioning has been enabled, a PCP Error will be generated on either one of the following events:

- A channel program executes a PRAM write instruction with a target area within the CSA. This prevents a channel from corrupting the context save region of any other channel.

- An incoming interrupt request causes the PCP to attempt to load a context from outside the CSA. This prevents the PCP from running an invalid channel program as a result of an invalid interrupt request.

Note: Enabling PRAM partitioning (PCP_CS.PPE = 1) with a CSA size of zero (PCP_CS.PPS = 0) is an invalid setting and will cause a PCP error event whenever any interrupt request is received by the PCP.

11.9.1.2 Protected Channel PRAM

When a Protected Channel PRAM area has been programmed (see **Section 11.7.2.2**) then any attempt by an Unprotected Channel Program to write to the Protected Channel PRAM area will generate a PCP error.

11.9.2 FPI Write Window Violation

When an FPI Write Window has been programmed (see **Section 11.8.1**) then any attempt by a Channel Program to write to an FPI address that has been disallowed will generate a PCP error.

11.9.3 Channel Watchdog

The Channel Watchdog is a PCP internal watchdog that optionally allows the user to ensure that the PCP will not become locked into executing a single channel due to an endless loop or unexpected software sequence. As each channel executes, the PCP maintains an internal count of the number of instructions that have been read from CMEM since the channel started. If the watchdog function is enabled (by programming PCP_CS.CWE = 1) and the internal instruction fetch counter reaches the threshold programmed by the user (programmed via PCP_CS.CWT), a PCP Error is generated. The threshold setting (PCP_CS.CWT) is global to all channels. From this it follows that the threshold must be selected to be greater than the maximum number of instructions that can be fetched by any channel program, taking all channels into consideration. It should be noted that the instruction width of the PCP is 16 bits and that therefore execution of an instruction that is encoded into 32 bits (e.g. LDL.IL) will generate two CMEM instruction reads. That will therefore cause the internal watchdog counter to be incremented twice.

Note: Enabling the Channel Watchdog function (PCP_CS.CWE = 1) with a threshold of zero (PCP_CS.CWT = 0) is an invalid setting and will cause a PCP error event whenever any interrupt request is received by the PCP.

11.9.4 Invalid Opcode

The PCP includes the Invalid Opcode mechanism to check that each instruction fetched from CMEM is a legal instruction. If the PCP attempts to execute an illegal instruction, then a PCP error is generated.

Note: The DEBUG instruction must be only used in DEBUG mode otherwise it will be considered to be an illegal operation and will generate an IOP error.

11.9.5 Instruction Address Error

An Instruction Address Error is generated if the PCP attempts to execute an instruction from an illegal address. An address is considered to be illegal if:

- The address is outside the available CMEM area (see **Page 11-157** for the CMEM size implemented in this derivative)

and/or

- The specified address could not be contained in the 16-bit PC (i.e. an address calculation yielded a 16-bit unsigned overflow).

The second of these cases can result from an address calculation either from the execution of a PC relative jump instruction (either a JC, JC.I, or JL instruction), or the PC being incremented following execution of the previous instruction.

11.10 Software In-System Test Support

The PCP protects against memory integrity errors by ECC protection of the PCP memories. This has the unfortunate side-effect of requiring memory blocks wider than the normal data access path to the memory. The additional ECC storage bits are not easily accessible via the existing data paths, causing significant problems where SIST based testing of the memories is required. In order to address this problem the PCP includes improved SIST support, allowing all PCP memory arrays to be accessedto allow the test and debug of the fault tolerant memory systems.

The mapping of hidden memory ECC bits into the PCP address space is controlled by the setting of bits within the SIST Mode Access Control Register (SMACON). The existence of the SMACON register is architecturally defined. However, the fields within SMACON and the effect of the fields on the memory map of the PCP are implementation specific.

Hidden ECC bits are mapped into the CMEM and PRAM areas by setting bits in the SMACON register. The SMACON register is a SFR which can only be written in supervisor mode and is endinit protected. The definition of the SMACON register for the PCP is shown on **Page 11-81**.

The control fields within the SMACON register allow individual control of the local memories. Each memory may be mapped to operate in a number of different modes.

Normal Operation, No Mapping, error detection/correction enabled

No mapping of the ECC bits is performed and normal operation is possible. Error detection/correction is active.

Data Array Mapping, no error detection/correction

No mapping of the ECC bits is performed. Writes to the memory will not affect the ECC bits. Error correction/detection for the memory is disabled. Normal operation (with the exception that ECC protection is not operational) is possible.

Check Array Mapping, no error detection/correction

The ECC bit array (only) of the memory is made visible in the address map (i.e. the memory data array cannot be accessed). Writes to the memory will not affect the data bits. Error correction/detection for the memory is disabled. The PCP must be disabled before, and remain disabled while, this mode is selected for any of the PCP memories.

When this mode is selected the memory ECC bit array replaces the memory data array in the address map. During a read the value of the ECC bits for a location can be determined from bits 6 to 0 of the value read from the location (all other bits read as '0'). During a write the ECC bits are updated from bits 6 to 0 of the written value. The written value of all bits other than bits 6 to 0 is discarded.

Data Array Mapping, error detection/correction enabled.

No mapping of the ECC bits is performed and normal operation is possible.

Note: Unlike TriCore the PCP has no hidden memory arrays (i.e. all PCP memories reside permanently in the system address map). As a result, for the PCP, this mode is identical to "Normal Operation". This mode is retained for compatibility with TriCore SIST.

11.11 Memory Integrity Error Detection and Correction

The PCP includes support for Memory Integrity Error Detection and Correction logic to address the increasing occurrence of memory errors in deep sub-micron CMOS technologies. Soft errors are transient errors in state (not permanent) typically caused by alpha particle hits to the die, causing induced charge which flips the state of storage elements. In current process geometries SRAM arrays are most susceptible to soft error events due to their small size and low stored charge. The detection and deterministic recovery from such memory integrity errors is especially important for automotive applications, such as electronic braking systems and engine management.

The PCP includes the following SRAM arrays:

- Code Memory (CMEM)
- Parameter Memory (PRAM)

Each of these memory arrays will be protected from memory integrity errors, with the specific mechanisms described in the following sections.

Note: Before enabling Error Detection/Correction on an SRAM (i.e. CMEM or PRAM) the user must ensure that all locations within the SRAM have been initialised. If this is not done then unwanted spurious memory errors can be generated.

11.11.1 Definitions

In the following sections memory integrity errors are considered to be either Correctable or Un-correctable. These are defined as follows:-

Un-correctable Memory Integrity Error

If on accessing a memory element containing a memory integrity error hardware is not able to provide the expected data to the core, the integrity error is defined as being Un-correctable.

Correctable Memory Integrity Error

If on accessing a memory element containing a memory integrity error hardware is able to provide the expected data to the core, the integrity error is defined as being correctable.

11.11.2 Architectural Extensions - Registers

A number of additional Special Function Registers (SFRs) have been added to the PCP in order to fully support memory integrity error handling. The function of these registers is explained below while the specific register information is detailed in **Section 11.15**.

11.11.3 Memory Integrity Error Control

The MIECON register controls whether memory errors generate a notification to the SCU or not. MIECON may only be written in supervisor mode and is ENDINIT protected.

Two status registers (MIESTATP for PRAM and MIESTATC for CMEM) are provided to allow software to easily identify locations that have generated memory error events. The xxIEE bits and the appropriate SMACON field settings interact to control the update of these registers.

Errors are reported and the MIESTATx registers are updated only when data read from the memory is actually being utilized (i.e. the memory is either being read via FPI or by the core). In the event of error detection being enabled, a PRAM (double word) location containing an error in both word lanes and the PCP performing a double word read (only during a context restore) the MIESTATP register will be updated as though the error was in the lower word of PRAM.

11.12 Instruction Set Overview

The following sections present an overview of the instruction set and the available addressing modes of the PCP in the TC1798.

11.12.1 DMA Primitives

Table 11-3 describes the two DMA instructions of the PCP.

Table 11-4 DMA Transfer Instructions

DMA Transfer	BCOPY	Move block of data value from FPI Bus source address location to FPI Bus destination address location. Optionally increment or decrement source and destination pointer registers. Optionally repeat instruction until counter CNT1 reaches 0.
	COPY	Move value from FPI Bus source address location to FPI Bus destination address location. Optionally increment or decrement source and destination pointer registers. Optionally repeat instruction until counter CNT1 reaches 0.

11.12.2 Load and Store

Table 11-4 describes the load and store instructions of the PCP.

Note: If a conditional instruction's condition code is false, the operation will be treated as a "No Operation". Register values will not be changed and the flags will not be updated.

Table 11-5 Load and Store Instructions

Load	LD.F	Load value from FPI Bus address location into register (FPI Bus address = register content)
	LD.I	Load immediate value into register
	LD.IF	Load value from FPI Bus address location into register (FPI Bus address = register content + immediate offset)
	LD.P	Load value from PRAM address location into register (PRAM address = DPTR + register offset)
	LD.PI	Load value from PRAM address location into register (PRAM address = DPTR + immediate offset)
	LDL.IL	Load 16-bit immediate value into lower bits [15:0] of register
	LDL.IU	Load 16-bit immediate value into upper bits [31:16] of register
Store	ST.F	Store register value to FPI Bus address location (FPI Bus address = register content)
	ST.IF	Store register value to FPI Bus address location (FPI Bus address = register content + immediate offset)
	ST.P	Store register value to PRAM address location (PRAM address = DPTR + register offset)
	ST.PI	Store register value to PRAM address location (PRAM address = DPTR + immediate offset)
Move	MOV	Conditionally move register value to register

11.12.3 Arithmetic and Logical Instructions

Arithmetic instructions that are fully register-based execute conditionally depending on the specified Condition Code A (see Page 11-99). All other arithmetic instructions such as PRAM (.PI), indirect (.I), and FPI (.F and .IF) execute unconditionally.

Note: If a conditional instruction's condition code is false, the operation will be treated as a "No Operation". Register values will not be changed and the flags will not be updated.

Table 11-6 Arithmetic Instructions

Add	ADD	Add register to register (conditionally)
	ADD.I	Add immediate value to register
	ADD.F	Add content of FPI Bus address location to register (byte, half-word or word)
	ADD.PI	Add content of PRAM address location to register
Subtract	SUB	Subtract register from register (conditionally)
	SUB.I	Subtract immediate value from register
	SUB.F	Subtract content of FPI Bus address location from register (byte, half-word or word)
	SUB.PI	Subtract content of PRAM address location from register
Compare	COMP	Compare register to register (conditionally)
	COMP.I	Compare immediate value to register
	COMP.F	Compare content of FPI Bus address location to register (byte, half-word or word)
	COMP.PI	Compare content of PRAM address location to register
Negate	NEG	Negate register (2's complement, conditionally)

Logical instructions that are fully register-based execute conditionally as determined by the specified Condition Code A. All other logical instructions, such as PRAM (.PI), indirect (.I), and FPI (.F and .IF) execute unconditionally.

Table 11-7 Logical Instructions

Logical And	AND	Register AND register (conditionally)
	AND.F	Content of FPI Bus address location AND register (byte, half-word or word)
	AND.PI	Content of PRAM address location AND register
	MCLR.PI	Clear specified bits within a PRAM location

Table 11-7 Logical Instructions (cont'd)

Logical Or	OR	Register OR register (conditionally)
	OR.F	Content of FPI Bus address location OR register (byte, half-word or word)
	OR.PI	Content of PRAM address location OR register
	MSET.PI	Set specified bits within a PRAM location
Logical Exclusive-Or	XOR	Register XOR register (conditionally)
	XOR.F	Content of FPI Bus address location XOR register (byte, half-word or word)
	XOR.PI	Content of PRAM address location XOR register
Logical Not	NOT	Invert register (1's complement, conditionally)
Shift	SHL	Shift left register
	SHR	Shift right register
Rotate	RL	Rotate left register
	RR	Rotate right register
Prioritize	PRI	Calculate position of first set bit (1-bit) in register, from left

Note: If a conditional instruction's condition code is false, the operation will be treated as a "No Operation". Register values will not be changed and the flags will not be updated.

11.12.4 Bit Manipulation

All bit manipulation instructions except INB are executed unconditionally. If conditional bit handling is required, INB should be used.

Table 11-8 Bit Manipulation Instructions

Set Bit	SET	Set bit in register
	SET.F	Set bit in FPI Bus address location
Clear Bit	CLR	Clear bit in register
	CLR.F	Clear bit in FPI Bus address location
Insert Bit	INB	Insert carry flag into register (position given by content of a register)
	INB.I	Insert carry flag into register (position given by immediate value)
Check Bit	CHKB	Set carry flag depending on value of specified register bit

11.12.5 Flow Control

Table 11-8 describes flow control instructions of the PCP in the TC1798.

Table 11-9 Flow Control Instructions

Jump	JC	Jump conditionally to PC + short immediate offset address
	JC.A	Jump conditionally to immediate absolute address
	JC.I	Jump conditionally to PC + register offset address
	JC.IA	Jump conditionally to register absolute address
	JL	Jump unconditionally to PC + long immediate offset address
Exit Channel	EXIT	Unconditionally exit channel program execution (optionally generate interrupt request and/or inhibit channel)
No Operation	NOP	Low-power No-Operation
Debug	DEBUG	Conditionally generate debug event (optionally stop channel program execution)

11.12.6 Addressing Modes

The PCP needs to address locations in memory in different ways, as determined by the type of memory being accessed and the type of action being performed on that location.

11.12.6.1 FPI Bus Addressing

All FPI Bus accesses from the PCP are indirect to some extent. The main indirect addressing on the FPI Bus uses a 32-bit absolute address located in the GPR indicated in the instruction. This address must be properly aligned for the type of data access – byte, half-word or word. If it is not aligned, the results are undefined.

- Effective Target Address [31:0] = <R[a]>

where a is the number of the register, for instance, R2. Instructions using this address mode are indicated through the ".F" suffix.

For indirect-plus-immediate addressing on the FPI Bus, the 32-bit absolute address located in the GPR indicated in the instruction is added to the immediate 5-bit offset value encoded in the instruction. This address must be properly aligned for the type of data access (byte, half-word or word). If it is not aligned, the results are undefined.

- Effective Target Address [31:0] = <R[a]> + #offset5

where a is the number of the register and #offset5 is a 5-bit immediate offset value. Instructions using this addressing mode are indicated through the ".IF" suffix (only available for load and store, LD.IF and ST.IF).

This addressing mode is particularly useful for managing peripherals, where the peripheral base address is held in R[a], and the offset can index directly into a specific control register.

The BCOPY and COPY instructions use the indirect absolute addressing with predefined PCP registers. Register R4 is used as the source address pointer, while R5 represents the destination address pointer.

- Effective Source Address [31:0] = <R4>
- Effective Destination Address [31:0] = <R5>

Note: All FPI Bus accesses by the PCP are performed in Supervisor mode.

Note: The PCP is not allowed to access its own registers via instructions executed in the PCP.

11.12.6.2 PRAM Addressing

The PRAM is always addressed indirectly by the PCP. The normal address used is the value of the R7.DPTR field (8 bits) concatenated with an immediate 6-bit offset value encoded in the instruction, yielding a 14-bit word address. This enables access to 16 Kwords (64 Kbytes). Because R7.DPTR is part of a channel program's context, a channel program may alter the DPTR value at any time.

- Effective PRAM Address[13:0] = <R7.DPTR> << 6 + #offset6

Instructions using this addressing mode are indicated through the ".PI" suffix.

To provide effective indexing into large tables or stores of data, an alternate form of indirect addressing can also be used on load and store operations to PRAM. The value of the DPTR field (8 bits) is concatenated with the least significant 6 bits of R[a], again yielding a 14-bit word address. The most significant bits [31:6] of R[a] are ignored.

- Effective PRAM Address[13:0] = <R7.DPTR> << 6 + <R[a][5:0]>

Instructions using this addressing mode are indicated through the ".P" suffix (load and store only, LD.P and ST.P).

11.12.6.3 Bit Addressing

Single bits can be addressed in the PCP GPRs or in FPI Bus address locations. A 5-bit value indicates the location of a bit in the register specified in the instruction. This bit location is either given through an immediate value in the instruction or through the lower five bits of a second register (indirect addressing).

- Effective Bit Position[31:0] = #imm5
- Effective Bit Position[31:0] = <R[a][5:0]>

The immediate bit addressing is used by instructions SET and CLR and their variants as well as by INB.I and CHKB. Indirect bit addressing is used by the INB instruction only.

11.12.6.4 Flow Control Destination Addressing

The jump instructions are split into two groups: PC-relative jumps, and jumps to an absolute address.

For PC-relative jumps, the destination address is a positive or negative offset from the PC of the next instruction. The offset is either contained in the lower 16 bits of a register (the upper 16 bits are ignored), or is given as immediate value of the instruction. The immediate values are sign-extended to 16 bits. If the effective jump address is outside the available CMEM area (or the jump address calculation caused an overflow), then a PCP error condition has occurred.

- Effective JUMP Address[15:0] = NextPC + Signed(R[a][15:0]); +/- 32K instructions
- Effective JUMP Address[15:0] = NextPC + Sign-Extend(#offset10);
  +/- 512 instructions

- Effective JUMP Address[15:0] = NextPC + Sign-Extend(#offset6);
  +/- 32 instructions

The function NextPC indicates the instruction that would be fetched next by the program counter. Instructions using this addressing are JL, JC and JC.I.

For absolute addressing, the actual address in CMEM where program flow is to resume is either an immediate value #imm16 in the CMEM location immediately following the jump instruction, or it is contained in the lower 16 bits of a register. If the value is greater than the PC size implemented, an error condition has occurred.

- Effective JUMP Address[15:0] = #imm16
- Effective JUMP Address[15:0] = <R[a]>

Instructions using these addressing modes are JC.A (immediate absolute address) and JC.IA (indirect absolute address).

11.13 FPI Interface

Any FPI Bus master (on the TC1798's System Peripheral Bus) can access the three distinct PCP address ranges from the FPI Bus side, on the other hand the PCP master interface can also access any address on the FPI bus. Normally, the CPU initializes the control registers via FPI Bus access. Thereafter, the PCP should not access its control registers itself through PCP instructions. Apart from the access via FPI Bus, there is no direct way to the PCP control registers.

Accesses to the PCP control and status register, the PRAM, and the CMEM are detailed in the following sections.

11.13.1 Access to the PCP Control Registers from the FPI Bus

FPI Bus accesses to the PCP control registers must always be performed in Supervisor Mode with word accesses; byte or half-word accesses will result in a bus error.

All PCP control registers can be read at any time. Register PCP_CS can be optionally Endinit-protected via bit PCP_CS.EIE (see **Page 11-69**). If CS.EIE & ENDINIT = True, then any write access to this register is inhibited. The clock control register PCP_CLC is endinit-protected. The Software In-System Test register is also endinit-protected.

Additionally (see below) for High Integrity applications the entire Register content can be ENDINIT protected (see below).

11.13.1.1 PCP Control Register Protection

To allow the PCP to handle system critical tasks it is necessary to ensure that the PCP can operate properly regardless of a failure in another part of the system or the PCP itself. This means that it is necessary to protect the Control and Status Registers from such failures.

The configuration register content can only be modified via the FPI. Protection of the PCP configuration therefore consists of prevention of unwanted FPI writes to the PCP registers.

The normal model of PCP operation is that the PCP is configured at system initialization and the configuration remains unchanged for the duration of operation of the system. Protection therefore consists of a simple locking scheme to prevent any write to registers once the PCP has been configured. Once the PCP has been configured (at system initialization) the Registers can be locked such that, unless ENDINIT is clear, all incoming FPI write accesses are issued with an error response and the PCP configuration will remain unmodified.

If is required to modify content of the registers once they have been locked it is necessary to clear the ENDINIT bit (via the system Watchdog Timer) such that the Registers become writeable again.

Regardless of protection the entire Register content remains readable via FPI.

This function is controlled by the RPROT register (**“Register Protection Register, PCP_RPROT” on Page 11-85**).

11.13.2 Access to the PRAM from the FPI Bus

FPI Bus accesses to the PRAM must always be performed with word accesses; byte or half-word accesses will result in a bus error.

Attention needs to be paid when accessing the CSAs and data sections of the PCP channel programs. The location of a specific channel’s CSA is dependent on the chosen Context Model, Full, Small or Minimum Context. **Table 11-10** shows these addresses.

Table 11-10 FPI Bus Access to CSAs

Channel	Full Context	Small Context	Minimum Context
0 (see note)	PRAM Base Address + 00_H	PRAM Base Address + 00_H	PRAM Base Address + 00_H
1	PRAM Base Address + 20_H	PRAM Base Address + 10_H	PRAM Base Address + 08_H
2	PRAM Base Address + 40_H	PRAM Base Address + 20_H	PRAM Base Address + 10_H
3	PRAM Base Address + 60_H	PRAM Base Address + 30_H	PRAM Base Address + 18_H
n	PRAM Base Address + $n \times 20_H$	PRAM Base Address + $n \times 10_H$	PRAM Base Address + $n \times 08_H$

Note: Since channel 0 is not defined (no service request with SRPN = 0), the first area is not an actual CSA. It is recommended that this area should not be used by PCP channel programs.

The FPI Bus address of a word location pointed to by the Data Pointer R7_DPTR is calculated by the following formula:

- Effective FPI Bus address[31:0] = (PRAM Base Address) + (<DPTR> << 6)

11.13.3 Access to the CMEM from the FPI Bus

FPI Bus accesses to the CMEM must always be performed with word accesses; byte or half-word accesses will result in a bus error.

When using a channel entry table, the FPI Bus address of a specific channel’s entry location is given by the following formula:

- Effective FPI Bus address[31:0] = (CMEM Base Address) + $04_H \times$ channel number

The FPI Bus address of an instruction pointed to by the PCP program counter, PC, is calculated by the following formula:

- Effective FPI Bus address[31:0] = (CMEM Base Address) + <PC> << 1

11.14 Debugging the PCP

For debugging the PCP, a special instruction, DEBUG, is provided. This instruction can only be used when the PCP is in Debug Mode. It can be placed at important locations inside the code to track and trace program execution. The execution of the instruction depends on a condition code specified with the instruction. The actions programmed for this instruction will only take place if the specified condition is true.

The following actions are performed when the DEBUG instruction is executed and the condition code is true:

- Store the current PC, i.e. the address of the DEBUG instruction, in register PCP_ES.EPC
- Store the current channel number in register PCP_ES.EPN

In addition, the following operations can be programmed through fields in the DEBUG instruction:

- Optionally stop the channel program execution (instruction field SDB)
- Optionally generate an external debug event at pin $\overline{\text{BRKOUT}}$ (instruction field EDA)
- Optionally prevent the PCP from executing any further channel programs (instruction field DAC)
- Optionally cause the PCP to decrement the PC prior to saving the channel context (instruction field RTA)

If the DEBUG instruction is programmed to stop the channel program execution, the action taken by the PCP depends on the value of the RTA instruction field:

- If RTA = 0, the PCP disables further invocations of the current channel through clearing bit R7.CEN, and then performs a context save. The execution of this channel is stopped at the point of the DEBUG instruction. If the DAC instruction field = 0, the PCP will continue to operate, accepting service requests for other channels as they arise. Since the stopped channel was disabled before saving its context, service requests for this channel will result in an error exit (see **Page 11-32**). When re-enabling the channel, its enable bit CEN in the saved context location CR7 must be set.
- If RTA = 1, the PCP does not modify bit R7.CEN (i.e. the channel remains enabled), decrements the PC (so that it again points to the DEBUG instruction), and then performs a context save. The execution of this channel is stopped at the point of the DEBUG instruction. If the DAC instruction field = 0, the PCP will continue to operate, accepting service requests for channels as they arise. Since the stopped channel was not disabled before saving its context, service requests for this channel will not result in an error exit, but will simply cause re-execution of the DEBUG instruction and hence a repeat of the channel exit.

Note: When a channel is stopped by DEBUG, the context of the stopped channel will be saved to the appropriate region of the CSA before the channel terminates. Where a Small or Minimum Context model is being used, the values of the GPRs not

included in the context will not be saved, and indeed these register values may be changed by the operation of another active channel. In this case, the required registers should be explicitly saved to PRAM by store instructions prior to execution of the DEBUG instruction.

If the DEBUG instruction is programmed to stop all channel program execution, the PCP disables further invocations of any channel by clearing bit PCP_CS.EN. The execution of this channel is only stopped according to the SDB instruction field value. The PCP will only start to reaccept service requests when PCP_CS.EN is written to 1.

Note: The DEBUG instruction must be only used in DEBUG mode; otherwise it will generate an IOP error.

Note: If PCP_CS.RCB = 0 (Channel Resume Mode), then the channel program will begin executing at whichever PC is restored from the context location CR7.PC. If PCP_CS.RCB = 1 (Channel Restart Mode), then the channel program is forced to always start at its channel entry table location, no matter what the restored context value is for the PC. This means that in Channel Restart Mode, it is not possible to restart the channel program from where it was halted by the debug event. It is recommended that when using Channel Restart Mode, the user should also program all EXIT instructions with the "EP = 0" setting to allow selection of Channel Resume Mode for debugging without changing operation of the channel programs.

11.15 PCP Registers

The PCP can be viewed as being a peripheral on the FPI Bus. As with any other peripheral, there are control registers, normally set by the CPU acting as an external FPI Bus master to the PCP during initialization. Control registers select the operating modes of the PCP, and status registers provide information about the current state of the PCP to the external FPI Bus master.

Accessing of Control Registers

The control registers are accessible by any master via the FPI Bus. The control registers must be configured at initialization and then left unaltered. This is typically done by the CPU. The only setting that can be dynamically modified is the PCP_CS.EN bit. All other bits must only be modified when PCP_CS.EN = 0 and PCP_CS.RS = 0.

The PCP control and status registers are accessible only to the CPU when it is operating in Supervisor mode. PCP control and status registers must be accessed with 32-bit read and write operations only.

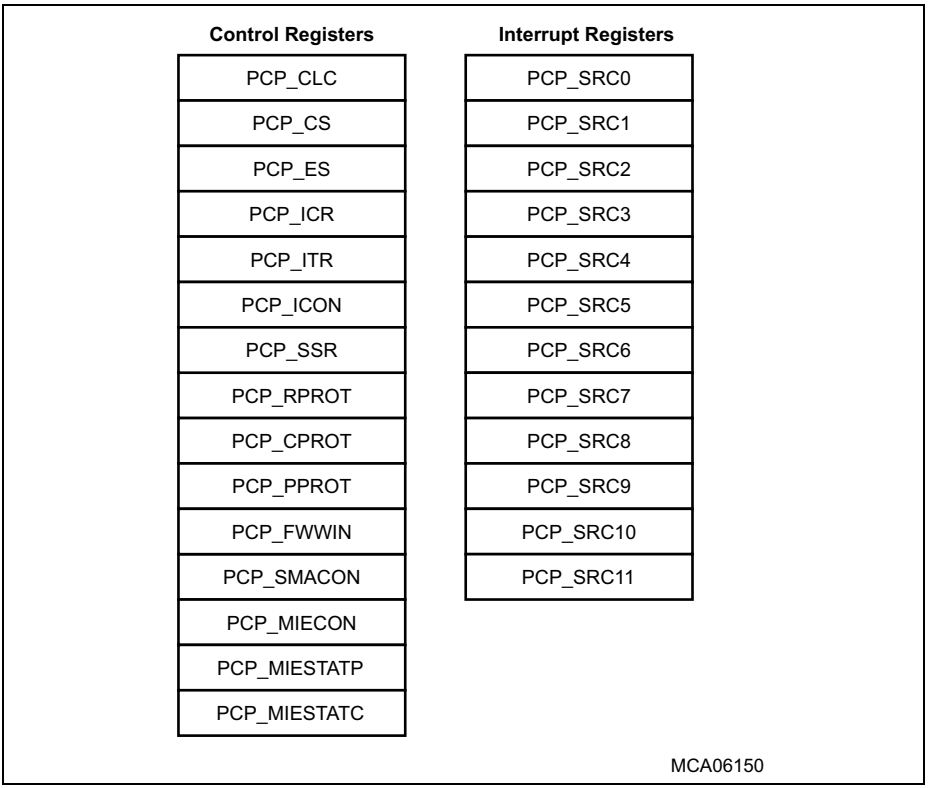

Figure 11-13 PCP Registers

PCP Register Overview

The address map of the PCP starts at its base address as shown in **Table 11-19**. The address offsets of the PCP registers are described in **Table 11-11**.

Table 11-11 Register Overview of PCP

1) The absolute register address is calculated as follows:
Module Base Address + Offset Address (shown in this column)

2) A write access is allowed to this register (i.e. no bus error is generated) but as there are no writable bits the register value is unaffected by the write.

3) Endinit protection is controlled by the EIE bit.

11.16 PCP Registers Address Space

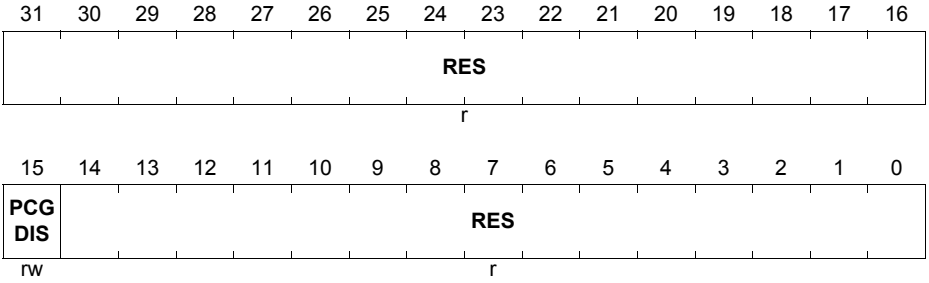
Table 11-12 Registers Address Space

Module	Base Address	End Address	Note
PCP	$F004\ 3F00_H$	$F004\ 3FFF_H$	

11.17 Registers

11.17.1 PCP Clock Control Register, PCP_CLC

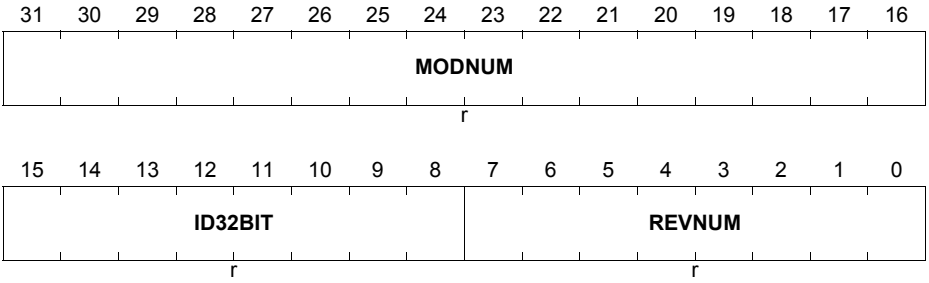
PCP_CLC
PCP Clock Control Register **(00_H)** **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
RES	[31:16]	r	**Reserved** Read as 0; should be written with 0.
PCGDIS	15	rw	**Clock Gating Disable Bit** Allows clock gating to be disabled. 0_B PCP Internal Clock stops when PCP is idle (default after reset) 1_B PCP Internal Clock always runs
RES	[14:0]	r	**Reserved** Read as 0; should be written with 0.

11.17.2 PCP Module Identification Register, PCP_ID

PCP_ID
PCP Module Identification Register (08_H) **Reset Value: 0020 C0XX$_H$**



Field	Bits	Type	Description
MODNUM	[31:16]	r	**PCP Identification Number** value = 0020_H
ID32BIT	[15:8]	r	**32-bit Module Identification Number Marker** value = $C0_H$
REVNUM	[7:0]	r	**PCP Revision Number** Implementation specific value = 08_H

11.17.3 PCP Control and Status Register, PCP_CS

This register can be Endinit-protected via bit EIE.

PCP_CS
PCP Control/Status Register **(10_H)** **Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ESR								CWT							CWE
rw								rw							rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PPS							PPE	CS		EIE	RCB	RES	RS	RES	EN
rw							rw	rw		rw	rw	r	rh	r	rw

Field	Bits	Type	Description
ESR	[31:24]	rw	**Error Service Request Number** SRPN for interrupt to CPU on an error condition. 00_H No interrupt request posted (default) 01_H Post an SRPN interrupt to CPU on an error condition 10_H Post an SRPN interrupt to CPU on an error condition
CWT	[23:17]	rw	**Channel Watchdog Threshold** 0_D Reserved 1_D Threshold = 16 instructions ...$_B$ ... 127_D From 1_D up to 127_D (n), the threshold = 16 × 'n' instructions
CWE	16	rw	**Channel Watchdog Enable** 0_B Disable Channel Watchdog 1_B Enable Channel Watchdog *Note: When enabled, the Channel Watchdog counts the number of instructions executed since the channel started. If this number exceeds the Channel Watchdog Threshold, a PCP error is generated.*

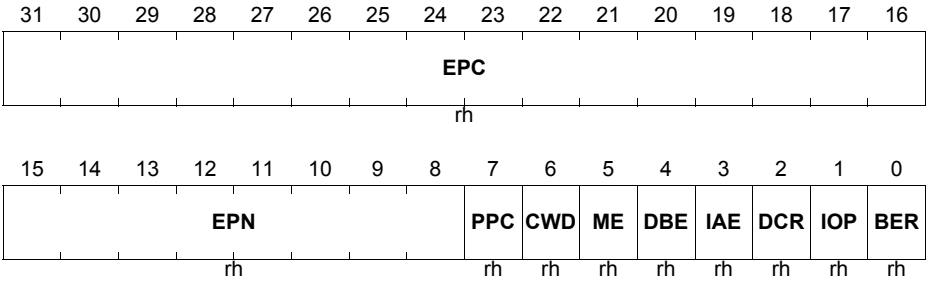
Field	Bits	Type	Description
PPS	[15:9]	rw	**PRAM Partition Size** 0_D Default, only allowed with PPE = 0 1_D CSA contains 3 context save regions $...B$ ... 127_D CSA contains 1 + 2 × 127 context save regions *Note: The actual size of the CSA (in words) is given by the formula (2 × n + 1) × m, where m is the number of registers in the selected Context Model.* *If PPE = 1 and the PCP attempts to perform a data write to PRAM addresses below the CSA, an error condition has occurred.* *This setting also controls the maximum channel number (MCN) used in system. The maximum channel number is MCN = 2 × n. If the SRPN is greater than MCN, an error condition has occurred.* *For example, setting PPS to n = 3 will give a CSA containing 7 context save regions. As channel 0 cannot be used and MCN = 6, channels 1 to 6 are allowed.*
PPE	8	rw	**PRAM Partitioning Enable** 0_B PRAM is not partitioned 1_B PRAM is partitioned *Note: When partitioned, the PRAM is divided into two areas (CSA and remainder). A PCP error will be generated on an inappropriate action in either region (PCP write operation with a target address in the CSA, or context restore from outside the CSA).*
CS	[7:6]	rw	**Context Size Selection** 00_B Use Full Context for all channels 01_B Use Small Context for all channels 10_B Use Minimum Context for all channels 11_B Reserved
EIE	5	rw	**Endinit Enable** 0_B PCP_CS is not Endinit protected. 1_B PCP_CS is Endinit protected.

Field	Bits	Type	Description
RCB	4	rw	**Channel Start Mode Control** 0_B Channel resume operation mode selected; channel start PC is taken from restored context 1_B Channel restart operation mode selected; channel start PC is derived from the requested channel number (= priority number of service request) *Note: This is a global control bit and applies to all channels.*
RES	3	r	**Reserved** Read as 0; should be written with 0.
RS	2	rh	**PCP Run/Stop Status Flag** 0_B PCP is stopped or idle (default) 1_B PCP is currently running
RES	1	r	**Reserved** Read as 0; should be written with 0.
EN	0	rw	**PCP Enable** 0_B PCP is disabled for operation (default) 1_B PCP is enabled for operation *Note: This bit does not enable/disable clocks for power saving. It stops the PCP from accepting new service requests.*

11.17.4 PCP Error/Debug Status Register, PCP_ES

This is a read-only register, providing state information about error and debug conditions.

PCP_ES
PCP Error/Debug Status Register (14_H) Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
EPC	[31:16]	rh	**Error PC** PC value of the instruction that was executing when an error or debug event occurred. Default = 0000_H.
EPN	[15:8]	rh	**Error Service Request Priority Number** Channel number of the channel that was operating when the last error/debug event occurred. The value stored is the SRPN which invoked this channel (= channel number), NOT the current PCP priority number stored in field CPPN in register PICR. Default = 00_H.
PPC	7	rh	**PRAM Partitioning Check** Set if the last error/debug event was an error generated by a channel program attempting to perform a write to a PRAM address within the CSA, or receipt of an interrupt request that would have caused a context restore from outside the CSA.
CWD	6	rh	**Channel Watchdog Triggered** Set if the last error/debug event was an error generated by a channel program attempting to execute more instructions than allowed by PCP_CS.CWT.
ME	5	rh	**Memory Error** This bit is set if a PCP internal memory error has occurred. See **Table 11.22 "Implementation of the PCP in the TC1798" on Page 11-157** for TC1798 specific implementation.
DBE	4	rh	**Debug Event Flag** Set if the last error/debug event was a debug event. *Note: A debug event does not cause the posting of an interrupt to the CPU.*
IAE	3	rh	**Instruction Address Error** Set if the last error/debug event was an error generated by the PCP attempting to fetch an instruction from an address outside the implemented CMEM range as a result of a jump or branch instruction; otherwise, clear.

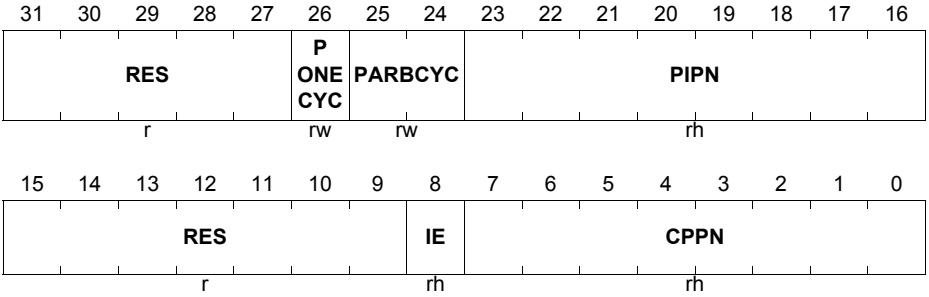
Field	Bits	Type	Description
DCR	2	rh	**Disabled Channel Request Flag** Set if the last error/debug event was an error generated by receipt of an interrupt request with an SRPN that attempted to start a disabled PCP channel; otherwise, clear.
IOP	1	rh	**Invalid Opcode** Set if the last error/debug event was an error generated by the PCP attempting to execute an Invalid Opcode (i.e. the value fetched from CMEM for execution by the PCP did not represent a valid instruction), otherwise clear.
BER	0	rh	**Bus Error Flag** Set if the last error/debug event was an error generated by an FPI Bus error or an invalid address access; otherwise, clear. *Note: An FPI Bus error event does not cause the PCP to post an error interrupt to the CPU. An FPI Bus error interrupt is, however, generated by the FPI control logic.*

Note: An interrupt request with the SRPN held in PCP_CS.ESR is posted to the CPU whenever a PCP error event, other than an FPI Bus error occurs. FPI Bus error interrupt generation is automatically handled by the FPI Bus control logic, rather than by the PCP. The execution of a DEBUG instruction is not classed as an error event and does not therefore generate an interrupt request to the CPU. The entire contents of the register are updated whenever there is a debug or an error event detected (i.e. all status/error bits, other than the bit representing the last PCP error/debug event, are cleared). This register therefore only provides a record of the last error/debug event encountered. The only way to clear this register is to reset the PCP.

11.17.5 PCP Interrupt Control Register, PCP_ICR

This register controls the operation of the PCP Interrupt Control Unit (PICU).

PCP_ICR
PCP Interrupt Control Register (20_H) Reset Value: 0000 0000$_H$

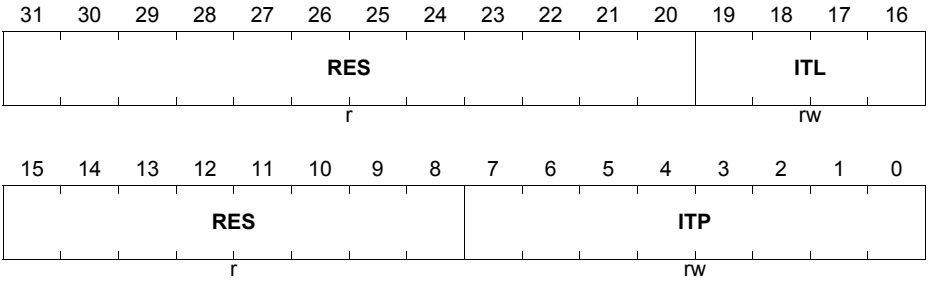


Field	Bits	Type	Description
RES	[31:27]	r	**Reserved** Read as 0; should be written with 0.
PONECYC	26	rw	**Clocks per Arbitration Cycle Control** This bit determines the number of clocks per arbitration cycle. 0_B Two clocks per arbitration cycle (default) 1_B One clock per arbitration cycle
PARBCYC	[25:24]	rw	**Number of Arbitration Cycles Control** This bit field controls the number of arbitration cycles used to determine the request with the highest priority. It follows the same coding scheme as described for the CPU interrupt arbitration. 00_B Four arbitration cycles (default) 01_B Three arbitration cycles 10_B Two arbitration cycles 11_B One arbitration cycle
PIPN	[23:16]	rh	**Pending Interrupt Priority Number** This read-only field is updated by the PICU at the end of each arbitration process, and indicates the priority number of a pending request. PIPN is set to 00_H when no request is pending and at the beginning of a new arbitration process.
RES	[15:9]	r	**Reserved** Read as 0; should be written with 0.

Field	Bits	Type	Description
IE	8	rh	**Reserved**
CPPN	[7:0]	rh	**Current PCP Priority Number** This field indicates the current priority level of the PCP and is automatically updated by hardware on entry into an interrupt service routine.

11.17.6 PCP Interrupt Threshold Register, PCP_ITR

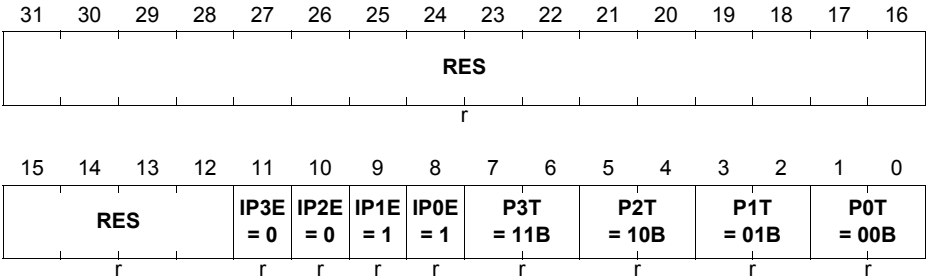
PCP_ITR
PCP Interrupt Threshold Control Register
(24_H) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
RES	[31:20]	r	**Reserved** Read as 0; should be written with 0.
ITL	[19:16]	rw	**Interrupt Threshold Level** This bit field specifies the number of active interrupt entries at which an warning interrupt should be issued to the interrupt queue associated with interrupt bus 0 (i.e. when the number of active port 0 interrupt requests stored in all SRCx registers reaches this value then an interrupt is posted to port 0 with the priority programmed into the ITP field). When ITL is programmed to 0 or is ≥ the number of SRCx registers that can contain port 0 interrupt requests, the threshold warning mechanism is disabled).
RES	[15:8]	r	**Reserved** Read as 0; should be written with 0.
ITP	[7:0]	rw	**PCP Interrupt Threshold Service Request Priority Number** This field contains the interrupt priority that is to be posted to the interrupt queue associated with interrupt bus 0 when the threshold condition is reached (setting this value to 0 or disables the threshold detection mechanism).

11.17.7 PCP Interrupt Configuration Register, PCP_ICON

PCP_ICON
PCP Interrupt Configuration Register (28_H) **Reset Value: 0000 03E4$_H$**

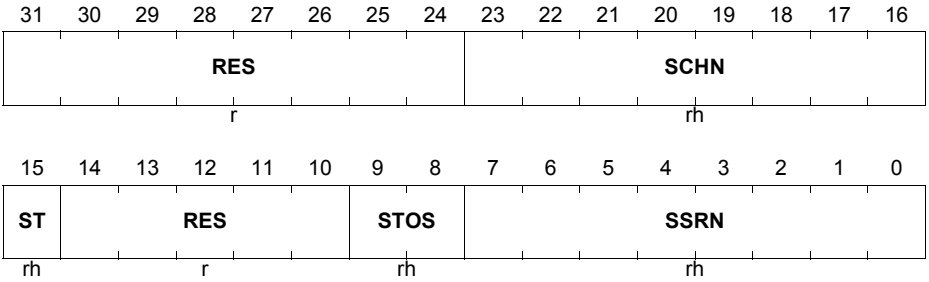


Field	Bits	Type	Description
RES	[31:12]	r	**Reserved** Read as 0.
IP3E	11	r	**PCP Interrupt Bus 3 Enable** This bit reflects the status of interrupt bus 3. Interrupt bus 3 is always disabled (not implemented in the TC1798).
IP2E	10	r	**PCP Interrupt Bus 2 Enable** This bit reflects the status of interrupt bus 2. Interrupt bus 2 is always disabled (not implemented in the TC1798).
IP1E	9	r	**PCP Interrupt Bus 1 Enable** This bit reflects the status of interrupt bus 1 (PCP interrupt arbitration bus). Interrupt bus 1 is always enabled.
IP0E	8	r	**PCP Interrupt Bus 0 Enable** This bit reflects the status of interrupt bus 0 (CPU interrupt arbitration bus). Interrupt bus 0 is always enabled.
P3T	[7:6]	r	**PCP Interrupt Bus 3 TOS Mapping** This field reflects the TOS associated with interrupt bus 3. *Note: Interrupt bus 3 is not available in the TC1798.*

Field	Bits	Type	Description
P2T	[5:4]	r	**PCP Interrupt Bus 2 TOS Mapping** This field reflects the TOS associated with interrupt bus 2. *Note: Interrupt bus 2 is not available in the TC1798.*
P1T	[3:2]	r	**PCP Interrupt Bus 1 TOS Mapping** This field reflects the TOS associated with interrupt bus 1 (PCP interrupt arbitration bus). The PCP should use this value in R6.TOS when it wishes to raise an interrupt request to itself (the PCP is always connected to interrupt bus 1).
P0T	[1:0]	r	**PCP Interrupt Bus 0 TOS Mapping** This field reflects the TOS associated with interrupt bus 0 (CPU interrupt arbitration bus). The PCP should use this value in R6.TOS when it wishes to raise an interrupt request via interrupt bus 0.

11.17.8 PCP Stall Status Register, PCP_SSR

PCP_SSR
PCP Stall Status Register **($2C_H$)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
RES	[31:24]	r	**Reserved** Read as 0.
SCHN	[23:16]	rh	**PCP Stalled Channel Number** This field shows the channel number of the channel that was executing when the last (or present) stall condition occurred. This field can only be cleared by a reset.
ST	15	rh	**PCP Stalled Status** This bit shows the stalled status of the PCP 0_B PCP is not stalled 1_B PCP is stalled
RES	[14:10]	r	**Reserved** Read as 0.
STOS	[9:8]	rh	**PCP Stalled Type-of-Service** This field shows the Type-Of-Service to which an interrupt was being posted that caused the last (or present) stall condition (i.e. the service request queue that was full when the PCP attempted to post a request to it). This field can only be cleared by a reset.

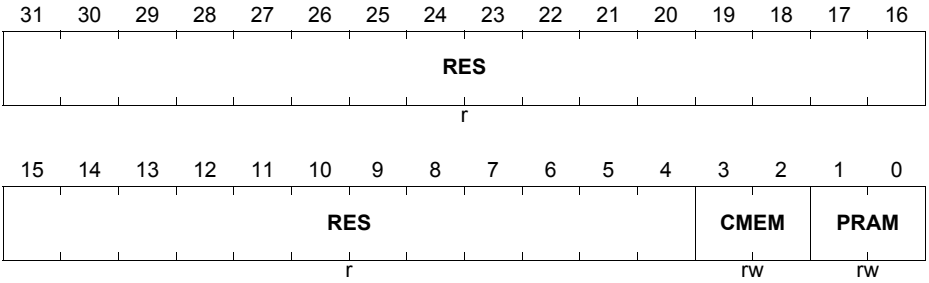
Field	Bits	Type	Description
SSRN	[7:0]	rh	**PCP Stalled Service Request Number** This field shows the Service Request Number that was being posted when the last (or present) stall condition occurred. This field can only be cleared by a reset.

11.17.9 SIST Mode Access Control Register, PCP_SMACON

*Note: Please see **Section 11.10** on **Page 11-46** for more information regarding the use of this register.*

This register is ENDINIT protected.

PCP_SMACON
SIST Mode Access Control Register (40_H) **Reset Value: $0000\ 0000_H$**



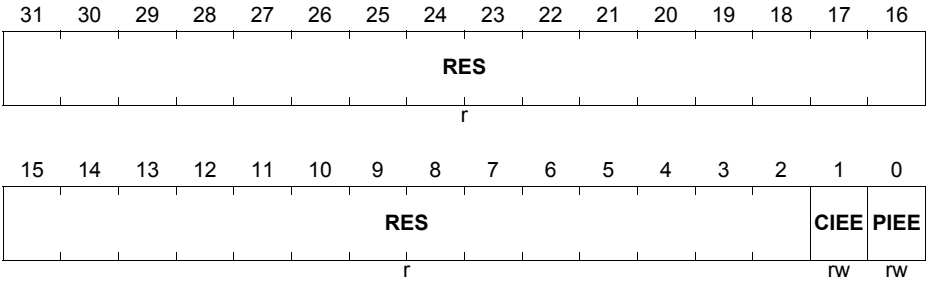
Field	Bits	Type	Description
RES	[31:4]	r	**Reserved** returns ‘0’ if read; should be written with ‘0’.
CMEM	[3:2]	rw	**CMEM SIST mode access control** 00_B Normal Operation, No Mapping 01_B Data Array Mapping, no error detection/correction 10_B Check Array Mapping, no error detection/correction 11_B Data Array Mapping, error detection/correction enabled
PRAM	[1:0]	rw	**PRAM SIST mode access control** 00_B Normal Operation, No Mapping 01_B Data Array Mapping, no error detection/correction 10_B Check Array Mapping, no error detection/correction 11_B Data Array Mapping, error detection/correction enabled

11.17.10 Memory Integrity Error Control Register, PCP_MIECON

*Note: Please see **Section 11.11** on **Page 11-47** for more information regarding the use of this register.*

This register is ENDINIT protected.

PCP_MIECON
SIST Mode Access Control Register (50_H) **Reset Value: $0000\ 0000_H$**

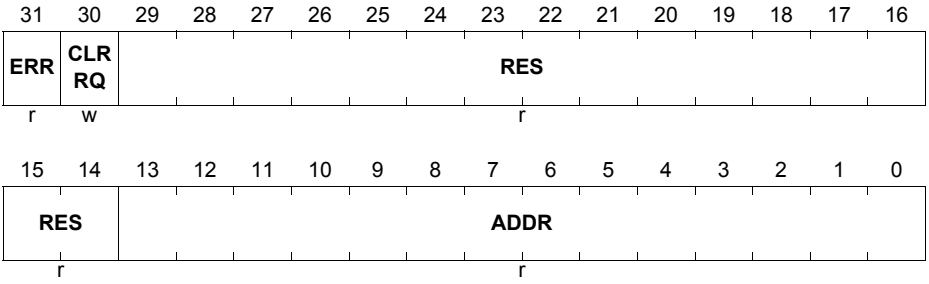


Field	Bits	Type	Description
RES	[31:2]	r	**Reserved** returns ‘0’ if read; should be written with ‘0’.
CIEE	1	rw	**CMEM Integrity Error Enable** Enables the integrity error handling for CMEM.
PIEE	0	rw	**PRAM Integrity Error Enable** Enables the integrity error handling for PRAM.

11.17.11 Memory Integrity Error Status Register for PRAM, PCP_MIESTATP

*Note: Please see **Section 11.11** on **Page 11-47** for more information regarding the use of this register.*

PCP_MIESTATP
Memory Integrity Error Status Register for PRAM(58_H) Reset Value: $0000\ 0000_H$

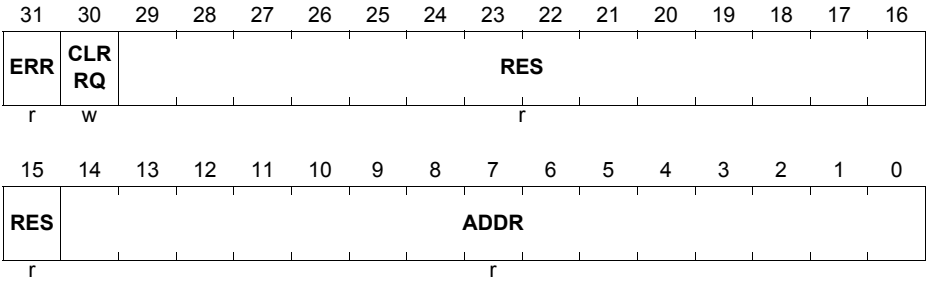


Field	Bits	Type	Description
ERR	31	r	**PRAM Memory Integrity Error Flag** Set when a memory integrity error is encountered . This bit remains set until the CLRRQ bit is written with ‘1’ or the PCP is reset.
CLRRQ	30	w	**Clear Status Request Bit** When written with ‘1’ this causes all other bits within the register to be cleared.
RES	[29:14]	r	**Reserved** returns ‘0’ if read; should be written with ‘0’.
ADDR	[13:0]	r	**PRAM Error Address** The (word) address of the PRAM location containing an error which caused the ERR bit to transition from ‘0’ to ‘1’.

11.17.12 Memory Integrity Error Status Register for CMEM, PCP_MIESTATC

*Note: Please see **Section 11.11** on **Page 11-47** for more information regarding the use of this register.*

PCP_MIESTATC
Memory Integrity Error Status Register for CMEM($5C_H$) Reset Value: $0000\ 0000_H$

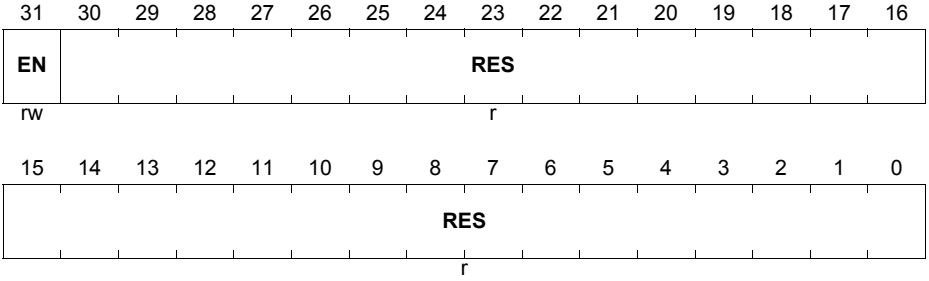


Field	Bits	Type	Description
ERR	31	r	**CMEM Memory Integrity Error Flag** Set when a memory integrity error is encountered. This bit remains set until the CLRRQ bit is written with ‘1’ or the PCP is reset.
CLRRQ	30	w	**Clear Status Request Bit** When written with ‘1’ this causes all other bits within the register to be cleared.
RES	[29:15]	r	**Reserved** returns ‘0’ if read; should be written with ‘0’.
ADDR	[14:0]	r	**CMEM Error Address** The (word) address of the CMEM location containing an error which caused the ERR bit to transition from ‘0’ to ‘1’.

11.17.13 Register Protection Register, PCP_RPROT

This register is ENDINIT protected.

PCP_RPROT
Register Protection Register **(70_H)** **Reset Value: 0000 0000_H**



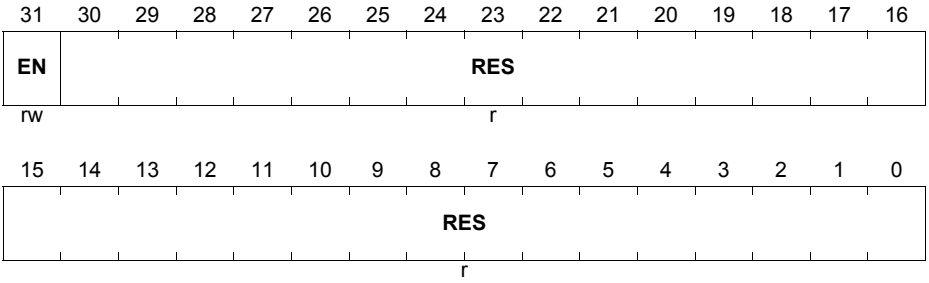
Field	Bits	Type	Description
EN	31	rw	**Register Protection Enable** 0_B Registers are not protected and can be written at any time. 1_B Registers are protected and can only be written when ENDINT is ‘0’.
RES	[30:0]	r	**Reserved** returns ‘0’ if read; should be written with ‘0’.

11.17.14 CMEM Protection Register, PCP_CPROT

*Note: Please see **Section 11.13.3** on **Page 11-58** for more information regarding the use of this register.*

This register is ENDINIT protected.

PCP_CPROT
CMEM Protection Register **(74_H)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
EN	31	rw	**Register Protection Enable** 0_B CMEM is not protected and can be written at any time. 1_B CMEM is protected and can not be written.
RES	[30:0]	r	**Reserved** returns ‘0’ if read; should be written with ‘0’.

11.17.15 PRAM Protection Register, PCP_PPROT

This register is ENDINIT protected.

PCP_PPROT
PRAM Protection Register **(78_H)** **Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
EN	ENI	RES					PCAT	PTHRES							
rw	rw	r					rw	rw							

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PSIZE								FBASE							
rw								rw							

Field	Bits	Type	Description
EN	31	rw	**PRAM Protection Enable for FPI Writes** 0_B PRAM is not protected and can be written via FPI at any time. 1_B All PRAM outside the Open Window is protected and can not be written via FPI. PRAM inside the Open Window remains writable via FPI.

Field	Bits	Type	Description
ENI	30	rw	**PRAM Protection Enable for Internal Writes** 0_B The entire PRAM (subject to PRAM partitioning) is not protected and can be written using PCP PRAM write instructions. 1_B All PRAM outside the Protected Window (and subject to PRAM partitioning) is not protected and can be written using PCP PRAM write instructions. PRAM inside the Protected Window remains writable using PCP PRAM write instructions only by a protected channel (subject to PRAM partitioning). *Note: PRAM partitioning (which is enabled/controlled by CS.PPE and CS.PPS) takes precedence over PRAM protection. Therefore if PRAM Partitioning is enabled, the entire Context Region will be protected against PCP PRAM write instructions, regardless of the Protection settings or whether the channel is Protected or not.*
RES	[29:25]	r	**Reserved** Returns ‘0’ if read. Should be written with ‘0’.
PCAT	24	rw	**Protected Channels Above Threshold** When ENI (above) is ‘0’, this bit has no effect. When ENI is ‘1’, this bit defines whether the Channel number defined in the PTHRES represents the lowest of the highest protected Channel; 0_B The Channel with the number defined by PPROT.PTHRES is the highest Channel Program that is treated as protected. All Channel’s with numbers below the value of PPROT.PTHRES are also treated as protected. 1_B The Channel with the number defined by PPROT.PTHRES is the lowest Channel program that is treated as protected. All Channel’s with numbers above the value of PPROT.PTHRES are also treated as protected.

Field	Bits	Type	Description
PTHRES	[23:16]	rw	**Protected Channel Threshold** When PPROT.ENI is ‘0’, this field has no effect. When PPROT.ENI is ‘1’, this field defines the Channel number which is used to distinguish between protected and non-protected Channels.
PSIZE	[15:8]	rw	**PRAM Internally Protected Window Size** When PPROT.ENI is ‘0’, this field has no effect. When PPROT.ENI is ‘1’, this field defines the size (in multiples of 256 bytes) of the region at the bottom of PRAM that can only be written (using PRAM write instructions) by Protected Channels. *Note: Each value n, from 1_D, up to the maximum 255_D,is multiplied by 256 Bytes* 0_D 0 Bytes (i.e. there is no Protected Window; the entire PRAM (subject to PRAM Partitioning) can be written by the use of PRAM write instructions by any Channel). 1_D 256 Bytes (i.e. the lowest 64 words of PRAM are protected against PRAM write instructions executed by non-protected Channels). ....$_B$ ... 255_D 255 * 256 Bytes *Note: Use of an eight bit field allows for the maximum PRAM size currently supported by the architecture (64Kbytes). Where a PCP is implemented with a smaller PRAM, setting a Protected Window size greater than the actual PRAM size will result in the entire PRAM being protected against PRAM write instructions executed by non-protected Channels.* *Note: When enabled, the PRAM Partitioning protection scheme (enabled via CS.PPE and CS.PPE) takes precedence and will protect the Context Save region from modification by PRAM write instructions (regardless of whether an instruction was executed by a Protected Channel or not).*

Field	Bits	Type	Description
FBASE	[7:0]	rw	**PRAM FPI Open Window Base** When PPROT.EN is ‘0’, this field has no effect. When PPROT.EN is '1' (see above) this field defines the base address (in multiples of 256 bytes and relative to the base of PRAM) of the region at the top of PRAM that remains writable by FPI writes. *Note: From 1_D up to 254_D: Base of PRAM + n * 256 Bytes* 0_D Base of PRAM (i.e. the entire PRAM can be written by FPI writes). 1_D Base of PRAM + 256 Bytes (i.e. all but the lowest 64 words of PRAM can be written via the FPI bus, the lowest 64 words of PRAM are protected against FPI Writes) …$_B$ … 254_D Base of PRAM + 254 * 256 Bytes. 255_D The entire PRAM is protected against FPI writes. *Note: Use of an eight bit field allows for the maximum PRAM size currently supported by the architecture (64Kbytes). Where a PCP is implemented with a smaller PRAM, setting an Open Window base above the actual top of PRAM will result in the entire PRAM being protected against FPI writes.* *Note: There is a small limitation with this scheme in that if a device is implemented with a 64K PRAM then it will not be possible to protect the entire PRAM (the top 64 words cannot be protected in this case). If this is a problem then bit 29 could be used as a “protect entire PRAM bit).*

11.17.16 FPI Write Window Register, PCP_FWWIN

*Note: Please see **Section 11.8.1** on **Page 11-42** for more information regarding the use of this register.*

This register is ENDINIT protected.

PCP_FWWIN
FPI Write Window Register **($7C_H$)** **Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
EN	EX	RES	SIZE					BASE							
rw	rw	r	rw					rw							

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BASE															
rw															

Field	Bits	Type	Description
EN	31	rw	**FPI Protection Enable** 0_B The addresses of outgoing FPI writes are not checked. 1_B During execution of an instruction that generates an FPI write, a check is performed that the target address within the programmed allowed address range. If the address not to an allowed address then an FPI write is not issued and the PCP exits the current Channel with IOP error.
EX	30	rw	**Window Mode** 0_B Limit mode. The destination address of FPI write instructions must lie within the defined window. 1_B Exclude mode. The destination address of FPI write instructions must lie outside the defined window.
RES	29	r	**Reserved** Returns ‘0’ if read. Should be written with ‘0’.

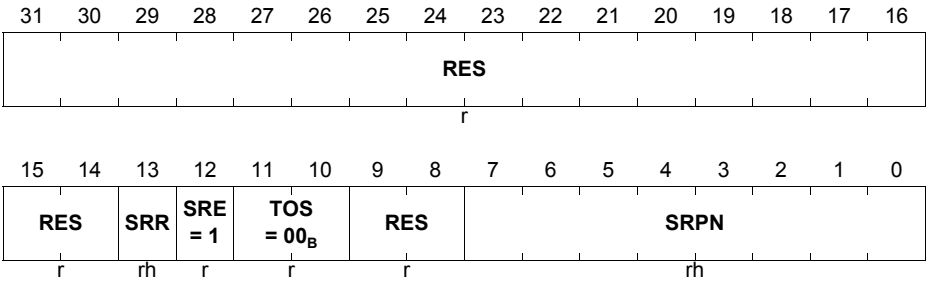
Field	Bits	Type	Description
SIZE	[28:24]	rw	**Window Size** The FPI window size (binary sizing) 0_D 256 bytes 1_D 512 bytes ...$_B$ ... 31_D $2^{(n+8)}$ bytes
BASE	[23:0]	rw	**Window Base Address** Controls the base address of the FPI window (binary aligned according to the window size. Bit 23 maps to the bit 31 of the FPI byte address. The appropriate number of subsequent bits defines the aligned address according to the window size (e.g. when using a 1Kbyte window, the lower 2 bits of this field are treated as zero, regardless of their actual value, in order to obtain the base address of the window).

11.17.17 PCP Service Request Control Registers m, PCP_SRC[1:0]

Service request nodes for interrupt bus 0 (CPU interrupt arbitration bus).

PCP_SRCm (m = 0-1)
PCP Service Request Control Register m

(FC_H-m*4_H) **Reset Value: 0000 1000$_H$**



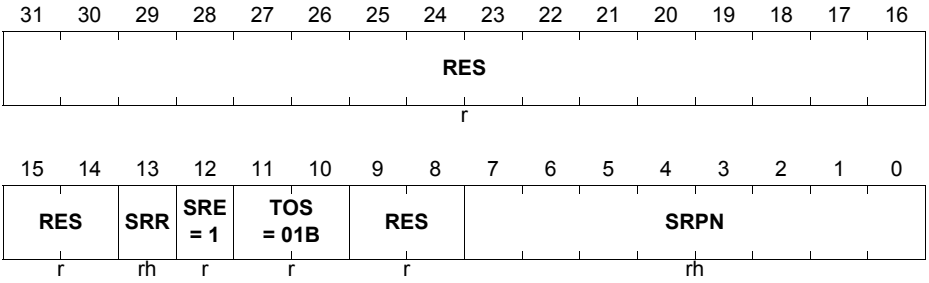
Field	Bits	Type	Description
RES	[31:14]	r	**Reserved** Read as 0.

Field	Bits	Type	Description
SRR	13	rh	**PCP Node m Service Request Flag** 0_B No service requested (default). 1_B Valid active service requested.
SRE	12	r	**PCP Node m Service Request Enable** Always read as 1 (enabled).
TOS	[11:10]	r	**PCP Node m Type-of-Service State** Always read as 00_B. This means TOS is associated with interrupt bus 0 (CPU interrupt arbitration bus).
RES	[9:8]	r	**Reserved** Read as 0.
SRPN	[7:0]	rh	**PCP Node m Service Request Priority Number** This number is automatically set by the PCP if it needs to place a service request on interrupt bus 0 (CPU interrupt arbitration bus). Default after reset is 00_H.

11.17.18 PCP Service Request Control Registers m, PCP_SRC[3:2]

Service request nodes for interrupt bus 1 (PCP interrupt arbitration bus).

PCP_SRCm (m = 2-3)
PCP Service Request Control Register m
(FC_H-m*4_H) **Reset Value: 0000 1400$_H$**

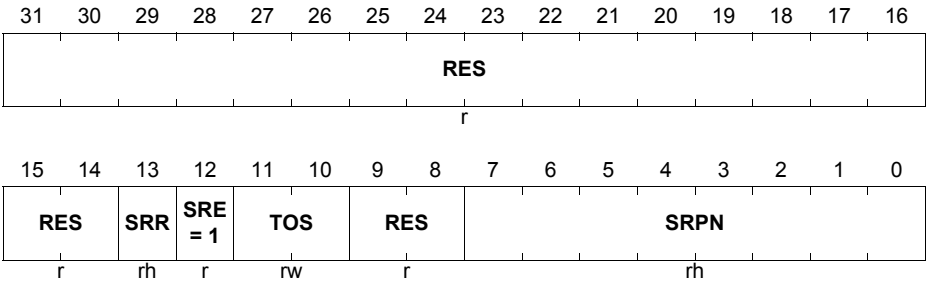


Field	Bits	Type	Description
RES	[31:14]	r	**Reserved** Read as 0.
SRR	13	rh	**PCP Node m Service Request Flag** 0_B No service requested (default). 1_B Valid active service requested.
SRE	12	r	**PCP Node m Service Request Enable** Always read as 1 (enabled).
TOS	[11:10]	r	**PCP Node m Type-of-Service State** Always read as 01_B. This means TOS is associated with interrupt bus 1 (PCP interrupt arbitration bus).
RES	[9:8]	r	**Reserved** Read as 0.
SRPN	[7:0]	rh	**PCP Node m Service Request Priority Number** This number is automatically set by the PCP if it needs to place a service request on interrupt bus 1 (PCP interrupt arbitration bus). Default after reset is 00_H.

11.17.19 PCP Service Request Control Registers m, PCP_SRC[8:4]

Service request nodes programmable for interrupt bus 0 (CPU interrupt arbitration bus) or 1 (PCP interrupt arbitration bus).

PCP_SRCm (m = 4-8)
PCP Service Request Control Register m
(FC_H-m*4_H) **Reset Value: 0000 1000$_H$**



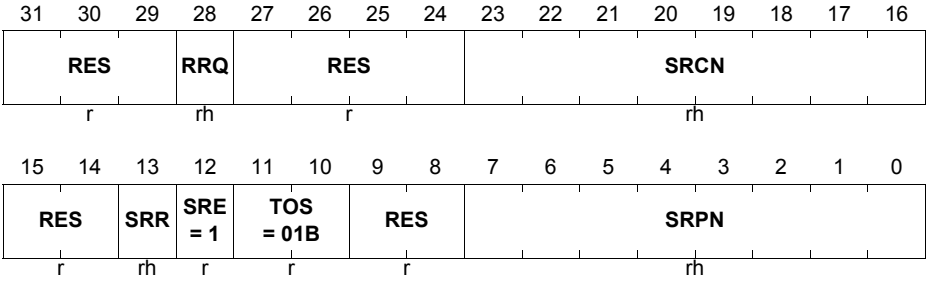
Field	Bits	Type	Description
RES	[31:14]	r	**Reserved** Read as 0. Should be written with 0.
SRR	13	rh	**PCP Node m Service Request Flag** 0_B No service requested (default). 1_B Valid active service requested.
SRE	12	r	**PCP Node m Service Request Enable** Always read as 1 (enabled).
TOS	[11:10]	rw	**PCP Node m Type-of-Service State/Control** TOS value depends on the interrupt mapping that has been selected (see **Page 11-151**). This bit field must be written at PCP configuration time and should not subsequently modified while the PCP is operating.
RES	[9:8]	r	**Reserved** Read as 0. Should be written with 0.

Field	Bits	Type	Description
SRPN	[7:0]	rh	**PCP Node m Service Request Priority Number** This number is automatically set by the PCP if it needs to place a service request on interrupt bus 0 (CPU interrupt arbitration bus) or 1 (PCP interrupt arbitration bus). Default after reset is 00_H.

11.17.20 PCP Service Request Control Registers m, PCP_SRC[11:9]

Service request nodes for interrupt bus 1 (PCP interrupt arbitration bus) with suspended interrupt capability.

PCP_SRCm (m = 9-11)
PCP Service Request Control Register m
(FC_H-m*4_H) **Reset Value: 0000 1400$_H$**



Field	Bits	Type	Description
RES	[31:29]	r	**Reserved** Read as 0.
RRQ	28	rh	**PCP Node m Channel Restart Request** Set when this service request register n contains an active service request that is associated with a suspended interrupt (i.e. a channel that has been interrupted by a higher-priority channel). 0_B The interrupt is not suspended 1_B The interrupt is suspended RRQ is always 0 when SRR is 0.
RES	[27:24]	r	**Reserved** Read as 0.

Field	Bits	Type	Description
SRCN	[23:16]	rh	**PCP Node m Service Request Channel Number** Channel Number Entry (default = 0). When the PCP interrupt request was raised by the PCP Processor Core when executing an EXIT instruction, then this bit field contains the SRPN value taken from R6 when the exit instruction was executed. When the PCP interrupt request was raised by the PCP Processor Core when suspending execution of a channel program in order to service a higher-priority interrupt then this bit field contains the channel number of the channel that was suspended.
RES	[15:14]	r	**Reserved** Read as 0.
SRR	13	rh	**PCP Node m Service Request Flag** 0_B No service requested (default) 1_B Valid active service requested
SRE	12	r	**PCP Node m Service Request Enable** Always read as 1 (enabled).
TOS	[11:10]	r	**PCP Node m Type-of-Service State** Always read as 01_B. This means TOS is associated with interrupt bus 1 (PCP interrupt arbitration bus).
RES	[9:8]	r	**Reserved** Read as 0.
SRPN	[7:0]	rh	**PCP Node m Service Request Priority Number** This number is automatically set by the PCP if it needs to place a service request on interrupt bus 0 (CPU interrupt arbitration bus) or 1 (PCP interrupt arbitration bus). When the PCP interrupt request contained was raised by the PCP Processor Core when executing an EXIT instruction then this bit field contains the SRPN value taken from R6 when the exit instruction was executed. When the PCP interrupt request was raised by the PCP Processor Core when suspending execution of a channel program in order to service a higher-priority interrupt then this bit field contains the CPPN value of the PCP when the interrupt was suspended.

11.18 PCP Instruction Set Details

This section describes the instruction set architecture of the PCP in detail.

11.18.1 Instruction Codes and Fields

All PCP instructions use a common set of fields to describe such things as the source register, and the state of flags. Additionally, many instructions (including arithmetic and many flow control instructions), are conditionally executed.

The descriptions of the PCP instructions are based on the following conventions.

>>, <<	Shift left or right, respectively.
[ ]	Indirect access based on contents of brackets (de-reference).
#immNN	Immediate value encoded into an instruction with width NN.
#offsetNN	Address offset immediate value with width NN.
NextPC	The current executing instruction’s address + 1. (The next instruction to be fetched.)
cc_A, cc_B	Condition Code CONDCA/CONDCB.

11.18.1.1 Conditional Codes

Many PCP instructions have the option of being executed conditionally. The condition code of an instruction is the field that specifies the condition to be tested before the instruction is executed. Depending on the type of instruction there are 8 or 16 condition codes available. The set of 8-condition codes is referred to as CONDCA, while the set of 16-condition codes is referred to as CONDCB. The condition codes are based on an equation of the Flags held in R7. See **Table 11-13**.

Table 11-13 Condition Codes

Description	CONDCA/B	Test (Flag Bits)	Code	Mnemonic
Unconditional	A / B	–	0_H	cc_UC
Zero/Equal	A / B	Z = 1	1_H	cc_Z
Not Zero/Not Equal	A / B	Z = 0	2_H	cc_NZ
Overflow	A / B	v = 1	3_H	cc_V
Carry/Unsigned Less Than/ Check Bit True	A / B	C = 1	4_H	cc_C, cc_ULT
Unsigned Greater Than	A / B	C OR Z = 0	5_H	cc_UGT
Signed Less Than	A / B	N XOR V = 1	6_H	cc_SLT
Signed Greater Than	A / B	(N XOR V) OR Z = 0	7_H	cc_SGT
Negative	B	N = 1	8_H	cc_N
Not Negative	B	N = 0	9_H	cc_NN
Not Overflow	B	V = 0	A_H	cc_NV
No Carry/Unsigned Greater than or Equal	B	C = 0	B_H	cc_NC, cc_UGE
Signed Greater Than or Equal	B	N XOR V = 0	C_H	cc_SGE
Signed Less than or Equal	B	(N XOR V) OR Z = 1	D_H	cc_SLE
CNT1 Equal Zero	B	CNZ1 = 1	E_H	cc_CNZ
CNT1 Not Equal Zero	B	CNZ1 = 0	F_H	cc_CNN

11.18.1.2 Instruction Fields

Table 11-14 lists the instruction field definitions of the PCP instruction set architecture.

Note: The exact syntax for these fields may be different depending on which tool (e.g. assembler) is used. Please refer to the respective tool descriptions.

Table 11-14 Instruction Field Definitions

Symbol	Syntax	Description
cc_A, cc_B	see Table 11-13	**Condition Code** Specifies conditional execution of instruction according to CONDCA or CONDCB.
CNC		**Counter Control** This field is used by the BCOPY/COPY instructions to control the number of repetitions of the data transfer. For BCOPY operation see Figure 11 - 2 on Page 11-104. For COPY operation see Figure 11 - 1 on Page 11-103.
	$CNC = 00_B$	Perform the number of transfers specified by CNT0 then proceed to next instruction.
	$CNC = 01_B$	Perform the number of transfers specified by CNT0 then decrement CNT1 and proceed to next instruction.
	$CNC = 10_B$	Perform the number of transfers specified by CNT0 then decrement CNT1. Repeat until CNT1 = 0, then proceed to next instruction.
	$CNC = 11_B$	Reserved.
CNT0		**Counter Reload Value (COPY)** The COPY instruction uses an implicit counter to generate multiple data transfers. The CNT0 value given in the instruction specifies how many data transfers are to be performed by the instruction. See also Figure 11 - 1 on Page 11-103.
	CNT0 = $001_B..111_B$	Perform 1..7 data transfers
	CNT0 = 000_B	Perform 8 data transfers
		Block Size (BCOPY) Selects the FPI block size used for a BCOPY instruction.
	$CNT0 = 00_B$	Use block size of 8 words.
	$CNT0 = 10_B$	Use block size of 2 words.
	$CNT0 = 11_B$	Use block size of 4 words.
	Others	Reserved

Table 11-14 Instruction Field Definitions (cont'd)

Symbol	Syntax	Description
DAC		**Stop PCP**
	DAC = 0	Allow the PCP to continue to execute channel programs in response to service requests.
	DAC = 1	Prevent the PCP from executing further channel programs (PCP_CS.EN = 0).
DST+-		**Destination Address Pointer Control**
	DST (00_B)	No Change (DST)
	DST+ (01_B)	Post Increment by Size (DST+)
	DST- (10_B)	Post Decrement by Size (DST-)
	(11_B)	Reserved
EC		**Exit Count Control**
	EC = 0	No action
	EC = 1	Decrement CNT1
EDA		**External Debug Action**
	EDA = 0	No External Debug Action caused
	EDA = 1	Cause an External Debug Action (breakpoint pin etc.)
EP		**Entry Point Control**
	EP = 0	Set the PC to channel program Start. EP = 0 assumes that a Channel Entry Table exists in the base of CMEM. Failure to provide such a table will cause improper operation.
	EP = 1	Set the PC to the address contained in NextPC (next instruction) address.
INT		**Interrupt Control**
	INT = 0	No Interrupt
	INT = 1	INT = 1 AND (cc_B = True) means Issue Interrupt
RTA		**Action on Debug Exit**
	RTA = 0	Stop channel program from accepting new service requests (clear R7.CEN)
	RTA = 1	Allow further channel program execution and decrement PC (so that DEBUG instruction is re-executed on next invocation) *Note: This field has no effect if SDB = 0 (see below)*
S/C		**Test Bit Control**
	S/C = 0	Check for Clear (0)
	S/C = 1	Check for Set (1)
SDB		**Stop on Debug**
	SDB = 0	Continue running if debug event triggered
	SDB = 1	Stop PCP if debug event triggered

Table 11-14 Instruction Field Definitions (cont'd)

Symbol	Syntax	Description
SIZE		**Data Size Control**
	SIZE = 00_B	Byte (8-bit)
	SIZE = 01_B	Half-word (16-bit)
	SIZE = 10_B	Word (32-bit)
	SIZE = 11_B	Reserved
SRC+-		**Source Address Pointer Control**
	SRC (00_B)	No Change (SRC)
	SRC+ (01_B)	Post Increment by Size (SRC+)
	SRC- (10_B)	Post Decrement by Size (SRC-)
	(11_B)	Reserved
ST		**Stop Channel**
	ST = 0	Continue channel execution, leave channel program enabled
	ST = 1	Stop Channel Execution, perform actions according to RTA setting (see above)

11.18.2 Counter Operation for COPY Instruction

Figure 11 - 1 shows the flow of a COPY instruction.

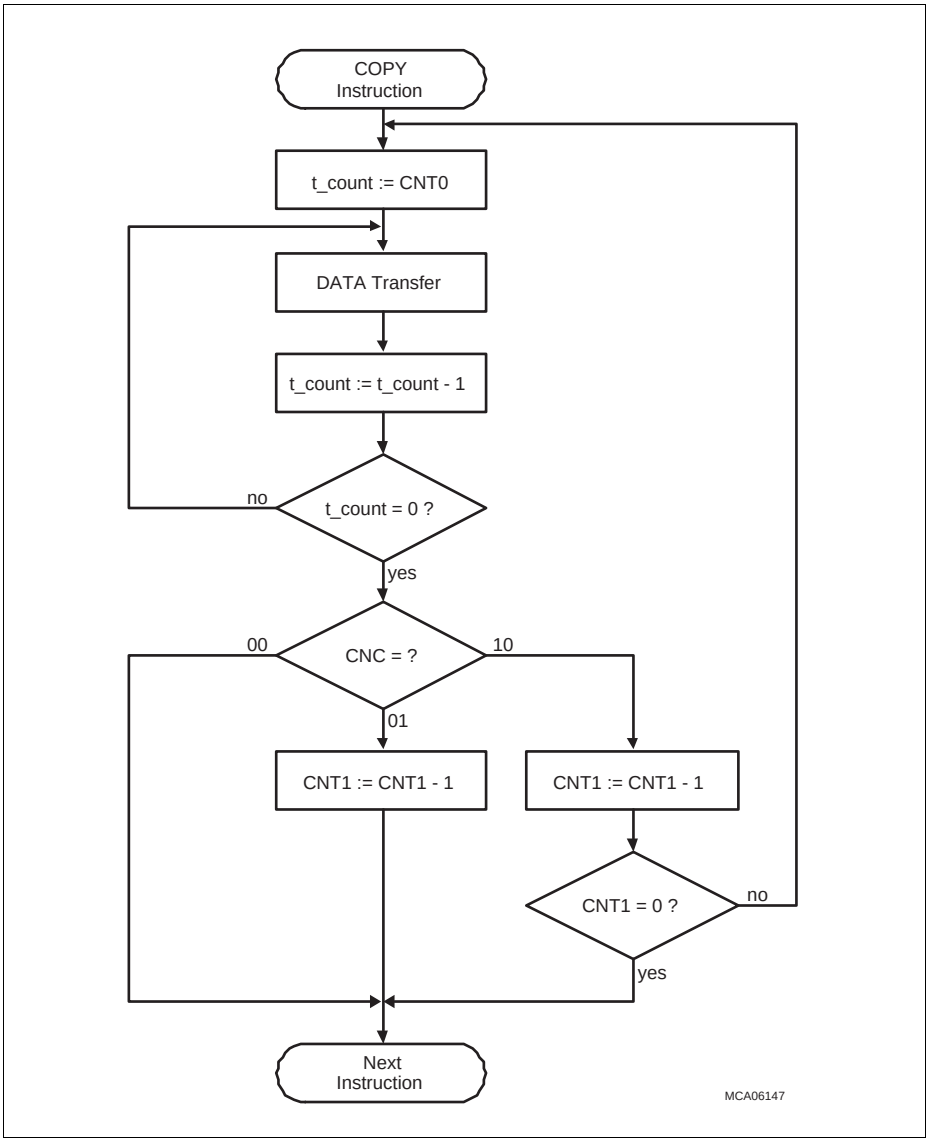


Figure 11 - 1 Counter Operation for COPY Instruction

11.18.3 Counter Operation for BCOPY Instruction

Figure 11 - 2 shows the flow of a BCOPY instruction.

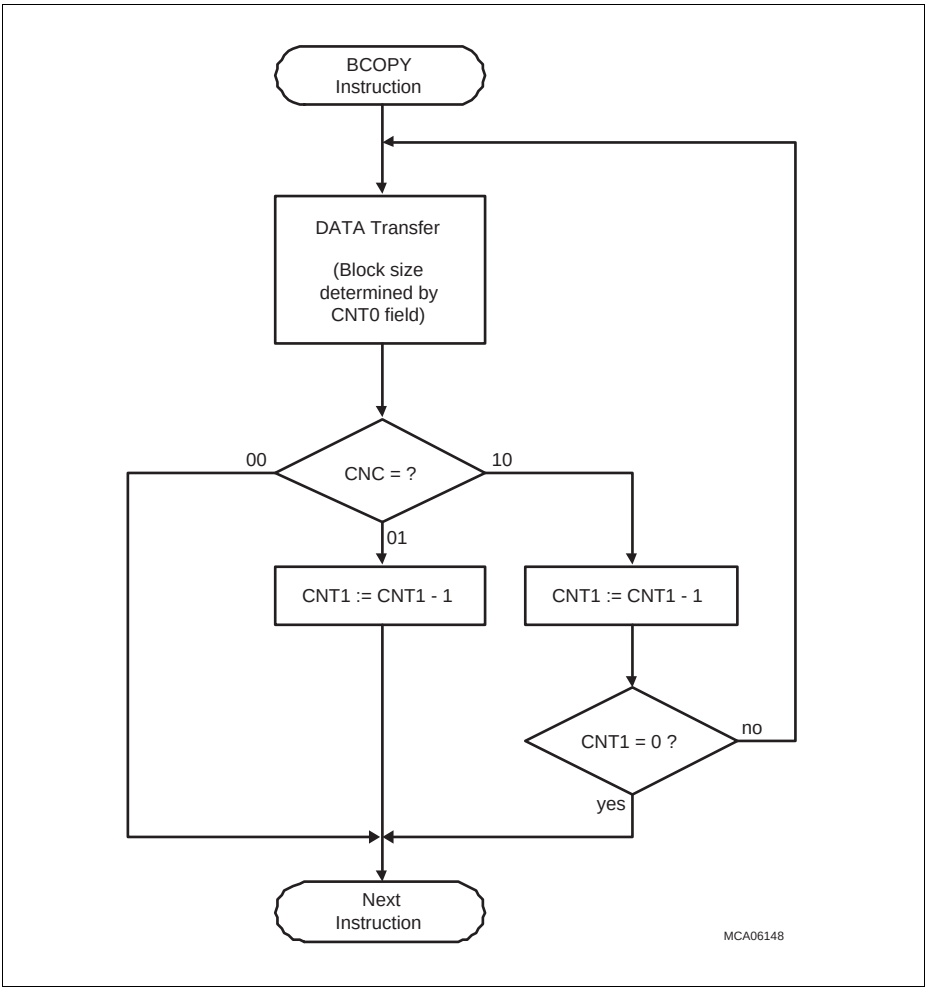

Figure 11 - 2 Counter Operation for BCOPY Instruction

11.18.4 Divide and Multiply Instructions

The PCP has Multiply and Divide capabilities (unsigned values only). All Multiply and divide instructions operate on 8 bits of data (taken from the dividend for divide, from the multiplicand for multiply). This strategy allows the user to implement the appropriate number of instructions (“steps”) as required for the user’s data format.

Each execution of a divide instruction (DSTEP) performs a division which generates 8 bits of result, and also manipulates the registers being used to allow the execution of consecutive divide (DSTEP) instructions to build divide algorithms in multiples of 8 bits (see **Page 11-154** for more details).

Each execution of a multiply instruction (MSTEP32 and MSTEP64) performs a multiplication on 8 bits of data (taken from the multiplicand) and also manipulates the registers to allow execution of consecutive multiply instructions to build multiply algorithms in multiples of 8 bits (see **Page 11-155** for more details).

The following restrictions apply to the use of Divide and Multiply instructions:

- The first instruction of any divide sequence must be the DINIT (initialization) instruction. Any additional instructions other than MINIT, MSTEP32 or MSTEP64 may also be used within the sequence as long as they do not modify any of the registers used for division (R0, Ra and Rb). All subsequent divide instructions within the sequence (DSTEP) must use the same register for dividend and the same register for divisor as used in the preceding DINIT instruction.
- The first instruction of any multiply sequence must be the MINIT (initialization) instruction. Any additional instructions other than DINIT or DSTEP may also be used within the sequence as long as they do not modify any of the registers used for multiplication (R0, Ra and Rb). All subsequent multiply instructions within the sequence (MSTEP32 and MSTEP64) must use the same register for multiplicand and the same register for multiplier as used in the preceding MINIT instruction.
- Neither of the operand registers (Ra or Rb) may be R0 (which is used implicitly within all the instructions), and the same register may not be supplied as both operand registers of an instruction (e.g. DSTEP R3, R3 is invalid).

Note: Failure to adhere to these restrictions will yield undefined results.

2. *Special care must be taken when using multiply and divide sequences when a channel program is interruptible. In this case it must be ensured that a sequence cannot be corrupted by the execution of multiply or divide instructions executed by a higher-priority channel. The R7.IEN bit can be used to ensure that a sequence is not interruptible (see* ***Page 11-153****).*

In the descriptions attached to each multiply and divide instruction, a pseudo-code model is supplied to provide an unambiguous definition of the function of the instruction. The models supplied for the DSTEP and MSTEP32 instructions use 32 bit unsigned integer arithmetic, ignoring any possible overflows. The model supplied for the MSTEP64 uses

a 40-bit unsigned multiply and then shifts this result right by 8 bits (discards the least significant 8 bits of the 40-bit result).

The DSTEP instruction also has some conditions stipulated regarding input values to the instruction. Use of the pseudo-code model for the DSTEP instruction with invalid input values will yield an invalid result.

11.18.5 ADD, 32-bit Addition

This section describes the ADD instructions of the PCP.

ADD	Syntax	**ADD Rb, Ra, cc_A**
	Description	If the condition CONDCA is true, then add the contents of register Ra to the contents of register Rb; place the result in Rb. If CONDCA is false, no operation is performed.
	Operation	if (CONDCA = True) then R[b] = R[b] + R[a] else NOP
	Flags	N, Z, V, C
ADD.I	Syntax	**ADD.I Ra, #imm6**
	Description	Add the zero-extended immediate value imm6 to the contents of register Ra; place the result in Ra.
	Operation	R[a] = R[a] + zero_ext(imm6)
	Flags	N, Z, V, C
ADD.F	Syntax	**ADD.F Rb, [Ra], Size**
	Description	Add the contents of the address location specified by the contents of register Ra to the contents of register Rb; place the result in Rb. *Note: Byte and Half-word values are zero-extended.*
	Operation	R[b] = R[b] + zero_ext(FPI[R[a]])
	Flags	N, Z, V, C
ADD.PI	Syntax	**ADD.PI Ra, [#offset6]**
	Description	Add the contents of the PRAM location specified by the addition of contents of the PRAM Data Pointer, shifted left by six bits, and the zero-extended 6-bit value offset6 to the contents of register Ra; place the result in Ra.
	Operation	R[a] = R[a] + PRAM[(DPTR<<6) + zero_ext(#offset6)]
	Flags	N, Z, V, C

11.18.6 AND, 32-bit Logical AND

This section describes the AND instructions of the PCP.

AND	Syntax	**AND Rb, Ra, cc_A**
	Description	If the condition CONDCA is true, then perform a bit-wise logical AND of the contents of register Ra and the contents of register Rb; place the result in Rb. If CONDCA is false, no operation is performed.
	Operation	if (CONDCA = True) then R[b] = R[b] AND R[a] else NOP
	Flags	N, Z
AND.F	Syntax	**AND.F Rb, [Ra], Size**
	Description	Perform a bit-wise logical AND of the contents of the address location, specified by the contents of register Ra, and the contents of register Rb; place the result in Rb.
	Operation	R[b] = R[b] AND zero_ext(FPI[R[a]])
	Flags	N, Z
AND.PI	Syntax	**AND.PI Ra, [#offset6]**
	Description	Perform a bit-wise logical AND of the contents of the PRAM location specified by the addition of contents of the PRAM Data Pointer, shifted left by six bits, and the zero-extended 6-bit value offset6, and the contents of register Ra; place the result in Ra.
	Operation	R[a] = R[a] AND PRAM[(DPTR<<6) + zero_ext(#offset6)]
	Flags	N, Z

11.18.7 BCOPY, DMA Operation

This section describes the BCOPY instruction of the PCP in the TC1798.

BCOPY	Syntax	**BCOPY DST+-, SRC+-, CNC, CNT0**
	Description	Allows the PCP to perform DMA type transfers using FPI block transfers. Moves the contents of FPI Bus source location to FPI Bus destination location. Source location is pointed to by the contents of register R4; destination location is pointed to by the contents of register R5. Options (see also **Table 11-14** at **Page 11-100**): Source pointer (SRC+-): Increment, decrement or unchanged Destination pointer (SRC+-): Increment, decrement or unchanged Counter control (CNC): see **Table 11-14** Block size value (CNT0): see **Table 11-14**
	Operation	temp = zero_ext(FPI[R[4]]); value loaded and extended depending on SIZE FPI(R[5]) = temp R4 = R4 +/- n; n depending on SRC+- and CNT0 R5 = R5 +/- n; n depending on DST+- and CNT0 For counter operation see **Figure 11 - 2** on **Page 11-104** and **Table 11-14** on **Page 11-100**.
	Flags	CN1Z

See also **Page 11-157** for TC1798 specific details of the BCOPY instruction.

11.18.8 CHKB, Check Bit

This section describes the CHKB instruction of the PCP.

CHKB	Syntax	**CHKB Ra, #imm5, S/C**
	Description	If bit imm5 of register Ra is equal to the specified test value S/C then set the carry flag R7.C, else clear the carry flag.
	Operation	if (R[a][imm5] = S/C) then R7_C = 1 else R7_C = 0
	Flags	C

11.18.9 CLR, Clear Bit

This section describes the CLR instructions of the PCP.

CLR	Syntax	**CLR Ra, #imm5**
	Description	Clear bit imm5 of register Ra to 0.
	Operation	R[a][imm5] = 0
	Flags	None
CLR.F	Syntax	**CLR.F [Ra], #imm5, Size**
	Description	Clear bit imm5 of the address location specified through the contents of register Ra to 0. This instruction is executed using a locked read-modify-write FPI Bus transaction.
	Operation	FPI[(R[a])][imm5] = 0
	Flags	None

11.18.10 COMP, 32-bit Compare

This section describes the COMP instructions of the PCP.

COMP	Syntax	**COMP Rb, Ra, cc_A**
	Description	If the condition CONDCA is true, then subtract the contents of register Ra from the contents of register Rb; set the flags in register R7 according to the result of the subtraction; discard the subtraction result. If CONDCA is false, no operation is performed.
	Operation	if (CONDCA = True) then R7_FLAGS = Flags(R[b] - R[a])
	Flags	N, Z, V, C
COMP.I	Syntax	**COMP.I Ra, #imm6**
	Description	Subtract the immediate value imm6 from the contents of register Ra; set the flags in register R7 according to the result of the subtraction; discard the subtraction result.
	Operation	R7_FLAGS = Flags(R[a] - zero_ext(imm6))
	Flags	N, Z, V, C
COMP.F	Syntax	**COMP.F Rb, [Ra], Size**
	Description	Subtract the contents of the address location specified by the contents of register Ra from the contents of register Rb; set the flags in register R7 according to the result of the subtraction; discard the subtraction result.
	Operation	R7_FLAGS = Flags(R[b] - zero_ext(FPI[R[a]]))
	Flags	N, Z, V, C
COMP.PI	Syntax	**COMP.PI Ra, [#offset6]**
	Description	Subtract the contents of the PRAM location specified by the addition of contents of the PRAM Data Pointer, shifted left by six bits, and the zero-extended 6-bit value offset6, from the contents of register Ra; set the flags in register R7 according to the result of the subtraction; discard the subtraction result.
	Operation	R7_FLAGS = Flags(R[a] - PRAM[(DPTR<<6) + zero_ext(#offset6)])
	Flags	N, Z, V, C

11.18.11 COPY, DMA Instruction

This section describes the COMP instruction of the PCP.

COPY	Syntax	**COPY DST+-, SRC+-, CNC, CNT0, SIZE**
	Description	Moves the contents of FPI Bus source location to FPI Bus destination location. Source location is pointed to by the contents of register R4; destination location is pointed to by the contents of register R5. Options (see also **Table 11-14** on **Page 11-100**): Source pointer (SRC+-): Increment, decrement or unchanged Destination pointer (SRC+-): Increment, decrement or unchanged Counter control (CNC): see **Table 11-14** Counter 0 reload value (CNT0): see **Table 11-14** Data transfer width (SIZE): byte, half-word, word (pointers are incremented/decremented based upon SIZE).
	Operation	temp = zero_ext(FPI[R[4]]); value loaded and extended depending on SIZE FPI(R[5]) = temp R4 = R4 +/- n; n depending on SRC+- and SIZE R5 = R5 +/- n; n depending on DST+- and SIZE For counter operation see **Figure 11 - 1** on **Page 11-103** and **Table 11-14** on **Page 11-100**.
	Flags	CN1Z

11.18.12 DEBUG, Debug Instruction

This section describes the DEBUG instruction of the PCP.

DEBUG	Syntax	**DEBUG EDA, DAC, RTA, SDB, cc_B**
	Description	Conditionally cause a debug event if condition CONDCB is true. Optionally stop channel execution (SDB = 1) and/or generate an external debug event (EDA = 1).

	Operation	if (CONDCB = True) then
		  if (EDA = 1) then activate BRK_OUT pin
		  if (SDB = 1) then
		  if (RTA = 0) then
		  R7_CEN = 0; disable further channel invocation
		  else
		  PC = PC - 1
		  endif
		  save_context
		  idle
		  endif
		  if (DAC = 1)
		  PCP_CS>EN = 0
		  endif
		  set ES.DBE; indicate debug event
		  ES.PC = NextPC
		  ES.PN = channel_number
		endif

	Flags	none

Note: Execution of the DEBUG command when not in Debug Mode will cause the PCP to generate an “Illegal Operation” Error Exit.

11.18.13 DINIT, Divide Initialization

This section describes the DINIT instruction of the PCP.

DINIT	Syntax	**DINIT <R0>, Rb, Ra**
	Description	Initialize Divide logic ready for divide sequence (Rb / Ra) and Clear R0. If value of Ra is 0 then set V (to flag divide by 0 error); otherwise, clear V. If value of Rb is 0 and value of Ra is not 0 then set Z (to flag a zero result); otherwise, clear Z.
	Operation	R0 = 0
	Flags	Z, V

11.18.14 DSTEP, Divide Instruction

This section describes the DSTEP instruction of the PCP.

DSTEP	Syntax	**DSTEP <R0>, Rb, Ra**
	Description	Perform 1 step (eight bits) of an unsigned 32- by 32-bit divide (Rb / Ra). Shift R0 left by 8 bits, copy the most significant byte of Rb into LS byte of R0. Shift Rb left by 8 bits and add (R0 divided by Ra). Load R0 with (the remainder of R0 divided by Ra).
	Operation	R0 = (R0 << 8) + (Rb >> 24) Rb = (Rb << 8) + R0 / Ra R0 = R0 % Ra
	Flags	Z

Note: The value in Ra must always be greater than the value in R0 prior to execution of the DSTEP instruction. If the rules specified on ***Page 11-105*** *are followed, then the above description and operation are correct. Failure to adhere to these rules will yield undefined results.*

11.18.15 EXIT, Exit Instruction

This section describes the EXIT instruction of the PCP.

EXIT	Syntax	**EXIT EC, ST, INT, EP, cc_B**
	Description	Unconditionally exit channel program execution. Optionally decrement counter CNT1 (EC = 1), disable further channel invocation (ST = 1), generate an interrupt request (INT = 1) if condition CONDCB is true. Field EP is used to set the channel code entry point in Channel Resume Mode to either the address of the next instruction (EP = 1) or to the start address of the channel (EP = 0). The EXIT instruction is finished with a context save operation. The EP option is only in effect when Channel Resume operation is globally selected through PCP_CS.RCB = 0. If PCP_CS.RCB = 1, Channel restart mode is selected for all channels, and the EP field of the EXIT instruction is disregarded.

	Operation	if (EC = 1) then CNT1 = CNT1 - 1
		if (ST = 1) then R7_CEN = 0
		if ((INT = 1) AND (cc_B = True)) then activate_interrupt_request
		if (EP = 1) then R7_PC = NextPC else R7_PC = channel_entry_point
		save_context

	Flags	CN1Z

11.18.16 INB, Insert Bit

This section describes the INB instructions of the PCP.

INB	Syntax	**INB Rb, Ra, cc_A**
	Description	If CONDCA is true, then insert the carry flag R7.C into register Rb at the bit position specified through bits [4..0] of register Ra. If CONDCA is false, no operation is performed.
	Operation	if (CONDCA = True) then R[b][R[a][4:0]] = R7_C else NOP
	Flags	None
INB.I	Syntax	**INB.I Ra, #imm5**
	Description	Insert the carry flag R7.C into register Ra at the bit position specified through the immediate value imm5.
	Operation	R[a][imm5] = R7_C
	Flags	None

11.18.17 JC, Jump Conditionally

This section describes the conditional jump instructions of the PCP.

JC	Syntax	**JC offset6, cc_B**
	Description	If CONDCB is true, then add the sign-extended value specified by offset6 to the contents of the PC, and jump to that address. If CONDCB is false, no operation is performed.
	Operation	if (CONDCB = True) then (PC = PC + sign_ext(offset6)) else NOP
	Flags	None
JC.A	Syntax	**JC.A #address16, cc_B**
	Description	If CONDCB is true, then load the value specified by address16 into the PC, and jump to that address. If CONDCB is false, no operation is performed.
	Operation	if (CONDCB = True) then (PC = address16) else NOP
	Flags	None
JC.I	Syntax	**JC.I Ra, cc_B**
	Description	If CONDCB is true, then add the value specified by Ra[15:0] to the contents of the PC, and jump to that address. Value Ra[15:0] is treated as a signed 16-bit number. If CONDCB is false, no operation is performed.
	Operation	if (CONDCB = True) then (PC = PC + (R[a][15:0])) else NOP
	Flags	None
JC.IA	Syntax	**JC.IA Ra, cc_B**
	Description	If CONDCB is true, then load the value specified by Ra[15:0] into the PC, and jump to that address. Value Ra[15:0] is treated as an unsigned 16-bit number. If CONDCB is false, no operation is performed.
	Operation	if (CONDCB = True) then (PC = (R[a][15:0])) else NOP
	Flags	None

11.18.18 JL, Jump Long Unconditional

This section describes the long jump instruction JL of the PCP.

JL	Syntax	**JL offset10**
	Description	Add the sign-extended value specified by offset10 to the contents of the PC, and jump to that address.
	Operation	PC = PC + sign_ext(offset10)
	Flags	None

11.18.19 LD, Load

This section describes the LD instructions of the PCP.

LD.F	Syntax	**LD.F Rb, [Ra], Size**
	Description	Load the zero-extended contents of the address location specified by the contents of register Ra into register Rb.
	Operation	R[b] = zero_ext(FPI[R[a]])
	Flags	N, Z
LD.I	Syntax	**LD.I Ra, #imm6**
	Description	Load the zero-extended value specified by imm6 into register Ra.
	Operation	R[a] = zero_ext(imm6)
	Flags	N, Z
LD.IF	Syntax	**LD.IF [Ra], #offset5, Size**
	Description	Load the zero-extended contents of the address location, specified by the addition of the contents of register Ra and the value specified by imm5, into register R0.
	Operation	R[0] = zero_ext(FPI[R[a] + zero_ext(imm5)])
	Flags	N, Z

LD.P	Syntax	**LD.P Rb, [Ra], cc_A**
	Description	If condition CONDCA is true, then load the contents of the PRAM address location, specified by the addition of contents of the PRAM Data Pointer, shifted left by six bits, and the zero-extended 6-bit value Ra[5:0] into register Rb. If condition CONDCA is false, no operation is performed.
	Operation	if (CONDCA = True) then R[b] = PRAM[(DPTR<<6) + zero_ext(R[a][5:0])] else NOP
	Flags	N, Z
LD.PI	Syntax	**LD.PI Ra, [#offset6]**
	Description	Load the contents of the PRAM location specified by the addition of contents of the PRAM Data Pointer, shifted left by six bits, and the zero-extended 6-bit value offset6 into register Ra.
	Operation	R[a] = PRAM[(DPTR<<6) + zero_ext(offset6)]
	Flags	N, Z

11.18.20 LDL, Load 16-bit Value

This section describes the LDL instructions of the PCP.

LDL.IL	Syntax	**LDL.IL Ra, #imm16**
	Description	Load the immediate value imm16 into the lower bits of register Ra (bits [15:0]). Bits [31:16] of register Ra are unaffected. Value imm16 is treated as an unsigned 16-bit number.
	Operation	R[a][15:0] = imm16
	Flags	N, Z
LDL.IU	Syntax	**LDL.IU Ra, #imm16**
	Description	Load the immediate value imm16 into the upper bits of register Ra (bits [31:16]). Bits [15:0] of register Ra are unaffected.
	Operation	R[a][31:16] = imm16
	Flags	N, Z

11.18.21 MINIT, Multiply Initialization

This section describes the MINIT instruction of the PCP.

MINIT	Syntax	**MINIT <R0>, Rb, Ra**
	Description	Initialize Multiply logic ready for multiply sequence. Clear R0. If value of Ra is zero or value of Rb is zero then set Z (to flag zero result) else clear Z.
	Operation	R0 = 0
	Flags	Z

11.18.22 MOV, Move Register to Register

This section describes the MOV instruction of the PCP.

MOV	Syntax	**MOV Rb, Ra, cc_A**
	Description	If condition CONDCA is true, then move the contents of register Ra into register Rb. If CONDCA is false, no operation is performed.
	Operation	if (CONDCA = True) then R[b] = R[a] else NOP
	Flags	N, Z

11.18.23 Multiply Instructions

This section describes the multiply instructions of the PCP.

MSTEP32	Syntax	**MSTEP32 <R0>, Rb, Ra**
	Description	Perform an unsigned multiply step, using eight bits of data taken from Rb, keeping the least significant 32 bits of a potential 64-bit result. Left rotate Rb by 8 bits. Shift R0 left by 8 bits. Add (Ra multiplied by the least significant 8 bits of Rb) to R0. If value of R0 is zero then set Z (to signal zero result) else clear Z.
	Operation	Rb = (Rb << 8) + (Rb >> 24) R0 = (R0 << 8) + (Rb & 0xff) × Ra
	Flags	Z
MSTEP64	Syntax	**MSTEP64 <R0>, Rb, Ra**
	Description	Perform an unsigned multiply step, using eight bits of data taken from Rb, keeping 40 bits of a potential 64-bit result. Add (Ra multiplied by the least significant 8 bits of Rb) to R0 and retain the 40 bit result (shown as temp below). Store the most significant 32 bits of the result (temp) in R0. Shift Rb right by 8 bits. Store the least significant 8 bits of the first result (temp) in the most significant 8 bits of Rb. If value of R0 is zero then set Z (to signal zero result) else clear Z.
	Operation	temp = R0 + Ra × (Rb & 0xff) R0 = temp >> 8 Rb = (Rb >> 8) + ((temp & 0xff) << 24)
	Flags	Z

Note: In the case of the MSTEP64 instruction above, the “temp” variable is a 40-bit variable and all calculations are performed using 40-bit unsigned arithmetic. All other calculations use 32-bit unsigned arithmetic.

11.18.24 NEG, Negate

This section describes the NEG instruction of the PCP.

NEG	Syntax	**NEG Rb, Ra, cc_A**
	Description	If condition CONDCA is true, then move the 2's complement of the contents of register Ra into register Rb. If CONDCA is false, no operation is performed.
	Operation	if (CONDCA = True) then R[b] = (- R[a]) else NOP
	Flags	N, Z, V, C

11.18.25 NOP, No Operation

This section describes the NOP instruction of the PCP.

NOP	Syntax	**NOP**
	Description	No operation. The NOP instruction puts the PCP in low-power operation.
	Operation	no operation
	Flags	None

11.18.26 NOT, Logical NOT

This section describes the NOT instruction of the PCP.

NOT	Syntax	**NOT Rb, Ra, cc_A**
	Description	If condition CONDCA is true, then move the 1's complement of the contents of register Ra into register Rb. If CONDCA is false, no operation is performed.
	Operation	if (CONDCA = True) then R[b] = NOT(R[a]) else NOP
	Flags	N, Z

11.18.27 OR, Logical OR

This section describes the OR instructions of the PCP.

OR	Syntax	**OR Rb, Ra, cc_A**
	Description	If the condition CONDCA is true, then perform a bit-wise logical OR of the contents of register Ra and the contents of register Rb; place the result in Rb. If CONDCA is false, no operation is performed.
	Operation	if (CONDCA = True) then R[b] = R[b] OR R[a] else NOP
	Flags	N, Z
OR.F	Syntax	**OR.F Rb, [Ra], Size**
	Description	Perform a bit-wise logical OR of the contents of the address location, specified by the contents of register Ra, and the contents of register Rb; place the result in Rb.
	Operation	R[b] = R[b] OR zero_ext(FPI[R[a]])
	Flags	N, Z
OR.PI	Syntax	**OR.PI Ra, [#offset6]**
	Description	Perform a bit-wise logical OR of the contents of the PRAM location specified by the addition of contents of the PRAM Data Pointer, shifted left by six bits, and the zero-extended 6-bit value offset6, and the contents of register Ra; place the result in Ra.
	Operation	R[a] = R[a] OR PRAM[(DPTR<<6) + zero_ext(#offset6)]
	Flags	N, Z

11.18.28 PRAM Bit Operations

This section describes the MCLR and MSET instructions of the PCP.

MCLR	Syntax	**MCLR.PI Ra, [#offset6]**
	Description	Perform an ‘AND’ of the contents of the specified register with the contents of the PRAM location specified by the addition of contents of the PRAM Data Pointer, shifted left by six bits, and the zero-extended 6-bit value offset. Write the result back to the PRAM location.
	Operation	R[a] = R[a].AND.PRAM[DPTR<<6 + #offset6] PRAM[DPTR<<6 + #offset6] = R[a]
	Flags	N, Z
MSET	Syntax	**MSET.PI Ra, [#offset6]**
	Description	Perform an ‘OR’ of the contents of the specified register with the contents of the PRAM location specified by the addition of contents of the PRAM Data Pointer, shifted left by six bits, and the zero-extended 6-bit value offset. Write the result back to the PRAM location.
	Operation	R[a] = R[a].OR.PRAM[DPTR<<6 + #offset6] PRAM[DPTR<<6 + #offset6] = R[a]
	Flags	N, Z

Note: MCLR and MSET are read/modify/write operations that cannot be interrupted by an access from another FPI master. They can be used to implement semaphore systems.

11.18.29 PRI, Prioritize

This section describes the PRI instruction of the PCP.

PRId	Syntax	**PRI Rb, Ra, cc_A**
	Description	If condition CONDCA is true, then find the bit position of the most significant 1 in register Ra and put the number into register Rb. The bit location, 31-0, is encoded as a 5-bit number stored in Rb[4:0]. If the contents of Ra is zero, bit Rb[5] is set, while all other bits in Rb are cleared. If CONDCA is false, no operation is performed.

	Operation	if (CONDCA = False) then
		NOP
		else
		if (R[a] = 0) then
		R[b] = 0x20
		else
		R[b] = bit_pos(most_significant_1(R[a]))

	Flags	N, Z

11.18.30 RL, Rotate Left

This section describes the RL instruction of the PCP.

RL	Syntax	**RL Ra, #imm5**
	Description	Rotate the contents of register Ra to the left by the number of bit positions specified through the 5-bit value imm5. The values defined for imm5 are 1, 2, 4 and 8. The carry flag, R7.C, is set to the last bit shifted out of bit 31 of register Ra.
	Operation	tmp = R[a] R[a] = R[a] << imm5; imm5 = 1, 2, 4, 8 R7_C = last bit shifted out of R[a] tmp = tmp >> 32 - imm5 R[a] = tmp OR R[a]
	Flags	N, Z

11.18.31 RR, Rotate Right

This section describes the RR instruction of the PCP.

RR	Syntax	**RR Ra, #imm5**
	Description	Rotate the contents of register Ra to the right by the number of bit positions specified through the 5-bit value imm5. The values allowed for imm5 are 1, 2, 4 and 8.
	Operation	tmp = R[a] R[a] = R[a] >> imm5; imm5 = 1, 2, 4, 8 tmp = tmp << 32 - imm5 R[a] = tmp OR R[a]
	Flags	N, Z

11.18.32 SET, Set Bit

This section describes the SET bit instruction of the PCP.

SET	Syntax	**SET Ra, #imm5**
	Description	Set bit imm5 of register Ra to 1.
	Operation	R[a][imm5] = 1
	Flags	None
SET.F	Syntax	**SET.F [Ra], #imm5, Size**
	Description	Set bit imm5 of the address location specified through the contents of register Ra to 1. This instruction is executed using a locked read-modify-write FPI Bus transaction.
	Operation	FPI[(R[a])][imm5] = 1
	Flags	None

11.18.33 SHL, Shift Left

This section describes the SHL instruction of the PCP.

SHL	Syntax	**SHL Ra, #imm5**
	Description	Shift the contents of register Ra to the left by the number of bit positions specified through the 5-bit value imm5. The values allowed for imm5 are 1, 2, 4 and 8. The carry flag, R7.C, is set to the last bit shifted out of bit 31 of register Ra. Zeros are shifted in from right.
	Operation	R[a] = R[a] << imm5; imm5 = 1, 2, 4, 8 R7_C = last bit shifted out of R[a]
	Flags	N, Z, C

11.18.34 SHR, Shift Right

This section describes the SHR instruction of the PCP.

SHR	Syntax	**SHR Ra, #imm5**
	Description	Shift the contents of register Ra to the right by the number of bit positions specified through the 5-bit value imm5. The values allowed for imm5 are 1, 2, 4 and 8. Zeros are shifted in from left.
	Operation	R[a] = R[a] >> imm5; imm5 = 1, 2, 4, 8
	Flags	N, Z

11.18.35 ST, Store

This section describes the ST instructions of the PCP.

ST.F	Syntax	**ST.F Rb, [Ra], Size**
	Description	Store the contents of register Rb to the address location specified by the contents of register Ra. When the Size is byte or half-word, the data is stored with the internal LSB (bit 0) properly aligned to the correct FPI Bus byte or half-word lane.
	Operation	FPI[R[a]] = R[b]
	Flags	None
ST.IF	Syntax	**ST.IF [Ra], #offset5, Size**
	Description	Store the contents of R0 to the address location specified by the addition of the contents of register Ra and the value specified by imm5. When the Size is byte or half-word, the data is stored with the internal LSB (bit 0) properly aligned to the correct FPI Bus byte or half-word lane.
	Operation	FPI[R[a] + zero_ext(imm5)] = R[0]
	Flags	None
ST.P	Syntax	**ST.P Rb, [Ra], cc_A**
	Description	If condition CONDCA is true, then store the contents of Rb to the PRAM address location specified by the addition of the contents of the PRAM Data Pointer, shifted left by six bits, and the zero-extended 6-bit value Ra[5:0]. If condition CONDCA is false, no operation is performed.
	Operation	if (CONDCA = True) then PRAM[(DPTR<<6) + zero_ext(R[a][5:0])] = R[b] else NOP
	Flags	None
ST.PI	Syntax	**ST.PI Rb, [#offset6]**
	Description	Store the contents of register Rb to the PRAM location specified by the addition of the contents of the PRAM Data Pointer, shifted left by six bits, and the zero-extended 6-bit value offset6.
	Operation	PRAM[(DPTR<<6) + zero_ext(offset6)] = R[b]
	Flags	None

11.18.36 SUB, 32-bit Subtract

This section describes the SUB instructions of the PCP.

SUB	Syntax	**SUB Rb, Ra, cc_A**
	Description	If the condition CONDCA is true, then subtract the contents of register Ra from the contents of register Rb; place the result in Rb. If CONDCA is false, no operation is performed.
	Operation	if (CONDCA = True) then R[b] = R[b] - R[a] else NOP
	Flags	N, Z, V, C
SUB.I	Syntax	**SUB.I Ra, #imm6**
	Description	Subtract the zero-extended immediate value imm6 from the contents of register Ra; place the result in Ra.
	Operation	R[a] = R[a] - zero_ext(imm6)
	Flags	N, Z, V, C
SUB.F	Syntax	**SUB.F Rb, [Ra], Size**
	Description	Subtract the zero-extended contents of the address location specified by the contents of register Ra from the contents of register Rb; place the result in Rb.
	Operation	R[b] = R[b] - zero_ext(FPI[R[a]])
	Flags	N, Z, V, C
SUB.PI	Syntax	**SUB.PI Ra, [#offset6]**
	Description	Subtract the contents of the PRAM location specified by the addition of contents of the PRAM Data Pointer, shifted left by six bits, and the zero-extended 6-bit value offset6 from the contents of register Ra; place the result in Ra.
	Operation	R[a] = R[a] - PRAM[(DPTR<<6) + zero_ext(#offset6)]
	Flags	N, Z, V, C

11.18.37 XCH, Exchange

This section describes the XCH instructions of the PCP.

XCH.F	Syntax	**XCH.F Rb, [Ra], Size**
	Description	Exchange contents of R[b] and FPI[R[a]] when Size is byte or half-word, the value is stored with the internal LSB (bit 0) properly aligned to the correct FPI byte or half-word lane. The exchange is done via a locked FPI bus transfer.
	Operation	temp = R[b] R[b] = zero_ext(FPI[R[a]]) FPI[R[a]] = temp
	Flags	N, Z
XCH.PI	Syntax	**XCH.PI Ra, [#offset6]**
	Description	Exchange contents of R[a] and PRAM[DPTR <<6 + #offset6]. *Note: The exchange is un-interruptible, and locks out external accesses; it will not be interrupted by any external FPI bus master transfer requests.*
	Operation	temp = R[a] R[a] = PRAM[(DPTR<<6) + zero_ext(#offset6)] PRAM[(DPTR<<6) + zero_ext(#offset6)] = temp
	Flags	N, Z

11.18.38 XOR, 32-bit Logical Exclusive OR

This section describes the XOR instructions of the PCP.

XOR	Syntax	**XOR Rb, Ra, cc_A**
	Description	If the condition CONDCA is true, then perform a bit-wise logical Exclusive-OR of the contents of register Ra and the contents of register Rb; place the result in Rb. If CONDCA is false, no operation is performed.
	Operation	if (CONDCA = True) then R[b] = R[b] XOR R[a] else NOP
	Flags	N, Z
XOR.F	Syntax	**XOR.F Rb, [Ra], Size**
	Description	Perform a bit-wise logical Exclusive-OR of the contents of the address location, specified by the contents of register Ra, and the contents of register Rb; place the result in Rb.
	Operation	R[b] = R[b] XOR zero_ext(FPI[R[a]])
	Flags	N, Z
XOR.PI	Syntax	**XOR.PI Ra, [#offset6]**
	Description	Perform a bit-wise logical Exclusive-OR of the contents of the PRAM location specified by the addition of contents of the PRAM Data Pointer, shifted left by six bits, and the zero-extended 6-bit value offset6, and the contents of register Ra; place the result in Ra.
	Operation	R[a] = R[a] XOR PRAM[(DPTR<<6) + zero_ext(#offset6)]
	Flags	N, Z

11.18.39 Flag Updates of Instructions

Most instructions update the state flags in R7. In **Table 11-15**, each instruction is shown with the flags that it updates.

Table 11-15 Flag Updates

Instruction	CN1Z	V	C	N	Z
ADD	–	yes	yes	yes	yes
AND	–	–	–	yes	yes
BCOPY	yes[1)]	–	–	–	–
CHKB	–	–	yes	–	–
CLR	–	–	–	–	–
COMP	–	yes	yes	yes	yes
COPY	yes[1)]	–	–	–	–
DEBUG	–	–	–	–	–
DINIT	–	yes	–	–	yes
DSTEP	–	–	–	–	yes
EXIT	yes[1)]	–	–	–	–
INB	–	–	–	–	–
JC	–	–	–	–	–
JL	–	–	–	–	–
LD	–	–	–	yes[2)]	yes
LDL	–	–	–	yes	yes
MCLR	–	–	–	yes	yes
MSET	–	–	–	yes	yes
MOV	–	–	–	yes	yes
NEG	–	yes	yes	yes	yes
NOP	–	–	–	–	–
NOT	–	–	–	yes	yes
OR	–	–	–	yes	yes
PRI	–	–	–	yes[3)]	yes
RR	–	–	–	yes	yes
RL	–	–	yes	yes	yes
SET	–	–	–	–	–

Table 11-15 Flag Updates (cont'd)

Instruction	CN1Z	V	C	N	Z
SHR	–	–	–	yes[3)]	yes
SHL	–	–	yes	yes	yes
ST	–	–	–	–	–
SUB	–	yes	yes	yes	yes
XCH	–	–	–	yes	yes
XOR	–	–	–	yes	yes

1) CN1Z is only modified by the BCOPY, COPY or EXIT instructions if the instruction has been configured to decrement R6.CNT1 (for BCOPY/COPY CNC = 1 or CNC = 2, for EXIT EC = 1). All other instructions have no effect on the CN1Z flag.

2) For the LD.I type of instruction, flag N is always cleared, as bit 31 of the result is always 0.

3) Flag N is always cleared, as bit 31 of the result is always 0.

11.18.40 Instruction Timing

This section gives some information about the duration of PCP instructions. Please note that there are various conditions that can further affect the duration of PCP instructions (e.g. external FPI accesses from another FPI Bus master to the PCP memories stall the PCP Processor Core).

*Note: The clock cycles listed in **Table 11-16** are PCP core clock cycles. When running in 2:1 clocking mode the maximum allowed PCP core clock frequency is 180 MHz (resulting in a minimum PCP core clock cycle time of 5.6ns). When running in 1:1 clocking mode the maximum PCP core clock frequency is the same as the maximum System Peripheral Bus frequency. In the TC1798 the System Peripheral Bus (which is an FPI Bus) is clocked with f_{FPI}, resulting in a minimum PCP core clock cycle time of 11.1ns (in 1:1 clocking mode).*

*Note: Where an execution time is stated for an FPI instruction this is always a **minimum** value. A number of FPI instructions must wait for the completion of an FPI transaction (or transactions). When running in 2:1 mode each FPI clock cycle consists of two core clock frequencies. Where this applies the cycle count is shown with an "FPI" superscript designation (e.g. "3^{FPI}"). In addition there may be an additional single core clock cycle taken according to alignment of execution of an FPI instruction relative to an FPI clock edge.*

1) The number of clock cycles for these instructions depends on several parameters such as the amount of data to be copied, the type of memory, and the effective bus load.

2) f = Full Context save, s = Small Context save, m = Minimum Context save time extended until any previous ST.F instruction has completed.

3) Cycles = 5 internal + 3 minimum for FPI read (with 0 wait cycles + 1 cycle for bus arbitration and assuming 1:1 clocking mode)

4) Cycles = 4 internal + 4 minimum for FPI read/modify/write (with 0 wait cycles + 1 cycle bus arbitration and assuming 1:1 clocking mode)

5) Cycles = 2 internal + 3 minimum for FPI write (with 0 wait cycles + 1 cycle for bus arbitration and assuming 1:1 clocking mode)
Time starts after any previous ST.F instruction has completed.

6) 32/32 bit divide requires instruction DINIT + JC + 4 × DSTEP = 1 + 4(2) + 4 × 10 = 45 cycles
8/32 bit divide requires instruction RR + DINIT + JC + DSTEP = 1 + 1 + 4(2) + 10 = 16 cycles

7) 32 × 8 bit multiply requires instructions RR + MINIT + MSTEP.L = 1 + 1 + 10 = 12 cycles
32 × 16 bit multiply requires instructions 2 × RR + MINIT + 2 × MSTEP.L = 2 × 1 + 1 + 2 × 10 = 23 cycles
32 × 32 bit multiply requires instructions MINIT + 4 × MSTEP.U= 1 + 4 × 11 = 45 cycles

8) sdb - 0 = Stop_on_Debug bit in instruction = 0 (disabling stop)
sdb - 1 = Stop_on_Debug bit in instruction = 1 (enabling stop)
exit_time = same time as for an exit instruction

9) y = jump taken, n = jump not taken

11.19 Instruction Encoding

Most instructions are encoded in 16 bits.

This allows two instruction to be fetched out of 32 bit instruction memory per access.

For example, a COPY and an EXIT instruction can be fetched simultaneously, performing a simple DMA transaction.

Table 11-17 Field Definitions

Symbol	Name	Description
CNC	Counter Control	00: Perform the number/type of transfers appropriate to the instruction, and proceed to the next instruction. 01: Perform the number/type of transfers appropriate to the instruction, then decrement CNT1 and proceed to next instruction. 10: Use CNT1 as an “outer loop counter”. Perform the number/type of transfers appropriate to the instruction, then decrement CNT1. Repeat until CNT1 = 0, then proceed to next instruction. If R[7].IEN = True (interrupts enabled) the instruction may be interrupted at the end of each iteration of the “outer loop”. 11: N/A (error)
CNT0	Internal Loop Counter /Block Size Control	Internal Loop Counter for COPY: 000: Perform a sequence of 8 read/write transfers n: Perform a sequence of n (1 <= n <= 7) read/write transfers Block Size control for BCOPY: 000: 8 Words 001: N/A (error) 010: 2 Words 011: 4 Words 1xx: N/A (error)
CONDCA/B	Condition Code	Condition Code for conditional execution of instruction.
DAC	Disable All Channels Control	0: no action 1: Clear CS.EN which stops the PCP executing and further channel programs.
DST+/-	Destination Address Increment / Decrement	00: No Change 01: Post Increment by Size 10: Post Decrement by Size 11: N/A (error)

Table 11-17 Field Definitions (cont'd)

Symbol	Name	Description
EC	Exit Count Control	0: no action 1: decrement CNT1
EDA	External Debug Action	0: No External Debug Action caused 1: Cause an External Debug Action (breakpoint pin etc.)
EP	Entry Point	Entry Point on next Channel Invocation: 0: Set the PC to Channel Start 1: Set the PC to the address contained in NextPC (next instruction) address. Note: EP=0 assumes that a Channel Entry Table exists in the base of Code Memory. Failure to provide one will cause improper operation.
INT	Interrupt	Issue interrupt 0: No 1: Yes if (CONDCB = True)
RTA	Return to This Address	0: The channel is disabled (R7.CEN=0) and the PC value stored in the context is NextPC. 1: The channel remains enabled and the PC value stored in the context is NextPC - 1.
SDB	Stop on Debug	0: Continue running if Debug Event Triggered 1: Stop PCP Channel if Debug Event Triggered
Set/Clr	Set/Clear	0: Check for Clear (0) 1: Check for Set (1)
SIZE	Data Size	00: Byte (8-bit) 01: Half Word (16-bit) 10: Word (32-bit) 11: Reserved
SRC+/-	Source Address Increment / Decrement	00: No Change 01: Post Increment by Size 10: Post Decrement by Size 11: N/A (error)
ST	Stop Channel	0: Leave Channel enabled 1: Stop Channel from accepting new Service Requests (clear R[7].CEN)

11.20 Programming of the PCP

In this section, several techniques are outlined to help design channel programs. There are also examples on configuring a channel program's context.

11.20.1 Initial PC of a Channel Program

A channel program can begin operation at the Channel Entry Table location corresponding to the priority of the interrupt. This is much like an interrupt vector location for that channel in a traditional processor architecture. When the channel program is started, the PC is set to two-times the channel number (SRPN). Since the base of the Channel Entry Table is the bottom of the CMEM address range, and since each entry in the table is two instructions long, this address computation results in the first instruction of the channel program for that SRPN being fetched from memory for execution.

Alternately, the channel program can be made to begin executing at whatever address its restored context holds in R7.PC.

If PCP_CS.RCB = 1, then the channel program is forced to always start at its Channel Entry Table location regardless of the PC value stored in the CSA. If PCP_CS.RCB = 0, then the channel program will simply begin executing at whatever PC value is restored in the context R7.PC.

It is important to be aware of the implications of these two approaches on how CMEM should be configured, and what the initial value of the PC should be in the channel program's context that is loaded in the PRAM CSA at boot time.

11.20.1.1 Channel Entry Table

When PCP_CS.RCB = 1, the program counter of the PCP is vectored to the appropriate channel entry table each time a channel program is invoked by the receipt of an interrupt. The PCP is forced to start executing from its channel entry table location, regardless of its previous context or PC state.

If the EXIT instruction is executed with EP = 0, the PC saved during the context save operation will be the channel entry table location for that channel. That means that the next time the channel program is started, it will begin operation at the appropriate location in the Channel Entry Table.

Note: If EP = 0 is set in any channel program, or if PCP_CS.RCB = 1, a Channel Entry Table must be provided at the base of CMEM. Otherwise this table is not needed.

11.20.1.2 Channel Resume

When PCP_CS.RCB = 0, the program counter of the PCP is vectored to the address that is restored from the channel program's context. This means that before exiting, a channel program must itself arrange for where it will resume execution by configuring the value of its PC in its saved context so that it restarts at the desired location.

In this way, arbitrarily complex interrupt-driven state machines can be created as individual channel programs. Channel programs can be constructed that always start at their beginning, pick up where they left off, or pick up elsewhere, or have a mix of these approaches.

An example of a restarting channel program is shown below. Before exiting, the channel branches back to the address of the START label minus 1 (note that START - 1 = CH16) and then exits. This will leave the next value of the PC in the channel program's context as the address of the START label.

```
CH16:                              ;channel program 16
     EXIT EC=1 ST=0 INT=0 EP=1 cc_UC
                                   ;exit, no intr., leave PC @ next
START:                             ;nominal channel start address
     ST.IFbase #0x8 SIZE=32        ;output note from R0
     JC   CH16, cc_UC              ;loop back before exit
```

Note that when the channel program is originally configured by the programmer, the PC field in the R7 context of this channel program should also be set to the address of the START label.

Similarly, an interrupt-driven state machine can be created by exiting with the next PC value pointing to the start of the next state in a state machine implemented by the channel program. The next example below shows a program starting at the address to the STATE0 label. It proceeds after the first interrupt to STATE1 - 1, where the channel program is left ready for the next state, STATE1 in the state machine. After the next interrupt, it executes to address STATE2 - 1 and the channel program is left ready for the next state, STATE2. After another interrupt, it proceeds through STATE2. The channel program jumps back to START, which is STATE0 - 1. The state machine has gone through one cycle and it is ready to restart in STATE0.

```
;This program is intended to test the sequence of exit/operate
;just as if you were implementing an interrupt driven
;state machine.
;It requires a periodic sequence of interrupts.

START:
     EXIT EC=1,ST=0,INT=0,EP=1,cc_UC;begin exit
STATE0:
     COMP.I     R5,#0x0            ;compare to interrupt number
                                   ;it should be
```

```
      JC          ERROR,cc_NZ      ;jump to error routine
                                   ;if not correct
      ADD.I       R5,#0x1          ;increment state number
      EXIT EC=1,ST=0,INT=0,EP=1,cc_UC      ;begin exit
STATE1:
      COMP.I      R5,#0x1          ;compare to interrupt number
                                   ;it should be
      JC          ERROR,cc_NZ      ;jump to error routine
                                   ;if not correct
      ADD.I       R5,#0x1          ;increment state number
      EXIT EC=1,ST=0,INT=0,EP=1,cc_UC      ;begin exit
STATE2:
      COMP.I      R5,#0x2          ;compare to interrupt number
                                   ;it should be
      JC          ERROR,cc_NZ      ;jump to error routine if
                                   ;not correct
      LD.I        R5,#0x0          ;reset state number
      JC          START,cc_UC      ;jump back to start of
                                   ;state machine
```

The last state could just as easily have ended with an EXIT that resets the PC to the Channel Entry Table (EP = 0) rather than jumping back to START.

11.20.2 Channel Management for Small and Minimum Contexts

If Small or Minimum Contexts are being used, only some of the registers are saved and restored. The integrity of the GPRs that are **not** included in the context must be handled explicitly by channel programs, since these are not saved and restored with the context of the interrupted channel program.

Channel programs may still use all registers reliably. Channel programs can be so designed that they either ignore the values in unsaved registers, or use those registers to store constants that no channel program changes. Hence, they never need to be saved and restored. Alternately, channel programs can use these unused GPRs as temporary variables as long as the values of such registers cannot be corrupted by the interrupt of the channel program by a higher-priority channel (see **Page 11-151**).

11.20.3 Unused Registers as Global's or Constants

Registers R0 through R3 (for the Small Context Model), or R0 through R5 (for the Minimum Context Model) can be used to store constants such as addresses that are available to all channel programs. Hence, these registers hold global data, and no channel program is allowed to change them.

Since the GPRs of the PCP are not directly accessible from the FPI Bus, there does need to be an initial channel program that sets these values at or near boot time. There are

two choices here. A boot-time interrupt channel program can be invoked once to perform initialization, or there can be a program that routinely loads these values as a matter of course, and is invoked at boot time or as upon receipt of the very first interrupt.

11.20.4 Dispatch of Low Priority Tasks

A higher-priority channel program may wish to start a low-priority background task, or periodically pause and re-start itself later when there is no other action required at the moment. This can be accomplished in several ways:

- Post an SRPN to a free SRN on the FPI Bus, then EXIT.
- Perform an EXIT, posting the interrupt to the PCP, and indicating the channel number to be started.
- Use a single channel program as a list-driven or state-driven task dispatcher.

The first approach is straightforward to program, but uses a system SRN resource. Its advantage is that it allows continuous channel operation without using the interrupt queue, or risk blocking other uses of the PCP.

The second approach can be implemented by having a looping channel program continue operation in the background. It will also always be superseded by any higher-priority tasks.

The third approach uses a channel program to dispatch other non-interrupt-driven channel programs in an arbitrary order determined by the channel program dispatcher. In this way, multiple tasks could be continuously operated without over-using the PCP service-request queue. This approach would be useful when the aim is to poll for service requests in the peripheral SRNs rather than having them started by PCP hardware.

11.20.5 Code Reuse Across Channels (Call and Return)

A special jump instruction is included in the PCP instruction set to allow subroutines to be called from multiple channel programs. A routine may be jumped to directly, and then returned from using the JC.IA instruction. JC.IA allows a calling channel program to set aside a register for its return address, which will typically be the value of the next PC. The called subprogram can then execute a JC.IA, to the address stored in the register specified, causing a return-from-subroutine operation. The programmer must adopt and enforce a calling convention to determine which register holds the return address. Register R2 is normally used for this purpose.

For example:

```
Main Routine:                    Subroutine:
     LD.IL     R2,#RETURN            SUB:  MOV...
     JC.A      #SUB                        ADD...
RETURN: MOV    ...                         ...
     ...                                   JC.IA R2
```

11.20.6 Case-like Code Switches (Computed Go-To)

The JC.I instruction can be used to implement a multi-way branch for branch-on-bit or branch-on-state conditional branches. This instruction allows a conditional relative jump based on an index held in a register. If this instruction is combined with a table of jump addresses, a switch-type statement can be implemented. The default case, that is when the condition code = False, is the next instruction, as is the jump with register index = 0. The table can be any arbitrary length. The index register should be checked for range before the jump into the table is performed.

For Example:

```
           COMP  R3,#5      ;compare R3 to #5 - the number
                            ;of entries in the table
           JC.I  R3,cc_ULE
DEFAULT:   JL    #case_0    ;destination if R3 = 0 or
                            ;condition = false
           JL    #case_1    ;destination if R3 = 1
           JL    #case_2    ;destination if R3 = 2
           JL    #case_3    ;destination if R3 = 3
           JL    #case_4    ;destination if R3 = 4
           JL    #case_5    ;destination if R3 = 5
```

11.20.7 Simple DMA Operation

A simple interrupt-driven DMA requires at least the Small Context Model to operate properly. Its operation is consists of three stages:

- The device interrupts the PCP to indicate it can receive or provide data.
- The PCP moves the amount of data it is programmed to move.
- The PCP eventually finishes and interrupts the CPU to notify it that the DMA is complete.

There are two options for implementing a simple DMA operation, copy and burst copy.

11.20.7.1 COPY Instruction

A simple DMA channel program can consist of only two instructions. In the example below, a device interrupts the PCP to notify it that it has data in its output buffer, which is 4 words deep. The COPY instruction copies 4 words to memory at a time. It decrements CNT1 (which is initialized by the CPU in CR6_CNT1 context) after each 4 word transfer. The EXIT command then executes, and if CNT1 was decremented to 0, the condition code causes it to issue an interrupt with the value held R6_SRPN.

```
COPY  DST+,SRC,CNC=1,BRST=4,SIZE=32   ;do peripheral -> memory DMA
EXIT  EC=0,ST=0,INT=1,EP=0,cc_CNZ     ;transfer done, so exit
```

In the example above, the COPY instruction increments the destination held in R5 (DST+), and the source address is left constant in R4 (SRC). All permutations of decrement, increment or do not modify can be applied to either pointer register (R4 and R5) by use of the SRC and DST fields (SRC-, SRC+ or SRC and DST-, DST+ or DST).

Building on this basic DMA method, scatter-gather DMA channels can be created.

11.20.7.2 BCOPY Instruction (Burst Copy)

The BCOPY instruction is in principle similar to the COPY instruction except that it uses the FPI Burst mode to perform the transfers rather than performing individual reads/writes. As for the COPY instruction, the FPI Bus is locked between the burst read and burst write to ensure that a valid set of data is transferred. The BCOPY instruction allows support of all burst sizes supported by FPI Burst Mode except a burst size of 1 (i.e. 2, 4 or 8 words). The CNT0 field is used to control the burst size. Both the source and destination addresses (R4 and R5) must be correctly aligned for the burst size being used (see the FPI Bus description for details). If either address is incorrectly aligned, the PCP will generate an Illegal Operation Error Exit.

See also **Page 11-157** for TC1798 specific details of the BCOPY instruction.

11.21 PCP Programming Notes and Tips

This section discusses constraints on the use of the PCP and points out some non-obvious issues.

11.21.1 Notes on PCP Configuration

For configuring of the PCP, some notes should be regarded.

- Only one Context Model may be used at a time for all channels, and the PCP must remain in that Context Model once started and configured.
- In order for a specific channel program to be enabled, its context must have R7.CEN = 1. If R7.CEN = 0, the channel program will terminate when invoked, and cause a Disabled Channel Request error.
- The Channel Context Address from the FPI Bus as viewed during channel configuration is as follows:
- Full Context Model: PRAM Base + $20_H \times n$
- Small Context Model: PRAM Base + $10_H \times n$
- Minimum Context Model: PRAM Base + $08_H \times n$
  where n is the channel number.
- PCP_CS.RCB and context must be consistent. If RCB is configured to 0, then each channel program will start at the PC restored from its context. If the wrong address is pre-configured in the context, the channel program will not operate properly.
- The programmer of the PCP may lock PCP_CS by setting PCP_CS.EIE = 1. When the global ENDINIT bit is set, the PCP_CS register will no longer be writable, and attempting to do so will cause an FPI Bus error.
- An error condition will result in an interrupt being sent to the local FPI Bus master. The targeted interrupt service routine must be capable of dealing with the cause as recorded in PCP_ES, and, if required, it must be able to return the halted channel program to operation. The minimum required to do that is to set the context value of R7.CEN = 1.
- The only PCP Register bit that can be dynamically modified during PCP operation is the PCP_CS.EN bit. When writing to any other PCP Register bits, the user must ensure that the PCP is disabled (PCP_CS.EN = 0) and that the PCP is quiescent (PCP_CS.RS = 0).

11.21.2 General Purpose Register Use

When using the general purpose registers of the PCP, some notes should be regarded.

- The most significant 16 bits of R7 may not be written, and will always read back as 0. However, no error will occur if a write to the most significant 16 bits occurs.
- Care must be taken with the use of R6 as a general-use register to ensure that R6 contains the correct value prior to execution of the EXIT command. As R6 contains the CNT1 (counter used in COPY and optionally in EXIT instructions), SRPN and

TOS (service request number to use during optional interrupt at channel program EXIT) fields, R6 should not be used to pass values from one invocation of a channel program to the next invocation.

- If PRAM is to be accessed programmatically, then R7.DPTR must be configured properly as a pointer into the PRAM. This points to the 64-word segment that may be addressed by the xx.P instructions and the xx.PI instructions. It is not recommended to set R7.DTPR to point into the CSA. Special care must be taken that the Context PRAM is not overwritten.
- The programmer must be careful not to inadvertently clear R7.CEN when updating R7.DTPR (or any other field in R7). This would cause the channel program to generate a disabled channel interrupt to the CPU when the next interrupt request to the channel occurs.
- Any update to the Flags that is caused by an instruction (e.g. MOV R7, R0 which updates Z and N) takes precedence over any explicit bits that are moved to R7. See **Page 11-11**.
- The interrupt system assumes SRPN 0 is not a request. Full Context packing leaves the least significant 8 × 32-bit entries where channel 0 would normally be unused. That is, PRAM Base -> PRAM Base + 1 channel. In addition, for Small Context, the least significant 4 × 32-bit entries are unused, and for Minimum Context the least significant 2 × 32-bit entries are un-used. These “unused” entries should not be used by channel programs.
- If EP = 0 is used, or if PCP_CS.RCB = 1, a Channel Entry Table must be provided at the base of CMEM.
- If there is a plan to use the Small or Minimum Context Model, and the lower registers are to hold global values, then there needs to be an initial channel program that sets these values at or near boot time. There are at least two choices for implementing this. For instance, a boot interrupt channel program can be invoked once to perform initialization, or there can be a program that routinely loads these values as a matter of course, and it is invoked at boot time, or at the very first interrupt. See **Page 11-147**.
- When using Small or Minimum Context models and allowing a channel to be interrupted, care must be taken to ensure that the value of any registers that are not included in the context but are being used by a channel are not corrupted by interruption of the channel and subsequent operation of a higher-priority channel. Particular care must be taken when using instructions that use R0 implicitly. If necessary, critical instruction sequences should be protected by use of the R7.IEN bit (see **Page 11-153**).

11.21.3 Use of Channel Interruption

For channel interruption, the following note should be regarded.

- When a channel program consists of only a few instructions, it is best to configure the channel to be non-interruptible. This increases overall efficiency by removing the context save/restore overhead that would be incurred if the channel were to be interruptible.

11.21.3.1 Dynamic Interrupt Masking

A channel program can dynamically control whether it can be interrupted by use of the R7.IEN bit. When masking interrupts (by clearing R7.IEN), it must be noted that there is a delay of one instruction before the mask becomes effective. As a result the instruction that clears R7.IEN must be placed at least one instruction before the instruction sequence that is to be un-interruptible. As an example, consider the following sequence:

```
CLR   R7,IEN     ;Clear the R7.IEN bit
                 ;<< Interrupt can occur here
NOP
                 ;<< Interrupt can occur here
                 ;First instruction of non-interruptible
                 ;code sequence
```

11.21.3.2 Control of Channel Priority (CPPN)

The PCP has three extended Service Request Nodes (PCP_SRC9, PCP_SRC10 and PCP_SCR11) that allow storage of suspended channel interrupt requests. This allows interrupt nesting to a depth of four. This limit on the nesting depth carries the danger that a high-priority service request will not be serviced because the PCP's interrupt nesting depth has been exceeded.

It is recommended that a four-level "grouping" scheme should be adopted to avoid this problem. All PCP interrupt sources should be listed in order of their SRPNs.This list should then be subdivided into four contiguous groups, Group 0 being the lowest priority and Group 3 the highest. The CSA for each channel program should be configured such that CR6.CPPN contains the SRPN value of the highest channel program within the group to which the channel belongs. As each channel starts, the Operating Priority (CPPN) of the channel is loaded from the context. Using the scheme recommended above, any channel program will run with the priority of the highest SRPN within the group. As a result, the channel can only be interrupted by a service request from a higher-priority group (e.g. a Group 0 channel program can be interrupted by a new service request for a channel in any group from 1 to 3, a group 2 channel program can only be interrupted by a new service request for a channel in group 3).

Note: When using this scheme, each channel program must ensure prior to channel exit that the R6.CPPN field contains the appropriate value, so that when the channel is next invoked, it will run at the correct priority.

11.21.4 Implementing Divide Algorithms

As discussed in **Section 11.18.4**, a divide algorithm **must** always start with a DINIT instruction followed by a number of DSTEP instructions (up to four depending on the data width that is required). Prior to execution of any DSTEP instruction, R0 always contains either 0 (if this is the first DSTEP instruction in a divide sequence R0 contains 0 due to the preceding DINIT instruction, or the remainder from the previous DSTEP instruction). The dividend to be used in this step is generated in R0 by taking 256 × the remainder of the last DSTEP instruction (R0 << 8) and adding the most significant byte of Rb (Rb >> 24) as the LSB of the new dividend.

Since the remainder of the last DSTEP instruction is by definition always less than the divisor (Ra), it can be guaranteed that the result of the division of the dividend (calculated as above) by the divisor (Ra) can always be contained within an 8-bit result. The description given on **Page 11-114** only holds true under this condition. If the restrictions on the use of the DSTEP instruction (specified on **Page 11-105**) are adhered to, the above condition will always be met and this description of the instruction is correct. Failure to adhere to these conditions will lead to invalid results, which are outside the scope of this document.

During execution of a divide sequence, Rb is used both to compile the final divide result and to hold the remnants of the original dividend. For example, in a 32-/32-bit divide sequence (which consists of 4 DSTEP instructions - see below), Rb will have the following content:

- After the 1st DSTEP instruction:
  The least significant 3 bytes (24 bits) of the original 32-bit dividend (held in the most significant 3 bytes of Rb) and the most significant byte of the final result (held in the least significant byte of Rb).
- After the 2nd DSTEP instruction:
  The least significant 2 bytes (16 bits) of the original 32-bit dividend (held in the most significant 2 bytes of Rb) and the most significant 2 bytes of the final result (held in the least significant 2 bytes of Rb).
- After the 3rd DSTEP instruction:
  The least significant byte of the original 32-bit dividend (held in the most significant byte of Rb) and the most significant 3 bytes of the final result (held in the least significant 3 bytes of Rb).
- After the final DSTEP instruction:
  The 32 bit final result.

Note that the DSTEP instruction **always** uses the divisor as a 32 bit value. In any divide sequence, the dividend can be 8, 16, 24 or 32 bits (according to the number of DSTEP

instructions in the sequence) but the divisor is **always** 32 bits. Prior to the DINIT instruction, the dividend must always occupy the appropriate most significant bits within the 32-bit dividend register (Rb).

Divide Examples

Example of a 32/32 bit divide (R5 / R3):

```
DINIT     R5, R3     ;Initialize ready for the divide
JC        HANDLE_DIVIDE_BY_ZERO, cc_V     ;V flag was set
                     ;so jump to divide
                     ;by zero error handler
DSTEP     R5, R3     ;4 DSTEP instructions
                     ;(4 * 8 = 32 bit
DSTEP     R5, R3     ;divide)
DSTEP     R5, R3
DSTEP     R5, R3
```

After this sequence, R5 holds the result, R0 the remainder and R3 is unchanged.

Example of a 8/32 bit divide (R4 / R2):

```
RR        R4, 8      ;Rotate R4 right by 8 to move
                     ;least significant byte into
                     ;most significant byte
DINIT     R4, R2     ;Initialize ready for the divide
JC        HANDLE_DIVIDE_BY_ZERO, cc_V     ;V flag was set
                     ;so jump to divide
                     ;by zero error handler
DSTEP     R4, R2     ;DSTEP instruction
                     ;(1 * 8 = 8 bit divide)
```

After this sequence, R4 holds the result, R0 the remainder and R2 is unchanged.

Note that the above example is specified as being a 8/32 bit divide rather than an 8/8 bit divide (see comments above).

11.21.5 Implementing Multiply Algorithms

As discussed in **Section 11.18.4**, a multiply algorithm **must** always start with a MINIT instruction, followed by a number of MSTEP32 or MSTEP64 instructions. The MSTEP32 instruction is used to compile a multiplication result contained in 32 bits, discarding any overflows. The MSTEP64 instruction is used to compile a 64-bit multiplication result with the least significant 32 bits of the result contained in Rb and the most significant 32 bits of the result contained in R0.

Multiply Examples

Example of a 32 $\times$ 8 bit multiply (R4 $\times$ R1) yielding a 32 bit result (R4 = 32 bit, R1 = 8 bit):

```
RR        R1, 8      ;Rotate least significant byte of R1
                     ;to most significant byte
MINIT     R1, R4     ;Initialize ready for multiply
MSTEP32   R1, R4     ;Perform one MSTEP32 instruction
                     ;(8 bit multiply)
```

After this sequence, R0 holds the result, R1 is left unchanged (right rotated by RR instruction then left rotated by MSTEP32 instruction), and R4 is unchanged. The result is only valid if there is no overflow (i.e. the product of the 8-bit number in R1 multiplied by the 32-bit number in R4 can be contained within 32 bits). It is the user's responsibility to ensure that this is the case. The overflow condition cannot be detected after execution of the multiply sequence.

Example of a 32 × 16 bit multiply (R3 × R2) yielding a 32 bit result
(R3 = 32 bit, R2 = 16 bit):

```
RR        R2, 8      ;Perform two 8 bit rotations
                     ;(RR instructions) to get original
                     ;least significant 16 bits into
                     ;most significant 16 bits
RR        R2, 8
MINIT     R2, R3     ;Initialize ready for multiply
MSTEP32   R2, R3     ;Perform two MSTEP32 instructions
                     ;(16 bit multiply)
MSTEP32   R2, R3
```

After this sequence, R0 holds the result, R2 is left unchanged (right rotated by two RR instructions, then left rotated by two MSTEP32 instructions), R3 is unchanged. The comment above regarding overflow also applies to this sequence.

Example of a 32 × 32 bit multiply (R5 × R2) yielding a 64 bit result
(R5 = 32 bit, R2 = 32 bit):

```
MINIT     R2, R5     ;Initialize ready for multiply
MSTEP64   R2, R5     ;Perform 4 MSTEP64 instructions
                     ;(64-bit multiply)
MSTEP64   R2, R5
MSTEP64   R2, R5
MSTEP64   R2, R5
```

After this sequence R0 and R2 hold the result (most significant word in R0, least significant word in R2), R5 is unchanged. There is no possibility of overflow as the result of 32 × 32 bits can always be contained in 64 bits.

11.22 Implementation of the PCP in the TC1798

The addresses of the PCP registers and memories in the TC1798 are given in the following subsections:

11.22.1 PCP Memories

In the TC1798, the location of the registers and the memories sizes of the PRAM and the CMEM are given in **Table 11-19**.

Table 11-19 General Block Address Map

Unit		Address Range	Access Mode		Size
			Read	Write	
PCP	Reserved	$F004\ 0000_H$ - $F004\ 3EFF_H$	BE	BE	–
	PCP Registers	$F004\ 3F00_H$ - $F004\ 3FFF_H$	see **Page 11-67**		256 byte
	Reserved	$F004\ 4000_H$ - $F004\ FFFF_H$	BE	BE	–

Note: "BE" means that in case of an access to this address region a bus error is generated.

11.22.2 BCOPY Instruction

In the TC1798, the BCOPY instruction can be used to perform burst transfers (2, 4, or 8 words) with DMI memories (Local data RAM) and the PCP memories. Other internal and external memories can be accessed using a burst size of 2 words only (CNT0 = 10_B).

11.22.3 PCP Reset Operation

The PCP module can be reset by a system hardware signal (hard reset).

PCP Hard Reset

A PCP hard reset is always triggered if at least one of these TC1798 reset sources becomes active:

- Watchdog Timer Reset
- Hardware Reset
- Power-on Reset

Each of these reset sources forces a hardware reset of the functional blocks within the PCP module. The effect of hard reset within the PCP is to:

- Halt any operating channel
- Reset all control registers to their reset values
- Reset the PCP Processor Core to its default state
- Reset the FPI Bus interface

12 Direct Memory Access Controller (DMA)

This chapter describes the Direct Memory Access (DMA) Controller and the Memory Checker Module (MCHK) of the TC1798. It contains the following sections:

- Functional description of the DMA controller kernel (see **Section 12.2**)
- DMA controller module register description (see **Section 12.3**)
- TC1798 implementation-specific details of the DMA controller (interrupt control, address decoding, clock control, see **Section 12.4**)
- Functional description of the Memory Checker (MCHK) module (see **Section 12.5**)
- Memory Checker module register description (see **Section 12.5.2**)

*Note: The DMA kernel register names described in **Section 12.3** are referenced in the TC1798 User´s Manual by the module name prefix "DMA_".*

12.1 What is new

Major differences of the AudoMax DMA compared to AudoFuture:

- The AudoMax system architecture uses an SRI-XBAR in place of an LMB-BUS. The DMA LMB-Master is replaced by an SRI-Master.
- The LMB-Master 64-bit buffer to support read accesses to cached addresses (Segment 8) is replaced by an SRI-Master 256-bit buffer. In AudoFuture a Segment 8 read access was translated to a Single Data Transfer Double-Word (SDTD) access; in AudoMax it is translated to a 4-Transfer Block Transfer Request (BTR4) access.
- The access protection is extended from 32 to 64 fixed address ranges by the addition of a second Move Engine Access Enable Register. The number of programmable address range extensions is increased from 4 to 8 by the addition of a second Move Engine Access Range Register.

12.2 DMA Controller Kernel Description

The DMA Controller of the TC1798 transfers data from data source locations to data destination locations without intervention of the CPU or other on-chip devices. One data move operation is controlled by one DMA channel. Eight DMA channels are provided in one DMA Sub-Block. The Bus Switch provides the connection of the DMA Sub-Blocks to the two On Chip Bus interfaces and a DMA Peripheral interface. In the TC1798, the two On Chip Bus interfaces are connected to the System Peripheral Bus and the SRI Bus. The DMA Peripheral interface provides a connection to the Cerberus module, Micro Link Interface modules and other DMA-related devices (Memory Checker module in the TC1798). Clock control, address decoding, DMA request wiring, and DMA interrupt service request control are implementation-specific and are managed outside the DMA controller kernel.

The index “m” in the following block diagram refers to the DMA Sub-Block number (m = 0-1).

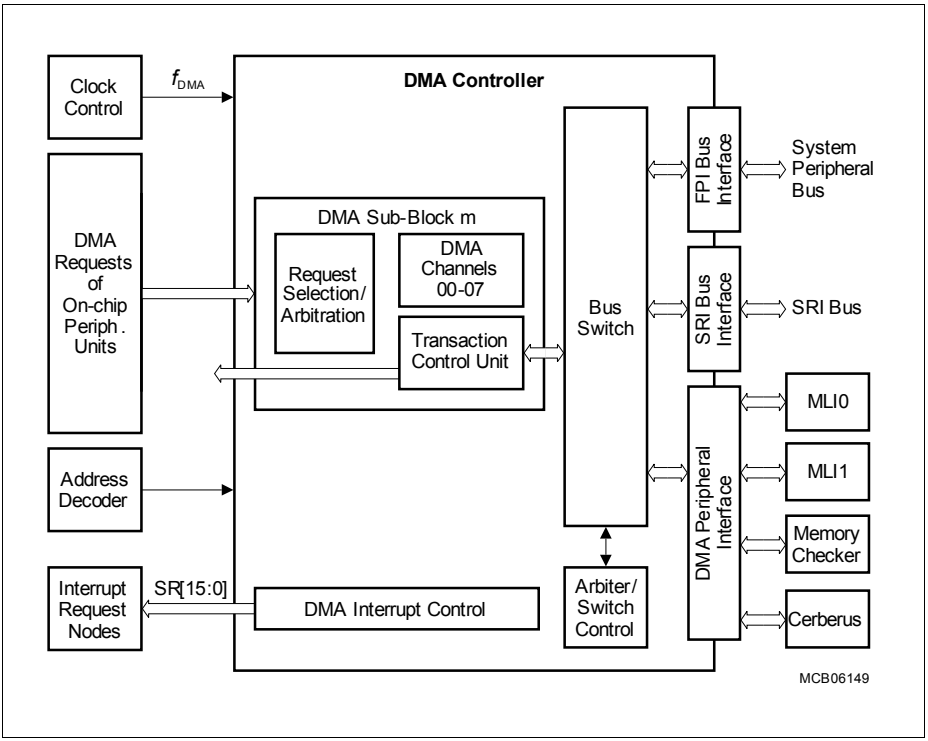

Figure 12-1 DMA Block Diagram

12.2.1 Features

The DMA controller is a fast and flexible DMA controller that has the following features:

- 16 independent DMA channels
  - 2 DMA Sub-Blocks with (8 DMA channels per DMA Sub-Block)
  - DMA Sub-Blocks with support of parallel channel execution (1 channel per Sub-Block, both Sub-Blocks in parallel)
  - Up to 16 selectable request inputs per DMA channel
  - 2-level programmable priority of DMA channels within the DMA Sub-Block
  - Software and hardware DMA request
  - Hardware requests by selected on-chip peripherals and external inputs
- 3-level programmable priority of the DMA Sub-Blocks on the chip bus interfaces
- Buffer capability for move actions on the buses (at least 1 move per bus is buffered)
- SRI Master Interface with 256-bit read buffer for read accesses to cached areas (Segment 8).
- Individually programmable operation modes for each DMA channel
  - Single Mode: stops and disables DMA channel after a predefined number of DMA transfers
  - Continuous Mode: DMA channel remains enabled after a predefined number of DMA transfers; DMA transaction can be repeated
  - Programmable address modification
  - Two shadow register modes (with / w/o automatic reset and direct write access).
- Full 32-bit addressing capability of each DMA channel
  - 4 Gbyte address range
  - Data block move > 32 Kbyte per DMA transaction
  - Circular buffer addressing mode with flexible circular buffer sizes
- Programmable data width of DMA transfer/transaction: 8-bit, 16-bit, or 32-bit
- Register set for each DMA channel
  - Source and destination address register
  - Channel control and status register
  - Transfer count register
- Flexible interrupt generation (the service request node logic for the MLI channels is also implemented in the DMA modules)
- DMA module is working on FPI frequency, SRI interface on SRI frequency.

Dependant on the target/destination address, Read/write requests from the Move Engines are directed to the FPI Bus, SRI Bus, MLIs or to the Cerberus module.

12.2.2 Definition of Terms

Some basic terms must be defined for the functional description of the DMA controller.

DMA Move

A DMA move is an operation that always consists of two parts:

1. A read move that loads data from a data source into the DMA controller
2. A write move that puts data from the DMA controller to a data destination

Within a DMA move, data is always moved from the data source via the DMA controller to the data destination. Data is temporarily stored in the DMA controller. The data widths of read move and write move are always identical (8-bit, 16-bit or 32-bit). Data assembly or disassembly is not supported.

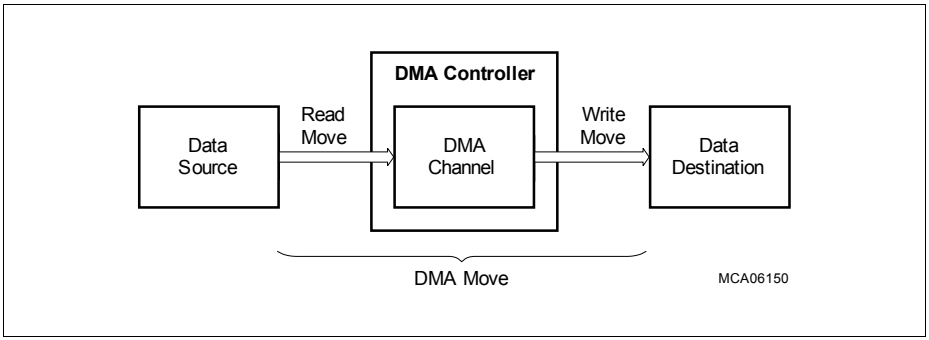

Figure 12-2 DMA Definition of Terms

DMA Transfer

A DMA transfer can be composed of 1, 2, 4, 8 or 16 DMA moves.

DMA Transaction

A DMA transaction is composed of several (at least one) DMA transfers. The Transfer Count determines the number of DMA transfers within one DMA transaction.

Example:
1024 word (32-bit wide) transactions can be composed of 256 transfers of four DMA word moves, or 128 transfers of eight DMA word moves.

12.2.3 DMA Principles

The DMA controller supports DMA moves from one address location to another one. DMA moves can be requested either by hardware or by software. DMA hardware requests are triggered by specific request lines from the peripheral modules or from other DMA channels (see **Figure 12-3**). The number of available DMA request lines from a peripheral module varies depending on the module functionality. Typically, the parallel occurrence of DMA requests and interrupts requests for DMA channels is possible. Therefore, the interrupt control unit and the DMA controller can react independently to interrupt and DMA requests that have been generated by one source.

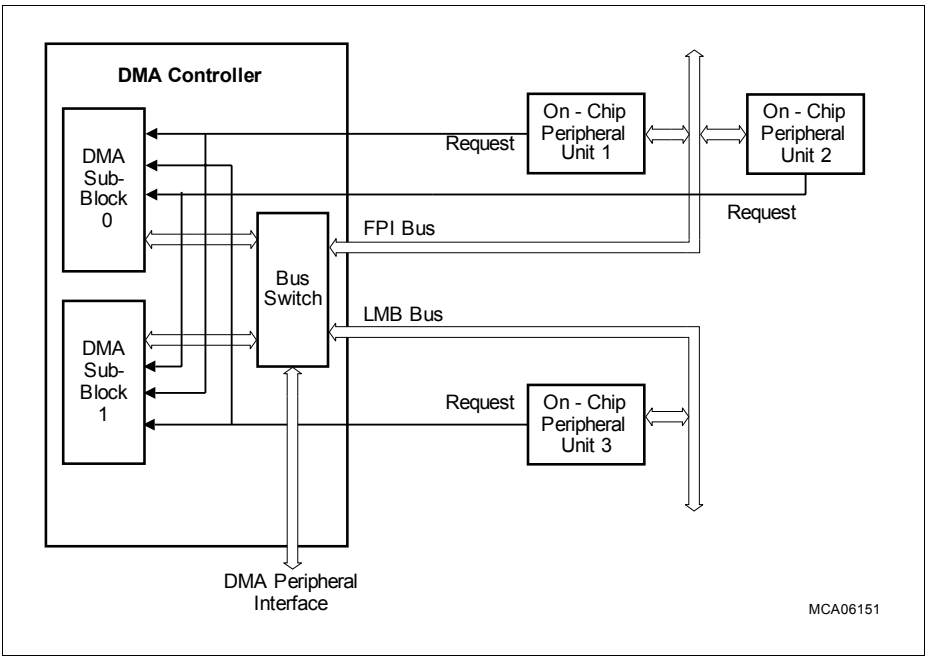

Figure 12-3 DMA Principle

The DMA controller mainly consists of two DMA Sub-Blocks and a Bus Switch. Once configured, the DMA Sub-Blocks are able to act as a master on the FPI Bus and on the SRI Bus.

12.2.4 DMA Channel Functionality

Each of the 16 DMA channels has one associated register set containing seven 32-bit registers. These registers are numbered by one index to indicate the related DMA Sub-Block and one index to indicate the related DMA channel: Index “m” refers to the DMA Sub-Block number (m = 0-1) and Index “n” refers to the channel number (n = 0-7) within the DMA Sub-Block.

Example: CHCR04 is the Control Register of DMA channel 4 in Sub-Block 0.

The register set of a DMA channel register contains the following registers:

- Channel mn Control Register CHCR0n (for details, see **Page 12-85**)
- Channel mn Status Register CHSR0n (for details, see **Page 12-89**)
- Channel mn Interrupt Control Register CHICR0n (for details, see **Page 12-90**)
- Channel mn Address Control Register ADRCR0n (for details, see **Page 12-92**)
- Channel mn Source Address Register SADR0n (for details, see **Page 12-97**)
- Channel mn Destination Address Register DADR0n (for details, see **Page 12-98**)
- Channel mn Shadow Address Register SHADR0n (for details, see **Page 12-99**)

12.2.4.1 Shadowed Source or Destination Address

As a typical application, an ASC module that receives data (fixed source address) has to deliver it to a memory buffer using a DMA transaction (variable destination address). After a certain amount of data has been transferred, a new DMA transaction should be initiated to deliver further ASC data into another memory buffer. While the destination address register is updated during a running DMA transaction with the actual destination address, a shadow mechanism allows programming of a new destination address without disturbing the content of the destination address register. In this case, the new destination address is written into a buffer register, i.e. the shadow address register. At the start of the next DMA transaction, the new address is transferred from this shadow address register to the destination address register without CPU intervention. This shadow mechanism avoids the CPU having to check for the end of a DMA transaction before reprogramming address registers.

The shadow address register can be used also to store a source address. However, it cannot store source and destination address at the same time. This means that the shadow mechanism makes it possible to automatically update either a new source address, or a new destination address at the start of a DMA transaction. If both address registers (for source and destination address) have to be updated for the next DMA transaction, a running DMA transaction for this channel must be finished. After that, source and destination address registers can be written before the next DMA transaction is started.

Figure 12-4 shows the actions that take place when a source address register is updated. The update of a destination register happens in an equivalent manner.

When writing a new address to the (address of) the source or destination address register and no DMA transaction is running, the new address value is directly written into the source or destination address register. In this case, no buffering of the address is required. When writing a new address to the (address of) the source or destination address register and a DMA transaction is running, no transfer to an address register can take place and SHADRmn holds the new address value that was written. For this operation, bit field ADRCRmn.SHCT must be set either to 01_B (address is a source address) or 10_B (new address is a destination address). At the start of the next DMA transaction, the shadow transfer takes place and the content of SHADRmn is written either into SADRmn or DADRmn (ADRCRmn.SHCT must be set accordingly). After the shadow transfer, SHADRmn is set to $0000\ 0000_H$ if the shadow register write enable bit is set to 0 (ADRCRmn.SHWEN = 0). In this case (ADRCRmn.SHWEN = 0), the software can check by reading the shadow address register whether or not the shadow transfer has already taken place.

Only one address register can be shadowed while a transaction is running, because the shadow register can only be assigned either to the source or to the destination address register. Note that the shadow address register transfer has the same behavior in Single and Continuous Mode. When the shadow mechanism is disabled (ADRCRmn.SHCT = 00_B), SHADRmn is always read as $0000\ 0000_H$.

If the shadow address register write enable bit is set to 1 (ADRCRmn.SHWEN = 1), the shadow register SHADRmn can be directly written. In this case (ADRCRmn.SHWEN = 1) the value stored in the SHADRmn is not modified when the shadow transfer takes place, and the shadow mechanism remains active and the shadow transfer will be repeated until Channel mn is reset or until the value in SHADR is $0000\ 0000_H$, is written into the shadow register (direct or indirect by writing to the source or destination address register according to the shadow control register ADRCRmn.SHCT).

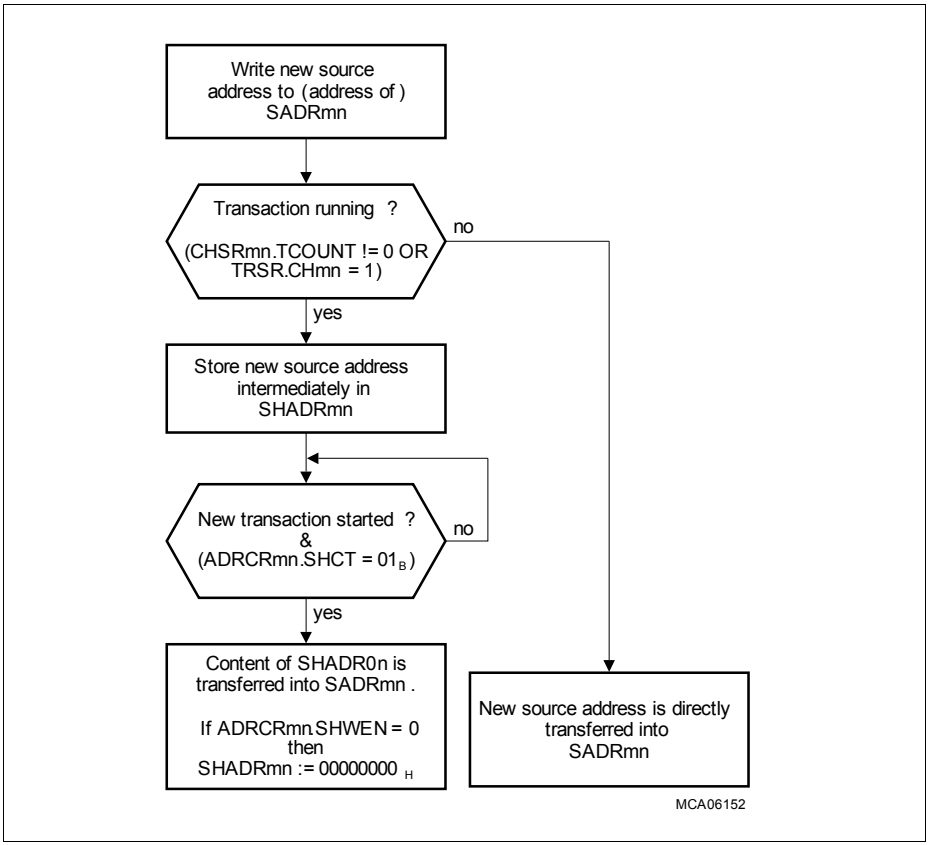

Figure 12-4 Source Address Update (m = 0-1)

The transfer count of a DMA transaction, stored in bit field CHCRmn.TREL, can also be programmed if the DMA transaction is running. At the start of a DMA transaction, TREL is transferred to bit field CHSRmn.TCOUNT, which is then updated during the DMA transaction.

No reload of address or counter will be done if TCOUNT is not equal to 0.

The reprogramming of channel specific values (except for the selected address shadow register) should be avoided while a DMA channel is active.

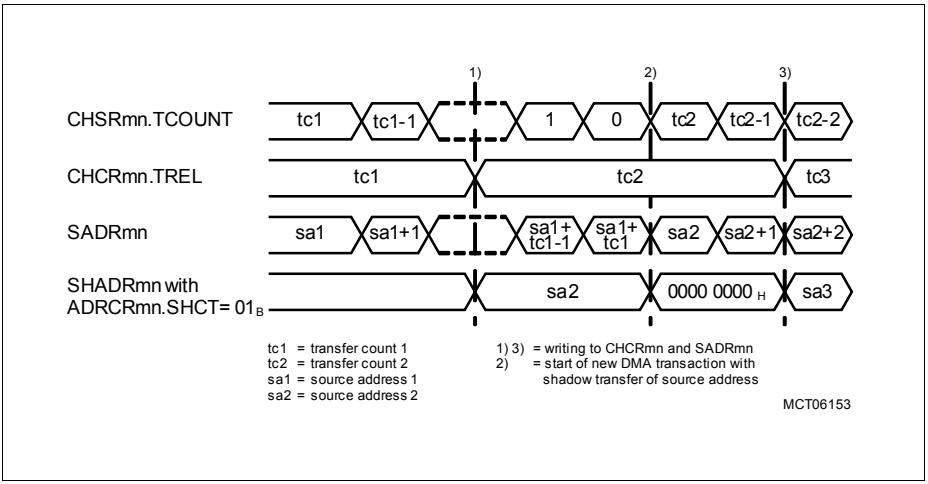

Figure 12-5 Shadow Source Address and Transfer Count Update with ADRCRmn.SHWEN = 0 (m = 0-1)

Figure 12-5 shows how the contents of the source address register SADRmn and the transfer count CHSRmn.TCOUNT are updated during two DMA transactions with a shadowed source address and transfer count update.

At reference point 2) the DMA transaction 1 is finished and DMA transaction 2 is started. At 1) the DMA channel is reprogrammed with two new parameters for the next DMA transaction: Transfer count tc2 and source address sa2. Source address sa2 is buffered in SADRmn and transferred to SADRmn when the new DMA transaction is started at 2). At this time, transfer count tc2 is also transferred to CHSRmn.TCOUNT. Note that the shadow address register is only reset by hardware to $0000\ 0000_H$ as shown in this example, if the write enable bit is set to 0 (ADRCRmn.SHWEN = 0).

12.2.4.2 DMA Channel Request Control

Figure 12-6 shows the control logic for DMA requests that is implemented for each DMA channel.

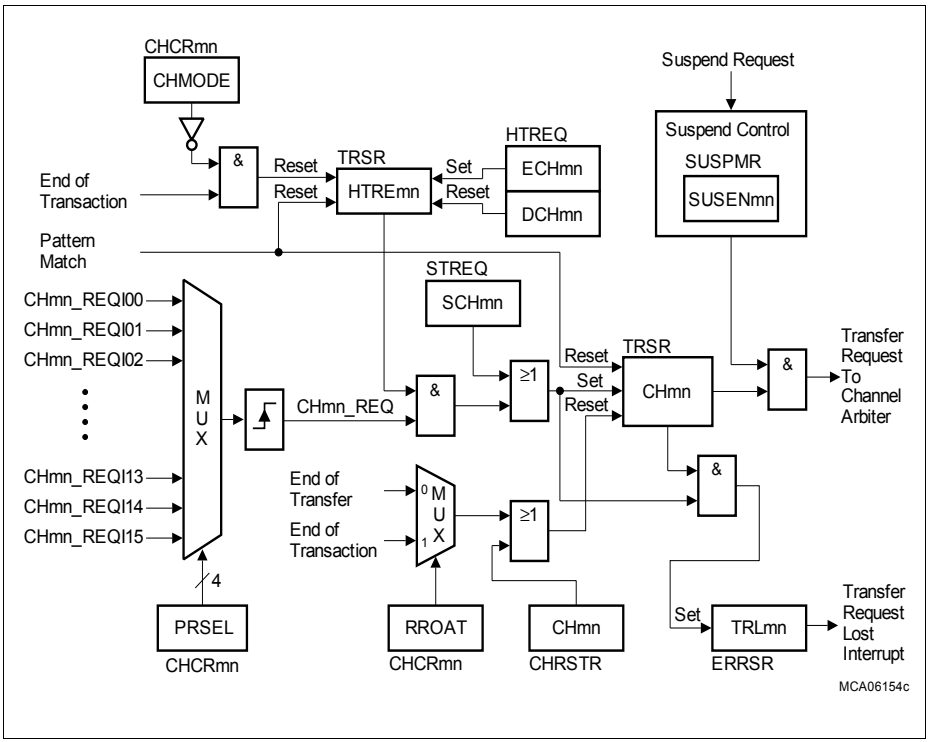

Figure 12-6 Channel Request Control (m = 0-1)

Two different types of DMA requests are possible:

- Hardware DMA requests
- Software DMA requests

The hardware request CHmn_REQ can be connected to one of sixteen possible hardware request input lines as selected by bit field CHCRmn.PRSEL. The hardware request input structure for CHCRmn.PRSEL includes a ´positive edge detector´ as the DMA channels requires single pulse requests.

Hardware requests are enabled/disabled by status bit TRSR.HTREmn. HTREmn can be set/reset by software or by hardware in Single Mode at the end of a DMA transaction. A software request can be generated by setting bit STREQ.SCHmn.

Status flag TRSR.CHmn indicates whether or not a software or hardware generated DMA request for DMA channel mn is pending. TRSR.CHmn can be reset by software or by hardware at the end of a DMA transfer (RROAT = 0) or at the end of a DMA transaction (RROAT = 1).

If a software or a hardware DMA request is detected for channel mn while TRSR.CHmn is set, a request lost event occurs. This error event indicates that the DMA is already processing a transfer and that another transfer has been requested before the end of the previous one. In this case, bit ERRSR.TRLmn will be set and a transfer lost interrupt can be generated.

12.2.4.3 DMA Channel Operation Modes

The operation mode of a DMA channel is individually programmable for each DMA channel mn. Basically, a DMA channel can operate in the following modes:

- Software controlled mode
- Hardware controlled mode, in Single or Continuous Mode

In software-controlled mode, a DMA channel request is generated by setting a control bit. In hardware-controlled mode, a DMA channel request is generated by request signals typically generated by on-chip peripheral units.

In hardware-controlled Single Mode, a DMA channel mn becomes disabled by hardware after the last DMA transfer of its DMA transaction. In hardware-controlled Continuous Mode, a DMA channel mn remains enabled after the last DMA transfer of its DMA transaction.

In hardware- and software-controlled mode, a DMA request signal can be configured to trigger a complete DMA transaction or one single transfer.

Software-controlled Modes

In software-controlled mode, one software request starts one complete DMA transaction or one single DMA transfer. Software-controlled modes are selected by writing HTREQ.DCHmn = 1. This forces status flag TRSR.HTREmn = 0 (hardware request of DMA channel mn is disabled).

The software-controlled mode that initiates one complete DMA transaction to be executed is selected for DMA channel mn by the following write operations:

- CHCRmn.RROAT = 1
- STREQ.SCHmn = 1

Setting STREQ.SCHmn to 1 (this is the software request) causes the DMA transaction of DMA channel mn to be started and TRSR.CHmn to be set. At the start of the DMA transaction, the value of CHCRmn.TREL is loaded into CHSRmn.TCOUNT (transfer count or tc) and the DMA transfers are executed. After each DMA transfer, TCOUNT becomes decremented and next source and destination addresses are calculated.

When TCOUNT reaches the 0, DMA channel mn becomes disabled and status flag TRSR.CHmn is reset. Setting STREQ.SCHmn again starts a new DMA transaction of DMA channel mn with the parameters as actually defined in the channel register set.

The software-controlled mode that initiates a single DMA transfer to be executed is selected for DMA channel mn by the following write operations:

- CHCRmn.RROAT = 0
- STREQ.SCHmn = 1, repeated for each DMA transfer

When CHCRmn.RROAT = 0, TRSR.CHmn becomes reset after each DMA transfer of the DMA transaction and a new software request (writing STREQ.SCHmn = 1) must be generated for starting the next DMA transfer.

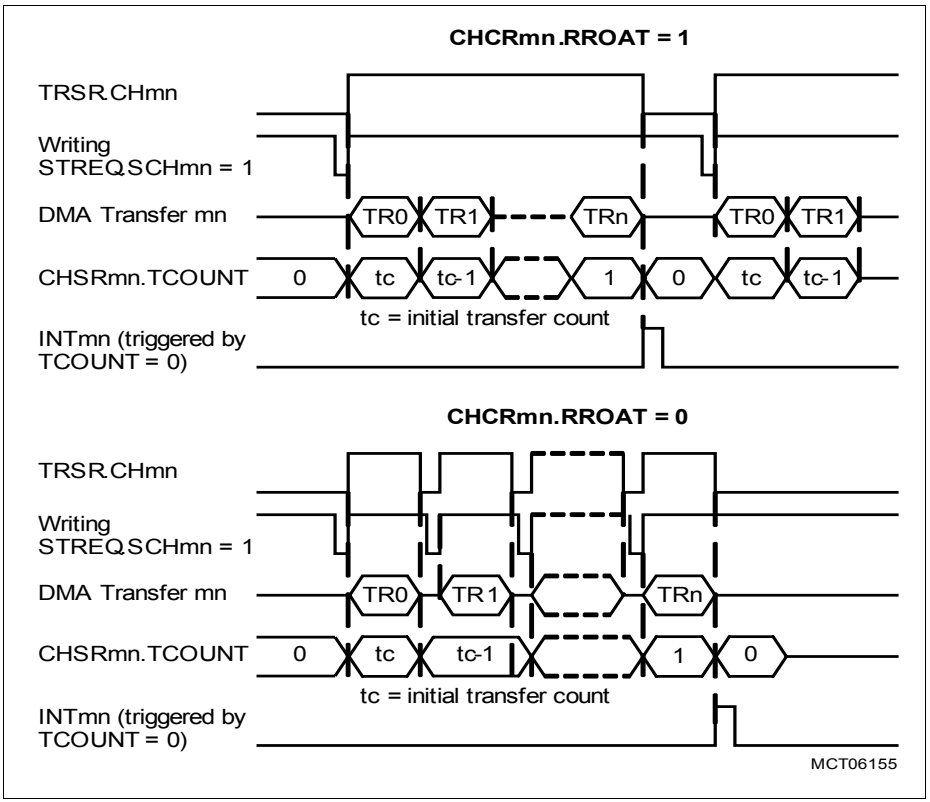

Figure 12-7 Software Controlled Mode Operation (m = 0-1)

Hardware-controlled Modes

In hardware-controlled modes, a hardware request signal starts a DMA transaction or a single DMA transfer. There are two hardware-controlled modes available:

- **Single Mode:**
  Hardware requests are disabled by hardware after a DMA transaction
- **Continuous Mode:**
  Hardware requests are not disabled by hardware after a DMA transaction

Hardware-controlled Single Mode

In hardware-controlled Single Modes, one hardware request starts one complete DMA transaction or one single DMA transfer. The hardware-controlled Single Mode that initiates one complete DMA transaction to be executed for DMA channel mn is selected by the following operations:

- CHCRmn.CHMODE = 0
- CHCRmn.RROAT = 1
- Selecting one of the sixteen hardware request inputs via CHCRmn.PRSEL
- HTREQ.ECHmn = 1

Setting HTREQ.ECHmn to 1 causes the hardware request CHmn_REQ of channel mn to be enabled (TRSR.HTREmn = 1). Whenever the hardware request CHmn_REQ becomes active, the value of CHCRmn.TREL is loaded into CHSRmn.TCOUNT and the DMA transaction is started by executing its first DMA transfer. After each DMA transfer, TCOUNT becomes decremented and next source and destination addresses are calculated. When TCOUNT reaches the 0, DMA channel 0n becomes disabled and status flags TRSR.CHmn and TRSR.HTREmn are reset. In order to start a new hardware-controlled DMA transaction, hardware requests must be enabled again by setting TRSR.HTREmn through HTREQ.ECHmn = 1. The hardware request disable function in Single Mode is typically needed when a reprogramming of the DMA channel register set (addresses, transfer count) is required before the next hardware triggered DMA transaction is started.

The hardware-controlled Single Mode in which each single DMA transfer has to be requested by a hardware request signal is selected as described above, with one difference:

- CHCRmn.RROAT = 0

In this operation mode, TRSR.CHmn becomes reset after each DMA transfer of the DMA transaction, and a new hardware request at CHmn_REQ must be generated for starting the next DMA transfer.

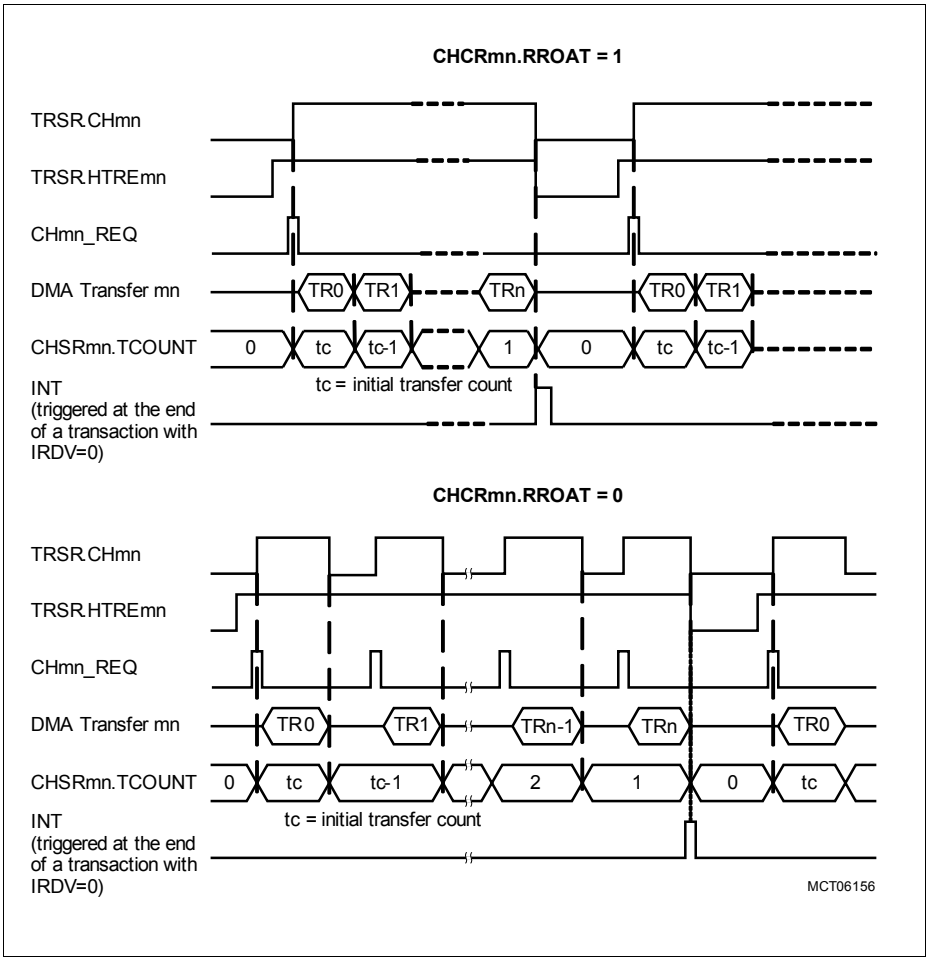

Figure 12-8 Hardware-controlled Single Mode Operation (m = 0-1)

Hardware-controlled Continuous Mode

In hardware-controlled Continuous Mode (CHCRmn.CHMODE = 1), the hardware transaction request enable bit HTREmn is not reset at the end of a DMA transaction. A new transaction of DMA channel mn with the parameters actually stored in the channel register set of DMA channel mn is started each time when CHSRmn.TCOUNT = 0 at the end of the DMA transaction. No software re-enable for a hardware request at CHmn_REQ is required.

Combined Software/Hardware-controlled Mode

Figure 12-9 shows how software- and hardware-controlled modes can be combined. In the example, the first DMA transfer is triggered by software when setting STREQ.SCHmn. Hardware requests are still disabled. After hardware requests have been enabled by setting HTREQ.ECHmn, subsequent DMA transfers are triggered now by hardware request coming from the CHmn_REQ line.

In the example, DMA channel mn operates in Single Mode (CHCRmn.CHMODE = 0). In this mode, TRSR.HTREmn becomes reset by hardware when CHSRmn.TCOUNT = 0 at the end of the DMA transaction.

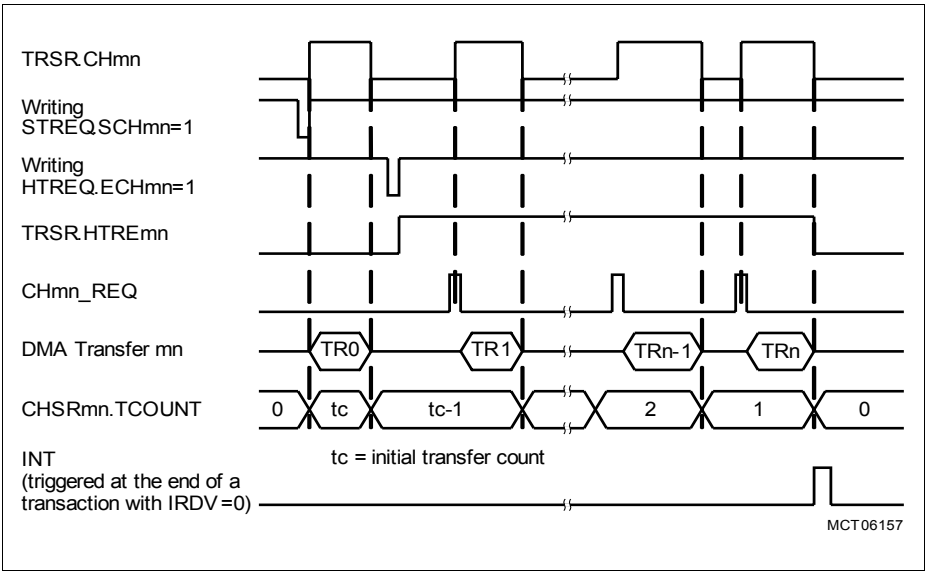

Figure 12-9 Transaction Start by Software, Continuation by Hardware (m = 0-1)

If a DMA channel is configured to be triggered by parallel hardware and software requests then if the requests collide in the same clock cycle then a Transaction/Transfer Request Lost event will be flagged in the DMA Error Status Register.

12.2.4.4 Error Conditions

The bus error flag ERRSR.FPIER indicates an FPI Bus error (SPB) that occurred during a source move (read or write) of a DMA module transaction. The bus error flag ERRSR.SRIER indicates an SRI Bus error that occurred during a source move (read or write) of a DMA module transaction.

The source error flags ERRSR.MEmSER indicates than an error occurred during source move (read) of a DMA transaction of DMA Sub-Block m.

The destination error flags ERRSR.MEmDER indicates than an error occurred during destination move (write) of a DMA transaction of DMA Sub-Block m
The transaction lost error flag ERRSR.TRLmn indicates if a DMA request for a DMA channel mn has been lost.

In the case of a read error, the write action is not executed, but the destination address is updated.

In the case of multiple errors, the error bits are set according to the error situations. This means that more than bus error flag can be set and that source/destination flags can be set.

12.2.4.5 Channel Reset Operation

A DMA transaction of DMA channel mn can be stopped (channel is reset) by setting bit CHRSTR.CHmn. When a read or write On Chip Bus transaction of DMA channel mn is executed at the time when CHRSTR.CH0n is set, this On Chip Bus transaction is finished normally. This behavior guarantees data consistency.

When CHRSTR.CHmn is set to 1:

- Bits TRSR.HTREmn, TRSR.CHmn, ERRSR.TRLmn, INTSR.ICHmn, INTSR.IPMmn, WRPSR.WRPDmn, WRPSR.WRPSmn, CHSRmn.LXO, and bit field CHSRmn.TCOUNT are reset.
- Source and destination address register will be set to the wrap boundary. SHADRmn will be cleared.
- All automatic functions are stopped for channel mn.

A user program must execute the following steps for resetting a DMA channel:

1. If hardware requests are enabled for the DMA channel mn, disable the DMA channel mn hardware requests by setting HTREQ.DCHmn = 1.
2. Writing a 1 to CHRSTR.CHmn.
3. Waiting (polling) until CHRSTR.CHmn = 0.

A user program should execute the following steps for restarting a DMA channel after it was reset:

1. Optionally (re-)configuring the address and other channel registers.
2. Restarting the DMA channel mn by setting HTREQ.ECHmn = 1 for hardware requests or STREQ.SCHmn = 1 for software requests.

The value of CHCRmn.TREL is copied to CHSRmn.TCOUNT when a new DMA transaction is requested and shadow address register contents is not equal $0000\ 0000_H$.

12.2.4.6 Transfer Count and Move Count

The move count determines the number of moves (consisting of one read and one write each) to be done in each transfer. It allows the user to indicate to the DMA the number of moves to be done after one request. The number of moves per transfer is selected by the block mode settings (CHCRmn.BLKM).

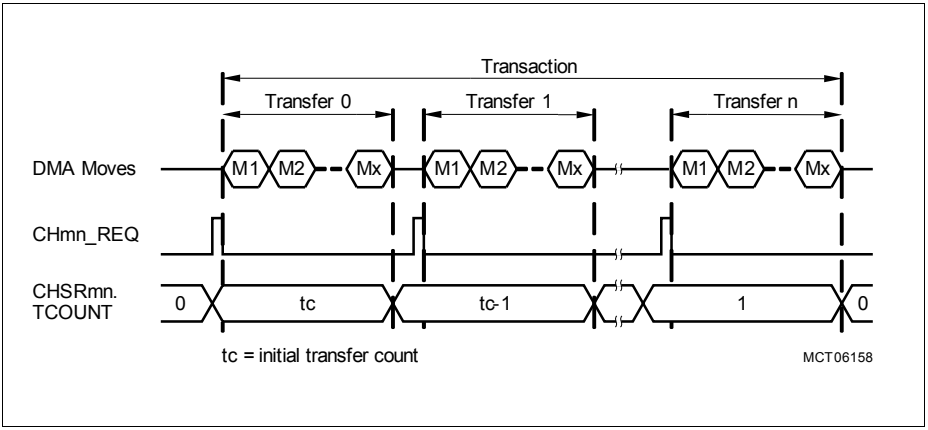

Figure 12-10 Transfer and Move Count (m = 0-1)

After a DMA move, the next source and destination addresses are calculated. Source and destination addresses are calculated independently of each other. The following address calculation parameters can be selected:

- The address offset, which is a multiple of the selected data width
- The offset direction: addition, subtraction, or none (unchanged address)

Control bits in address control register ADRCRmn determine how the addresses are incremented/decremented. Further, the data width as defined in CHCRmn.CHDW is taken into account for the address calculation.

Figure 12-11 and **Figure 12-12** show two examples of address calculation. In both examples, a data width of 16-bit (CHCRmn.CHDW = 01B) is assumed.

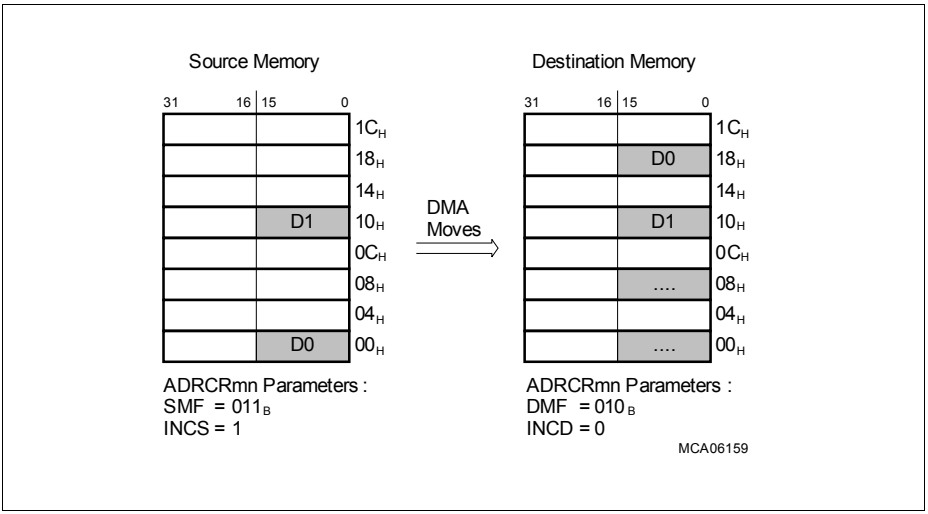

Figure 12-11 Programmable Address Modification - Example 1 (m = 0-1)

In **Figure 12-11**, 16-bit half-words are transferred from a source memory with an incrementing source address offset of 10_H to a destination memory with decrementing destination addresses offset of 08_H.

In **Figure 12-12**, 16-bit half-words are transferred from a source memory with an incrementing source address offset of 02_H to a destination memory with incrementing destination addresses offset of 04_H.

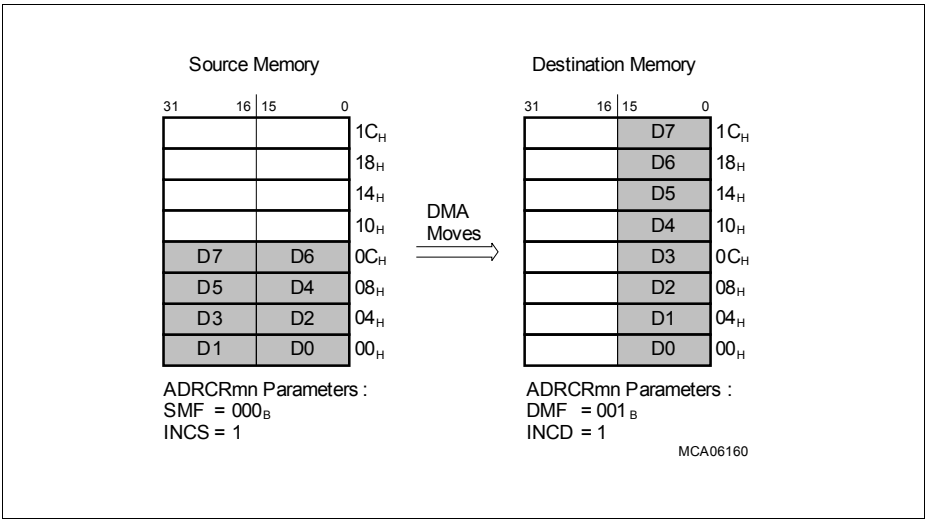

Figure 12-12 Programmable Address Modification - Example 2 (m = 0-1)

12.2.4.7 Circular Buffer

Destination and source address can be configured to build a circular buffer separately for source and destination data. Within this circular buffer, addresses are updated as defined in **Figure 12-11** and **Figure 12-12** with a wrap-around at the buffer limits. The circular buffer length is determined by bit fields ADRCRmn.CBLS (for the source buffer) and ADRCRmn.CBLD (for the destination buffer). These 4-bit wide bit fields determine which bits of the 32-bit address remain unchanged at an address update. Possible buffer sizes of the circular buffers can be 2^{CBLS} or 2^{CBLD} bytes (= 1, 2, 4, 8, 16, … up to 32k bytes).

When source or destination addresses are updated (incremented or decremented) after a DMA move, all upper bits [31:CBLS] of source address and [31:CBLD] of destination address are frozen and remain unchanged, even if a wrap-around from the lower address bits [CBLS:0] or [CBLD:0] occurred. This address-freezing mechanism always causes the circular buffers to be aligned to a multiple integer value of its size.

If the circular buffer size is less or equal than the selected address offset (see **Figure 12-9**), the same circular buffer address will always be accessed.

12.2.5 Transaction Control Engine

Each DMA Sub-Block has a Transaction Control Unit. The Transaction Control Unit in the DMA Sub-Block, as shown in the DMA Controller block diagram in **Figure 12-1**, contains a Channel Arbiter and a Move Engine.

The Channel Arbiter arbitrates the transfer requests of the DMA channels, and submits the transfers parameters of the DMA channel with the highest channel priority that are needed for a DMA transfer to the Move Engine. DMA channels within a DMA Sub-Block have a two-level programmable channel priority as defined by bit CHCRmn.CHPRIO. When two transfer requests of two different DMA channels with identical channel priority become active at the same time, the DMA channel with the lowest channel number (n) is serviced first.

The Move Engine handles the execution of a DMA transfer that has been detected by the Channel Arbiter to be the next one. The Move Engine requests the required buses and loads or stores data according to the parameters of a DMA transfer. It is able to wait if a targeted bus is not available. In the Move Engine, a DMA transfer of a DMA transaction cannot be interrupted and always get finished. This means that a DMA transfer, which can also be composed of several data moves (read move and write move), cannot be interrupted by a transfer of another DMA channel.

After a DMA transfer is finished, the Move Engine will send back the actualized address register information to the related DMA channel. Possible error conditions are also reported.

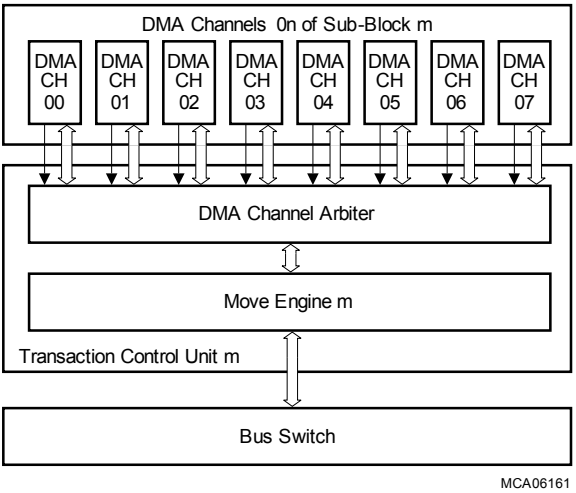

Figure 12-13 Transaction Control Engine (m = 0-1)

12.2.6 Bus Switch, Bus Switch Priorities

The Bus Switch of the DMA controller provides the connection from the DMA Sub-Blocks to the two On Chip Bus master interfaces (connected to System Peripheral Bus and SRI Bus) and to the DMA Peripheral Interface (see **Figure 12-14**).

The FPI Bus interface of the DMA includes a slave interface which provides the access to the DMA and the peripherals connected to the DMA Peripheral Interface (MLI, Cerberus and Memory Checker modules).

The SRI Bus interface of the DMA is a master interface.

The DMA module, the DMA Sub-Blocks as well as the MLI, the Memory Checker and the Cerberus module working frequencies are identical to the FPI Bus frequency. The working frequency of the SRI master interface is identical to the SRI/CPU working frequency.

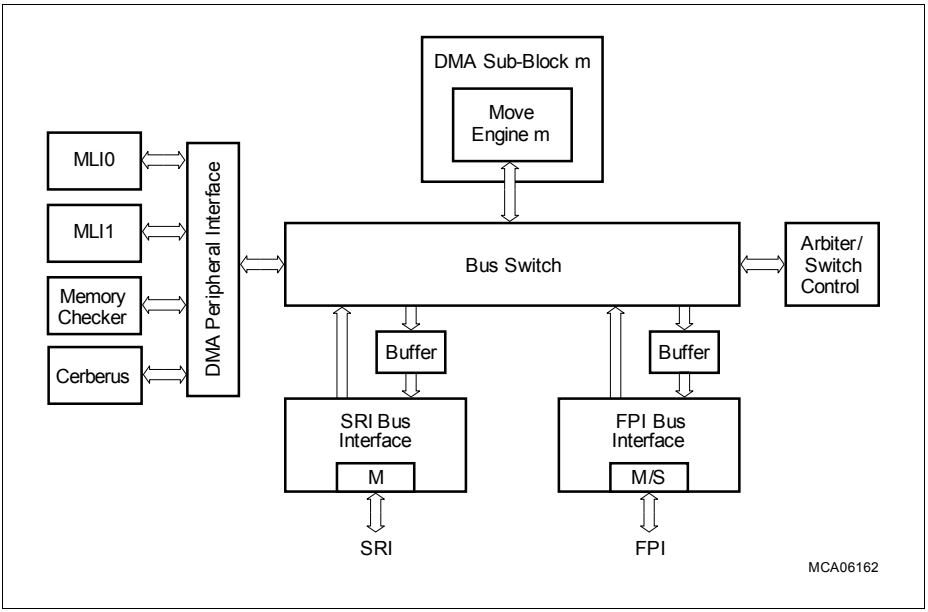

Figure 12-14 Bus Switch

One access can be buffered in the bus interfaces.

Note: The accesses of the DMA Move Engine's bus interfaces to the On Chip Bus interfaces are always done in Supervisor Mode.

The arbiter/switch control unit arbitrates the requests from the connected active interfaces (FPI Bus Interface, DMA Move Engines, MLIs, Cerberus,...) and grants the buses connected to the switch for data transfers. **Table 12-1** and **Table 12-2** define the Bus Switch priorities for requests to the same On Chip Bus Interface. The arbitration scheme is valid in case of a collision of requests from active peripherals connected to the DMA Bus Switch (Move Engine, MLIs, Cerberus) for the same resource (FPI Bus Interface, SRI Bus Interface, DMA Peripheral Interface, Move Engine). The arbitration is done for each Bus Switch request.

The general overview of the Bus Switch Priorities is given in **Table 12-1**. Additional detailed information about the Move Engine priorities for concurrent accesses on the Bus Switch is described in **Table 12-2**.

In case of a collision of the DMA Move Engine requests on the DMA Bus switch for the the same resource, a Move Engine Write has priority over a Move Engine Read. In case of a collision of both Move Engines with concurrent read requests or concurrent write requests for the same resource, the Move Engine number together with the

CHCRmn.DMAPRIO value determines the priority on the DMA Bus Switch (see Table 12-2).

Table 12-1 DMA Bus Switch Priorities

Priority	Agent Requests	Comment
Highest	Cerberus to On Chip Bus High	Priority selection by software in Cerberus.
	FPI Bus to DMA Peripheral Interface accesses	Reason: minimizing wait states on the FPI Bus.
	DMA Move Engine Write	The detailed Bus Switch priorities for the two Engines with concurrent reads or concurrent writes are listed in Table 12-2.
	DMA Move Engine Read	The detailed Bus Switch priorities for the two Engines with concurrent reads or concurrent writes are listed in Table 12-2.
	MLI0 access	–
	MLI1 access	–
Lowest	Cerberus to On Chip Bus Low	Priority selection by software in Cerberus.

Table 12-2 DMA Bus Switch Priorities of DMA Move Engines

Priority	DMA Move Engine Request	Comment
Highest	Move Engine 0 CHCR0x.DMAPRIO = “11” or CHCR0x.DMAPRIO = “01”	(x=7-0). x reflects the channel of Move 0 that won the Move Engine internal arbitration.
	Move Engine 1 CHCR1y.DMAPRIO = “11” or CHCR1y.DMAPRIO = “01”	(y=7-0). y reflects the channel of Move 1 that won the Move Engine internal arbitration.
	Move Engine 0 CHCR0x.DMAPRIO = “00”	(x=7-0). x reflects the channel of Move 0 that won the Move Engine internal arbitration.
Lowest	Move Engine 1 CHCR1x.DMAPRIO = “00”	(y=7-0). y reflects the channel of Move 1 that won the Move Engine internal arbitration.

12.2.7 DMA Module Priorities on On Chip Busses (FPI Bus, SRI Bus)

Every active peripheral connected to the DMA Bus Switch that requests for access to FPI Bus or SRI Bus has to go through two arbitration stages before accessing the On Chip

Bus: DMA Module internal arbitration at the DMA Bus Switch and DMA Module external arbitration at the On Chip Bus.

The DMA Module is connected to the FPI Bus and to the SRI Bus with master interfaces. The DMA SRI Master and the DMA FPI Master is each connected with three priorities to its On Chip Bus (low, medium and high priority), where it competes against the other bus masters connected to the On Chip Bus for bus access. The mapping of the Move Engines and the peripherals connected to the DMA Peripheral Interface to the DMA Module priorities on the FPI Bus and on the SRI Bus is described in **Table 12-3**.

The MLI modules are mapped to the low priority On Chip Bus requests of the DMA Module, while the mapping of the Cerberus and the Move Engines to the On Chip Bus requests is selected by software (control register bits).

The complete list of FPI master priorities can be found in the FPI Bus Control Unit Chapter.

The complete list of SRI master priorities can be found in the Shared Resource Interconnect Chapter.

Table 12-3 DMA Module Priorities on On Chip Busses

On Chip Bus Priority	DMA On Chip Bus Request	Comment
High	Cerberus High	Priority selection by SW in Cerberus.
	Move Engine m: CHCRmx.DMAPRIO = “11”	Priority selection by SW in Move Engine. (x=7-0) (m=1-0)
Medium	Move Engine m: CHCRmx.DMAPRIO = “01”	Priority selection by SW in Move Engine. (x=7-0) (m=1-0)
Low	Move Engine m: CHCRmx.DMAPRIO = “00”	Priority selection by SW in Move Engine. (x=7-0) (m=1-0)
	MLI0	-
	MLI1	-
	Cerberus Low	Priority selection by SW in Cerberus.

12.2.8 DMA Module: On Chip Bus Access Rights, RMW support

All accesses triggered by the DMA Move Engines, the MLI modules or the Cerberus module are always done in SV mode.

The DMA module does not support read/modify write instructions to the peripherals connected to the DMA Peripheral Interface (the MLI, Memory Checker and Cerberus modules).

12.2.9 DMA Module On Chip Bus Master Interfaces

This chapter describes the features of the DMA On Chip Bus Master Interfaces to the FPI Bus and to the SRI Bus.

The DMA FPI master interface supports:

- single data read and write transactions (8bit, 16bit, 32bit)
- generation of pipe lined FPI transactions from different sources (Move Engines, Cerberus, MLI´s)
- de-assertion of request after retry in order to prevent bus blocking.
- out of order transactions from different sources in order to avoid side effects (blocking) between the different sources (Move Engines, Cerberus, MLI´s)
- three dedicated FPI requests (medium, low, high priority. See **Table 12-3**)[1].

A single move engine supports only one transaction at a time. Due to the fact that the move engines do generate read - write sequences, it is unlikely that the DMA module generates permanent, pipeline, high priority requests.

The DMA SRI master interface supports:

- single data read and write transactions (8bit, 16bit, 32bit)
- 4-Transfer Burst Transfer (BTR4) for read accesses to Segment 8 (cached area)
- pipeline transactions from different sources (Move Engines, Cerberus, MLI´s)
- de-assertion of request after retry in order to prevent bus blocking.
- out of order transactions from different sources in order to avoid side effects (blocking) between the different sources (Move Engines, Cerberus, MLI´s)
- three dedicated SRI requests (medium, low, high priority. See **Table 12-3**)[2].

A single move engine supports only one transaction at a time. Due to the fact that the move engines do generate read - write sequences, it is unlikely that the DMA module generates permanent, pipeline, high priority requests.

DMA SRI Master Read Buffer:

The DMA SRI master interface includes a 256bit buffer for read accesses to cached addresses (Segment 8). The DMA SRI Master Interface contains a data read buffer for read accesses to cached addresses. The read buffer allows to read four double words (=256 bit) of data read from specific memory areas on SRI side (Segment 8: $8000\ 0000_H$ - $8FFF\ FFFF_H$)

A read request to an Segment 8 address (8bit, 16bit or 32bit) will be translated by the DMA SRI master interface into an SRI 4-Transfer Block Transfer Request. The DMA SRI master will forward the requested 8bit, 16bit or 32bit data to the DMA Bus switch and

1) The complete list of FPI master priorities can be found in the FPI Bus Control Unit Chapter.

2) The complete list of SRI master priorities can be found in the Shared Resource Interconnect Chapter.

save the 256bit read data together with the related 64bit aligned address in the DMA SRI master read buffer. If the next and subsequent read access to a segment 8 address is identical (64bit aligned) to the actual read buffer contents, the requested read data will be read from the read buffer by the DMA SRI master instead of reading it from the SRI bus.

If the next read to a read from a segment 8 address is not identical (64bit aligned) to the actual read buffer contents, the contents of the read buffer is invalidated. A 4-Transfer Block Transfer Request SRI read is generated by the DMA SRI master interface, the requested 8bit, 16bit or 32 bit data is forwarded to the DMA Bus switch and the read buffer is updated with the new 256bit data and its related address.

A DMA write to a segment 8 address (8bit, 16bit, 32bit write, 64bit write is not supported) invalidates the read buffer.

12.2.10 DMA Module Bridge Functionality

The DMA module includes bridge functionality:

- from the FPI Bus to the DMA Peripheral Interface
- from the DMA Peripheral Interface to the FPI Bus and SRI Bus.

FPI Bus -> SRI Bus

The DMA module does not forward transaction from the FPI Bus to the SRI Bus. The DMA module does not support / include bridge functionality between FPI Bus and SRI Bus.

FPI Bus -> DMA Peripheral Interface (MLI, Memory Check, Cerberus,...)

The DMA module forwards transactions from the FPI bus to the DMA Peripheral Interface (FPI -> MLI, Memory Check, Cerberus,...). The identification of the target module on the DMA Peripheral Interface is done by address decoding.

DMA Peripheral Interface -> On Chip Bus (FPI Bus, SRI Bus)

The DMA module forwards transactions from the active modules that are connected to the DMA Peripheral Interface (Cerberus, MLI,...) to the FPI Bus and SRI Bus. The identification of the target On Chip Bus is done by address decoding.

12.2.11 On-Chip Debug Capabilities

The DMA controller in the TC1798 provides some debugging capabilities. These debug features support:

- Soft-suspend Mode of DMA channels
- Break signal generation
- Trace signal generation

In Soft-suspend mode, the operations of DMA channels are stopped. Pending read or write transfers in the DMA module On Chip Bus Master Interfaces (SRI Master Interface, FPI Master Interface) are finished. Under certain conditions also a break signal is generated for the on-chip debug support logic. Further, DMA trace information can be output.

In Soft-suspend mode, the DMA module provides access to all control registers of the DMA module (inc. Move Engines and Memory Checker Module) and to the peripherals connected to the DMA Peripheral Interface.

12.2.11.1 Hard-suspend Mode

The Hard-Suspend Mode is controlled in the TC1798 DMA module CLC register but should not be used in order to guarantee access to the device via JTAG (Cerberus). Possible support of the Hard-suspend mode by the peripherals connected to the DMA Peripheral Interface is described in the related module chapters.

12.2.11.2 Soft-suspend Mode

The TC1798 on-chip debug control unit is able to generate a Soft-suspend Mode request (SUSREQ) for the DMA controller. When this soft-suspend request becomes active, the state of a DMA channel becomes frozen regarding hardware changes to ensure that the state of the DMA channels can be analyzed by reading the register contents. Pending read or write transfers in the DMA module On Chip Bus Master Interfaces (SRI Master Interface, FPI Master Interface) are finished. The DMA controller signals its soft suspend mode back to the on-chip debug control via an Soft-suspend acknowledge. The Soft-suspend acknowledge becomes active when all DMA channels mn that are enabled for the Soft-suspend Mode have set its suspend active status flag SUSPMR.SUSACmn.

Soft-suspend Mode of DMA channel mn is entered if its suspend enable bit SUSENmn in the Suspend Mode Register SUSPMR is set. When SUSREQ becomes active, the operation of all DMA channels mn that are enabled for Soft-suspend Mode is stopped automatically after its current DMA transfers have been finished in the transaction control unit. Afterwards, the suspend active status flag SUSPMR.SUSACmn is set, indicating that DMA channel mn is in Soft-suspend Mode. DMA channels that are disabled for Suspend Mode (SUSENmn = 0) continue with its normal operation.

In Soft-suspend Mode, register contents can be modified. These modifications are taken into account for further DMA transactions or DMA transfers of the related DMA channel

after Suspend Mode has been left again. Suspend Mode of DMA channel mn is left and its normal operation continues if either the SUSREQ signal becomes inactive, or if the enable bit SUSENmn is reset by software.

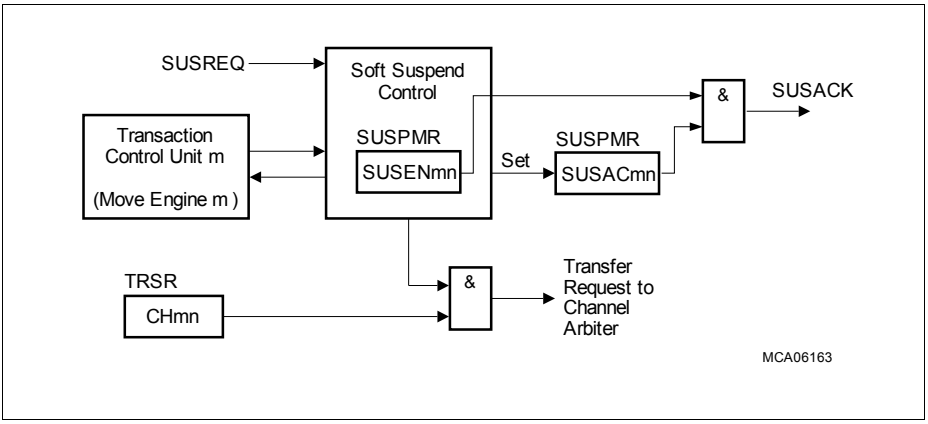

Figure 12-15 Soft-suspend Mode Control (m = 0-1)

12.2.11.3 Break Signal Generation

The DMA controller provides one BREAK output signal that is generated for the on-chip debug support logic (see **Figure 12-16**). The DMA sub-block is able to detect two break conditions:

- Transaction lost interrupt has occurred
- DMA request transitions, indicated by bits TRSR.CHmn

The output lines of the two break conditions in the DMA sub-block are OR-ed together to the BREAK output signal.

A transaction lost break condition occurs in DMA Sub-Block m whenever at least one of its eight transaction lost interrupts becomes active, and when enable bit OCDSR.BRL0 is set. The transaction lost interrupts do not generate a break condition if OCDSR.BRL0 = 0. Transaction interrupt control is described in **Section 12.2.12.2**.

The second break condition of DMA Sub-Block m becomes active when the transaction request bit TRSR.CHmn of one of its eight DMA channels n (as selected by OCDSR.BCHSn) indicates a transition of its state. The CHmn transition type (change from ´no request is pending´ to ´request is pending´, change from ´request is pending´ to ´no request is pending´, changes in both directions) is selected by bit field OCDSR.BTCRn.

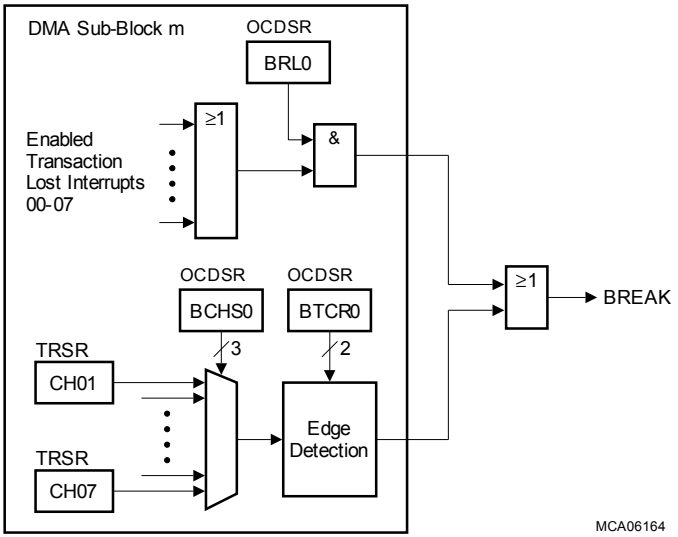

Figure 12-16 DMA Break Event Generation (m = 0-1)

12.2.12 Interrupts

The interrupt structure of the DMA controller is a very flexible control logic that allows an interrupt coming from an interrupt source within four interrupt source types to be connected to each of the sixteen interrupt outputs. This permits, for example, DMA channels that very rarely generate interrupts to share one interrupt node. The remaining interrupt nodes can be assigned to dedicated DMA channels to reduce the interrupt overhead for these channels. The four interrupt source types are:

- Channel interrupts
- Transaction lost interrupt
- Move Engine interrupts
- Wrap buffer interrupts

Some of the interrupt functions are common to all of the four interrupt source types. An interrupt event, internally generated as a request pulse, is always stored in an interrupt status flag. This interrupt status flag can be reset by software. Further, the interrupt event can be enabled or disabled. When an interrupt event is enabled, a 4-bit Interrupt Node Pointer determines which of the sixteen interrupt outputs will be activated.

The following sections describe each of the four interrupt source types in more detail.

12.2.12.1 Channel Interrupts

Each DMA channel mn has one associated channel interrupt. It can always be activated after a DMA transfer, or when CHSRmn.TCOUNT matches with the value of bit field CHICRmn.IRDV after it has been decremented after a DMA transfer. The pattern detection interrupts that are combined with the channel interrupts (one common Interrupt Node Pointer CHICRmn.INTP) are activated when the pattern detection interrupt of DMA channel mn becomes active (when enabled by CHCRmn.PATSEL not equal 00_B).

A channel interrupt of DMA channel mn is indicated when status flag INTSR.ICHmn is set. The status flags ICHmn and IPMmn can be reset together by software when setting bit INTCR.CICHmn (or CHRSTR.CHmn). The channel interrupt of DMA channel mn is enabled when bit CHICRmn.INTCT[1] is set. The channel interrupt pointer CHICRmn.INTP determines which of the interrupt outputs SR[15:0][1)] will be activated on an active channel interrupt or pattern detection interrupt. Note that the signal that is set signal for the ICHmn flag is available as CHmn_OUT signal at the DMA module boundary.

Bit CHICRmn.INTCT[0] selects these two types of interrupt sources. For the compare operation, bit field IRDV (4-bit) is zero-extended to 10-bit and then compared with the 10-bit TCOUNT value. This means that a TCOUNT match interrupt can be generated after one of the last 16 DMA transfers of a DMA transaction. Note that with

1) In the TC1798, only SR[7:0] are connected to interrupt nodes. SR[8:15] are used for DMA channel triggering/connections.

IRDV = 0000_B, the match interrupt is generated at the end of a DMA transaction (after the last DMA transfer).

The pattern detection interrupt is indicated when status flag INTSR.IPMmn is set. The status flags IPMmn and ICHmn can be reset together by software when setting bit INTCR.CICHmn (or CHRSTR.CHmn). The pattern detection interrupt of DMA channel mn is enabled when bit CHCRmn.PATSEL is set to a value not equal to 00_B. The channel interrupt pointer CHICRmn.INTP defines which of the interrupt outputs SR[15:0] will be activated on a pattern detection interrupt or the channel interrupt pointer CHICRmn.INTP determines which of the interrupt outputs SR[15:0][1] will be activated on a pattern detection or channel interrupt.

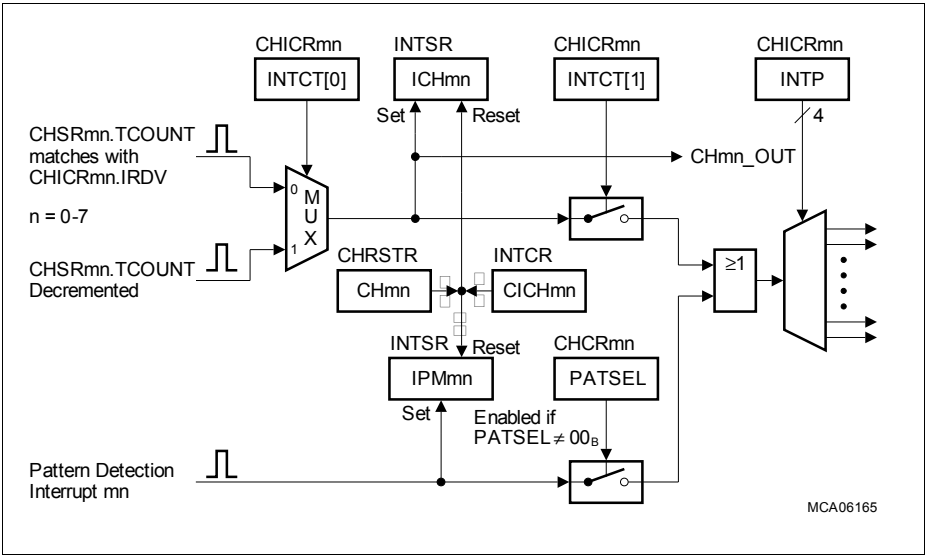

Figure 12-17 Channel Interrupts (m = 0-1)

1) In the TC1798, SR[7:0] are connected to interrupt nodes. SR[8:15] are used for DMA channel triggering/connections.

12.2.12.2 Transaction Lost Interrupt

Each DMA channel mn is able to detect a transaction request lost condition. This condition becomes true when a new hardware or software DMA request occurs while the previous transaction or transfer on DMA channel mn is not finished, indicated by TRSR.CHmn still set. If such a transaction request lost condition occurs, bit ERRSR.TRLmn is set. The transaction lost interrupts of all DMA channels are OR-ed together to one common transaction lost interrupt that can be directed to one of the interrupt outputs SR[15:0][1] by setting the transaction lost interrupt pointer EER.TRLINP with a corresponding value.

A transaction request lost condition of DMA channel mn is indicated by status flag ERRSR.TRLmn, which can be reset by setting bit CLRE.CTLmn or CHRSTR.CHmn. The transaction lost interrupt for DMA channel mn is enabled when bit EER.ETRLmn is set.

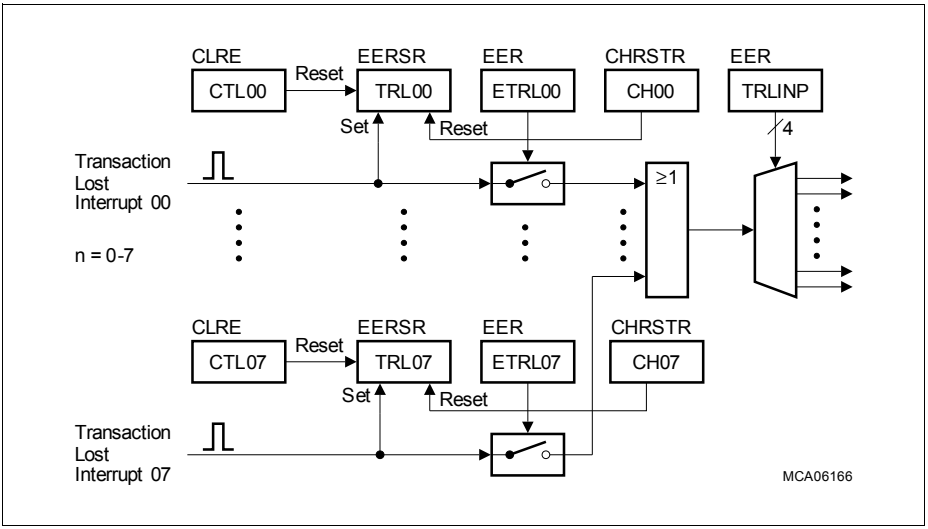

Figure 12-18 Transaction Lost Interrupt

1) In the TC1798 SR[7:0] are connected to interrupt nodes. SR[15:8] are used as DMA channel trigger signals.

12.2.12.3 Move Engine Interrupts

The Move Engine is able to detect error conditions that occur during accesses to the FPI Bus and SRI Bus interfaces of the Bus Switch (see **Figure 12-14**). Two error conditions can be detected:

- Source error
- Destination error

A source error indicates an FPI Bus or SRI Bus error that occurred during a read move from the data source. A destination error indicates an FPI Bus or SRI Bus error that occurred during a write move to the data destination.

A source error of Move Engine 0 is indicated by the status flag ERRSR.ME0SER. Status flag ME0SER can be reset by software when setting bit CLRE.CME0SER. The source error interrupt of Move Engine 0 is enabled when bit EER.EME0SER is set. Separate reset, status, and enable bits are available in the Move Engines for source error condition, as well as for destination error condition. The Move Engine's interrupts can be directed to one of the interrupt outputs SR[15:0][1] by setting the Move Engine interrupt pointer EER.ME0INP with a corresponding value.

Note that in case of a read move error, the write move is not executed but the destination address is updated.

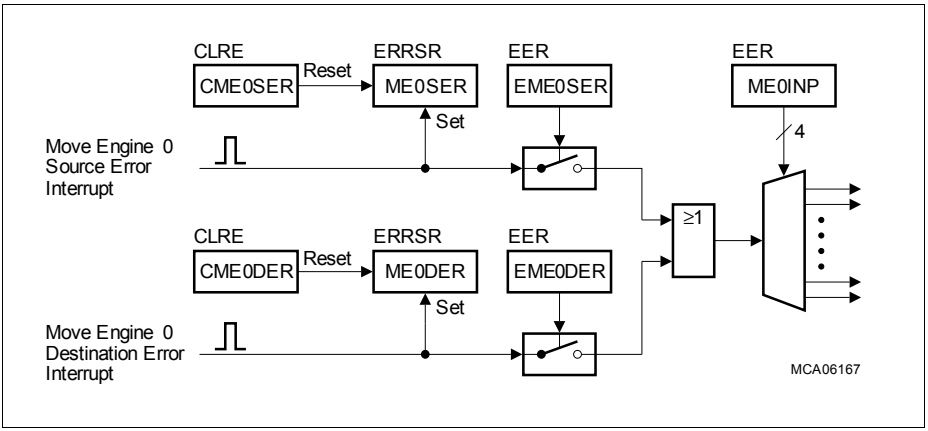

Figure 12-19 Move Engine Interrupts

1) In the TC1798 SR[7:0] are connected to interrupt nodes. SR[15:8] are used as DMA channel trigger signals.

When a Move Engine 0 source or destination error occurs, additional status bits and bit fields are provided in the error status register ERRSR to indicate the following two status conditions:

- At which On Chip Bus interface a Move Engine 0 error occurred (FPI or SRI)
- For which DMA channel a Move Engine 0 read or write move error was reported (LECME0)

These error status bits and bit fields are required by error handler software to detect in detail at which On Chip Bus interface and DMA channel the Move Engine error has been generated. ERRSR.FPIER or ERRSR.SRIER is reset when bits CLRE.CFPI0ER or CLRE.CFPI1ER is respectively set.

12.2.12.4 Wrap Buffer Interrupts

Each DMA channel mn is able to generate a wrap buffer interrupt for source buffer or destination buffer overflow. Further details on the pattern detection are described in **Section 12.2.13**.

A wrap source buffer interrupt of DMA channel mn is indicated by status flag WRPSR.WRPSmn. A wrap destination buffer interrupt of DMA channel mn is indicated by the status flag WRPSR.WRPDmn. Both interrupt status flags can be reset by software when bit INTCR.CWRPmn (or CHRSTR.CHmn becomes set). The wrap source buffer interrupt is enabled when bit CHICRmn.WRPSE is set. The wrap destination buffer interrupt is enabled when bit CHICRmn.WRPDE is set. The two interrupts for wrap source buffer and wrap destination buffer are OR-ed together to one common wrap buffer interrupt of DMA channel mn that can be directed to one of the interrupt outputs SR[15:0][1] by setting the wrap buffer interrupt pointer CHICRmn.WRPP with a corresponding value. Note that the pattern match should not be enabled while a wrap interrupt is enabled for the same channel.

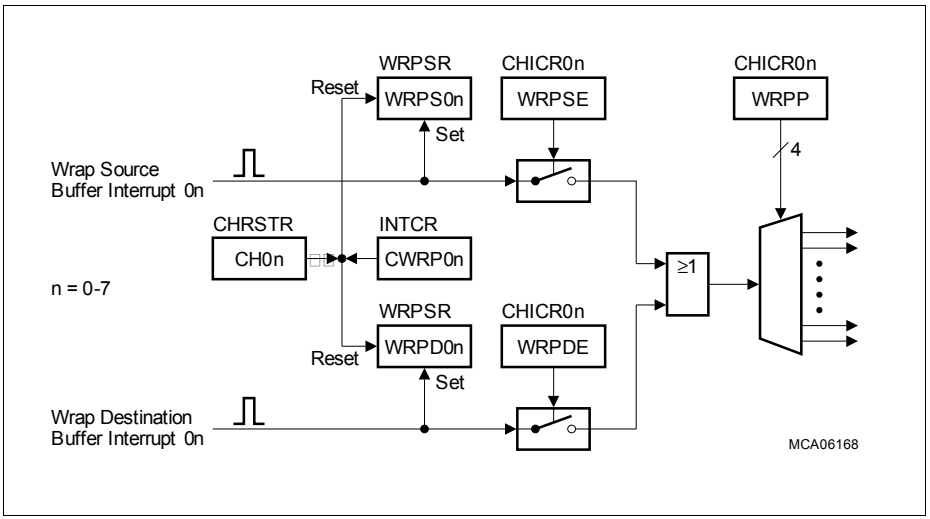

Figure 12-20 DMA Wrap Buffer Interrupts (m = 0-1)

1) In the TC1798 SR[7:0] are connected to interrupt nodes. SR[15:8] are used as DMA channel trigger signals.

12.2.12.5 Interrupt Request Compressor

The interrupt control logic of the DMA controller uses an interrupt compressing scheme that allows high flexibility in interrupt processing. The request compressor logic as shown in **Figure 12-21** condenses the 8 + 1 + 1 + 8 = 18 interrupt sources to the sixteen interrupt outputs. Each internal interrupt source can be directed to one of the sixteen interrupt outputs SR[15:0][1)] by using a 4-bit Interrupt Node Pointer. This also allows the connection of more than one interrupt source to one interrupt output SRx. Each interrupt output SR[15:0][1)] can also be activated by writing a 1 to the corresponding bit GINTR.SIDMAx.

1) In the TC1798 SR[7:0] are connected to interrupt nodes. SR[15:8] are used as DMA channel trigger signals.

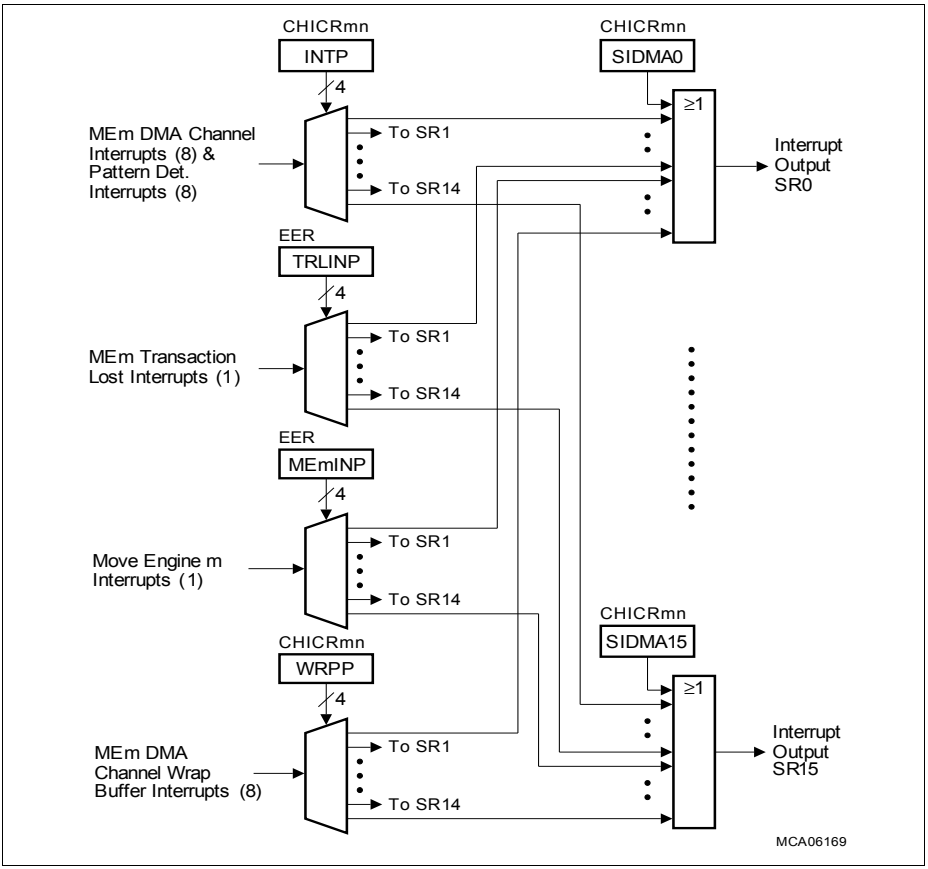

Figure 12-21 DMA Interrupt Request Compressor (m = 0-1)

12.2.13 Pattern Detection

The Move Engine in the DMA Sub-Block provides a register ME0R that contains the data that was read during the last read move. Parts of this read move data can be compared after the read move to data that is stored in the Move Engine pattern register ME0PR of DMA Sub-Block 0. The result of this pattern compare match is always stored in a bit (LXO) of the channel status register of the DMA channel mn that is currently executing the DMA move. Therefore, the pattern match result LXO of the previous read move can also be combined together with the pattern match result of the actual read move. ME0R is overwritten with each read move.

As the compare match patterns are stored in the Move Engine 0 (register ME0PR), its compare patterns are used for all DMA channels that are assigned to Move Engine 0 (all DMA channels of the DMA Sub-Block 0.

The configuration and capabilities of the pattern detection logic further depends on the settings of CHCRmn.CHDW. CHDW determines the data width for the read and write moves individually for each DMA channel mn. Another control bit, CHCRmn.PATSEL, selects among the different operating modes for a specific value of CHDW.

Depending on CHCRmn.PATSEL and on the positive result of the comparison, two actions follow (if CHCRmn.PATSEL=00, no action will be taken when a pattern match is detected, so the wrap interrupt can be used):

- The activation of the interrupt corresponding to the current active channel mn using the Interrupt Pointer defined in CHICRmn.INTP.
- Reset TRSR.HTREmn and TRSR.CHmn in order to stop the current transaction (Hardware and Software request enable). The value of CHSRmn.TCOUNT can be read out by the interrupt software.

The software will have to service the interrupt and to activate again the channel.

12.2.13.1 Pattern Compare Logic

Read move data and compare match patterns are compared on a bit-wise level. The logic as shown in **Figure 12-22** is implemented in each COMP block of **Figure 12-23**, **Figure 12-24**, and **Figure 12-25**. One COMP block controls either 8 bits or 16 bits of data and makes it possible to mask each data bit for the compare operation.

In the compare logic for one bit of the COMP block, a data bit from register ME0R is compared to the corresponding pattern bit stored in register ME0PR. If both bits are equal and a pattern mask bit stored in another part of register ME0PR is 0, the compare matched condition becomes active. When the pattern mask bit is set to 1, the compare matched condition is always active (set) for the related bit. When the compare matched conditions for each bit within a COMP block are true, the compare match output line of the COMP block becomes active.

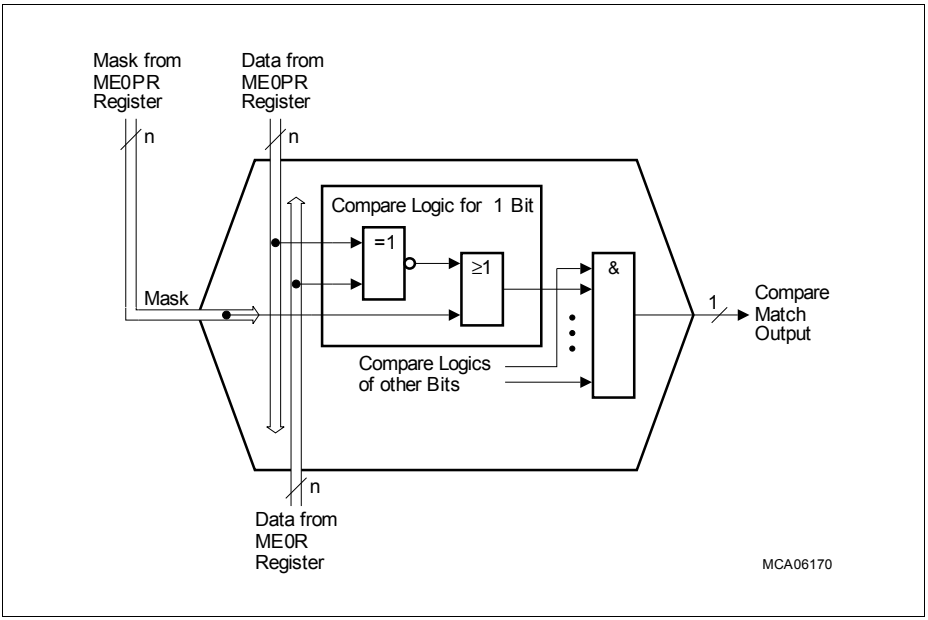

Figure 12-22 Pattern Compare Logic (COMP Block)

12.2.13.2 Pattern Detection for 8-bit Data Width

When 8-bit channel data width is selected (CHCRmn.CHDW = 00_B), the pattern detection logic is configured as shown in **Figure 12-23**. Three compare match configurations are possible.

Table 12-4 Pattern Detection for 8-bit Data Width

CHCRmn. PATSEL	Pattern Detection Operating Modes
00_B	Pattern detection disabled
01_B	Pattern compare of RD00 to PAT00, masked by PAT02
10_B	Pattern compare of RD00 to PAT01, masked by PAT03
11_B	Pattern compare of RD00 to PAT00, masked by PAT02 of the actual read move **and** Pattern compare of RD00 to PAT01, masked by PAT03 of the previous read move of DMA channel mn

When 8-bit channel data width is selected, the pattern detection logic allows the byte of one read move to be compared with two different patterns. Further, after each read move the pattern match result “RD00 with PAT01, masked by PAT03” is stored in bit CHCRmn.LXO. This operating mode allows, for example, two-byte sequences to be detected in an 8-bit data stream coming from a serial peripheral unit with 8-bit data width (e.g.: recognition of carriage-return, line-feed characters). A mask operation of each compared bit is possible.

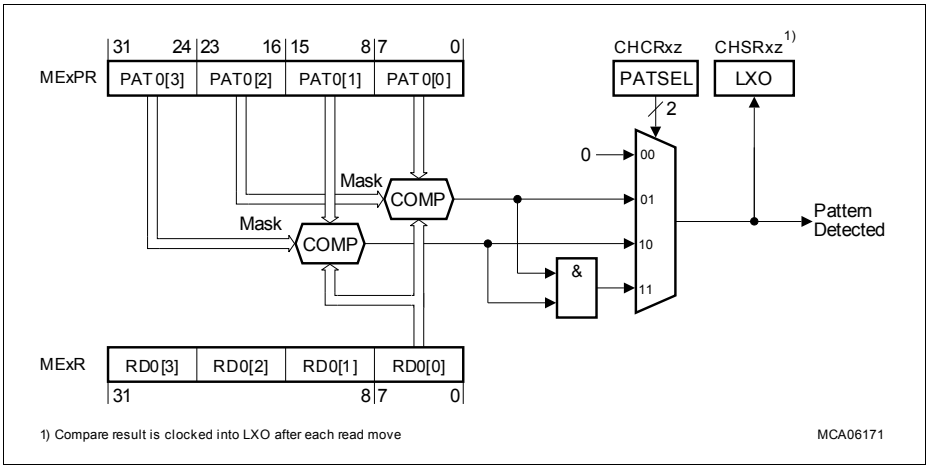

Figure 12-23 Pattern Detection for 8-bit Data Width (CHCRmn.CHDW = 00_B) (m = 0-

1)

12.2.13.3 Pattern Detection for 16-bit Data Width

When 16-bit channel data width is selected (CHCRmn.CHDW = 01_B) the pattern detection logic can be configured as shown in **Figure 12-24**. Three compare match configurations are possible.

Table 12-5 Pattern Detection for 16-bit Data Width

CHCRmn. **PATSEL**	**ADRCR**mn. **INCS**	**Pattern Detection Operating Modes**
00_B	–	Pattern detection disabled
01_B	–	**Aligned Mode:** Pattern compare of RD0[1:0] to PAT0[1:0], masked by PAT0[3:2]
10_B	0	**Unaligned Mode 1 (Source Address Decrement):** Pattern compare of RD01 to PAT00, masked by PAT02 of the actual read move **and** Pattern compare of RD00 to PAT01, masked by PAT03 (LXO) of the previous read move of DMA channel mn
	1	**Unaligned Mode 2 (Source Address Increment):** Pattern compare of RD00 to PAT01, masked by PAT03 of the actual read move **and** Pattern compare of RD01 to PAT00, masked by PAT02 (LXO) of the previous read move of DMA channel mn
11_B	0 or 1	**Combined Mode:** Pattern compare for aligned mode (PATSEL = 01_B) **or** unaligned modes (PATSEL = 10_B)

When 16-bit channel data width is selected, the pattern detection logic makes it possible to compare the complete half-word of one read move only (aligned mode) or to compare upper and lower byte of two consecutive read moves (unaligned modes). Both modes can be combined (combined mode) too. A mask operation of each compared bit is possible.

In unaligned mode 1 (source address decremented), the high byte (RD01) of the current and the low byte (RD00) of the previous 16-bit read move are compared.

In unaligned mode 2 (source address incremented), the low byte (RD00) of the current and the high byte (RD01) of the previous 16-bit read move are compared.

If it is not known on which byte boundary (even or odd address) the 16-bit pattern to be detected is located, the combined mode should be used. This mode is the most flexible

mode that combines the pattern search capability for aligned and unaligned 16-bit data searches.

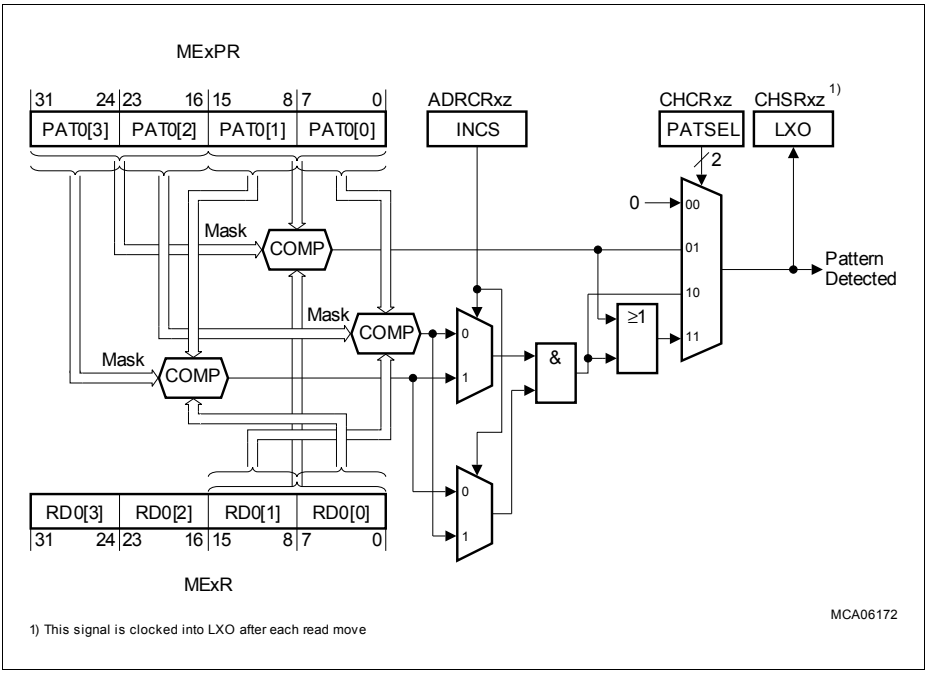

Figure 12-24 Pattern Detection for 16-bit Data Width (CHCRmn.CHDW = 01_B)
(m = 0-1)

12.2.13.4 Pattern Detection for 32-bit Data Width

When 32-bit channel data width is selected (CHCRmn.CHDW = 10_B) the pattern detection logic is configured as shown in **Figure 12-25**. Three compare match configurations are possible.

Table 12-6 Pattern Detection for 32-bit Data Width

CHCRmn. PATSEL	Pattern Detection Operating Modes
00_B	Pattern detection disabled
01_B	Unmasked pattern compare of RD0[1:0] to PAT0[1:0]
10_B	Unmasked pattern compare of RD0[3:2] to PAT0[3:2]
11_B	Unmasked pattern compare of RD0[3:0] to PAT0[3:0]

In 32-bit channel data width mode, the pattern detection logic makes it possible to compare the lower half-word only, the upper half-word only, or the complete 32-bit word with a pattern stored in the ME0PR register. A mask operation is not possible.

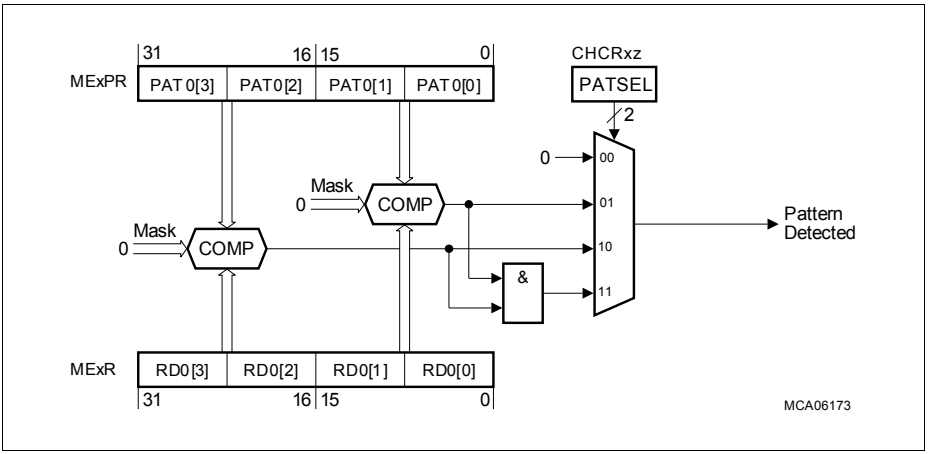

Figure 12-25 Pattern Detection for 32-bit Data Width (CHCRmn.CHDW = 10_B)
(m = 0-1)

12.2.14 Access Protection

The DMA controller provides an access protection logic that makes it possible to disable read and write accesses of the Move Engines to specific parts of the memory map. Each address of a read move and a write move is always checked to determine if it is within an address range that is enabled for read/write access. If no address range is valid for an actual move address, a Move Engine interrupt can be generated. Accesses outside of specific locations of the memory map (AEN address ranges) are invalid and will not be executed by the Move Engines or MLIs and will result in an access protection violation.

The access protection logic handles two levels of address range definitions:

- Fixed address range
- Programmable address range extension

There are 32 fixed address ranges available that can be individually enabled/disabled in the Move Engine by the address range enable bits AENx (x = 0-31): These bits are located in the Move Engine m Access Enable Registers MEmAENR0 and MEmAENR1. If bit AENx is set, read/write accesses to the associated address range x are allowed. If bit AENx is cleared (default after reset), read/write accesses to the associated address range x are not executed and a Move Engine interrupt for source or destination move is generated (see also **Section 12.2.12.3**).

Additionally eight programmable address range extensions are available for each of the two Move Engines that are fixed assigned to the Program Scratch SRAM, the Data Scratch SRAM, the LMU SRAM and PCP Data SRAM (see also **Section 12.4.2**). Each programmable address range extension makes it possible to define a sub-range within the corresponding address range where an access will be executed by the corresponding Move Engine if the address range is not disabled by the corresponding AENx bit. An access to the address range outside the defined sub-range will not be executed by the corresponding Move Engine. The parameters for the sub-ranges are stored in the Move Engine m Access Range Registers MEmARR0 and MEmARR1. The programmable address range extension is a feature that is applicable for memory access protection of memory blocks. In such an application, several memory sections are defined as sub-ranges of a complete memory block.

Figure 12-26 shows the two levels of address range definitions with the resulting address sub-ranges of the programmable address range extension. In a fixed address range, the width of fixed and variable address bits is constant. Number “a” determines the lowest bit position of the fixed address, and is fixed individually and product-specific for each of the 32 fixed address ranges. With the programmable address range extension, the variable address part of the fixed address range definition (as defined by AENx) is reduced by the definition of a programmable number (up to 32) of sub-ranges. Bit field MEmARR0.SIZE/MEmARR1.SIZE determines the sub-range size and bit field MEmARR0.SLICE/MEmARR1.SLICE determines which of the sub-ranges is currently

selected for access protection control. The two parameters (SIZE, SLICE) of the eight address range extensions of a move engine are numbered by index “n” (n = 0-3).

In the TC1798 the number “a” is defined in the following way:

- ARR0.SIZE0/ARR0.SLICE0 covering the Program Scratch SRAM, “a” = 16
- ARR0.SIZE1/ARR0.SLICE1 covering the LMU SRAM, “a” = 17
- ARR0.SIZE2/ARR0.SLICE2 covering the Data Scratch SRAM, “a” = 17
- ARR0.SIZE3/ARR0.SLICE3 covering the PCP Data SRAM, “a” = 16

Two sub-range examples (see **Figure 12-26**):

- 2^3 = 8 sub-ranges are available with SIZE = 100_B. SLICE[2:0] selects one out of the eight sub-ranges. SLICE[4:3] is “don’t care”.
- 2^7 = 128 sub-ranges are basically available with SIZEn = 000_B. SLICEn[4:0] selects one out of the lowest 32 sub-ranges. The upper 3 x 32 = 96 sub-ranges are not selectable (fixed address bits a-1 and a-2).

*Note: The definition of the fixed address ranges x and the assignment of each sub-range to one of the fixed address ranges is product-specific. The definitions of the address ranges for the DMA controller as implemented in the TC1798 are defined on **Page 12-111**.*

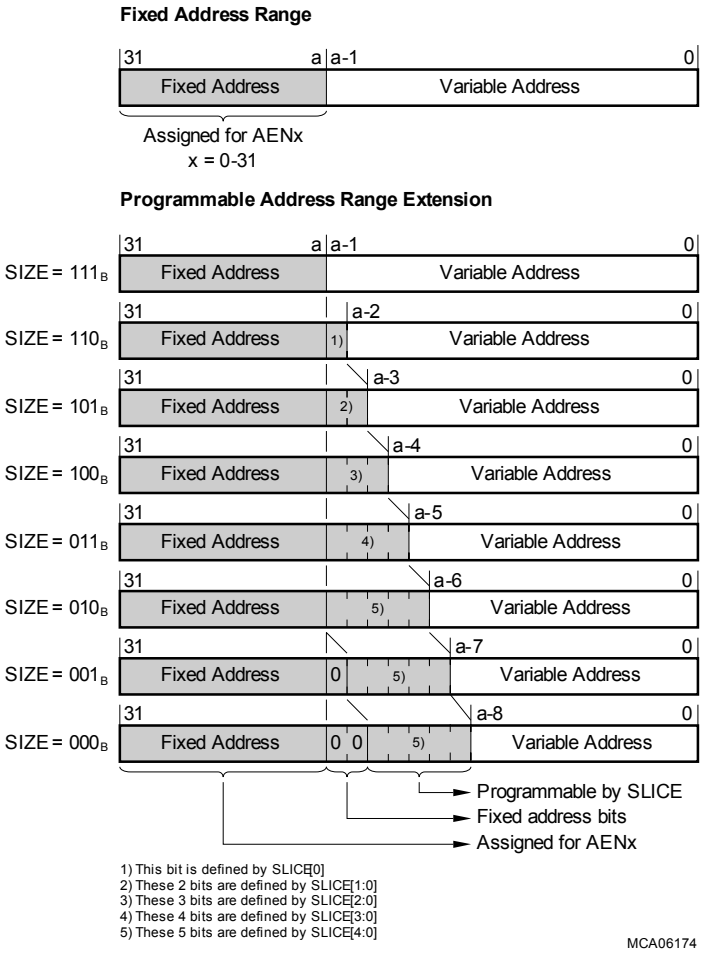

Figure 12-26 Access Protection Address Range Definitions

12.3 DMA Module Registers

Figure 12-27 and Table 12-8 show all registers associated with the DMA Controller Kernel. Additionally, Table 12-8 includes the DMA module specific registers. All DMA kernel register names described in this section are also referenced in other parts of the TC1798 User´s Manual by the module name prefix “DMA_”.

The registers are numbered by one index to indicate the related DMA Sub-Block and one index to indicate the related DMA channel: Index “m” refers to the DMA Sub-Block number (m = 0-1) and Index “n” or “x” refers to the channel number (n = 0-7 or x = 0-7) within the DMA Sub-Block.

1) The absolute register address is calculated as follows:
Module Base Address (Table 12-7) + Offset Address (shown in this column)
Further, the following ranges for parameters i, k, x, and n are valid: i = 0-7, k = 0-7, x = 0-1, n = 0-63.

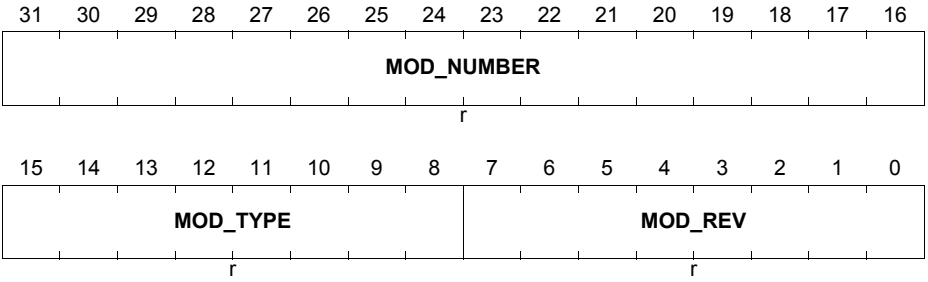
2) Write access mode to DMA_SHADRmn is controlled by the register bit DMA_ADRCRmn.SHWEN. DMA_ADRCRmn.SHWEN=´0´ -> Access Mode Write for DMA_SHADRmn is BE. DMA_ADRCRmn.SHWEN=´1´ -> Access Mode Write for DMA_SHADRmn is SV.

Note: Register bits marked “w” in the following register description are virtual registers and do not contain flip-flops. They are always read as 0.

12.3.1 System Registers

DMA Module Identification Register.

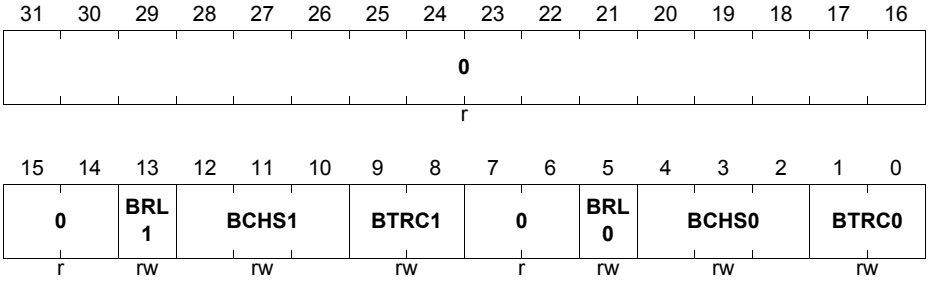
DMA_ID
Module Identification Register **(008_H)** **Reset Value: 001A C0XX$_H$**



Field	Bits	Type	Description
MOD_REV	[7:0]	r	**Module Revision Number** This bit field defines the module revision number. The value of a module revision starts with 01_H (first revision).
MOD_TYPE	[15:8]	r	**Module Type** The bit field is set to $C0_H$ which defines the module as a 32-bit module.
MOD_NUMBER	[31:16]	r	**Module Number Value** This bit field defines a module identification number. The value for the DMA module is $001A_H$.

The OCDS Register describes the break capability of the DMA module. OCDSR is only reset with the OCDS Reset.

DMA_OCDSR
DMA OCDS Register **(064_H)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
BTRC0	[1:0]	rw	**Break Trigger Condition In Sub-Block 0** This bit field determines the transition type for the transaction request bit TRSR.CH0n that leads to a break condition in DMA Sub-Block 0. 00_B No break condition is generated 01_B A break condition is generated when TRSR.CH0n changes from 0 to 1 10_B A break condition is generated when TRSR.CH0n changes from 1 to 0 11_B A break condition is generated when TRSR.CH0n changes its state
BCHS0	[4:2]	rw	**Break Channel Select In Sub-Block 0** This bit field determines the DMA channel n of DMA Sub-Block 0 whose transaction request bit TRSR.CH0n is observed for signal transitions as defined by BTRC0. 000_B DMA channel 00 selected 001_B DMA channel 01 selected …$_B$ … 110_B DMA channel 06 selected 111_B DMA channel 07 selected

Field	Bits	Type	Description
BRL0	5	rw	**Break On Request Lost in Sub-Block 0** This bit field determines whether a BREAK signal is generated for DMA Sub-Block 0 when at least one of its eight transaction lost interrupts becomes active. 0_B No break condition is generated 1_B A break condition is generated for DMA Sub-Block 0 when at least one of its eight transaction lost interrupts becomes active
BTRC1	[9:8]	rw	**Break Trigger Condition In Sub-Block 1** This bit field determines the transition type for the transaction request bit TRSR.CH1n that leads to a break condition in DMA Sub-Block 1. 00_B No break condition is generated 01_B A break condition is generated when TRSR.CH1n changes from 0 to 1 10_B A break condition is generated when TRSR.CH1n changes from 1 to 0 11_B A break condition is generated when TRSR.CH1n changes its state
BCHS1	[12:10]	rw	**Break Channel Select In Sub-Block 1** This bit field determines the DMA channel n of DMA Sub-Block 1 whose transaction request bit TRSR.CH1n is observed for signal transitions as defined by BTRC1. 000_B DMA channel 10 selected 001_B DMA channel 11 selected ...B ... 110_B DMA channel 16 selected 111_B DMA channel 17 selected
BRL1	13	rw	**Break On Request Lost in Sub-Block 1** This bit field determines whether a BREAK signal is generated for DMA Sub-Block 1 when at least one of its eight transaction lost interrupts becomes active. 0_B No break condition is generated 1_B A break condition is generated for DMA Sub-Block 1when at least one of its eight transaction lost interrupts becomes active
0	[7:6], [31:14]	r	**Reserved** Read as 0; should be written with 0.

The Suspend Mode Register contains bits for each DMA channel that make it possible to enable/disable its Soft-suspend Mode capability and that indicate its suspend status.

DMA_SUSPMR
DMA Suspend Mode Register **(068_H)** **Reset Value: $0000\ 0000_H$**

Field	Bits	Type	Description
CH0n (n = 0-7)	n	rwh	**Channel 0n Reset** These bits force the DMA channel 0n to stop its current DMA transaction. Once set by software, this bit will be automatically cleared when the channel has been reset. Writing a 0 to CH0n has no effect. 0_B No action (write) or the requested channel reset has been reset (read). 1_B DMA channel 0n is stopped. More details see Page 12-16.
CH1n (n = 0-7)	8+n	rwh	**Channel 1n Reset** These bits force the DMA channel 1n to stop its current DMA transaction. Once set by software, this bit will be automatically cleared when the channel has been reset. Writing a 0 to CH1n has no effect. 0_B No action (write) or the requested channel reset has been reset (read). 1_B DMA channel 1n is stopped. More details see Page 12-16.
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

The bits in the Transaction Request State Register indicates which DMA channel is processing a request, and which DMA channel has hardware transaction requests enabled.

DMA_TRSR
DMA Transaction Request State Register

Field	Bits	Type	Description
CH0n (n = 0-7)	n	rh	**Transaction Request State of DMA Channel 0n** 0_B No DMA request is pending for channel 0n. 1_B A DMA request is pending for channel 0n.
CH1n (n = 0-7)	8+n	rh	**Transaction Request State of DMA Channel 1n** 0_B No DMA request is pending for channel 1n. 1_B A DMA request is pending for channel 1n.
HTRE0n (n = 0-7)	16+n	rh	**Hardware Transaction Request Enable State of DMA Channel 0n** 0_B Hardware transaction request for DMA Channel 0n is disabled. An input DMA request will not trigger the channel 0n. 1_B Hardware transaction request for DMA Channel 0n is enabled. The transfers of a DMA transaction are controlled by the corresponding channel request line of the DMA requesting source. HTRE0n is set to 0 when CHSR0n.TCOUNT is decremented and CHSR0n.TCOUNT = 0. HTRE0n can be enabled and disabled with HTREQ.ECH0n or HTREQ.DCH0n.

Field	Bits	Type	Description
HTRE1n (n = 0-7)	24+n	rh	**Hardware Transaction Request Enable State of DMA Channel 1n** 0_B Hardware transaction request for DMA Channel 1n is disabled. An input DMA request will not trigger the channel 1n. 1_B Hardware transaction request for DMA Channel 1n is enabled. The transfers of a DMA transaction are controlled by the corresponding channel request line of the DMA requesting source. HTRE1n is set to 0 when CHSR1n.TCOUNT is decremented and CHSR1n.TCOUNT = 0. HTRE1n can be enabled and disabled with HTREQ.ECH1n or HTREQ.DCH1n.

The bits in the Software Transaction Request Register are used to generate a DMA transaction request by software.

DMA_STREQ
DMA Software Transaction Request Register
(018_H) **Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Bits	Type	Description
ETRL0n (n = 0-7)	n	rw	**Enable Transaction Request Lost for DMA Channel 0n** This bit enables the generation of an interrupt when the set condition for ERRSR.TRL0n is detected. 0_B The interrupt generation for a request lost event for channel 0n is disabled. 1_B The interrupt generation for a request lost event for channel 0n is enabled.
ETRL1n (n = 0-7)	8+n	rw	**Enable Transaction Request Lost for DMA Channel 1n** This bit enables the generation of an interrupt when the set condition for ERRSR.TRL1n is detected. 0_B The interrupt generation for a request lost event for channel 1n is disabled. 1_B The interrupt generation for a request lost event for channel 1n is enabled.
EME0SER	16	rw	**Enable Move Engine 0 Source Error** This bit enables the generation of a Move Engine 0 source error interrupt. 0_B Move Engine 0 source error interrupt is disabled. 1_B Move Engine 0 source error interrupt is enabled.

Field	Bits	Type	Description
EME0DER	17	rw	**Enable Move Engine 0 Destination Error** This bit enables the generation of a Move Engine 0 destination error interrupt. 0_B Move Engine 0 destination error interrupt is disabled. 1_B Move Engine 0 destination error interrupt is enabled.
EME1SER	18	rw	**Enable Move Engine 1 Source Error** This bit enables the generation of a Move Engine 1 source error interrupt. 0_B Move Engine 1 source error interrupt is disabled. 1_B Move Engine 1 source error interrupt is enabled.
EME1DER	19	rw	**Enable Move Engine 1 Destination Error** This bit enables the generation of a Move Engine 0 destination error interrupt. 0_B Move Engine 1 destination error interrupt is disabled. 1_B Move Engine 1 destination error interrupt is enabled.
ME0INP	[23:20]	rw	**Move Engine 0 Error Interrupt Node Pointer** ME0INP determines the number n (n = 0-15) of the service request output SRn that becomes active on a Move Engine 0 source or destination interrupt. 0000_B SR0 selected for Move Engine 0 interrupt 0001_B SR1 selected for Move Engine 0 interrupt $\ldots_B$ … 1111_B SR15 selected for Move Engine 0 interrupt *Note: In the TC1798, SR[7:0] are connected to interrupt nodes. SR[15:8] are used as DMA channel request inputs (**Page 12-101**).*

Field	Bits	Type	Description
ME1INP	[27:24]	rw	**Move Engine 1 Error Interrupt Node Pointer** ME1INP determines the number n (n = 0-15) of the service request output SRn that becomes active on a Move Engine 1 source or destination interrupt. 0000_B SR0 selected for Move Engine 1 interrupt 0001_B SR1 selected for Move Engine 1 interrupt …$_B$ … 1111_B SR15 selected for Move Engine 1 interrupt *Note: In the TC1798, SR[7:0] are connected to interrupt nodes. SR[15:8] are used as DMA channel request inputs (**Page 12-101**).*
TRLINP	[31:28]	rw	**Transaction Lost Interrupt Node Pointer** TRLINP determines the number n (n = 0-15) of the service request output SRn that becomes active on a transaction lost interrupt. 0000_B SR0 selected for transaction lost interrupt 0001_B SR1 selected for transaction lost interrupt …$_B$ … 1111_B SR15 selected for transaction lost interrupt *Note: In the TC1798, SR[7:0] are connected to interrupt nodes. SR[15:8] are used as DMA channel request inputs (**Page 12-101**).*

The Error Status Register indicates if the DMA controller could not answer to a request because the previous request was not terminated (see **Section 12.2.4.4**). It indicates also the FPI Bus accesses that have been terminated with errors.

DMA_ERRSR
DMA Error Status Register **(024_H)** **Reset Value: 0000 0000$_H$**

Field	Bits	Type	Description
TRL0n (n = 0-7)	n	rh	**Transaction/Transfer Request Lost of DMA Channel 0n** 0_B 0 No request lost event has been detected for channel 0n. 1_B 1 A new DMA request was detected while TRSR.CH0n=1 (request lost event). This bit is reset by software when writing a 1 to CLRE.CTL0n, or by a channel reset (writing CHRSTR.CH0n = 1).
TRL1n (n = 0-7)	8+n	rh	**Transaction/Transfer Request Lost of DMA Channel 1n** 0_B No request lost event has been detected for channel 1n. 1_B A new DMA request was detected while TRSR.CH1n=1 (request lost event). This bit is reset by software when writing a 1 to CLRE.CTL1n, or by a channel reset (writing CHRSTR.CH1n = 1).

Field	Bits	Type	Description
ME0SER	16	rh	**Move Engine 0 Source Error** This bit is set whenever a Move Engine 0 error occurred during a source (read) move of a DMA transfer, or a request could not been serviced due to the access protection. 0_B No Move Engine 0 source error has occurred. 1_B A Move Engine 0 source error has occurred.
ME0DER	17	rh	**Move Engine 0 Destination Error** This bit is set whenever a Move Engine 0 error occurred during a destination (write) move of a DMA transfer, or a request could not been serviced due to the access protection. 0_B No Move Engine 0 destination error has occurred. 1_B A Move Engine 0 destination error has occurred.
ME1SER	18	rh	**Move Engine 1 Source Error** This bit is set whenever a Move Engine 1 error occurred during a source (read) move of a DMA transfer, or a request could not been serviced due to the access protection. 0_B No Move Engine 1 source error has occurred. 1_B A Move Engine 1 source error has occurred.
ME1DER	19	rh	**Move Engine 1 Destination Error** This bit is set whenever a Move Engine 1 error occurred during a destination (write) move of a DMA transfer, or a request could not been serviced due to the access protection. 0_B No Move Engine 1 destination error has occurred. 1_B A Move Engine 1 destination error has occurred.
FPIER	20	rh	**SPB Error** This bit is set whenever a move that has been started by the DMA/MLI FPI master interface leads to an error on the FPI Bus. 0_B No error occurred. 1_B An error occurred on FPI Bus interface.

Field	Bits	Type	Description
SRIER	21	rh	**SRI Error** This bit is set whenever a move that has been started by the DMA/MLI SRI master interface leads to an error on the SRI Bus. 0_B No error occurred. 1_B An error occurred on SRI Bus interface.
CERBERUSER	22	rh	**Cerberus Error Source** This bit is set whenever an On Chip Bus error occurred due to an action of Cerberus. 0_B No On Chip Bus error occurred due to Cerberus. 1_B An On Chip Bus error occurred due to Cerberus.
LECME0	[26:24]	rh	**Last Error Channel Move Engine 0** This bit field indicates the channel number of the last channel of Move Engine 0 leading to an On Chip Bus error that has occurred.
MLI0	27	rh	**MLI0 Error Source** This bit is set whenever an On Chip Bus error occurred due to an action of MLI0. 0_B No On Chip Bus error occurred due to MLI0. 1_B An On Chip Bus error occurred due to MLI0.
LECME1	[30:28]	rh	**Last Error Channel Move Engine 1** This bit field indicates the channel number of the last channel of Move Engine 1 leading to an On Chip Bus error that has occurred.
MLI1	31	rh	**MLI1 Error Source** This bit is set whenever an On Chip Bus error occurred due to an action of MLI1. 0_B No On Chip Bus error occurred due to MLI1. 1_B An On Chip Bus error occurred due to MLI1.
0	23	r	**Reserved** Read as 0; should be written with 0.

The Clear Error contains bits that make it possible to clear the Transaction Request Lost flags or the Move Engine error flags.

Field	Bits	Type	Description
ICH0n (n = 0-7)	n	rh	**Interrupt from Channel 0n** This bit indicates that channel 0n has raised an interrupt for TCOUNT = IRDV or if TCOUNT has been decremented (depending on CHICR.INTCT[0]. This bit (and IP0n) is reset by software when writing a 1 to INTCR.CICH0n or by a channel reset (writing CHRSTR.CH0n = 1). 0_B A channel interrupt has not been detected. 1_B A channel interrupt has been detected.
ICH1n (n = 0-7)	8+n	rh	**Interrupt from Channel 1n** This bit indicates that channel 1n has raised an interrupt for TCOUNT = IRDV or if TCOUNT has been decremented (depending on CHICR.INTCT[0]. This bit (and IP1n) is reset by software when writing a 1 to INTCR.CICH1n or by a channel reset (writing CHRSTR.CH1n = 1). 0_B A channel interrupt has not been detected. 1_B A channel interrupt has been detected.

Field	Bits	Type	Description
IPM0n (n = 0-7)	16+n	rh	**Pattern Detection from Channel 0n** This bit indicates that a pattern has been detected for channel 0n while the pattern detection has been enabled. This bit (and ICH0n) is reset by software when writing a 1 to INTCR.CICH0n or by a channel reset (writing CHRSTR.CH0n = 1). 0_B A pattern has not been detected. 1_B A pattern has been detected.
IPM1n (n = 0-7)	24+n	rh	**Pattern Detection from Channel 1n** This bit indicates that a pattern has been detected for channel 1n while the pattern detection has been enabled. This bit (and ICH1n) is reset by software when writing a 1 to INTCR.CICH1n or by a channel reset (writing CHRSTR.CH1n = 1). 0_B A pattern has not been detected. 1_B A pattern has been detected.

The Wrap Status Register gives information about the channels that did a wrap-around on their source or destination buffer(s). This condition can also lead to an interrupt if it is enabled.

DMA_WRPSR
DMA Wrap Status Register **($05C_H$)** **Reset Value: 0000 0000$_H$**

Field	Bits	Type	Description
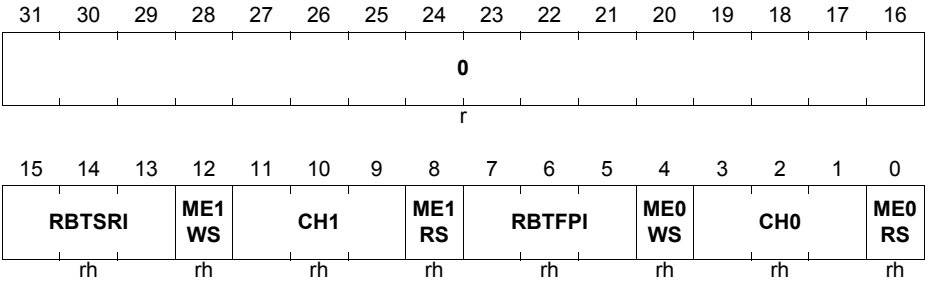
CICH0n (n = 0-7)	n	w	**Clear Interrupt for DMA Channel 0n** These bits make it possible to reset the channel interrupt flags INTSR.ICH0n and INTSR.IPM0n of DMA channel 0n by software. 0_B No action. 1_B Bits INTSR.ICH0n and INTSR.IPM0n are reset.
CICH1n (n = 0-7)	8+n	w	**Clear Interrupt for DMA Channel 1n** These bits make it possible to reset the channel interrupt flags INTSR.ICH1n and INTSR.IPM1n of DMA channel 1n by software. 0_B No action. 1_B Bits INTSR.ICH1n and INTSR.IPM1n are reset.
CWRP0n (n = 0-7)	16+n	w	**Clear Wrap Buffer Interrupt for DMA Channel 0n** These bits make it possible to reset the wrap source buffer interrupt flag WRPSR.WRPS0n and the wrap destination buffer interrupt flag WRPSR.WRPD0n (both together) of DMA channel 0n by software. 0_B No action. 1_B Bits WRPSR.WRPS0n and WRPSR.WRPD0n are reset.

Field	Bits	Type	Description
CWRP1n (n = 0-7)	24+n	w	**Clear Wrap Buffer Interrupt for DMA Channel 1n** These bits make it possible to reset the wrap source buffer interrupt flag WRPSR.WRPS1n and the wrap destination buffer interrupt flag WRPSR.WRPD1n (both together) of DMA channel 1n by software. 0_B No action. 1_B Bits WRPSR.WRPS1n and WRPSR.WRPD1n are reset.

12.3.3 Move Engine Registers

The Move Engine Status Register is a read-only register that holds status information about the transaction handled by the Move Engines.

DMA_MESR
DMA Move Engine Status Register (030_H) Reset Value: $0000\ 0000_H$

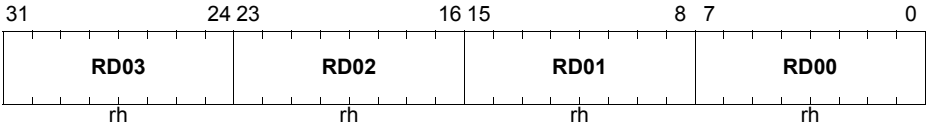


Field	Bits	Type	Description
ME0RS	0	rh	**Move Engine 0 Read Status** 0_B Move Engine 0 is not performing a read. 1_B Move Engine 0 is performing a read.
CH0	[3:1]	rh	**Reading Channel in Move Engine 0** This bit field indicates which channel number is currently being processed by the Move Engine 0.
ME0WS	4	rh	**Move Engine 0 Write Status** 0_B Move Engine 0 is not performing a write. 1_B Move Engine 0 is performing a write.

Field	Bits	Type	Description
RBTFPI	[7:5]	rh	**Read Buffer Trace for FPI Bus Interface** This bit field contains trace information from the buffer in the FPI Bus Interface. In the TC1798 it indicates the source of a bus access to the FPI Bus. 000_B Default value. 001_B DMA Move Engine 0 010_B DMA Move Engine 1 011_B MLI0 100_B MLI1 101_B Cerberus Other bit combinations are reserved. RBTFPI is useful for emulation purposes. It is not recommended to evaluate this bit field during normal operation of the TC1798.
ME1RS	8	rh	**Move Engine 1 Read Status** 0_B Move Engine 1 is not performing a read. 1_B Move Engine 1 is performing a read.
CH1	[11:9]	rh	**Reading Channel in Move Engine 1** These bit field indicates which channel number is currently being processed by the Move Engine 1.
ME1WS	12	rh	**Move Engine 1 Write Status** 0_B Move Engine 1 is not performing a write. 1_B Move Engine 1 is performing a write.
RBTSRI	[15:13]	rh	**Read Buffer Trace for SRI Bus Interface** This bit field contains trace information from the buffer in the SRI Bus Interface. In the TC1798, it indicates the source of a bus access to the SRI Bus. 000_B Default value 001_B DMA Move Engine 0 010_B DMA Move Engine 1 011_B MLI0 100_B MLI1 101_B Cerberus Other bit combinations are reserved. RBTSRI is useful for emulation purposes. It is not recommended to evaluate this bit field during normal operation of the TC1798.
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

The Move Engine 0 Read Register indicates the value that has just been read by Move Engine 0. The value in this register is compared to the bits in register ME0PR according to the bit fields CHCRmn.PATSEL.

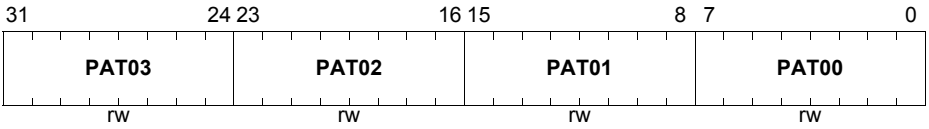
DMA_ME0R
DMA Move Engine 0 Read Register (034_H) **Reset Value: $0000\ 0000_H$**
DMA_ME1R
DMA Move Engine 1 Read Register (038_H) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
RD00, RD01, RD02, RD03	[7:0], [15:8], [23:16], [31:24]	rh	**Read Value for Move Engine 0** Contains the 32-bit read data (four bytes RD0[3:0]) that is stored in the Move Engine 0 after each read move. The content of ME0R is overwritten after each read move of a DMA channel belonging to DMA Sub-block 0.

The Move Engine 0 Pattern Register contains the patterns (mask and/or compare bits) to be processed by the pattern detection logic in Move Engine 0.

DMA_ME0PR
DMA Move Engine 0 Pattern Register ($03C_H$) **Reset Value: $0000\ 0000_H$**
DMA_ME1PR
DMA Move Engine 1Pattern Register (040_H) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
PAT00, PAT01, PAT02, PAT03	[7:0], [15:8], [23:16], [31:24]	rw	**Pattern for Move Engine 0** Determines up to four 8-bit compare patterns/mask patterns to be processed by the pattern detection logic in Move Engine 0. Depending on the pattern detection configuration (CHCR0n.PATSEL) and channel data width (CHCR0n.CHDW), the patterns are processed as bytes or half-words.

The DMA Move Engine 0 Access Enable Register controls the access protection. It enables/disables the address protection ranges x (x = 0-31) for Move Engine 0.

DMA_ME0AENR0
DMA Move Engine 0 Access Enable Register 0
(044_H) **Reset Value: $0000\ 0000_H$**

DMA_ME1AENR0
DMA Move Engine 1 Access Enable Register 0
($04C_H$) **Reset Value: $0000\ 0000_H$**

DMA_ME0AENR1
DMA Move Engine 0 Access Enable Register 1
($06C_H$) **Reset Value: $0000\ 0000_H$**

DMA_ME1AENR1
DMA Move Engine 1 Access Enable Register 1
(074_H) **Reset Value: $0000\ 0000_H$**

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
AENx (x = 0-31)	x	rw	**Address Range x Enable** This bit enables the read and write capability of the DMA Move Engines for address range x (x = 0-31). 0_B DMA read and write moves to address range x are disabled 1_B DMA read and write moves to address range x are enabled If AENx = 0 for a read/write move to address range x, the read/write move is not executed and a source/destination Move Engine interrupt is generated.

*Note: See **Table 12-13** on **Page 12-111** for the TC1798-specific address range definition.*

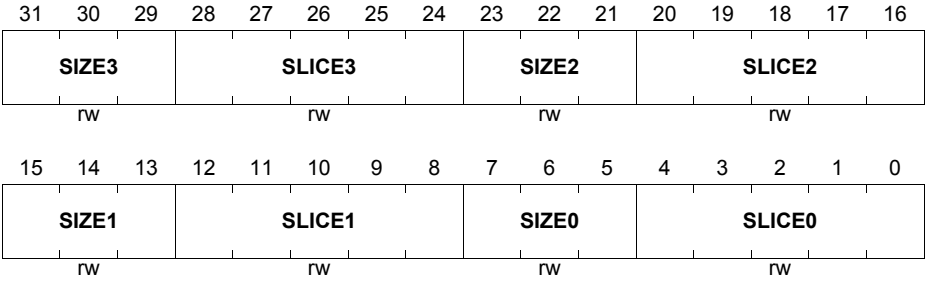
The DMA Move Engine 0 Access Range Register determines number and size of the sub-ranges for address range extension n (n = 0-3). See also **Figure 12-26** for bit field definitions.

DMA_ME0ARR0
DMA Move Engine 0 Access Range Register 0
(048_H) **Reset Value: 0000 0000_H**

DMA_ME1ARR0
DMA Move Engine 1 Access Range Register 0
(050_H) **Reset Value: 0000 0000_H**

DMA_ME0ARR1
DMA Move Engine 0 Access Range Register 1
(070_H) **Reset Value: 0000 0000_H**

DMA_ME1ARR1
DMA Move Engine 1 Access Range Register 1
(078_H) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
SLICE0	[4:0]	rw	**Address Slice 0** SLICE0 selects a specific sub-range within address range extension 0.
SIZE0	[7:5]	rw	**Address Size 0** SIZE0 determines the sub-range size within address range extension 0.
SLICE1	[12:8]	rw	**Address Slice 1** SLICE1 selects a specific sub-range within address range extension 1.
SIZE1	[15:13]	rw	**Address Size 1** SIZE1 determines the sub-range size within address range extension 1.

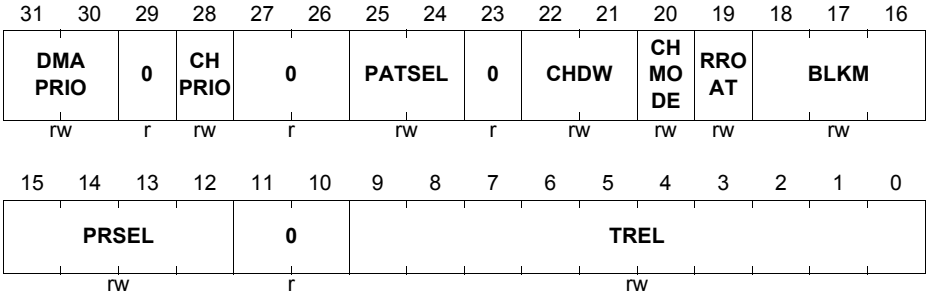
Field	Bits	Type	Description
SLICE2	[20:16]	rw	**Address Slice 2** SLICE2 selects a specific sub-range within address range extension 2.
SIZE2	[23:21]	rw	**Address Size 2** SIZE2 determines the sub-range size within address range extension 2.
SLICE3	[28:24]	rw	**Address Slice 3** SLICE3 selects a specific sub-range within address range extension 3.
SIZE3	[31:29]	rw	**Address Size 3** SIZE3 determines the sub-range size within address range extension 3.

*Note: See **Section 12.4.2** on **Page 12-111** for the TC1798-specific address range and address range extension definitions.*

12.3.4 Channel Control/Status Registers

The Channel Control Register for DMA channel mn contains its configuration and its control bits and bit fields.

DMA_CHCR0x (x = 0-7)
DMA Channel 0x Control Register (084_H+x*20_H) **Reset Value: 0000 0000_H**
DMA_CHCR1x (x = 0-7)
DMA Channel 1x Control Register (184_H+x*20_H) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
TREL	[9:0]	rw	**Transfer Reload Value** This bit field contains the number of DMA transfers for a DMA transaction of DMA channel mn. This10-bit transfer count value is loaded into CHSRmn.TCOUNT at the start of a DMA transaction (when TRSR.CHmn becomes set and CHSRmn.TCOUNT = 0). A write to CHSRmn.TREL during a running DMA transaction has no influence to the running DMA transaction. If CHSRmn.TREL = 0 or if CHSRmn.TREL = 1, CHSRmn.TCOUNT will be loaded with 1 when a new transaction is started (at least one DMA transfer must be executed per DMA transaction).

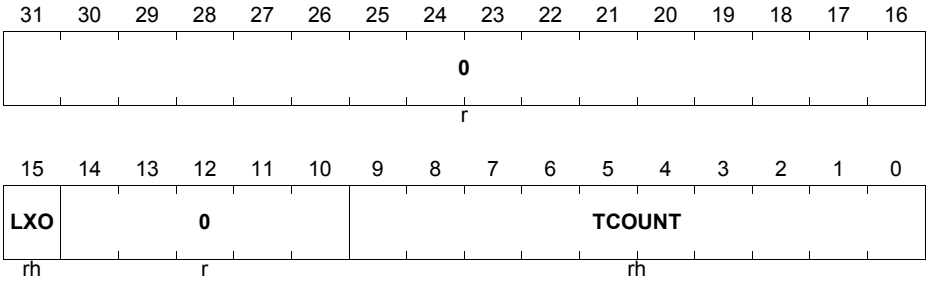
Field	Bits	Type	Description
PRSEL	[15:12]	rw	**Peripheral Request Select** This bit field controls the hardware request input multiplexer of DMA channel mn (see **Figure 12-6** on **Page 12-10**). 0000_B Input CHmn_REQI0 selected 0001_B Input CHmn_REQI1 selected 0010_B Input CHmn_REQI2 selected 0011_B Input CHmn_REQI3 selected 0100_B Input CHmn_REQI4 selected 0101_B Input CHmn_REQI5 selected 0110_B Input CHmn_REQI6 selected 0111_B Input CHmn_REQI7 selected 1000_B Input CHmn_REQI8 selected 1001_B Input CHmn_REQI9 selected 1010_B Input CHmn_REQI10 selected 1011_B Input CHmn_REQI11 selected 1100_B Input CHmn_REQI12 selected 1101_B Input CHmn_REQI13 selected 1110_B Input CHmn_REQI14 selected 1111_B Input CHmn_REQI15 selected
BLKM	[18:16]	rw	**Block Mode** BLKM determines the number of DMA moves executed during one DMA transfer. 000_B One DMA transfer has 1 DMA move 001_B One DMA transfer has 2 DMA move 010_B One DMA transfer has 4 DMA move 011_B One DMA transfer has 8 DMA move 100_B One DMA transfer has 16 DMA move Other bit combinations are reserved and must not be used. See also **Figure 12-10** on **Page 12-17**.
RROAT	19	rw	**Reset Request Only After Transaction** RROAT determines whether or not the TRSR.CHmn transfer request state flag is reset after each transfer. 0_B TRSR.CHmn is reset after each transfer. A transfer request is required for each transfer. 1_B TRSR.CHmn is reset when CHSRmn.TCOUNT = 0 after a transfer. One transfer request starts a complete DMA transaction

Field	Bits	Type	Description
CHMODE	20	rw	**Channel Operation Mode** CHMODE determines the reset condition for control bit TRSR.HTREmn of DMA channel mn. 0_B Single Mode operation is selected for DMA channel mn. After a transaction, DMA channel mn is disabled for further hardware requests (TRSR.HTREmn is reset by hardware) TRSR.HTREmn must be set again by software for starting a new transaction. 1_B Continuous Mode operation is selected for DMA channel mn. After a transaction, bit TRSR.HTREmn remains set
CHDW	[22:21]	rw	**Channel Data Width** CHDW determines the data width for the read and write moves of DMA channel mn. 00_B 8-bit (byte) data width for moves selected 01_B 16-bit (half-word) data width for moves selected 10_B 32-bit (word) data width for moves selected 11_B Reserved
PATSEL	[25:24]	rw	**Pattern Select** This bit field selects the mode of the pattern detection logic. Depending on the channel data width, PATSEL selects different pattern detection configurations. If pattern detection is enabled (PATSEL not equal 00_B), the pattern detection interrupt line will be activated on the selected pattern match. **8-bit channel data width (CHDW = 00_B):** Selected pattern detection configuration see **Table 12-4** on **Page 12-40**. **16-bit channel data width (CHDW = 01_B):** Selected pattern detection configuration see **Table 12-5** on **Page 12-41**. **32-bit channel data width (CHDW = 10_B):** Selected pattern detection configuration see **Table 12-6** on **Page 12-43**.

Field	Bits	Type	Description
CHPRIO	28	rw	**Channel Priority** CHPRIO determines the priority of DMA channel n for the Move Engine m internal channel arbitration. This priority is used for the case when multiple channels of Move Engine m are triggered in parallel. 0_B DMA channel mn has a low channel priority 1_B DMA channel mn has a high channel priority
DMAPRIO	[31:30]	rw	**DMA Priority** This bit determines the DMA the request priority that is used when a move operation related to channel mn is requesting an On Chip Bus. This bit has no effect in channel prioritization inside the Move Engine m in. 00_B Low priority selected 01_B Medium priority selected 10_B Reserved 11_B High priority selected
0	[11:10], 23, [27:26], 29	r	**Reserved** Read as 0; should be written with 0.

The Channel Status Register contains the current transfer count and a pattern detection compare result.

DMA_CHSR0x (x = 0-7)
DMA Channel 0x Status Register (080_H+x*20_H) **Reset Value: 0000 0000_H**
DMA_CHSR1x (x = 0-7)
DMA Channel 1x Status Register (180_H+x*20_H) **Reset Value: 0000 0000_H**

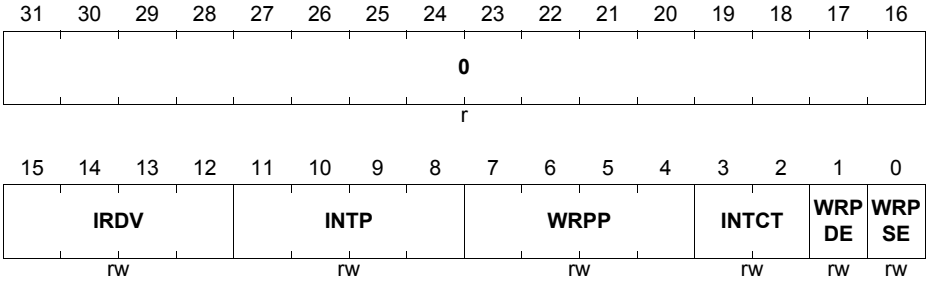


Field	Bits	Type	Description
TCOUNT	[9:0]	rh	**Transfer Count Status** TCOUNT holds the actual value of the DMA transfer count for DMA channel mx. TCOUNT is loaded with the value of CHCRmx.TREL when TRSR.CHmx becomes set (and TCOUNT = 0). After each DMA transfer, TCOUNT is decremented by 1.
LXO	15	rh	**Old Value of Pattern Detection** This bit contains the compare result of a pattern compare operation when 8-bit or 16-bit data width is selected. 8-bit data width: see **Table 12-4** and **Figure 12-23** 16-bit data width: see **Table 12-5** and **Figure 12-24** 0_B The corresponding pattern compare operation did not find a pattern match on the last move 1_B The corresponding pattern compare operation found a pattern match at the last move
0	[14:10], [31:16]	r	**Reserved** Read as 0; should be written with 0.

The Channel Interrupt Control Register controls the interrupts generation.

DMA_CHICR0x (x = 0-7)
DMA Channel 0x Interrupt Control Register
(088_H+x*20_H) **Reset Value: 0000 0000_H**

DMA_CHICR1x (x = 0-7)
DMA Channel 1x Interrupt Control Register
(188_H+x*20_H) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
WRPSE	0	rw	**Wrap Source Enable** 0_B Wrap source buffer interrupt disabled 1_B Wrap source buffer interrupt enabled
WRPDE	1	rw	**Wrap Destination Enable** 0_B Wrap destination buffer interrupt disabled 1_B Wrap destination buffer interrupt enabled
INTCT	[3:2]	rw	**Interrupt Control** 00_B No interrupt will be generated on changing the TCOUNT value. The bit INTSR.ICHmx is set when TCOUNT equals IRDV. 01_B No interrupt will be generated on changing the TCOUNT value. The bit INTSR.ICHmx is set when TCOUNT is decremented 10_B An interrupt is generated and bit INTSR.ICHmx is set each time TCOUNT equals IRDV 11_B Interrupt is generated and bit INTSR.ICHmx is set each time TCOUNT is decremented *Note: see **Figure 12-17**.*

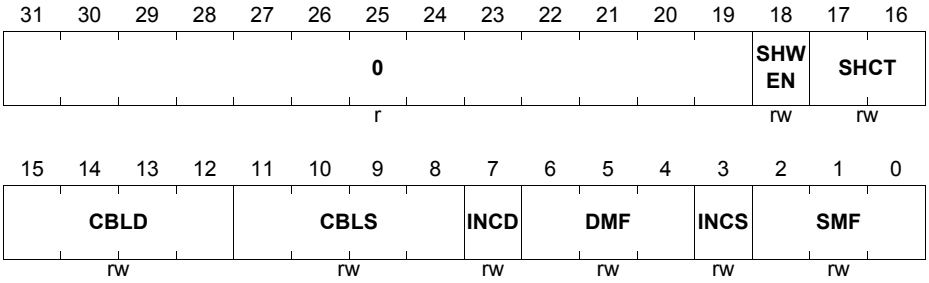
Field	Bits	Type	Description
WRPP	[7:4]	rw	**Wrap Pointer** WRPP determines the number n (n = 0-15) of the service request output SRn that becomes active on a wrap buffer interrupt. 0000_B SR0 selected for channel mx wrap buffer interrupt 0001_B SR1 selected for channel mx wrap buffer interrupt …$_B$ … 1111_B SR15 selected for channel mx wrap buffer interrupt *Note: In the TC1798, SR[7:0] are connected to interrupt nodes. SR[15:8] are used as DMA channel request inputs (**Page 12-101**).*
INTP	[11:8]	rw	**Interrupt Pointer** INTP determines the number n (n = 0-15) of the service request output SRn that becomes active on a channel interrupt. 0000_B SR0 selected for channel mx interrupt 0001_B SR1 selected for channel mx interrupt …$_B$ … 1111_B SR15 selected for channel mx interrupt *Note: In the TC1798, SR[7:0] are connected to interrupt nodes. SR[15:8] are used as DMA channel request inputs (**Page 12-101**).*
IRDV	[15:12]	rw	**Interrupt Raise Detect Value** These bits specify the value of CHSRmx.TCOUNT for which the Interrupt Threshold Limit should be raised.
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

Note: The interrupt node of the wrap-around interrupts is shared with the pattern match interrupt. In order to support interrupt generation in case of a pattern match, the wrap-around interrupt should be disabled. If the wrap-around interrupts are used, the pattern match interrupt should not be used. The settings are independent for each DMA channel.

The Address Control Register controls how source and destination addresses are updated after a DMA move. Furthermore, it determines whether or not a source or destination address register update is shadowed.

DMA_ADRCR0x (x = 0-7)
DMA Channel 0x Address Control Register
($08C_H$+x*20_H) **Reset Value: 0000 0000_H**

DMA_ADRCR1x (x = 0-7)
DMA Channel 1x Address Control Register
($18C_H$+x*20_H) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
SMF	[2:0]	rw	**Source Address Modification Factor** This bit field and the data width as defined in CHCRmx.CHDW determine an address offset value by which the source address is modified after each DMA move. See also **Table 12-10**. 000_B Address offset is 1 x CHCRmx.CHDW 001_B Address offset is 2 x CHCRmx.CHDW 010_B Address offset is 4 x CHCRmx.CHDW 011_B Address offset is 8 x CHCRmx.CHDW 100_B Address offset is 16 x CHCRmx.CHDW 101_B Address offset is 32 x CHCRmx.CHDW 110_B Address offset is 64 x CHCRmx.CHDW 111_B Address offset is 128 x CHCRmx.CHDW

Field	Bits	Type	Description
INCS	3	rw	**Increment of Source Address** This bit determines whether the address offset as selected by SMF will be added to or subtracted from the source address after each DMA move. The source address is not modified if CBLS = 0000_B. 0_B Address offset will be subtracted 1_B Address offset will be added.
DMF	[6:4]	rw	**Destination Address Modification Factor** This bit field and the data width as defined in CHCRmx.CHDW determines an address offset value by which the destination address is modified after each DMA move. The destination address is not modified if CBLD = 0000_B. See also **Table 12-10**. 000_B Address offset is 1 x CHDW 001_B Address offset is 2 x CHDW 010_B Address offset is 4 x CHDW 011_B Address offset is 8 x CHDW 100_B Address offset is 16 x CHDW 101_B Address offset is 32 x CHDW 110_B Address offset is 64 x CHDW 111_B Address offset is 128 x CHDW
INCD	7	rw	**Increment of Destination Address** This bit determines whether the address offset as selected by DMF will be added to or subtracted from the destination address after each DMA move. The destination address is not modified if CBLD = 0000_B. 0_B Address offset will be subtracted 1_B Address offset will be added

Field	Bits	Type	Description
CBLS	[11:8]	rw	**Circular Buffer Length Source** This bit field determines which part of the 32-bit source address register remains unchanged and is not updated after a DMA move operation (see also **Section 12.2.4.7**). Therefore, CBLS also determines the size of the circular source buffer. 0000_B Source address SADR[31:0] is not updated 0001_B Source address SADR[31:1] is not updated 0010_B Source address SADR[31:2] is not updated 0011_B Source address SADR[31:3] is not updated $\cdots_B$ ... 1110_B Source address SADR[31:14] is not updated 1111_B Source address SADR[31:15] is not updated
CBLD	[15:12]	rw	**Circular Buffer Length Destination** This bit field determines which part of the 32-bit destination address register remains unchanged and is not updated after a DMA move operation (see also **Page 12-19**). Therefore, CBLD also determines the size of the circular destination buffer. 0000_B Destination address DADR[31:0] is not updated 0001_B Destination address DADR[31:1] is not updated 0010_B Destination address DADR[31:2] is not updated 0011_B Destination address DADR[31:3] is not updated $\cdots_B$ ... 1110_B Destination address DADR[31:14] is not updated 1111_B Destination address DADR[31:15] is not updated

Field	Bits	Type	Description
SHCT	[17:16]	rw	**Shadow Control** This bit field determines whether an address is transferred into the shadow address register when writing to source or destination address register. 00_B Shadow address register not used. Source and destination address register are written directly 01_B Shadow address register used for source address buffering. When writing to SADRmx, the address is buffered in SHADRmx and transferred to SADRmx with the start of the next DMA transaction 10_B Shadow address register used for destination address buffering. When writing to DADRmx, the address is buffered in SHADRmx and transferred to DADRmx with the start of the next DMA transaction 11_B Reserved In case of SHCT = 01_B or 10_B, SHCT must not be changed until the next DMA transaction has been started.
SHWEN	18	rw	**Shadow Address Register Write Enable** This bit determines whether the shadow address register SHADRmx is read only and automatically set to 0000 0000_H or if the shadow register can also be directly written and not modified when and shadow transfer takes place. 0_B Shadow address register is read only and the value stored in the SHADRmx is automatically set to 0000 0000_H when the shadow transfer takes place 1_B Shadow address register SHADRmx can be read and can be directly written. The value stored in the SHADRmx is not automatically modified when the shadow transfer takes place
0	[31:19]	r	**Reserved** Read as 0; should be written with 0.

Table 12-10 shows the offset values that are added or subtracted to/from a source or destination address register after a DMA move. Bit field SMF and bit INCS determine the offset value for the source address. Bit field DMF and bit INCD determine the offset value for the destination address.

Table 12-10 Address Offset Calculation Table

CHCRmn.CHDW = 00_B (8-bit Data Width)			CHCRmn.CHDW = 01_B (16-bit Data Width)			CHCRmn.CHDW = 10_B (32-bit Data Width)		
SMF DMF	**INCS INCD**	**Address Offset**	**SMF DMF**	**INCS INCD**	**Address Offset**	**SMF DMF**	**INCS INCD**	**Address Offset**

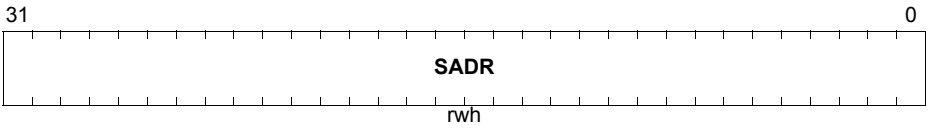
Note: CHCRmn.CHDW = 11_B is reserved and should not be used.

12.3.5 Channel Address Registers

The Source Address Register contains the 32-bit source address. If a DMA channel mn is active, SADRmn is updated continuously (if programmed) and shows the actual source address that is used for read moves within DMA transfers.

DMA_SADR0x (x = 0-7)
DMA Channel 0x Source Address Register
(090_H+x*20_H) **Reset Value: 0000 0000_H**

DMA_SADR1x (x = 0-7)
DMA Channel 1x Source Address Register
(190_H+x*20_H) **Reset Value: 0000 0000_H**



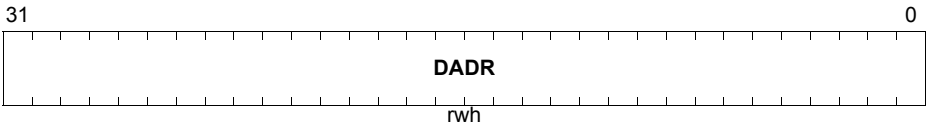
Field	Bits	Type	Description
SADR	[31:0]	rwh	**Source Start Address** This bit field holds the actual 32-bit source address of DMA channel mx that is used for read moves.

A write to SADRmn is executed directly only when the DMA channel mn is inactive (CHSRmn.TCOUNT = 0 and TRSR.CHmn = 0). If DMA channel mn is active when writing to SADRmn, the source address will not be written into SADRmn directly but will be buffered in the shadow register SHADRmn until the start of the next DMA transaction. During this shadowed address register operation, bit field ADRCRmn.SHCT must be set to 01_B.

The Destination Address Register contains the 32-bit destination address. If a DMA channel is active, DADRmn is updated continuously (if programmed) and shows the actual destination address that is used for write moves within DMA transfers.

DMA_DADR0x (x = 0-7)
DMA Channel 0x Destination Address Register
(094_H+x*20_H) **Reset Value: 0000 0000_H**

DMA_DADR1x (x = 0-7)
DMA Channel 1x Destination Address Register
(194_H+x*20_H) **Reset Value: 0000 0000_H**



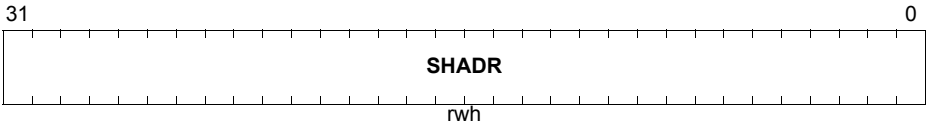
Field	Bits	Type	Description
DADR	[31:0]	rwh	**Destination Address** This bit field holds the actual 32-bit destination address of DMA channel mx that is used for write moves.

A write to DADRmn is executed directly only when the DMA channel mn is inactive (CHSRmn.TCOUNT = 0 and TRSR.CHmn = 0). If DMA channel mn is active when writing to DADRmn, the source address will not be written into DADRmn directly but will be buffered in the shadow register SHADRmn until the start of the next DMA transaction. During this shadowed address register operation, bit field ADRCRmn.SHCT must be set to 10_B.

The Shadow Address Register holds the shadowed source or destination address before it is written into the source or destination address register. SHADRmn can be read only.

DMA_SHADR0x (x = 0-7)
DMA Channel 0x Shadow Address Register
(098_H+x*20_H) **Reset Value: 0000 0000_H**

DMA_SHADR1x (x = 0-7)
DMA Channel 1x Shadow Address Register
(198_H+x*20_H) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
SHADR	[31:0]	rwh	**Shadowed Address** This bit field holds the shadowed 32-bit source or destination address of DMA channel mx.

SHADRmn is written when source or destination address buffering is selected (ADRCRmn.SHCT = 01_B or ADRCRmn.SHCT = 10_B) and a transaction is running. While the shadow mechanism is disabled, SHADR is set to 0000 0000_H.

If ADRCRmn.SHWEN = 0 the value stored in the SHADR is automatically set to 0000 0000_H when the shadow transfer takes place. The user can read the shadow register in order to detect if the shadow transfer has already taken place. If the value in SHADR is 0000 0000_H, no shadow transfer can take place and the corresponding address register is modified according to the circular buffer rules.

If ADRCRmn.SHWEN = 1 shadow register SHADRmn can be directly written. The value stored in the SHADRmn is not modified when the shadow transfer takes place, the shadow mechanism remains active and the shadow transfer will be repeated until Channel mn is reset or until the value in SHADR is 0000 0000_H, is written into the shadow register.

12.4 DMA Module Implementation

This section describes the TC1798 DMA module interfaces with the clock control, interrupt control, and address decoding.

Chapter 12-28 shows the TC1798-specific implementation details and interconnections of the DMA module. The DMA module is supplied with a separate clock control, address decoding, interrupt control, and the request input wiring matrix.

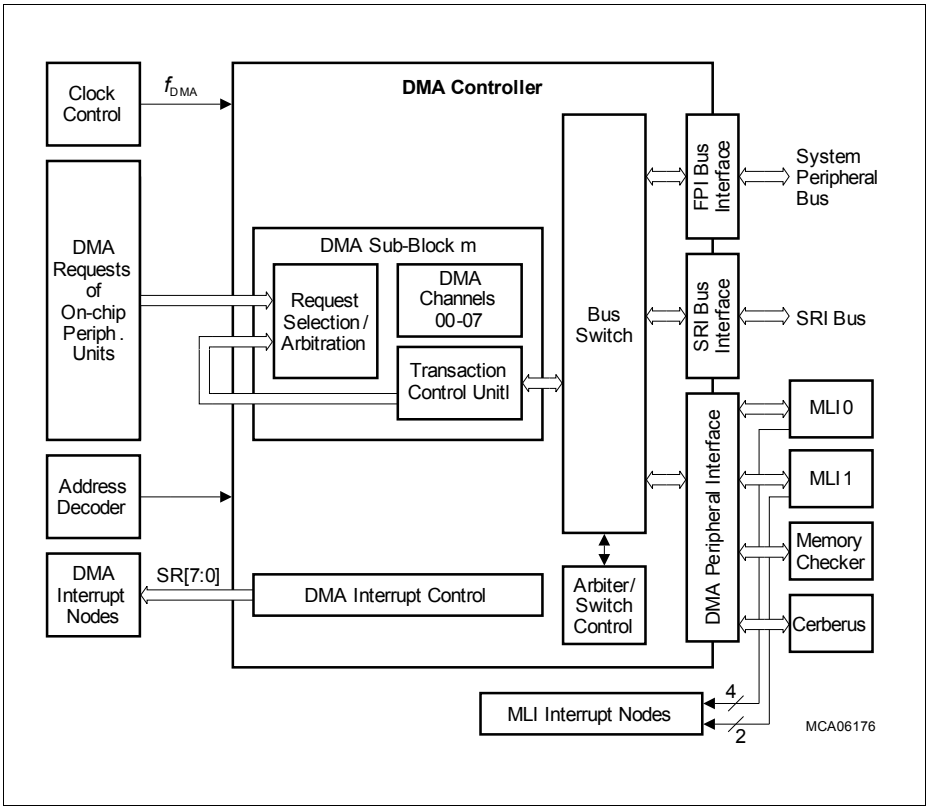


Figure 12-28 DMA Module Implementation and Interconnections

The request sources of the peripheral modules (ADC0, MSC0, MLI0/1, FADC, MultiCAN, and SCU) are associated with Interrupt Node Pointers and individual interrupt enable bits. As a result, each of the internal requests of a module can be routed independently to any of the interrupt output lines (INT_Ox) of the module.

12.4.1 DMA Request Wiring Matrix

The DMA request input lines of each DMA channel within DMA Sub-Block 0 and DMA Sub-Block 1 are connected to request output lines from the peripheral modules according to **Table 12-11**.

1) GPTA_TRIG signals are per default level sensitive signals while a DMA channel is activated with every active request signal cycle. The DMA internal positive edge detection will generate the channel request with the rising edge of the GPTA_TRIG signal, if selected. If channel requests for the positive and/or negative GPTA_TRIG signal is required, this can be realized either via the ERU (some GPTA_TRIG signals are mapped to it) or via GPTA programming by using additional GPTA cells.

2) Reserved PRSEL combinations do not result to DMA Channel requests.

1) GPTA_TRIG signals are per default level sensitive signals while a DMA channel is activated with every active request signal cycle. The DMA internal positive edge detection will generate the channel request with the rising edge of the GPTA_TRIG signal, if selected. If channel requests for the positive and/or negative GPTA_TRIG signal is required, this can be realized either via the ERU (some GPTA_TRIG signals are mapped to it) or via GPTA programming by using additional GPTA cells.
2) Reserved PRSEL combinations do not result to DMA Channel requests.

12.4.2 Access Protection Assignment

DMA access protection as described on Page 12-44 requires the assignment of 32 fixed address range. Table 12-13 shows this address range assignment as implemented in the TC1798 (see also: Page 12-81, Page 12-81).

In the TC1798, four internal memory areas (Program Scratch SRAM, Data Scratch SRAM, LMU SRAM and PCP Data SRAM) are protected by an address range verification in addition to the access enable bits. The address range verification is based on the bit fields SIZEx and SLICEx (x = 3-0), which are located in the registers MEmARR0 and MEmARR1 (m = 1-0). An access to one of these four memory areas is only processed if it is enabled by the corresponding AENx bit and if the address is inside the sub-range defined by the corresponding SIZEx and SLICEx. If the address is outside of the defined sub-range, the transfer will not be processed and an error interrupt is generated (indicated by the corresponding MExDER, MExSER bit). If a protected memory is available from DMA under multiple address ranges (SRI, FPI, cached and or un-cached segments), the access protection is valid for all memory views in parallel, starting always with the base address of the memory views, ending always with the end address of the address range.

The address ranges described by SLICEx and SIZEx are defined as follows:

- MEmARR0.SLICE0, MEmARR0.SIZE0:
  32-KB Program Scratch SRAM, assigned to address range 31 (AEN31). The sub-ranges are controlled by bit fields MEmARR0.SIZE0 and ME0ARR0.SLICE0 with a minimum granularity of 0,5 KB (see **Table 12-15**).
- MEmARR0.SIZE1 and MEmARR0.SLICE1:
  128-KB LMU SRAM, assigned to address range 29 (AEN29). The sub-ranges are controlled by bit fields MEmARR0.SIZE1 and MEmARR0.SLICE1 with a minimum granularity of 1 KB (see **Table 12-16**).
- MEmARR0.SIZE2 and MEmARR0.SLICE2:
  128-KB Data Scratch SRAM, assigned to address range 30 (AEN30). The sub-ranges are controlled by bit fields MEmARR0.SIZE2 and MEmARR0.SLICE2 with a minimum granularity of 1 KB (see **Table 12-17**).
- MEmARR0.SIZE3 and MEmARR0.SLICE3:
  16-Kbyte PCP Data SRAM, assigned to address range 13 (AEN13). The sub-range is controlled by bit fields MEmARR0.SIZE3 and MEmARR0.SLICE3 with a minimum granularity of 0,5 KB (see **Table 12-18**).
- MEmARR1.SIZE0 and MEmARR1.SLICE0:
  Reserved.
- MEmARR1.SIZE1 and MEmARR1.SLICE1:
  Reserved.
- MEmARR1.SIZE2 and MEmARR1.SLICE2:
  Reserved.
- MEmARR1.SIZE3 and MEmARR1.SLICE3:
  Reserved.

DMA_MEmARR0.SIZE0 and DMA_MEmARR0.SLICE0 bit fields: Program Scratch SRAM sub-range access protection

Bit fields SIZE0 and SLICE0 for the PMI memory sub-range access protection (32 KB PSPR) as shown in **Table 12-15**.

The PMI memory is protected with a min. granularity of 0,5 KB up to the end address Cx00 $FFFF_H$.

PMI address ranges that are protected by the bit fields SIZE0 and SLICE0:

- C000 0000_H - C000 $7FFF_H$ (Program Scratch RAM)
- C800 0000_H - C800 $7FFF_H$ (Program Scratch RAM)

Table 12-15 Program Scratch SRAM Address Protection Sub-Range Definition

DMA_MEmARR0.SIZE1 and DMA_MEmARR0.SLICE1 bit fields: LMU SRAM sub-range access protection

Bit fields SIZE1 and SLICE1 for the LMU SRAM sub-range access protection (128 KB) are coded as shown in **Table 12-16**.

The 128 KB LMU SRAM memory is protected with a minimum granularity of 1 KB up to the end address x001 $FFFF_H$.

OVRAM address ranges that are protected by the bit fields SIZE1 and SLICE1:

- $9000\ 0000_H$ - $9001\ FFFF_H$ (LMU SRAM)
- $B000\ 0000_H$ - $B001\ FFFF_H$ (LMU SRAM)

DMA_MEmARR0.SIZE2 and DMA_MEmARR0.SLICE2 bit fields: Data Scratch SRAM sub-range access protection

Bit fields SIZE2 and SLICE2 for the Data Scratch SRAM sub-range access protection. These bit fields are covering the 128 KB Data Scratch SRAM.

The Data Scratch SRAM is protected with a min. granularity of 1 KB (**Table 12-17**) up to the end address Dx01 $FFFF_H$.

Data Scratch SRAM address ranges that are protected by the bit fields SIZE2 and SLICE2:

- D000 0000_H - D001 $FFFF_H$ (Data Scratch SRAM)
- D800 0000_H - D801 $FFFF_H$ (Data Scratch SRAM)

DMA_MEmARR0.SIZE3 and DMA_MEmARR0.SLICE3 bit fields: PCP Data SRAM sub-range access protection

Bit fields SIZE3 and SLICE3 for the PCP Data SRAM sub-range access protection. These bit fields are covering PCP Data SRAM memory.

The PCP Data SRAM memory is protected with a min. granularity of 0,5 KB (**Table 12-18**) up to the end address F005 $FFFF_H$ (16KB PRAM and 48KB Reserved Address Space).

PCP Data SRAM address range that is protected by the bit fields SIZE3 and SLICE3:

- F005 0000_H - F005 $3FFF_H$ (PCP Data SRAM on FPI Bus, 16 KB)

Table 12-18 PCP Data SRAM SIZE3 and SLICE3 Address Protection Sub-Range Definition Scheme

SIZE3	Sub-Ranges	SLICE3	Selected Address Range
000_B	32 sub-ranges of 512 bytes	00000_B 00001_B … 11111_B	$F005\ 0000_H$ - $F005\ 01FF_H$ $F005\ 0200_H$ - $F005\ 03FF_H$ … $F005\ 3E00_H$ - $F005\ 3FFF_H$
001_B	32 sub-ranges of 1 Kbyte	00000_B 00001_B … 11111_B	$F005\ 0000_H$ - $F005\ 03FF_H$ $F005\ 0400_H$ - $F005\ 07FF_H$ … $F005\ 7C00_H$ - $F005\ 7FFF_H$

12.4.3 Implementation-specific DMA Registers

The DMA controller as implemented in the TC1798 contains the following additional registers:

- DMA clock control register
- Service request control registers for DMA controller interrupts (DMA_SRCx)
- Service request control registers for MLI module interrupts (DMA_MLI0ySRC.x)

Figure 12-29 provides an overview of these registers.

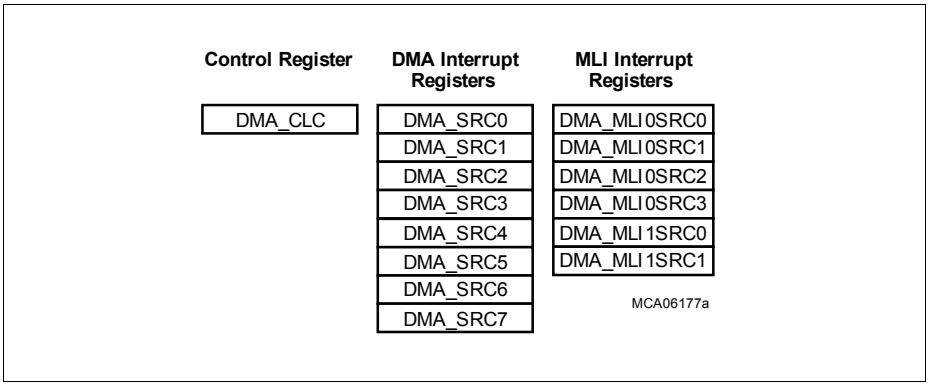

Figure 12-29 DMA Implementation-specific Registers

Note: Further details on interrupt handling and processing are described in the "Interrupt System" chapter of the TC1798 System Units User´s Manual.

The clock generation and interrupt control configuration as implemented in the DMA controller module is shown in **Figure 12-29**.

The DMA controller, the Cerberus and the two MLI modules (MLI0 and MLI1) are supplied from a common module clock f_{DMA} that has the frequency of the system clock f_{FPI} and is controlled via the DMA_CLC clock control register. The MLI modules nor the Cerberus module do not have their own clock control registers. Their input clock is derived from the DMA clock divided by separate fractional divider registers.

The control of the suspend and break features is done independently inside each module.

The DMA controller module contains in total 14 interrupt request nodes with its interrupt service request control registers:

- Eight interrupt requests SR[7:0] = INT_O[7:0] from the DMA controller; upper eight interrupt requests of the DMA controller INT_O[15:8] are used ad DMA channel trigger inputs.
- Four interrupt requests SR[3:0] = INT_O[3:0] from the MLI0 module; upper four interrupt requests of the MLI0 module INT_O[7:4] are not connected.
- Two interrupt requests SR[1:0] = INT_O[1:0] from the MLI1 module; upper six interrupt requests of the MLI1 module INT_O[7:2] are not connected.

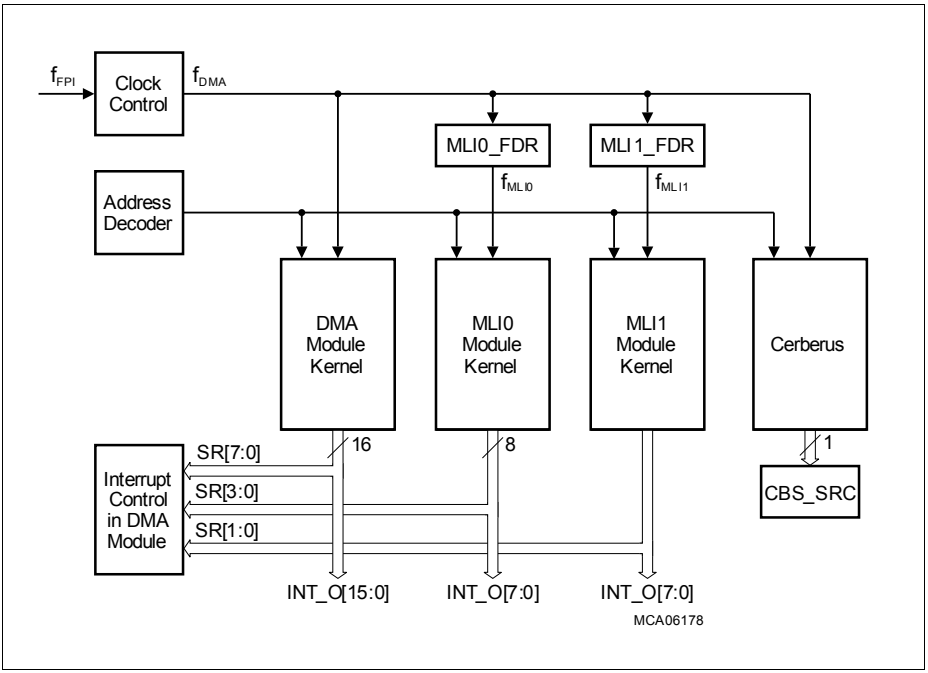

Figure 12-30 Implementation of the DMA Module and the MLI Modules

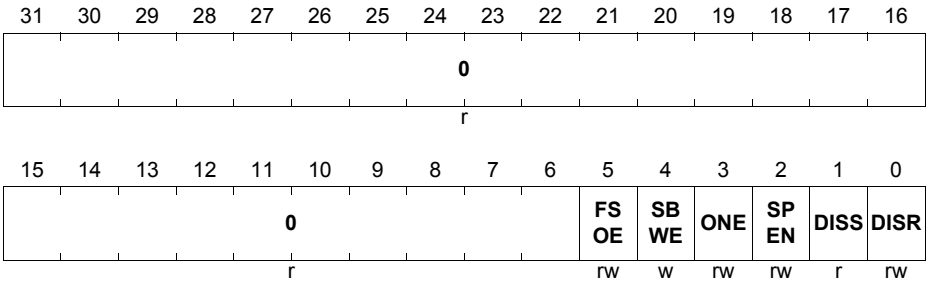
12.4.3.1 Clock Control Register

The Clock Control Register controls the DMA module internal f_{DMA} clock signal. This clock is also used for the MLI modules as a common clock that can be individually divided for the MLI modules.

DMA_CLC
DMA Clock Control Register **(000_H)** **Reset Value: 0000 0008$_H$**



Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module
DISS	1	r	**Module Disable Status Bit** Bit indicates the current status of the module
SPEN	2	rw	**Module Suspend Enable for OCDS** Used to enable the Suspend Mode
ONE	3	rw	**Reserved;** returns 1 if read; must be written with 1.
SBWE	4	w	**Module Suspend Bit Write Enable for OCDS** Determines whether SPEN and FSOE are write-protected.
0	5	rw	**Reserved;** returns 0 if read; must be written with 0.
0	[31:6]	r	**Reserved** Read as 0; should be written with 0.

Note: After a hardware reset operation, the DMA module is enabled.

Note: The suspend mode does not modify any of the registers.

12.4.3.2 DMA Interrupt Registers

In the TC1798, the lower eight DMA controller interrupts SR[7:0] are connected to service request control registers. The upper eight DMA controller interrupt outputs SR[15:8] are used as DMA channel request inputs (Page 12-101).

DMA_SRCx (x = 0-7)
DMA Service Request Control Register x
($2FC_H$ - x*4_H) **Reset Value: 0000 0000_H**

12.4.3.3 MLI Interrupt Registers

The Service Request Control Registers of the MLI module are located inside the DMA address area, because the MLI module does not have its own FPI Bus interfaces. The MLI modules shares one FPI Bus slave interface with the DMA controller.

The MLI0 module has eight interrupt output lines. Only four of them [3:0] are controlled by the MLI0 service request registers. The MLI1 module has also eight interrupt output lines, but only two of them [1:0] are controlled by the MLI1 service request registers.

Note: The bit coding of the MLI0/MLI1 service request registers is identical to that of the DMA Service Request Control Registers shown on the previous page.

12.4.4 Address Map

The DMA controller register block address map is shown in **Figure 12-31**. It shows how the different register blocks are arranged and adds the absolute address information.

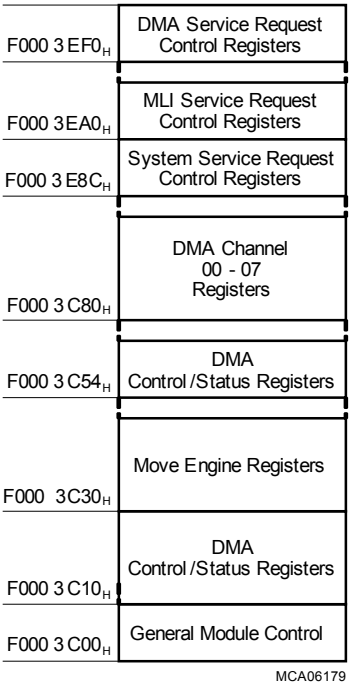

Figure 12-31 DMA Controller Register Block Address Map

12.5 Memory Checker Module

The Memory Checker Module (MCHK) supports the checking of data consistency in memories. It includes two parallel Cyclic Redundancy Checkers (CRCs) that can be used to check the data consistency of two memories in parallel. Each CRC block contains two algorithm engines:

1. A legacy data compaction algorithm based on a Multiple Input Shift Register (MISR) implementation.
2. A CRC-32 ethernet polynomial implementation.

Both algorithm engines use a common input register and simultaneously compute a checksum.

12.5.1 Functional Description

The Memory Checker module is connected to the DMA Peripheral Interface and can be accessed via the SPB. Preferable the module is used in combination with the DMA as it as described hereafter: a DMA channel can be used to read 8-bit, 16-bit, or 32-bit data from an address area and to write the data in one of the two memory checker input register. With each write operation to the chosen memory checker input register a polynomial checksum calculation is triggered and the result of the calculation is stored in the corresponding memory checker result register. The MISR algorithm engine supports 8-bit, 16-bit and 32-bit read data accesses. The CRC-32 ethernet polynomial is limited to 32-bit accesses.

In order to start a memory check sequence, the memory checker MISR and CRC-32 Ethernet polynomial result registers must be initialized (e.g. written with $FFFFFFFF_H$ or with a desired start value) and a DMA transaction must be set up (start address, length, etc.). When programming the DMA channel for the memory checker with CHCRmn.RROAT = 1, one DMA transfer request (software or hardware triggered) starts the DMA transaction.

During the read move operations of the DMA transaction, data is always read from the memory and then written into the memory checker input register for the polynomial checksum calculation. At the end of the transaction (CHSRmn.TCOUNT = 0), an interrupt can be generated by the DMA channel (if CHCRmn.RROAT = 1), and the memory checker result register can be read out by software.

Both the MISR and CRC-32 memory checkers use the IEEE 802.3 Standard polynomial, which is given by:

$$G^{32} = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1 \quad (12.1)$$

Note: Although the polynomial above is used for generation, the generation algorithm differs from the one that is used by the Ethernet protocol.

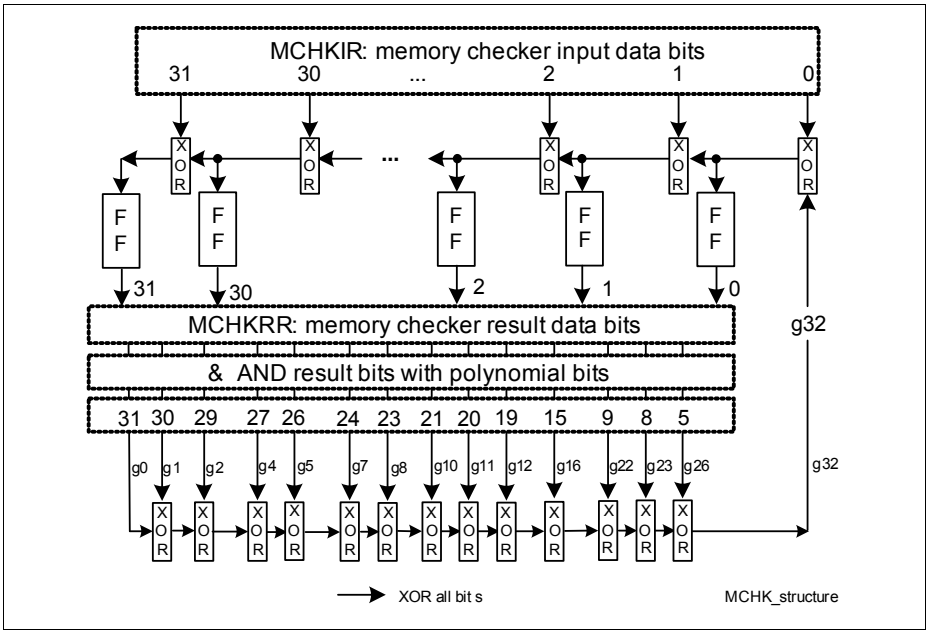

Figure 12-32 Implementation of the Multiple Input Shift Register

12.5.1.1 Ethernet CRC-32 Endianness

In order to comply with the Ethernet CRC-32 standard the endianness of the input word needs to be big endian. This is important only when the input stream is made up of bytes, because each CPU architecture may have a different endianness.

TriCore is little endian, and when a byte pointer (to a byte array) is cast into a 32-bit word pointer, the compiler packs the bytes in little endian format and therefore the CRC-32 checksum result provided by the MCHK Ethernet CRC-32 hardware differs from that generated by an Ethernet CRC-32 software model using a byte stream. In order to generate a checksum compliant with the Ethernet CRC-32 checksum then the software must swap the order of the bytes.

12.5.2 Memory Checker Module Registers

This section describes the kernel registers of the Memory Checker module.

MCHK Register Overview

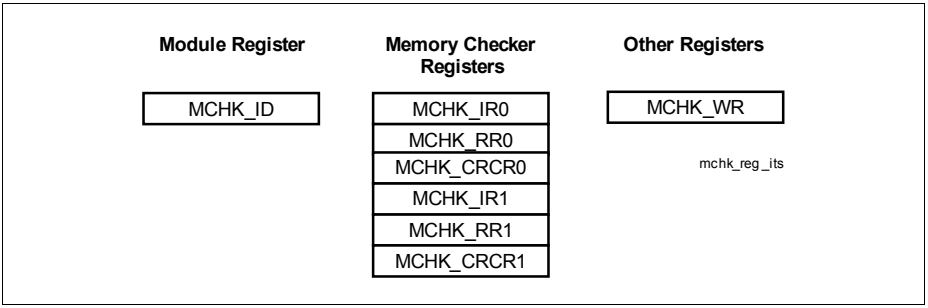

Figure 12-33 Memory Checker Registers

Table 12-24 Registers Overview - Memory Checker Module Control Registers

Short Name	Description	Offset Addr.[1]	Access Mode		Reset Class	Description See
			Read	Write		
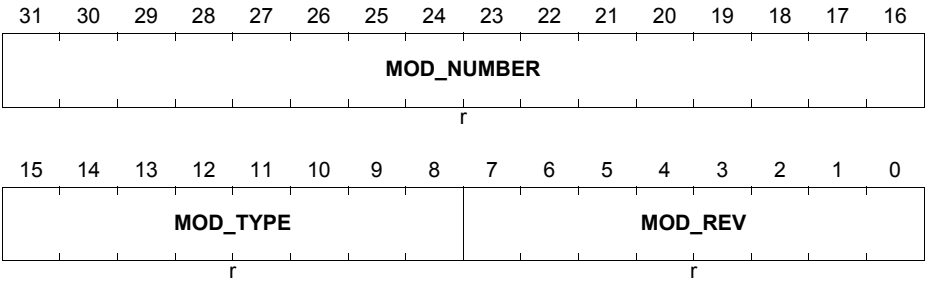
MCHK_WR	Memory Checker Write Register	020_H	U, SV	U, SV	3	Page 12-136
MCHK_CRCR0	Memory Checker Result Register	024_H	U, SV	U, SV, 32	3	Page 12-136
MCHK_CRCR1	Memory Checker Result Register	028_H	U, SV	U, SV, 32	3	Page 12-136
-	Reserved	$02C_H$ - $2FF_H$	BE	BE	-	-

1) The absolute register address is calculated as follows:
Module Base Address (Table 12-23) + Offset Address (shown in this column)

12.5.2.1 Memory Checker Module Control Registers

The identification register allows the programmer version-tracking of the module. The table below shows the identification register which is implemented in the MCHK module.

MCHK_ID
Module Identification Register (008_H) Reset Value: 001B C0XX$_H$

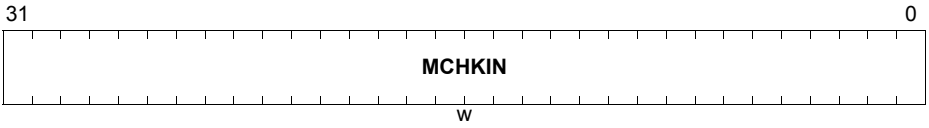


Field	Bits	Type	Description
MOD_REV	[7:0]	r	**Module Revision Number** This bit field defines the module revision number. The value of a module revision starts with 01_H (first revision).

Field	Bits	Type	Description
MOD_TYPE	[15:8]	r	**Module Type** The bit field is set to $C0_H$ which defines the module as a 32-bit module.
MOD_NUMBER	[31:16]	r	**Module Number Value** This bit field defines a module identification number. The value for the Memory Checker module is $001B_H$.

A Memory Checker Input Register is used during write moves of a memory checker related DMA transaction as data destination with its fixed register address. If the DMA moves to register, for example MCHK_IR0 are 8-bit or 16-bit wide, the unused register bits of the 32-bit MCHKIN0 value are taken as 0s for the current result calculation.

MCHK_IRx (x = 0-1)
Memory Checker Input Register (010_H+x*08_H) Reset Value: 0000 0000_H

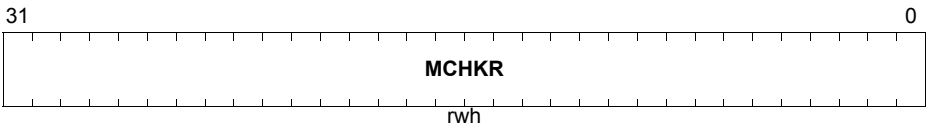


Field	Bits	Type	Description
MCHKIN	[31:0]	w	**Memory Checker Input** The value written to MCHKIN is used for the next checksum calculation. Any read action will deliver 0.

Note: MCHK_IR is a write-only register. Any read action will deliver 0000 0000_H.

A Memory Checker Result Register contains the result of the memory check operation. Before starting a checksum calculation operation, it should be written with an initial checksum calculation value.

MCHK_RRx (x = 0-1)
Memory Checker Result Register (014_H+x*08_H) Reset Value: 0000 0000_H

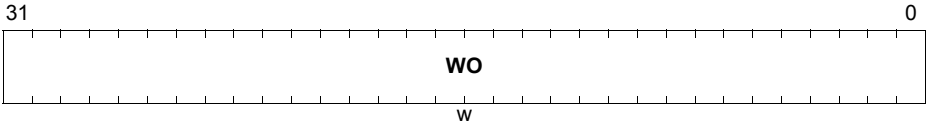


Field	Bits	Type	Description
MCHKR	[31:0]	rwh	**Memory Checker Result** This bit field contains the current result of the memory checksum calculation operation.

The Memory Checker Write Register is a dummy write-only register that is located within the memory checker address range.

The Memory Checker Write Register can be used as dummy write register at the write back action of the DMA or MLI controller Move Engine when the pattern detection feature of the DMA controller is used. Accessing MCHK_WR with the Move Engine of the MLI or DMA controller via the Bus Switch of the DMA controller (see) does not request the two FPI buses of the TC1798, SPB and DMA, because it is near the MLI modules address ranges.

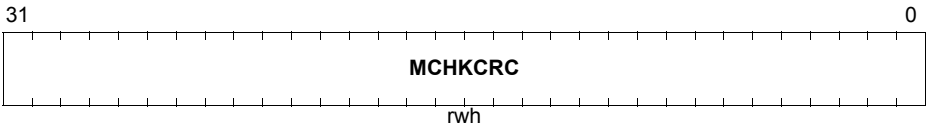
MCHK_WR
Memory Checker Write Register (020_H) Reset Value: 0000 0000_H



Field	Bits	Type	Description
WO	[31:0]	w	**Write-Only** This write-only bit field is used to write dummy data during DMA pattern detection. The data written to WO is not taken into account for any action. Any read action of WO will deliver 0000 0000_H.

The CRC Registers store the working CRC32 ethernet polynomial checksum. Only 32-bit word accesses are permitted to the CRC registers. In order to start a CRC32 sequence the CRC register must be initialised (e.g. written with 00000000_H or with a desired start value) and a DMA transaction set up (start address, length, etc.). When data is written to MCHK_IRx then a polynomial checksum calculation is performed and MCHK_CRCx is updated.

MCHK_CRCx (x = 0-1)
Memory Checker CRC Register (024_H+x*04_H) Reset Value: 0000 0000_H



Field	Bits	Type	Description
MCHKCRC	[31:0]	rwh	**Memory Checker CRC** This bit field contains the working CRC32 ethernet polynomial checksum. The stored value is inverted and reflected prior to a read. Therefore if the register is written with all 1’s then the output will be all 0’s.

13 Safe Direct Memory Access Controller (SDMA)

This chapter describes the Safe Direct Memory Access (SDMA) Controller of the TC1798. It contains the following sections:

- Functional description of the SDMA controller kernel (see **Section 13.2**)
- SDMA controller module register description (see **Section 13.3**)
- TC1798 implementation-specific details of the SDMA controller (interrupt control, address decoding, clock control, see **Section 13.4**)

*Note: The SDMA kernel register names described in **Section 13.3** are referenced in the TC1798 User´s Manual by the module name prefix "SDMA_".*

13.1 What is new

SDMA is based on the DMA peripheral. SDMA has additional features to support safety critical applications. The principal differences are:

- Upper and lower address boundary checking of the source and destination address.
- Generation of unique CRC checksums for source and destination addresses.
- Generation of in-line CRC checksum for read data.

13.2 SDMA Controller Kernel Description

The SDMA Controller of the TC1798 transfers data from data source locations to data destination locations without intervention of the CPU or other on-chip devices. One data move operation is controlled by one SDMA channel. Eight SDMA channels are provided in one SDMA Sub-Block. The Bus Switch provides the connection of the SDMA Sub-Block to the On Chip Bus interfaces and a SDMA Peripheral interface. In the TC1798, the two On Chip Bus interfaces are connected to the System Peripheral Bus. Clock control, address decoding, SDMA request wiring, and SDMA interrupt service request control are implementation-specific and are managed outside the SDMA controller kernel.

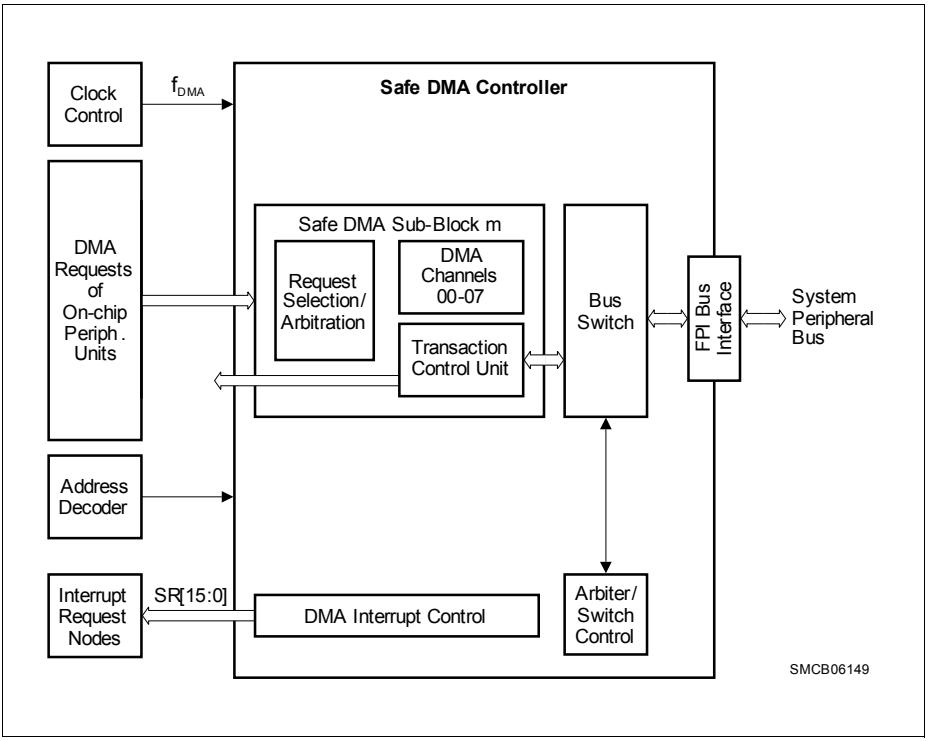


Figure 13-1 SDMA Block Diagram

13.2.1 Features

The SDMA controller has the following features:

- 8 independent SDMA channels
  - 1 SDMA Sub-Block with 8 SDMA channels
  - Parallel channel execution
  - Up to 16 selectable request inputs per SDMA channel
  - 2-level programmable priority of SDMA channels within the SDMA Sub-Block
  - Software and hardware SDMA request
  - Hardware requests by selected on-chip peripherals and external inputs
- Individually programmable operation modes for each SDMA channel
  - Single Mode: stops and disables SDMA channel after a predefined number of SDMA transfers
  - Continuous Mode: SDMA channel remains enabled after a predefined number of SDMA transfers; SDMA transaction can be repeated
  - Programmable address modification
  - Two shadow register modes (with / w/o automatic reset and direct write access).
- Full 32-bit addressing capability of each SDMA channel
  - 4 Gbyte address range
  - Data block move > 32 Kbyte per SDMA transaction
  - Circular buffer addressing mode with flexible circular buffer sizes
- Programmable data width of SDMA transfer/transaction: 8-bit, 16-bit, or 32-bit
- Register set for each SDMA channel
  - Source and destination address register
  - Channel control and status register
  - Transfer count register
- SDMA module is working on FPI frequency.
- Read/write requests from the Move Engine are directed to the FPI Bus.

13.2.2 Definition of Terms

Some basic terms must be defined for the functional description of the SDMA controller.

SDMA Move

A SDMA move is an operation that always consists of two parts:

1. A read move that loads data from a data source into the SDMA controller
2. A write move that puts data from the SDMA controller to a data destination

Within a SDMA move, data is always moved from the data source via the SDMA controller to the data destination. Data is temporarily stored in the SDMA controller. The data widths of read move and write move are always identical (8-bit, 16-bit or 32-bit). Data assembly or disassembly is not supported.

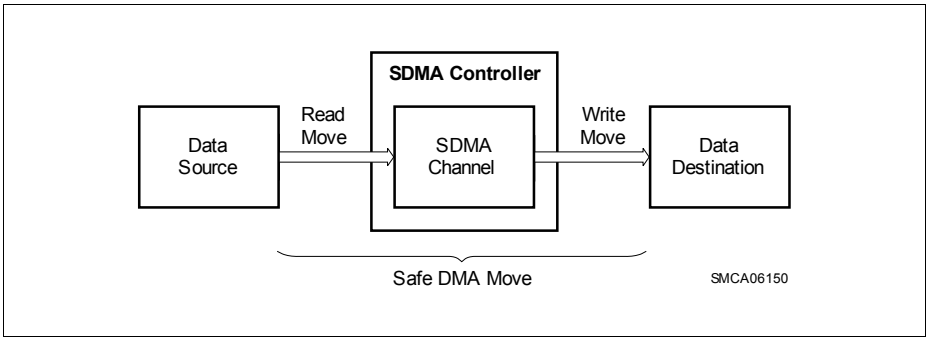

Figure 13-2 SDMA Definition of Terms

SDMA Transfer

A SDMA transfer can be composed of 1, 2, 4, 8 or 16 SDMA moves.

SDMA Transaction

A SDMA transaction is composed of several (at least one) SDMA transfers. The Transfer Count determines the number of SDMA transfers within one SDMA transaction.

Example:
1024 word (32-bit wide) transactions can be composed of 256 transfers of four SDMA word moves, or 128 transfers of eight SDMA word moves.

13.2.3 SDMA Principles

The SDMA controller supports SDMA moves from one address location to another one. SDMA moves can be requested either by hardware or by software. SDMA hardware requests are triggered by specific request lines from the peripheral modules or from other SDMA channels (see **Figure 13-3**). The number of available SDMA request lines from a peripheral module varies depending on the module functionality. Typically, the parallel occurrence of SDMA requests and interrupts requests for SDMA channels is possible. Therefore, the interrupt control unit and the SDMA controller can react independently to interrupt and SDMA requests that have been generated by one source.

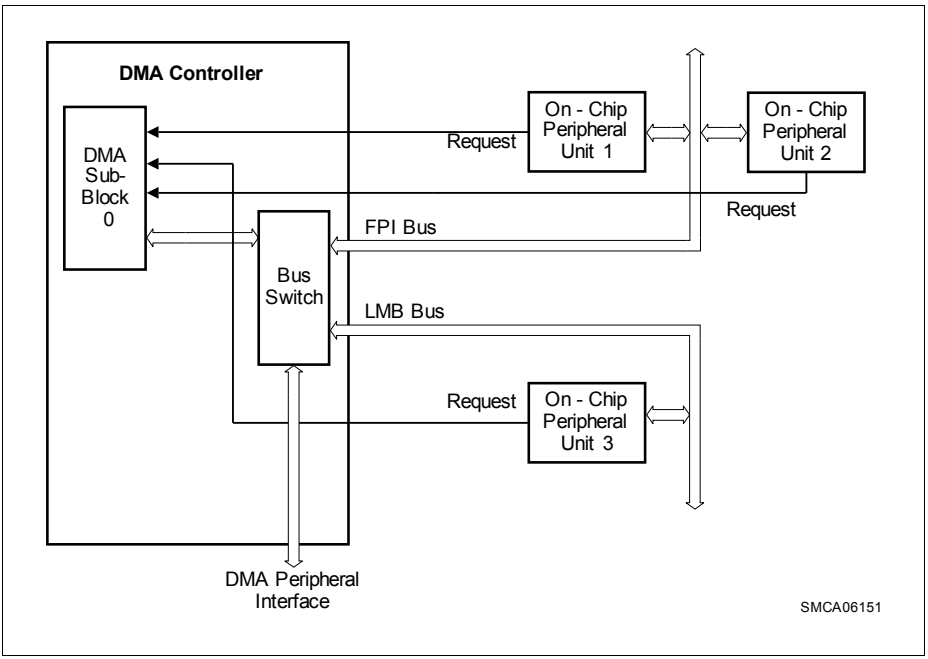

Figure 13-3 SDMA Principle

The SDMA controller mainly consists of a SDMA Sub-Block and a Bus Switch. Once configured, the SDMA Sub-Block is able to act as a master on the FPI Bus.

13.2.4 SDMA Channel Functionality

Each of the 8 SDMA channels has one associated register set containing ten 32-bit registers. These registers are numbered by one index to indicate the related SDMA channel: Index “n” refers to the channel number (n = 0-7) within the SDMA Sub-Block.

Example: CHCR04 is the Control Register of SDMA channel 4 in Sub-Block 0.

The register set of a SDMA channel register contains the following registers:

- Channel 0n Control Register CHCR0n (for details, see **Page 13-65**)
- Channel 0n Status Register CHSR0n (for details, see **Page 13-69**)
- Channel 0n Interrupt Control Register CHICR0n (for details, see **Page 13-70**)
- Channel 0n Address Control Register ADRCR0n (for details, see **Page 13-72**)
- Channel 0n Source Address Register SADR0n (for details, see **Page 13-77**)
- Channel 0n Destination Address Register DADR0n (for details, see **Page 13-78**)
- Channel 0n Shadow Address Register SHADR0n (for details, see **Page 13-79**)

13.2.4.1 Shadowed Source or Destination Address

As a typical application, an ASC module that receives data (fixed source address) has to deliver it to a memory buffer using a SDMA transaction (variable destination address). After a certain amount of data has been transferred, a new SDMA transaction should be initiated to deliver further ASC data into another memory buffer. While the destination address register is updated during a running SDMA transaction with the actual destination address, a shadow mechanism allows programming of a new destination address without disturbing the content of the destination address register. In this case, the new destination address is written into a buffer register, i.e. the shadow address register. At the start of the next SDMA transaction, the new address is transferred from this shadow address register to the destination address register without CPU intervention. This shadow mechanism avoids the CPU having to check for the end of a SDMA transaction before reprogramming address registers.

The shadow address register can be used also to store a source address. However, it cannot store source and destination address at the same time. This means that the shadow mechanism makes it possible to automatically update either a new source address, or a new destination address at the start of a SDMA transaction. If both address registers (for source and destination address) have to be updated for the next SDMA transaction, a running SDMA transaction for this channel must be finished. After that, source and destination address registers can be written before the next SDMA transaction is started.

Figure 13-4 shows the actions that take place when a source address register is updated. The update of a destination register happens in an equivalent manner.

When writing a new address to the (address of) the source or destination address register and no SDMA transaction is running, the new address value is directly written into the source or destination address register. In this case, no buffering of the address

is required. When writing a new address to the (address of) the source or destination address register and a SDMA transaction is running, no transfer to an address register can take place and SHADR0n holds the new address value that was written. For this operation, bit field ADRCR0n.SHCT must be set either to 01_B (address is a source address) or 10_B (new address is a destination address). At the start of the next SDMA transaction, the shadow transfer takes place and the content of SHADR0n is written either into SADR0n or DADR0n (ADRCR0n.SHCT must be set accordingly). After the shadow transfer, SHADR0n is set to 0000 0000_H if the shadow register write enable bit is set to 0 (ADRCR0n.SHWEN = 0). In this case (ADRCR0n.SHWEN = 0), the software can check by reading the shadow address register whether or not the shadow transfer has already taken place.

Only one address register can be shadowed while a transaction is running, because the shadow register can only be assigned either to the source or to the destination address register. Note that the shadow address register transfer has the same behavior in Single and Continuous Mode. When the shadow mechanism is disabled (ADRCR0n.SHCT = 00_B), SHADR0n is always read as 0000 0000_H.

If the shadow address register write enable bit is set to 1 (ADRCR0n.SHWEN = 1), the shadow register SHADR0n can be directly written. In this case (ADRCR0n.SHWEN = 1) the value stored in the SHADR0n is not modified when the shadow transfer takes place, and the shadow mechanism remains active and the shadow transfer will be repeated until Channel 0n is reset or until the value in SHADR is 0000 0000_H, is written into the shadow register (direct or indirect by writing to the source or destination address register according to the shadow control register ADRCR0n.SHCT).

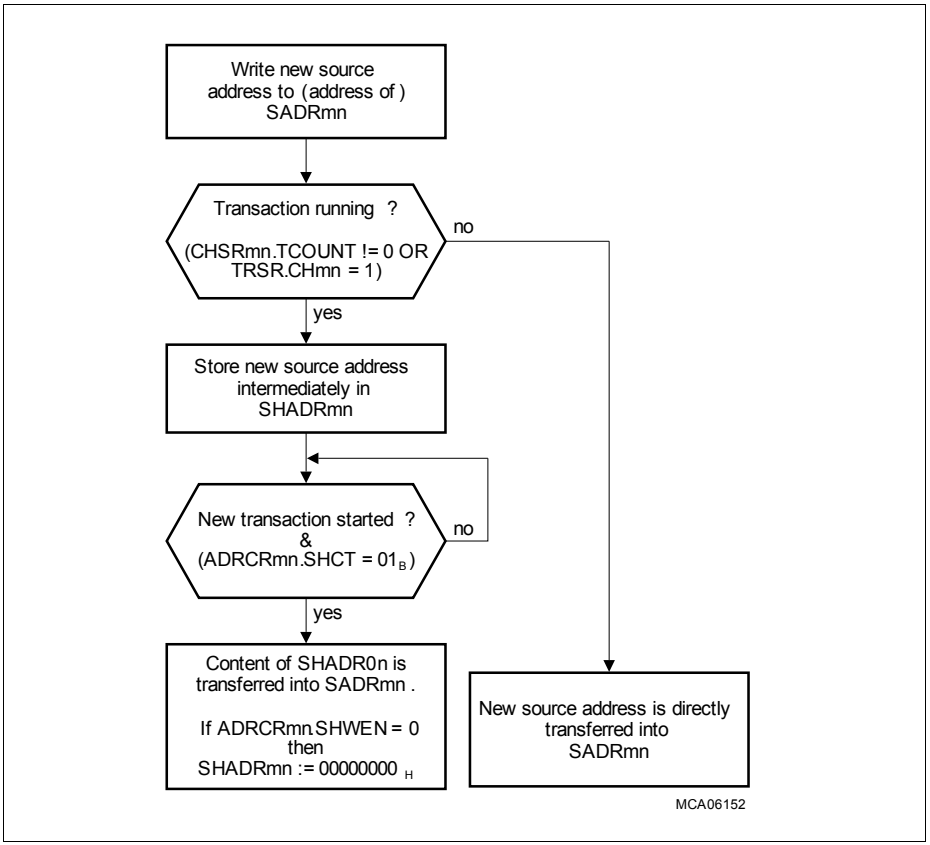

Figure 13-4 Source Address Update (m=0)

The transfer count of a SDMA transaction, stored in bit field CHCR0n.TREL, can also be programmed if the SDMA transaction is running. At the start of a SDMA transaction, TREL is transferred to bit field CHSR0n.TCOUNT, which is then updated during the SDMA transaction.

No reload of address or counter will be done if TCOUNT is not equal to 0.

The reprogramming of channel specific values (except for the selected address shadow register) should be avoided while a SDMA channel is active.

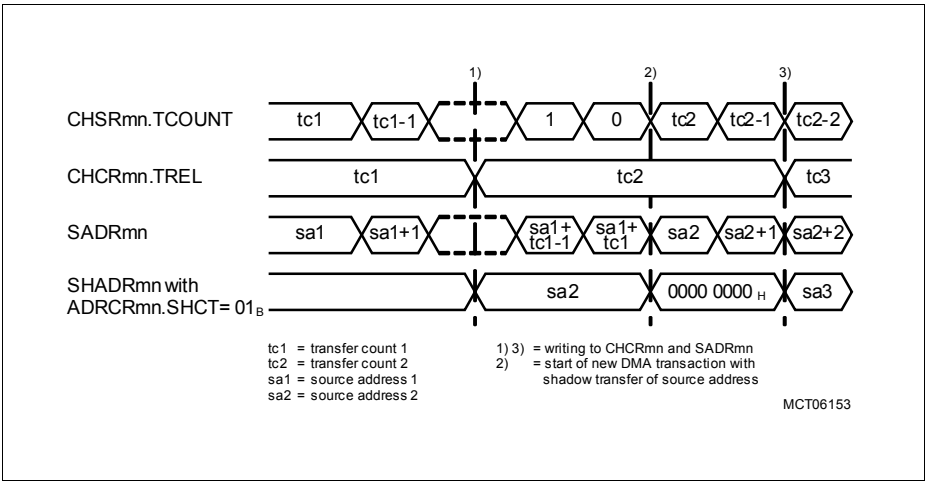

Figure 13-5 Shadow Source Address and Transfer Count Update with ADRCR0n.SHWEN = 0 (m = 0)

Figure 13-5 shows how the contents of the source address register SADR0n and the transfer count CHSR0n.TCOUNT are updated during two SDMA transactions with a shadowed source address and transfer count update.

At reference point 2) the SDMA transaction 1 is finished and SDMA transaction 2 is started. At 1) the SDMA channel is reprogrammed with two new parameters for the next SDMA transaction: Transfer count tc2 and source address sa2. Source address sa2 is buffered in SADR0n and transferred to SADR0n when the new SDMA transaction is started at 2). At this time, transfer count tc2 is also transferred to CHSR0n.TCOUNT. Note that the shadow address register is only reset by hardware to 0000 0000_H as shown in this example, if the write enable bit is set to 0 (ADRCR0n.SHWEN = 0).

13.2.4.2 SDMA Channel Request Control

Figure 13-6 shows the control logic for SDMA requests that is implemented for each SDMA channel.

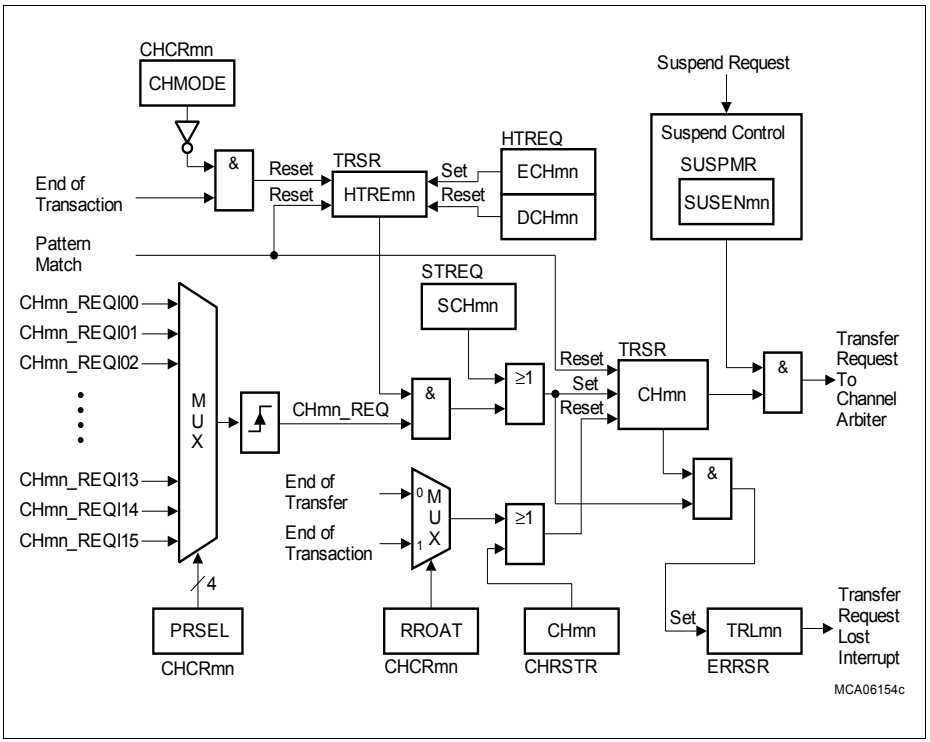

Figure 13-6 Channel Request Control(m = 0)

Two different types of SDMA requests are possible:

- Hardware SDMA requests
- Software SDMA requests

The hardware request CH0n_REQ can be connected to one of sixteen possible hardware request input lines as selected by bit field CHCR0n.PRSEL. The hardware request input structure for CHCR0n.PRSEL includes a ´positive edge detector´ as the SDMA channels requires single pulse requests.

Hardware requests are enabled/disabled by status bit TRSR.HTRE0n. HTRE0n can be set/reset by software or by hardware in Single Mode at the end of a SDMA transaction. A software request can be generated by setting bit STREQ.SCH0n.

Status flag TRSR.CH0n indicates whether or not a software or hardware generated SDMA request for SDMA channel 0n is pending. TRSR.CH0n can be reset by software or by hardware at the end of a SDMA transfer (RROAT = 0) or at the end of a SDMA transaction (RROAT = 1).

If a software or a hardware SDMA request is detected for channel 0n while TRSR.CH0n is set, a request lost event occurs. This error event indicates that the SDMA is already processing a transfer and that another transfer has been requested before the end of the previous one. In this case, bit ERRSR.TRL0n will be set and a transfer lost interrupt can be generated.

13.2.4.3 SDMA Channel Operation Modes

The operation mode of a SDMA channel is individually programmable for each SDMA channel n. Basically, a SDMA channel can operate in the following modes:

- Software controlled mode
- Hardware controlled mode, in Single or Continuous Mode

In software-controlled mode, a SDMA channel request is generated by setting a control bit. In hardware-controlled mode, a SDMA channel request is generated by request signals typically generated by on-chip peripheral units.

In hardware-controlled Single Mode, a SDMA channel n becomes disabled by hardware after the last SDMA transfer of its SDMA transaction. In hardware-controlled Continuous Mode, a SDMA channel n remains enabled after the last SDMA transfer of its SDMA transaction.

In hardware- and software-controlled mode, a SDMA request signal can be configured to trigger a complete SDMA transaction or one single transfer.

Software-controlled Modes

In software-controlled mode, one software request starts one complete SDMA transaction or one single SDMA transfer. Software-controlled modes are selected by writing HTREQ.DCH0n = 1. This forces status flag TRSR.HTRE0n = 0 (hardware request of SDMA channel 0n is disabled).

The software-controlled mode that initiates one complete SDMA transaction to be executed is selected for SDMA channel 0n by the following write operations:

- CHCR0n.RROAT = 1
- STREQ.SCH0n = 1

Setting STREQ.SCH0n to 1 (this is the software request) causes the SDMA transaction of SDMA channel 0n to be started and TRSR.CH0n to be set. At the start of the SDMA transaction, the value of CHCR0n.TREL is loaded into CHSR0n.TCOUNT (transfer count or tc) and the SDMA transfers are executed. After each SDMA transfer, TCOUNT becomes decremented and next source and destination addresses are calculated.

When TCOUNT reaches the 0, SDMA channel 0n becomes disabled and status flag TRSR.CH0n is reset. Setting STREQ.SCH0n again starts a new SDMA transaction of SDMA channel 0n with the parameters as actually defined in the channel register set.

The software-controlled mode that initiates a single SDMA transfer to be executed is selected for SDMA channel 0n by the following write operations:

- CHCR0n.RROAT = 0
- STREQ.SCH0n = 1, repeated for each SDMA transfer

When CHCR0n.RROAT = 0, TRSR.CH0n becomes reset after each SDMA transfer of the SDMA transaction and a new software request (writing STREQ.SCH0n = 1) must be generated for starting the next SDMA transfer.

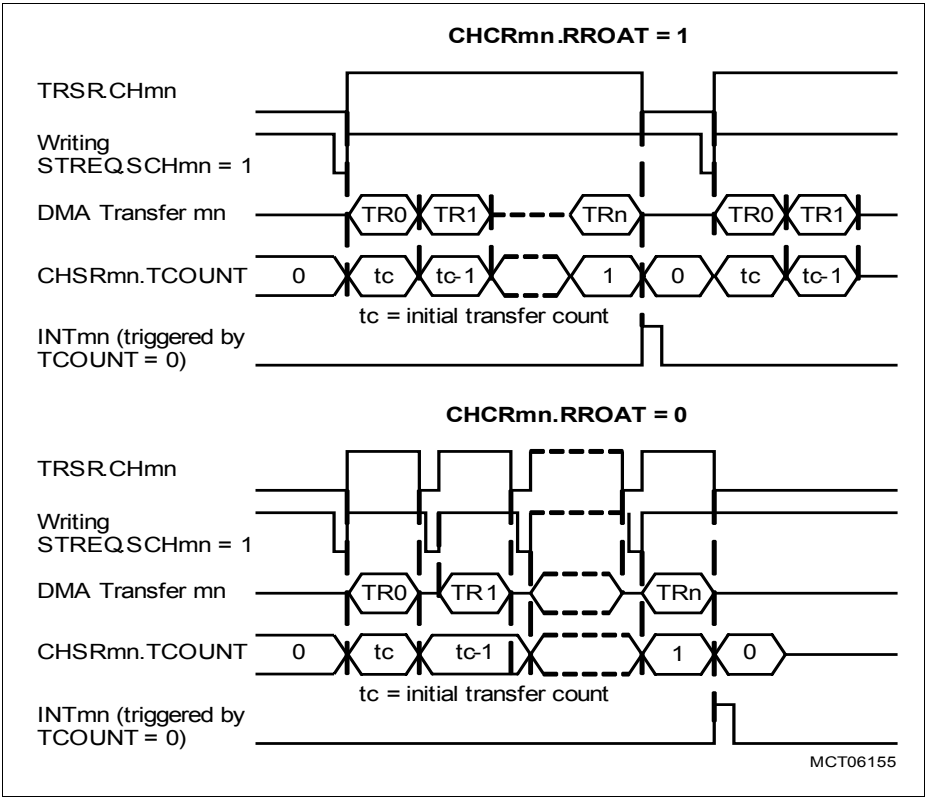

Figure 13-7 Software Controlled Mode Operation (m = 0)

Hardware-controlled Modes

In hardware-controlled modes, a hardware request signal starts a SDMA transaction or a single SDMA transfer. There are two hardware-controlled modes available:

- **Single Mode:**
  Hardware requests are disabled by hardware after a SDMA transaction
- **Continuous Mode:**
  Hardware requests are not disabled by hardware after a SDMA transaction

Hardware-controlled Single Mode

In hardware-controlled Single Modes, one hardware request starts one complete SDMA transaction or one single SDMA transfer. The hardware-controlled Single Mode that initiates one complete SDMA transaction to be executed for SDMA channel 0n is selected by the following operations:

- CHCR0n.CHMODE = 0
- CHCR0n.RROAT = 1
- Selecting one of the sixteen hardware request inputs via CHCR0n.PRSEL
- HTREQ.ECH0n = 1

Setting HTREQ.ECH0n to 1 causes the hardware request CH0n_REQ of channel 0n to be enabled (TRSR.HTRE0n = 1). Whenever the hardware request CH0n_REQ becomes active, the value of CHCR0n.TREL is loaded into CHSR0n.TCOUNT and the SDMA transaction is started by executing its first SDMA transfer. After each SDMA transfer, TCOUNT becomes decremented and next source and destination addresses are calculated. When TCOUNT reaches the 0, SDMA channel 0n becomes disabled and status flags TRSR.CH0n and TRSR.HTRE0n are reset. In order to start a new hardware-controlled SDMA transaction, hardware requests must be enabled again by setting TRSR.HTRE0n through HTREQ.ECH0n = 1. The hardware request disable function in Single Mode is typically needed when a reprogramming of the SDMA channel register set (addresses, transfer count) is required before the next hardware triggered SDMA transaction is started.

The hardware-controlled Single Mode in which each single SDMA transfer has to be requested by a hardware request signal is selected as described above, with one difference:

- CHCR0n.RROAT = 0

In this operation mode, TRSR.CH0n becomes reset after each SDMA transfer of the SDMA transaction, and a new hardware request at CH0n_REQ must be generated for starting the next SDMA transfer.

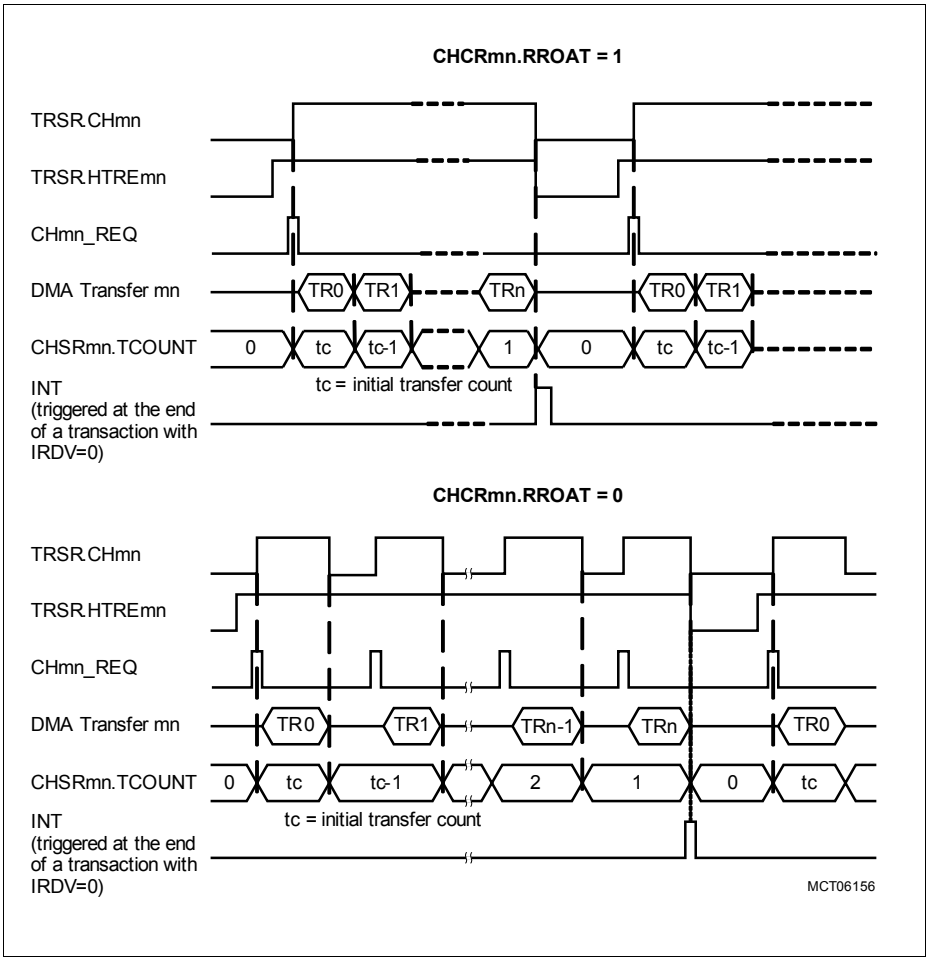

Figure 13-8 Hardware-controlled Single Mode Operation (m = 0)

Hardware-controlled Continuous Mode

In hardware-controlled Continuous Mode (CHCR0n.CHMODE = 1), the hardware transaction request enable bit HTRE0n is not reset at the end of a SDMA transaction. A new transaction of SDMA channel 0n with the parameters actually stored in the channel register set of SDMA channel 0n is started each time when CHSR0n.TCOUNT = 0 at the end of the SDMA transaction. No software re-enable for a hardware request at CH0n_REQ is required.

Combined Software/Hardware-controlled Mode

Figure 13-9 shows how software- and hardware-controlled modes can be combined. In the example, the first SDMA transfer is triggered by software when setting STREQ.SCH0n. Hardware requests are still disabled. After hardware requests have been enabled by setting HTREQ.ECH0n, subsequent SDMA transfers are triggered now by hardware request coming from the CH0n_REQ line.

In the example, SDMA channel 0n operates in Single Mode (CHCR0n.CHMODE = 0). In this mode, TRSR.HTRE0n becomes reset by hardware when CHSR0n.TCOUNT = 0 at the end of the SDMA transaction.

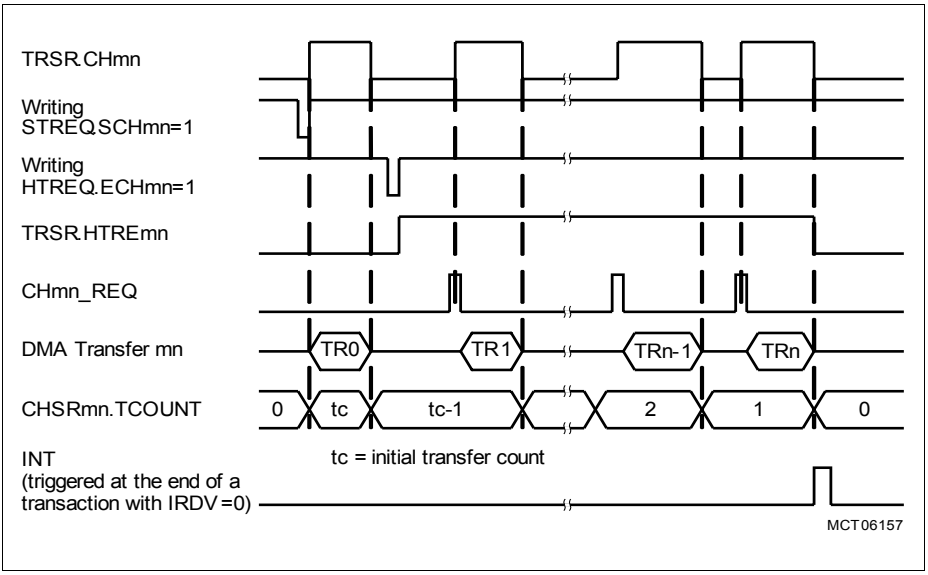

Figure 13-9 Transaction Start by Software, Continuation by Hardware (m = 0)

If an SDMA channel is configured to be triggered by parallel hardware and software requests then if the requests collide in the same clock cycle then a Transaction/Transfer Request Lost event will be flagged in the SDMA Error Status Register.

13.2.4.4 Error Conditions

The bus error flag ERRSR.FPIER indicates an FPI Bus error (SPB) that occurred during a source move (read or write) of a SDMA module transaction.

The source error flag ERRSR.ME0SER indicates than an error occurred during source move (read) of a SDMA transaction of SDMA Sub-Block 0.

The destination error flag ERRSR.ME0DER indicates than an error occurred during destination move (write) of a SDMA transaction of SDMA Sub-Block 0
The transaction lost error flag ERRSR.TRL0n indicates if a SDMA request for a SDMA channel 0n has been lost.

In the case of a read error, the write action is not executed, but the destination address is updated.

In the case of multiple errors, the error bits are set according to the error situations. This means that more than bus error flag can be set and that source/destination flags can be set.

13.2.4.5 Channel Reset Operation

A SDMA transaction of SDMA channel 0n can be stopped (channel is reset) by setting bit CHRSTR.CH0n. When a read or write On Chip Bus transaction of SDMA channel 0n is executed at the time when CHRSTR.CH0n is set, this On Chip Bus transaction is finished normally. This behavior guarantees data consistency.

When CHRSTR.CH0n is set to 1:

- Bits TRSR.HTRE0n, TRSR.CH0n, ERRSR.TRL0n, INTSR.ICH0n, INTSR.IPM0n, WRPSR.WRPD0n, WRPSR.WRPS0n, CHSR0n.LXO, and bit field CHSR0n.TCOUNT are reset.
- Source and destination address register will be set to the wrap boundary. SHADR0n will be cleared.
- All automatic functions are stopped for channel 0n.

A user program must execute the following steps for resetting a SDMA channel:

1. If hardware requests are enabled for the SDMA channel 0n, disable the SDMA channel 0n hardware requests by setting HTREQ.ECH0n = 0.
2. Writing a 1 to CHRSTR.CH0n.
3. Waiting (polling) until CHRSTR.CH0n = 0.

A user program should execute the following steps for restarting a SDMA channel after it was reset:

1. Optionally (re-)configuring the address and other channel registers.
2. Restarting the SDMA channel 0n by setting HTREQ.ECH0n = 1 for hardware requests or STREQ.SCH0n = 1 for software requests.

The value of CHCR0n.TREL is copied to CHSR0n.TCOUNT when a new SDMA transaction is requested and shadow address register contents is not equal $0000\ 0000_H$.

13.2.4.6 Transfer Count and Move Count

The move count determines the number of moves (consisting of one read and one write each) to be done in each transfer. It allows the user to indicate to the SDMA the number of moves to be done after one request. The number of moves per transfer is selected by the block mode settings (CHCR0n.BLKM).

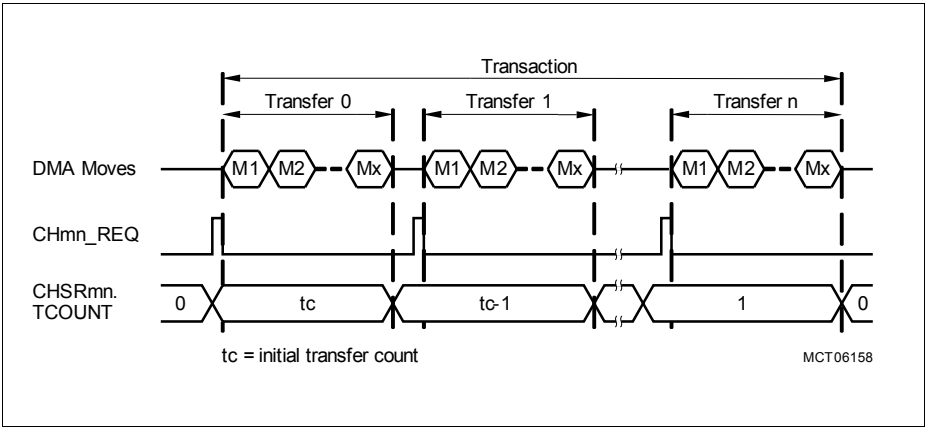

Figure 13-10 Transfer and Move Count (m = 0)

After a SDMA move, the next source and destination addresses are calculated. Source and destination addresses are calculated independently of each other. The following address calculation parameters can be selected:

- The address offset, which is a multiple of the selected data width
- The offset direction: addition, subtraction, or none (unchanged address)

Control bits in address control register ADRCR0n determine how the addresses are incremented/decremented. Further, the data width as defined in CHCR0n.CHDW is taken into account for the address calculation.

Figure 13-11 and **Figure 13-12** show two examples of address calculation. In both examples, a data width of 16-bit (CHCR0n.CHDW = 01_B) is assumed.

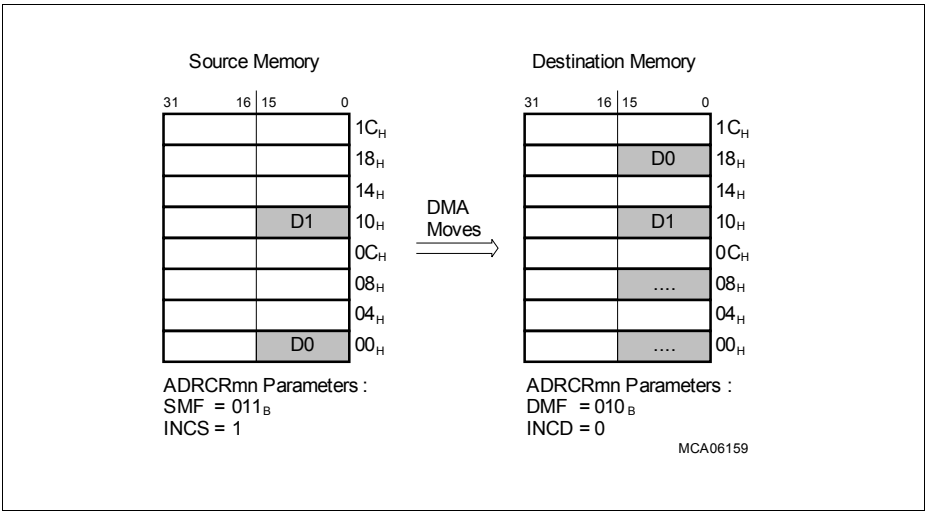

Figure 13-11 Programmable Address Modification - Example 1 (m = 0)

In **Figure 13-11**, 16-bit half-words are transferred from a source memory with an incrementing source address offset of 10_H to a destination memory with decrementing destination addresses offset of 08_H.

In **Figure 13-12**, 16-bit half-words are transferred from a source memory with an incrementing source address offset of 02_H to a destination memory with incrementing destination addresses offset of 04_H.

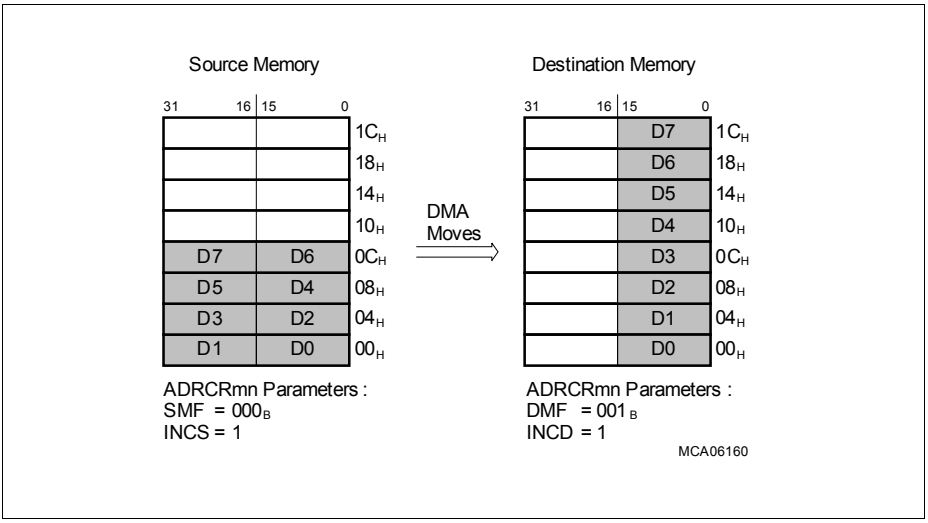

Figure 13-12 Programmable Address Modification - Example 2 (m = 0)

13.2.4.7 Circular Buffer

Destination and source address can be configured to build a circular buffer separately for source and destination data. Within this circular buffer, addresses are updated as defined in **Figure 13-11** and **Figure 13-12** with a wrap-around at the buffer limits. The circular buffer length is determined by bit fields ADRCR0n.CBLS (for the source buffer) and ADRCR0n.CBLD (for the destination buffer). These 4-bit wide bit fields determine which bits of the 32-bit address remain unchanged at an address update. Possible buffer sizes of the circular buffers can be 2^{CBLS} or 2^{CBLD} bytes (= 1, 2, 4, 8, 16, … up to 32k bytes).

When source or destination addresses are updated (incremented or decremented) after a SDMA move, all upper bits [31:CBLS] of source address and [31:CBLD] of destination address are frozen and remain unchanged, even if a wrap-around from the lower address bits [CBLS:0] or [CBLD:0] occurred. This address-freezing mechanism always causes the circular buffers to be aligned to a multiple integer value of its size.

If the circular buffer size is less or equal than the selected address offset (see **Table 13-7**), the same circular buffer address will always be accessed.

13.2.5 Transaction Control Engine

The Transaction Control Unit in the SDMA Sub-Block, as shown in the SDMA Controller block diagram in **Figure 13-1**, contains a Channel Arbiter and a Move Engine.

The Channel Arbiter arbitrates the transfer requests of the SDMA channels, and submits the transfers parameters of the SDMA channel with the highest channel priority that are needed for a SDMA transfer to the Move Engine. SDMA channels within a SDMA Sub-Block have a two-level programmable channel priority as defined by bit CHCR0n.CHPRIO. When two transfer requests of two different SDMA channels with identical channel priority become active at the same time, the SDMA channel with the lowest channel number (n) is serviced first.

The Move Engine handles the execution of a SDMA transfer that has been detected by the Channel Arbiter to be the next one. The Move Engine requests the required buses and loads or stores data according to the parameters of a SDMA transfer. It is able to wait if a targeted bus is not available. In the Move Engine, a SDMA transfer of a SDMA transaction cannot be interrupted and always get finished. This means that a SDMA transfer, which can also be composed of several data moves (read move and write move), cannot be interrupted by a transfer of another SDMA channel.

After a SDMA transfer is finished, the Move Engine will send back the actualized address register information to the related SDMA channel. Possible error conditions are also reported.

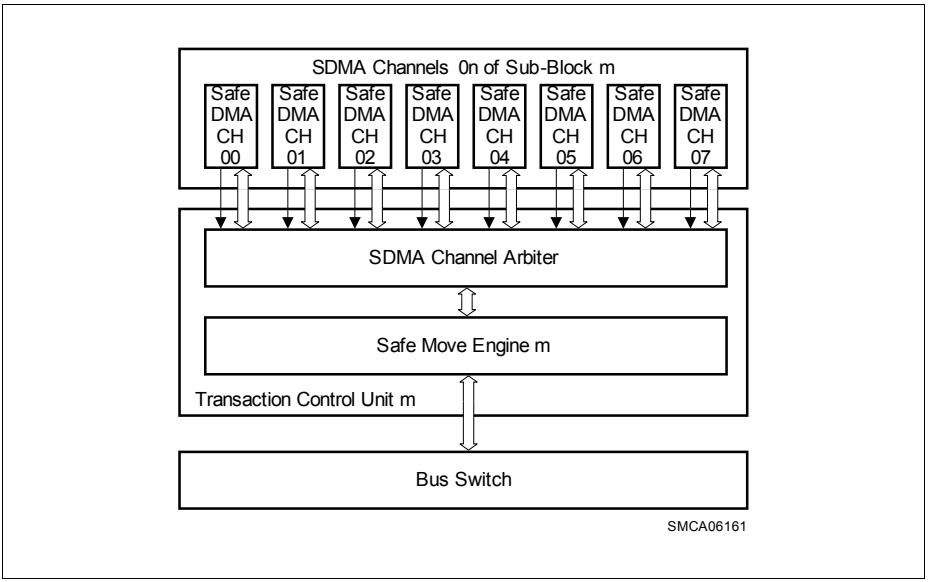

Figure 13-13 Transaction Control Engine (m = 0)

13.2.6 Bus Switch, Bus Switch Priorities

The Bus Switch of the SDMA controller provides the connection from the SDMA Sub-Block to the On Chip Bus System Peripheral Bus master interface and to the SDMA Peripheral Interface (see **Figure 13-14**).

The SDMA module working frequency is identical to the FPI Bus frequency.

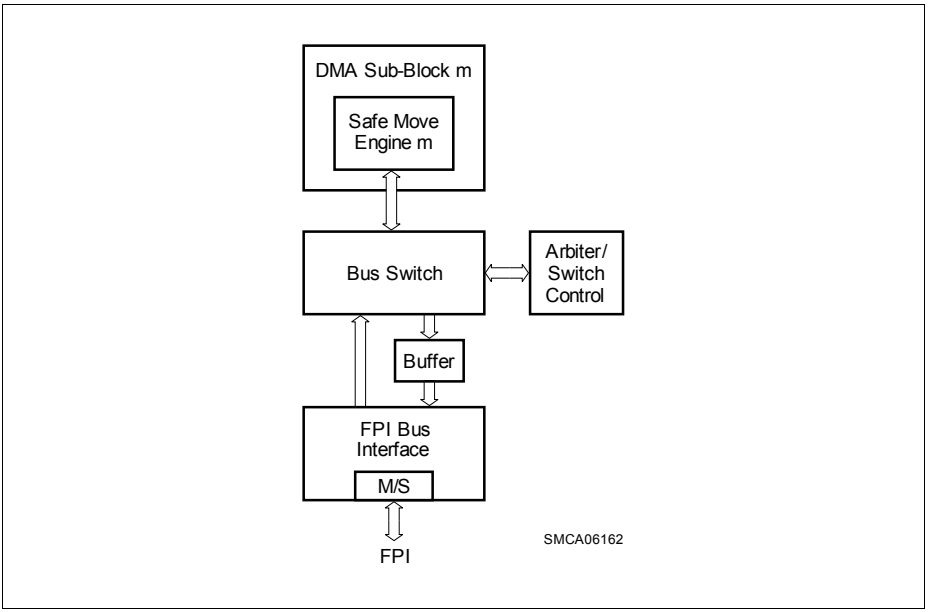

Figure 13-14 Bus Switch

One access can be buffered in the bus interface.

Note: The accesses of the SDMA Move Engine's bus interfaces to the On Chip Bus interfaces are always done in Supervisor Mode.

A Move Engine Write has priority over a Move Engine Read.

13.2.7 SDMA Module: On Chip Bus Access Rights, RMW support

All accesses triggered by the SDMA Move Engine are always done in SV mode.

The SDMA module does not support read/modify write instructions.

13.2.8 SDMA On Chip Bus FPI Master Interface

The SDMA On Chip Bus FPI Master Interfaces supports:

- single data read and write transactions (8bit, 16bit, 32bit)
- de-assertion of request after retry in order to prevent bus blocking.

The move engine generates read - write sequences and supports only one transaction at a time.

13.2.9 On-Chip Debug Capabilities

The SDMA controller in the TC1798 provides some debugging capabilities. These debug features support:

- Soft-suspend Mode of SDMA channels
- Break signal generation
- Trace signal generation

In Soft-suspend mode, the operations of SDMA channels are stopped. Pending read or write transfers in the SDMA module On Chip Bus Master Interface are finished. Under certain conditions also a break signal is generated for the on-chip debug support logic. Further, SDMA trace information can be output.

In Soft-suspend mode, the SDMA module provides access to all control registers of the SDMA module.

13.2.9.1 Hard-suspend Mode

The Hard-Suspend Mode is controlled in the TC1798 SDMA module CLC register.

13.2.9.2 Soft-suspend Mode

The TC1798 on-chip debug control unit is able to generate a Soft-suspend Mode request (SUSREQ) for the SDMA controller. When this soft-suspend request becomes active, the state of a SDMA channel becomes frozen regarding hardware changes to ensure that the state of the SDMA channels can be analyzed by reading the register contents. Pending read or write transfers in the SDMA module On Chip Bus FPI Master Interface are finished. The SDMA controller signals its soft suspend mode back to the on-chip debug control via an Soft-suspend acknowledge. The Soft-suspend acknowledge becomes active when all SDMA channels 0n that are enabled for the Soft-suspend Mode have set its suspend active status flag SUSPMR.SUSAC0n.

Soft-suspend Mode of SDMA channel 0n is entered if its suspend enable bit SUSEN0n in the Suspend Mode Register SUSPMR is set. When SUSREQ becomes active, the operation of all SDMA channels 0n that are enabled for Soft-suspend Mode is stopped automatically after its current SDMA transfers have been finished in the transaction control unit. Afterwards, the suspend active status flag SUSPMR.SUSAC0n is set, indicating that SDMA channel 0n is in Soft-suspend Mode. SDMA channels that are disabled for Suspend Mode (SUSEN0n = 0) continue with its normal operation.

In Soft-suspend Mode, register contents can be modified. These modifications are taken into account for further SDMA transactions or SDMA transfers of the related SDMA channel after Suspend Mode has been left again. Suspend Mode of SDMA channel 0n is left and its normal operation continues if either the SUSREQ signal becomes inactive, or if the enable bit SUSEN0n is reset by software.

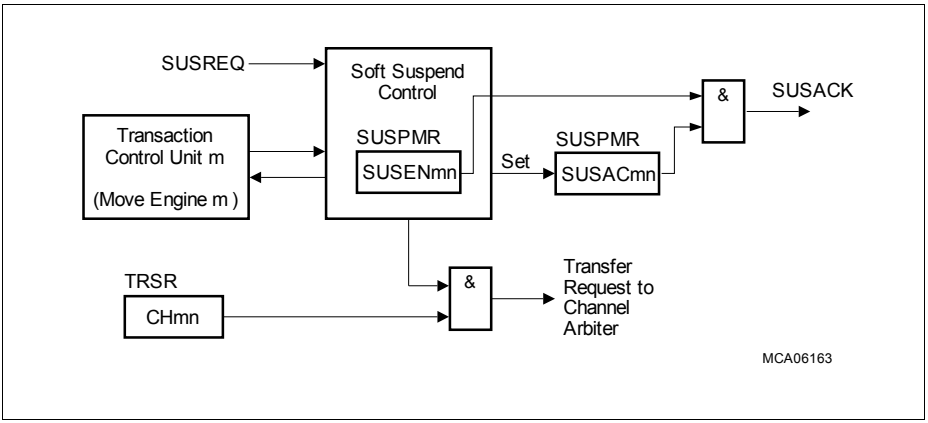

Figure 13-15 Soft-suspend Mode Control (m = 0)

13.2.9.3 Break Signal Generation

The SDMA controller provides one BREAK output signal that is generated for the on-chip debug support logic (see **Figure 13-16**). The SDMA sub-block is able to detect two break conditions:

- Transaction lost interrupt has occurred
- SDMA request transitions, indicated by bits TRSR.CH0n

The output lines of the two break conditions in the SDMA sub-block are OR-ed together to the BREAK output signal.

A transaction lost break condition occurs in SDMA Sub-Block whenever at least one of its eight transaction lost interrupts becomes active, and when enable bit OCDSR.BRL0 is set. The transaction lost interrupts do not generate a break condition if OCDSR.BRL0 = 0. Transaction interrupt control is described in **Section 13.2.10.2**.

The second break condition of SDMA Sub-Block becomes active when the transaction request bit TRSR.CH0n of one of its eight SDMA channels n (as selected by OCDSR.BCHSn) indicates a transition of its state. The CH0n transition type (change from ´no request is pending´ to ´request is pending´, change from ´request is pending´ to ´no request is pending´, changes in both directions) is selected by bit field OCDSR.BTCRn.

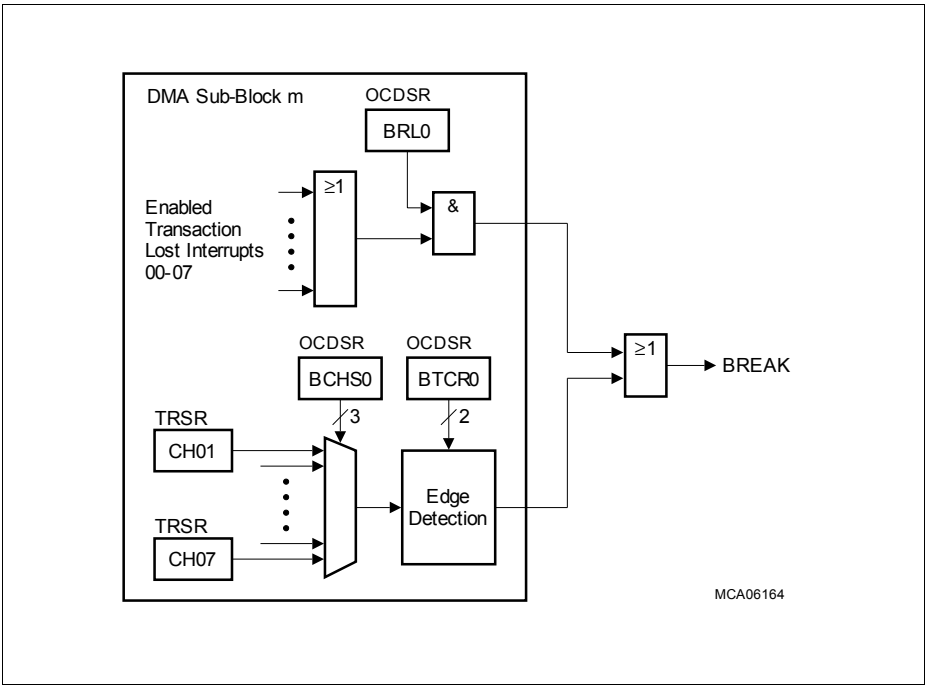

Figure 13-16 SDMA Break Event Generation (m = 0)

13.2.10 Interrupts

The interrupt structure of the SDMA controller is a very flexible control logic that allows an interrupt coming from an interrupt source within four interrupt source types to be connected to each of the sixteen interrupt outputs. This permits, for example, SDMA channels that very rarely generate interrupts to share one interrupt node. The remaining interrupt nodes can be assigned to dedicated SDMA channels to reduce the interrupt overhead for these channels. The four interrupt source types are:

- Channel interrupts
- Transaction lost interrupt
- Move Engine interrupts
- Wrap buffer interrupts

Some of the interrupt functions are common to all of the four interrupt source types. An interrupt event, internally generated as a request pulse, is always stored in an interrupt status flag. This interrupt status flag can be reset by software. Further, the interrupt event can be enabled or disabled. When an interrupt event is enabled, a 4-bit Interrupt Node Pointer determines which of the sixteen interrupt outputs will be activated.

The following sections describe each of the four interrupt source types in more detail.

13.2.10.1 Channel Interrupts

Each SDMA channel 0n has one associated channel interrupt. It can always be activated after a SDMA transfer, or when CHSR0n.TCOUNT matches with the value of bit field CHICR0n.IRDV after it has been decremented after a SDMA transfer. The pattern detection interrupts that are combined with the channel interrupts (one common Interrupt Node Pointer CHICR0n.INTP) are activated when the pattern detection interrupt of SDMA channel 0n becomes active (when enabled by CHCR0n.PATSEL not equal 00_B).

A channel interrupt of SDMA channel 0n is indicated when status flag INTSR.ICH0n is set. The status flags ICH0n and IPM0n can be reset together by software when setting bit INTCR.CICH0n (or CHRSTR.CH0n). The channel interrupt of SDMA channel 0n is enabled when bit CHICR0n.INTCT[1] is set. The channel interrupt pointer CHICR0n.INTP determines which of the interrupt outputs SR[15:0][1)] will be activated on an active channel interrupt or pattern detection interrupt. Note that the signal that is set signal for the ICH0n flag is available as CH0n_OUT signal at the SDMA module boundary.

Bit CHICR0n.INTCT[0] selects these two types of interrupt sources. For the compare operation, bit field IRDV (4-bit) is zero-extended to 10-bit and then compared with the 10-bit TCOUNT value. This means that a TCOUNT match interrupt can be generated after one of the last 16 SDMA transfers of a SDMA transaction. Note that with

1) In the TC1798, only SR[7:0] are connected to interrupt nodes. SR[8:15] are used for SDMA channel triggering/connections.

IRDV = 0000_B, the match interrupt is generated at the end of a SDMA transaction (after the last SDMA transfer).

The pattern detection interrupt is indicated when status flag INTSR.IPM0n is set. The status flags IPM0n and ICH0n can be reset together by software when setting bit INTCR.CICH0n (or CHRSTR.CH0n). The pattern detection interrupt of SDMA channel 0n is enabled when bit CHCR0n.PATSEL is set to a value not equal to 00_B. The channel interrupt pointer CHICR0n.INTP defines which of the interrupt outputs SR[15:0] will be activated on a pattern detection interrupt or the channel interrupt pointer CHICR0n.INTP determines which of the interrupt outputs SR[15:0][1] will be activated on a pattern detection or channel interrupt.

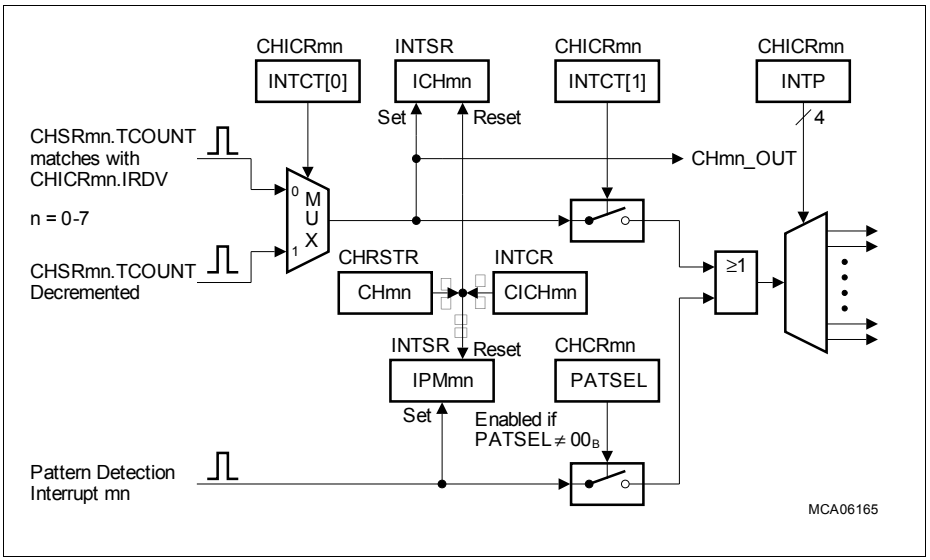

Figure 13-17 Channel Interrupts (m = 0)

1) In the TC1798, SR[7:0] are connected to interrupt nodes. SR[8:15] are used for SDMA channel triggering/connections.

13.2.10.2 Transaction Lost Interrupt

Each SDMA channel 0n is able to detect a transaction request lost condition. This condition becomes true when a new hardware or software SDMA request occurs while the previous transaction or transfer on SDMA channel 0n is not finished, indicated by TRSR.CH0n still set. If such a transaction request lost condition occurs, bit ERRSR.TRL0n is set. The transaction lost interrupts of all SDMA channels are OR-ed together to one common transaction lost interrupt that can be directed to one of the interrupt outputs SR[15:0][1] by setting the transaction lost interrupt pointer EER.TRLINP with a corresponding value.

A transaction request lost condition of SDMA channel 0n is indicated by status flag ERRSR.TRL0n, which can be reset by setting bit CLRE.CTL0n or CHRSTR.CH0n. The transaction lost interrupt for SDMA channel 0n is enabled when bit EER.ETRL0n is set.

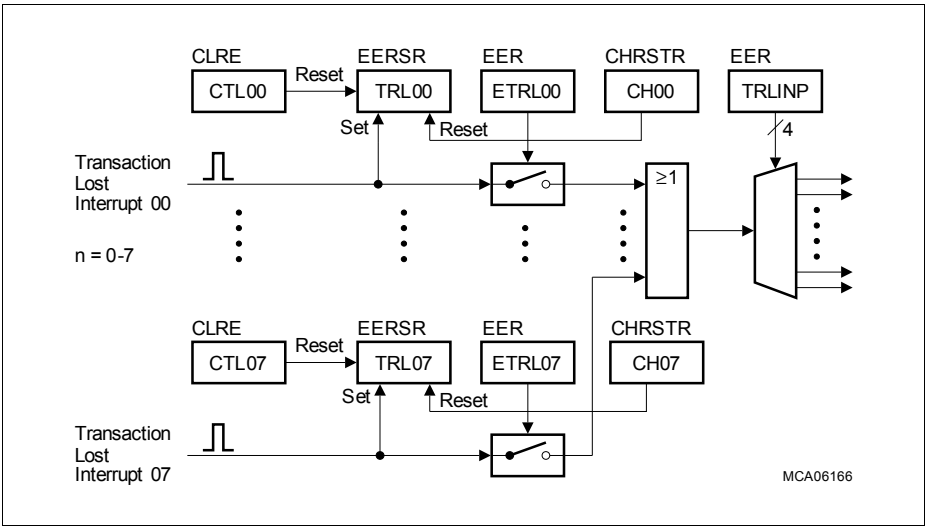

Figure 13-18 Transaction Lost Interrupt

1) In the TC1798 SR[7:0] are connected to interrupt nodes. SR[15:8] are used as SDMA channel trigger signals.

13.2.10.3 Move Engine Interrupt

The Move Engine is able to detect error conditions that occur during accesses to the FPI Bus interfaces of the Bus Switch (see **Figure 13-14**). Two error conditions can be detected:

- Source error
- Destination error

A source error indicates an FPI Bus error that occurred during a read move from the data source. A destination error indicates an FPI Bus error that occurred during a write move to the data destination.

A source error of Move Engine 0 is indicated by the status flag ERRSR.ME0SER. Status flag ME0SER can be reset by software when setting bit CLRE.CME0SER. The source error interrupt of the Move Engine 0 is enabled when bit EER.EME0SER is set. Separate reset, status, and enable bits are available in the Move Engine for source error condition, as well as for destination error condition. The Move Engine's interrupts can be directed to one of the interrupt outputs SR[15:0][1)] by setting the Move Engine interrupt pointer EER.ME0INP with a corresponding value.

Note that in case of a read move error, the write move is not executed but the destination address is updated.

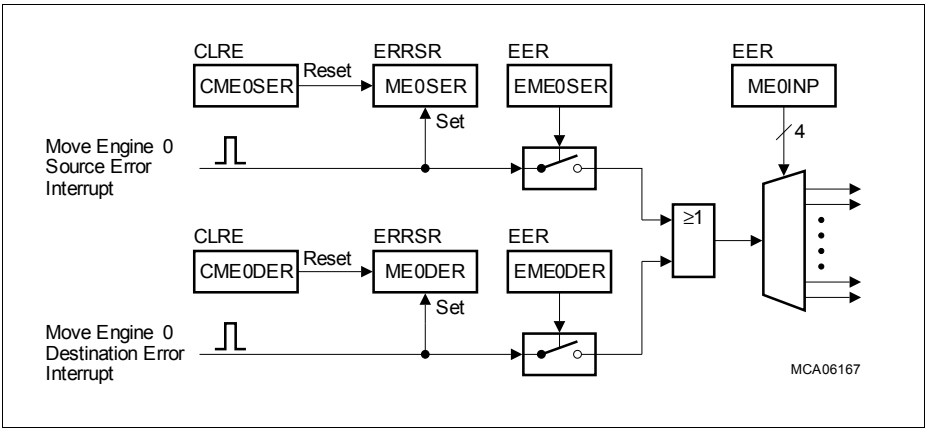

Figure 13-19 Move Engine Interrupts

1) In the TC1798 SR[7:0] are connected to interrupt nodes. SR[15:8] are used as SDMA channel trigger signals.

13.2.10.4 Wrap Buffer Interrupts

Each SDMA channel 0n is able to generate a wrap buffer interrupt for source buffer or destination buffer overflow. Further details on the pattern detection are described in **Section 13.2.11**.

A wrap source buffer interrupt of SDMA channel 0n is indicated by status flag WRPSR.WRPS0n. A wrap destination buffer interrupt of SDMA channel 0n is indicated by the status flag WRPSR.WRPD0n. Both interrupt status flags can be reset by software when bit INTCR.CWRP0n (or CHRSTR.CH0n becomes set). The wrap source buffer interrupt is enabled when bit CHICR0n.WRPSE is set. The wrap destination buffer interrupt is enabled when bit CHICR0n.WRPDE is set. The two interrupts for wrap source buffer and wrap destination buffer are OR-ed together to one common wrap buffer interrupt of SDMA channel 0n that can be directed to one of the interrupt outputs SR[15:0][1] by setting the wrap buffer interrupt pointer CHICR0n.WRPP with a corresponding value. Note that the pattern match should not be enabled while a wrap interrupt is enabled for the same channel.

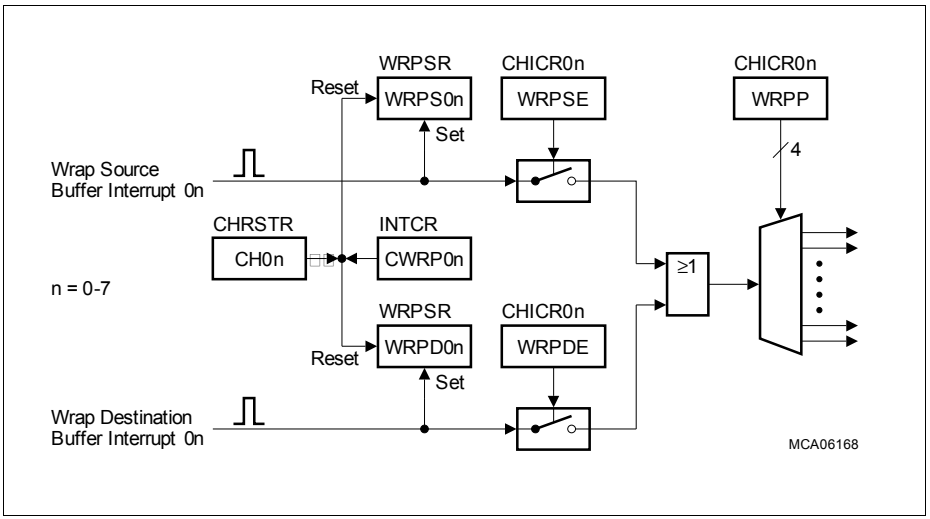

Figure 13-20 SDMA Wrap Buffer Interrupts (m = 0)

1) In the TC1798 SR[7:0] are connected to interrupt nodes. SR[15:8] are used as SDMA channel trigger signals.

13.2.10.5 Interrupt Request Compressor

The interrupt control logic of the SDMA controller uses an interrupt compressing scheme that allows high flexibility in interrupt processing. The request compressor logic as shown in **Figure 13-21** condenses the 8 + 1 + 1 + 8 = 18 interrupt sources to the sixteen interrupt outputs. Each internal interrupt source can be directed to one of the sixteen interrupt outputs SR[15:0][1)] by using a 4-bit Interrupt Node Pointer. This also allows the connection of more than one interrupt source to one interrupt output SRx. Each interrupt output SR[15:0][1)] can also be activated by writing a 1 to the corresponding bit GINTR.SIDMAx.

1) In the TC1798 SR[7:0] are connected to interrupt nodes. SR[15:8] are used as SDMA channel trigger signals.

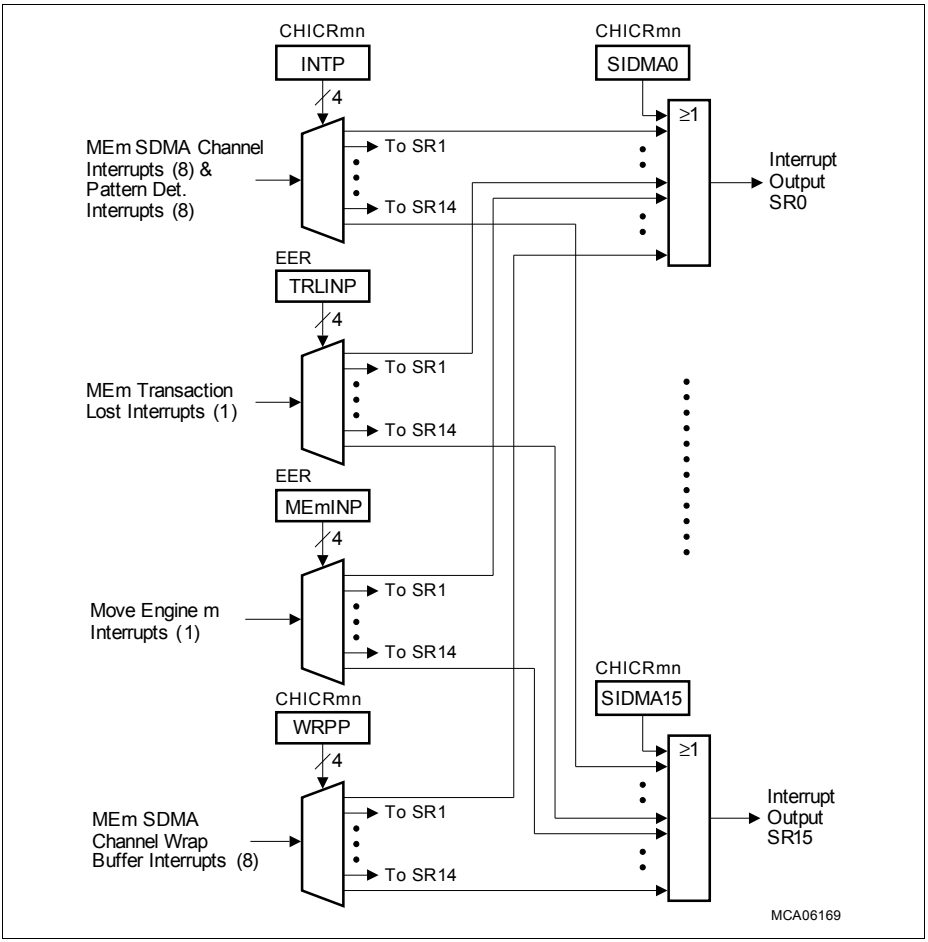

Figure 13-21 SDMA Interrupt Request Compressor (m = 0)

13.2.11 Pattern Detection

The Move Engine in the SDMA Sub-Block provides a register ME0R that contains the data that was read during the last read move. Parts of this read move data can be compared after the read move to data that is stored in the Move Engine pattern register ME0PR of SDMA Sub-Block 0. The result of this pattern compare match is always stored in a bit (LXO) of the channel status register of the SDMA channel 0n that is currently executing the SDMA move. Therefore, the pattern match result LXO of the previous read

move can also be combined together with the pattern match result of the actual read move. ME0R is overwritten with each read move.

As the compare match patterns are stored in the Move Engine 0 (register ME0PR), its compare patterns are used for all SDMA channels that are assigned to Move Engine 0 (all SDMA channels of the SDMA Sub-Block 0).

The configuration and capabilities of the pattern detection logic further depends on the settings of CHCR0n.CHDW. CHDW determines the data width for the read and write moves individually for each SDMA channel 0n. Another control bit, CHCR0n.PATSEL, selects among the different operating modes for a specific value of CHDW.

Depending on CHCR0n.PATSEL and on the positive result of the comparison, two actions follow (if CHCR0n.PATSEL=00, no action will be taken when a pattern match is detected, so the wrap interrupt can be used):

- The activation of the interrupt corresponding to the current active channel 0n using the Interrupt Pointer defined in CHICR0n.INTP.
- Reset TRSR.HTRE0n and TRSR.CH0n in order to stop the current transaction (Hardware and Software request enable). The value of CHSR0n.TCOUNT can be read out by the interrupt software.

The software will have to service the interrupt and to activate again the channel.

13.2.11.1 Pattern Compare Logic

Read move data and compare match patterns are compared on a bit-wise level. The logic as shown in **Figure 13-22** is implemented in each COMP block of **Figure 13-23**, **Figure 13-24**, and **Figure 13-25**. One COMP block controls either 8 bits or 16 bits of data and makes it possible to mask each data bit for the compare operation.

In the compare logic for one bit of the COMP block, a data bit from register ME0R is compared to the corresponding pattern bit stored in register ME0PR. If both bits are equal and a pattern mask bit stored in another part of register ME0PR is 0, the compare matched condition becomes active. When the pattern mask bit is set to 1, the compare matched condition is always active (set) for the related bit. When the compare matched conditions for each bit within a COMP block are true, the compare match output line of the COMP block becomes active.

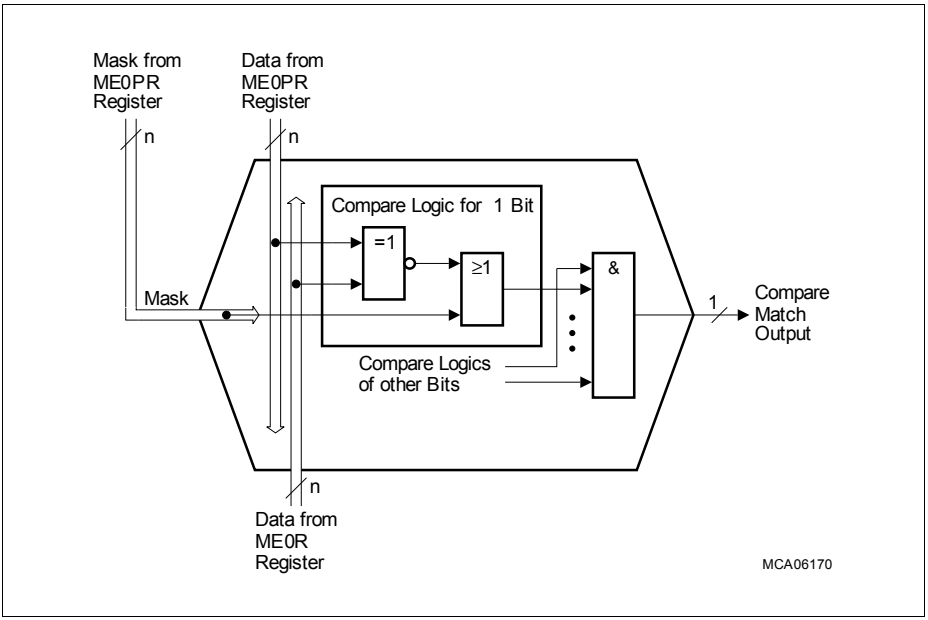

Figure 13-22 Pattern Compare Logic (COMP Block)

13.2.11.2 Pattern Detection for 8-bit Data Width

When 8-bit channel data width is selected (CHCR0n.CHDW = 00_B), the pattern detection logic is configured as shown in **Figure 13-23**. Three compare match configurations are possible.

Table 13-1 Pattern Detection for 8-bit Data Width

CHCR0n. PATSEL	Pattern Detection Operating Modes
00_B	Pattern detection disabled
01_B	Pattern compare of RD00 to PAT00, masked by PAT02
10_B	Pattern compare of RD00 to PAT01, masked by PAT03
11_B	Pattern compare of RD00 to PAT00, masked by PAT02 of the actual read move **and** Pattern compare of RD00 to PAT01, masked by PAT03 of the previous read move of SDMA channel 0n

When 8-bit channel data width is selected, the pattern detection logic allows the byte of one read move to be compared with two different patterns. Further, after each read move the pattern match result “RD00 with PAT01, masked by PAT03” is stored in bit CHCR0n.LXO. This operating mode allows, for example, two-byte sequences to be detected in an 8-bit data stream coming from a serial peripheral unit with 8-bit data width (e.g.: recognition of carriage-return, line-feed characters). A mask operation of each compared bit is possible.

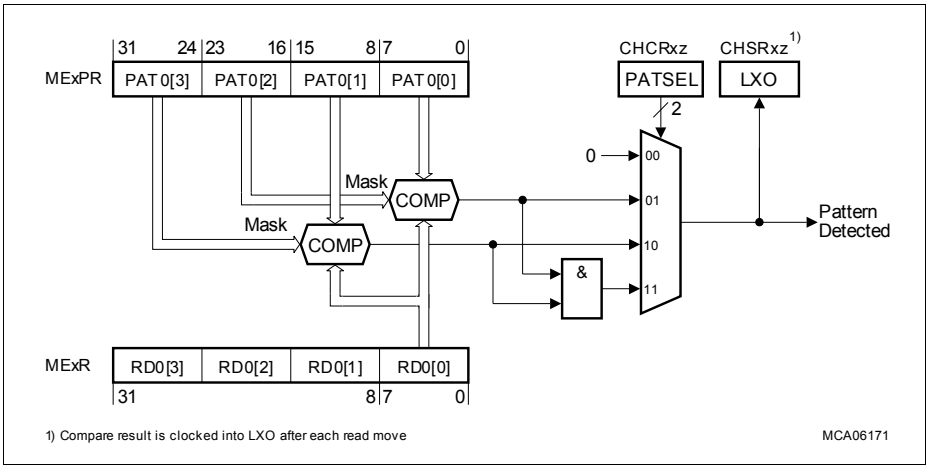

Figure 13-23 Pattern Detection for 8-bit Data Width (CHCRmn.CHDW = 00_B)

(m = 0)

13.2.11.3 Pattern Detection for 16-bit Data Width

When 16-bit channel data width is selected (CHCR0n.CHDW = 01B) the pattern detection logic can be configured as shown in **Figure 13-24**. Three compare match configurations are possible.

Table 13-2 Pattern Detection for 16-bit Data Width

CHCR0n. PATSEL	ADRCR0n. INCS	Pattern Detection Operating Modes
00_B	–	Pattern detection disabled
01_B	–	**Aligned Mode:** Pattern compare of RD0[1:0] to PAT0[1:0], masked by PAT0[3:2]
10_B	0	**Unaligned Mode 1 (Source Address Decrement):** Pattern compare of RD01 to PAT00, masked by PAT02 of the actual read move **and** Pattern compare of RD00 to PAT01, masked by PAT03 (LXO) of the previous read move of SDMA channel 0n
	1	**Unaligned Mode 2 (Source Address Increment):** Pattern compare of RD00 to PAT01, masked by PAT03 of the actual read move **and** Pattern compare of RD01 to PAT00, masked by PAT02 (LXO) of the previous read move of SDMA channel 0n
11_B	0 or 1	**Combined Mode:** Pattern compare for aligned mode (PATSEL = 01_B) **or** unaligned modes (PATSEL = 10_B)

When 16-bit channel data width is selected, the pattern detection logic makes it possible to compare the complete half-word of one read move only (aligned mode) or to compare upper and lower byte of two consecutive read moves (unaligned modes). Both modes can be combined (combined mode) too. A mask operation of each compared bit is possible.

In unaligned mode 1 (source address decremented), the high byte (RD01) of the current and the low byte (RD00) of the previous 16-bit read move are compared.

In unaligned mode 2 (source address incremented), the low byte (RD00) of the current and the high byte (RD01) of the previous 16-bit read move are compared.

If it is not known on which byte boundary (even or odd address) the 16-bit pattern to be detected is located, the combined mode should be used. This mode is the most flexible

mode that combines the pattern search capability for aligned and unaligned 16-bit data searches.

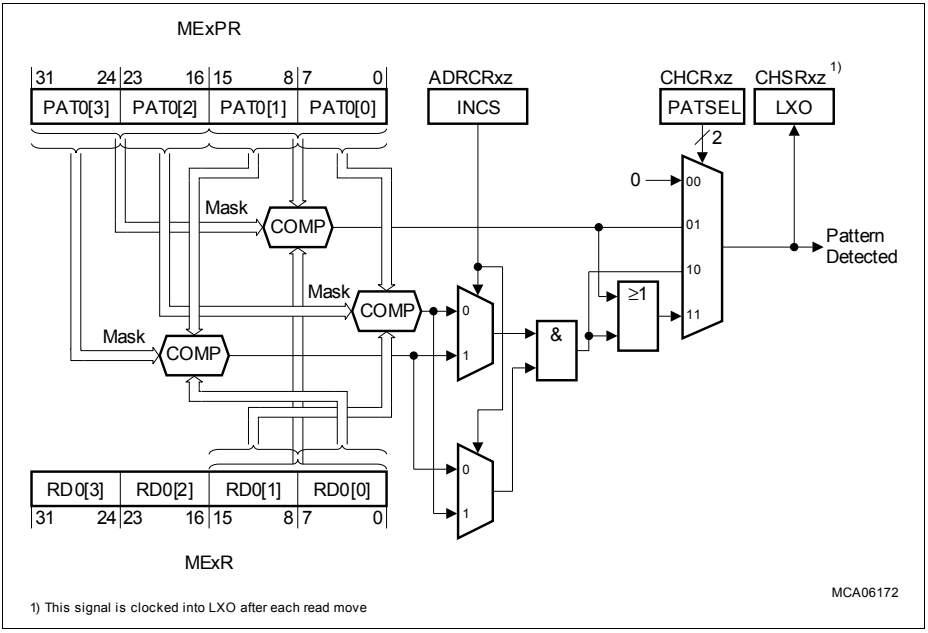

Figure 13-24 Pattern Detection for 16-bit Data Width (CHCRmn.CHDW = 01_B) (m = 0)

13.2.11.4 Pattern Detection for 32-bit Data Width

When 32-bit channel data width is selected (CHCR0n.CHDW = 10_B) the pattern detection logic is configured as shown in **Figure 13-25**. Three compare match configurations are possible.

Table 13-3 Pattern Detection for 32-bit Data Width

CHCR0n. PATSEL	Pattern Detection Operating Modes
00_B	Pattern detection disabled
01_B	Unmasked pattern compare of RD0[1:0] to PAT0[1:0]
10_B	Unmasked pattern compare of RD0[3:2] to PAT0[3:2]
11_B	Unmasked pattern compare of RD0[3:0] to PAT0[3:0]

In 32-bit channel data width mode, the pattern detection logic makes it possible to compare the lower half-word only, the upper half-word only, or the complete 32-bit word with a pattern stored in the ME0PR register. A mask operation is not possible.

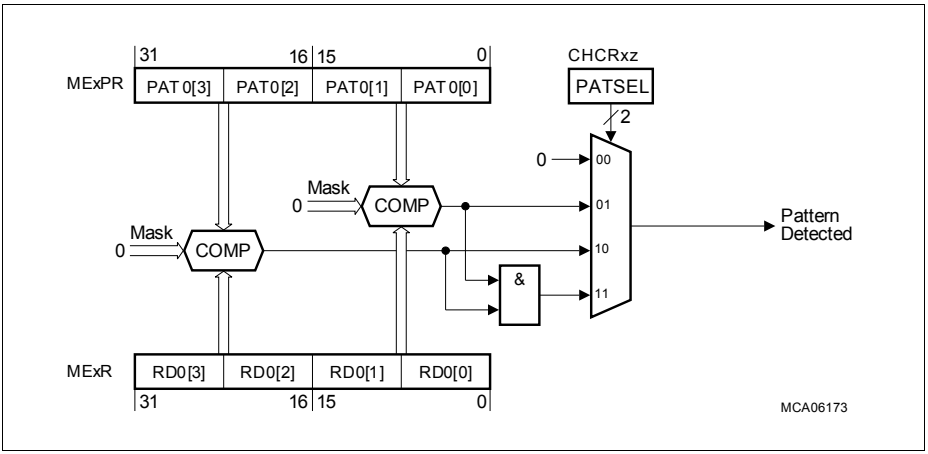

Figure 13-25 Pattern Detection for 32-bit Data Width (CHCRmn.CHDW = 10_B) (m = 0)

13.2.12 Memory Protection

The SDMA controller provides a memory protection system that makes it possible to disable read and write accesses of the Move Engine to specific parts of the memory map. Each address of a read move and write move is checked to determine if it is within the

lower and upper range limits that are enabled for the read/write access. If no address range is valid for an actual move address, a Move Engine interrupt can be generated.

Each channel has lower and upper source and destination address boundary registers. Memory protection within a channel is permanently enabled. The lower boundary register is reset to 00000000_H and the upper boundary is reset to $FFFFFFFF_H$.

13.2.13 SDMA Checksums

THE SDMA controller uses the CRC-32 IEEE 802.3 Standard polynomial to generate unique checksum calculations for the source address, destination address and read data. The source and destination address checksums are used to verify that the correct address sequence was followed. The read data checksum is calculated as a read move loads data from a data source into the SDMA controller. The checksum is used to verify the integrity of data transfers.

In order to start the generation of a checksum sequence the CRC register(s) must be initialized (e.g. written with 00000000_H or with a desired start value) and a SDMA transaction must be set up (start address, length, etc.).

The address checkums are calculated as the source or destination address changes. The read data checksum is calculated as the value in the Read Value in the Move Engine Read Register is refreshed. The checksum calculation is limited to 32-bit accesses.

13.3 SDMA Module Registers

Figure 13-26 and Table 13-5 show all registers associated with the SDMA Controller Kernel. Additionally, Table 13-5 includes the SDMA module specific registers that are shown in Figure 13-26. All SDMA kernel register names described in this section are also referenced in other parts of the TC1798 User´s Manual by the module name prefix “SDMA_”.

The registers are numbered by one index to indicate the related SDMA Sub-Block and one index to indicate the related SDMA channel: Index “m” refers to the SDMA Sub-Block number (m = 0) and Index “n” or “x” refers to the channel number (n = 0-7 or x = 0-7) within the SDMA Sub-Block.

1) The absolute register address is calculated as follows:
Module Base Address (Table 13-4) + Offset Address (shown in this column)
Further, the following ranges for parameters i, k, x, and n are valid: i = 0-7, k = 0-7, x = 0-1, n = 0-63.

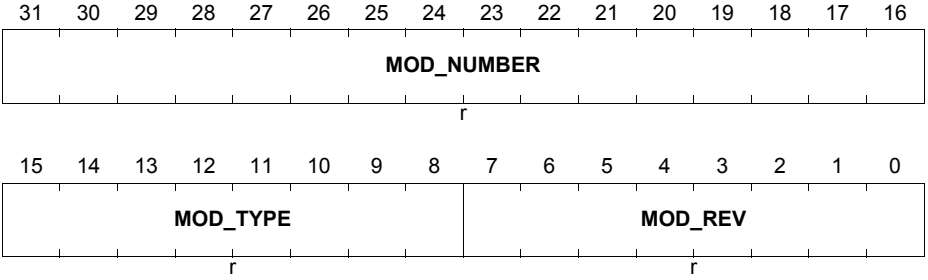
2) Write access mode to SDMA_SHADR0n is controlled by the register bit SDMA_ADRCR0n.SHWEN. SDMA_ADRCR0n.SHWEN=´0´ -> Access Mode Write for SDMA_SHADR0n is BE. SDMA_ADRCR0n.SHWEN=´1´ -> Access Mode Write for SDMA_SHADR0n is SV.

Note: Register bits marked "w" in the following register description are virtual registers and do not contain flip-flops. They are always read as 0.

13.3.1 System Registers

SDMA Module Identification Register.

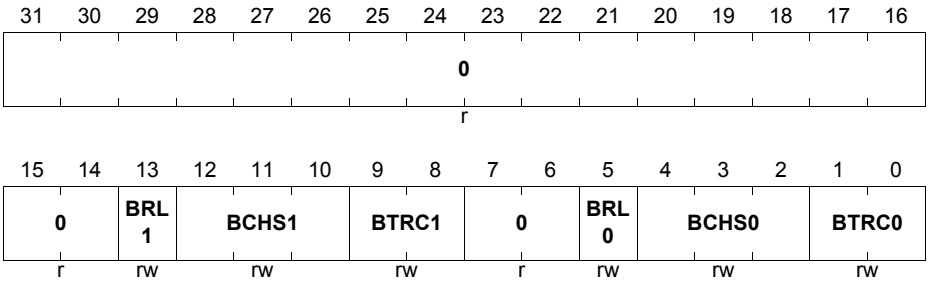
SDMA_ID
Module Identification Register **(008_H)** **Reset Value: 0087 C0XX$_H$**



Field	Bits	Type	Description
MOD_REV	[7:0]	r	**Module Revision Number** This bit field defines the module revision number. The value of a module revision starts with 01_H (first revision).
MOD_TYPE	[15:8]	r	**Module Type** The bit field is set to $C0_H$ which defines the module as a 32-bit module.
MOD_NUMBER	[31:16]	r	**Module Number Value** This bit field defines a module identification number. The value for the SDMA module is 0087_H.

The OCDS Register describes the break capability of the SDMA module. OCDSR is only reset with the OCDS Reset.

SDMA_OCDSR
SDMA OCDS Register **(064_H)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
BTRC0	[1:0]	rw	**Break Trigger Condition In Sub-Block 0** This bit field determines the transition type for the transaction request bit TRSR.CH0n that leads to a break condition in SDMA Sub-Block 0. 00_B No break condition is generated 01_B A break condition is generated when TRSR.CH0n changes from 0 to 1 10_B A break condition is generated when TRSR.CH0n changes from 1 to 0 11_B A break condition is generated when TRSR.CH0n changes its state
BCHS0	[4:2]	rw	**Break Channel Select In Sub-Block 0** This bit field determines the SDMA channel n of SDMA Sub-Block 0 whose transaction request bit TRSR.CH0n is observed for signal transitions as defined by BTRC0. 000_B SDMA channel 00 selected 001_B SDMA channel 01 selected …$_B$ … 110_B SDMA channel 06 selected 111_B SDMA channel 07 selected

Field	Bits	Type	Description
BRL0	5	rw	**Break On Request Lost in Sub-Block 0** This bit field determines whether a BREAK signal is generated for SDMA Sub-Block 0 when at least one of its eight transaction lost interrupts becomes active. 0_B No break condition is generated 1_B A break condition is generated for SDMA Sub-Block 0 when at least one of its eight transaction lost interrupts becomes active
BTRC1	[9:8]	rw	**Break Trigger Condition In Sub-Block 1** This bit field determines the transition type for the transaction request bit TRSR.CH1n that leads to a break condition in SDMA Sub-Block 1. 00_B No break condition is generated 01_B A break condition is generated when TRSR.CH1n changes from 0 to 1 10_B A break condition is generated when TRSR.CH1n changes from 1 to 0 11_B A break condition is generated when TRSR.CH1n changes its state
BCHS1	[12:10]	rw	**Break Channel Select In Sub-Block 1** This bit field determines the SDMA channel n of SDMA Sub-Block 1 whose transaction request bit TRSR.CH1n is observed for signal transitions as defined by BTRC1. 000_B SDMA channel 10 selected 001_B SDMA channel 11 selected ...$_B$ ... 110_B SDMA channel 16 selected 111_B SDMA channel 17 selected
BRL1	13	rw	**Break On Request Lost in Sub-Block 1** This bit field determines whether a BREAK signal is generated for SDMA Sub-Block 1 when at least one of its eight transaction lost interrupts becomes active. 0_B No break condition is generated 1_B A break condition is generated for SDMA Sub-Block 1when at least one of its eight transaction lost interrupts becomes active
0	[7:6], [31:14]	r	**Reserved** Read as 0; should be written with 0.

The Suspend Mode Register contains bits for each SDMA channel that allow the enabling/disabling of its soft suspend mode capability and to indicate its suspend status.

SDMA_SUSPMR
SDMA Suspend Mode Register **(068_H)** **Reset Value: $0000\ 0000_H$**

0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

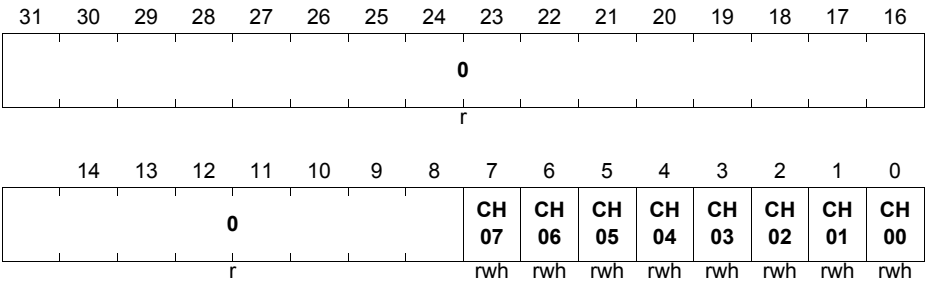
Note: In the TC1798, SR[7:0] are connected to interrupt nodes. SR[15:8] are used as SDMA channel request inputs.

13.3.2 General Control/Status Registers

The bits in the Channel Reset Request Register are used to reset SDMA channel mn.

SDMA_CHRSTR
SDMA Channel Reset Request Register

(010_H) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
CH0n (n = 0-7)	n	rwh	**Channel 0n Reset** These bits force the SDMA channel 0n to stop its current SDMA transaction. Once set by software, this bit will be automatically cleared when the channel has been reset. Writing a 0 to CH0n has no effect. 0_B No action (write) or the requested channel reset has been reset (read). 1_B SDMA channel 0n is stopped. More details see Page 13-16.
0	[31:8]	r	**Reserved** Read as 0; should be written with 0.

The bits in the Transaction Request State Register indicates which SDMA channel is processing a request, and which SDMA channel has hardware transaction requests enabled.

SDMA_TRSR
SDMA Transaction Request State Register
(014_H) **Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

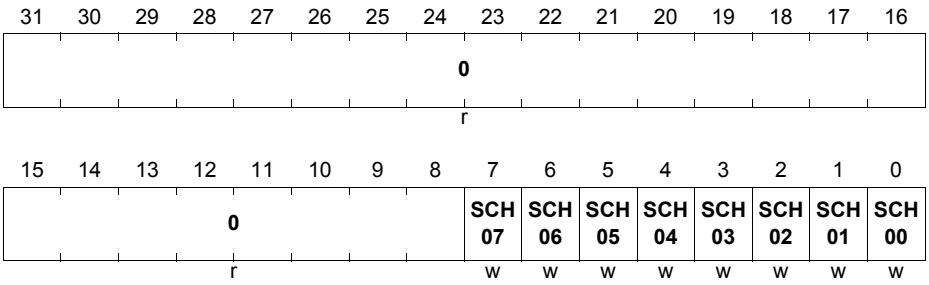
0								CH07	CH06	CH05	CH04	CH03	CH02	CH01	CH00
r								rh	rh	rh	rh	rh	rh	rh	rh

Field	Bits	Type	Description
CH0n (n = 0-7)	n	rh	**Transaction Request State of SDMA Channel 0n** 0_B No SDMA request is pending for channel 0n. 1_B A SDMA request is pending for channel 0n. CH0n is reset when a pattern match is detected.
HTRE0n (n = 0-7)	n+16	rh	**Hardware Transaction Request Enable State of SDMA Channel 0n** 0_B Hardware transaction request for SDMA Channel 0n is disabled. An input SDMA request will not trigger the channel 0n. 1_B Hardware transaction request for SDMA Channel 0n is enabled. The transfers of a SDMA transaction are controlled by the corresponding channel request line of the SDMA requesting source. HTRE0n is set to 0 when CHSR0n.TCOUNT is decremented and CHSR0n.TCOUNT = 0. HTRE0n can be enabled and disabled with HTREQ.ECH0n or HTREQ.DCH0n. HTRE0n is reset when a pattern match is detected.
0	[31:24], [15:8]	r	**Reserved** Read as 0; should be written with 0.

The bits in the Software Transaction Request Register are used to generate a SDMA transaction request by software.

SDMA_STREQ
SDMA Software Transaction Request Register
(018_H) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
SCH0n (n = 0-7)	n	w	**Set Transaction Request for SDMA Channel 0n** 0_B No action. 1_B A transaction for SDMA channel 0n is requested. When setting SCH0n, TRSR.CH0n becomes set to indicate that a SDMA request is pending for SDMA channel 0n.
0	[31:8]	r	**Reserved** Read as 0; should be written with 0.

Note: Register bits marked with "w" are virtual and are not stored in flip-flops. Reading STREQ returns 0 when read.

The bits in the Hardware Transaction Request Register enable or disable SDMA hardware requests.

SDMA_HTREQ
SDMA Hardware Transaction Request Register
($01C_H$) **Reset Value: $0000\ 0000_H$**

Field	Bits	Type	Description
ETRL0n (n = 0-7)	n	rw	**Enable Transaction Request Lost for SDMA Channel 0n** This bit enables the generation of an interrupt when the set condition for ERRSR.TRL0n is detected. 0_B The interrupt generation for a request lost event for channel 0n is disabled. 1_B The interrupt generation for a request lost event for channel 0n is enabled.
EME0SER	16	rw	**Enable Move Engine 0 Source Error** This bit enables the generation of a Move Engine 0 source error interrupt. 0_B Move Engine 0 source error interrupt is disabled. 1_B Move Engine 0 source error interrupt is enabled.
EME0DER	17	rw	**Enable Move Engine 0 Destination Error** This bit enables the generation of a Move Engine 0 destination error interrupt. 0_B Move Engine 0 destination error interrupt is disabled. 1_B Move Engine 0 destination error interrupt is enabled.

Field	Bits	Type	Description
ME0INP	[23:20]	rw	**Move Engine 0 Error Interrupt Node Pointer** ME0INP determines the number n (n = 0-15) of the service request output SRn that becomes active on a Move Engine 0 source or destination interrupt. 0000_B SR0 selected for Move Engine 0 interrupt 0001_B SR1 selected for Move Engine 0 interrupt $\ldots_B$ … 1111_B SR15 selected for Move Engine 0 interrupt *Note: In the TC1798, SR[7:0] are connected to interrupt nodes. SR[15:8] are used as SDMA channel request inputs.*
TRLINP	[31:28]	rw	**Transaction Lost Interrupt Node Pointer** TRLINP determines the number n (n = 0-15) of the service request output SRn that becomes active on a transaction lost interrupt. 0000_B SR0 selected for transaction lost interrupt 0001_B SR1 selected for transaction lost interrupt $\ldots_B$ … 1111_B SR15 selected for transaction lost interrupt *Note: In the TC1798, SR[7:0] are connected to interrupt nodes. SR[15:8] are used as SDMA channel request inputs.*
0	[15:8], [19:18], [27:24]	r	**Reserved** Read as 0; should be written with 0.

The Error Status Register indicates if the SDMA controller could not answer to a request because the previous request was not terminated (see **Section 13.2.4.4**). It indicates also the FPI Bus accesses that have been terminated with errors.

SDMA_ERRSR
SDMA Error Status Register **(024_H)** **Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

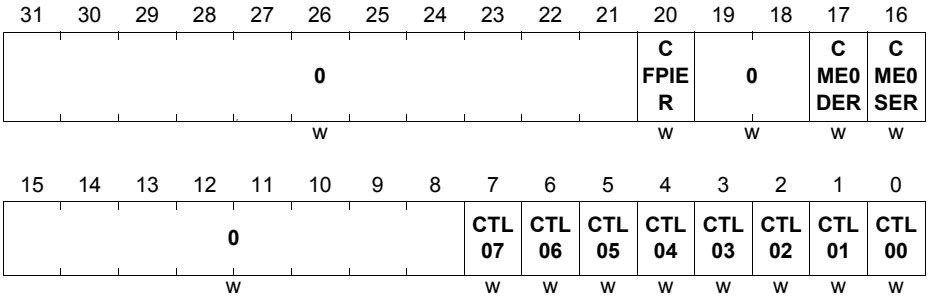
0								TRL07	TRL06	TRL05	TRL04	TRL03	TRL02	TRL01	TRL00
r								rh	rh	rh	rh	rh	rh	rh	rh

Field	Bits	Type	Description
TRL0n (n = 0-7)	n	rh	**Transaction/Transfer Request Lost of SDMA Channel 0n** 0_B 0 No request lost event has been detected for channel 0n. 1_B 1 A new SDMA request was detected while TRSR.CH0n=1 (request lost event). This bit is reset by software when writing a 1 to CLRE.CTL0n, or by a channel reset (writing CHRSTR.CH0n = 1).
ME0SER	16	rh	**Move Engine 0 Source Error** This bit is set whenever a Move Engine 0 error occurred during a source (read) move of a SDMA transfer, or a request could not been serviced due to the access protection. 0_B No Move Engine 0 source error has occurred. 1_B A Move Engine 0 source error has occurred.

Field	Bits	Type	Description
ME0DER	17	rh	**Move Engine 0 Destination Error** This bit is set whenever a Move Engine 0 error occurred during a destination (write) move of a SDMA transfer, or a request could not been serviced due to the access protection. 0_B No Move Engine 0 destination error has occurred. 1_B A Move Engine 0 destination error has occurred.
FPIER	20	rh	**SPB Error** This bit is set whenever a move that has been started by the SDMA FPI master interface leads to an error on the FPI Bus. 0_B No error occurred. 1_B An error occurred on FPI Bus interface.
LECME0	[26:24]	rh	**Last Error Channel Move Engine 0** This bit field indicates the channel number of the last channel of Move Engine 0 leading to an On Chip Bus error that has occurred.
0	[15:8], [19:18], [23:21], [31:27]	r	**Reserved** Read as 0; should be written with 0.

The Clear Error contains bits that make it possible to clear the Transaction Request Lost flags or the Move Engine error flags.

SDMA_CLRE
SDMA Clear Error Register **(028_H)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
CTL0n (n = 0-7)	n	w	**Clear Transaction Request Lost for SDMA Channel 0n** 0_B No action 1_B Clear SDMA channel 0n transaction request lost flag ERRSR.TRL0n
CME0SER	16	w	**Clear Move Engine 0 Source Error** 0_B No action 1_B Clear source error flag ERRSR.ME0SER.
CME0DER	17	w	**Clear Move Engine 0 Destination Error** 0_B No action 1_B Clear destination error flag ERRSR.ME0DER.
CFPIER	20	w	**Clear FPI Error** 0_B No action 1_B Clear error flag ERRSR.FPIER.
0	[15:8], [19:18], [31:21]	r	**Reserved** Should be written with 0.

The Interrupt Status Register indicates if CHSR0n.TCOUNT matches with CHCR0n.IRDV, or if CHSR0n.TCOUNT has been decremented (depending on CHICR0n.INTCT[0]), or if a pattern has been detected. These conditions can also generate an interrupt if enabled (see **Figure 13-17** on **Page 13-27**).

SDMA_INTSR
SDMA Interrupt Status Register (054_H) Reset Value: $0000\ 0000_H$

r								rh	rh	rh	rh	rh	rh	rh	rh

Field	Bits	Type	Description
ICH0n (n = 0-7)	n	rh	**Interrupt from Channel 0n** This bit indicates that channel 0n has raised an interrupt for TCOUNT = IRDV or if TCOUNT has been decremented (depending on CHICR.INTCT[0]. This bit (and IP0n) is reset by software when writing a 1 to INTCR.CICH0n or by a channel reset (writing CHRSTR.CH0n = 1). 0_B A channel interrupt has not been detected. 1_B A channel interrupt has been detected.
IPM0n (n = 0-7)	n + 16	rh	**Pattern Detection from Channel 0n** This bit indicates that a pattern has been detected for channel 0n while the pattern detection has been enabled. This bit (and ICH0n) is reset by software when writing a 1 to INTCR.CICH0n or by a channel reset (writing CHRSTR.CH0n = 1). 0_B A pattern has not been detected. 1_B A pattern has been detected.
0	[15:8], [31:24]	r	**Reserved** Read as 0; should be written with 0.

The Wrap Status Register provides information on the channels that perform a wraparound on their source or destination buffer(s). This condition can also lead to an interrupt if it is enabled.

SDMA_WRPSR
SDMA Wrap Status Register (05C$_H$) Reset Value: 0000 0000$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r								w	w	w	w	w	w	w	w

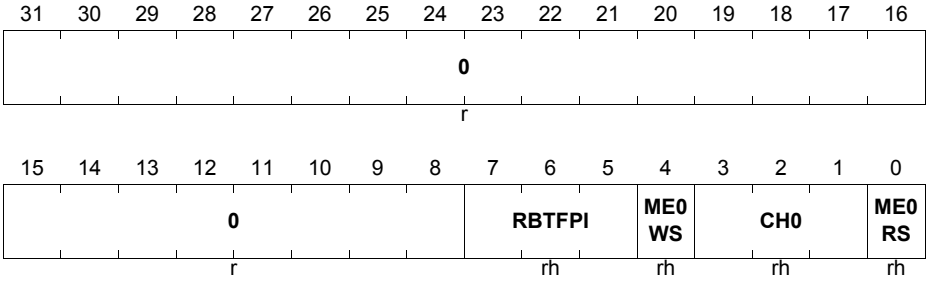
Field	Bits	Type	Description
CICH0n (n = 0-7)	n	w	**Clear Interrupt for SDMA Channel 0n** These bits allow the channel interrupt flags INTSR.ICH0n and INTSR.IPM0n of SDMA channel 0n to be reset by software. 0_B No action. 1_B Bits INTSR.ICH0n and INTSR.IPM0n are reset.
CWRP0n (n = 0-7)	n + 16	w	**Clear Wrap Buffer Interrupt for SDMA Channel 0n** These bits allow the wrap source buffer interrupt flag WRPSR.WRPS0n and the wrap destination buffer interrupt flag WRPSR.WRPD0n (both together) of SDMA channel 0n to be reset by software. 0_B No action. 1_B Bits WRPSR.WRPS0n and WRPSR.WRPD0n are reset.
0	[15:8], [31:24]	r	**Reserved** Read as 0; should be written with 0.

13.3.3 Move Engine Registers

The Move Engine Status Register is a read-only register that holds status information about the transaction handled by the Move Engines.

SDMA_MESR

SDMA Move Engine Status Register (030$_H$) **Reset Value: 0000 0000$_H$**

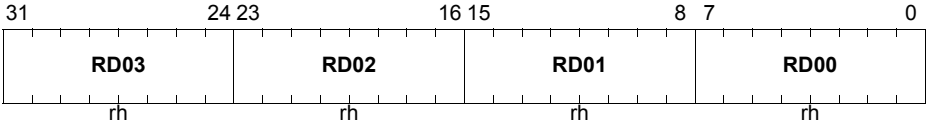


Field	Bits	Type	Description
ME0RS	0	rh	**Move Engine 0 Read Status** 0_B Move Engine 0 is not performing a read. 1_B Move Engine 0 is performing a read.
CH0	[3:1]	rh	**Reading Channel in Move Engine 0** This bit field indicates which channel number is currently being processed by the Move Engine 0.
ME0WS	4	rh	**Move Engine 0 Write Status** 0_B Move Engine 0 is not performing a write. 1_B Move Engine 0 is performing a write.
RBTFPI	[7:5]	rh	**Read Buffer Trace for FPI Bus Interface** This bit field contains trace information from the buffer in the FPI Bus Interface. In the TC1798 it indicates the source of a bus access to the FPI Bus. 000_B SDMA Move Engine 0 Other bit combinations are reserved. RBTFPI is useful for emulation purposes. It is not recommended to evaluate this bit field during normal operation of the TC1798.
0	[31:8]	r	**Reserved** Read as 0; should be written with 0.

The Move Engine 0 Read Register indicates the value that has just been read by Move Engine 0. The value in this register is compared to the bits in register ME0PR according to the bit fields CHCR0n.PATSEL.

SDMA_ME0R

SDMA Move Engine 0 Read Register (034_H) **Reset Value: $0000\ 0000_H$**

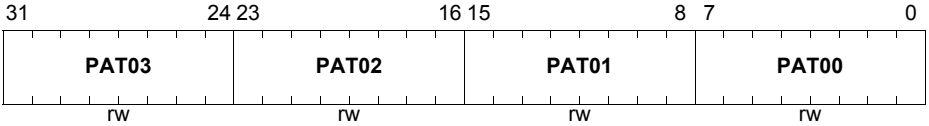


Field	Bits	Type	Description
RD00, RD01, RD02, RD03	[7:0], [15:8], [23:16], [31:24]	rh	**Read Value for Move Engine 0** Contains the 32-bit read data (four bytes RD0[3:0]) that is stored in the Move Engine after each read move. The content of ME0R is overwritten after each read move of a SDMA channel belonging to SDMA Sub-block.

The Move Engine 0 Pattern Register contains the patterns (mask and/or compare bits) to be processed by the pattern detection logic in Move Engine 0.

SDMA_ME0PR

SDMA Move Engine 0 Pattern Register($03C_H$) **Reset Value: $0000\ 0000_H$**



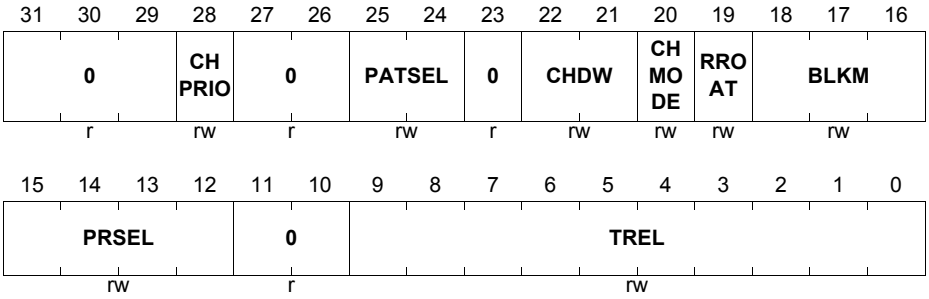
Field	Bits	Type	Description
PAT00, PAT01, PAT02, PAT03	[7:0], [15:8], [23:16], [31:24]	rw	**Pattern for Move Engine 0** Determines up to four 8-bit compare patterns/mask patterns to be processed by the pattern detection logic in Move Engine 0. Depending on the pattern detection configuration (CHCR0n.PATSEL) and channel data width (CHCR0n.CHDW), the patterns are processed as bytes or half-words.

13.3.4 Channel Control/Status Registers

The Channel Control Register for SDMA channel 0n contains its configuration and its control bits and bit fields.

SDMA_CHCR0x (x = 0-7)

SDMA Channel 0x Control Register(084_H+x*20_H) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
TREL	[9:0]	rw	**Transfer Reload Value** This bit field contains the number of SDMA transfers for a SDMA transaction of SDMA channel 0n. This10-bit transfer count value is loaded into CHSR0n.TCOUNT at the start of a SDMA transaction (when TRSR.CH0n becomes set and CHSR0n.TCOUNT = 0). A write to CHSR0n.TREL during a running SDMA transaction has no influence to the running SDMA transaction. If CHSR0n.TREL = 0 or if CHSR0n.TREL = 1, CHSR0n.TCOUNT will be loaded with 1 when a new transaction is started (at least one SDMA transfer must be executed per SDMA transaction).

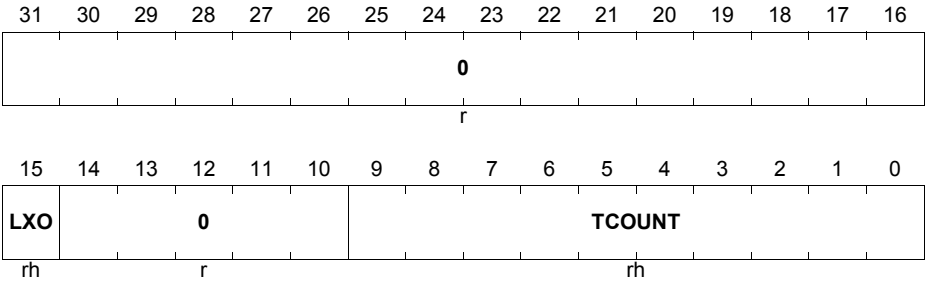
Field	Bits	Type	Description
PRSEL	[15:12]	rw	**Peripheral Request Select** This bit field controls the hardware request input multiplexer of SDMA channel 0n (see **Figure 13-6** on **Page 13-10**). 0000_B Input CH0n_REQI0 selected 0001_B Input CH0n_REQI1 selected 0010_B Input CH0n_REQI2 selected 0011_B Input CH0n_REQI3 selected 0100_B Input CH0n_REQI4 selected 0101_B Input CH0n_REQI5 selected 0110_B Input CH0n_REQI6 selected 0111_B Input CH0n_REQI7 selected 1000_B Input CH0n_REQI8 selected 1001_B Input CH0n_REQI9 selected 1010_B Input CH0n_REQI10 selected 1011_B Input CH0n_REQI11 selected 1100_B Input CH0n_REQI12 selected 1101_B Input CH0n_REQI13 selected 1110_B Input CH0n_REQI14 selected 1111_B Input CH0n_REQI15 selected
BLKM	[18:16]	rw	**Block Mode** BLKM determines the number of SDMA moves executed during one SDMA transfer. 000_B One SDMA transfer has 1 SDMA move 001_B One SDMA transfer has 2 SDMA move 010_B One SDMA transfer has 4 SDMA move 011_B One SDMA transfer has 8 SDMA move 100_B One SDMA transfer has 16 SDMA move Other bit combinations are reserved and must not be used. See also **Figure 13-10** on **Page 13-17**.
RROAT	19	rw	**Reset Request Only After Transaction** RROAT determines whether or not the TRSR.CH0n transfer request state flag is reset after each transfer. 0_B TRSR.CH0n is reset after each transfer. A transfer request is required for each transfer. 1_B TRSR.CH0n is reset when CHSR0n.TCOUNT = 0 after a transfer. One transfer request starts a complete SDMA transaction

Field	Bits	Type	Description
CHMODE	20	rw	**Channel Operation Mode** CHMODE determines the reset condition for control bit TRSR.HTRE0n of SDMA channel 0n. 0_B Single Mode operation is selected for SDMA channel 0n. After a transaction, SDMA channel 0n is disabled for further hardware requests (TRSR.HTRE0n is reset by hardware) TRSR.HTRE0n must be set again by software for starting a new transaction. 1_B Continuous Mode operation is selected for SDMA channel 0n. After a transaction, bit TRSR.HTRE0n remains set
CHDW	[22:21]	rw	**Channel Data Width** CHDW determines the data width for the read and write moves of SDMA channel 0n. 00_B 8-bit (byte) data width for moves selected 01_B 16-bit (half-word) data width for moves selected 10_B 32-bit (word) data width for moves selected 11_B Reserved
PATSEL	[25:24]	rw	**Pattern Select** This bit field selects the mode of the pattern detection logic. Depending on the channel data width, PATSEL selects different pattern detection configurations. If pattern detection is enabled (PATSEL not equal 00_B), the pattern detection interrupt line will be activated on the selected pattern match. **8-bit channel data width (CHDW = 00_B):** Selected pattern detection configuration see **Table 13-1** on **Page 13-35**. **16-bit channel data width (CHDW = 01_B):** Selected pattern detection configuration see **Table 13-2** on **Page 13-36**. **32-bit channel data width (CHDW = 10_B):** Selected pattern detection configuration see **Table 13-3** on **Page 13-38**.

Field	Bits	Type	Description
CHPRIO	28	rw	**Channel Priority** CHPRIO determines the priority of SDMA channel n for the Move Engine 0 internal channel arbitration. This priority is used for the case when multiple channels of Move Engine 0 are triggered in parallel. 0_B SDMA channel 0n has a low channel priority 1_B SDMA channel 0n has a high channel priority
0	[11:10], 23, [27:26], [31:29]	r	**Reserved** Read as 0; should be written with 0.

The Channel Status Register contains the current transfer count and a pattern detection compare result.

SDMA_CHSR0x (x = 0-7)
SDMA Channel 0x Status Register (080_H+x*20_H) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
TCOUNT	[9:0]	rh	**Transfer Count Status** TCOUNT holds the actual value of the SDMA transfer count for SDMA channel 0x. TCOUNT is loaded with the value of CHCR0x.TREL when TRSR.CH0x becomes set (and TCOUNT = 0). After each SDMA transfer, TCOUNT is decremented by 1.
LXO	15	rh	**Old Value of Pattern Detection** This bit contains the compare result of a pattern compare operation when 8-bit or 16-bit data width is selected. 8-bit data width: see **Table 13-1** and **Figure 13-23** 16-bit data width: see **Table 13-2** and **Figure 13-24** 0_B The corresponding pattern compare operation did not find a pattern match on the last move 1_B The corresponding pattern compare operation found a pattern match at the last move
0	[14:10], [31:16]	r	**Reserved** Read as 0; should be written with 0.

The Channel Interrupt Control Register controls the interrupts generation.

SDMA_CHICR0x (x = 0-7)
SDMA Channel 0x Interrupt Control Register
(088_H+x*20_H) **Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

IRDV				INTP				WRPP				INTCT		WRPDE	WRPSE
rw				rw				rw				rw		rw	rw

Field	Bits	Type	Description
WRPSE	0	rw	**Wrap Source Enable** 0_B Wrap source buffer interrupt disabled 1_B Wrap source buffer interrupt enabled
WRPDE	1	rw	**Wrap Destination Enable** 0_B Wrap destination buffer interrupt disabled 1_B Wrap destination buffer interrupt enabled
INTCT	[3:2]	rw	**Interrupt Control** 00_B No interrupt will be generated on changing the TCOUNT value. The bit INTSR.ICH0x is set when TCOUNT equals IRDV. 01_B No interrupt will be generated on changing the TCOUNT value. The bit INTSR.ICH0x is set when TCOUNT is decremented 10_B An interrupt is generated and bit INTSR.ICH0x is set each time TCOUNT equals IRDV 11_B Interrupt is generated and bit INTSR.ICH0x is set each time TCOUNT is decremented *Note: see **Figure 13-17**.*

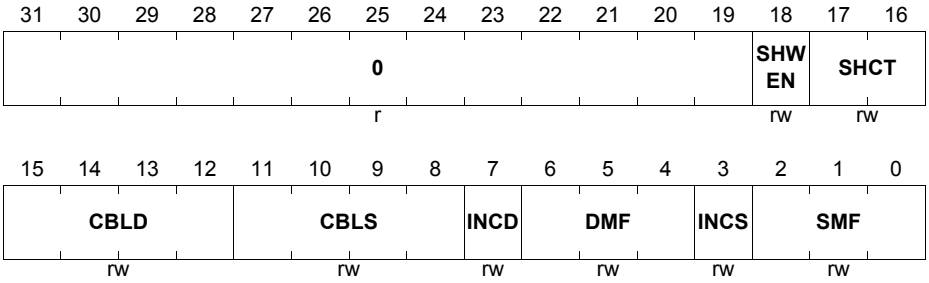
Field	Bits	Type	Description
WRPP	[7:4]	rw	**Wrap Pointer** WRPP determines the number n (n = 0-15) of the service request output SRn that becomes active on a wrap buffer interrupt. 0000_B SR0 selected for channel 0x wrap buffer interrupt 0001_B SR1 selected for channel 0x wrap buffer interrupt …$_B$ … 1111_B SR15 selected for channel 0x wrap buffer interrupt *Note: In the TC1798, SR[7:0] are connected to interrupt nodes. SR[15:8] are used as SDMA channel request inputs.*
INTP	[11:8]	rw	**Interrupt Pointer** INTP determines the number n (n = 0-15) of the service request output SRn that becomes active on a channel interrupt. 0000_B SR0 selected for channel 0x interrupt 0001_B SR1 selected for channel 0x interrupt …$_B$ … 1111_B SR15 selected for channel 0x interrupt *Note: In the TC1798, SR[7:0] are connected to interrupt nodes. SR[15:8] are used as SDMA channel request inputs.*
IRDV	[15:12]	rw	**Interrupt Raise Detect Value** These bits specify the value of CHSR0x.TCOUNT for which the Interrupt Threshold Limit should be raised.
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

Note: The interrupt node of the wrap-around interrupts is shared with the pattern match interrupt. In order to support interrupt generation in case of a pattern match, the wrap-around interrupt should be disabled. If the wrap-around interrupts are used, the pattern match interrupt should not be used. The settings are independent for each SDMA channel.

The Address Control Register controls how source and destination addresses are updated after a SDMA move. Furthermore, it determines whether or not a source or destination address register update is shadowed.

SDMA_ADRCR0x (x = 0-7)
SDMA Channel 0x Address Control Register

($08C_H$+x*20_H) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
SMF	[2:0]	rw	**Source Address Modification Factor** This bit field and the data width as defined in CHCRx.CHDW determine an address offset value by which the source address is modified after each SDMA move. See also **Table 13-7**. 000_B Address offset is 1 x CHCR0x.CHDW 001_B Address offset is 2 x CHCR0x.CHDW 010_B Address offset is 4 x CHCR0x.CHDW 011_B Address offset is 8 x CHCR0x.CHDW 100_B Address offset is 16 x CHCR0x.CHDW 101_B Address offset is 32 x CHCR0x.CHDW 110_B Address offset is 64 x CHCR0x.CHDW 111_B Address offset is 128 x CHCR0x.CHDW
INCS	3	rw	**Increment of Source Address** This bit determines whether the address offset as selected by SMF will be added to or subtracted from the source address after each SDMA move. The source address is not modified if CBLS = 0000_B. 0_B Address offset will be subtracted 1_B Address offset will be added.

Field	Bits	Type	Description
DMF	[6:4]	rw	**Destination Address Modification Factor** This bit field and the data width as defined in CHCR0x.CHDW determines an address offset value by which the destination address is modified after each SDMA move. The destination address is not modified if CBLD = 0000_B. See also **Table 13-7**. 000_B Address offset is 1 x CHDW 001_B Address offset is 2 x CHDW 010_B Address offset is 4 x CHDW 011_B Address offset is 8 x CHDW 100_B Address offset is 16 x CHDW 101_B Address offset is 32 x CHDW 110_B Address offset is 64 x CHDW 111_B Address offset is 128 x CHDW
INCD	7	rw	**Increment of Destination Address** This bit determines whether the address offset as selected by DMF will be added to or subtracted from the destination address after each SDMA move. The destination address is not modified if CBLD = 0000_B. 0_B Address offset will be subtracted 1_B Address offset will be added
CBLS	[11:8]	rw	**Circular Buffer Length Source** This bit field determines which part of the 32-bit source address register remains unchanged and is not updated after a SDMA move operation (see also **Section 13.2.4.7**). Therefore, CBLS also determines the size of the circular source buffer. 0000_B Source address SADR[31:0] is not updated 0001_B Source address SADR[31:1] is not updated 0010_B Source address SADR[31:2] is not updated 0011_B Source address SADR[31:3] is not updated $\ldots_B$ ... 1110_B Source address SADR[31:14] is not updated 1111_B Source address SADR[31:15] is not updated

Field	Bits	Type	Description
CBLD	[15:12]	rw	**Circular Buffer Length Destination** This bit field determines which part of the 32-bit destination address register remains unchanged and is not updated after a SDMA move operation (see also Page 13-19). Therefore, CBLD also determines the size of the circular destination buffer. 0000_B Destination address DADR[31:0] is not updated 0001_B Destination address DADR[31:1] is not updated 0010_B Destination address DADR[31:2] is not updated 0011_B Destination address DADR[31:3] is not updated $\ldots_B$ ... 1110_B Destination address DADR[31:14] is not updated 1111_B Destination address DADR[31:15] is not updated
SHCT	[17:16]	rw	**Shadow Control** This bit field determines whether an address is transferred into the shadow address register when writing to source or destination address register. 00_B Shadow address register not used. Source and destination address register are written directly 01_B Shadow address register used for source address buffering. When writing to SADR0x, the address is buffered in SHADR0x and transferred to SADR0x with the start of the next SDMA transaction 10_B Shadow address register used for destination address buffering. When writing to DADR0x, the address is buffered in SHADR0x and transferred to DADR0x with the start of the next SDMA transaction 11_B Reserved In case of SHCT = 01_B or 10_B, SHCT must not be changed until the next SDMA transaction has been started.

Field	Bits	Type	Description
SHWEN	18	rw	**Shadow Address Register Write Enable** This bit determines whether the shadow address register SHADR0x is read only and automatically set to 0000 0000_H or if the shadow register can also be directly written and not modified when and shadow transfer takes place. 0_B Shadow address register is read only and the value stored in the SHADR0x is automatically set to 0000 0000_H when the shadow transfer takes place 1_B Shadow address register SHADR0x can be read and can be directly written. The value stored in the SHADR0x is not automatically modified when the shadow transfer takes place
0	[31:19]	r	**Reserved** Read as 0; should be written with 0.

Table 13-7 shows the offset values that are added or subtracted to/from a source or destination address register after a SDMA move. Bit field SMF and bit INCS determine the offset value for the source address. Bit field DMF and bit INCD determine the offset value for the destination address.

Table 13-7 Address Offset Calculation Table

CHCR0n.CHDW = 00_B (8-bit Data Width)			CHCR0n.CHDW = 01_B (16-bit Data Width)			CHCR0n.CHDW = 10_B (32-bit Data Width)		
SMF DMF	**INCS INCD**	**Address Offset**	**SMF DMF**	**INCS INCD**	**Address Offset**	**SMF DMF**	**INCS INCD**	**Address Offset**

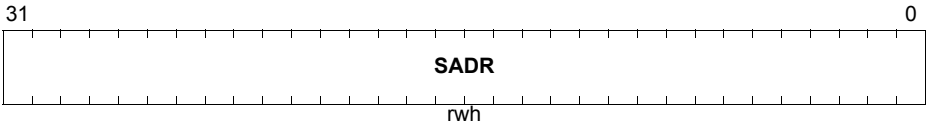
	1	+128		1	+256		1	+512

Note: CHCR0n.CHDW = 11_B is reserved and should not be used.

13.3.5 Channel Address Registers

The Source Address Register contains the 32-bit source address. If a SDMA channel 0n is active, SADR0n is updated continuously (if programmed) and shows the actual source address that is used for read moves within SDMA transfers.

SDMA_SADR0x (x = 0-7)
SDMA Channel 0x Source Address Register
(090_H+x*20_H) **Reset Value: 0000 0000_H**

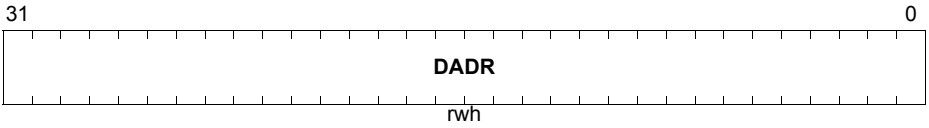


Field	Bits	Type	Description
SADR	[31:0]	rwh	**Source Start Address** This bit field holds the actual 32-bit source address of SDMA channel 0x that is used for read moves.

A write to SADR0n is executed directly only when the SDMA channel 0n is inactive (CHSR0n.TCOUNT = 0 and TRSR.CH0n = 0). If SDMA channel 0n is active when writing to SADR0n, the source address will not be written into SADR0n directly but will be buffered in the shadow register SHADR0n until the start of the next SDMA transaction. During this shadowed address register operation, bit field ADRCR0n.SHCT must be set to 01_B.

The Destination Address Register contains the 32-bit destination address. If a SDMA channel is active, DADR0n is updated continuously (if programmed) and shows the actual destination address that is used for write moves within SDMA transfers.

SDMA_DADR0x (x = 0-7)
SDMA Channel 0x Destination Address Register
(094_H+x*20_H) **Reset Value: 0000 0000_H**

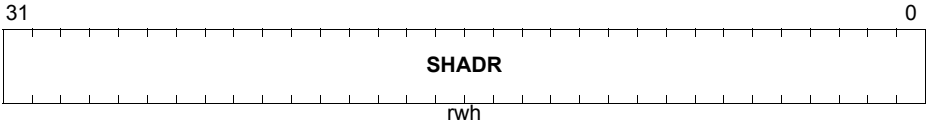


Field	Bits	Type	Description
DADR	[31:0]	rwh	**Destination Address** This bit field holds the actual 32-bit destination address of SDMA channel 0x that is used for write moves.

A write to DADR0n is executed directly only when the SDMA channel 0n is inactive (CHSR0n.TCOUNT = 0 and TRSR.CH0n = 0). If SDMA channel 0n is active when writing to DADR0n, the source address will not be written into DADR0n directly but will be buffered in the shadow register SHADR0n until the start of the next SDMA transaction. During this shadowed address register operation, bit field ADRCR0n.SHCT must be set to 10_B.

The Shadow Address Register holds the shadowed source or destination address before it is written into the source or destination address register. SHADR0n can be read only.

SDMA_SHADR0x (x = 0-7)
SDMA Channel 0x Shadow Address Register
(098_H+x*20_H) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
SHADR	[31:0]	rwh	**Shadowed Address** This bit field holds the shadowed 32-bit source or destination address of SDMA channel x.

SHADR0n is written when source or destination address buffering is selected (ADRCR0n.SHCT = 01_B or ADRCR0n.SHCT = 10_B) and a transaction is running. While the shadow mechanism is disabled, SHADR is set to 0000 0000_H.

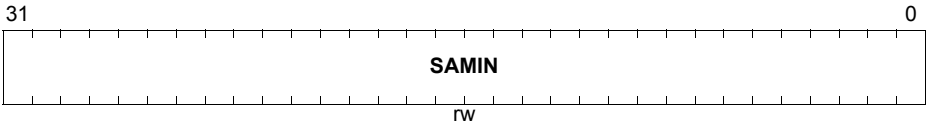
If ADRCR0n.SHWEN = 0 the value stored in the SHADR is automatically set to 0000 0000_H when the shadow transfer takes place. The user can read the shadow register in order to detect if the shadow transfer has already taken place. If the value in SHADR is 0000 0000_H, no shadow transfer can take place and the corresponding address register is modified according to the circular buffer rules.

If ADRCR0n.SHWEN = 1 shadow register SHADR0n can be directly written. The value stored in the SHADR0n is not modified when the shadow transfer takes place, the shadow mechanism remains active and the shadow transfer will be repeated until Channel 0n is reset or until the value in SHADR is 0000 0000_H, is written into the shadow register.

13.3.6 Memory Protection Registers

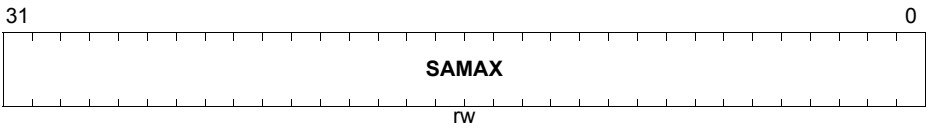
The Memory Protection Registers control the lower and upper source and destination address boundaries. Only 32-bit word accesses are permitted to the memory protection registers. Byte and half word accesses will return a bus error.

SDMA_SAMIN0x (x = 0-7)
SDMA Channel 0x Source Address Lower Boundary Register
(180_H+x*20_H) Reset Value: 0000 0000_H



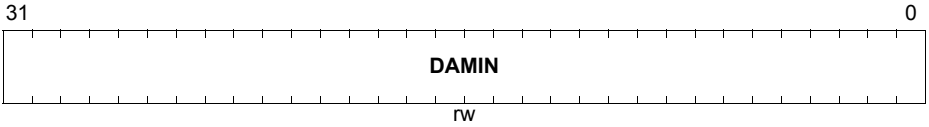
Field	Bits	Type	Description
SAMIN	[31:0]	rw	**Source Address Lower Boundary** This bit field holds the 32-bit source address lower boundary value of SDMA channel 0x that is used for read moves.

SDMA_SAMAX0x (x = 0-7)
SDMA Channel 0x Source Address Lower Boundary Register
(184_H+x*20_H) Reset Value: FFFF $FFFF_H$



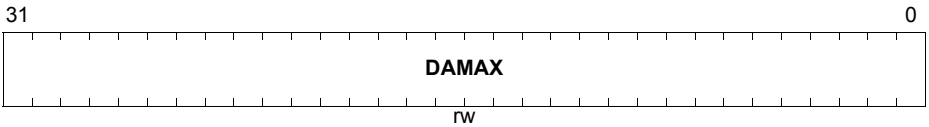
Field	Bits	Type	Description
SAMAX	[31:0]	rw	**Source Address Upper Boundary** This bit field holds the 32-bit source address upper boundary value of SDMA channel 0x that is used for read moves.

SDMA_DAMIN0x (x = 0-7)
SDMA Channel 0x Destination Address Lower Boundary Register
(188_H+x*20_H) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
DAMIN	[31:0]	rw	**Destination Address Lower Boundary** This bit field holds the 32-bit destination address lower boundary value of SDMA channel 0x that is used for write moves.

SDMA_DAMAX0x (x = 0-7)
SDMA Channel 0x Destination Address Upper Boundary Register
($18C_H$+x*20_H) **Reset Value: FFFF $FFFF_H$**



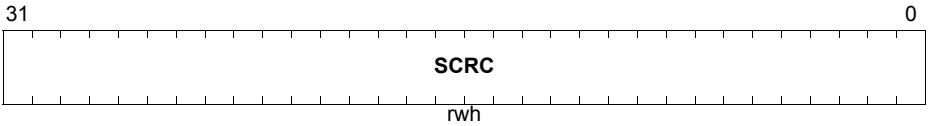
Field	Bits	Type	Description
DAMAX	[31:0]	rw	**Destination Address Upper Boundary** This bit field holds the 32-bit destination address upper boundary value of SDMA channel 0x that is used for write moves.

13.3.7 Channel CRC Registers

The Channel CRC Registers store the working CRC32 ethernet polynomial checksum. Only 32-bit word accesses are permitted to the CRC registers. Byte and half word accesses will return a bus error.

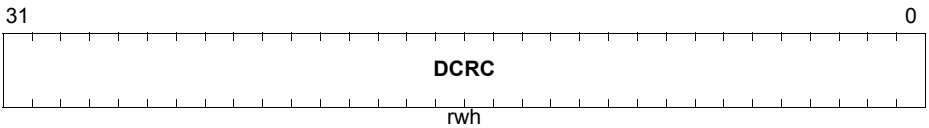
In order to start a CRC32 sequence the CRC registers must be initialized (e.g. written with 00000000_H or with a desired start value) and an SDMA transaction must be set up (start address, length, etc.). During each SDMA Move a read move loads data from a data source to the SDMA Controller and a write move puts data from the SDMA controller to a DMA destination. During an SDMA Move each CRC register will perform one polynomial checksum calculation.

SDMA_SCRC0x (x = 0-7)
SDMA Channel 0x Source Address CRC Register
(190_H+x*20_H) **Reset Value: 0000 0000_H**



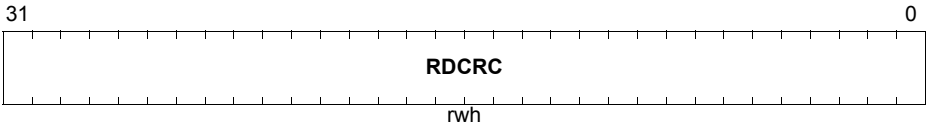
Field	Bits	Type	Description
SCRC	[31:0]	rwh	**Source Address CRC** This bit field contains the working CRC32 ethernet polynomial checksum for the source address.

SDMA_DCRC0x (x = 0-7)
SDMA Channel 0x Destination Address CRC Register
(194_H+x*20_H) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
DCRC	[31:0]	rwh	**Destination Address CRC** This bit field contains the working CRC32 ethernet polynomial checksum for the destination address.

SDMA_RDCRC0x (x = 0-7)
SDMA Channel 0x Read Data CRC Register
(198_H+x*20_H) **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
RDCRC	[31:0]	rwh	**Read Data CRC** This bit field contains the working CRC32 ethernet polynomial checksum for read data.

13.4 SDMA Module Implementation

This section describes the TC1798 SDMA module interfaces with the clock control, interrupt control, and address decoding.

Figure 13-27 shows the TC1798-specific implementation details and interconnections of the SDMA module. The SDMA module is supplied with a separate clock control, address decoding, interrupt control, and the request input wiring matrix.

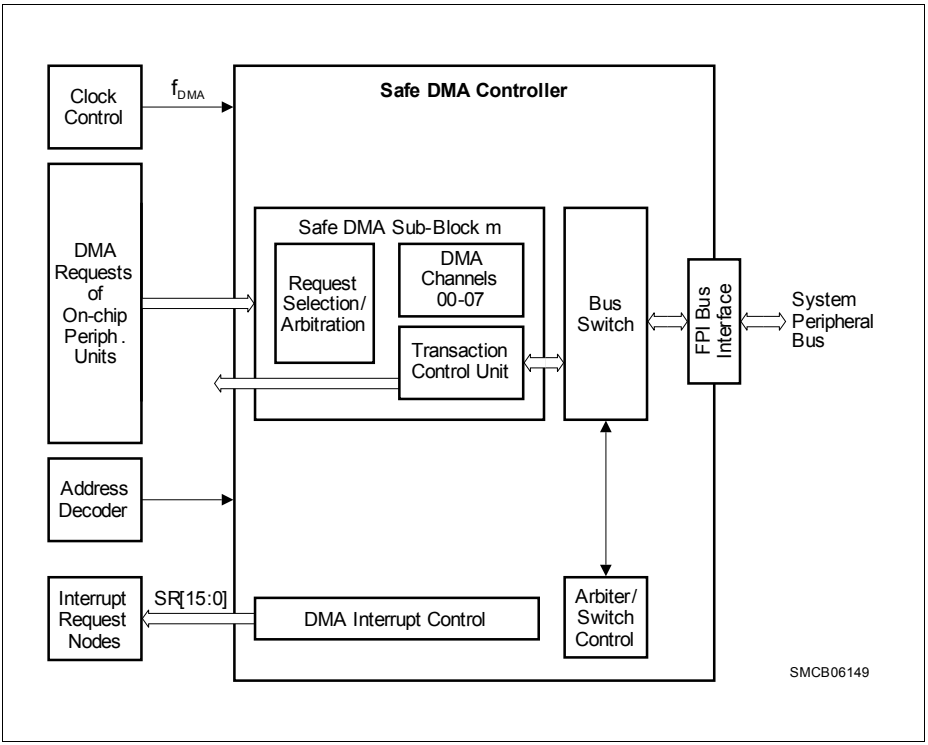


Figure 13-27 SDMA Module Implementation and Interconnections

The request sources of the peripheral modules (ADC0, MultiCAN, and SCU) are associated with Interrupt Node Pointers and individual interrupt enable bits. As a result, each of the internal requests of a module can be routed independently to any of the interrupt output lines (INT_Ox) of the module.

13.4.1 SDMA Request Wiring Matrix

The SDMA request input lines of each SDMA channel within the SDMA Sub-Block are connected to request output lines from the peripheral modules according to **Table 13-8**.

Table 13-8 SDMA Request Assignment for SDMA Sub-Block

13.4.2 Implementation-specific SDMA Registers

The SDMA controller as implemented in the TC1798 contains the following additional registers:

- SDMA clock control register
- Service request control registers for SDMA controller interrupts (SDMA_SRCx)

Figure 13-28 provides an overview of these registers.

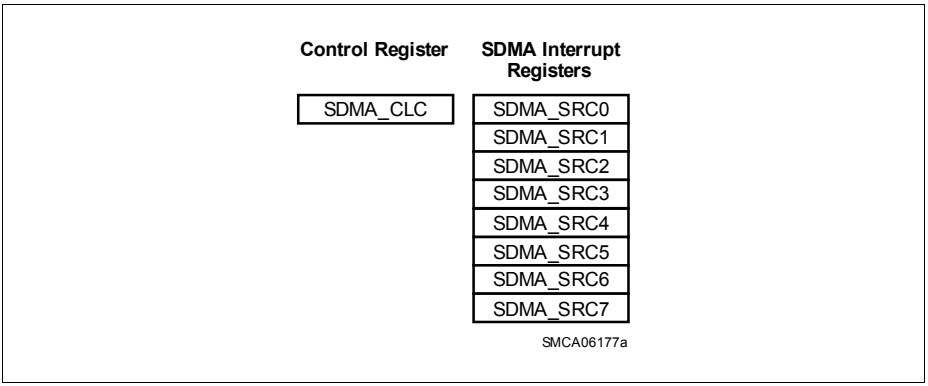

Figure 13-28 SDMA Implementation-specific Registers

Note: Further details on interrupt handling and processing are described in the "Interrupt System" chapter of the TC1798 System Units User´s Manual.

The clock generation and interrupt control configuration as implemented in the SDMA controller module is shown in **Figure 13-29**.

The SDMA controller is supplied from a common module clock f_{SDMA} that has the frequency of the FPI-Bus clock f_{FPI} and is controlled via the SDMA_CLC clock control register.

The SDMA controller module contains in total 8 interrupt request nodes with its interrupt service request control registers:

- Eight interrupt requests SR[7:0] = INT_O[7:0] from the SDMA controller; upper eight interrupt requests of the SDMA controller INT_O[15:8] are used as SDMA channel trigger inputs.

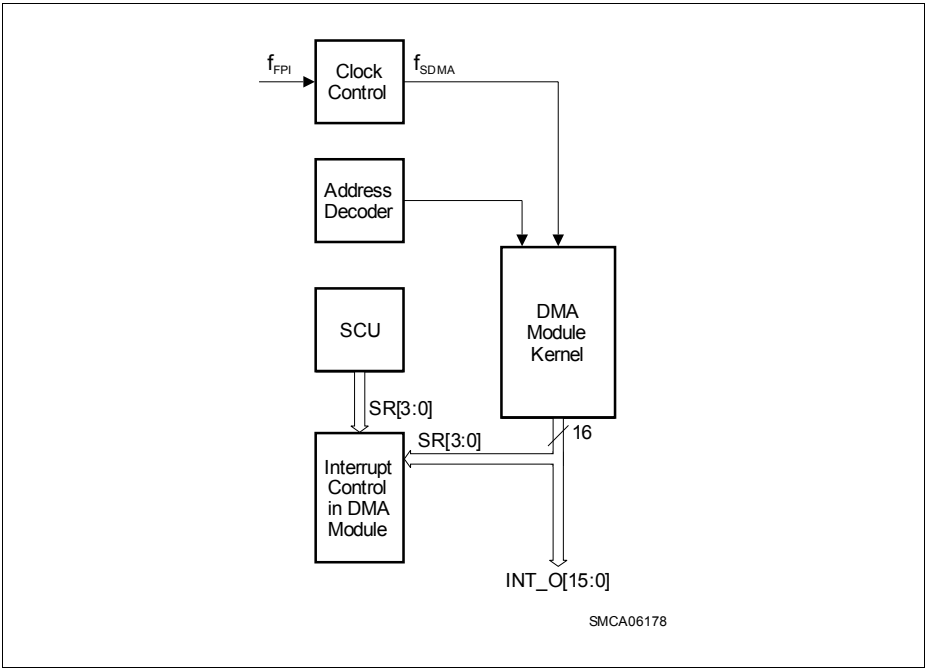

Figure 13-29 Implementation of the SDMA Module

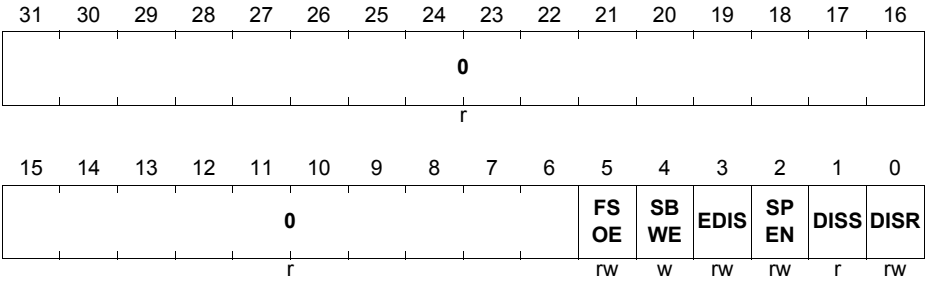
13.4.2.1 Clock Control Register

The Clock Control Register controls the SDMA module internal f_{SDMA} clock signal.

SDMA_CLC
SDMA Clock Control Register (000_H) Reset Value: 0000 0000_H



Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module
DISS	1	r	**Module Disable Status Bit** Bit indicates the current status of the module
SPEN	2	rw	**Module Suspend Enable for OCDS** Used to enable the Suspend Mode
EDIS	3	rw	**Sleep Mode Enable Control** Used for module sleep mode control. 0_B Sleep mode request is regarded. Module is enabled to go into sleep mode. 1_B Sleep mode request is disregarded. Sleep mode cannot be entered on a request.
SBWE	4	w	**Module Suspend Bit Write Enable for OCDS** Determines whether SPEN and FSOE are write-protected.

Field	Bits	Type	Description
FSOE	5	rw	**Fast Switch Off Enable** Used for fast clock switch-off in Suspend Mode. 0_B Clock switch-off in Suspend Mode via Disable Control Feature (Secure Clock Switch Off) selected 1_B Fast clock switch off in Suspend Mode selected This bit can be written only if SBWE is set during the same write operation.
0	[31:6]	r	**Reserved** Read as 0; should be written with 0.

Note: After a hardware reset operation, the SDMA module is enabled.

Note: The suspend mode does not modify any of the registers.

13.4.2.2 SDMA Interrupt Registers

In the TC1798, the lower eight SDMA controller interrupts SR[7:0] are connected to service request control registers. The upper eight SDMA controller interrupt outputs SR[15:8] are used as SDMA channel request inputs.

SDMA_SRCx (x = 0-7)
SDMA Service Request Control Register x

13.4.3 Address Map

The SDMA controller register block address map is shown in **Figure 13-30**. It shows how the different register blocks are arranged and adds the absolute address information.

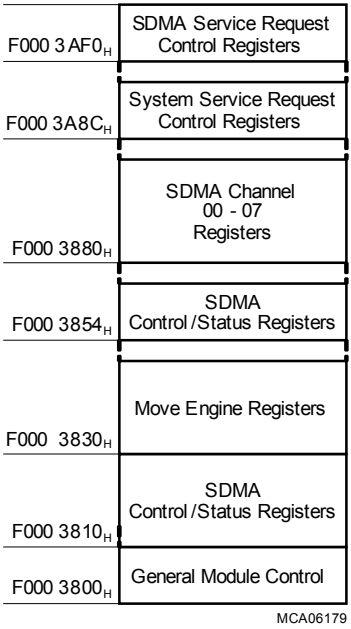

Figure 13-30 SDMA Controller Register Block Address Map

14 Flexible CRC Engine (FCE)

This document describes the Flexible CRC Engine (FCE) module. The FCE provides a parallel implementation of one or more Cyclic Redundancy Code (CRC) algorithms. The current FCE version for the TC1798 microcontroller implements the IEEE 802.3 ethernet CRC32 and the Castagnoli CRC32C polynomials. FCE's generic structure enables it to be extended with multiple CRC polynomials. The primary target of FCE is to be used as an hardware acceleration engine for software applications or operating systems services (compatible with Autosar CRC "specification of CRC Routines") using CRC signatures. CRC algorithms are commonly used to calculate unique message signatures that can be used to check message integrity during transport over communication channels like internal busses or interfaces between micro-controllers. CRC signatures are also suitable to sign blocks of data residing in variable or invariable storage elements. Signatures computed based on polynomial division provide a very high bit error detection capability. The FCE operates as a standard FPI bus slave peripheral and is fully controlled through a set of configuration and control registers.

This chapter is structured as follows:

- **"FCE Features" on Page 14-3**
- **"Operational overview" on Page 14-4**
- **"FCE Functional Description" on Page 14-6**
- **"FCE Module Registers" on Page 14-14**
- **"Interfaces of the FCE Module" on Page 14-13**
- **"Programming Guide" on Page 14-28**
- **"Properties of CRC code" on Page 14-31**

*Note: The FCE kernel register names described in **"FCE Module Registers" on Page 14-14** are referenced in a product User´s Manual by the module name prefix "FCE_".*

Note: The FCE may in the future be used as well in a 16-bit microcontroller. There is no such requirement currently, but this possible extension can already be considered during the development phase.

14.2 FCE Features

The FCE provides the following features:

- Architecture supports up to 4 different CRC polynomials. Current FCE version implements:
  - IEEE 802.3 CRC32 ethernet polynomial: 0x82608EDB[1)] (crc kernel 0)
  - CRC32C Castagnoli polynomial: 0x8F6E37A0 (crc kernel 1)
- Parallel CRC implementation (32-bits wide)
  - Data blocks to be computed by FCE shall be a multiple of 32-bits
  - Start address of Data blocks to be computed by FCE shall be at least 32-bits aligned
- Only 32-bit write accesses are allowed to the kernel input register.
  - 8 or 16-bit write accesses to the configuration registers are supported.
- Register Interface compliant with Autosar specification for CRC routines. Enables to support reentrant software routines via a software-based save/restore mechanism.
- Extended register interface to control reliability of FCE execution.
- Critical Registers controlling the FCE operation are implemented redundant to capture transient errors
- Error notification scheme via dedicated interrupt node for:
  - transient error detection: error interrupt generation (maskable) with local status register (cleared by software)
  - Checksum failure: error interrupt generation (maskable) with local status register (cleared by software)
- FCE implements its own Interrupt Service Node

1) The polynomial hexadecimal representation covers the coefficients 32 down to 1 (x^0 is implicit) enabling to use 32-bits to characterize the polynomial.

14.3 Operational overview

The FCE is a standard FPI slave module. The FCE is fully synchronous with the FPI bus and runs with a 1:1 clock ratio. It connects to the FPI peripheral bus of a micro-controller.

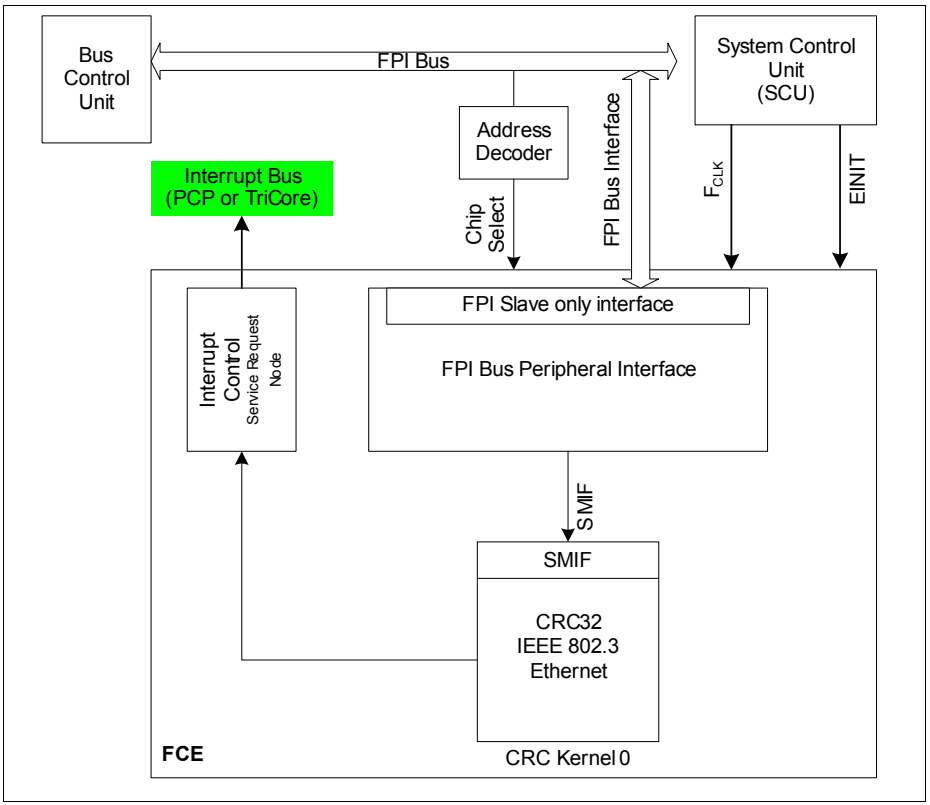

Figure 14-1 FCE system integration: single CRC kernel

The FCE operation is controlled over a set of memory mapped registers. The main purpose is to serve as hardware acceleration for software applications requiring CRC checksum computation. The register set has been designed to enable the FCE. Depending on the hardware configuration the FCE may implement more crc kernels with different CRC polynomials. The specific configuration for a product will be described into the product customizing chapter. Every crc kernel will present the same hardware and software architecture. The rest of this document will focus only on the description of the generic CRC kernel architecture. The **Figure 14-2** shows a multi kernel configuration.

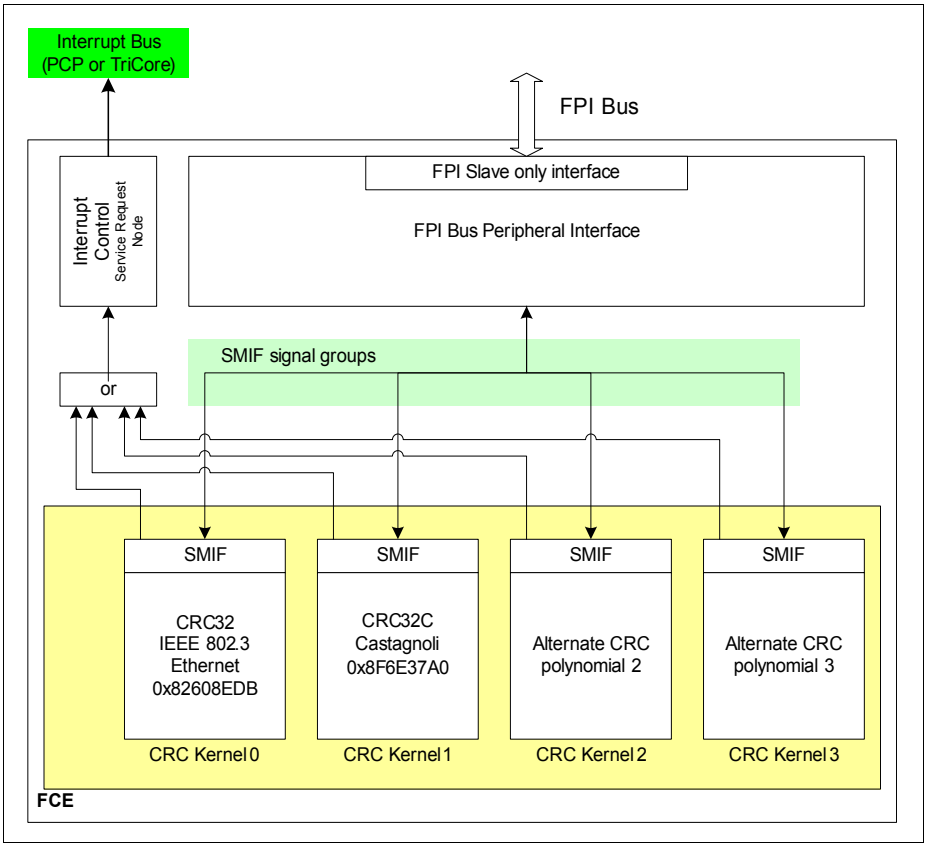

Figure 14-2 FCE system integration: multi-crc kernels

In a multi-kernel implementation the interrupt lines are ored together, the FCE only present a single interrupt node to the system. Each crc kernel implements a status register that enables the software to identify which interrupt source is active. Please refer to the STS register description for a detailed description of the status and interrupt handling.

14.4 FCE Functional Description

.

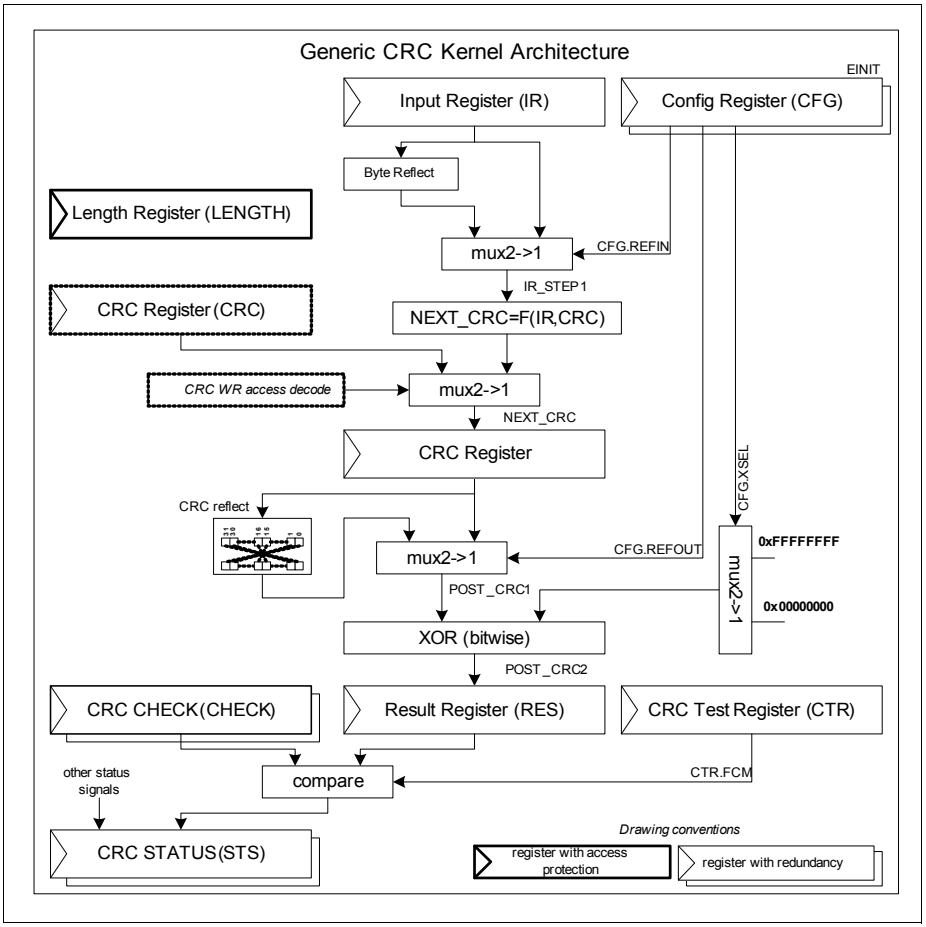

Figure 14-3 CRC kernel architecture

A checksum algorithm based on CRC polynomial division is characterized by the following properties:

- [1] polynomial degree (e.g. 32, that represents the highest power of two of the polynomial)
- [2] polynomial (e.g. 0x04C11DB7: the 33rd bit is omitted because always equal to 1)
- [3] init value: the initial value of the CRC register

- [4] input data reflected: indicates if each byte of the input parallel data is reflected before being used to compute the CRC
- [4] result data reflected: indicates if the final CRC value is reflected or not
- [5] XOR value: indicates if a final XOR operation is done before returning the CRC result

All the properties are static once a polynomial has been chosen. However the FCE provides the capability to control the two reflection steps and the final xor as depicted in **Figure 14-3** through the CFG register. The reset values are compatible with the implemented algorithm. The final xor control enables to select either 0xFFFFFFFF or 0x00000000 to be xored with the POST_CRC1 (see **Figure 14-3**) value. These two values are those used by the most common CRC polynomials.

Note: The reflection steps and final XOR do not modify the properties of the CRC algorithm in terms of error detection, only the CRC final signature is affected.

CRC operation

Software must first ensure that the CRC kernel is properly configured, especially the initial CRC register value written via the **CRC** register. If the software whishes to use the automatic signature check at the end of a message, the LENGTH register and CHECK registers must be configured with respectively the length (as number of 32-bit words) of the message and the expected signature (**CHECK**). The **CHECK** value takes into account the final CRC reflection and XOR operation. The self check is enable by the **CFG.CCE** bit field.

Property:
If the input message M1 consists of a message M0 appended with the CRC signature of M0, then the CRC signature of M1 shall be 0.

The software writes as many times as necessary into the **IR** register according to the length of the message. If **CFG.CCE** bit field is set, every time the IR register is written, the LENGH register is decremented by one. If **LENGTH** is already at zero but software still writes to **IR** (by mistake) every bit of the **LENGTH** should be set to 1 and hold this value until software initializes it again for the processing of a new message. In such case the STS.MLF (Message Length Flag) should be set and an interrupt generated if the CFG.MLE (Message length Error) is set. The hardware monitors the transition of the **LENGTH** register from 1 to 0 to detect the end of the message and proceed with the comparison of the POST_CRC2 (see **Figure 14-3**) value with the **CHECK** register value.

The next two figures provides an overview of the control and status features of a CRC kernel.

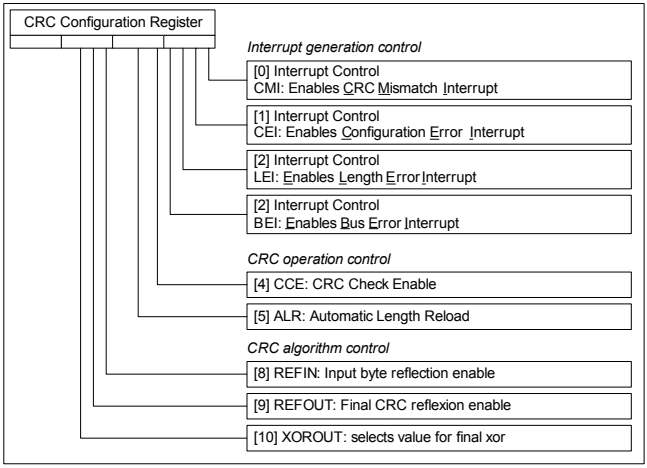

Figure 14-4 CRC kernel configuration register

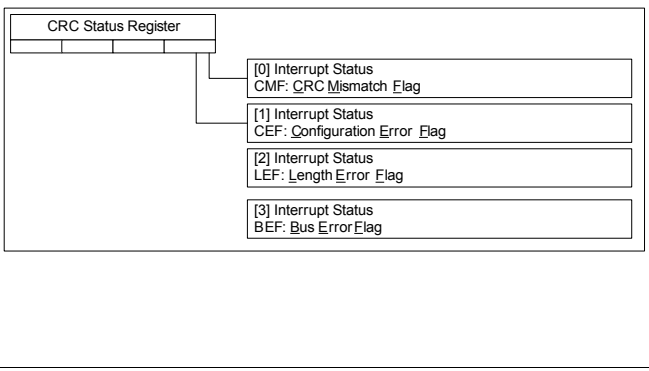

Figure 14-5 CRC kernel status register

Register Protection and Monitoring methods

Register Monitoring: applied to CFG and CHECK registers

Because CFG and CHECK registers are critical to the CRC operation, some mechanisms to detect and log transient errors are provided. Early detection of transient failures enables to improve the failure detection time and asses the severity of the failure. The monitoring mechanisms are implemented using two redundant instances as presented in **Figure 14-6**.

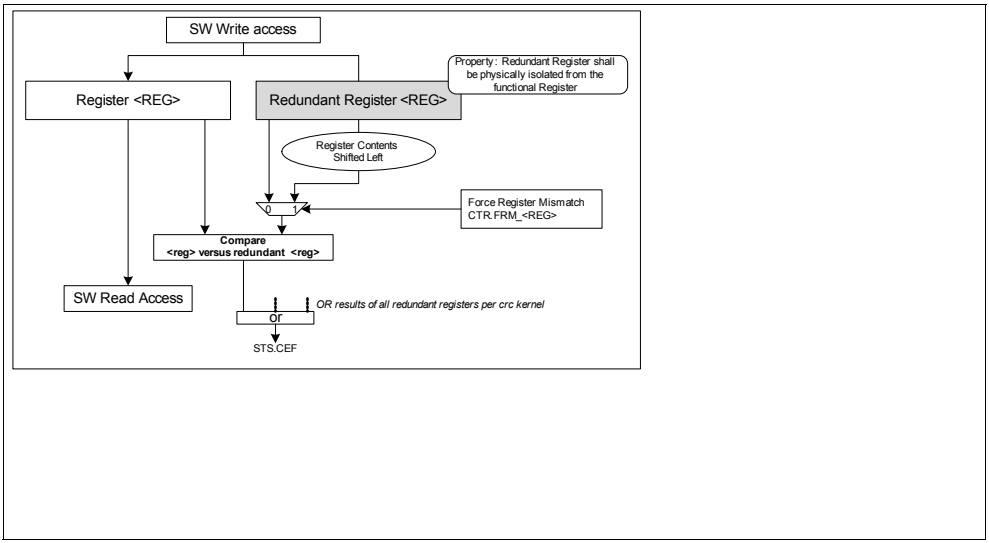

Figure 14-6 Register monitoring scheme

Let <REG> designate either CFG or CHECK registers. When a write to <REG> takes place a copy of the redundant register is also updated. **Redundant registers are not visible to software**. Bits of <REG> reserved have no storage and are not used for redundancy. A compare logic continuously compares the two stored values and provides a signal that indicates if the compare is successful or not. The result of all compare blocks are ored together to provide a single flag information. If a mismatch is detected the **STS.CEF** (Configuration Error Flag) bit is set. For run-time validation of the compare logic a Force Register Mismatch bit field (**CTR.FRM_<REG>**) is provided. When set to 1 by software the contents of the redundant register is shifted left by one bit position (redundant bit 0 position is always replaced by a logical 0 value) and is given to the compare logic instead of the redundant register value. This enables to check the compare logic is functional. Using a walking bit pattern, the software can completely check the full operation of the compare logic.

Register Access Protection: applies to LENGTH and CHECK registers

In order to reduce the probability of a mis-configuration of the CHECK and LENGTH registers (in the case the automatic check is used), the write access to the CHECK and LENGTH registers must follow the procedure depicted in **Figure 14-7**:

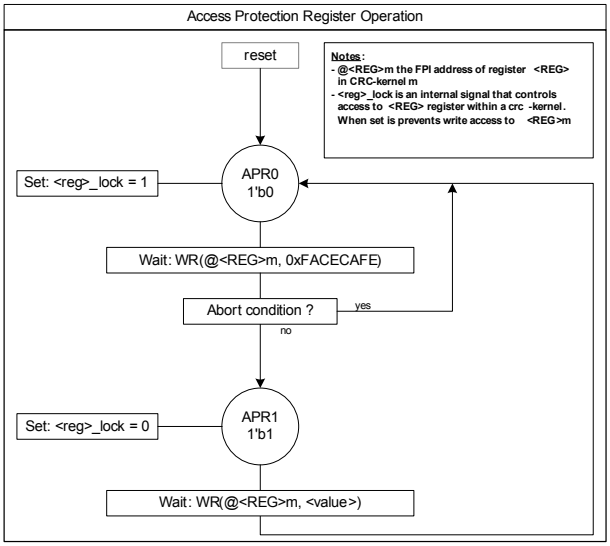

Figure 14-7 Access control to CHECK register

Let **<REG>** designate **CHECK** or **LENGTH** registers. Before being able to configure a new <value> value into the CHECK register of a crc kernel, software must first write the 0xFACECAFE value to the CHECK address. The 0xFACECAFE is not written into the CHECK register. The next write access will proceed as a normal FPI write access. This procedure will then be repeated every time software wants to configure a new <REG> value. If software reads the CHECK register just after writing 0xFACECAFE it returns the current <REG> contents and not 0xFACECAFE. **A read access to <REG> has no effect on the protection mechanism**.

FCE interrupts

Each FCE crc kernel provides one internal interrupt source. The interrupt lines from each crc kernel are ored together to be sent to the FCE interrupt control block that implements the standard interrupt node logic and register. When multiple crc kernels are present within a FCE, the interrupt lines from each crc kernel are ored together to provide a single interrupt source to the interrupt control block. If the interrupt from the FCE is arbitrated, the FCE interrupt handler must use the status information located within the **STS** status register of each crc kernel.

Each crc kernel provides the following interrupt sources:

- CRC Mismatch Interrupt controlled by **CFG.CMI** bit field and observable via the status bit field **STS.CMF** (CRC Mismatch Flag).
- Configuration Error Interrupt controlled by **CFG.CEI** bit field and observable via the status bit field **STS.CEF** (Configuration Error Flag).
- Length Error Interrupt controlled by **CFG.LEI** bit field and observable via the status bit field **STS.LEF** (Length Error Flag).
- FPI Error Interrupt controlled by **CFG.FEI** bit field and observable via the status bit field **STS.FEF** (FPI Error Flag).

Interrupt generation rules

- A status flag shall be cleared by software by writing a **1** to the corresponding bit position.
- If an status flag is set and a new hardware condition occurs, no new interrupt is generated by the kernel: the STS.<FLAG> bit field masks the generation of a new interrupt from the same source. If a SW access to clear the interrupt status bit takes place and in the same cycle the hardware wants to set the bit, the hardware condition wins the arbitration.

As all the interrupts are caused by an error condition, the interrupt shall be handled by a Error Management software layer. The software services using the FCE as acceleration engine may not directly deal with error conditions but let the upper layer using the service to deal with the error handling.

14.5 Interfaces of the FCE Module

The FCE module implements its own interrupt node, therefore implements an interface to the TriCore and PCP interrupt controllers. For protection purposes it uses the EINIT information to control the configuration of critical resources. The EINIT protection is described in the register chapter.

Table 14-1 Generic FCE Digital Connections

Signal	from/to Module	I/O to FCE
EINIT	SCU	I

14.6 FCE Module Registers

Figure 14-8 and Table 14-3 show all registers associated with a FCE crc-kernel. All FCE kernel register names are described in this section. They should get the prefix “FCE_” when used in the context of a product specification.

The registers are numbered by one index to indicate the related FCE CRC Kernel (m = 0-1).

FCE Registers Overview

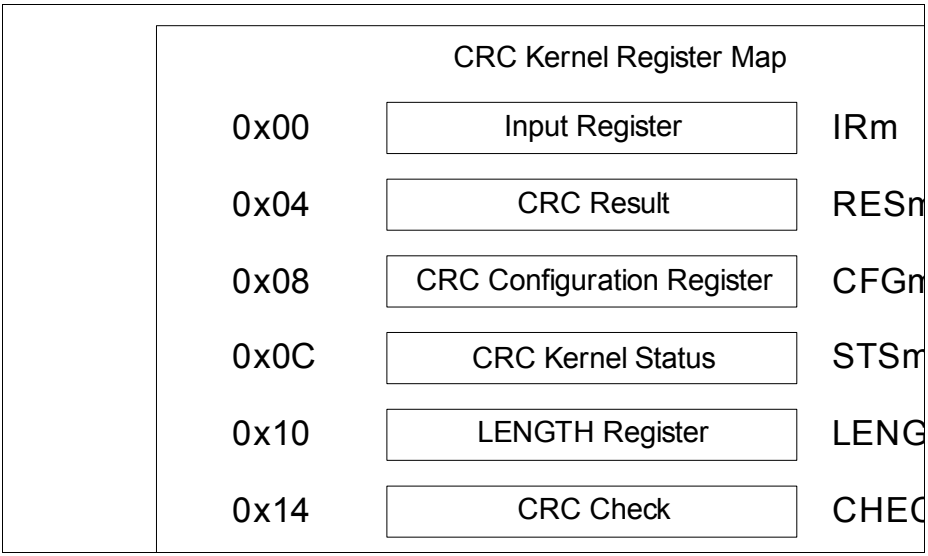

Figure 14-8 FCE Kernel Registers

Figure 14-9 shows the FCE module register map. The system registers region comprises the interrupt service request node and module identifier registers.

1) The absolute register byte address for each crc kernel m is calculated as follows:
CRC kernel register base Address (Table 14-2) + m*20H, m = 0-1

Access Mode Rules

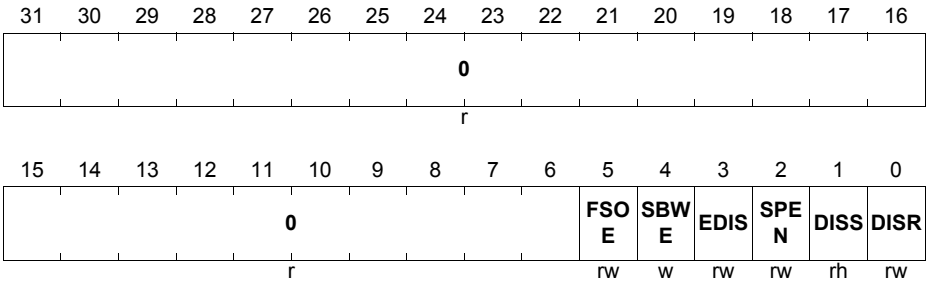
The Table 14-3 “Registers Overview - CRC Kernel Registers” on Page 14-15 uses the standard access mode conventions.

- **E** indicates that an access is only possible if the **end of initialization** signal from the System Control Unit is active. In this case Supervisor Mode (SV) is also mandatory.
- When U, SV are both listed it means that a read or write access can be done either in user mode (U) or supervisor mode (V).
- BE stands for Bus Error, NSC stands for No Special Condition.

14.6.1 System Registers

FCE Module Clock Control Register. This register is global to FCE and not part of a crc kernel. FCE does not implement a fractional divider, the FCE kernel (when enabled) always runs with the peripheral bus clock.

FCE_CLC
Control Clock Register **(00_H)** **Reset Value: 0000 0003$_H$**



Field	Bits	Type	Description
DISR	0	rw	**Module Disable Bit Request** Used for enable/disable control of the module 0_B Module disable is not requested 1_B Module disable is requested
DISS	1	rh	**Module Disable Bit Status** Bit indicates the current status of the module 0_B Module is enabled 1_B Module is disabled
SPEN	2	rw	**Module Suspend Enable** Used for enabling the Suspend Mode. 0_B Module cannot be suspended (suspend is disabled) 1_B Module can be suspended (suspend is enabled) This bit can be written only if SBWE is set during the same write operation.

Field	Bits	Type	Description
EDIS	3	rw	**Sleep Mode Enable Control** Used for module Sleep Mode control. 0_B Sleep Mode request is regarded. Module is enabled to go into Sleep Mode. 1_B Sleep Mode request is disregarded: Sleep Mode cannot be entered on a request.
SBWE	4	w	**Module Suspend Bit Write Enable for OCDS** Determines whether SPEN and FSOE are write-protected. 0_B Bits SPEN and FSOE are write-protected 1_B Bits SPEN and FSOE are overwritten by respective value of SPEN or FSOE Reading this bit returns always 0.
FSOE	5	rw	**Fast Switch Off Enable** Used for fast clock switch-off in Suspend Mode. 0_B Clock switch-off in Suspend Mode via Disable Control Feature (Secure Clock Switch Off) selected 1_B Fast clock switch off in Suspend Mode selected This bit can be written only if SBWE is set during the same write operation.
0	[31:6]	r	**Reserved** Read as 0; should be written with 0.

FCE_SRC

Service Request Control Register (FC_H) Reset Value: 0000 0000$_H$

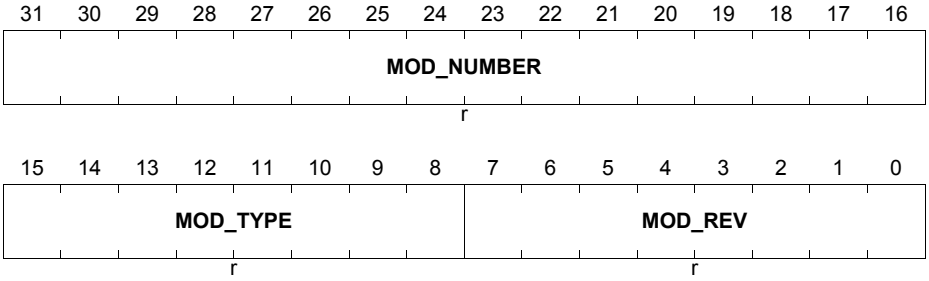
w	w	rwh	rw	r	rw	r		rw							

Field	Bits	Type	Description
SRPN	[7:0]	rw	**Service Request Priority Number** 00_H Service request is never serviced 01_H Service request is on lowest priority ... FF_H Service request is on highest priority
TOS	10	rw	**Type of Service Control** 0_B CPU service is initiated 1_B PCP service is initiated
SRE	12	rw	**Service Request Enable** 0_B Service request is disabled 1_B Service request is enabled
SRR	13	rwh	**Service Request Flag** 0_B No service request is pending 1_B A service request is pending[1)]
CLRR	14	w	**Request Clear Bit** CLRR is required to clear SRR. 0_B No action 1_B Clear SRR; bit value is not stored; read always returns 0; no action if SETR is set also.
SETR	15	w	**Request Set Bit** SETR is required to set SRR. 0_B No action 1_B Set SRR; bit value is not stored; read always returns 0; no action if CLRR is set also.
0	[9:8], 11, [31:16]	r	**Reserved** Read as 0; should be written with 0.

1) The bit field SRR is automatically cleared by hardware at the end of an interrupt arbitration round if the node was the winner, therefore this information is not suitable for interrupt plausibility checks.

FCE Module Identification Register. This register is global to FCE and not part of a crc kernel.

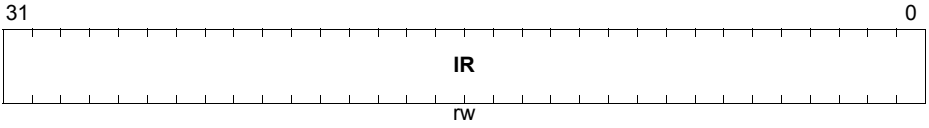
FCE_ID
Module Identification Register (08$_H$) Reset Value: 008A C001$_H$



Field	Bits	Type	Description
MOD_REV	[7:0]	r	**Module Revision Number** This bit field defines the module revision number. The value of a module revision starts with 01$_H$ (first revision).
MOD_TYPE	[15:8]	r	**Module Type** The bit field is set to C0$_H$ which defines the module as a 32-bit module.
MOD_NUMBER	[31:16]	r	**Module Number Value** This bit field defines a module identification number. The value for the FCE module is 008A$_H$.

14.6.2 CRC Kernel Control/Status Registers

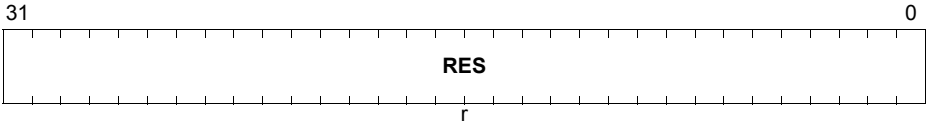
IRm (m = 0-1)
Input Register m **(20_H + m*20_H)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
IR	[31:0]	rw	**Input Register** This bit field holds the 32-bit data to be computed

A write to IRm triggers the CRC kernel to update the message checksum according to the IR contents and to the current CRC register contents. Only 32-bit write transactions are allowed to IRm registers, any other FPI write transaction will lead to a Bus Error.

RESm (m = 0-1)
CRC Result Register m **(24_H + m*20_H)** **Reset Value: FFFF $FFFF_H$**



Field	Bits	Type	Description
RES	[31:0]	r	**Result Register** Returns the final CRC value including CRC reflection and final XOR according to the CFG register configuration. Writing to this register has no effect.

CFGm (m = 0-1)
CRC Configuration Register m

(28_H + m*20_H) **Reset Value: 0000 0700_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

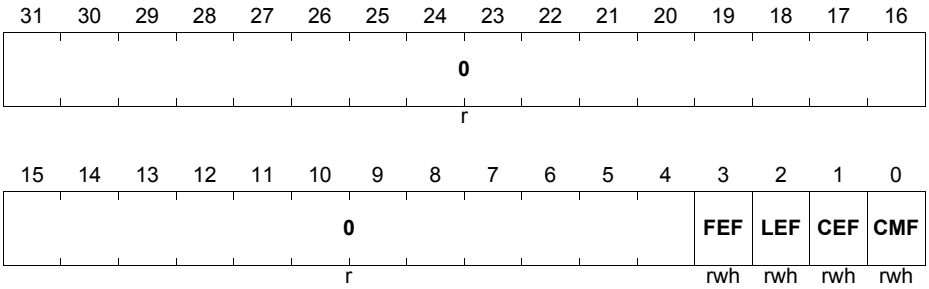
XSEL	10	rw	**Selects the value to be xored with the final CRC** 0_B 0x00000000 1_B 0xFFFFFFFF
0	[7:5], [31:11]	r	**Reserved** Read as 0; should be written with 0.

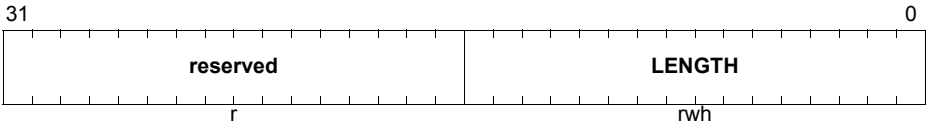
STSm (m = 0-1)
CRC Status Register m **($2C_H$ + m*20_H)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
CMF	0	rwh	**CRC Mismatch Flag** This bit is set per hardware only. To clear this bit, software must write a 1 to this bit field location. Writing 0 per software has no effect. If this bit is equal to 1 and a new interrupt is raised by hardware, it will not be propagated to the FCE interrupt service node.
CEF	1	rwh	**Configuration Error Flag** This bit is set per hardware only. To clear this bit, software must write a 1 to this bit field location. Writing 0 per software has no effect. If this bit is equal to 1 and a new interrupt is raised by hardware, it will not be propagated to the FCE interrupt service node.
LEF	2	rwh	**Length Error Flag** This bit is set per hardware only. To clear this bit, software must write a 1 to this bit field location. Writing 0 per software has no effect. If this bit is equal to 1 and a new interrupt is raised by hardware, it will not be propagated to the FCE interrupt service node.
FEF	3	rwh	**FPI Error Flag** This bit is set per hardware only. To clear this bit, software must write a 1 to this bit field location. Writing 0 per software has no effect. If this bit is equal to 1 and a new interrupt is raised by hardware, it will not be propagated to the FCE interrupt service node.

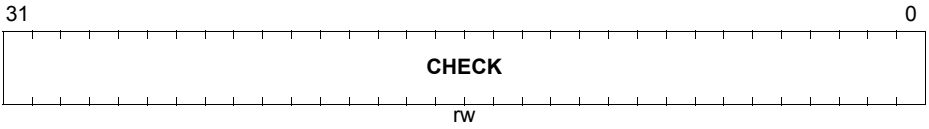
Field	Bits	Type	Description
0	[31:4]	r	**Reserved** Read as 0; should be written with 0.

LENGTHm (m = 0-1)
CRC Length Register m **(30_H + m*20_H)** **Reset Value: 0000 0000_H**



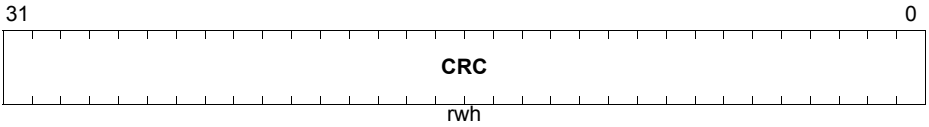
Field	Bits	Type	Description
LENGTH	[15:0]	rwh	**Message Length Register** Number of 32-bits words building the message over which the CRC checksum is calculated. This bit field is modified by the hardware: every write to the IR register decrements the value of the LENGTH bit field.
0	[31:16]	r	**Reserved** Read as 0; should be written with 0.

CHECKm (m = 0-1)
CRC Check Register m **(34_H + m*20_H)** **Reset Value: 0000 0000_H**



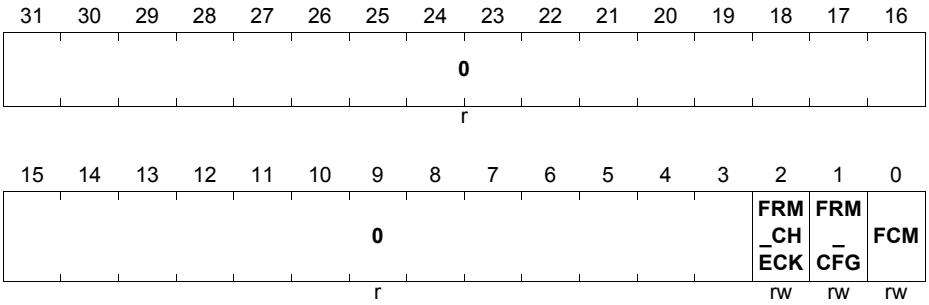
Field	Bits	Type	Description
CHECK	[31:0]	rw	**CHECK Register** Expected CRC value to be checked by the hardware upon detection of a 1 to 0 transition of the LENGTH register. The comparison is enabled by the CFG.CCE bit field

CRCm (m = 0-1)
CRC Register m **(38_H + m*20_H)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
CRC	[31:0]	rwh	**CRC Register** This register enables to directly access the internal CRC register

CTRm (m = 0-1)
CRC Test Register m **($3C_H$ + m*20_H)** **Reset Value: 0000 0000_H**



Field	Bits	Type	Description
FCM	0	rw	**Force CRC Mismatch** Forces the CRC compare logic to issue an error regardless of the CHECK and CRC values. The hardware detects a 0 to 1 transition of this bit field and triggers a CRC Mismatch interrupt
FRM_CFG	1	rw	**Force CFG Register Mismatch** This field is used to control the error injection mechanism used to check the compare logic of the redundant CFG registers. This is a one shot operation. When the hardware detects a 0 to 1 transition of this bit field it triggers a Configuration Mismatch interrupt (if enabled by the corresponding CFGm register).
FRM_CHECK	2	rw	**Force Check Register Mismatch** This field is used to control the error injection mechanism used to check the compare logic of the redundant CHECK registers. This is a one shot operation. The hardware detects a 0 to 1 transition of this bit field and triggers a Check Register Mismatch interrupt (if enabled by the corresponding CFGm register).
0	[31:3]	r	**Reserved** Read as 0; should be written with 0.

14.7 Programming Guide

This section provides some guidelines showing how the FCE configuration features can be mapped to the AUTOSAR API for CRC32 routines.

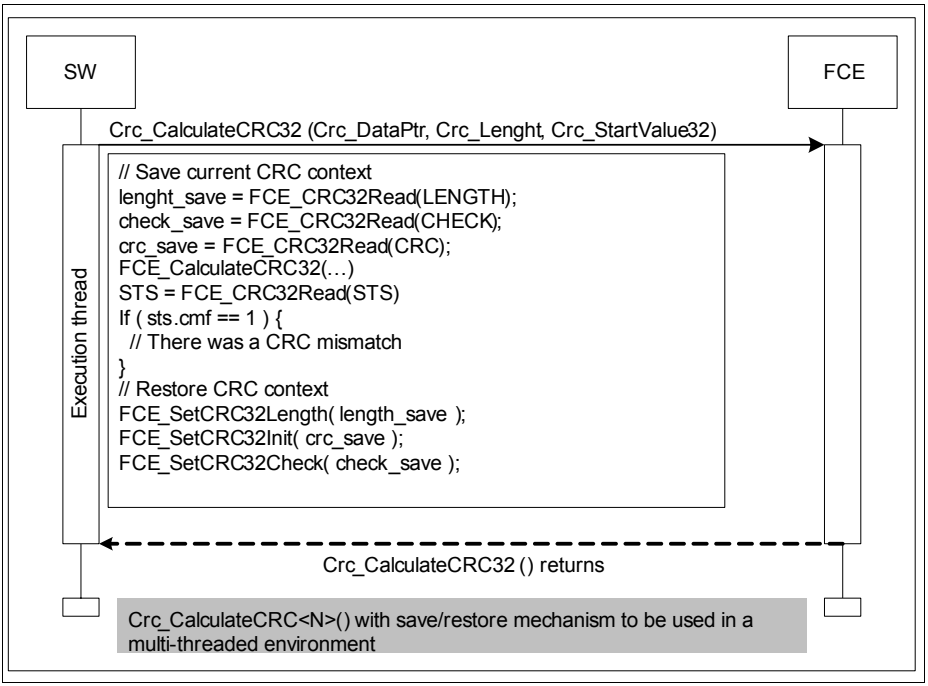

Figure 14-12 Autosar CRC_calculate API with save/restore

14.8 Properties of CRC code

Hamming Distance

The Hamming distance defines the error detection capability of a CRC polynomial. A cyclic code with a Hamming Distance of D can detect all D-1 bit errors. **Table 14-4 "Hamming Distance as a function of message length (bits)" on Page 14-31** shows the dependency of the Hamming Distance with the length of the message.

Table 14-4 Hamming Distance as a function of message length (bits)[1)]

Hamming Distance	IEEE CRC32	Castagnoli
15	8 - 10	
14	8 - 10	
13	8 - 10	
12	11 - 12	8 - 17
11	13 - 21	18 - 21
10	22 - 34	22 - 27
9	35 - 57	22 - 27
8	58 - 91	28 - 58
7	92 - 171	59 - 81
6	172 - 268	82 - 1060
5	269 - 2974	1061 - 65504
4	2973 - 91607	1061 - 65504
3	91607 - 131072	65506 - 131072

15 SRI External Bus Unit (EBU)

The External Bus Unit (EBU), TC1798 controls the transactions between external memories or peripheral units, and the internal memories and peripheral units. The basic interfaces of the EBU are shown in **Figure 15-1**.

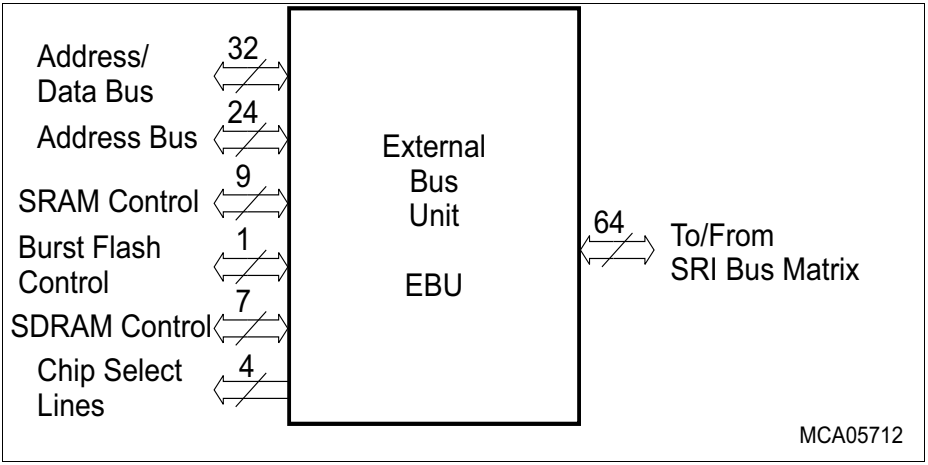

Figure 15-1 EBU Interface Diagram

The EBU is internally connected to the SRI Bus Matrix by a single slave interface.

15.1 Overview

The Memory Controller module for SRI-based systems connects on-chip controller cores (e.g. Tricore CPU, DMA Controller) to external resources such as memories and peripherals. **Figure 15-2** shows Memory Controller within a typical system.

Any SRI master can (in conjunction with an SRI Matrix) access external memories through the Memory Controller.

15.2 References

The EBU complies with the requirements of the following specifications when generating accesses to external memories:

- JESD21-C revision 18A, sections relating to SDRAM & LPSDRAM (3.11.5.1)
- JESD21-C revision 18A, section relating to LPDDR NVM (3.6.3).
- JESD209, Low Power Double Data Rate (LPDDR) SDRAM Standard
- Open NAND Flash Interface Specification. Revision 2.0, 27-February-2008
- Intel™, PC SDRAM Specification, revision 1.7, November 1999.

15.3 Feature List

Features supported in the Memory Controller:-

- Highly programmable access parameters.
- Intel-style peripheral/device support.
- Burst FLASH support (see **Section 15.17** for specific device types).
- Cellular RAM support (see **Section 15.17** for specific device types).
- NAND flash
- Multiplexed access (address & data on the same bus)
- Data Buffering: Two read buffers. Single write buffer in the SRI interface.
- Four programmable address regions.
- External bus frequency: Module frequency:flash clock = 1:1, 1:2, 1:3 or 1:4.
- JEDEC 42.4 LPDDR NVM support
- DDR burst flash support.
- SDRAM support (see **Section 15.18** for specific device types).
- DDRAM support (see **Section 15.18** for specific device types).
- ONFI 2.0 NAND flash support
- Configurable clock generation and edge recovery logic using a programmable DLL (Delay Locked Loop) to control clock phase and edge positioning
- External bus frequency: Module frequency:DDR device clock = 1:1, 1:2, or 1:4.

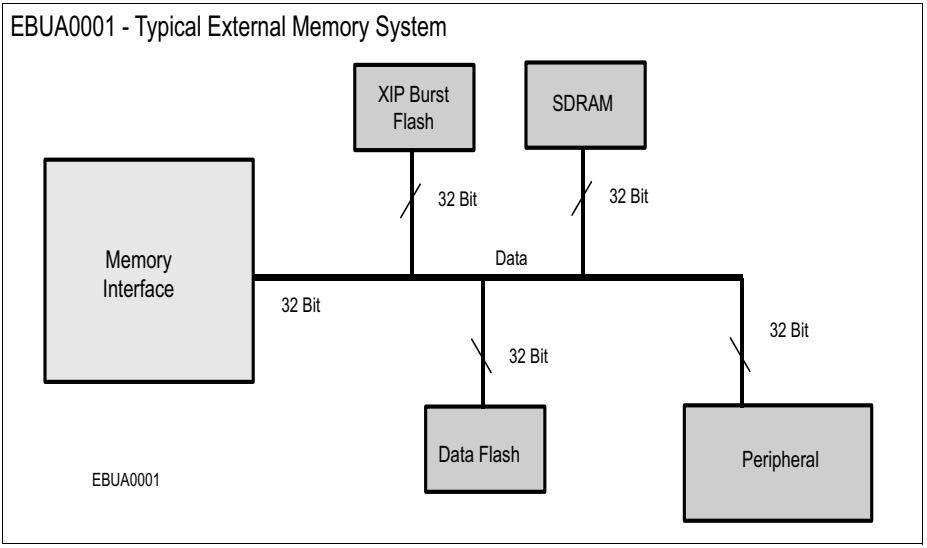

Figure 15-2 Typical External Memory System

15.4 Differences between Audo-Future and Audo-Max EBUs

The clocking scheme of the EBU has been upgraded. A DLL has been added to allow reconstruction of a 50% duty cycle clock and the generation of phase shifted clocks for DDR device support. This has added a new register, **EBU_DLLCON**, to the EBU register space.

The EBU can now also be configured to run at half the CPU frequency or asynchronously to the CPU using the Flexray PLL as its clock source. The features are programmed using the **SYNC** and **DIV2** fields in **EBU_CLC**.

New features have been added to the **EBU_MODCON** register:

- **BUSSTATE**, a monitor bit which is set to 1_B when the EBU owns the external bus
- **FAST_SRI**, The normal address process decode takes 2 clock cycles. If the SRI clock frequency is 180 MHz or lower, then this bit can be set to reduce the decode time to 1 clock cycle.
- **FIFO_BYPASS**, a control bit for the data read mode for devices using an SDRAM protocol or DDR data transfer protocol. Under normal circumstances the read data from these devices is considered to be asynchronous and is resynchronised to the EBU clock using a data FIFO. If the external bus frequency is low enough, this bit can be set to load the data directly into the internal read buffers. This will remove one external bus clock from the access latency.

To make space for these, the four bit GLOBALCS field previously in MODCON has been made region specific and moved to individual **GLOBALCS** fields for each $\overline{CS}$ in **EBU_ADDRSELx (x = 0-3).**

Support for three new memory protocols has been added. All of these can be grouped under the heading DDR flash:

- LPDDR-NVM (JEDEC 42.4). This is a DDR memory protocol based on the PC100 SDRAM standard. Adding this protocol also allows the EBU to support DDRAM and SDRAM (where environmental conditions allow).
  - The following registers have been added to the EBU to allow configuration of the new protocol: **EBU_SDRMCON**; **EBU_SDRMOD**; **EBU_SDRMREF**; **EBU_SDRSTAT**; **EBU_DDRNCON**; **EBU_DDRNMOD**; **EBU_DDRNMOD2**; **EBU_DDRNSRR**; **EBU_DDRNPRLD** and **EBU_DDRNTAGx (x=0-3)**
  - The EBU will now also recognise values of 8_D (SDRAM), 10_D (LPDDR-NVM) and 12_D (DDRAM) as being valid for the **AGEN** fields in **EBU_BUSRCONx (x = 0-3)** and **EBU_BUSWCONx (x = 0-3)**
  - A new differential clock output (DDRCLKO & $\overline{DDRCLKO}$), new control signals ($\overline{RAS}$, $\overline{CAS}$, CKE), and data strobes (DQS[3:0]) have been added to the EBU pinout. The byte control signals (BC[3:0]) now have an alternate function as data modifiers (DQM[3:0]).
- Spansion 29DS032J. (1.8v I/O mode only) This is a hybrid device using a standard flash command protocol and DDR transfer of read data. Support for this device is configured using an **AGEN** value of 9_D.

- ONFI 2.0. DDR interface protocol for NAND flash memories. Support for this device type is configured using an **AGEN** value of 13_D. Adding this device has required the following changes to the EBU:
  - The **PORTW** field in **EBU_BUSRCONx (x = 0-3)** now takes 00_B as a valid value configuring an 8 bit device. This is valid for all values of **AGEN** except 8_D, 9_D, 10_D and 12_D.
  - NAND flash control signals ALE and CRE are now output on ADV and BAA respectively. This applies to **AGEN** value 2_D as well as 13_D.
  - The timing of the MR/$\overline{W}$ signal has been changed for accesses to memories configured using **AGEN** values 2_D and 13_D. For these accesses the timing of MR/$\overline{W}$ will follow the standard RD/$\overline{WR}$ signal.

Additional fields have also been added to the **EBU_USERCON** register to provide finer control of switching pins between EBU and GPIO functions. This will now allow individual high order address bits to be reallocated for GPIO if not required by attached memory devices and also address bits 15 down to 0 to be allocated for GPIO if all attached memories have multiplexed address and data connections.

15.5 EBU Interface Signals

The external EBU interface signals are listed in Table 15-1 below. In many case, the EBU pins have multiple functions depending on the memory devices configured and being accessed. In these cases, the primary designation of the pin is emphasised.

Table 15-1 EBU Interface Signals

Signal/Pin	Type	Function
AD[31:0]	O	Multiplexed Address/Data bus lines 0-31
A[27:0]	O	Address bus lines 0-27.
DQS[3:0]	I/O	data strobe lines for DDR devices. Can also be used as A[27:24] if DDR devices are not attached to the EBU. DQS[3]->A[24], DQS[2]->A[25], DQS[1]->A[26], DQS[0]->A[27]
A[27:24]	O	
$\overline{\text{CS}}$[3:0]	O	Chip select 0-3
$\overline{\text{CSCOMB}}$	O	Combined chip select for global select
$\overline{\text{RD}}$	O	Read control line
RD/$\overline{\text{WR}}$	O	Write control line
$\overline{\text{ADV}}$	O	Address valid output. Can be inverted for use as Address Latch Enable. Also used as ALE for NAND flash.
ALE	O	
$\overline{\text{BC}}$[3:0]	O	Byte control lines 3 to 0 Alternatively, these pins are used as Data Mask outputs when accessing JEDEC 42.4 LPDDR-NVM Memory, DDRAM orSDRAM
DQM[3:0]	O	
BFCLKO	O	Clock Output for Synchronous Accesses
BFCLKI	I	Feedback clock input for Synchronous Accesses
DDRCLKO	O	Clock Output for JEDEC 42.4 LPDDR-NVM Memory Accesses & DDRAM Memory Accesses. Alternately, SDRAM clock output.
SDCLKO	O	
$\overline{\text{DDRCLKO}}$	O	Negative phase of balanced DDRCLKO signal Alternatively, can also be used as the negative phase of BFCLKO if a DDR NOR flash memory is attached or the feedback Clock for SDCLKO.
SDCLKI	I	
$\overline{\text{BFCLKO}}$	O	
CKE	O	Clock Enable Output for JEDEC 42.4 LPDDR-NVM Memory, DDRAM and SDRAM
$\overline{\text{RAS}}$	O	Row Address Strobe for JEDEC 42.4 LPDDR-NVM Memory, DDRAM and SDRAM

Table 15-1 EBU Interface Signals (cont'd)

Signal/Pin	Type	Function
CAS	O	Column Address Strobe for JEDEC 42.4 LPDDR-NVM Memory, DDRAM and SDRAM
WAIT	I	Wait input
MR/W	O	Write Control line with timing suitable for Motorola Peripherals. ONFI 2.0 flash clock output
OCLKO	O	
BAA	O	Burst address advance output. Also Control Register Enable (CRE) for NAND flash accesses
CRE	O	
HOLD	I	Hold request input
HLDA	O	Hold acknowledge output
BREQ	O	Bus request output

15.5.1 Address/Data Bus, AD[31:0]

This bus transfers address and data information. The width of this bus is 32 bits. External devices with 8, 16 or 32 bits of data width can be connected to the data bus.

The EBU adjusts the data on the data bus to the width of the external device, according to the programmed parameters in its control registers. The byte control signals BC[3:0] specify which parts of the data bus carry valid data.

15.5.2 Address Bus, A[27:0]

The total address bus of the EBU consists of 24 address output lines, giving a directly addressable range of 64 Mbytes (2^{24}, 32 bit words). An external device can be selected via one of the chip select lines. Since there are four chip select lines, four such devices with up to 256 Mbytes of address range can be used in the external system.

15.5.3 Global Chip Select, CSCOMB

The EBU provides a combined or global chip select line. This can be programmed to be asserted with any combination of the normal chip selects CS[3:0]. See **Chapter 15.13.7** for more details.

15.5.4 Chip Selects, CS[3:0]

The EBU provides four chip select outputs, CS0, CS1, CS2 and CS3. The address ranges for which these chip selects are generated are programmed separately for each chip select line in a very flexible way via the address select registers EBU_ADDRSELx. More details are described on **Page 15-53**.

15.5.5 Read/Write Control Lines, $\overline{RD}$, RD/$\overline{WR}$

Two lines are provided to trigger the read ($\overline{RD}$) and write (RD/$\overline{WR}$) operations of external devices. While some read/write devices require both signals, there are devices with only one control input. The RD/$\overline{WR}$ line is then used for these devices. This line will go to an active-low level on a write, and will stay inactive high on a read. The external device should only evaluate this signal in conjunction with an active chip select. Thus, an active chip select in combination with a high level on the RD/$\overline{WR}$ line indicates a read access to this device.

15.5.6 Address Valid, $\overline{ADV}$

The address valid signal, $\overline{ADV}$, validates the address lines A[23:0] (and also the address placed on the data bus AD[31:0] when attaching multiplexed address/data devices). It can be used to latch these addresses externally. The polarity can be inverted to allow use as a positive logic Address Latch Enable signal (ALE).

It is also used as ALE when accessing NAND flash. In this case, the timing will be adjusted so that it is stable for the entire access.

15.5.7 Byte Controls, $\overline{BC[3:0]}$

The byte control signals $\overline{BC[3:0]}$ select the appropriate byte lanes of the data bus for both read and write accesses. **Table 15-2** shows the activation on access to a 16-bit or 8-bit external device. Please note that this scheme supports little-endian devices.

Table 15-2 Byte Control Pin Usage

Width of External Device	$\overline{BC3}$	$\overline{BC2}$	$\overline{BC1}$	$\overline{BC0}$
32-bit device with byte write capability	D[31:24]	D[23:16]	D[15:8]	D[7:0]
16-bit device with byte write capability	inactive (high)	inactive (high)	D[15:8]	D[7:0]
8-bit device	inactive (high)	inactive (high)	inactive (high)	D[7:0]

Signals BCx can be programmed for different timing. The available modes cover a wide range of external devices, such as RAM with separate byte write-enable signals, and RAM with separate byte chip select signals. This allows external devices to connect without any external “glue” logic.

Table 15-3 Byte Control Signal Timing Options

Mode	EBU_BUSCONx. BCGEN	Description
Chip Select Mode	00_B	$\overline{BCx}$ signals have the same timing as the generated chip select $\overline{CS}$.
Control Mode	01_B	$\overline{BCx}$ signals have the same timing as the generated control signals $\overline{RD}$ or RD/$\overline{WR}$.
Write Enable Mode	10_B	$\overline{BCx}$ signals have the same timing as the generated control signal RD/$\overline{WR}$.
DQM Mode	11_B	$\overline{BCx}$ signals are used as DQM for SDRAM/DDRAM.

15.5.8 Burst Flash Clock Output/Input, BFCLKO/$\overline{BFCLKO}$/BFCLKI

The flash clock output signal of the EBU is provided at pin BFCLKO. It is used for timing purposes (timing reference) during Burst Mode accesses. BFCLKO is, by default, only generated during synchronous accesses.

The clock input BFCLKI of the EBU is used to latch read data into the EBU. Normally BFCLKI is directly fedback and connected to BFCLKO. This feedback path can be configured externally to maximize the operating fiuency for a given Flash device or to compensate the BFCLKO clock pad delay. More details are given on **Page 15-91**.

DDR flash devices require a differential clock. If a DDR flash device is configured, then $\overline{BFCLKO}$ will be generated on the $\overline{DDRCLKO}$ pin.

15.5.9 Wait Input, $\overline{WAIT}$

This is an input signal to the EBU that is used to dynamically insert wait states into read or write data cycles controlled by the device on the external bus.

15.5.10 Burst Address Advance, $\overline{BAA}$

The Burst Address Advance output, $\overline{BAA}$, is provided for advancing the addresses during a Burst Flash read cycle. This signal is not asserted for burst flash writes.

This pin also functions as the Control Register Enable (CRE) for accesses to NAND flash.

15.5.11 Motorola Peripheral Write Signal, MR/$\overline{W}$

A write control signal held valid for the duration of an access (from chip select asserted to chip select negated).

15.5.12 ONFI 2.0 clock Output, OCLKO

The ONFI 2.0 devices require a clock input when working as a synchronous, DDR memory. The input pin on the device is also used as the write input, WR, when the device is operating in asynchronous mode. To enable the device to be successfully connected, a copy of the BFCLKO signal will be generated on the MR/W pin as OCLCKO when a region is configured for ONFI 2.0 memory.

15.5.13 DDR Clock Output/Input DDRCLKO/DDRCLKO/SDCLKI

The EBU provides a clock output for SDRAM devices on the SDCLKO pin. SDCLKO is, by default, a continuously running signal but can also be configured to switch off between accesses to conserve power.

The feedback clock input, SDCLKI, is used as a timing reference for the capture of read data on SDRAM accesses. It should be connected via a PCB trace to the clock pin of the SDRAM device.

For DDR devices a differential clock is required but the use of DQS lines to clock read data means that SDCLKI is not necessary. In this case, the negative phase clock, SDCLKO, is output on the SDCLKI pin.

If the combined clock mode is selected, SDCLKO will be output on the BFCLKO pin.

15.5.14 LPDDR-NVM, DDRAM, SDRAM Control Signals, CKE, CAS and RAS

These signals implement, along with the RD/WR signal, the command interface for an attached memory device using an PC100 SDRAM type control protocol.

15.5.15 DDR Data Strobes, DQS[3:0]

The DQS signals are used as clocks for data being transferred using DDR protocols. They are driven by the EBU on write accesses and by the attached memory device on read accesses.

15.5.16 Bus Arbitration Signals, HOLD, HLDA, and BREQ

The HOLD input signal is the external bus arbitration signal that indicates to the EBU when an external bus master requests to obtain ownership of the external bus.

The HLDA output signal is the external bus arbitration signal that indicates to a external bus master that it has obtained ownership of the external bus from the EBU.

The BREQ output signal is the external bus arbitration signal that is asserted by the EBU when it requests to obtain back the ownership of the external bus.

15.5.17 EBU Reset

The EBU is asynchronously initialised by the application reset.

15.5.17.1 Allocation of Unused Signals as GPIO

The EBU will allow pins not required for its programmed configuration to be allocated for use as GPIO. The signals required are as defined below:

Table 15-4 EBU Interface Signals Required by Operating Mode

Signal/Pin	When Needed by EBU
AD[15:0]	Always needed when the EBU is enabled. EBU_MODCON.ARBMODE != 00_B [1)]
$\overline{RD}$	
RD/$\overline{WR}$	
MR/$\overline{W}$	
$\overline{BC}$[1:0]	
A[18:16]	
$\overline{WAIT}$	This signal is required by the EBU when any enable region is configured to use WAIT by setting the BUSCONx.WAIT field to a value other than 00_B (EBU_MODCON.ARBMODE != 00_B) AND (EBU_ADDRSELx.REGENAB=1_B OR EBU_ADDRSELx.ALTENAB=1_B) AND (BUSRCONx.WAIT != 00_B)
A[27:19]	These address bits can be indvidually enabled for use as GPIO by setting the relevant enable bit in the USERCON register. Setting EBU_MODCON.ARBMODE = 00_B will also enable for GPIO. If DDR devices are connected, then the 4 MSBs of the address are used for DQS and will be enabled regardless of the state of the USERCON bits.
A[15:0]	These address bits are not required if the only devices connected have a multiplexed address/data bus. In this case they will be made available for GPIO if USERCON.ADDRLSW=1_B. Setting EBU_MODCON.ARBMODE = 00_B will also enable for GPIO.
$\overline{ADV}$	The ADV output can be made available for GPIO by setting the **ADVIO** bit in the USERCON register to 1_B. Setting EBU_MODCON.ARBMODE = 00_B will also enable for GPIO.

Table 15-4 EBU Interface Signals Required by Operating Mode (cont'd)

Signal/Pin	When Needed by EBU
BFCLKO BFCLKI $\overline{\text{BAA}}$	These signals are required by the EBU when the EBU is enabled and an enabled region is configured for burst device support (EBU_MODCON.ARBMODE != 00_B) AND (((EBU_ADDRSELx.REGENAB=1_B) OR (EBU_ADDRSELx.ALTENAB=1_B) OR (BUSRCONx.BFCMSEL=0_B)) AND (BUSCONx.AGEN = 1_H OR 3_H OR 6_H OR 5_H OR 7_H OR 9_H OR B_H)) OR (MODCON.CLKCOMB = 1_B))
$\overline{\text{RAS}}$ $\overline{\text{CAS}}$ CKE DDRCLKO $\overline{\text{DDRCLKO}}$	These signals are required by the EBU when the EBU is enabled and an enabled region is configured for SDRAM, DDRAM or LPDDR-NVM support. (DDRCLKO is also required if DDR burst flash is connected and will additionally be enabled in this case) (EBU_MODCON.ARBMODE != 00_B) AND ((EBU_ADDRSELx.REGENAB=1_B OR EBU_ADDRSELx.ALTENAB=1_B) AND (BUSRCONx.AGEN = 8_D OR 10_D OR 12_D)
$\overline{\text{HOLD}}$ $\overline{\text{BREQ}}$ $\overline{\text{HLDA}}$	These signals are required by the EBU when the EBU is configured to arbitrate for the external bus. e.g. EBU_MODCON.ARBMODE = 01_B or 10_B
AD[31:16] DQS[3:2] $\overline{\text{BC}}$[3:2]	These signals are required by the EBU when the EBU is enabled and an enabled region is configured for accessing 32 bit memory (EBU_MODCON.ARBMODE != 00_B) AND ((EBU_ADDRSELx.REGENAB=1_B OR EBU_ADDRSELx.ALTENAB=1_B) AND (BUSRCONx.PORTW = 10_B or 11_B)
$\overline{\text{CS}}$[3:0]	The Chip select lines are individually controlled and will be required for EBU operation when the associated memory region is enabled. (EBU_MODCON.ARBMODE != 00_B) AND (EBU_ADDRSELx.REGENAB=1_B OR EBU_ADDRSELx.ALTENAB=1_B)
$\overline{\text{CSCOMB}}$	The Global Chip Select line is required by the EBU when any EBU_ADDRSEL.**GLOBALCS** != 0_B and the EBU is enabled (EBU_MODCON.ARBMODE != 00_B)

1) If the EBU is disabled by writing 00 to the EBUCON.ARBMODE field, there will be a delay before the signals become available for GPIO usage as the EBU will wait for all pending external memory accesses to be completed and the arbitration logic to return to the "nobus" state before releasing the signals.

15.6 Bus State During Reset

The state of the various bus signals is controlled by Memory Controller during reset as follows:-

Table 15-5 Memory Controller External Bus pin states during reset

Pin Name	State during Reset[1)]	State during Idle[2)]	State during "no bus" mode
AD(31:16)	GPIO	High Impedance - pull ups enabled to pull to '1'.	GPIO
AD(15:0)	High impedance pull to '1' (high).	High Impedance - pull ups enabled to pull to '1'.	High Impedance - pull ups enabled to pull to '1' (High).
A(27:19)	GPIO	Driven to '0' after reset, otherwise last used address	GPIO
A(19:0)	High impedance pull to '1' (high).	Driven to '1' (High) at reset, last used address when idle	High impedance pull to '1' (high).
$\overline{CS}$(0)	High impedance pull to '1' (high).	Driven to '1' (High).	High impedance pull to '1' (high).
$\overline{CS}$(3:1)	GPIO	Driven to '1' (High).	GPIO
$\overline{RD}$	High impedance pull to '1' (high).	Driven to '1' (High).	High impedance pull to '1' (high).
$\overline{WR}$	High impedance pull to '1' (high).	Driven to '1' (High).	High impedance pull to '1' (high).
$\overline{CAS}$	GPIO	Driven to '1' (High).	GPIO
$\overline{RAS}$	GPIO	Driven to '1' (High).	GPIO
CKE	GPIO	Dependant on SDRAM clocking/power save mode	GPIO
$\overline{ADV}$	GPIO	Driven to '1' (High).	GPIO
DDRCLKO	GPIO	Driven to '0' (Low).	GPIO

Table 15-5 Memory Controller External Bus pin states during reset (cont'd)

Pin Name	State during Reset[1)]	State during Idle[2)]	State during "no bus" mode
$\overline{\text{DDRCLKO}}$	GPIO	High Impedance	GPIO
BFCLKI	GPIO	High Impedance	GPIO
BFCLKO	GPIO	Driven to '0' (Low).	GPIO
$\overline{\text{BC}}$(3:2)	GPIO	Driven to '1' (High).	GPIO
$\overline{\text{BC}}$(1:0)	High impedance pull to '1' (high).	Driven to '1' (High).	High impedance pull to '1' (high).
$\overline{\text{WAIT}}$	GPIO	Always an input (must have a pull-resistor to inactive state).	GPIO
$\overline{\text{CSCOMB}}$	GPIO	Driven to '1' (High).	GPIO
$\overline{\text{HOLD}}$	GPIO	depends on state of bus arbitration logic	GPIO
$\overline{\text{HLDA}}$	GPIO		GPIO
$\overline{\text{BREQ}}$	GPIO		GPIO
MR/$\overline{\text{W}}$	GPIO	Driven to '1' (High).	GPIO
$\overline{\text{BAA}}$	GPIO	Driven to '1' (High).	GPIO

1) GPIO controlled pins should be high impedance with pull up during reset.

2) Assuming that the pins have not been made available as GPIO.

Applicable reset is cgu_con_clk_rst_n_i.

15.7 Memory Controller Structure

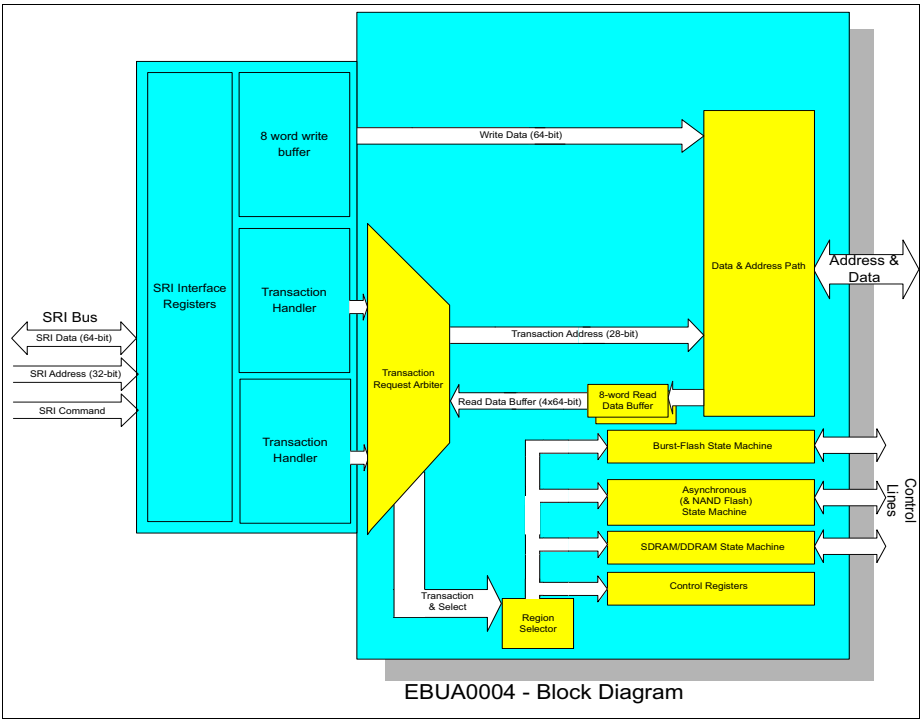

Figure 15-3 Memory Controller Block Diagram

The SRI interface translates SRI transactions from the ports into appropriate transaction requests which can be transferred to the arbiter. The interface can handle two transactions simultaneously as required by the SRI protocol which has a two deep, command pipeline. The interface will also generate an ECC code for all read data returned and will check ECC codes received along with each SRI transaction. In the event of a transaction failing the ECC check, an error will be flagged to the system for further processing and the transaction will be terminated with an SRI error.

The arbiter looks at the transaction requests and schedules corresponding requests to the relevant state machine. Only one state machine can be active at any time and the arbiter is designed to prevent out-of-order execution. The dedicated state machines are used to sequence control signals and to co-ordinate accesses to each of the different external memory/device types and also the internal registers.

If two consecutive accesses are to the same state machine, the second access will be queued before the first has completed. This allows accesses to run “back-to-back” on the external bus and maximises bandwidth utilisation.

15.8 Memory Controller Read Architecture

The memory controller contains two, identical read buffers each with a capacity of 4, 64 bit words. A read access will be allowed to proceed if one of the buffers is flagged as available. The data read from the external memory will be stored in the read buffer and the outputs from the read buffer will be multiplexed to the SRI port. Once the SRI port signals that all data has been returned to the requesting SRI master, the read buffer will again be flagged as available.

This architecture allows reads to be in progress simultaneously, as a second read can be running while the first read is still waiting for data to be returned to the SRI master.

15.9 Access Arbitration

Arbitration of SRI accesses is handled by the SRI matrix. The EBU will only ensure that accesses are processed in the order that they arrive at the SRI port

15.9.1 Programming Sequence Locking

Programming sequences for some Burst Flash devices require that the source of the programming transactions has exclusive access to the external memory device for the duration of the write sequence. If such devices are used and can be accessed by multiple transaction sources then the “Locked Programming Sequence” feature can be enabled via register bit EBU_BUSWCONx.LOCKCS.

A programming sequence is considered to start when the processor data port carries out an initial write transaction.

Note: It has been assumed that the processor data port is the only port that will ever attempt programming operations to a NOR flash.

A programming sequence is considered to have ended when the processor data port carries out a subsequent read transaction to a CS which it has locked, or when the processor data port, which has locked CSx, carries out a write to CSy resulting in the locking of CSy, or when an internal fail-safe timeout expires.

A programming sequence lock is aborted if an access is attempted from the processor instruction port to the locked device. An aborted sequence will be flagged by the status bit. LCKABRT, in the EBU_MODCON register. This flag will be cleared by writing 1_B to the LCKABRT field.

Note: This is to prevent a system livelock in the event that the code running the programming sequence is interrupted.

If programming sequence locking is enabled for $\overline{CSx}$, then once a write transaction to $\overline{CSx}$ is accepted from the processor data port, the SRI interface automatically “locks” ownership of the device on $\overline{CSx}$ to that port. Any transaction requests (read or write) to the same $\overline{CSx}$ from other transaction sources wil be errored until the end of the

programming sequence. Accesses to other $\overline{CS}$y or $\overline{CS}$z devices from the other initiators will be permitted.

Sequence “locking” takes place in the SRI interface block.

The fail-safe timeout timer defaults to a count of 255 and is decremented at a frequency of EBU_CLK/16. It commences counting from the preload value every time a write completes. The default value can be changed by writing to the EBU_BUSCON.LOCKTIMEOUT register field.

15.9.2 Source Access Inhibit

Transactions not initiated by the processor can be temporarily denied access to external memory by setting the EBU_MODCON.access_inh bit. This is to allow reprogramming of access parameters for external memory by the processor while preventing the other potential masters from attempting to access with invalid settings. While this bit is set accesses which do not originate from one of the processor ports will be errored. Port Access Inhibit will be enabled after reset.

Note: If a DLL relock is trigged while access inhibit is active, then access inhibit should not be removed until a DLL relock has completed.

15.10 Clocking Strategy and Local Clock Generation

The Memory Controller can be configured to operate from several possible clock sources. The clock generation logic is used to select between these clock sources and generate the internal clock used for the memory controller, EBU_CLK.

15.10.1 Clocking Modes

The bridges can be operated in one of two modes using one of two clocks:-

- Asynchronous mode: The SRI clock and Memory Controller internal clock (EBU_CLK) are assumed to be asynchronous. EBU_CLK is derived from the Flexray PLL output.
- Synchronous mode: The EBU_CLK is derived from the controller (SRI) clock. The EBU_CLK and SRI interface clocks have aligned edges (although pulse swallowing can be used on the EBU_CLK clock, so that the EBU core can run at a lower frequency than the SRI bus matrix).
- Synchronous or Asynchronous mode at half of SRI clock: The EBU clock is running at half the frequency of the processor clock. The EBU clock is edge aligned with the processor and SRI interface clocks.

The clock for the SRI interface of the memory controller, is always be derived from the same synchronous source (the processor clock, .

Operation of the bridge in Asynchronous mode provides maximum flexibility in clocking different domains at different frequencies. This is, however, at the cost of additional latency (for signal resynchronisation) through the bridge.

Operation of the bridge in synchronous mode minimises the latency through the bridge at the cost of forcing the SRI and EBU_CLK domains to run from the same source clock (the processor clock).

The mode of operation of the bridge is controlled by the **EBU_CLC.SYNC** register field. The **EBU_CLC.SYNCACK** field will be updated to report the current operating mode.

The **EBU_CLC.SYNC** register field can be used (dynamically) to switch between these two modes. The Memory Controller contains internal control logic to sequence the switching between modes to ensure that external bus accesses are not corrupted as a result of switching clocking modes. The Memory Controller updates the **EBU_CLC.SYNCACK** to signal the status of the bridge (‘1’ = operating in Synchronous Mode, ‘0’ = operating in Asynchronous Mode).

If **EBU_CLC.DIV2** is set to 0_B, then **EBU_CLC.SYNC** also controls the clock input and switches it between the processor clock and the Flexray PLL output.

However, if **EBU_CLC.DIV2** is set to 1_B, then EBU clock source is forced to be half the frequency of the processor clock and **EBU_CLC.SYNC** only enables and disables the resynchronisation stages necessary for asynchronous operation. Setting **EBU_CLC.SYNC** to 0_B will only activate the resynchronisation stages, the EBU clock will remain fixed at half the processor clock frequency . The value of **DIV2** in use by the memory controller is stored in the **EBU_CLC.DIV2ACK** field.

15.10.2 Local Clock Divider

A local divider can be used to reduce the frequency of EBU_CLK. The divider can be programmed to for divide ratios of 1:1, 2:1, 3:1 or 4:1 using the **EBU_CLC.EBUDIV** register field. The ratio currently in use is provided in the **EBU_CLC.EBUDIVACK** register field.

The purposes of the divider is to allow the memory controller core to operate synchronously at an integer divide ratio of the SRI clock.

By also setting the **EBU_CLC.DIV2** bitfield, the available divide ratios between the SRI clock and the EBU_CLK become 1:2, 1:4, 1:6 and 1:8

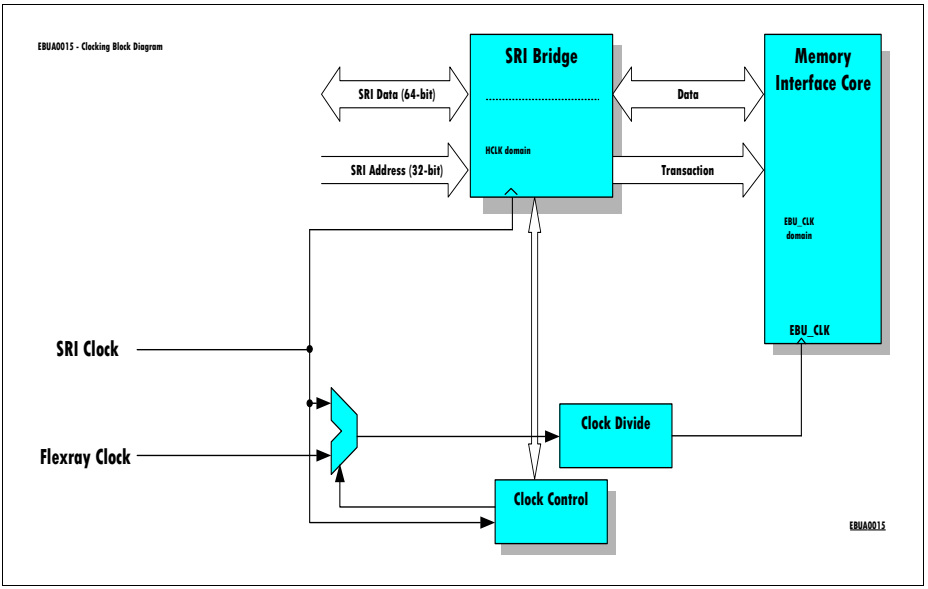

Figure 15-4 SRI/Memory Controller Clock Domains

If a divide ratio of 1:3 is selected using the local clock divider and a memory device is being used at a 1:1 or 1:3 external clock ratio, then the device clock outputs, BFCLKO and SDCLKO, will not have a 50% duty cycle unless the DLL is used to correct the duty cycle. This is because the local divider operates by pulse swallowing the module input clock to generate EBU_CLK.

For all clock ratios other than 1:3 the negative phase clock can be generated using a shifted pulse swallowing control signal but accurate positioning of the negative edge of a 1:3 clock is not possible.[1)]

1) All clock duty cycle ratios are nominal and will be affected by PLL jitter and pad rise/fall asymmetry

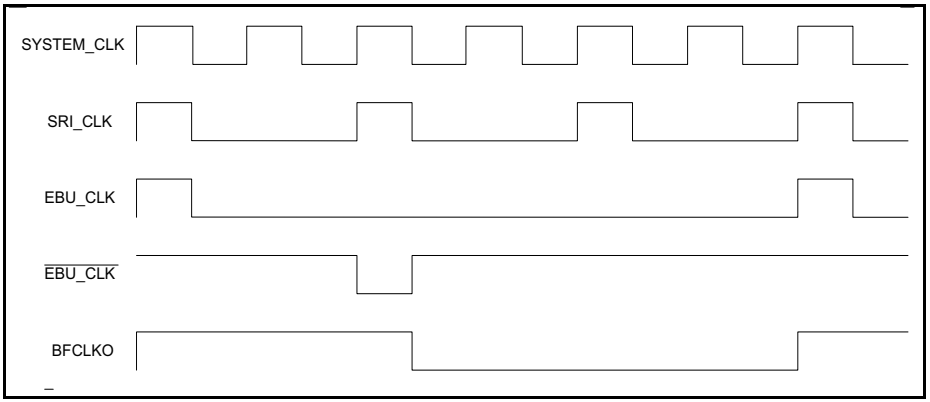

Figure 15-5 Example of BFCLKO Generation using 1:3 case

The figure above shows an example of external bus clock generation.

- Firstly, the system clock is divided to generate the SRI clock
- Then the EBU local clock divider divides the SRI clock to generate the EBU internal clock
- An $\overline{\text{EBU\_CLK}}$ signal is also generated from the SRI clock by shifting the pulse swallowing control signal and inverting the signal if required
  - For 1:1 division, there is no phase shift and the clock is inverted only
  - For 1:2 division, the phase shift is one period of the SRI clock and there is no inversion
  - For 1:3 division, the phase shift is one period of the SRI clock and the signal is inverted
  - For 1:4 division, the phase shift is two periods of the SRI clock and there is no inversion.
  - For 1:6 division, the phase shift is three periods of the SRI clock and there is no inversion.
  - For 1:8 division, the phase shift is four periods of the SRI clock and there is no inversion.
- The inverted clock signal is used to position the negative edge of the external bus clock in 1:1 EBU_CLK:BFCLKO mode (BUSCONx.**EXTCLOCK**=00_B) and also the edges of control signals shifted by one half of an EBU_CLK period (See **Chapter 15.16.4** and **Chapter 15.17.8**).

15.10.3 Standby Mode

The Memory Controller can be configured to disable its internal clock and enter standby mode by writing a logic ‘1’ to the **EBU_CLC.DISR** register field.

Once the register field is written, the Memory Controller will wait for any running accesses to finish and will then disable the clock to the core logic of the Memory Controller (EBU_CLK). As this will also disable the refresh counters, it is necessary to set the **EBU_SDRMREF.AUTOSELFR** register field if this mode is to be used with SDRAM. This will instruct the MEMCTRL to place any attached SDRAM into self refresh mode before allowing clock mode switching or standby.

Exit from standby mode is triggered by writing 0_B to the **EBU_CLC.DISR** field

An access arriving on any of the Memory Controller, SRI interfaces will trigger an automatic exit from standby mode to service the access request. This condition may also prevent standby mode being entered at all depending upon when the new access arrives at the SRI interface

Note: Once a pending SRI access has triggered an exit from standby mode, if all pending SRI accesses have been serviced and the standby request is still active, the memory controller will not return to standby mode.

An automatic exit from standby mode will not clear the **EBU_CLC.DISR** field. If automatic exit is used, then the **EBU_CLC.DISR** field will have to be cleared by an explicit write of 0_B before standby mode can be used again.

15.10.4 DLL Operation

The DLL is required for the following reasons:

- It is used to delay the DQS signals from the external DDR memory and enable read data to be successfully transferred between the DDR SDRAM and the memory controller. This is enabled by setting **EBU_DLLCON.RD_EN** to 1_B.
- It is used to delay the write data output from the memory controller to the DDR memory device and enable the correct relationship between the DQ, DQM and DQS lines to be estabilised when the external bus clock is running at the same frequency as EBU_CLK. (For signal timing with other clock ratios see **"Generation of DDR Control Signals without using the DLL" on Page 15-24**). This is enabled by setting **EBU_DLLCON.WR_EN** to 1_B.
- It is used to adjust the duty cycle of the clocks to external memory to the optimum 50% when the ratio between internal and external clock is 1:1. This is enabled by setting **EBU_DLLCON.DCC_EN** to 1_B

The calibrated delay value used by the slave delay lines will only be updated when it is safe to do so.

- The delays affecting write data (DQ and DQM) will only be updated when a DDR write is not taking place
- The delays affecting the DQS inputs will only be updated when a DDR read is not taking place
- The delays used to compensate the duty cycle will be continuously updated but using a clocking signal that is phase shifted so that glitches cannot occur on the output.

15.10.4.1 Locking the DLL

Once enabled by setting **EBU_DLLCON.DLL_DIS** to 0_B, the DLL can be initialised by writing 1_B to **EBU_DLLCON.DLL_RST**. This will trigger the DLL to lock to the current DDR clock frequency. If the EBU_CLK frequency is modified, then this field should be rewritten to lock the DLL to the new frequency.

A status bit is provided, **EBU_DLLCON.DLL_LCK**. This will be set when The DLL successfully locks to the current EBU_CLK frequency.

It will be cleared after reset and when either

- 1_B is written to **EBU_DLLCON.DLL_RST**
- The DLL loses lock with EBU_CLK.

Once initial lock has been achieved, the DLL will continually update its lock point. This behaviour will be inhibited when **EBU_DLLCON.DLL_DIS** is set to logic one.

The DLL will only flag "loss of lock" by setting **EBU_DLLCON.DLL_LCK** to 0_B if the input frequency is sufficiently low that the master delay line has too few delay line elements to enable a lock point to be achieved. In all other cases, the delay line will attempt to track the input frequency. If the input frequency is changed using the CGU control logic, signal positioning will be incorrect while the delay line tries to relock. However the lock signal will remain set unless the new frequency is out of range. For this reason, it is recommended that frequency changes are always performed using the clock source control logic. See **“Clocking Modes” on Page 15-16**.

After reset, the DLL will be disabled with **EBU_DLLCON.DLL_DIS** set to logic ’1’.

The DLL has two possible locking algorithms selected by the **EBU_DLLCON.ALGO** bit. when set to 0_B, the DLL will use a fast locking algorithm to rapidly scan the delay setting using intervals of four delay cells from zero to just past the lock point. It will then adjust the delay back down incrementally until the lock point is reached.

If **EBU_DLLCON.ALGO** is set to 1, the DLL will use a slow locking algorithm where the delay is scanned using increments of one delay cell until the lock point is passed. This mode has a lesser risk of spurious errors if the clock period is sufficiently small that the four delay cell increments of the fast locking mode are a significant proportion of the clock period.

15.10.4.2 DLL Operating Modes

The DLL is only designed to lock at frequencies between 80 MHz and 180 MHz. At lower frequencies, the DLL can be operated unlocked with a a static delay programmed by the **EBU_DLLCON.DLL_VALUE** register field.

In this mode, ’1’ should be written to **EBU_DLLCON.DLL_DIS**. This will prevent the DLL from trying to lock. The DLL value will then remain at the value written to the **EBU_DLLCON.DLL_VALUE** register field (permitted values 0 to 425).

This preprogrammed value should therefore provide sufficient margin between clock and delayed DQS edges for the interface to operate.

Note: Each delay element should have a delay of between 35ps and 120ps depending on the operating conditions of the device.

*Note: The master delay line can add 425 delay elements to the input clock and the logic is therefore designed to cope with a master delay line output of 0 to 425. Writing a larger value than 425_D to **EBU_DLLCON.DLL_VALUE** when **EBU_DLLCON.DLL_DIS** is set will cause arithmetic overflows in the slave delay elements and cause the delayed signals to be disabled*

15.10.4.3 DLL Related Access Error Conditions

Accesses to DDR memory will return an SRI error if:

- **EBU_DLLCON.DLL_LCK** is 0_B and
- **EBU_DLLCON.DLL_DIS** is 0_B and
- **EBU_DLLCON.WR_EN** is 1_B or **EBU_DLLCON.RD_EN** is 1_B

Accesses to any external memory will return an error if:

- **EBU_DLLCON.DLL_LCK** is 0_B and
- **EBU_DLLCON.DLL_DIS** is 0_B and
- **EBU_DLLCON.DCC_EN** is 1_B

15.10.4.4 DQ and DQM Outputs (EBU_DLLCON.WR_EN=1_B)

The DQ and DQM outputs will be delayed by 25% of a clock cycle. There will be two delay elements adjusting the clocks of the flipflops driving the DQ and DQM outputs (one for positive edge and one for negative edge). The optimum value can be adjusted manually by up to +3/64 and -4/64 of a clock cycle by writing the appropriate signed value to the **EBU_DLLCON.WR_D_ADJ** register field[1)].

The delay lines will only be allowed to update when a write is not in progress.

15.10.4.5 DQS Inputs (EBU_DLLCON.RD_EN=1_B)

The DQS inputs will be individually delayed by 25% of a clock period (EBU_CLK) before being used as the capture clock for the read data (one delay per byte lane). The optimum value can be adjusted manually by up to +3/64 and -4/64 of a clock cycle by writing the appropriate signed value to the **EBU_DLLCON.RD_DQS_ADJ** register field1).

The setpoint of the delay lines can only be updated when a read is not in progress. This is not a problem for DDR devices using the synchronous state machine where the device protocols enforce a gap on the databus between “back-to-back” reads but can be an

1) The field allows for a signed number with a value between -4 and +3..

issue for devices using the SDRAM state machine where reads can be aggressively pipelined. See **Chapter 15.19** and **Chapter 15.20** for more information on managing updates of the slave delay lines.

15.10.4.6 Duty Cycle Correction

The negative clock edge is used to clock the flipflops used to generate the negative edge of the external memory clocks when 1:1 clock ratio is selected. It also clocks the flipflops generating those control signals generated on the negative edge of the internal clock. If EBU_CLK does not have a 50% duty cycle then the edges will deviate for the nominal position.

The duty cycle correction delay is used to compensate for the duty cycle distortion caused by the pulse swallowing circuit used to locally divide the input clock to generate EBU_CLK. A delay line with a nominal value of 50% of clock period is used to generate a clock edge at the same position in the clock cycle as the negative edge of a 50% duty cycle clock of the same period.

If duty cycle correction is disabled by setting the **EBU_DLLCON.DCC_EN** register bit to 0_B, the negative edge flipflops are connected directly to an anti-phase version of the EBU_CLK clock signal. See **"Local Clock Divider" on Page 15-17** for information on how this anti-phase clock is generated.

Note: This is intended to allow the correct generation of the external interface signals at lower frequencies of the memory controller input clock (outside the DLL lock range) when the duty cycle is 50% and the local clock division circuit is set to 1:1.

15.10.5 DLL Drift detector

The DLL contains a modified phase detector with an expanded detection window intended to detect when the drift rate of the locking point has exceeded the tracking limit of the DLL.

This circuit is enabled when the following conditions are true:

- The DLL has achieved lock.
- 1_B is written to the **EBU_DLLCON.WIN_EN** bitfield.

Once enabled the drift detector will monitor the phase of the DLL input and output clocks. If the phase variation of the input and output clocks exceeds the window of the detector, all accesses to DDR memory will be stalled by the EBU and the **EBU_SDRSTAT.DRIFT_WARN** bitfield will be set to 1_B. Once the drift detector registers that the phase variation has decreased to within the window, the stalled accesses will be allowed to proceed. **EBU_SDRSTAT.DRIFT_WARN** will not clear until written with 0_B.

The size of the window is set to be ±6 delay elements.

The principle of operation is that the error on the lockpoint should never exceed one delay element if the DLL control logic can keep up with the current rate of drift.

If this feature is to be relied on to prevent data corruption, it must be ensured that the operating frequency of the DDR interface is limited so that the worst case signal positioning error does not cause a timing violation.

15.10.6 Generation of DDR Control Signals without using the DLL

The previous section covered the principles of using the DLL to generate the correct signal timing for DDR signals when the internal to external clock ratio is 1:1.

If the ratio of the internal to external clocks is not 1:1, then the internal clock is used to generate the necessary signal timing for outputs without the use of the DLL. For this to work correctly, the shifting of write DQ and DQM by the DLL must be disabled (**EBU_DLLCON.WR_EN** must be 0_B)

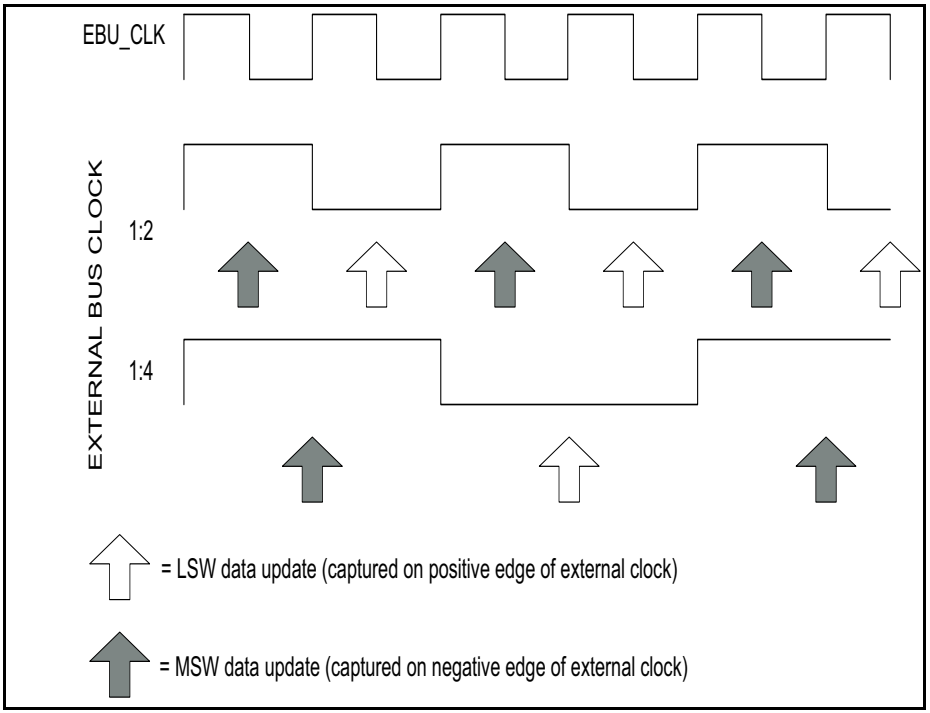

Figure 15-6 Write Data Update Points

15.10.7 Read Data Capture for DDR Devices

The EBU has two possible methods of capturing the data read from DDR devices:

15.10.7.1 Read Data FIFO

The read data FIFO is clocked by the DQS signals generated by the DDR memory device. As the memory device will generate DQS edges aligned with data changes, the DQS signals have to be phase shifted using the delay lines to guarantee safe capture of the data. See **"DQS Inputs (EBU_DLLCON.RD_EN=1B)" on Page 15-22** for the method used to generate a fixed delay of 25% of an EBU_CLK period (nominal). This method can be used at any setting of the EBU_CLK to external clock ratio provided that 25% of an EBU_CLK period provides sufficient setup time to successfully capture the data.

If the DLL is not locked, then a fixed delay value can be written into **EBU_DLLCON.DLL_VALUE**. This will insert a fixed number of delay cells into the DQS input path (**DLL_VALUE**/4). As there is no feedback mechanism in this mode to compensate for changes in operating conditions, the value of the delay inserted will vary as voltage and temperature of the device changes.

This method treats the DQS inputs as asynchronous clocks and the data is resynchronised to EBU_CLK.

15.10.7.2 FIFO Bypass Mode

At lower frequencies it is possible to capture the read data from DDR memories without using the data FIFO to resynchronise it to the internal clock domain. This allows DDR memories to be accessed without requiring the DLL. For this mode to work correctly, the following constraints must be met:

- The rising edge of the feedback clock must be guaranteed not to coincide with the rising edge of the internal clock. For the TC1798, this is possible up to a maximum external bus frequency frequency of 45 MHz.
- The external bus frequency must be sufficiently low to allow the DQS & DQ to be generated from one clock edge and reach a stable state before the next clock edge.
- The first DQS/DQ transition must be triggered by a rising clock edge
- Once the first DQS/DQ transition has occurred all clock edges must trigger a DQS/DQ transition until the access completes.

In this mode $\overline{\text{DDRCLKO}}$ will be used as the feedback clock and both edges of the feedback clock will be used to register DQ (data) and DQS lines from the memory. A change in state of the DQS will cause the sampled data to be transferred into the read FIFO.

FIFO bypass mode is enabled by writing 1_B to the **EBU_MODCON.FIFO_BYPASS** bitfield.

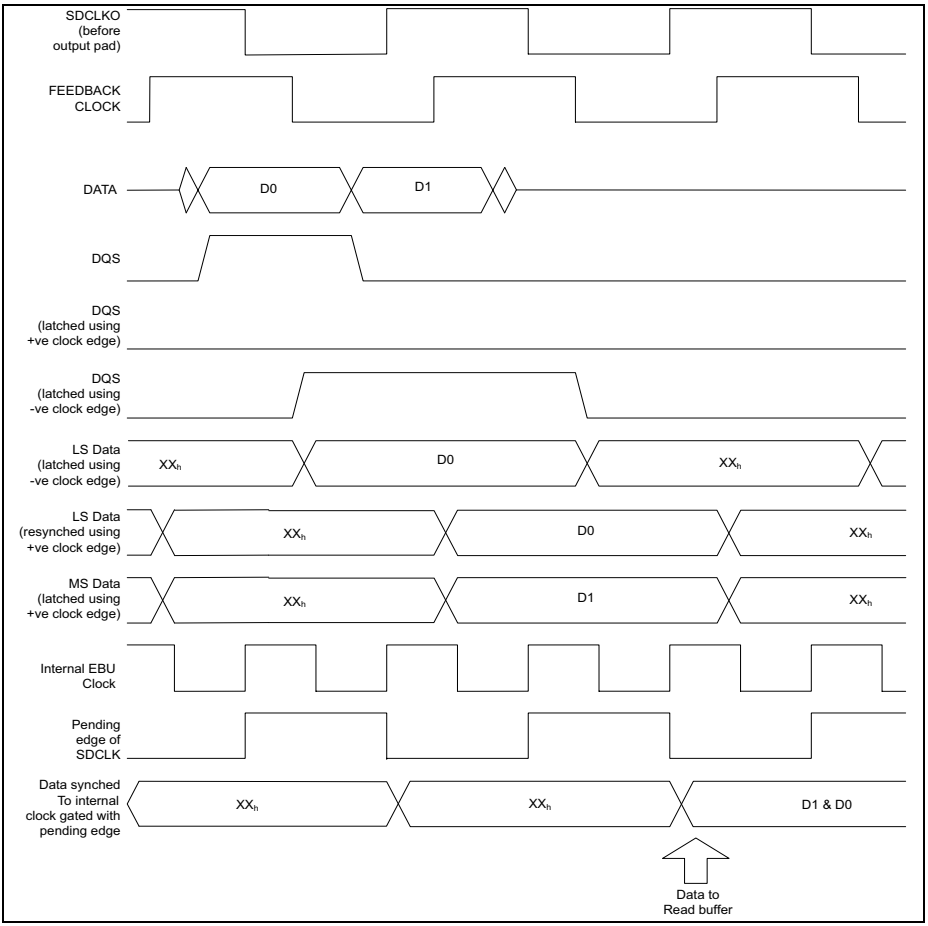

Figure 15-7 Data Read Timing for Accesses bypassing the FIFO

15.10.8 External Bus Clock Generation

The memory controller can generate two external bus clocks.

One of these is intended for use with SDRAM/DDRAM type devices controlled by the SDRAM state machine[1)] and is output on DDRCLKO (and $\overline{\text{DDRCLKO}}$ if a differential clock is required). See **"SDRAM External Bus Clock Generation" on Page 15-117**

1) See **"Programmable Device Types" on Page 15-54** for the device types supported by the EBU and the state machines used to control them

The other is intended for use with other synchronous memories such as burst flash and is output on BFCLKO (and DDRCLKO if a differential clock is required). See **"Burst Flash Clock" on Page 15-91**

For devices without DQS outputs, clock feedback is used to correct for pad output and PCB track delays and each clock output therefore has an equivalent clock input. These are SDCLKI (DDRCLKO alternate function) and BFCLKI respectively. If a device does have DQS outputs, these are used to time read data capture (for the only exception see **"FIFO Bypass Mode" on Page 15-25**).

If a DDR memory is attached to the EBU, it will normally require a differential clock. For devices using the SDRAM control state machine this is DDRCLK & DDRCLK. For devices using the burst flash control state machine, the differential clock will be BFCLKO and DDRCLK.

The clocking mode will be determined by the **AGEN** fields of the configured memory regions.

- If any region is configured for LPDDR NVM (**AGEN** = 10_D) or DDRAM (**AGEN** = 12_D), then the differential DDRCLK will be output on DDRCLK and DDRCLK.
- If any region is configured for DDR burst flash (**AGEN** = 9_D) or ONFI 2 DDR flash (**AGEN** = 13_D), the differential DDRCLK will be output on BFCLKO and DDRCLK.
- Configuring both of the above conditions will force the DDRCLK and BFCLKO outputs to use identical settings, In this case both regions must be configured with identical **EXTCLOCK** and **SDCMSEL**/**BFCMSEL** settings. If this is not done, the the EBU contains logic which will try and configure sensible clock settings as follows:
  - the frequency of the output clock will be set by the **EXTCLOCK** setting of the highest priority region configured for DDR memory[1].
  - BFCLKO and SDCLKO will both output the positive phase of DDRCLK
  - If an enabled region configured as DDR burst flash has **BFCMSEL** set to 0_B or an enabled region is configured for DDRAM or LPDDR NVM with **SDCMSEL** set to 0_B then the clock will run continuously at the frequency specified by the **EXTCLOCK** setting of that region.
  - Clock feedback for both memory types (if required) will be taken from the SDCLKI pin.
- Setting the **CLK_COMB** bit in the **EBU_MODCON** register will have an identical effect to configuring both types of DDR memory. This is not dependent on having any DDR memory configured. (e.g. this could be used to run SDRAM off the BFCLKO clock output.)

Note: All attached DDR memories use the same DQS signals and read/write datapaths. Due to the practical difficulties of dynamically switching the clock frequency of a DDR interface, this effectively forces all DDR devices attached to the EBU to be run at the same clock frequency.

1) region 0 has the highest priority and region 3 the lowest

15.11 External Bus Arbitration

External bus arbitration is provided to allow the EBU to share its external bus with other master devices. This capability allows other external master devices to obtain ownership of the external bus, and to use the bus to access external devices connected to this bus. The scheme provided by the EBU is compatible with other TriCore and XC2XXX devices and therefore allows the use of such devices as (external bus) masters together with the TC1798.

*Note: In this section, the term "external master" is used to denote a device which is located on the **external** bus and is capable of generating accesses across the external bus (i.e. is capable of driving the external bus). An external master is not able to access units that are located inside the TC1798.*

15.11.1 External Bus Modes

The EBU can be in one of two bus states on the external bus:

- Owner State
- Hold State

When in Owner State, the EBU operates as the master of the external bus. In other words, the EBU drives the external bus as required in order to access devices located on the external bus. While the EBU is in Owner State it is not possible for any other master to perform any accesses on the external bus. When the EBU is in Owner State, **EBU_MODCON.BUSSTATE** is set to 1_B.

In Hold State, the EBU tri-states the appropriate signal on the external bus in order to allow another external bus master to perform accesses on the external bus (i.e. to allow another master to drive the various external bus signals without contention with EBU). When the EBU is in Hold State, **EBU_MODCON.BUSSTATE** is set to 0_B.

15.11.2 Arbitration Signals and Parameters

The arbitration scheme consists of an external bus master that is responsible for controlling the allocation of the external bus. This master is referred to as the "Arbiter" within this document. The other external bus master (termed Participant within this document) requests ownership of the bus, and when necessary, from the Arbiter. The EBU can be programmed to operate either as an Arbiter or as a Participant (see **Page 15-30**). The following three lines are used by the EBU to arbitrate the external bus.

Table 15-6 EBU External Bus Arbitration Signals

Signal	Direction	Function
$\overline{\text{HOLD}}$	In	$\overline{\text{HOLD}}$ is asserted (low) by an external bus master when the external bus master requests to obtain ownership of the external bus from the EBU.
$\overline{\text{HLDA}}$	In/Out[1)]	$\overline{\text{HLDA}}$ is asserted (low) by the Arbiter to signal that the external bus is available for use by the Participant (i.e. the bus is not being used by the Arbiter). $\overline{\text{HLDA}}$ is sampled by the Participant to detect when it may use the external bus.
$\overline{\text{BREQ}}$	Out	$\overline{\text{BREQ}}$ is asserted (low) by the EBU when the EBU requests to obtain ownership of the external bus.

1) The direction of this signal depends upon the mode in which the EBU is operating (see Page 15-30).

Two components that are equipped with the EBU arbitration protocol can be directly connected together (without additional external logic) as shown below:

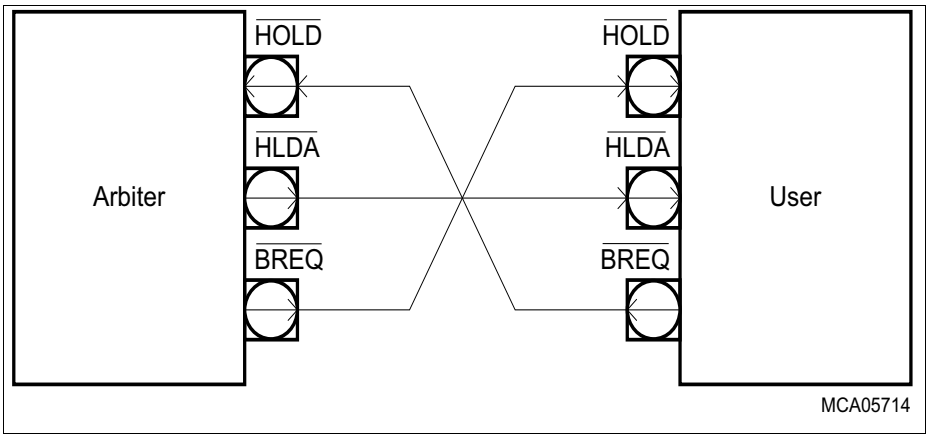

Figure 15-8 Connection of Bus Arbitration Signals

*Note: In the example of **Figure 15-8**, it is possible for the EBU to perform the function or either Arbiter or Participant (or indeed both the Arbiter and Participant may be the EBU).*

Table 15-7 lists the programmable parameters for the external bus arbitration.

Table 15-7 External Bus Arbitration Programmable Parameters

Parameter	Function	Description See
EBU_MODCON.ARBMODE	Arbitration mode selection	Page 15-30
EBU_MODCON.ARBSYNC	Arbitration input signal sampling control	
EBU_MODCON.EXTLOCK	External bus ownership locking control	
EBU_MODCON.TIMEOUTC	External bus time-out control	

15.11.3 Arbitration Modes

The arbitration mode of the EBU can be selected through configuration pins during reset or by programming the EBU_MODCON.ARBMODE bit field (see Page 15-30) after reset. Four different modes are available:

- No Bus Mode
- Sole Master Mode
- Arbiter Mode
- Participant Mode

15.11.3.1 No Bus Arbitration Mode

All accesses of the EBU to devices on the external bus are prohibited and will generate an SRI bus error. The EBU is in hold state all the time. The HOLD and HLDA arbitration inputs are ignored and BREQ arbitration output remains at high (inactive) level.

No Bus Mode is selected by EBU_MODCON.ARBMODE = 00_B.

15.11.3.2 Sole Master Arbitration Mode

The EBU is the only master on the external bus; therefore no arbitration is necessary and the EBU has access to the external bus at any time. The EBU is in owner state all the time. The HOLD arbitration input is ignored, and the HLDA and BREQ arbitration outputs remain at high (inactive) level.

Sole Master Mode is selected by EBU_MODCON.ARBMODE = 11_B.

15.11.3.3 Arbiter Mode Arbitration Mode

The EBU is the default owner of the external bus (e.g. applicable when operating from external memory). Arbitration is performed if an external master (e.g. second TriCore) needs to access the external bus.

The EBU is cooperative in relinquishing ownership of the external bus while operating in Arbiter Mode. When the HOLD input is active, the EBU will generate delay any attempt to access the external bus from the internal SRI. However, the EBU is aggressive in

regaining ownership of the external bus while operating in Arbiter Mode. The EBU, having yielded ownership of the bus, will always request return of ownership even if there is no EBU external bus access pending.

Arbiter Mode is selected by EBU_MODCON.ARBMODE = 01_B.

Table 15-8 and **Figure 15-9** show the functionality of the arbitration signals in Arbiter Mode.

Table 15-8 Function of Arbitration Pins in Arbiter Mode

Pin	Type	Pin Function in Arbiter Mode
$\overline{\text{HOLD}}$	In	In owner state (EBU is the owner of the external bus), a low level at $\overline{\text{HOLD}}$ indicates a request for bus ownership from the external master. In hold state (EBU is not the owner of the external bus), a high level at $\overline{\text{HOLD}}$ indicates that the external master has relinquished bus ownership, which causes the EBU to exit hold state.
$\overline{\text{HLDA}}$	Out	While $\overline{\text{HLDA}}$ is high, the EBU is operating in owner state. A high-to-low transition indicates that the EBU has entered hold state and that the external bus is available to the external master. While $\overline{\text{HLDA}}$ is low, the EBU is operating in hold state. A low-to-high transition indicates that the EBU has exited hold state, and has retaken ownership of the external bus.
$\overline{\text{BREQ}}$	Out	$\overline{\text{BREQ}}$ is high during normal operation. The EBU drives $\overline{\text{BREQ}}$ low two EBU clock cycles after entering hold state (after asserting $\overline{\text{HLDA}}$ low). $\overline{\text{BREQ}}$ returns high one clock cycle after the EBU has exited hold state (after driving $\overline{\text{HLDA}}$ high).

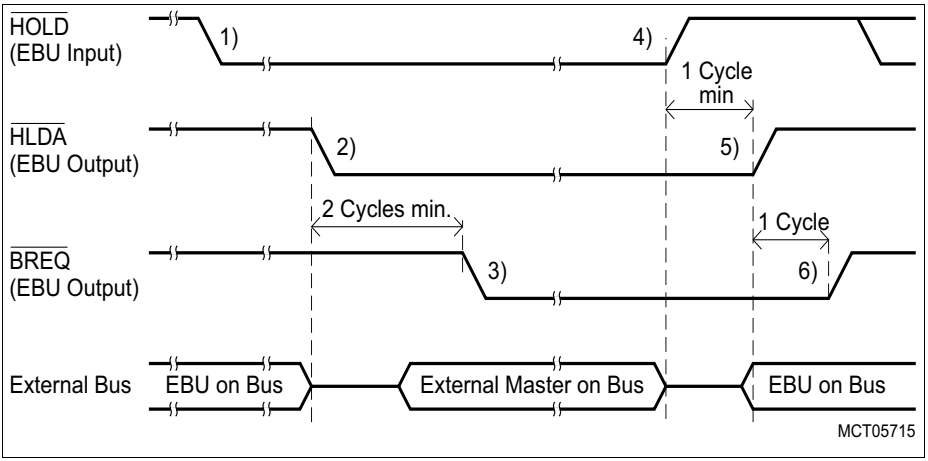

Figure 15-9 Arbitration Sequence with the EBU in Arbiter Mode

In Arbiter Mode, the arbitration sequence starts with the EBU as owner of the external bus.

1. The external master wants to perform an external bus access by asserting a low signal on the HOLD input.
2. When the EBU is able to release bus ownership, it enters hold state by tri-stating its bus interface lines and drives HLDA = 0 to indicate that it has released the bus. At this point, the external master ia allowed to drive the bus.
3. Two clock (EBU_CLK) cycles minimum after issuing HLDA low, the EBU drives BREQ low in order to regain bus ownership. This bus request is issued whether or not the EBU has a pending external bus access. However, the external master will ignore this signal until it has finished its bus access. This scheme assures that the external master can perform at least one complete external bus access.
4. When the external master has completed its access, it tri-states its bus interface and sets HOLD to inactive (high) level to signal that it has released the bus back to the EBU.
5. When the EBU detects that the bus has been released, it returns HLDA to high level and returns to owner state by actively driving the bus interface lines. There is always at least one clock (EBU_CLK) cycle delay from the release of the HOLD input to the EBU driving the bus.
6. Finally, the EBU deactivates the BREQ signal a minimum of one clock (EBU_CLK) cycle after deactivation of HLDA. Now (and not earlier) the external master can generate a new hold request to the EBU.

This sequence assures that the EBU can perform at least one complete bus cycle before it re-enters hold state as a result of a request from the external master.

The conditions that cause change of bus ownership when the EBU is operating in Arbiter Mode are shown in **Figure 15-10**.

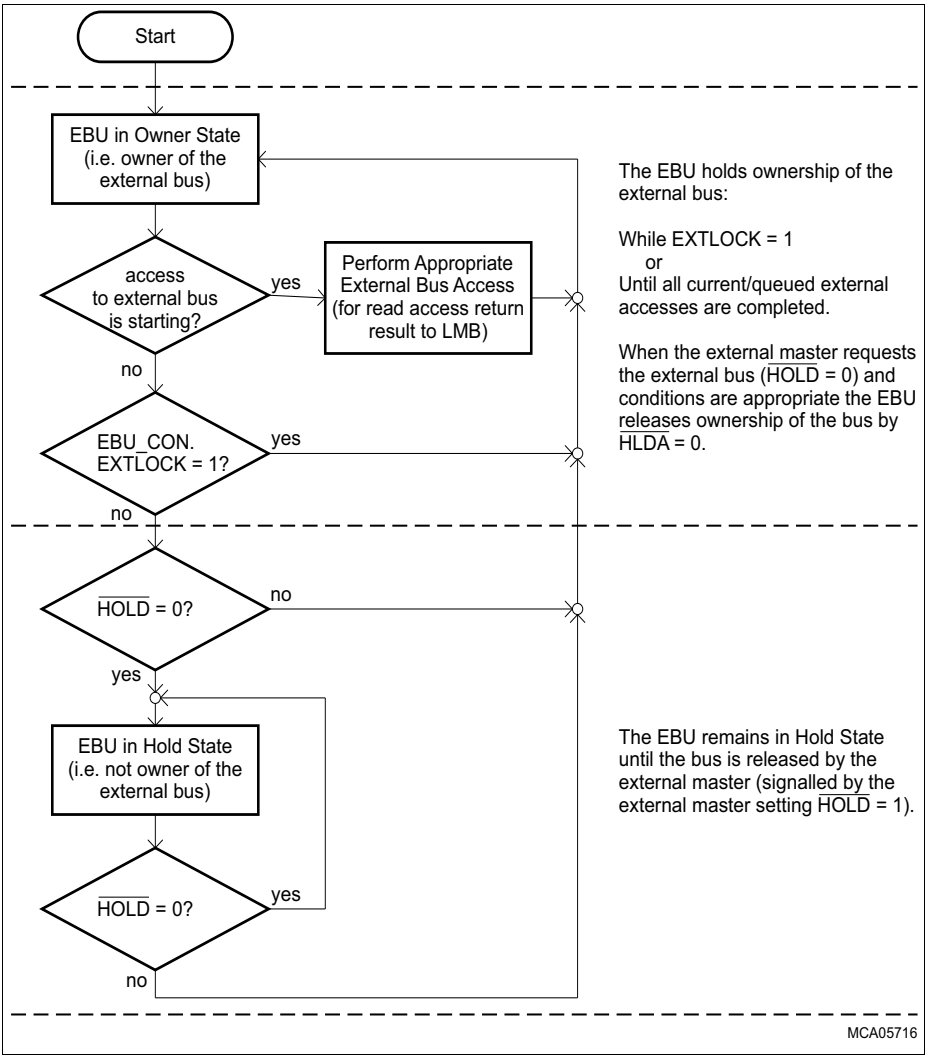

Figure 15-10 Bus Ownership Control in Arbiter Mode

15.11.3.4 “Participant Mode” Arbitration Mode

The EBU tries to gain bus ownership only in case of pending transfers (e.g. when operating from internal memory and performing stores to external memory). While the EBU is not the owner of the external bus (default state), any SRI access to the external bus will be delayed by the EBU. Any such access will cause the EBU to arbitrate for ownership of the external bus.

Once the access has been completed, the EBU will continue to accept requests from the SRI bus until the external master asserts $\overline{HOLD}$ = 0. After the external master has asserted $\overline{HOLD}$ = 0, the EBU will respond by delaying subsequent SRI accesses to external memory and will return ownership of the bus to the external master once any ongoing transaction is complete.

The use of the arbitration signals in Participant Mode is:

Table 15-9 Function of Arbitration Pins in Participant Mode

Pin	Type	Pin Function in Participant Mode
$\overline{HOLD}$	In	When the EBU is not in hold state ($\overline{HLDA}$ = 0) and has completely taken over control of the external bus, a low level at $\overline{HOLD}$ requests the EBU to return to hold state.
$\overline{HLDA}$	In	When the $\overline{HLDA}$ signal is high, the EBU is in hold state. When the EBU has requested ownership of the bus, the EBU is released from hold state by a high-to-low transition at $\overline{HLDA}$.
$\overline{BREQ}$	Out	$\overline{BREQ}$ remains high as long as the EBU does not need to access the external bus. When the EBU detects that an external access is required, it sets $\overline{BREQ}$ = 0 and waits for signal $\overline{HLDA}$ to become low. When the EBU has completed the external bus access (and has re-entered hold state), it will set $\overline{BREQ}$ = 1 to signal that it has relinquished ownership of the external bus.

Participant Mode arbitration mode is selected by EBU_CON.ARBMODE = 10_B.

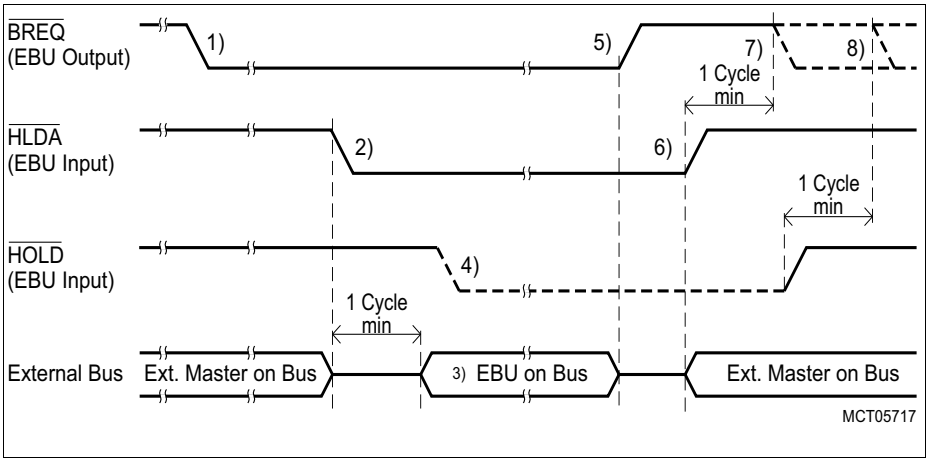

Figure 15-11 Arbitration Sequence with the EBU in Participant Mode

In Participant Mode, the arbitration sequence starts with the EBU in hold state.

1. The EBU detects that it has to perform an external bus access by asserting a low signal on the $\overline{\text{BREQ}}$ output.
2. When the external master is able to release bus ownership, the external master releases the external bus by tri-stating its bus interface lines and drives the $\overline{\text{HLDA}}$ = 0.
3. At least one clock (EBU_CLK) cycle after detecting $\overline{\text{HLDA}}$ = 0, the EBU will start to drive the external bus.
4. When the EBU is in owner state, the external master may optionally drive $\overline{\text{HOLD}}$ = 0 to signal that it wants to regain ownership of the external bus.
5. When the criterias are met for the EBU to release the bus ownership, the EBU enters hold state and drives $\overline{\text{BREQ}}$ = 1 output high to signal that it has released the bus.
6. When the external master detects that the EBU has released the bus ($\overline{\text{BREQ}}$ = 1), it returns $\overline{\text{HLDA}}$ to high level and takes ownership of the external bus.
7. The EBU will not request ownership of the external bus again ($\overline{\text{BREQ}}$ = 0) at least one clock (EBU_CLK) cycle after $\overline{\text{HLDA}}$ has been driven high).
8. In owner state, the EBU will not request ownership of the external bus $\overline{\text{BREQ}}$ = 0) for at least one clock (EBU_CLK) cycle after its $\overline{\text{HOLD}}$ input has been driven high.

The conditions that cause change of bus ownership when the EBU is operating in Participant Mode is shown in **Figure 15-10**.

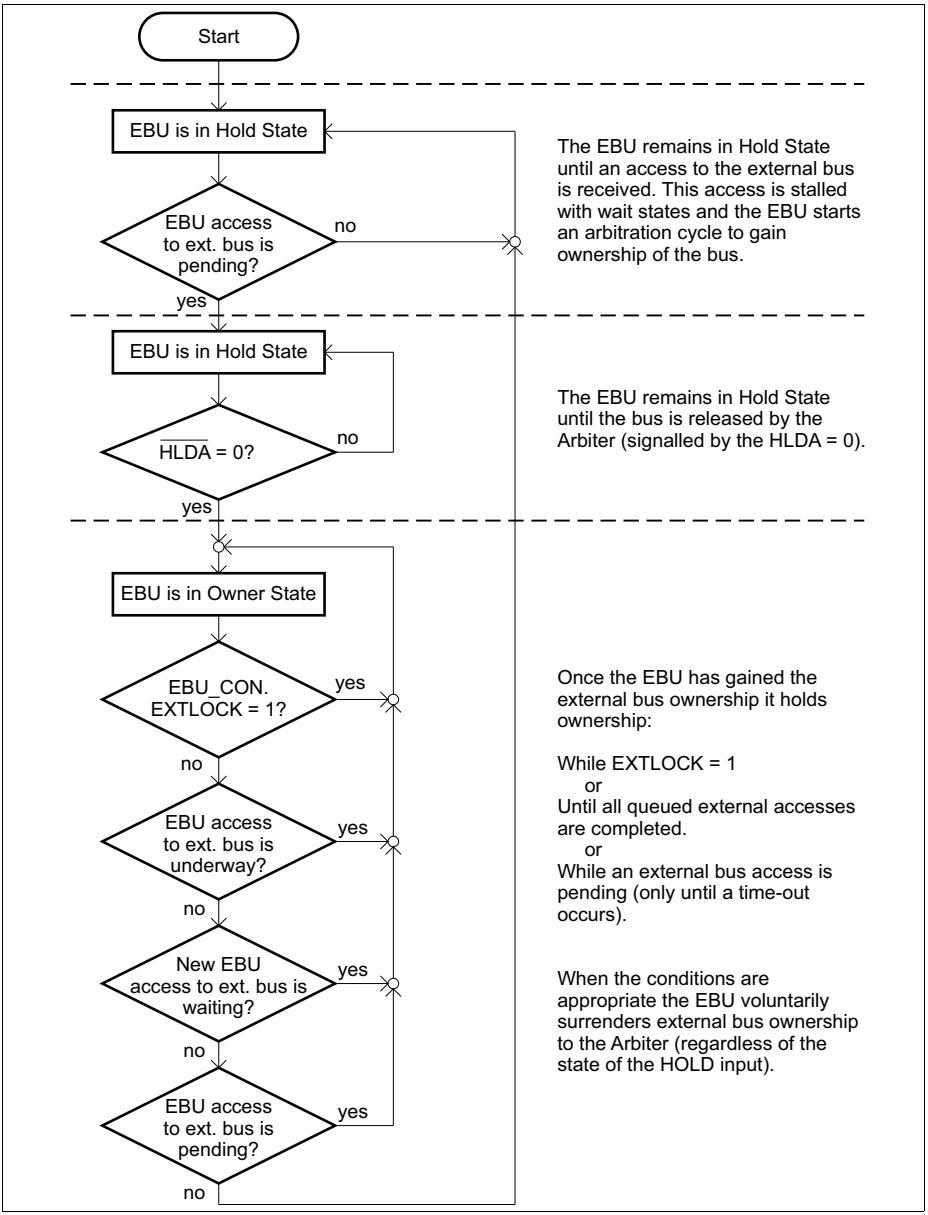

Figure 15-12 Bus Ownership Control with the EBU in Participant Mode

15.11.4 Switching Arbitration Modes

The arbitration logic will allow arbitration modes to be switched “on-the-fly” and will switch between modes as described in the following sections. However it is recommended that the arbitration mode is set as soon as possible after power on and that it is then not modified.

If this is not possible, then changes in arbitration mode should use “no bus” mode as an intermediate state with the arbiter in participant mode being placed in no bus mode first. Once both arbiters are in no bus mode, then the new modes can be set.

Note: It should be remembered that the arbitration logic drives the HLDA pin in arbiter or sole master modes and that having both sets of logic in one of these modes should be avoided to prevent contention on the signal.

15.11.4.1 Exiting No Bus Mode

As arbitration is disabled in this mode, there will be no attempt to gain or release the bus when exiting the mode. A transfer to participant mode will occur immediately and the arbitration logic will directly enter the hold state.

Transfers to sole master or arbiter mode will occur immediately and will result in the arbitration logic entering the owner state directly.

If an attached SDRAM is configured for automatic self refresh, the SDRAM will be taken out of self refresh as part of the transition to owner state.

15.11.4.2 Exiting Sole Master Mode

The arbitration logic will switch directly from sole master to arbiter mode remaining in the owner state.

The arbitration logic will exit sole master mode and transfer to no bus or participant modes only when in the hold state. If the arbitration logic is in owner state when the request to change mode is made, then the arbitration logic will release the bus before entering the new mode.

15.11.4.3 Exiting Arbiter Mode

The arbitration logic will exit arbiter mode and transfer to sole master mode only when in the owner state. If the arbitration logic is in hold state when the request to change mode is made, then the arbitration logic will request the bus and wait until ownership is granted before switching mode.

The arbitration logic will exit arbiter mode and transfer to no bus or participant modes only when in the hold state. If the arbitration logic is in owner state when the request to change mode is made, then the arbitration logic will release the bus before entering the new mode.

Note: If a transfer to participant mode results in both arbiters being in participant mode then there is a high possibility of a system deadlock. Any attempt to access external memory will result in the bus being requested. However, neither arbiter can drive HLDA so the bus cannot be granted. The external memory access will therefore stall indefinitely, blocking any further attempt to write to the EBU_MODCON register to change arbitration mode.

15.11.4.4 Exiting Participant Mode

The arbitration logic will exit participant mode and transfer to no bus mode only when in the hold state. If the arbitration logic is in owner state when the request to change mode is made, then the arbitration logic will release the bus before switching mode.

The arbitration logic will exit participant mode and transfer to sole master or arbiter modes only when in the owner state. If the arbitration logic is in hold state when the request to change mode is made, then the arbitration logic will request the bus and wait until ownership is granted before entering the new mode.

Note: As switching to sole master or arbiter mode requires ownership of the bus, it follows that the other arbiter in the system must be in arbiter mode to grant the bus. This will result in contention on the HLDA signal when the mode change completes.

15.11.5 Arbitration Input Signal Sampling

The sampling of the arbitration inputs can be programmed for two modes:

- Synchronous Arbitration
- Asynchronous Arbitration

When synchronous arbitration signal sampling is selected (ARBSYNC = 0), the arbitration input signals are sampled and evaluated in the same clock cycle. This mode provides the least overhead during arbitration (i.e. when changing bus ownership). The disadvantage is that the input signals must adhere to setup and hold times with respect to EBU_CLK to prevent the propagation of meta-stable signals in the EBU.

When asynchronous arbitration signal sampling is selected (ARBSYNC = 1), the arbitration signals are sampled and then fed to an additional register to be evaluated in the cycle following that in which they were sampled. This provides the EBU with good immunity to signals changing state at or around the time at which they are sampled. The disadvantage is the introduction of additional latency during arbitration (i.e. when changing bus ownership).

15.11.6 Locking the External Bus

The external bus can be locked to allow the EBU to perform uninterrupted sequences of external bus accesses. The EBU allows two methods of locking the external bus:

- Locked SRI accesses (i.e Read-Modify-Write)
- Lock bit EXTLOCK

When the EBU has ownership of the external bus and is performing external bus accesses in response to a locked SRI access sequence, the ownership of the external bus will not be relinquished until the locked SRI access sequence has been completed.

When lock bit EXTLOCK = 1, the EBU will hold the ownership of the external bus until EXTLOCK is subsequently cleared. If EXTLOCK is written to 1 while the EBU is the owner of the external bus, the EBU is immediately prevented from responding to requests for the external bus until EXTLOCK is cleared[1]. If EXTLOCK is written to 1 while the EBU is not the owner of the external bus, the EBU will immediately attempt to gain ownership. When the EBU gains the ownership of the external bus the next time, the external master is prevented from regaining ownership of the external bus until EXTLOCK is again cleared.

Note: There is no time-out mechanism available for the EXTLOCK bit. When the EBU is owner of the external bus with EXTLOCK bit set, the external master will remain locked off the bus until the EXTLOCK bit is cleared by software.

15.11.7 Interaction with Debug System

The EBU monitors the OCDS suspend signal used to freeze peripheral state when the system receives a break command. If the EBU detects a break it will request the external bus (if it is not the current owner). Once the EBU owns the bus, it will refuse any further arbitration requests until the suspend is released. This allows the external memories to be read by the attached debugger.

If this behaviour is not required, setting the **EBU_MODCON.OCDS_SUSP_DIS** bitfield will cause ecternal bus arbitration to continue to operate normally during a break.

15.11.8 Arbitrating SDRAM control signals

Normally, the memory controller will not surrender control of a connected SDRAM type device[2] when arbitrating the external bus. This is because the memory controller needs to keep track of which pages are open in the SDRAM and also because of restrictions on the SDRAM clock.

However, the memory controller can be programmed to tri-state the SDRAM control signals SDCLKO, CKE, $\overline{RAS}$ and $\overline{CAS}$ by setting the EBU_MODCON.SDTRI bit to 1_B. When this bit is set, SDRAM can be shared with another controller provided certain conditions are met by both memory controllers.

1) Requests for the external bus already pending when EXTLOCK is set will not be cancelled so the EBU can give up control of the external bus after EXTLOCK is set provided that the request occurs before the EXTLOCK bit is set.

2) SDRAM, DDRAM & LPDDR-NVM devices

- The SDRAM must be in self refresh mode with the clock safely stopped before ownership of the external bus is transferred. This ensures that all pages in the SDRAM are closed and that the CKE signal is at logic zero. This can be achieved for the memory controller by setting the SDRMREF.AUTOSELFR to 1_B.
- The SDRAM CKE input must have a pull down sufficient to ensure that there is a guaranteed logic zero on the input while bus ownership is being transferred.

15.12 Start-Up/Boot Process

During reset, the EBU will be in “nobus” mode and all pins will be controlled by the Port I/O logic. After reset is removed, the EBU will check to see if external boot has been requested. If external boot is required, then the EBU will set the BUSCONx.PORTW and BUSRCONx.AGEN fields to the appropriate values and enable the necessary pins for use by the EBU. If external boot is not requested then the EBU will remain in “nobus” mode until configured by software.

15.12.1 Disabled (arbitration mode is “nobus”)

The EBU will come up with access to the external bus disabled after reset (i.e. no access from SRI to external memory is possible without EBU re-configuration).

15.12.2 External Boot Mode

The External Boot Mode of the EBU allows the EBU to boot (i.e. run all start-up code) from external memory. Immediately after reset a system may have no knowledge as to the type of memory connected to the external bus. When external boot mode is selected, the EBU will exit reset with the registers configures to allow slow (safe) accesses to both mexed and non-muxed asynchronous memories.

When External Boot Mode is selected, the EBU will be configured to automatically read a 32-bit Boot Configuration Value from an external memory (connected to $\overline{CS0}$, chip select region 0). The Boot Configuration Value in the external boot memory makes it possible to initialize the EBU with more appropriate configuration values for the external boot memory. These configuration values will, in turn, be used for the subsequent read accesses from the external boot memory (i.e. instruction fetches).

The boot configuration fetch can be triggered using two methods:

- Setting the SYSCON.SETEXTBEN bit and then resetting the EBU. In this case all accesses to the EBU will be held while the configuration fetch is in progress
- Writing 1_B to the EBU_EXTBOOT.EBUCFG bit before the end of system boot[1)]. In this case the EBU_EXTBOOT.CFGEND bit should be polled to determine when the fetch has ended and the registers updated.

1) This is determined by the state of the BOOT_ACTIVE flag generated by the SCU.

In both cases the EBU_EXTBOOT.CFGERR bit will be set if the configuration word fetch fails to retrieve valid data. See **"Configuration Word Fetch Process" on Page 15-42** for a full description of the configuration process.

Note: External boot cannot be used if an SDRAM/DDRAM or LPDDR_NVM is connected. This is because these devices do not have an external reset input and will therefore be in an indeterminate state after a reset of the EBU. This state could cause the memory device to drive the databus and, as the DDRCLKO output is disabled after reset, the memory device will remain in this state during the external boot process and interfere with the reads from the boot memory.

15.12.2.1 Configuration Word Fetch Process

If an External Boot configuration fetch is enabled, the EBU will perform one external bus read access to external bus address 000004_H of the memory device attached to chip select line $\overline{CS0}$. As it is assumed by the that the attached memory device has a 32 bit data bus, this is equivalent to a SRI or byte address of 000010_H because of the address translation implemented in the EBU (see **Chapter 15.13.4** on **Page 15-52**).

The data read by this read access is used to configure the EBU with parameters (see **Page 15-44**). The boot read access itself is performed as an asynchronous access cycle with all timing parameters set to their maximum values. This access scheme supports ROMs, EPROMs or Flash memories with both separate address and data connections and also multiplexed address and data connections. **Figure 15-13** shows a timing example of booting from a standard demultiplexed asynchronous memory device.

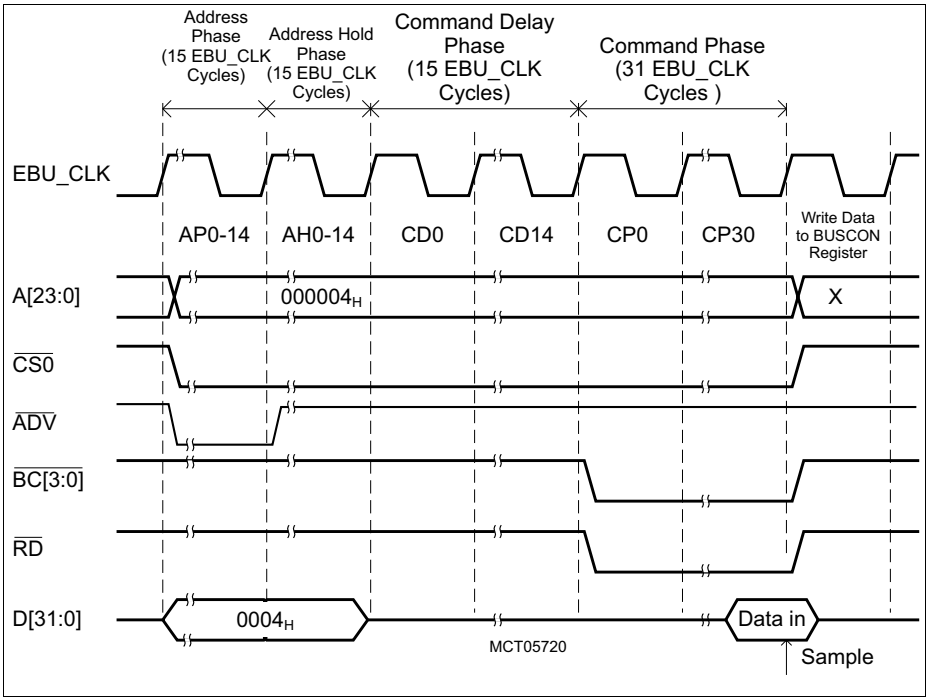

Figure 15-13 Boot Read Access Cycle

When a configuration fetch is triggered, the EBU waits 256 EBU_CLK clock cycles until the access is initiated, as shown in **Figure 15-13**. This gap is inserted to fulfill the recovery times needed by external synchronous devices such as Flash ROMs. During the read access, the maximum number of programmable EBU_CLK cycles is inserted (WAITRDC = 31), and the evaluation of the $\overline{\text{WAIT}}$ signal is inhibited.

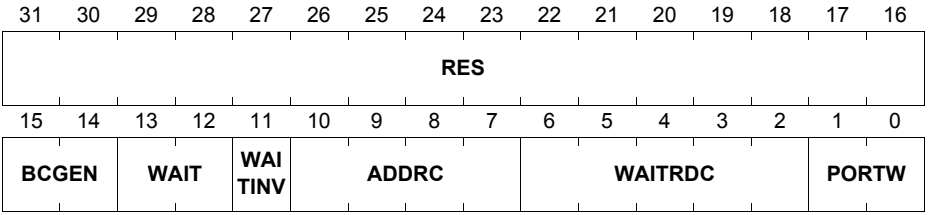
Note: The boot memory must be connected to chip select line $\overline{CS0}$. The EBU assumes that the boot memory is 32-bits wide and, therefore, always reads a 32-bit configuration word at the "Data in" point shown above.

*Note: If $FFFF_H$ is returned as on bits 15 downto 0 of the configuration word during the boot read cycle (e.g. by reading the configuration word from an erased external boot memory device), the arbitration mode is set to No Bus Mode (ARBMODE = 00_B, see **"No Bus Arbitration Mode" on Page 15-30**). However since a value for the BCGEN field of 11_B is not legal for boot, at least one bit of the fetched word will be 0_B for valid data*

15.12.2.2 Boot Configuration Value

The EBU supports boot operation from 32-bit wide memories. The format of the Boot Configuration Value is as follows (Bits 31 to 16 are reserved for future expansion):

Boot Configuration Value



Field	Bits	Description
PORTW	1:0	**Port Width** 00_B external memory is 8 bit 01_B external memory is 16 bit 10_B external memory is two 16 bit memories in parallel to make a 32 bit memory 11_B external memory is 32 bit
WAITRDC	[6:2]	**Number of Wait States for Read Accesses** Loaded into EBU_BUSRAP0.WAITRDC.
ADDRC	[10:7]	**Number of Cycles in the Address Phase** Loaded into EBU_BUSRAP0.ADDRC.
WAITINV	11	**WAIT Input Polarity Control** Loaded into EBU_BUSRCON0.WAITINV.
WAIT	[13:12]	**External Wait State Control** Loaded into EBU_BUSRCON0.WAIT.
BCGEN	[15:14]	**Byte Control Signal Control** Loaded into EBU_BUSRCON0.BCGEN.
RES	[31:16]	**Reserved** This bit field is reserved for future use. In the TC1798, RES should always be set to 0_H.

15.13 Accessing the External Bus

Each internal SRI master can access external devices via the EBU. The EBU provides four user-programmable external memory regions. Each of these regions is provided with a set of registers that determine the parameters of the external bus transaction and one chip select signal. An SRI transaction that matches one of these user-programmable external memory regions is translated by the EBU to the appropriate external access(es).

In the TC1798, the EBU responds to the address ranges as defined in **Table 15-10**.

Table 15-10 EBU External Address Ranges

Address Range	Description	Action
$8300\ 0000_H$ - $8EFF\ FFFF_H$	External memory space (cached area)	compare
$A300\ 0000_H$ - $AEFF\ FFFF_H$	External memory space (non-cached area)	
$F800\ 0000_H$ - $F800\ 03FF_H$	EBU Registers	access registers

The “compare” action means that the EBU compares the supplied SRI address to all its external regions. If a match is found, the EBU performs the appropriate external bus access. Otherwise, the EBU generates an SRI Error Acknowledge.

The “access registers” action means that the EBU is selected for a control/status register access. The EBU performs the requested register access (or generates an SRI Error Acknowledge if there is no register at the supplied address).

For all address ranges that not listed in **Table 15-10** the EBU is not selected and SRI requests are ignored.

15.13.1 External Memory Regions

Each of the external memory regions has its own associated chip select output $\overline{CS}[3:0]$ and a set of control registers to specify the type of memory/peripheral device and the access parameters.

The access parameters for each of the regions can be programmed individually to accommodate different types of external devices. Separate control registers are available to control read and write accesses. This allows optimal access types, speeds and parameters to be chosen. Access type is configured via BUSRCONx and BUSWCONx. Access parameters are configured via BUSRAPx and BUWAPx.

Throughout this document the generic term EBU_BUSCONx is used when either of BUSRCONx or BUSWCONx is applicable and EBU_BUSAPx is used when either of BUSRAPx or BUSWAPx is applicable.

Table 15-11 EBU Address Regions, Registers and Chip Selects

Region	Associated Chip Select	Address Select Registers	Bus Configuration Registers	Bus Access Parameters Registers
Region 0	$\overline{CS0}$	EBU_ADDRSEL0	EBU_BUSRCON0 EBU_BUSWCON0	EBU_BUSRAP0 EBU_BUSWAP0
Region 1	$\overline{CS1}$	EBU_ADDRSEL1	EBU_BUSRCON1 EBU_BUSWCON1	EBU_BUSRAP1 EBU_BUSWAP1
Region 2	$\overline{CS2}$	EBU_ADDRSEL2	EBU_BUSRCON2 EBU_BUSWCON2	EBU_BUSRAP2 EBU_BUSWAP2
Region 3	$\overline{CS3}$	EBU_ADDRSEL3	EBU_BUSRCON3 EUB_BUSWCON3	EBU_BUSRAP3 EBU_BUSWAP3

Table 15-12 lists the programmable parameters that are available for the four external regions (regions 0 to 3) independent of the attached memory device.

Table 15-12 Programmable Parameters of Regions

Register	Parameter (Bit/Bit field)	Function
EBU_ADDRSELx	ALTSEG	Alternate segment of region to be compared to SRI address bits [31:28].
	BASE	Region base address to be compared with SRI address in conjunction with the MASK parameter.
	MASK	Address mask for each external region. Specifies the number of right-most bits in the base address starting from bit 26.
	WPROT	Write Protect bit for each region.
	ALTENAB	Alternate segment enable of a region. Determines whether or not parameter ALTSEG is always compared to SRI address.
	REGENAB	Enable bit for each region. A disabled region will always generate a miss during address comparison.
EBU_BUSCONx	AGEN	Region access type: See **Section 15.14.1**

15.13.2 Address Comparison

Address Comparison is implemented in addition to the address decoding in the SRI bus matrix and is used to map SRI addresses to the EBU regions. The address comparison operation will, by default, take two clock cycles. If the frequency of the SRI bus is set to be less than or equal to 180 MHZ, then the SRI interface of the EBU can be set to use single cycle decode. This is controlled by the **EBU_MODCON.FAST_SRI** bitfield. When set to 1_B, the SRI interface will use a single cycle for address decode.

Note: As the FAST_SRI bit modifies the SRI interface behaviour dynamically, some care is needed when changing the mode of operation. When setting or clearing the bit, time should be allowed after writing the register for the setting to take effect before attempting a read from the EBU. To ensure the new setting has taken effect, it is suggested that the EBU_MODCON register is written twice with the new setting. This is because internal architecture constraints mean that the data from the first write must have been transferred to the register before the second write can proceed.

15.13.2.1 Operation Address Comparison

Each of the four EBU regions can be programmed for independent base addresses and lengths by bits and bit fields in registers EBU_ADDRSELx.

- Bit REGEN is the enable control of a region. If the region is disabled (REGEN = 0), no address comparison will take place for the region.
- Bit field BASE specifies address bits A[31:12] of region x, where A[31:28] must only point to segments 8, 10, 13, and 14 (see **Table 15-13** on **Page 15-50**).[1)]
- Bit field MASK determines the length of a region. It specifies how many bits of anSRI SRI address must match the contents of the BASE(x) bit field (to a maximum of 15, starting with A[26]). Note that address bits A[31:27] must always match.
- Bit WPROT write protects a region. If the region is protected (WPROT = 1), no address comparison will take place for that region on a write access[2)]
- Bit field ALTSEG determines the number of an alternate segment that can be used for address comparison with A[31:28] (if enabled by ALTENAB = 1).
- Bit ALTENAB determines whether an additional alternate segment number as defined by ALTSEG is used for address comparison.

1) There is no hardware lockout preventing other values being written to A[31:28], but in most cases this will result in an inaccessible memory. Enabling a memory region at segment $F8_H$ will result in the memory region conflicting with the registers. The EBU will not work correctly if this is done.

2) The WPROT bit also appiles to the read phase of a read modify write, SRI transaction. This is to prevent two possible error conditions. The first would be where the read phase was accepted and the write phase errored. This is an SRI protocol violation. The second would be where the read and write accesses occurred to different memory addresses (if the read took place to a write protected region and there was an unprotected, lower priority, region mapped to the same address space).

The address comparison scheme is shown in **Figure 15-14**.

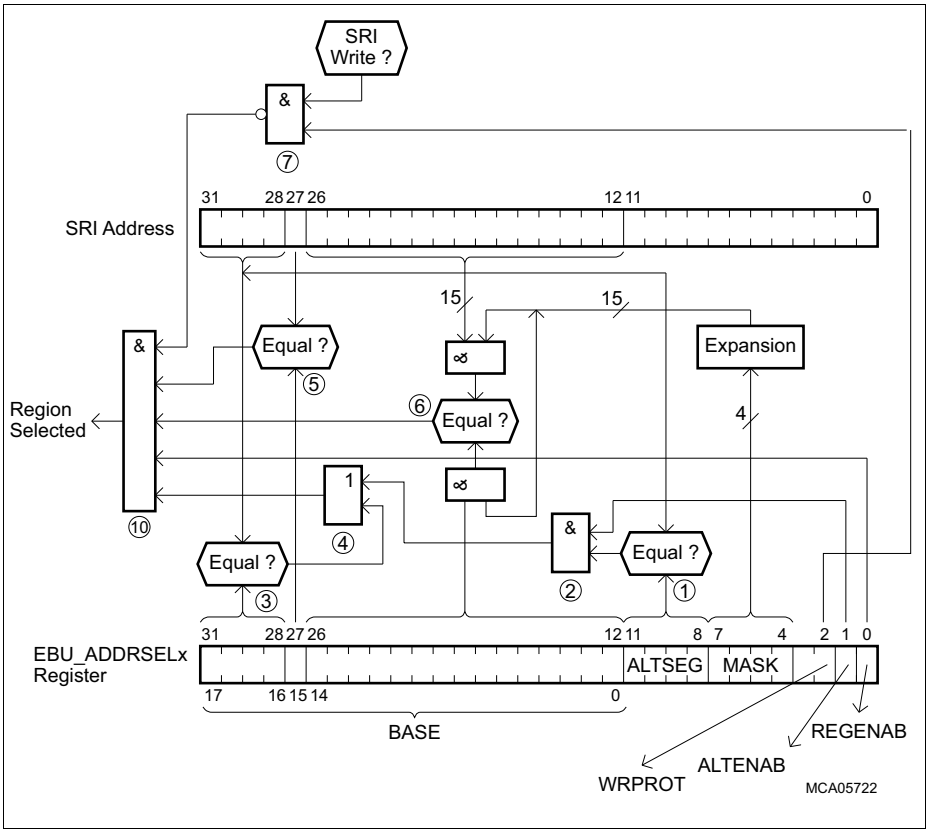


Figure 15-14 Address Comparison to Detect Access to External Region

When the EBU is processing an SRI access, the address is compared in parallel to the parameters of all four regions. The address comparison process for one region is shown in **Figure 15-14**. This process is as follows:

1. The most significant four bits of the SRI address are compared with the ALTSEG bit field (“alternate” segment address). The result of the comparison (1 if equal, otherwise 0) is fed to an AND gate.
2. If ALTENAB = 0, the alternate segment function is disabled and the output of the AND gate is 0. With ALTENAB = 1, the alternate segment function is enabled, and the result of the comparison between ALTSEG and the segment part of the SRI address is fed to an OR gate.

3. The most significant four bits of the SRI address (“main” segment address) are compared to the most significant four bits of the BASE bit field. The result of the comparison (1 if equal, otherwise 0) is fed to the OR gate.
4. The OR gate combines the result of the “main” and “alternate” segment comparisons generates a 1 if the SRI address is in the selected segment(s) for the region, otherwise it generates 0. The output of the OR gate is fed to the final AND gate.
5. Bit 27 of the SRI address is (unconditionally) compared with bit 15 of the BASE bit field. The result of the comparison (1 if equal, otherwise 0) is fed to the final AND gate.
6. The appropriate number of SRI address bits from bit 26 downwards is compared with the corresponding bits from bit field BASE bit 14 downwards. The number of bits used for the comparison is controlled by the MASK bit field. The result of the comparison (1 if the appropriate bits are equal, otherwise 0) is fed to the final AND gate.
7. The NAND gate delivers a 0 if a write is performed to a read-only region (WRPROT=1), and prevents the region from being selected. The output of the NAND gate is fed to the final AND gate.
8. The final AND gate delivers a 1 if a match occurs at the address comparison, and the region x is enabled by REGENAB = 1, and the access is not a write access when the region is defined as read-only access.

This address decoding scheme has the following effects:

- The smallest possible address region is 2^{12} bytes (4 Kbyte)
- The largest possible address region is 2^{27} bytes (128 Mbyte)
- The start address of a region depends on the size of the region. It must be at an address that is a multiple of the size of a region; for example, the smallest region can be placed on any 4-Kbyte boundary, while the largest region can be placed on 8-Mbyte boundaries only.

Table 15-13 shows the possible region sizes and start granularity, as determined by the programming of the MASK bit field. The range of the offset address within such a region is also given.

Table 15-13 EBU Address Regions Size and Start Address Relations

MASK	No. of Address Bits compared to BASE[26:12]	Range of Address Bits compared to BASE[26:12]	Region Size and Start Address Granularity	Range of Offset Address Bits within Region
1111_B	15	A[26:12]	4 Kbyte	A[11:0]
1110_B	14	A[26:13]	8 Kbyte	A[12:0]
1101_B	13	A[26:14]	16 Kbyte	A[13:0]
1100_B	12	A[26:15]	32 Kbyte	A[14:0]
1011_B	11	A[26:16]	64 Kbyte	A[15:0]

Table 15-13 EBU Address Regions Size and Start Address Relations (cont'd)

MASK	No. of Address Bits compared to BASE[26:12]	Range of Address Bits compared to BASE[26:12]	Region Size and Start Address Granularity	Range of Offset Address Bits within Region
1010_B	10	A[26:17]	128 Kbyte	A[16:0]
1001_B	9	A[26:18]	256 Kbyte	A[17:0]
1000_B	8	A[26:19]	512 Kbyte	A[18:0]
0111_B	7	A[26:20]	1 Mbyte	A[19:0]
0110_B	6	A[26:21]	2 Mbyte	A[20:0]
0101_B	5	A[26:22]	4 Mbyte	A[21:0]
0100_B	4	A[26:23]	8 Mbyte	A[22:0]
0011_B	3	A[26:24]	16 Mbyte	A[23:0]
0010_B	2	A[26:25]	32 Mbyte	A[24:0]
0001_B	1	A[26]	64 Mbyte	A[25:0]
0000_B	0	–	128 Mbyte	A[26:0]

The EBU uses the four region select outputs from the above scheme, in conjunction with its own address decode logic, to react to SRI accesses as follows:

1. **Address is in the EBU register space:**
   An EBU register access is executed, and in case of a illegal register address, SRI Error Acknowledge is returned.
2. **Address matches exactly one enabled external region:**
   The requested access is performed to external memory.
3. **Address matches more than one enabled region (overlapping regions):**
   The requested access is performed using the parameters from the region with highest priority. Region 0 has the highest priority and region 3 the lowest priority.
4. **Address matches disabled region(s) or no address match:**
   The EBU returns an SRI Error Acknowledge.

When defining mirrored segments, the user is responsible for ensuring that there is no collision. There is no checking mechanism in hardware that ensures that each segment defined (either in BASE[31:28] or ALTSEG[11:8] or both) is exclusive. Therefore, the user must ensure that each mapping from region 0 to 3 does not interfere with any other; otherwise, only the mapping with the highest priority will take effect.

15.13.3 SRI Bus Width Translation

If the SRI access size is wider than the external bus width specified for the selected external region, the internal access is split in the EBU into several external accesses. For example, if the SRI requests to read a 64-bit word and the external device is only 16-bit

wide, the EBU will automatically perform four external 16-bit accesses. When multiple accesses are generated in this way, external bus arbitration is blocked until the multiple access is complete. This means that the EBU remains the owner of the external bus for the duration of the access sequence. The external accesses are performed in ascending SRI address order.

15.13.4 Address Alignment During Bus Accesses

During an external bus access, the EBU will align the internal byte address to generate the appropriate external word or half-word address aligned to the external address pins. The address alignment will be done as follows:

- For 8 bit memory accesses
  - AD[15:0] will be driven with the value from A_{SRI}[15:0] (mutiplexed accesses only)
  - A[27:0] will be driven with the value from A_{SRI}[27:0]
- For 16 bit memory accesses
  - AD[15:0] will be driven with the value from A_{SRI}[16:1] (mutiplexed accesses only)
  - A[27:0] will be driven with the value from A_{SRI}[28:1]
- For 32 bit memory accesses
  - AD[15:0] and AD[31:16] will both be driven with the value from A_{SRI}[17:2] (accesses to paired 16-bit multiplexed devices only)
  - AD[31:0] will be driven with the right-justified and zero-padded value from A_{SRI}[31:2] (accesses to paired 32-bit multiplexed devices only)
  - A[27:0] will be driven with the value from A_{SRI}[28:2]

15.13.5 SRI Data Buffering

The data for all SRI writes are “posted” into a buffer in the SRI interface before the access is passed to the state machine blocks for execution. This means that all the write data is available to the state machine before the access starts independent of the relative clock frequencies of the internal and external buses and that the write completes at the initiating master before the data is written to the external memory.

15.13.6 Chip Select Control

The EBU generates four chip select signals, $\overline{CSx}$, which are all available at dedicated chip select outputs. Each chip select is associated exclusively with an EBU region. See **"External Memory Regions" on Page 15-45** for a complete description....

15.13.7 Combined Chip Select ($\overline{CSCOMB}$)

The EBU can also generate a combined, global chip select. This is controlled using the EBU_ADDRSELx.GLOBALCS register fields. If this is set to 1_B in a register, then the $\overline{CSCOMB}$ chip select is asserted whenever the associated normal chip select is asserted. Multiple GLOBALCS fields can be set simultaneously.

15.14 Connecting External Memories

The EBU supports interconnection to a wide variety of memory/peripheral devices with flexible programming of the access parameters. In the following sections, the basic features for these access modes are described. The types of external access cycles provided by the EBU are:

- Asynchronous accesses with multiplexed or demultiplexed address and data bus
  - ROMs, EPROMs
  - NOR flash devices
  - NAND flash devices
  - Static RAMs and PSRAMs
- Synchronous accesses with multiplexed or demultiplexed address and data bus
  - NOR flash devices (operating in burst mode)
  - DDR flash devices
  - PSRAMs
  - Page mode flash[1)]
- Accesses using SDRAM Type Command Protocol
  - Mobile SDRAM
  - Mobile DDRAM
  - LPDDR-NVM

Note: Not all memory types supported by the memory controller are known to be available in all quality grades and temperature ranges.

Each type of access is controlled by a state machine in the EBU kernel. See **Table 15-14** for a list of the access types supported and the controlling state machine.

SDRAM type accesses comply with the relevant protocol and have limited programmability. Asynchronous and Synchronous accesses use the concept of access

1) Page mode flash devices are not synchronous but have in common with synchronous devices the ability to return multiple data words for each supplied address. They are therefore handled by the synchronous state machine of the EBU

phases of programmable duration and are more fully described in **“Phases for Asynchronous and Synchronous Accesses” on Page 15-62**

15.14.1 Programmable Device Types

Each CS region (0 to 3) can be individually configured using the BUSCONx.AGEN register field, to be connected to one of the following external memory/device types:

Table 15-14 agen description

agen value	Device Type	State Machine
0	Muxed Asynchronous Type (default after reset)	Asynchronous
1	Muxed Burst Type	Synchronous
2	NAND flash (page optimised)	Asynchronous
3	Muxed Cellular RAM	Synchronous
4	Demuxed Asynchronous Type	Asynchronous
5	Demuxed Burst Type	Synchronous
6	Demuxed Page Mode	Synchronous
7	Demuxed Cellular RAM	Synchronous
8	SDRAM	SDRAM
9	DDR Burst Flash (Spansion protocol)	Synchronous
10	LPDDR NVM (Jedec 42.4 DDR non-volatile memory)	SDRAM
11	reserved	-
12	DDRAM	SDRAM
13	ONFI 2.0 NAND flash	Synchronous
14	reserved	-
15	reserved	-

The AGEN fields for the BUSRCONx and BUSWCONx can, in most cases, be set independently. This allows devices such as burst flash, which require synchronous reads and asynchronous writes to be supported efficiently.

There are device types where this capability does not confer any advantage. In these cases, writing to the BUSRCONx.AGEN field will also update the BUSWCONx.AGEN field.

The AGEN values which trigger the automatic BUSWCONx.AGEN update are:

- SDRAM: 8_D
- LPDDR NVM: 10_D

- DDRAM: 12_D

While the BUSRCONx.AGEN field is set to one of these values, any attempt to set the value of the related BUSWCONx.AGEN field will be ignored.

15.14.2 Support for Multiplexed Device Configurations

Memory Controller supports a number of configurations of Multiplexed memory/peripheral devices using different values of the EBU_BUSRCONx.PORTW bit-field. The EBU_BUSWCONx registers also contain the PORTW field but in this case the field is read only and reflects the value set in the related one of the EBU_BUSRCONx registers. The values set in the EBU_BUSRCONx registers are used for both read and write accesses.

Note: When using multiplexed devices a non-zero recovery phase is mandatory for all devices to prevent read data from one access conflicting with the address for the next access to the multiplexed memory.

Table 15-15 Pins used to connect Multiplexed Devices to Memory Controller

Memory Device Configuration	Memory Controller Pins			Section
	A(27:0)[1]	AD(31:16)	AD(15:0)	
8-bit MUX	A(27:0)	-	A(7:0)/ D(7:0)	8-bit Multiplexed Memory/Peripheral Configuration
16-bit MUX	A(27:0)	-	A(15:0)/ D(15:0)	16-bit Multiplexed Memory/Peripheral Configuration
Twin 16-bit MUX	A(27:0)	A(15:0)/ D(31:16)	A(15:0)/ D(15:0)	Twin 16-bit Multiplexed Device Configuration
32-bit MUX	-	A(31:16)/ D(31:16)	A(15:0)/ D(15:0)	32-bit Multiplexed Memory/Peripheral Configuration

1) These pins are always outputs which are connected to address pins on the Multiplexed device(s)

Table 15-16 Selection of Multiplexed Device Configuration

PORTW value	
00_B	8-bit multiplexed (deprecated)[1]
01_B	16-bit multiplexed[2]

Table 15-16 Selection of Multiplexed Device Configuration (cont'd)

PORTW value	
10_B	Twin, 16-bit Multiplexed[3)]
11_B	32 bit multiplexed[4)]

1) 8-bit port width is only intended for NAND flash and ONFI devices which do not require particular values on the address bus. Correct operation of multiplexed addressing is not verified or guaranteed.

2) Address will only be driven onto AD(15:0) during the address and address hold phases. A(15:0) will be driven with address for duration of access

3) Lower 16 bits of address will be driven onto both A(15:0) and AD(15:0) during the address and address hold phases

4) Full address will be driven onto A(15:0) and AD(15:0) during the address and address hold phases

15.14.2.1 Twin 16-bit Multiplexed Device Configuration

This mode allows the use of two 16-bit multiplexed devices to create a 32-bit wide bus. Throughout the complete external bus cycle the address[1)] is driven onto Memory Controller pins A(27:0). During the address phase the low 16 bits of the address are driven (in parallel) to Memory Controller pins AD(15:0) and AD(31:16). This ensures that both multiplexed devices are issued with the same address during the address phase. Data (32-bit) is written to/read from the AD(31:16) pins for MSW and the AD(15:0) pins for LSW during the data phase. The interconnect between Memory Controller and two 16-bit Multiplexed devices in this mode is shown below (note: for clarity only the address/data signals are shown):-

1) This address is pre-aligned according to the bus width as detailed in **Section 15.13.4**.

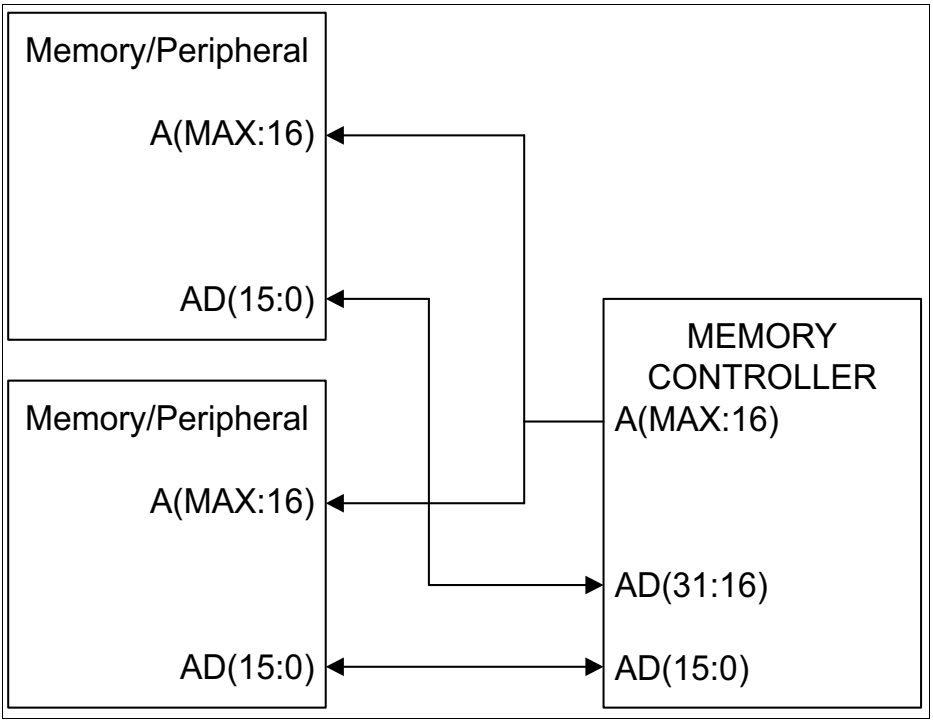

Figure 15-15 Connection of twin 16-bit Multiplexed Device's to Memory Controller

15.14.2.2 16-bit Multiplexed Memory/Peripheral Configuration

Throughout the complete external bus cycle the address[1)] is driven onto Memory Controller pins A(27:0). During the address phase the low 16 bits of the address are driven to Memory Controller pins AD(15:0). Data (16-bit) is driven to/read back from the AD(15:0) pins during the data phase. The interconnect between Memory Controller and a 16-bit Multiplexed device in this mode is shown below (note: for clarity only the address/data signals are shown):-

1) This address is pre-aligned according to the bus width as detailed in **Section 15.13.4**.

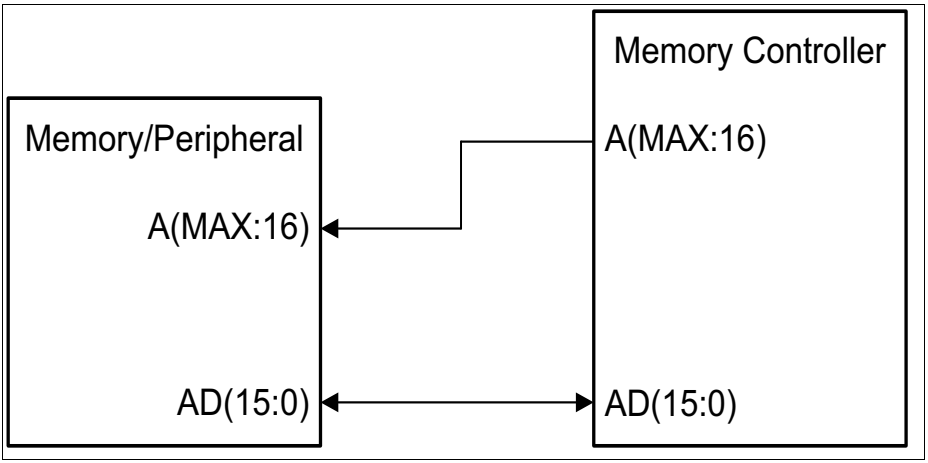

Figure 15-16 Connection of a 16-bit Multiplexed Device to Memory Controller

15.14.2.3 8-bit Multiplexed Memory/Peripheral Configuration

The EBU drives signals for 8 bit devices in an identical manner to 16 bit devices. AD(15:0) are driven for address and write data and BC(1:0) are enabled. However valid write data only appears on AD(7:0) and BC(1) is always inactive. Read data is only sampled from AD(7:0).

15.14.2.4 32-bit Multiplexed Memory/Peripheral Configuration

During the address phase the lower 16 bits of the 25 bit address are driven to Memory Controller pins AD(15:0), the most significant 9 bits of the address are driven to pins AD(24:16) and pins AD(31:17) are driven with 0 (zero). Data (32-bit) is driven to/read from the AD(31:0) pins during the data phase. The interconnect between Memory Controller and a 32-bit Multiplexed device in this mode is shown below (note: for clarity only the address/data signals are shown):-

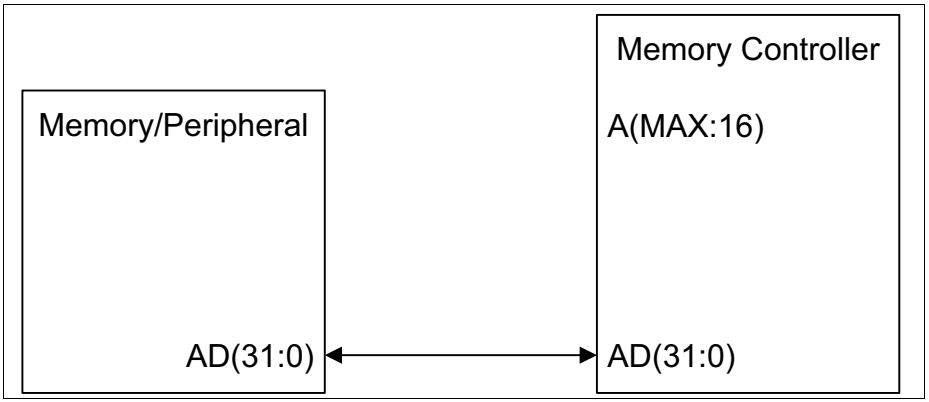

Figure 15-17 Connection of a 32-bit Multiplexed Device to Memory Controller

15.14.3 Support for Non-Multiplexed Device Configurations

The Memory Controller supports 16-bit and 32-bit non-multiplexed memory devices.

Table 15-17 Pins used to connect non-multiplexed Devices to Memory Controller

Memory Device Configuration	Memory Controller Pins			Section
	A(27:0)	AD(31:16)	AD(15:0)	
8-bit non-MUX	A(27:0)	-	D(7:0)	8-bit non-Multiplexed Memory/Peripheral Configuration
16-bit non-MUX	A(27:0)	-	D(15:0)	16-bit non-Multiplexed Memory/Peripheral Configuration
twin, 16-bit non-MUX	A(27:0)	D(31:16)	D(15:0)	32-bit non-Multiplexed Memory/Peripheral Configuration
32-bit non-MUX	A(27:0)	D(31:16)	D(15:0)	32-bit non-Multiplexed Memory/Peripheral Configuration

Table 15-18 Selection of non-Multiplexed Device Configuration

PORTW value	
00_B	8-bit[1)]
01_B	16-bit
10_B	Twin 16-bit
11_B	32-bit

1) 8-bit port width is only intended for NAND flash and ONFI devices which do not require particular values on the address bus. Correct operation of addressing for other device types is not verified or guaranteed

15.14.3.1 16-bit non-Multiplexed Memory/Peripheral Configuration

Throughout the complete external bus cycle the address[1)] is driven onto Memory Controller pins A(27:0). Data (16-bit) is driven to/read back from the AD(15:0) pins during the data phase. The interconnect between Memory Controller and a 16-bit non-Multiplexed device in this mode is shown below (note: for clarity only the address/data signals are shown):-

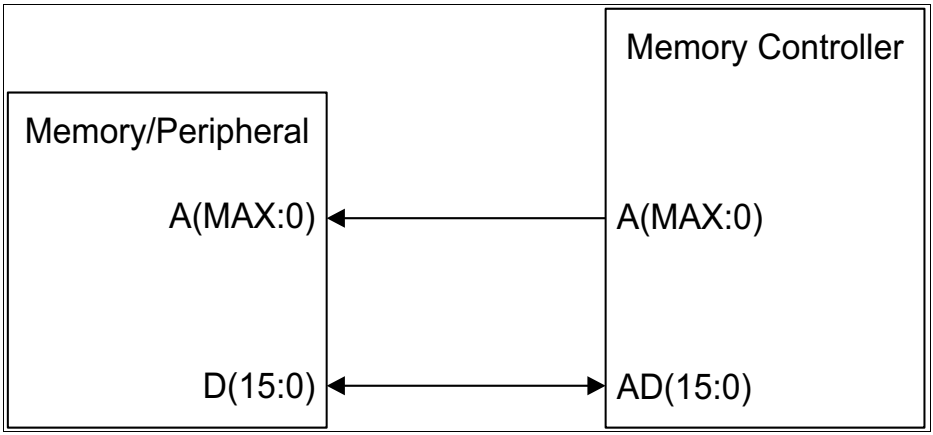

Figure 15-18 Connection of a 16-bit non-Multiplexed Device to Memory Controller

15.14.3.2 8-bit non-Multiplexed Memory/Peripheral Configuration

The EBU drives signals for 8 bit devices in an identical manner to 16 bit devices. AD(15:0) are driven for address and write data and BC(1:0) are enabled. However valid

1) This address is pre-aligned according to the bus width as detailed in **Section 15.13.4**.

write data only appears on AD(7:0) and BC(1) is always inactive. Read data is only sampled from AD(7:0).

15.14.3.3 32-bit non-Multiplexed Memory/Peripheral Configuration

Throughout the complete external bus cycle the address[1] is driven onto Memory Controller pins A(27:0). Data (32-bit) is driven to/read back from the AD(31:0) pins during the data phase. The interconnect between Memory Controller and a 16-bit non-Multiplexed device in this mode is shown below (note: for clarity only the address/data signals are shown):-

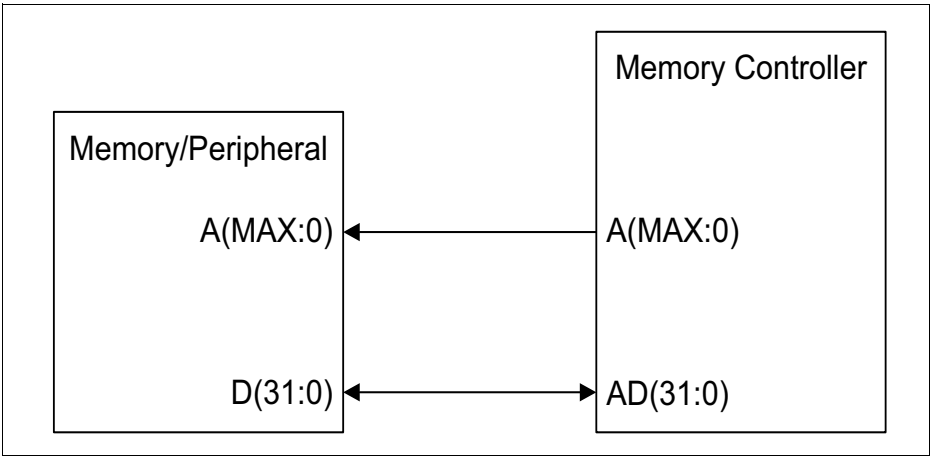

Figure 15-19 Connection of a 32-bit non-Multiplexed Device to Memory Controller

15.14.3.4 Twin, 16-bit non-Multiplexed Memory/Peripheral Configuration

Throughout the complete external bus cycle the address[2] is driven onto Memory Controller pins A(27:0). Data (32-bit) is driven to/read back from the AD(31:0) pins during the data phase. The interconnect between Memory Controller and two, 16-bit non-Multiplexed devices in this mode is shown below (note: for clarity only the address/data signals are shown):-

1) This address is pre-aligned according to the bus width as detailed in **Section 15.13.4**.

2) This address is pre-aligned according to the bus width as detailed in **Section 15.13.4**.

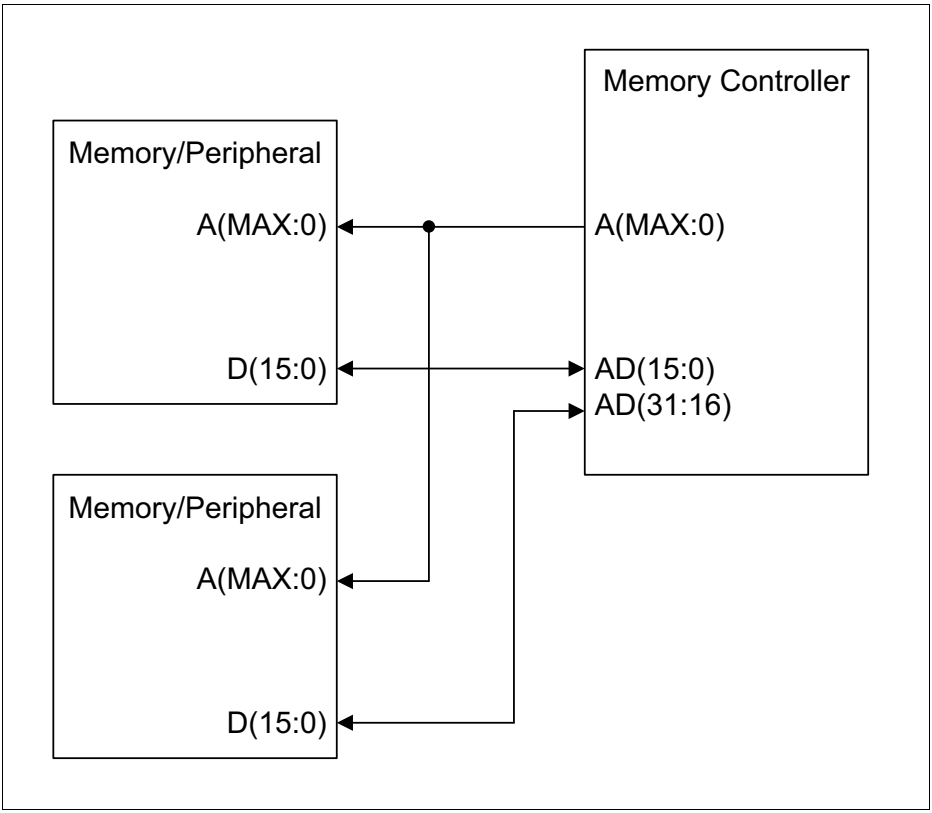

Figure 15-20 Connection of two 16-bit non-Multiplexed Devices to the Memory Controller

This mode primarily affects the mode register and status register operations for SDRAM, DDRAM and LPDDR-NVM devices. If the region is configured as twin, 16-bit, then the mode register data will be replicated on both halves of the 32 bit data bus to ensure that both the connected devices are written with an identical configuration.

15.15 Phases for Asynchronous and Synchronous Accesses

Accesses to asynchronous and synchronous devices are composed of a number of standard access phases (according to the type of device and the type of access). Each output signal for the EBU is active in defined phases. The length of the phases can be programmed to adjust the pulse width and timing relationships of the output signals

There are six access phases defined:

- Address Phase AP (mandatory for read and write cycles of both device types)
- Command Delay Phase CD (optional)
- Command Phase CP (mandatory)
- Burst Phase BP (Synchronous Accesses only)
- Control Hold CH (optional, Synchronous Accesses to DDR NOR flash only)
- Data Hold Phase DH (optional, only applies to write cycles)
- Recovery Phase RP (optional)

Throughout the remainder of this document, a short-hand notation is adopted to represent any clock cycle in any phase. This notation consists of two or three letters followed by a number. The letters identify the access phase within which the clock cycle is located (e.g. AP for Address Phase). The number denotes the number of EBU_CLK clock cycles within the phase (i.e. 1 = first, etc.). In the case of delays that can be extended by external control inputs the lower case letters “e” and “i” are inserted following the two letter phase identifier to differentiate between internally (“i”) and externally (“e”) generated delays. For example, AP2 identifies the second clock in the Address Phase. CPe3 identifies the third clock in the Command Phase which is being extended by external wait-states.

15.15.1 Address Phase (AP)

The Address Phase is mandatory. It always consists of at least one or more EBU_CLK cycles. The phase can be optionally extended to accommodate slower devices.

At the start of the Address Phase, the EBU:

- Selects the device to be accessed by asserting the appropriate $\overline{\text{CSx}}$ signal,
- Issues the address which is to be accessed on the address bus,
- For multiplexed devices, drives the address onto the muliplexed address/data bus,
- Asserts the $\overline{\text{ADV}}$ signal low,[1)]
- Asserts the appropriate $\overline{\text{BCx}}$ signals if these are programmed to be asserted with the $\overline{\text{CSx}}$ signal,
- Asserts the MR/$\overline{\text{W}}$ signal according to the type of access to be performed (low in the case of a write access, not used in burst read cycles). This level is retained until the start of the next Address Phase.
- At the end of the Address Phase the EBU returns the $\overline{\text{ADV}}$ signal to high.

The length (number of EBU_CLK cycles) of the Address Phase is programmed via the EBU_BUSAPx.ADDRC bit field parameter.

1) If an active high, ALE, signal is required, the polarity of the $\overline{\text{ADV}}$ output can be inverted by setting the ALE field of the EBU_MODCON register.

15.15.2 Address Hold Phase (AH)

The Address Hold Phase is optional. It consists of zero or more EBU_CLK cycles. It is intended to provide hold time for the multiplexed address bits after the ADV signal has returned to the inactive state.

At the end of the address hold phase, the multiplexed address can be removed from the bus:

- During a read access, the multiplexed address/data bus can return to the high impedance condition to allow the read data to be driven by the external memory
- During a write access, the write data can be driven onto the multiplexed address/data bus

15.15.3 Command Delay Phase (CD)

The Command Delay phase is optional. This means that it can also be programmed for a length of zero EBU_CLK clock cycles. The CD phase allows for the insertion of a delay between Address Phase (or optional Address Hold phase) and Command Phase(s). This phase accommodates devices that are not fast enough to receive commands immediately after getting the address or multiplexed devices which require a bus turnaround delay on reads.

The length (number of EBU_CLK cycles) of the Command Delay phase is programmed via the EBU_BUSAPx.CMDDELAY bit field. This parameter makes it possible to select between zero to seven Command Delay phases.

15.15.4 Command Phase (CP)

The Command Phase is mandatory for asynchronous devices. It always consists of at least one or more EBU_CLK cycles. The phase can optionally be extended to accommodate slower devices.

The length (number of EBU_CLK cycles) of the Command Phase is separately programmable for read and write accesses. Bit field EBU_BUSAPx.WAITRDC determines the basic length of Command Phases during read cycles and bit field EBU_BUSAPx.WAITWRC determines the basic length of Command Phases during write cycles.

Additionally, when accessing asynchronous devices, a Command Phase can also be extended externally using the WAIT signal when the region being accessed is programmed for external command delay control via bit EBU_BUSCONx.WAIT or EBU_EMUBC.WAIT.

The Command Phase is further subdivided into:

- CPi (= internally-programmed Command Phase)
- CPe (= externally-prolonged Command Phase, i.e. prolonged by the assertion of the WAIT signal).

At the start of the Command Phase, the EBU:

- Asserts the appropriate control signal $\overline{RD}$ or RD/$\overline{WR}$ low according to the access type (read or write),
- Issues the data to be written on the data bus AD[15:0] (in the case of a write cycle),
- Asserts the appropriate $\overline{BCx}$ low (in the case where $\overline{BCx}$ is programmed to be asserted with the $\overline{RD}$ or RD/$\overline{WR}$ signals).

At the end of the Command Phase during an asynchronous access, the EBU:

- Returns the appropriate control signal $\overline{RD}$ or RD/$\overline{WR}$ high according to the type of access type (read or write),
- Latches the data from the data bus AD[15:0] (in the case of a read cycle),
- Returns the appropriate $\overline{BCx}$ high (in the case where $\overline{BCx}$ is programmed to be asserted with the $\overline{RD}$ or RD/$\overline{WR}$ signals).

At the end of the Command Phase during a synchronous access, the $\overline{RD}$ or RD/$\overline{WR}$ signals hold their state and the state machine transfers to the Burst Phase. Transition to Burst Phase will always occur synchrnously with a rising edge of BFCLKO. If necessary, the Command Phase will be extended to ensure that this happens.

15.15.5 Data Hold Phase (DH)

The Data Hold phase is optional. This means that it can also be programmed for a length of zero EBU_CLK clock cycles. Furthermore, it is only available for asynchronous write accesses (with two exceptions, see below). The Data Hold phase extends the amount of time for which data is still held on the bus after the rising edge of the RD/$\overline{WR}$ signal occurred. The Data Hold phase is used to accommodate external devices that require a data hold time after the rising edge of the RD/$\overline{WR}$ signal. The length (number of EBU_CLK cycles) of the Data Hold phase is programmed via the EBU_BUSAPx.DATAC bit field.

15.15.5.1 Exceptional use of Data Hold

In two cases, signals other than the data bus may need to have a hold time maintained relative to RD/$\overline{WR}$ or $\overline{RD}$. These cases occur when $\overline{ADV}$ and $\overline{BAA}$ are being used as NAND flash control signals which happens for AGEN settings of 2_D or 13_D. For these two settings, the Data Hold Phase will apply to both reads and writes.

15.15.6 Burst Phase (BP)

The Burst Phase is mandatory during burst accesses. At the end of the Burst Phase the EBU reads data from the data bus or updates the write data. During a burst access, Burst Phases are repeated as many times as required in order to read or write the required amount of data from or to the external memory device.

At the start of the first Burst Phase during a burst read access, the EBU:

- Drives the $\overline{BAA}$ signal low to cause the Burst Flash device to advance the address with each subsequent BFCLKO positive edge.

The first burst phase of an access will always start on arising edge of BFCLKO. If necessary, the length of the previous phase will be extended to ensure that this happens.

At the end of the last Burst Phase during a burst access, the EBU:

- Returns the $\overline{BAA}$ signal high,
- Returns the $\overline{CSx}$ signal high,
- Returns the $\overline{RD}$ signal high.
- Returns the RD/$\overline{WR}$ signal high

provided that a Control Hold phase has not been programmed.

During accesses to Burst Flash devices the length of the Burst Phase will be programmed such that the end of the Burst Phase always coincides with a positive edge of the appropriate BFCLKO (Burst Flash Clock) signal.

A Burst Phase is always at least one clock cycle in length. The length of each Burst Phase (i.e. the number of EBU_CLK cycles) is derived from the value of the EXTCLOCK and EXTDATA fields in the EBU_BUSAPx register. The length of the burst phase will be either be:

- one period of BFCLKO if EXTDATA is 00_B,
- two periods of BFCLKO if EXTDATA is 01_B.
- four periods of BFCLKO if EXTDATA is 10_B.
- eight periods of BFCLKO if EXTDATA is 11_B.

15.15.7 Control Hold (CH)

The Control Hold phase applies to synchronous reads to DDR burst flash (BUSRCONx.AGEN = 9_D and BUSRCONx.AGEN = 13_D). The length of this phase will be forced to zero clocks for write accesses.

It is an optional phase designed to allow for a variable delay between the memory device clock input and the device outputs. For DDR memories, this can potentially be more than a device clock cycle.

Programming a Control Hold phase allows the active state of the RD, BAA and CSx signals to maintained while the device completes the read access.

The length of the Control Hold phase is controlled using the EBU_BUSRAPx.DATAC bitfield.

If an Control Hold phase is programmed for an ONFI 2.0 device (BUSRCONx.AGEN = 13_D), then an additional cycle of BFCLKO will be added at the end of the programmed length with $\overline{CS}$ active and all other control signals inactive. This is needed to ensure that the memory device registers an IDLE command at the end of the access and returns the DQS and AD lines to a high impedance state.

15.15.8 Recovery Phase (RP)

The Recovery Phase is optional (although for access types which would cause a bus contention a single cycle of recovery is normally forced by the memory controller logic). This means that it can also be programmed for a length of zero EBU_CLK clock cycles. This phase allows the insertion of a delay following an external bus access that delays the start of the Address Phase for the next external bus access. This permits flexible adjustment of the delay between accesses to the various external devices. The following individually programmable delays are provided on a region by region basis for the following conditions:

- Bit fields EBU_BUSAPx.RDRECOVC determine the basic length of the Recovery Phase after a read access.
- Bit fields EBU_BUSAPx.WRRECOVC determine the basic length of the Recovery Phase after a write access.
- Bit fields EBU_BUSAPx.DTACS determine the length (basic number of EBU_CLK clock cycles) of the Recovery Phase after a read/write access of one region that is followed by a read/write access of another region or a read to one region is followed by a write to the same region (BUSRAPx.DTACS) or a write to one region is followed by a read to the same region (BUSWAPx.DTACS).

The EBU implements a “highest wins” algorithm to ensure that the longest applicable recovery delay is always used between consecutive accesses to the external bus. **Table 15-19** shows the scheme for determining this delay for all possible circumstances. For example, if a read access to a region associated with $\overline{CS1}$ is followed by a write to a region associated with $\overline{CS2}$, the delay will be the highest of BUSRAP1.DTACS and BUSRAP1.RDRECOVC. In this case, if BUSRAP1.DTACS is greater than BUSRAP1.RDRECOVC, then the number of recovery cycles between the two accesses is BUSRAP1.DTACS clock cycles (minimum).

Table 15-19 Parameters for Recovery Phase

Case			Parameter(s) used to calculate "Highest Wins" Recovery Phase
Region	**Current Access**	**Next Access**	
Same $\overline{CSn}$	Read	Read	RDRECOVC
	Write	Write	WRRECOVC
	Read	Write	BUSRAPx.DTACS
	Write	Read	BUSWAPx.DTACS
Different $\overline{CSn}$	Read	Read	BUSRAPx.DTACS, RDRECOVC
	Write	Write	BUSWAPx.DTACS, WRRECOVC
	Read	Write	BUSRAPx.DTACS, RDRECOVC
	Write	Read	BUSWAPx.DTACS, WRRECOVC

15.16 Asynchronous Read/Write Accesses

Asynchronous read/write access of the EBU support the following features:

- EBU_CLK clock-synchronous signal generation
- Support for 8-bit, 16-bit and 32-bit bus width
  Performing an SRI access with a data size greater than that of the external device automatically triggers a sequence of the appropriate number of external accesses to match the SRI access width.
- Demultiplexed address/data lines
- Programmable access parameters
  - Internal control of command delay cycles
  - External and/or internal control of wait states
  - Variable data hold cycles for write operation (to allow flexible hold time adjustment)
  - Variable inactive/recovery cycles when:
    Switching between different memory regions (CS),
    Switching between read and write operations,
    After each read cycle,
    After each write cycle.

Software driver routines are required in order to support Nand Flash devices using asynchronous device accesses. A single Nand Flash access sequence is performed by generating the appropriate sequence of discrete asynchronous device accesses in software.

15.16.1 Signal List

The following signals of the EBU are used for asynchronous accesses:

Table 15-20 Asynchronous Mode Signal List

Signal/Pin	Type	Function
AD[31:0]	O	Address/Data bus lines 0-31
A[27:0]	O	Address bus lines 0-27
$\overline{\text{CS}}$[3:0]	O	Chip select 0-3
$\overline{\text{RD}}$	O	Read control line
RD/$\overline{\text{WR}}$	O	Write control line
$\overline{\text{BC}}$[3:0]	O	Byte control lines 0-3
$\overline{\text{WAIT}}$	I	Wait input
MR/$\overline{\text{W}}$	O	Read/Write signal with timimg for Motorola peripherals

15.16.2 Standard Asynchronous Access Phases

Accesses to asynchronous devices are composed of a subset of the standard access phases which are detailed in **Section 15.15**. The standard access phases for asynchronous devices are:

- AP: Address Phase (compulsory - see **Page 15-63**)
- AH: Address Hold Phase (Optional - see **Page 15-64**)
- CD: Command Delay Phase (optional - see **Page 15-64**)
- CP: Command Phase (compulsory - see **Page 15-64**)
- DH: Data Hold Phase (optional - see **Page 15-65**)
- RP: Recovery Phase (optional - see **Page 15-67**)

Figure 15-21 above shows an example of an access to a non-multiplexed device and **Figure 15-22** an example of an access to a multiplexed device.

15.16.3 Example Waveforms

The following figures show example waveforms for asynchronous accesses

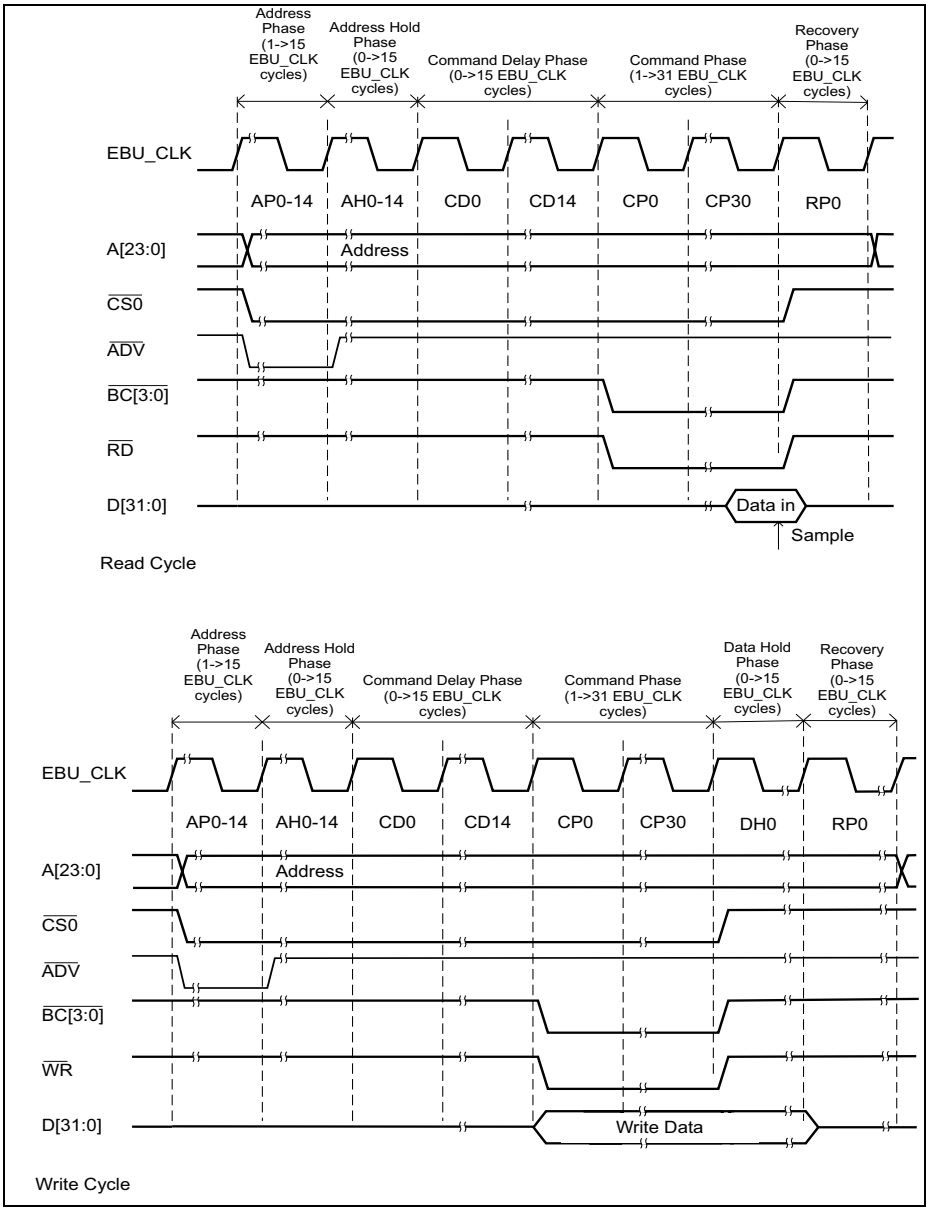

Figure 15-21 Asynchronous non-muxed Access

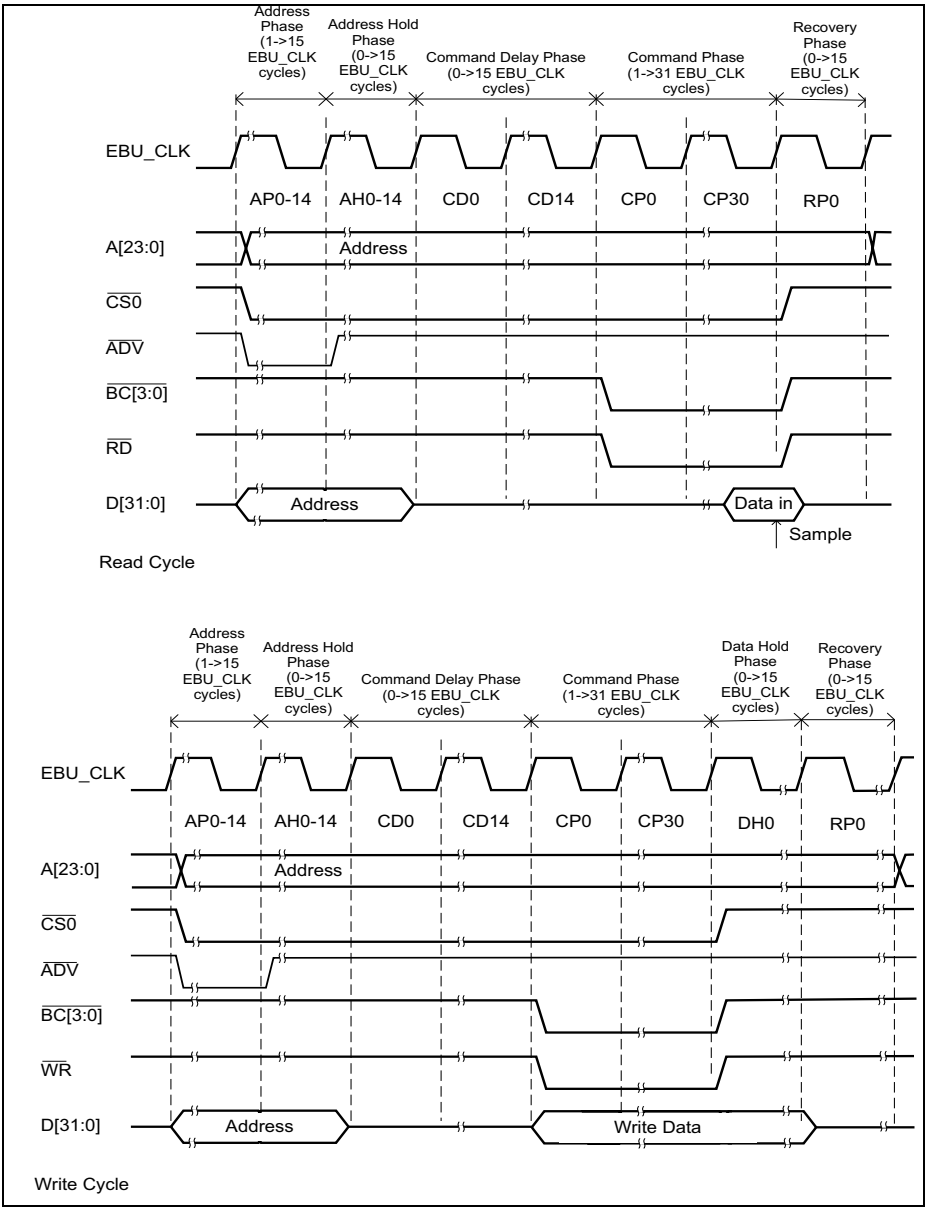

Figure 15-22 Asynchronous muxed Access

15.16.4 Control of $\overline{ADV}$ & Other Signal Delays During Asynchronous Accesses

For asynchronous accesses, the Memory Controller output signals: $\overline{ADV}$, $\overline{CS}$, $\overline{RD}$, RD/$\overline{WR}$, and $\overline{BC}$ signals can be delayed with respect to the start of the access phases they are asserted in. The amount by which the signal is delayed depends on the setting of the EBU_BUSRAPx.EXTCLOCK field of the region being addressed for read accesses and the EBU_BUSWAPx.EXTCLOCK field of the region being addressed for writes:-

- When EXTCLOCK is set to 00_B, control signals are asserted on the negative edge of EBU_CLK. i.e. they are in effect delayed by an EBU_CLK high pulse width (T_{PH})with respect to the other signals.
- When EXTCLOCK is not set to 00_B, control signals are asserted on the next positive edge of EBU_CLK. i.e. they are in effect delayed by an EBU_CLK cycle (T_{CLK}) with respect to the other signals.

The Memory Controller allows these delays to be enabled and disabled independently via the register bits EBU_BUSCONx.EBSE for $\overline{ADV}$ and EBU_BUSCONCx.ECSE for the other control signals. The default setting after reset has the delay disabled.

Table 15-21 $\overline{ADV}$ Signal Timing

EXTCLOCK is set to	ADV Falling Edge Position		ADV Rising Edge Position	
	Delay Disabled[1)]	Delay Enabled	Delay Disabled[1)]	Delay Enabled
00_B	Start of AP1	Start of AP1 + T_{PH}	Start of AP1	Start of AP1 + T_{PH}
01_B, 10_B, 11_B	Start of AP1	End of AP1	Start of AP1	End of AP1

1) See **Figure 15-21** for details of this signal positioning.

Table 15-22 $\overline{RD}$ and RD/$\overline{WR}$ Signal Timing

EXTCLOCK is set to	Set at:		Cleared at:	
	Delay Disabled[1)]	Delay Enabled	Delay Disabled[1)]	Delay Enabled
00_B	Start of CP1	Start of CP1 + T_{PH}	End of CPn[2)]	End of CPn + T_{PH}
01_B, 10_B, 11_B	Start of CP1	End of CP1	End of CPn	End of CPn + T_{CLK}

1) See **Figure 15-21** for details of this signal positioning.

2) CPn indicates the final Command Phase.

Table 15-23 $\overline{CS}$ Signal Timing

EXTCLOCK is set to	Set at:		Cleared at:	
	Delay Disabled[1)]	Delay Enabled	Delay Disabled[1)]	Delay Enabled
00_B	Start of AP1	Start of AP1 + T_{PH}	End of DHn[2)]	End of DHn + T_{PH}
01_B, 10_B, 11_B	Start of AP1	End of AP1	End of DHn	End of DHn + T_{CLK}

1) See **Figure 15-21** for details of this signal positioning.

2) DHn indicates the final Data Hold Phase. This is replaced by CPn, the final Command Phase, if the programmed Data Hold phase length is zero clocks.

The byte control signals, $\overline{BC}$x, can either use the timing in **Table 15-22** if EBU_BUSCONx.BCGEN is set to 01_B or 10_B or the timing in **Table 15-23** if EBU_BUSCONx.BCGEN is set to 00_B. A EBU_BUSCONx.BCGEN value of 11_B is not valid for asynchronous accesses.

Write data is handled differently to the other signals. Delays are never applied to the write data.

Note: If the control signals are delayed a recovery phase must be used to prevent conflicts between accesses as the rising edge of the control signals will be delayed past the end of the command phase. If a multiplexed access is used without a recovery phase, the address for the next access will be delayed by one clock cycle to enforce a bus turnaround time on the data bus, resulting in the valid address being driven one clock after $\overline{ADV}$ is asserted.

15.16.5 Programmable Parameters

Table 15-24 lists the programmable parameters for asynchronous accesses.

Table 15-24 Asynchronous Access Programmable Parameters

Register	Parameter (Bit/Bit field)	Function
EBU_BUSAPx	ADDRC	Number of cycles in address phase
	CMDDELAY	Number of programmed command delay cycles[1].
	AHOLD	Number of Cycles in Address Hold Phase[1]
	WAITRDC	Number of programmed wait states for read accesses.
	WAITWRC	Number of programmed wait states for write accesses.
	DATAC	Number of Data Hold cycles.
EBU_BUSAPx	RDRECOVC	Number of minimum recovery cycles after a read access.
	WRRECOVC	Number of minimum recovery cycles after a write access.
	DTARDWR	Number of minimum recovery cycles between a read access and a write access.
	DTACS	Number of minimum recovery cycles when the next access going to a different memory region.
EBU_BUSCONx	WAIT	External Wait State control (OFF, asynchronous, synchronous)
	WAITINV	Reversed polarity at $\overline{\text{WAIT}}$: active low or active high

1) This phase can be programmed for devices without multiplexed address and data busses but serves no purpose other than extending the access

15.16.6 Asynchronous Access Control

In general, there are only two critical phase during accesses to asynchronous devices with separate address and data buses. These phases are:

- **Command Phase** (see **Page 15-64**) which is used to control the widths of the Output Enable and Write Enable pulses. The length of the Command Phase is set by the bit fields EBU_BUSRAPx.WAITRDC and EBU_BUSWAPx.WAITWRC.
- **Data Hold Phase** (see **Page 15-65**) which is used to ensure that the write data is stable long enough to allow it to be successfully latched into the device. The length of the Command Phase is set by the bit field EBU_BUSWAPx.DATAC

As the “address to data valid” and the “chip select to data” valid parameters of asynchronous devices are usually greater than “output enable to data valid” parameter,

the lengths of the “Address”, “Address Hold” and “Command Delay” phases can be used to extend the time between the start of the access when the address and chip select are driven and the end of the Command Phase when the read or write event occurs.

For devices with a multiplexed address and data buses two additional phases control the latching of the address into the device and also critical:

- **Address Phase** (see **Page 15-63**) which is used to control the width of the $\overline{ADV}$ pulse. The length of the Address Phase is available via bit fields EBU_BUSAPx.**ADDRC**
- **Address Hold Phase** (see **Page 15-64**) which is used to ensure that the address is stable long enough to allow it to be successfully latched into the device. The length of the Address Phase is available via bit fields EBU_BUSAPx.**AHOLDC**

15.16.6.1 External Extension of the Command Phase by WAIT

The $\overline{WAIT}$ input can be used to cause the EBU to extend the Command Phase by inserting additional cycles prior to deactivation of the $\overline{RD}$ and RD/$\overline{WR}$ lines. This signal can be programmed separately for each region to be ignored or sampled either synchronously or asynchronously (selected via the EBU_BUSCONx.WAIT bit field). Additionally, the polarity of $\overline{WAIT}$ can be programmed for active low (default after reset) or active high function via bit EBU_BUSCONx.WAITINV. The signal will only take effect after the programmed number of Command Phase cycles has passed. This means that the signal can only be used to extend the phase, not to shorten it.

Table 15-25 Operation of WAIT input

Value of BUSCONx.WAIT	Mode of the $\overline{WAIT}$ input
0_D	OFF (default after reset).
1_D	Asynchronous input at WAIT.
2_D	Synchronous input at WAIT.
3_D	reserved

When programmed for synchronous operation, $\overline{WAIT}$ is sampled on every rising edge of EBU_CLK during the Command Phase. The sampled value is then used on the next rising edge of EBU_CLK to decide whether to prolong the Command Phase or to start the next phase. **Figure 15-23** shows an example of $\overline{WAIT}$ used in Synchronous Mode.

Note: Due to the one-cycle delay in Synchronous Mode between the sampling of the $\overline{WAIT}$ input and its evaluation by the EBU, the Command Phase must always be programmed to be at least one EBU_CLK cycle (via EBU_BUSAPx.WAITRDC or EBU_BUSAPx.WAITWRC) in this mode.

When programmed for asynchronous operation, WAIT is also sampled at each rising edge of EBU_CLK during the Command Phase. However, an extra synchronization cycle is inserted prior to the use of the sampled value. This means that the sampled value is not used until the second following rising edge of EBU_CLK. **Figure 15-24** shows an example of WAIT used in Asynchronous Mode.

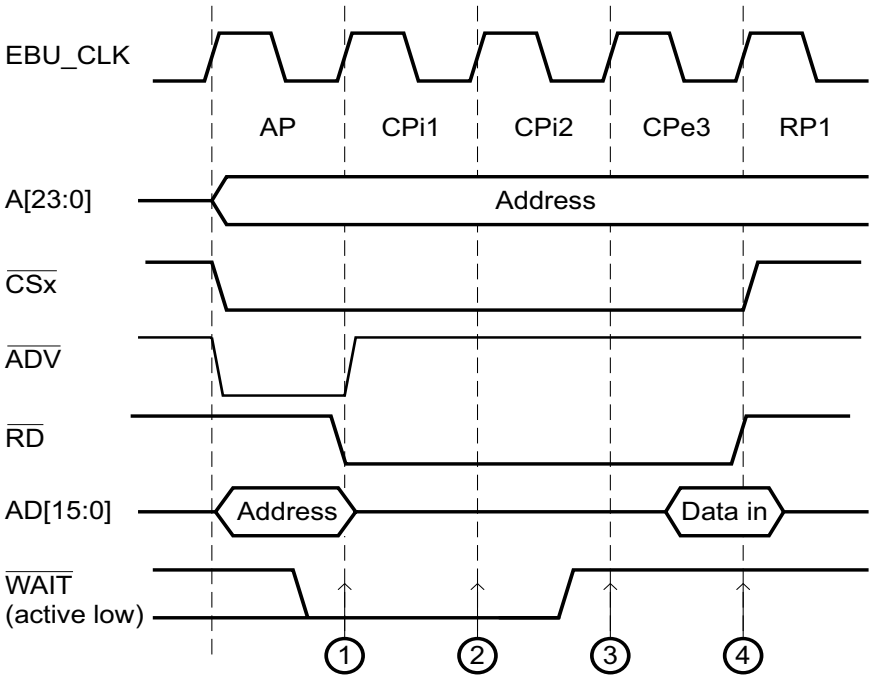
Note: Due to the two-cycle delay in Asynchronous Mode between the sampling of the WAIT input and its evaluation by the EBU, the Command Phase must always be programmed to be at least two EBU_CLK cycles (via EBU_BUSAPx.WAITRDC or EBU_BUSAP.WAITWRC) in this mode.

Figure 15-23 shows an example of the extension of the Command Phase through the WAIT input in synchronous mode:

- At EBU_CLK edge 1 (at the end of the Address Phase), the EBU samples the WAIT input as low and starts the first cycle of the Command Phase (CPi1 - internally programmed).
- At EBU_CLK edge 2, the EBU samples the WAIT input as low and starts an additional Command Phase cycle (CPe2 - externally generated) as a result of the WAIT input sampled as low at EBU_CLK edge 1.
- At EBU_CLK edge 3, the EBU samples the WAIT input as high and starts an additional Command Phase cycle (CPe3 - externally generated) as a result of the WAIT input sampled as low at EBU_CLK edge 2.
- Finally at EBU_CLK edge 4, as a result of the WAIT input sampled as high at point 3, the EBU terminates the Command Phase, reads the input data from D[31:0] and starts the Recovery Phase.

Note: Synchronous operation means that even though access to the device may be asynchronous, the control logic generating the control signals must meet setup and hold time requirements with respect to EBU_CLK.

Read Access with Synchronous $\overline{\text{WAIT}}$



Note: In the example above, the Command Delay phase is internally programmed to zero EBU_CLK cycles (no Command Delay phase).
The Command Phase is internally programmed to one EBU_CLK cycle. All other phases are programmed for one EBU_CLK cycle.

Figure 15-23 External Wait Insertion (Synchronous Mode)

Figure 15-24 shows an example of the extension of the Command Phase through the $\overline{\text{WAIT}}$ input in asynchronous mode:

- At EBU_CLK edge 1 (at the end of the Address Phase), the EBU samples the $\overline{\text{WAIT}}$ input as low and starts the first cycle of the Command Phase (CPi1 - internally programmed).

- At EBU_CLK edge 2, the EBU samples the $\overline{\text{WAIT}}$ input as low and starts the second cycle of the Command Phase (CPi2 - internally programmed).
- At EBU_CLK edge 3, the EBU samples the $\overline{\text{WAIT}}$ input as high and starts an additional Command Phase cycle (CPe3 - externally generated) as a result of the $\overline{\text{WAIT}}$ input sampled as low at EBU_CLK edge 1.
- At EBU_CLK edge 4, the EBU starts an additional Command Phase cycle (CPe4 - externally generated) as a result of the $\overline{\text{WAIT}}$ input sampled as low at EBU_CLK edge 2.
- Finally at EBU_CLK edge 5, as a result of the $\overline{\text{WAIT}}$ input sampled as high at EBU_CLK edge 3, the EBU terminates the Command Phase, reads the input data from AD[15:0],and starts the Recovery Phase.

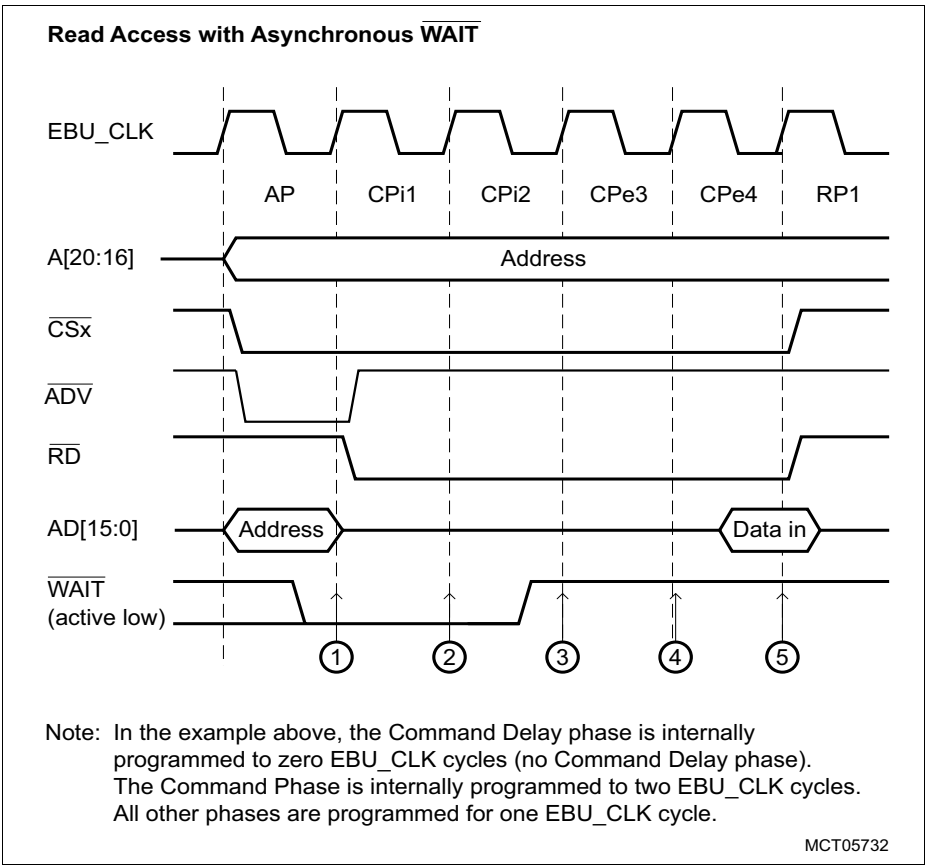


Figure 15-24 External Wait Insertion (Asynchronous Mode)

15.16.7 Interaction with DDR Signal Timing

If a DDR device is attached and **EBU_DLLCON.WR_EN** is enabled, then the write data and byte control signal timing will be affected. The storage elements used to drive the signal outputs will be operating off a shifted clock controlled by the DLL. This will shift the outputs relative to the expected timing.

For these reasons, asynchronous writes to single data rate devices when **EBU_DLLCON.WR_EN** is enabled will require additional data hold time. The recommendation is to allow an extra two clock cycles of Data Hold phase.

15.16.8 Interfacing to Asynchronous Nand Flash Devices

The memory controller provides support for specific Nand Flash devices. The required access sequences (read or write) are generated by connecting the Nand Flash device as an Asynchronous Device and using appropriate processor generated access sequences to emulate the NAND flash commands. **Figure 15-25** Shows an example of Memory Controller connected to a Nand Flash device:-

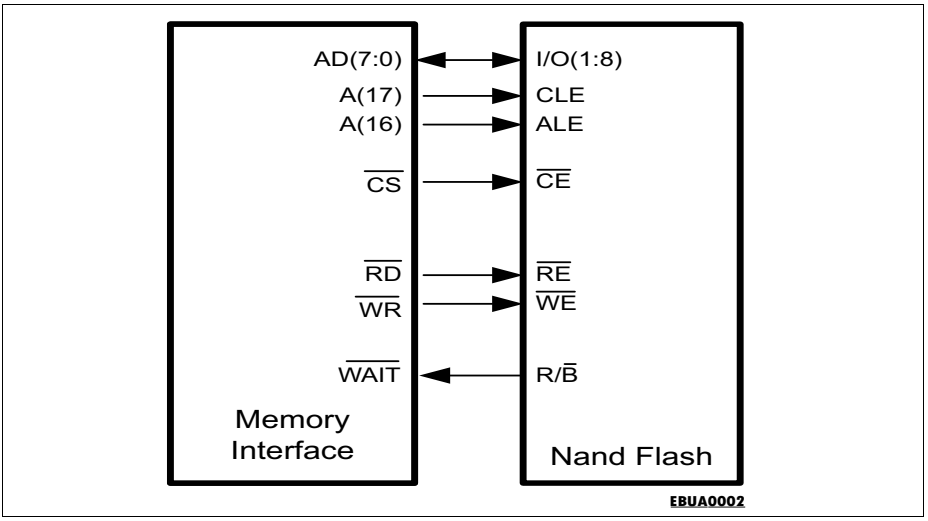

Figure 15-25 Example of interfacing a Nand Flash device to the Memory Controller

The R/$\overline{B}$ input from the NAND flash is connected to the memory controller $\overline{WAIT}$ input and is available as the EBU_MODCON.STS. This enables a NAND flash to be driven by software from the processor.

In the instance shown above two address lines are connected to the Nand Flash, and rather than being connected to address inputs, they are connected to control inputs. This allows access to three “registers” in the Nand Flash as follows:-

Table 15-26 Nand Flash "Registers" (8 bit device)

SRI Address	"Register"	Comment
Base + 00000_H	Data Register	Read/Write: Used to read data from and write data to the device.
Base + 10000_H	Address Register	Write only: Used to write the required access address to the device.
Base + 20000_H	Command Register	Write only: Used to write the required command to the device.

Note: SRI addresses are byte addresses and addresses on the external bus are word addresses. The SRI address of the virtual register will depend on the port width. of the addressed memory region. See ***"SRI Bus Width Translation" on Page 15-51***

15.16.8.1 NAND flash page mode

NAND flash memories are page oriented devices capable of extended read operations with a single setup phase for command signals at the beginning of the access. The asynchronous controller of the Memory Controller will split a large transfer into multiple accesses to external memory but each of these accesses will have the overhead of the initial setup phase. Enabling page mode, by setting the agen field in EBU_BUSCONx to 2_D, will cause the standard flow of the controller to be modified as follows:

- For a read, if data remains to be fetched at the end of a command phase, the controller will start a new command delay phase, instead of a new address phase or recovery phase and the address will not be incremented. If EBU_BUSRAPx.cmddelay is set to zero, the command delay phase will have a duration of one clock cycle but in this case the command delay phase is mandatory to ensure that the $\overline{RD}$ and RD/$\overline{WR}$ signals return to the high state.
- For a write, if data remains to be written at the end of a data hold phase (or command phase if the length of data hold is zero), the controller will start a new command phase, instead of a new address phase or recovery phase and the address will not be incremented. If EBU_BUSWAPx.datac is set to zero, the data hold phase will have a duration of one clock cycle as in this case the data hold phase is mandatory to ensure that the $\overline{RD}$ and RD/$\overline{WR}$ signals return to the high state. The command phase will be forced to have a minimum length of two clocks.

Enabling NAND flash page mode will also reconfigure the EBU signals used for ALE and CLE. While A(17:16) can still be used directly, the same values will also be output on $\overline{ADV}$ and $\overline{BAA}$.

- $\overline{ADV}$ will be used as ALE and will output the value of A(16).
- $\overline{BAA}$ will be used as CRE and will output the value of A(17).

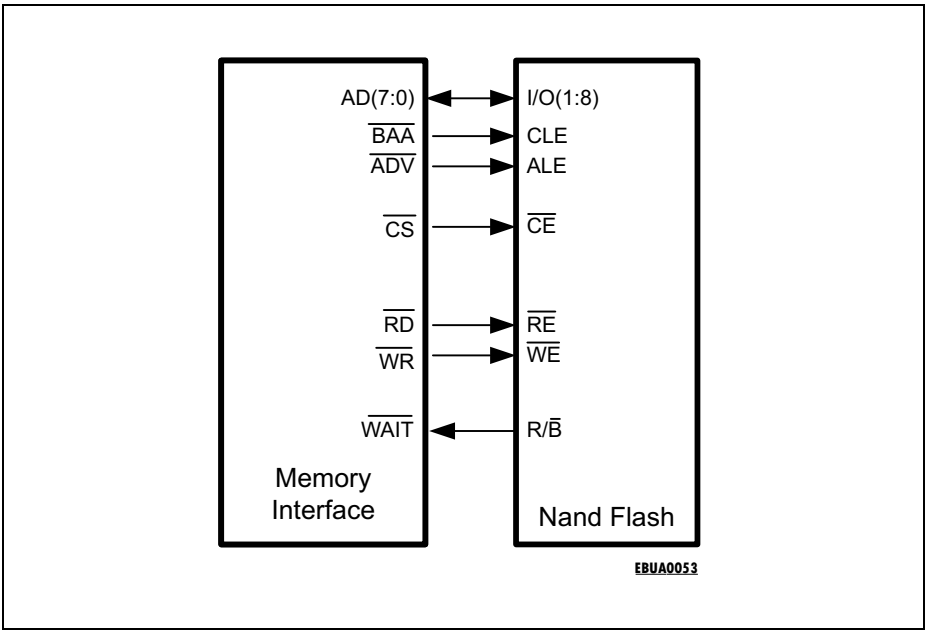

Figure 15-26 NAND Flash Connection for AGEN=3_D

To allow accesses to run consecutively without violating $\overline{\text{ADV}}$ and $\overline{\text{BAA}}$ timing restrictions, both signals will be set inactive (1_B) at the beginning of the recovery phase of the access.

See **Figure 15-27** for example waveforms.

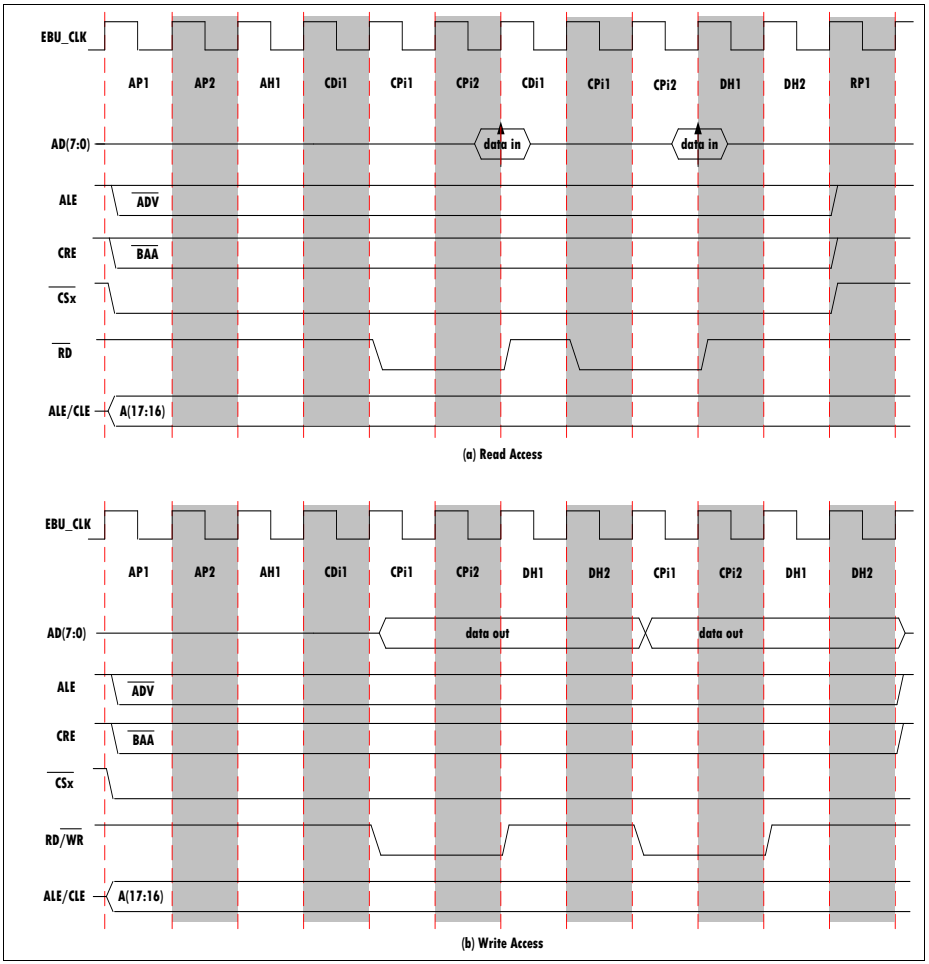

Figure 15-27 NAND Flash Page Mode Accesses

Example Nand Flash Read Sequence

Figure 15-28 shows an example of how the processor can generate a Nand Flash read access sequence given this configuration:-

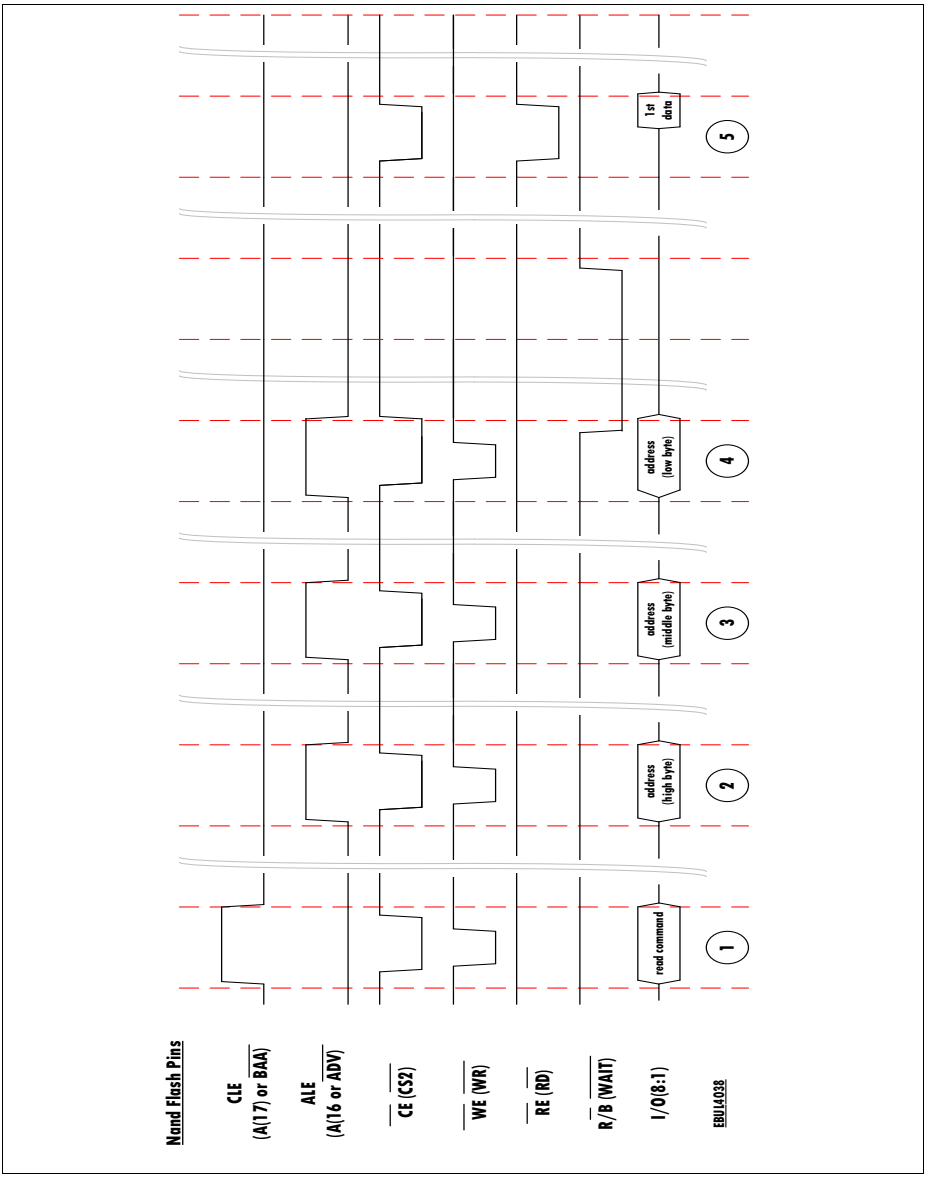

Figure 15-28 Example of an Memory Controller Nand Flash access sequence (read)

1. In the cycle marked ‘1’ in **Figure 15-28** the processor initiates a read sequence by writing the “Read Command” value to address “NAND_FLASH_BASE + 0x20000”. This generates a write sequence with CLE (A(17)) driven high and ALE (A(16)) driven low.
2. In the cycle marked ‘2’ the processor loads the most significant byte of the read address by writing to address “NAND_FLASH_BASE + 0x10000”. This generates a write sequence with CLE (A(17)) driven low and ALE (A(16)) driven high.
3. In the cycle marked ‘3’ the processor loads the middle significant byte of the read address by repeating the access specified in ‘2’ above.
4. In the cycle marked ‘4’ the processor loads the least significant byte of the read address by repeating the access specified in ‘2’ above. The Nand Flash responds to this final address byte by driving it’s R/$\overline{B}$ output low. The processor monitors this pin (using the EBU_MODCON.sts bit) until the Nand Flash has completed it’s internal data fetch.
5. In the cycle marked ‘5’ the processor reads the first byte of data by reading address “NAND_FLASH_BASE + 0x00000”. The processor can subsequently read any additionally required (sequential) data bytes by repeating cycle ‘5’.

Note: A similar scheme can be used to generate write access sequences.

15.17 Synchronous Read/Write Accesses

The Memory Controller is designed to generate waveforms compatible with the burst modes of:

1. INTEL and compatible burst flash devices
2. SPANSION and compatible burst flash devices
3. INFINEON and MICRON cellular RAM
4. Fujitsu and Compatible FCRAM/uTRAM/CosmoRAM
5. Samsung OneNAND burst capable NAND flash and compatible devices
6. M-Systems DiskOnchipG3 and compatible devices
7. GSI SSRAM
8. DDR burst flash (XIP)
9. ONFI 2.0 NAND flash

Note: Not all of the supported synchronous memory types are known to be available in automotive grade

Features

The Synchronous Access Controller is primarily designed to perform burst mode read and write cycles for an external instruction memories, external Cellular RAM and FCRAM data memories. In general, the features are:-

- Fully synchronous timing with flexible programmable timing parameters (address cycles, read wait cycles, data cycles).
- Programmable $\overline{WAIT}$ function.

- Programmable burst (mode and length)
- 8-bit device width.
- 16-bit device width.
- 32-bit device width
- Page mode read accesses.
- Resynchronisation of read data to a feedback clock to maximise the frequency of operation (optional).
- DDR device support

15.17.1 Signals

The following signals are used for the Burst FLASH interface:-

Table 15-27 Burst Flash Signal List

Signal	Type	Function
AD(31:0)	I/O	Multiplexed Address/Data bus
$\overline{RD}$	O	Read control
$\overline{WR}$	O	Write control
A(27:0)	O	Address bus
$\overline{ADV}$	O	Address valid strobe
$\overline{WAIT}$	I	Wait/terminate burst control
$\overline{CS}$(3:0)	O	Chip select
BFCLKO	O	Burst FLASH Clock, running equal to, 1/2, 1/3 or 1/4 of the frequency of EBU_CLK.
BFCLKI	I	Burst FLASH Clock Feedback.
$\overline{DDRCLKO}$	O	Negative phase of differential DDR clock
$\overline{BAA}$	O	Advance Burst Address
STS	I	Burst FLASH Status Input (Optional, value of $\overline{WAIT}$ pin available through status register)
MR/$\overline{W}$	O	Read/Write signal for Motorola type peripherals
OCLKO	O	Clock signal for ONFI2 memory devices. Output on the $\overline{WR}$ pin

15.17.2 Support for four Burst FLASH device types

Support is provided for a maximum of four different Burst FLASH configurations on the external bus - i.e. one on each external chip select.

Bit-fields EBU_BUSCONx.EBSE, EBU_BUSCONx.ECSE, EBU_BUSCONx.wait, EBU_BUSCONx.FBBMSEL, EBU_BUSCONx.BFCMSEL and

EBU_BUSCONx.FETBLEN are used to configure specific characteristics for burst access cycles.

15.17.3 Typical Burst Flash Connection

The figure below shows a typical burst flash connection.

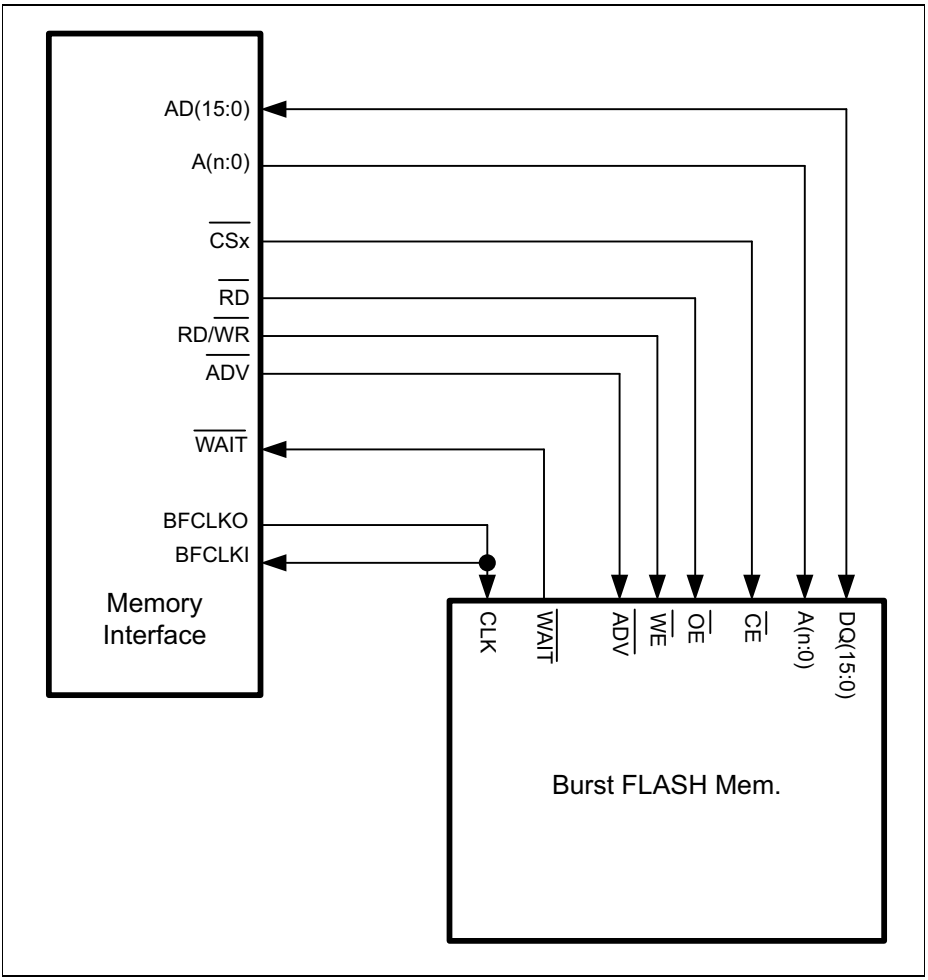

Figure 15-29 Typical Burst Flash Connection

15.17.4 Standard Access Phases

Accesses to burst FLASH devices are composed of a number of “Standard Access Phases” (which are detailed in **Section 15.15**). The Standard Access Phases for Burst FLASH devices are:-

- AP: Address Phase (compulsory - see **“Address Phase (AP)” on Page 15-63**).
- AH: Address Hold Phase (optional see **“Address Hold Phase (AH)” on Page 15-64**).
- CD: Command Delay Phase (optional - see **“Command Delay Phase (CD)” on Page 15-64**).
- CP: Command Phase (optional - see **“Command Phase (CP)” on Page 15-64**).
- BP: Burst Phase (compulsory - see **“Burst Phase (BP)” on Page 15-65**).
- CH: Command Hold Phase (optional - see **“Control Hold (CH)” on Page 15-66**)
- RP: Recovery Phase (optional - see **“Recovery Phase (RP)” on Page 15-67**).

Note: During a burst access the Burst Phase (BP) is repeated the required number of times to complete the burst length.

See **Figure 15-30** for an example synchronous access to a non-multiplexed device and **Figure 15-31** for an example synchronous access to a multiplexed device.

15.17.5 Example Waveforms

The following figures show example waveforms for synchronous accesses

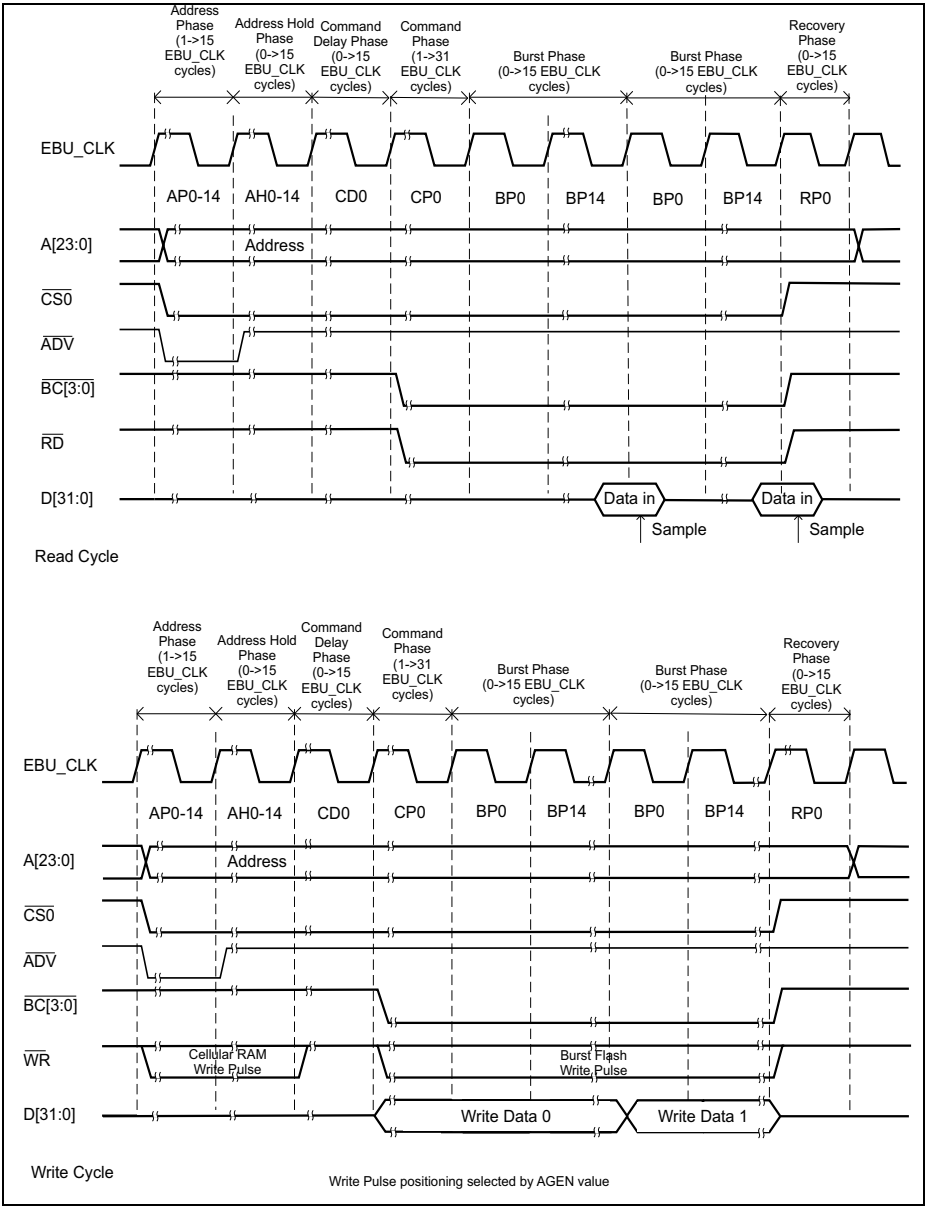

Figure 15-30 Synchronous non-muxed Access

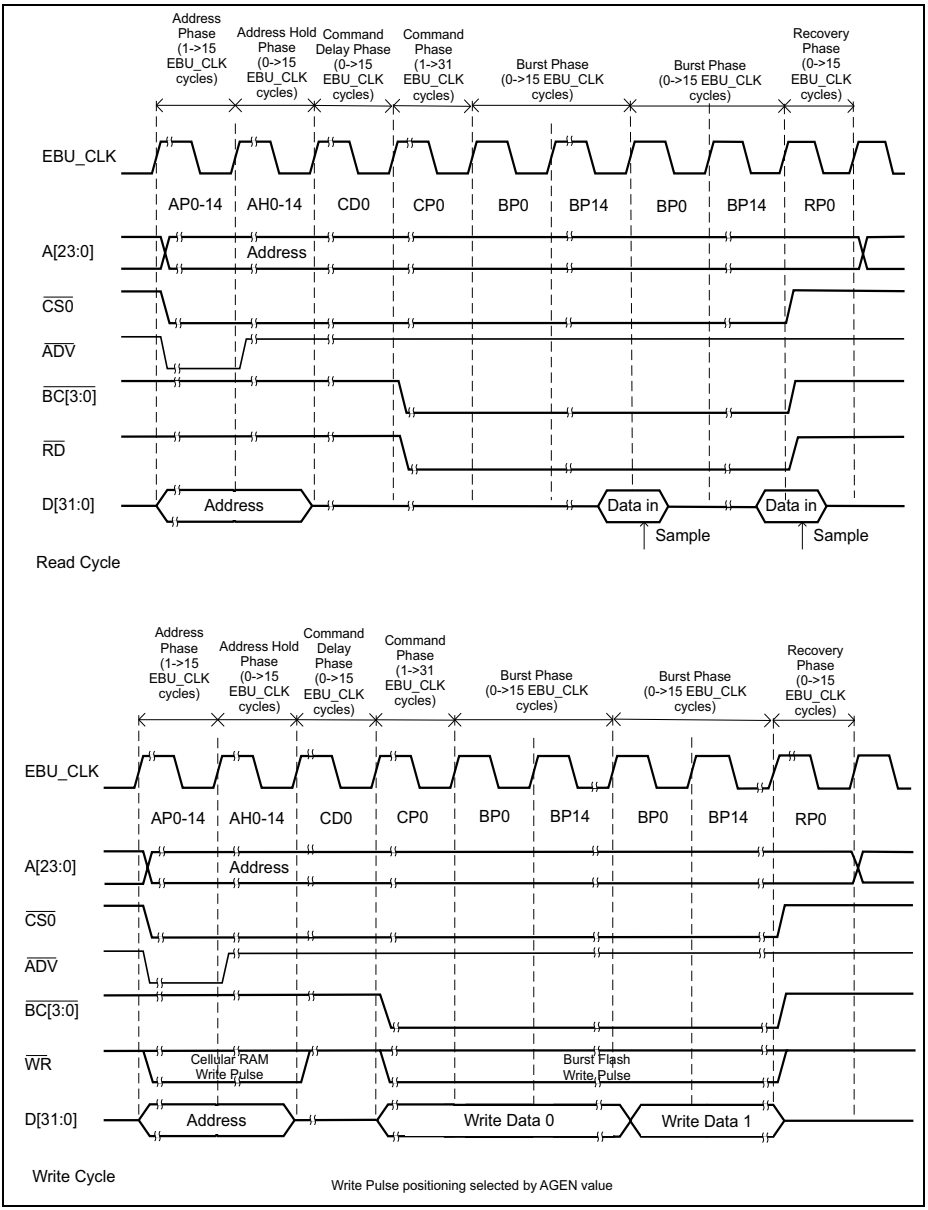

Figure 15-31 Synchronous muxed Access

15.17.6 Burst Length Control

The maximum number of valid data samples that can be generated by a flash device in a single read access is set by the EBU_BUSCONx.FBBMSEL bit and the EBU_BUSCONx.FETBLEN bit field.

The EBU_BUSCONx.FBBMSEL bit is used to select Continuous Burst Mode where there is no limit to the number of data samples in a burst read access.

The EBU_BUSCONx.FBBMSEL and EBU_BUSCONx.FETBLEN bit-fields are used to select the maximum number of data samples in a single access. Where an SRI request exceeds the amount of data that can be fetched or stored by the programmed number of data samples, the EBU will automatically generate the appropriate number of burst accesses to transfer the required amount of data.

Note: Selection of Continuous Burst Mode (by use of the 'FBBMSEL' bit) overrides the maximum burst setting (specified by the FETBLEN bit-field).

15.17.7 Burst Flash Clock

Since the EBU_CLK can run too fast for clocking Burst FLASH devices, the Memory Controller provides an additional clock source (BFCLKO). This signal is generated by a programmable clock divider driven by EBU_CLK and allows EBU_CLK to BFCLKO ratios of 1:1, 2:1, 3:1 and 4:1 to be selected. The frequency of the signal is determined by bit-field EBU_BUSRP.EXTCLOCK. Note that it is possible to set a different clock rate for synchronous writes to the same device by programming EBU_BUSWP.EXTCLOCK to a different value.

If a continuously running BFCLKO is required, then the BUSRCONx.BFCMSEL field can be used to enable an ungated flash clock. This bit is normally set to 1_B in all the BUSRCONx registers after reset. If cleared, the related BUSRAPx.EXTCLOCK field will be used to generate a stable BFCLKO. If multiple BUSRCONx.BFCMSEL fields are set to 0_B, then the highest priority (lowest index) BUSRAPx.EXTCLOCK field will be used.

During a burst access to a synchronous device, BFCLKO will generate correctly aligned clock edges as shown in **Figure 15-32**. The BFCLKO signal is gated to ensure that it is low (zero) at all other times (including asynchronous read/writes of/to synchronous devices). This provides power savings and ensures correct asynchronous accesses to Burst FLASH device(s).

The start of the address and burst phases are synchronised, by hardware, to the rising edge of BFCLKO. Exiting from a phase extended by the WAIT input will also be synchronised to the rising edge of BFCLKO.

Attaching DDR memory devices to the memory controller will impose additional restrictions on external bus clock generation. See **"External Bus Clock Generation" on Page 15-26**

Note: The length of the standard accesses phases during Burst FLASH accesses are programmed as a multiple of EBU_CLK independent of the BFCLKO frequency. It is the users responsibility to program the access phases to ensure that the sampling of data by Memory Controller guarantees valid sampling of the data from the Burst FLASH device.

The EBU uses the EBU_CLK clock to generate all external bus access sequences.

Table 15-28 EXTCLOCK to clock ratio mapping

EXTCLOCK value	BFCLKO divide ratio
00	1:1
01	1:2
10	1:3
11	1:4

Unless documented elsewhere, all outputs to the external bus are generated of the rising edge of EBU_CLK.

The BFCLKO phase is controlled so that control signal changes will normally occur at the rising edge of BFCLKO unless configured otherwise by register settings.

15.17.8 Control of $\overline{\text{ADV}}$ & Control Signal Delays During Synchronous Accesses

The Memory Controller output signals: $\overline{\text{ADV}}$, $\overline{\text{CS}}$, $\overline{\text{RD}}$, RD/$\overline{\text{WR}}$, $\overline{\text{BC}}$ and AD signals can be delayed with respect to the BFCLKO clock signal.

The delays can be enabled and disabled by the register bits EBU_BUSCONx.EBSE for the $\overline{\text{ADV}}$ signal and by EBU_BUSCON.ECSE for the $\overline{\text{CS}}$, $\overline{\text{RD}}$, RD/$\overline{\text{WR}}$, $\overline{\text{BAA}}$ and write data signals

The amount by which the signal is delayed depends on the ratio of EBU_CLK to the Burst FLASH clock as follows:-

- When the ratio of EBU_CLK to BFCLKO is 1:1, signals are asserted on the negative edge of EBU_CLK. i.e. it is in effect delayed by an EBU_CLK high pulse width (T_{PH}) with respect to BFCLKO.
- When the ratio of EBU_CLK to BFCLKO is 1:2 or 1:3, control signals are asserted on the next positive edge of EBU_CLK. i.e. it is in effect delayed by an EBU_CLK cycle (T_{CLK}) with respect to BFCLKO.
- When the ratio of EBU_CLK to BFCLKO is 1:4, control signals are asserted on the negative edge of BFCLKO. i.e. it is in effect delayed by two EBU_CLK cycles (2*T_{CLK}) with respect to BFCLKO.

- If the access is to a Cellular RAM (BUSWCONx.AGEN=3_D or 7_D), then the RD/$\overline{WR}$ signal is treated as a qualifier to the address and its timing will therefore not be affected by the setting of EBU.BUSWCON.ECSE.

For read accesses the EXTCLOCK field used will be from the BUSRAPx register of the region being accessed. For write accesses the EXTCLOCK field used will be from the BUSWAPx register of the region being accessed. However if a continuous BFCLKO is being generated (BUSRCONx.BFCMSEL=0_B), for all accesses, the EXTCLOCK value from the register with BFCMSEL set to 0_B will be used when calculating delays. This ensures that the signals are always delayed correclty relative to the clock on the BFLCKO output.

The default setting after reset has the delays disabled.

If the delay is disabled, then the signals will not be delayed in 1:1 mode (except for ADV which will be guaranteed to be after the edge of BFCLKO). In 2:1, 3:1 and 4:1 mode, the signals will be delayed by an EBU_CLK high pulse width (T_{PH}) from the start of the cycle in which they are asserted.

Table 15-29 $\overline{ADV}$ Signal Timing

EXTCLOCK is set to	$\overline{ADV}$ Falling Edge position		$\overline{ADV}$ Rising Edge position	
	Delay Disabled[1]	Delay Enabled	Delay Disabled[1]	Delay Enabled
00_B	Start of AP1	Start of AP1+T_{PH}	End of APn	End of APn+T_{PH}
01_B, 10_B	Start of AP1+T_{PH}	End of AP1	End of APn+T_{PH}	End of APn+ T_{CLK}
11_B	Start of AP1+T_{PH}	End of AP1 + T_{CLK}	End of APn+T_{PH}	End of APn + 2*T_{CLK}

1) See **Figure 15-30** for details of this signal positioning.

1) See **Figure 15-30** for details of this signal positioning.

2) CPn indicates the final Command Phase.

Table 15-31 $\overline{CS}$ Data Signal Timing

EXTCLOCK is set to	Set at:		Cleared at:	
	Delay Disabled[1)]	**Delay Enabled**	**Delay Disabled**	**Delay Enabled**
00_B	Start of AP1	Start of AP1 + T_{PH}	End of DHn[2)]	End of DHn + T_{PH}
01_B, 10_B	Start of AP1 + T_{PH}	End of AP1	End of DHn + T_{PH}	End of DHn + T_{CLK}
11_B	Start of AP1 + T_{PH}	End of AP1 + T_{CLK}	End of DHn + T_{PH}	End of DHn + 2*T_{CLK}

1) See **Figure 15-30** for details of this signal positioning.

2) DHn indicates the final Data Hold Phase. This is replaced by CPn if the programmed Data Hold phase length is zero clocks.

The byte control signals, $\overline{BC}$x, can either use the timing in **Table 15-30** if EBU_BUSCONx.BCGEN is set to 01_B or 10_B or the timing in **Table 15-31** if EBU_BUSCONx.BCGEN is set to 00_B. A EBU_BUSCONx.BCGEN value of 11_B is not valid for synchronous accesses.

Table 15-32 Write Data Signal Timing

EXTCLOCK is set to	Data Driven at:		Data Cleared at:		Data Changes at:	
	Delay Disabled[1)]	Delay Enabled	Delay Disabled	Delay Enabled	Delay Disabled	Delay Enabled
00_B	Start of CP1	Start of CP1 + T_{PH}	End of DHn[2)]	End of DHn + T_{PH}	Start of BP1	Start of BP1 + T_{PH}
01_B, 10_B	Start of CP1 + T_{PH}[3)]	End of CP1[3)]	End of DHn + T_{PH}	End of DHn + T_{CLK}	Start of BP1 + T_{PH}	End of BP1
11_B	Start of CP1 + T_{PH}[3)]	End of CP1 + T_{CLK}[3)]	End of DHn + T_{PH}	End of DHn + 2*T_{CLK}	Start of BP1 + T_{PH}	End of BP1 + T_{CLK}

1) See **Figure 15-30** for details of this signal positioning.

2) DHn indicates the final Data Hold Phase. This is replaced by CPn if the programmed Data Hold phase length is zero clocks.

3) Data bus will be enabled at the start of CP1

These delay options apply to write data only. Addresses which are output on the data bus to support devices with multiplexed address and data connections are not delayed.

Note: If the control signals are delayed a recovery phase must be used to prevent conflicts between accesses as the rising edge of the control signals will be delayed past the end of the command phase. If a multiplexed access is used without a recovery phase, the address for the next access will be delayed by one clock cycle to enforce a bus turnaround time on the data bus, resulting in the valid address being driven one clock after ADV is asserted.

15.17.9 Interaction with DDR Signal Timing

If a DDR device is attached and **EBU_DLLCON.WR_EN** is enabled, then the write data and byte control signal timing will be affected. The storage elements used to drive the signal outputs will be operating off a shifted clock controlled by the DLL. This will degrade the timing margins relative to the BFCLKO output and may shift the outputs by a complete clock cycle due to the different resynchronisation stages used.

For these reasons, correct operation of synchronous writes to single data rate devices when **EBU_DLLCON.WR_EN** is enabled cannot be guaranteed and this combination of settings should be avoided.

15.17.10 Burst Flash Clock Feedback

The Memory Controller can be configured to use clock feedback to optimise the operating frequency for a given flash device. This is enabled by setting the EBU_BUSCONx.FDBKEN bit to one. With this bit enabled the first sampling stage for read data has its own clock (PD_BFCLKFEEDBK_I). This will be derived from the BFCLKO output by using a second pad (BFCLKI) to monitor the BFCLKO signal after the output pad delay.

Clock feedback should be used whenever possible as it allows the best possible performance

A side effect of using this mode is an increase in data latency by one BFCLKO cycle compared with not using clock feedback.

Note: Clock feedback will be automatically disabled for burst writes as the additional latency on the $\overline{WAIT}$ input would prevent correct operation of the memory controller.

15.17.11 Asynchronous Address Phase

As operating frequency increases, it becomes increasingly hard to avoid violating some timing parameters. The asynchronous address phase allows the address to be latched into the flash memory using the ADV signal before the clock is enabled. This is only possible if explicitly allowed by the flash data sheet.

If the EBU_BUSCONx.AAP is set, then the clock will not start until the end of the address hold phase of the access. The rising edge of the clock will always be co-incident with the transition from the address hold phase. If the address hold phase has zero length then the first rising edge of the clock will coincide with the tranistion from the address phase. If this mode is enabled a recovery phase of one BFCLK period will be enforced at the end of the previous transaction to ensure that the clock has time to turn off before the start of the next access.

Setting this mode for any region will force the clocks on all synchronous accesses to be disabled in the recovery phase. Only one clock pulse will occur during the recovery phase.

AAP mode is incompatible with the continuous clock mode and will be disabled automatically if continuous clocking is enabled by setting any BUSRCONx.BFCMSEL bit to 0_B.

15.17.12 Critical Word First Read Accesses

In the default case, the memory controller will always start a burst at the lowest address possible and wrapping of the burst data is handled internally to the memory controller. However, some burst devices implement a wrapping feature which is compatible with the wrapped bursts used by the processor cache fill requests. If this is the case, there is an

advantage to using the wrapping mode in the device as the instruction required by the processor (the critical word) can be fetched first from the external memory.

The mode is enabled by setting the EBU_BUSCONx.dba bit for the appropriate region. Once enabled, the memory controller will not align the start address for the burst and the device will be relied on to return data in the correct order. The memory controller must fetch all the data in a single burst. If the transaction is split into multiple accesses on the external bus by use of the FETBLEN field, the issued addresses will be incorrect.

Note: The cache line fill will use an SRI, BTR4 transfer. This translates to a 16 word burst for a 16 bit device. The device must therefore support a 16 word wrap setting. A 32 bit memory must support a 8 word wrap setting. The memory controller supports a 16 word burst using the continuous burst setting for FBBMSEL. Other burst opcodes must not be generated for accesses to the external memory by the system if this mode is enabled, otherwise data corruption will occur.

15.17.13 Example Burst Flash Access Cycle

The figure below shows an example burst flash access without clock feedback configured.

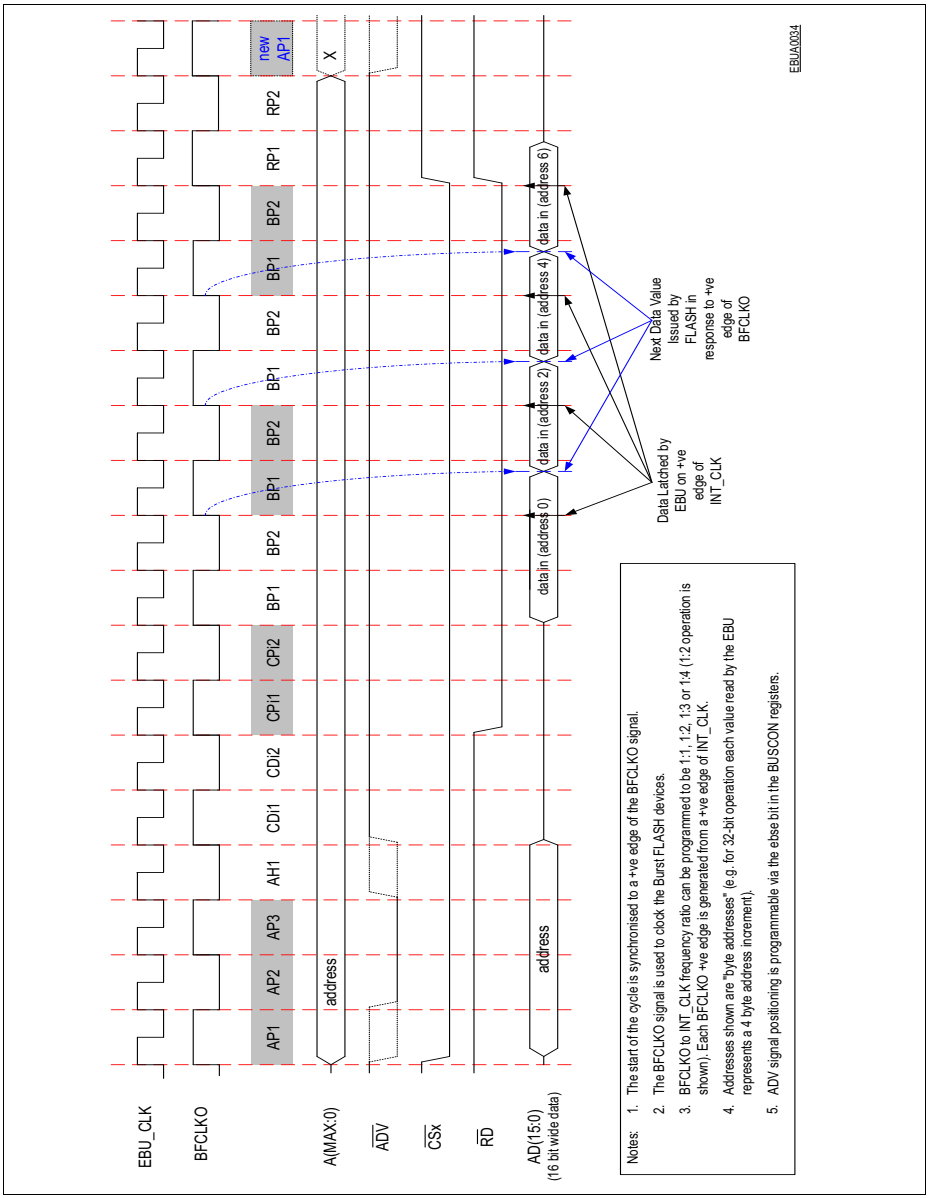

Figure 15-32 Burst FLASH Read without Clock Feedback (burst length of 4)

Figure 15-32 shows an example of a burst read access (burst length of four) to a Burst FLASH device with WAIT and clock feedback functions disabled.

Programmability of the length of the Address, Command Delay and Command phases allows flexible configuration to meet the initial read access time of a Burst FLASH device.

Data is sampled at the end of each Burst Phase cycle. The Burst Phase is repeated the appropriate number of times for the programmed burst length (programmable for lengths of 1, 2, 4 or 8 via the EBU_BUSCONx.FETBLEN bit-field).

Figure 15-32 shows an access cycle with the following settings:-

- Clock Feedback disabled.
- Address Phase length = 3 EBU_CLK cycles (see ADDRC and **"Address Phase (AP)" on Page 15-63**).
- Command Delay Phase length = 3 EBU_CLK cycles (see CMDDELAY and **"Command Delay Phase (CD)" on Page 15-64**).
- Command Phase length = 2 EBU_CLK cycles (see WAITRDC and **"Command Phase (CP)" on Page 15-64**).
- Burst Phase length = 2 EBU_CLK cycles (see EXTCLOCK, EXTDATA and **"Burst Phase (BP)" on Page 15-65**).
- Recovery Phase length = 2 EBU_CLK cycles (see **"Recovery Phase (RP)" on Page 15-67**).
- Burst Length = 4 (see FETBLEN).
- BFCLKO frequency = 1/2 of EBU_CLK frequency (see EXTCLOCK).

15.17.14 External Cycle Control via the WAIT Input

Memory Controller provides control of the Burst FLASH device via the WAIT input. This allows Memory Controller to support operation of Burst FLASH while crossing Burst FLASH page boundaries. During a Burst FLASH access the WAIT input operates in one of four modes:-

- Disabled
- Early Wait for Page Load.
- Wait for Page Load.
- Abort and Retry Access.

Selection of the mode in which the WAIT input operates during Burst FLASH reads is selected via the EBU_BUSCONx.WAIT bits.

Table 15-33 Operation of WAIT input

Value of BUSCONx.WAIT	Mode of the WAIT input
0_D	OFF (default after reset).
1_D	Wait for page load (Early WAIT).

Table 15-33 Operation of WAIT input (cont'd)

Value of BUSCONx.WAIT	Mode of the $\overline{\text{WAIT}}$ input
2_D	Wait for page load (WAIT with data).
3_D	reserved

Note: Selection of "Disabled" via the wait bit-field prevents the $\overline{WAIT}$ input having any effect on a Burst FLASH access cycle

Wait for Page Load Mode

This mode supports devices which assert a $\overline{\text{WAIT}}$ output for the duration of clock cycles in which the data output by the device is invalid or, alternatively, one clock cycle earlier than the data output is invalid. This includes Intel and AMD Burst FLASH devices (and compatibles) configured for Early Wait Generation Mode (EBU_BUSCONX.wait=01_B) and standard wait generation (EBU_BUSCONx.wait=10_B).

In operation, the burst flash controller loads a counter with the required number of samples at the start of each burst. At the end of each burst phase, the burst flash controller samples the $\overline{\text{WAIT}}$ input and the data bus at the end of each Burst phase. If $\overline{\text{WAIT}}$ is inactive, the sample is valid, the sample counter is decremented and the sampled data is passed to the datapath of the Memory Controller. This synchronous sampling means that the validity of the sample can not be determined until the clock cycle after the end of the burst phase. The Burst Flash controller will therefore overrun and generate extra burst phases until the sample counter is decremented to zero. Extra data samples returned after the sample counter is zero will be discarded.

The only difference if early wait is used is that the validity of data in burst phase "n" is determined by the value of $\overline{\text{WAIT}}$ in burst phase "n-1".

This mode of operation is compatible with the use of clock feedback as, with feedback enabled, $\overline{\text{WAIT}}$ is fed through the same resynchronisation signals as the data bus. The only effect on operation is that the number of overrun cycles will increase as the decrementing of the sample counter will be lagged by the resynchronisation stages.

During the initial phases of an access, $\overline{\text{WAIT}}$ is sampled on every edge of EBU_CLK. This is so the first burst phase is working with an accurate value for the $\overline{\text{WAIT}}$ signal. To ensure this is the case, the command phase should be of sufficient length to allow the device to drive $\overline{\text{WAIT}}$ and for the signal to propagate to the controller.

Abort and Retry Access

In this mode, the $\overline{\text{WAIT}}$ input is polled during the address and address hold phases only. If an active state on $\overline{\text{WAIT}}$ is detected, the address phase of the access will be restarted after the end of the address hold phase.

In this mode $\overline{\text{WAIT}}$ cannot be used to extend the command phase of an access.

15.17.15 Flash Non-Array Access Support

Several types of flash memories will assert $\overline{\text{WAIT}}$ permanently during an access which is not directed to the memory array. An example of this would be polling the status register to check if a programming operation has completed. If the BUSRCON[3:0].NAA field is set, then an access to the region with SRI A(26) set will proceed as if the appropriate wait field in BUSRCON[3:0] or BUSWCON[3:0] was set to 00_B and $\overline{\text{WAIT}}$ was disabled. When set, this field affects both read and write accesses.

15.17.16 Termination of a Burst Access

A burst read operation is terminated by de-asserting $\overline{\text{CSx}}$ signal followed by the appropriate length Recovery Phase. **Figure 15-33** shows an example of termination of a burst access following the read of two locations (i.e. two Burst Phases) from a 16-bit non-multiplexed Burst FLASH device.

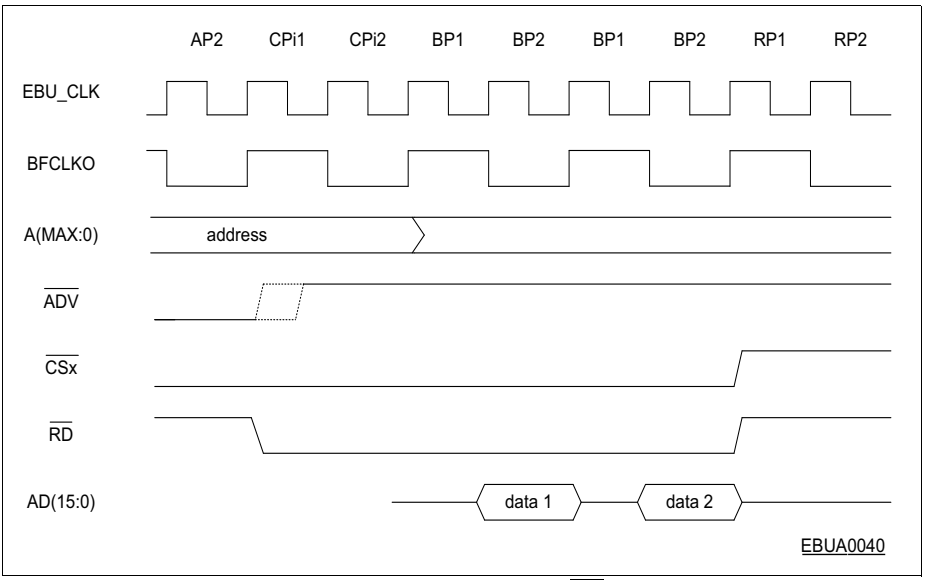

Figure 15-33 Terminating a Burst by de-asserting $\overline{\text{CS}}$

15.17.17 Burst Flash Device Programming Sequences

Programming sequences for some Burst Flash devices must not be interrupted by other read/write operations to the same device. There is an optional hardware lock feature to

guarantee that programming sequences are not interrupted. See **Section 15.9.1** for details.

15.17.18 Cellular RAM

Cellular RAM devices have been designed to meet the growing memory and bandwidth demands of modern cellular phone designs. The devices have been designed with a “multi-protocol” interface to allow use of the devices with existing memory interfaces (i.e. by re-use of existing memory protocols). The supported interface protocols supported by Cellular RAM devices are:-

1. SRAM (Asynchronous Read and Write).
2. NOR Flash (Synchronous Burst Read, Asynchronous Write).
3. Synchronous (Synchronous Burst Read and Write).

In principle, when using previous versions of Memory Controller, the first two of the above modes (1 and 2 above) provided Cellular RAM support. For maximum performance, the Memory Controller now supports Synchronous Mode (3 above) for Cellular RAM (Synchronous Burst Read and Write).

As Cellular RAM Synchronous Mode consists of a Burst FLASH compatible Burst Read access, Cellular RAM support has been provided by enhancing the Burst FLASH interface by the inclusion of a Burst Write capability. For this reason Cellular RAM is treated as a special type of Burst FLASH device.

Cellular RAM support is selected by programming the desired region as cellular RAM via the EBU_BUSCONx.AGEN bit-field.

Synchronous Read Access

A Synchronous Cellular RAM Burst Read Access is compatible with a Burst FLASH Burst Read Access. As a result preceding sections applying to Burst FLASH devices apply and should be consulted for details of Cellular RAM Burst Read Accesses.

15.17.18.1Synchronous Write Access

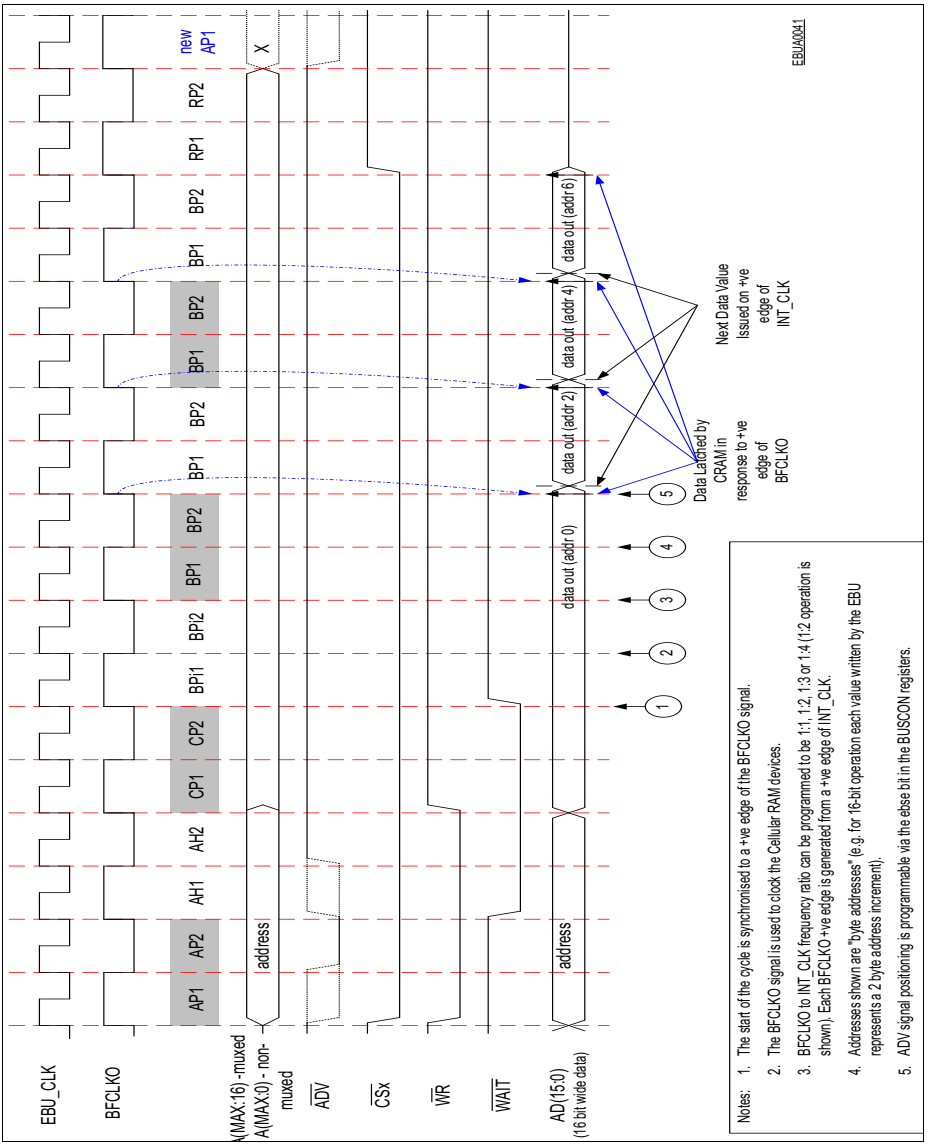

Figure 15-34 Burst Cellular RAM Burst Write Access (burst length of 4)

Figure 15-34 shows an example of a Cellular RAM burst write access.

*Note: **Figure 15-34** shows operation with a BFCLKO to EBU_CLK ratio of 1:2.*

The Start of the access cycle is the same as for a Synchronous Read access (see **Figure 15-32**) except that the WR signal is treated as an address phase signal (i.e. it is asserted active during the Address Phase and Address Hold Phase and is then deasserted). See **"Fujitsu FCRAM Support (burst write with WR active during data phase)" on Page 15-104** for alternative WR timing during burst write.

The remaining sequence is as follows (with reference to the figure above):-

1. At the positive edge of EBU_CLK labelled as '1' above the first Burst Phase starts. As the state machine is currently in the command phase, the interface samples the WAIT input. This is sampled as "active". By coincidence, in this example, the Cellular RAM also deasserts it's WAIT output as a response to this clock edge to signal that it will start to take the data from the data bus on the BFCLKO rising clock edge after the next (i.e. the rising edge of BFCLKO labelled as '5' above) - this need not be the case.
2. At the positive edge of EBU_CLK labelled as '2' above the second programmed EBU_CLK period of the Burst Phase begins.
3. At the positive edge of EBU_CLK labelled as '3' above the Burst FLASH evaluates the WAIT sample from '1' above. As this sample was "active" the write data is not updated. As this clock edge is coincident with the end of a burst phase the WAIT input is resampled. The value of this new WAIT sample is "inactive".
4. At the positive edge of EBU_CLK labelled as '5' above the Burst FLASH again evaluates the WAIT sample from '3' above. As this sample was "in-active", and the edge is coincident with the end of a burst phase, the next data value is issued to the AD(15:0) pins and the next Burst Phase is started.

This process continues until all the data is written.

15.17.18.2 Fujitsu FCRAM Support (burst write with WR active during data phase)

The FCRAM device type can be supported in two ways. Later FCRAMs have a compatibility bit in the device configuration register which programmes the device to expect the WR signal to be active with the address and to be latched with the ADV signal. In this mode, FCRAM can be treated as an Infineon/Micron cellular RAM.

Alternatively, if a write is attempted to a region configured as a burst flash, the memory controller will generate a burst write with the WR signal asserted with the write data. This should be directly compatible with an FCRAM operating in its native mode.

15.17.19 DDR Burst Flash Support

The memory controller includes features which allow the support of flash memories using a DDR data bus protocol. The memory types supported are:

- DDR NOR flash memory, supporting DDR read and write accesses

- ONFI 2.0 NAND flash

Configuring a region to support either of the memory types will enable the requisite number of DQS lines to support the attached memory.

The DQS lines will be multiplexed onto the most significant address lines as these will not be required for the supported DDR memories. Once enabled as DQS, the address lines will not be available as addresses for any devices attached to the EBU.

It is recommended that DDR flash is only used with other DDR memories due to the critical load matching requirements on the DQ/DQS/DQM lines. Mixing memory types may limit the supportable operating frequency.

DDR flash support using an BUSCONx.EXTCLOCK setting of 00_B (1:1 internal to external clock ratio) requires the use of the memory controller DLL. Other clock ratios are supported using edges of the internal clock signal to generate the signal waveforms (See **“Generation of DDR Control Signals without using the DLL” on Page 15-24**).

15.17.19.1 DDR NOR Burst Flash

DDR NOR burst flash support is configured by setting the **AGEN** fields of the BUSCONx register to 9_D. However, at present there are no devices that are known to support writes using this protocol so it is expected that the device will be configured for DDR reads and asynchrnonous writes.

Configuring support for this type of device will enable the differential BFCLK clock (See **“External Bus Clock Generation” on Page 15-26**). It will also enable the generation of addresses on the AD bus to allow support multiplexed address/data memories.

DDR NOR burst flash can have an internal PLL. If this is the case, the clock must be set to continuous mode by setting the **BFCMSEL** field of the BUSRCON register to 0_B.

Note: Once the differential clock has been enabled, there will be a delay while the PLL locks. During this delay, the device cannot be accessed synchronously.

For accesses to DDR NOR flash, the reading of data will be handled in the same way as for DDRAM. See **Chapter 15.10.4** and **Chapter 15.10.6** for a full description of the methods available.

Due to uncertainty in the read signal output timing of the attached device, read accesses will always use the full burst length programmed in the **FETBLEN** bitfield. Continuous burst mode is not available. Setting continuous burst mode using the **FBBMSEL** bitfield will result in a burst length of sixteen being programmed.

For read accesses, any unused data words will be discarded.

As the burst length of the EBU is defined in cycles of BFCLKO and the burst length of the flash may be defined in data words, there may be a mismatch for DDR devices. If the device burst length is defined in data words per read then the programmed EBU burst length must be half the burst length programmed into the device configuration register. The EBU will expect two data words per Burst Phase when accessing DDR devices.

DDR NOR flash read accesses should be extended using a Control Hold phase (**“Control Hold (CH)” on Page 15-66**). This is used to prevent the device outputs being disabled before the last data word can be output by the device. This is necessary as the worst case timing delay between the clock input to the device and the output of the DQS and data word may be great enough to move the output signals into the next clock period. Cancelling the control signals at the end of the burst phase may therefore diable the device outputs before the last data can be latched into the EBU.

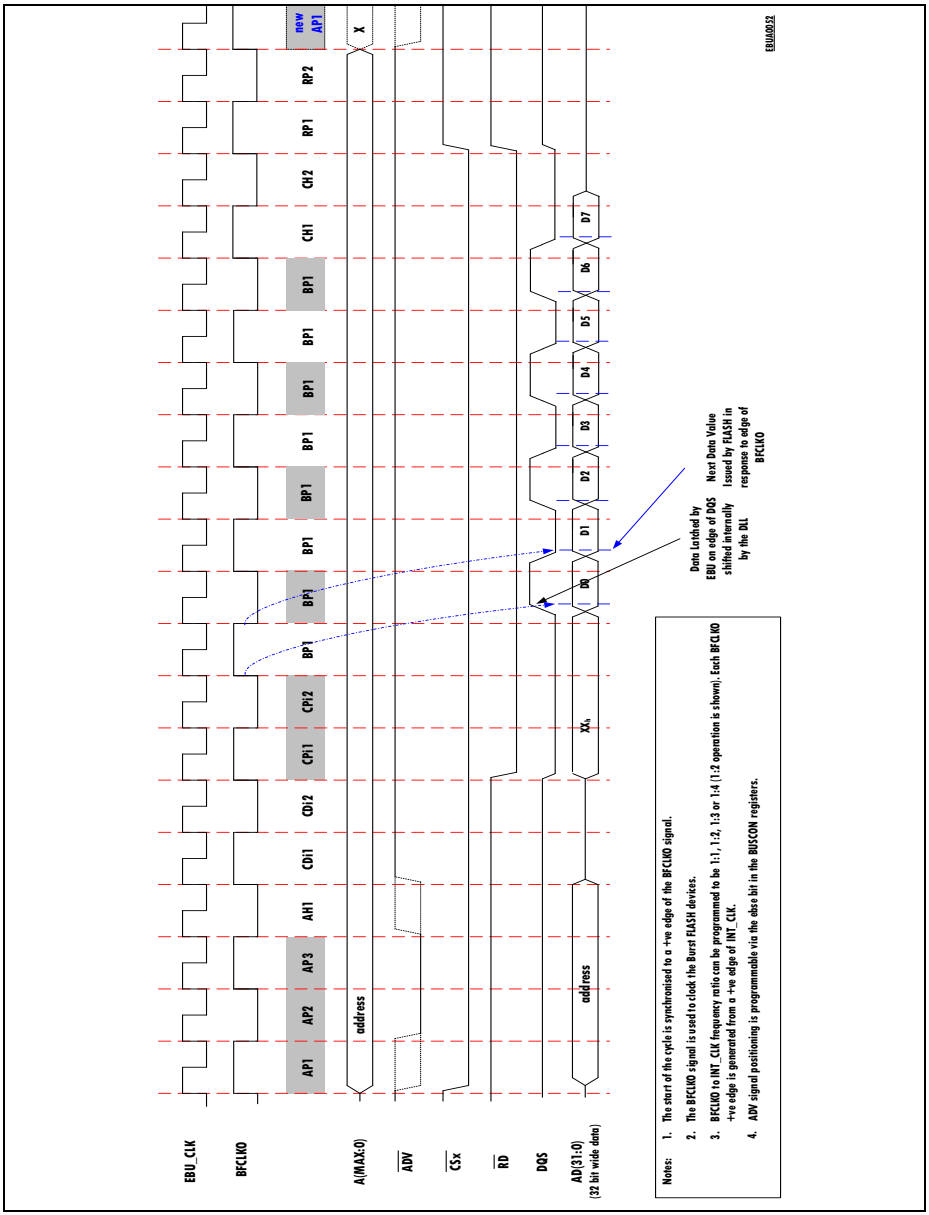

Figure 15-35 DDR NOR Burst Flash Read Cycle

15.17.19.2 ONFI 2.0 NAND Flash

The EBU can interface to NAND flash memories complying with the ONFI 2.0 specification. Initial, asynchronous, operation is handled using the AGEN value 2_D (NAND flash page mode). Once configured for synchronous operation, the AGEN field should be set to 13_D.

Connection of an eight bit device is as in below. Connection of 16 and 32 bit devices is the same with the additional AD and DQS connections. A 16 bit device will need AD(15:8) and DQS(1). A 32 bit device will also need AD(31:16) and DQS(3:2). Multiple devices can also be connected in parallel to make up a large word width.

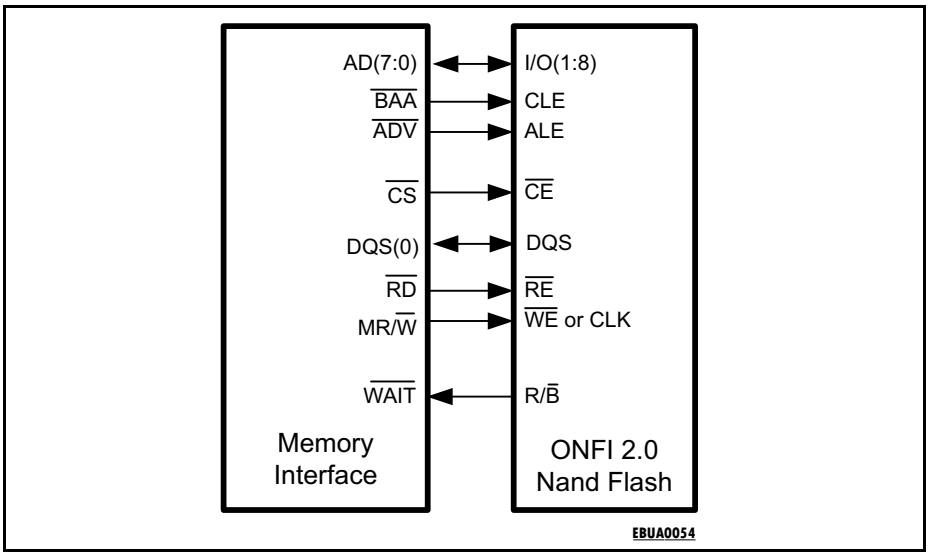

Figure 15-36 Connection of 8 bit ONFI 2.0 NAND Flash

While AGEN is set to 2_D, the state of the DQS signal(s) on a write access will be determined by A(18) of the access. This is equivalent to A_{SRI}(18) for 8 bit devices.

When AGEN is set to 13_D, the state of the DQS signal(s) during a write access will be determined by A(18) unless both A(17) ands A(16) are set to 1_B.

If A_{EBU}(17:16) is set to 11_B, a data transfer (as defined in the ONFI specification) is in progress and the DQS lines will be used to clock the data.

If AGEN is 13_D and a data transfer is not in progress then the burst length of all transfers to the device should be restricted by software to a single data phase. This is to enable the successful writes of command and address data.

Write data will be transferred at single data rate if a data transfer is not in progress as the attached device will use the clock to latch the write data and will not expect DQS.

Table 15-34 ONFI 2.0 Nand Flash Command SIgnal Control (8 bit device)

SRI Address	Signal(s) set	Asynchronous mode usage	Synchronous Mode Usage
Base + 00000_H	No command signals set	Read/Write: Used to read data from and write data to the device.	Bus Idle.[1]
Base + 10000_H	ALE	Write only: Used to write the required access address to the device.	
Base + 20000_H	CRE	Write only: Used to write the required command to the device.	
Base + 30000_H	ALE+CRE	Invalid	Data Transfer
Base + 40000_H	DQS	Read/Write: Use Base + 0000_H instead	Bus Idle
Base + 50000_H	ALE+DQS	Write only: Used to write the required access address to the device. Use Base + 10000_H instead.	
Base + 60000_H	CRE+DQS	Write only: Used to write the “set features” command to the device.	
Base + 70000_H	ALE+CRE	Invalid	Data Transfer

1) If used on a read access, the EBU will stall indefinitely waiting for read data.

Example waveforms for the ONFI 2.0 interface protocol are shown below.

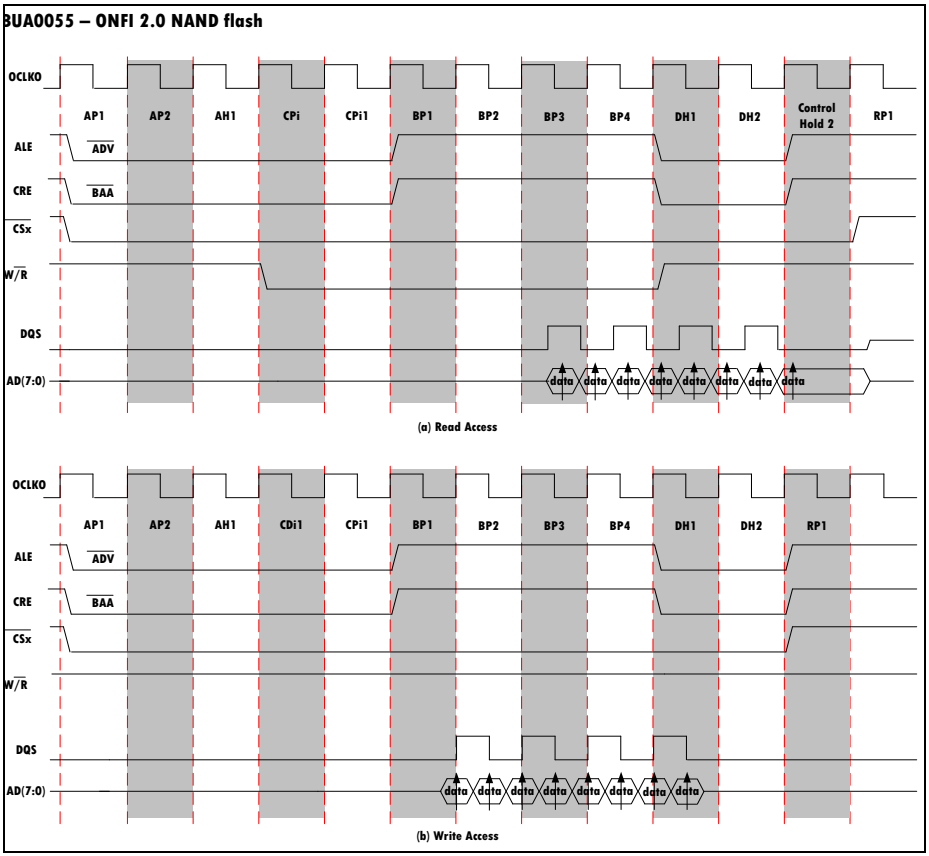

Figure 15-37 ONFI 2.0 NAND Flash: Data Transfer Cycles

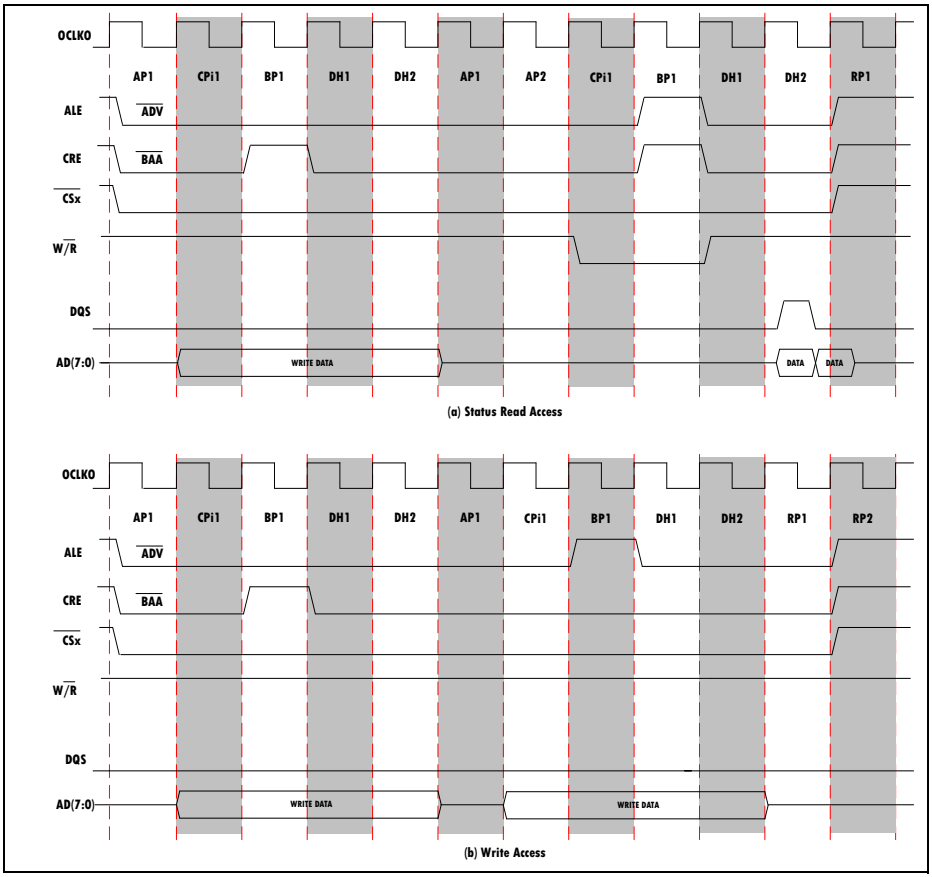

Figure 15-38 ONFI 2.0 Command Cycles

Note: The ONFI 2.0 specification does not support byte transfers to/from 16 or 32 bit devices in source synchronous mode. The EBU will translate requests for byte reads into a word read and discard the extra data. Writes, however, will always transfer 16 bits of data to the device (the superfluous data will not be masked).

15.17.20 Programmable Parameters

The following table lists the programmable parameters for burst flash accesses. These parameters only apply when the EBU_BUSCONx.agen parameter for a particular memory region is set for access to synchronous burst devices (page mode or otherwise).

Table 15-35 Burst Flash Access Programmable Parameters

Parameter	Function	Register
ADDRC	Number of cycles in Address Phase.	EBU_BUSAPx
AHOLDC	Number of cycles in Address Hold.	EBU_BUSAPx
CMDDELAY	Number of programmed Command Delay cycles.	EBU_BUSAPx
WAITRDC	Number of programmed wait states for read accesses.	EBU_BUSAPx
WAITWRC	Number of programmed wait states for write accesses.	EBU_BUSWAPx
EXTDATA	Extended data	EBU_BUSAPx
RDRECOVC	Number of minimum recovery cycles after a read access when the next access is to the same region.	EBU_BUSRAPx
WRRECOVC	Number of minimum recovery cycles after a write access when the next access is to the same region.	EBU_BUSWAPx
RDDTACS	Number of minimum recovery cycles after a read access when the next access is to a different region.	EBU_BUSRAPx
WRDTACS	Number of minimum recovery cycles after a write access when the next access is to a different region.	EBU_BUSWAPx
WAIT	Sampling of $\overline{\text{WAIT}}$ input: OFF, SYNCHRONOUS, ASYNCHRONOUS or WAIT_CELLULAR_RAM	EBU_BUSCONx
FBBMSEL	Flash synchronous burst mode: CONTINUOUS or DEFINED (as in FETBLEN)	EBU_BUSCONX
FETBLEN	Synchronous burst length: SINGLE, BURST2, BURST4 or BURST8	EBU_BUSCONx
BFCMSEL	Flash Clock Mode, continuous or gated	EBU_BUSRCONx

Table 15-35 Burst Flash Access Programmable Parameters (cont'd)

Parameter	Function	Register
EXTCLOCK	Frequency of external clock at pin OCLKO: equal, 1/2 or 1/4 of EBU_CLK	EBU_BUSAPx
EBSE	delay $\overline{ADV}$ output to improve hold margin	EBU_BUSCONx
ECSE	delay $\overline{CS}$, $\overline{WR}$ and write data outputs to improve hold margin	EBU_BUSCONx
LOCKCS	enable locked write sequences for this region	EBU_BUSWCONx
FDBKEN	enable clock feedback to improve read data margins	EBU_BUSRCONx
DBA	disable alignment of read bursts on external bus	EBU_BUSRCONx
AAP	enable the "asynchronous address phase" mode.	EBU_BUSCONx
PORTW	memory port width	EBU_BUSRCONx

Note: datac is not used for burst write accesses

15.18 SDRAM Interface

The SDRAM interface supports 16 and 32 bit bit SDRAM configurations with four banks at densities up to 1 GBit.

Please see the Intel™ PC100 specification for signalling waveforms for this interface.

The Memory Controller can support a single SDRAM region. To enable SDRAM support the **AGEN** fields of a single register pair of EBU_BUSRCON and EBU_BUSWCON must be set to "8_D".

*Note: Programming the **AGEN** fields of multiple regions for SDRAM and connecting multiple SDRAMs will result in data corruption as the "page open" tags in the SDRAM controller will be applied indiscriminately to all connected devices.*

15.18.1 Features

- Compatible with mobile PC133 memories at 125 MHz (if maximum bus load is not exceeded) when used with optimised pads.
- Mobile SDRAM support.

- Support for 64, 128, 256, 512 MBit and 1 GBit SDRAM devices.
- Auto-refresh mode support.
- Support for 16 and 32 bit bus widths.
- Power-on/mode-set sequence triggered by SRI write to **EBU_SDRMOD** configuration register.
- Programmable refresh rate.
- Programmable timing parameters (row-to-column delay, row-precharge time, mode-register setup time, initialization refresh cycles, refresh periods).
- Multiple power save modes supported
  - Clock Stop
  - power down without precharge
  - power down with Auto-precharge
  - power down with precharge
  - self refresh

15.18.2 Signal List

The following signals are used for the SDRAM interface:-

Table 15-36 SDRAM Signal List (16 bit support)

Signal	Type	Function
AD(15:0)	I/O	Data bus
A(27:0)	O	Address bus
RD/$\overline{WR}$	O	Read and write control
CKE	O	Clock enable
CS(3:0)	O	Chip select
SDCLK0	O/I	External SDRAM Clock.
SDCLKI	I	External SDRAM Clock Feedback
RAS	O	Row Address Strobe for SDRAM accesses.
CAS	O	Column Address Strobe for SDRAM accesses.
DQM(3:0)	O	Data Qualifiers (output on $\overline{BC}$(3:0))

Table 15-37 SDRAM Signal List (32 bit support)

Signal	Type	Function
AD(31:16)	I/O	Data bus MSW
AD(15:0)	I/O	Data bus LSW
A(15:0)	O	Address bus (A(27:16) not needed for SDRAM)

Table 15-37 SDRAM Signal List (32 bit support) (cont'd)

Signal	Type	Function
RD/$\overline{WR}$	O	Read and write control
CKE[1)]	O	Clock enable
CS(3:0)	O	Chip select
SDCLK0	O/I	External SDRAM Clock
SDCLKI	I	External SDRAM Clock Feedback
RAS	O	Row Address Strobe for SDRAM accesses.
CAS	O	Column Address Strobe for SDRAM accesses.
DQM(3:0)	O	Data Qualifiers (output on $\overline{BC}$(3:0))

1) Pull down resistor required to maintain a valid logic level when the EBU is not driving the bus. See **Chapter 15.18.3**

15.18.3 External Interface

The external interface can be directly connected to DRAM chips without any glue-logic. Special board layout and timing constraints may apply when additional memory/peripherals (in addition to SDRAM devices) are directly connected to the bus.

16 and 32 bit devices are supported. Additionally, two 16 bit devices connected in parallel to make a 32 bit device are also supported. In this case, the memory controller region should be configured to support a 32 bit device but with the BUSCON PORTW fields set to 10_B to indicate a twin, 16 bit configuration.

Note: The memory controller always resets to "no bus" arbitration mode and will then synchronously transition to the appropriate mode and enable the required pins based on the register settings. This means that the SDRAM specific pins will be under the control of the ports I/O logic after reset. CKE must either be driven to an appropriate value for the application by the reset value of the ports logic or held to a valid state by a pull resistor on the PCB.

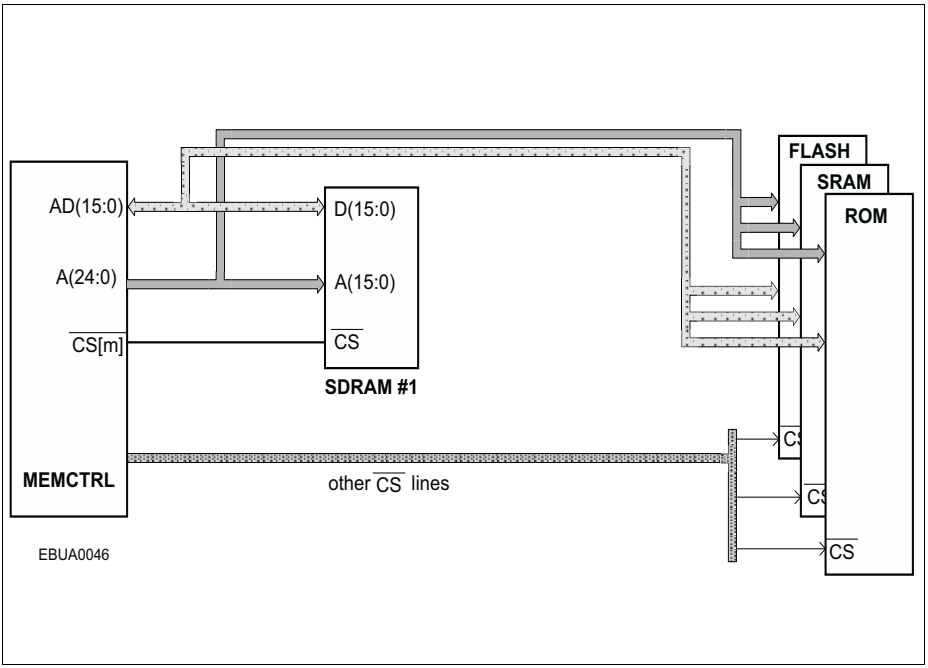

Figure 15-39 Connectivity for 16 bit SDRAM

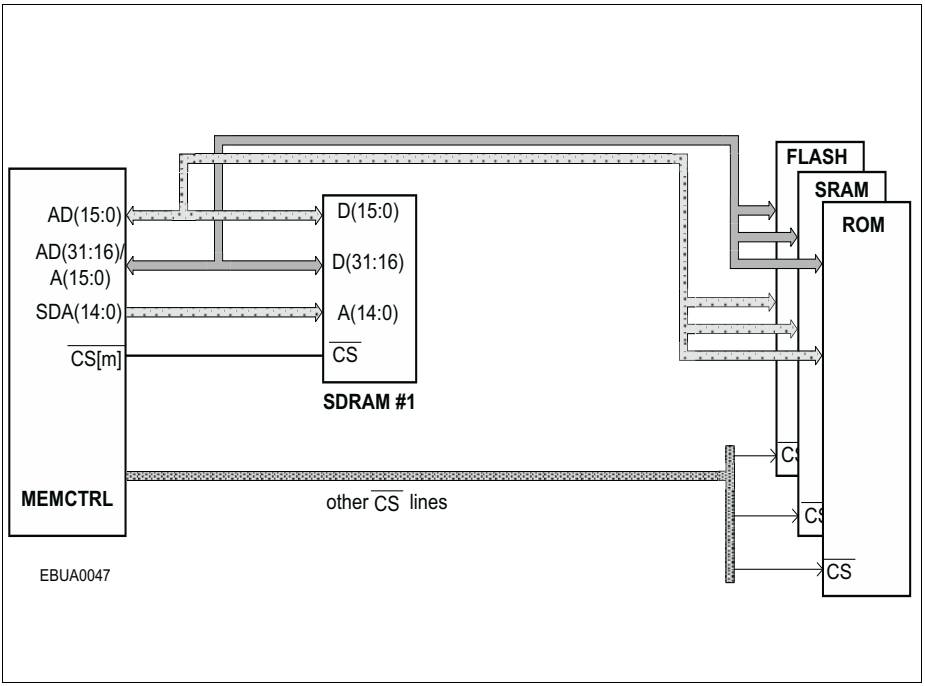

Figure 15-40 Connectivity for 32 bit SDRAM

15.18.4 SDRAM External Bus Clock Generation

The Memory Controller uses the EBU_CLK clock as a reference to generate all external bus access sequences.

SDCLKO is required by SDRAM memories and the frequency of this output is controlled by the EBU_BUSRAP.EXTCLOCK field of the highest priority (lowest region number) region which has EBU_BUSRCON.AGEN set to 8_D, 10_D or 12_D which are the values used to select the SDRAM state machine. EBU_BUSWAP.EXTCLOCK has no effect for SDRAM.

Unless documented elsewhere, all outputs to the external bus are generated synchronously to the falling edge of SDCLKO. This means that the SDRAM memory device sees control signal changes occur on the negative clock edge.

Connecting DDR memories to the EBU will impose additional constaints on the external bus clocks. See **“External Bus Clock Generation” on Page 15-26**.

Table 15-38 EXTCLOCK to clock ratio mapping

EXTCLOCK value	SDCLKO divide ratio
00	1:1
01	1:2
10	1:4
11	1:4

15.18.5 SDRAM Characteristics

SDRAMs are synchronous DRAMs with burst read/write capability which are controlled by a set of commands at the pins $\overline{CS}$, $\overline{RAS}$, $\overline{CAS}$, $\overline{WE}$, DQM and A10. As for standard DRAMs, a periodic refresh must be performed.

SDRAM devices are subdivided into “banks”. Each bank is subdivided into a number of “rows[1)]”. Each row is, in turn, subdivided into a number of “columns”. The number of banks and the size of a row varies from one SDRAM device to another. A specific location (half-word) within a device is specified by supplying a bank, row and column address. Devices supported by Memory Controller must conform to the following criteria:-

- **Number of Banks:** 2 or 4 only.
- **Row Size:** 256, 512 or 1024 only.

SDRAM devices produce high speed data transfer rates by use of the bank and row architecture. When an initial access is made to a specific row within a specific bank then Memory Controller must issue a “row” address to specifiy which row in which bank is to accessed. In response to this the SDRAM device loads the entire row to a local (high speed) buffer area. At this point (i.e. when the local buffer associated with a bank contains data from the main SDRAM array) the bank is said to be “open”. Memory Controller then issues a “column” address to specifiy which location(s) within the row are to be accessed. Subsequent accesses to locations within the same row can then be performed at high speed (with Memory Controller supplying only a column address) since the appropriate data is already contained within the local buffer and there is no requirement for the SDRAM to fetch data from the main SDRAM array. Prior to accessing a location in a different row Memory Controller must issue a “precharge” command so that the local buffer is written back to the main SDRAM array.

An SDRAM device provides a local buffer for each bank within the device, thus it is simultaneously possible for each of the banks to be “open”, this is termed “Multibanking”. Multibanking is supported in order to allow interleaved bank accesses. Comparison of

1) Previous Memory Controller documentation uses the term “page” to refer to a “row”. Where possible this has been changed to reflect the more commonly used term “row”.

banks is done prior to initiating external memory accesses (see **"SDRAM Bank Management" on Page 15-131**).

15.18.6 Supported SDRAM commands

Table 15-39 lists the supported SDRAM commands, how they are triggered and which signals are activated:-

Table 15-39 Supported SDRAM commands

Command	Event	CKE (n-1)	CKE (n)	CS	RAS	CAS	RD/ WR	See Section 15.18.17 for Memory Controller pins			
								A12[1] A11	A10	A (9:0)	BA (1:0)
Device deselect	region not sel'ted	H	-	H	-	-	-	-	-	-	-
Nop	idle	H	-	L	H	H	H	-	-	-	-
Bank activate	open a closed bank	H	-	L	L	H	H	valid address			
Read	read access	H	-	L	H	L	H	valid addr	L	valid address	
Write	write access	H	-	L	H	L	L	valid addr	L	valid address	
Read with autoprecharge	read access	H	-	L	H	L	H	valid addr	H	valid address	
Write with autoprecharge	write access	H	-	L	H	L	L	valid addr	H	valid address	
Precharge selective	bank or row miss	H	-	L	L	H	L	-	L	-	bank
Precharge all	refresh is due or going into power down	H	-	L	L	H	L	-	H	-	-

Table 15-39 Supported SDRAM commands (cont'd)

Command	Event	CKE (n-1)	CKE (n)	CS	RAS	CAS	RD/ WR	See Section 15.18.17 for Memory Controller pins			
								A12[1)] A11	A10	A (9:0)	BA (1:0)
Autorefresh	refresh is due, after precharge all is done	H	H	L	L	L	H	-	-	-	-
Self refresh entry	going into power down after precharge all is done	H	L	L	L	L	H	-	-	-	-
Self refresh exit	coming out of power down	L	H	H	-	-	-	-	-	-	-
Mode register set	during initialization	H	-	L	L	L	L	valid mode (see register EBU_SDRMOD)			00_B
Extended Mode register set	during initialization	H	-	L	L	L	L	valid mode (see register EBU_SDRMOD)			10_B[2)]

1) A12 is required by larger memories

2) 10_B is default value for SDRAM. This can be changed using the **EBU_SDRMOD.XBA** field

15.18.7 SDRAM device size

The Memory Controller supports SDRAM's with the following sizes:-

- **Size**[1)]**:** 64MBit, 128MBit, 256MBit, 512MBit and 1Gbit.

1) In addition verified support is limited to specific SDRAM device geometries (number of banks and row size). Support for other sizes/geometries may be possible but this has not been verified.

15.18.8 Power Up Sequence

During power-up the SDRAM should be initialized with the proper sequence. This includes the requirement of bringing up the VDD, VDDQ and the stable clock (minimum 200 µs before any accesses to SDRAM) and $\overline{CS}$ remains inactive.

15.18.9 Initialization sequence

SDRAMs must be initialised before being used. Application of power must be followed by 200 µs pause (timed by software) with a stable clock. Then a Precharge All Banks command must be issued. Following this, the device must go through Auto Refresh Cycles (the number of refresh commands is programmable through **Crfsh** in SDRMCON registers and the number of NOP cycles in between is programmable through **Crc**). At the end of it, the Mode Register must be programmed through the address lines. Following that some number of NOP cycles programmable through **Crsc** in EBU_SDRMCON.

Note: This sequence will be referred to as a "cold start",and is necessary when both the memory and the memory controller have just had power applied. Conversely a "warm start" will be required when the memory controller has just been powered up but data has been retained in the external memory by the use of self refresh mode.

The SDRAM controller will power up with the SDRAM clock disabled and CKE high.

Care must be taken during software configuration of Memory Controller to ensure the correct SDRAM initialisation sequence is generated for both cold start and warm start.

15.18.9.1 Cold Start Initialisation

The recomended sequence for Memory Controller register initialisation after a cold start when using SDRAM devices is as follows:-

1. If the EBU is in “no bus” arbitration mode, write to EBU_MODCON to switch to an arbitration mode which allows external bus accesses
2. Write to BUSCON to define which region has SDRAM connected and the required divide ratio for the SDRAM clock.
3. Write to EBU_SDRMCON to configure the controller for the attached SDRAM device(s) and to enable the SDRAM clock. (**SDCMSEL** = $0_B$and **CLKDIS**=0_B.)
4. Initialise all other Memory Controller registers except SDRAM specific registers (i.e. other than those listed below).
5. Wait for 200µs (or the appropriate initialisation delay required by the attached device)
6. Write to EBU_SDRMOD with the "**COLDSTART**" bit set to precharge tall banks in he device, perform the required refresh commands and write the mode register values to the SDRAM mode register.
7. Write to EBU_SDRMREF to configure refresh rate. (see **“Refresh Cycles” on Page 15-133**.)

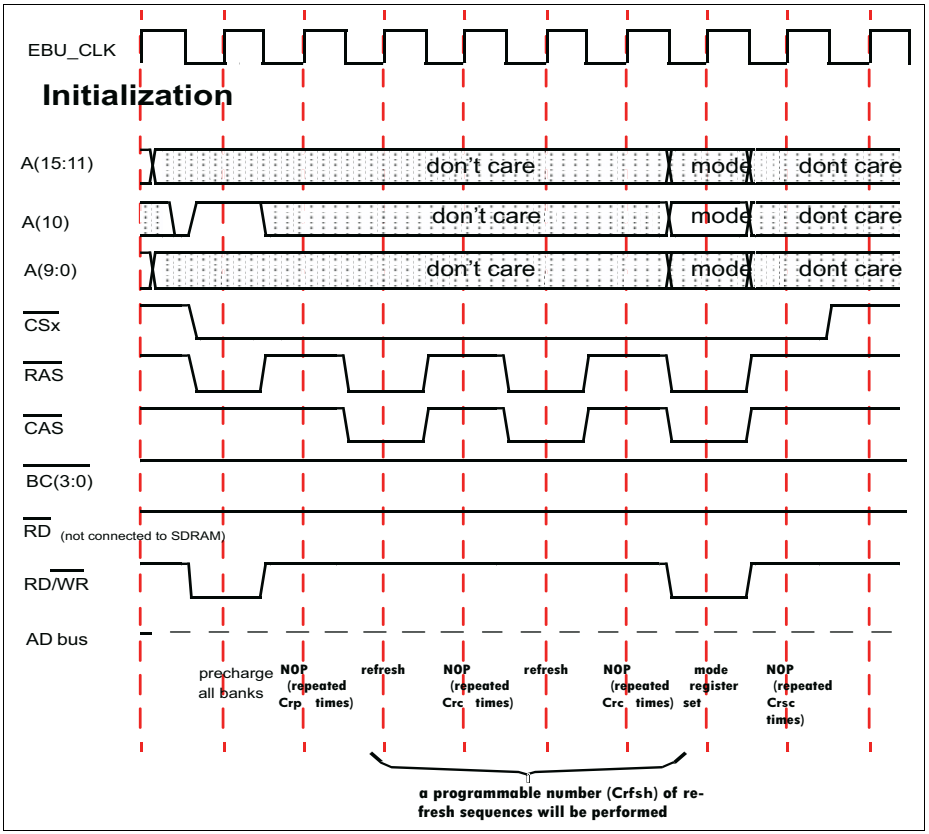

Figure 15-41 SDRAM Initialization

The sequence is triggered by a write to the SDRAM mode register SDRMOD. A device attached to a region having **agen** in BUSCONx set to '1000_B' will be configured with the mode from SDRMOD. While this sequence is being executed, **sdrmbusy** flag in the SDRMSTAT status register will be set accordingly.

Note: As no other accesses are permitted in the current implementation while the SDRAM initialisation sequence is running, it will not be possible to poll the sdrmbusy bit at '1' unless there has been a failure in the controller logic.

The user has to make sure that the SDRAM is programmed in the following way:

Table 15-40 SDRAM Mode Register Setting

Field	Value	Meaning	SDRMOD Position	Corresponding Address Pins
Burst length	"100" “011” “010” “001” "000"	bursts of length 16 bursts of length 8 bursts of length 4 bursts of length 2 bursts of length 1	**burstl**[2:0]	A[2:0]
Burst type	‘0’	sequential bursts	**btyp**[3]	A[3]
$\overline{\text{CAS}}$ latency	“001” “010” “011” “1xx”	reserved latency 2 latency 3 reserved	**caslat**[6:4]	A[6:4]
Operation Mode	all ‘0’	burst read and burst write	**opmode** [13:7]	A[12:7]

The Memory Controller uses the $\overline{\text{CAS}}$ latency value and burst length to adjust the burst read timing. All other fields have no influence on the Memory Controller, which means only a single value is accepted for those fields.

The complete initialization sequence described will only be issued on the first write (since reset) to the **EBU_SDRMOD** register with the **COLDSTART** field set to logic ’1’. On subsequent writes with the **COLDSTART** field set to logic ’1’, the SDRAM device does not need to be initialized, so a simple mode register set command can be issued to refresh the contents of the registers in the SDRAM. A precharge-all command needs to be issued to the SDRAM before this can happen.

An initialisation sequence will write to both the mode register and the extended mode register (if the extended mode register has been enabled).

A write to the **EBU_SDRMOD** register with the **COLDSTART** cleared will update the EBU register and will also write to the config registers of the SDRAM but will not execute the refresh cycles which are part of the full initialisation required at cold start.

15.18.9.2 Warm Start Initialisation

The recomended sequence for Memory Controller register initialisation after a warm start when using SDRAM devices requires a pull-down resistor on the CKE pin and is as follows:

1. If the EBU is in “no bus” arbitration mode, write to EBU_MODCON to switch to an arbitration mode which allows external bus accesses

2. Write to EBU_BUSRCON to define which region has SDRAM connected and the required divide ratio for the SDRAM clock.
3. Write to **EBU_SDRMCON** to configure the controller for the attached SDRAM device(s) and to enable the SDRAM clock. (**SDCMSEL**=0_B and **CLKDIS**=0_B.)
4. Write to **EBU_SDRMREF** to configure refresh rate.
5. All other Memory Controller registers except SDRAM specific registers (i.e. other than those listed below).
6. Write to **EBU_SDRMOD** with the "**COLDSTART**" bit cleared to update the mode register values.

The SDRAM will be taken out of self-refresh when step two is completed. Auto-refresh by the EBU will start at the completion of step 4 when the refresh counters in the SDRAM controller expire. Care should be taken when setting the registers to ensure that the maximum refresh period is not exceeded.

15.18.10 Mobile SDRAM Support

Mobile SDRAMs include an “Extended Mode Register”. This is accessed using a similar mechanism to the existing PC-133 Mode Register but with an additional select code on the SDRAM device BA pins.

The **EBU_SDRMOD.XBA** bits are used to select “Mobile” SDRAM support for each of the SDRAM devices. If this field is non-zero, then the Extended Mode Register will be automatically written during the Initialization phase (immediately after the “standard” Mode Register write). In addition writes to the Extended Mode Register(s) will be triggered by writes to the **EBU_SDRMOD** register (i.e. whenever the “standard” Mode Register is written). The **EBU_SDRMOD.XOPM** bit-field is used to program the value that is to be written to the Extended Mode Register. The **EBU_SDRMOD.XBA** bit-field is used to program the logic levels asserted on the device BA(1:0) pins (i.e. to program the specific command used to access the extended mode register).

Note: In order to cater for possible future device variations the Memory Controller allows the user to select the logic levels issued on the BA(1:0) pins during an Extended Mode Register. Care should be taken in programming this bit field since it is possible to generate an unwanted “standard” Mode Register write by use of this bit field.

15.18.11 Burst Accesses

The Memory Controller supports SDRAM burst lengths of 1, 2, 4, 8 and 16. Bursts of other lengths are supported but are implemented using data-masking. Burst length 16 is currently not supported by available SDR memories.

15.18.12 Short Burst Accesses and Byte Writes

The Memory Controller can be configured to generate SDRAM bursts lengths of either one, two, four, eight or sixteen via the EBU_SDRMOD.**BURSTL** bit fields. When configured for burst lengths of four or eight the interface will use data masking to support shorter write accesses. However, when configured for a burst length of one data masking is not used. **Figure 15-42** shows how short burst write accesses are handled. During the write access data masking is activated (with zero clock latency) to prevent unwanted write operation. Data masking is activated through the $\overline{BCx}$ outputs (connected to $\overline{DQM}$ on the SDRAM device) during a write cycle.

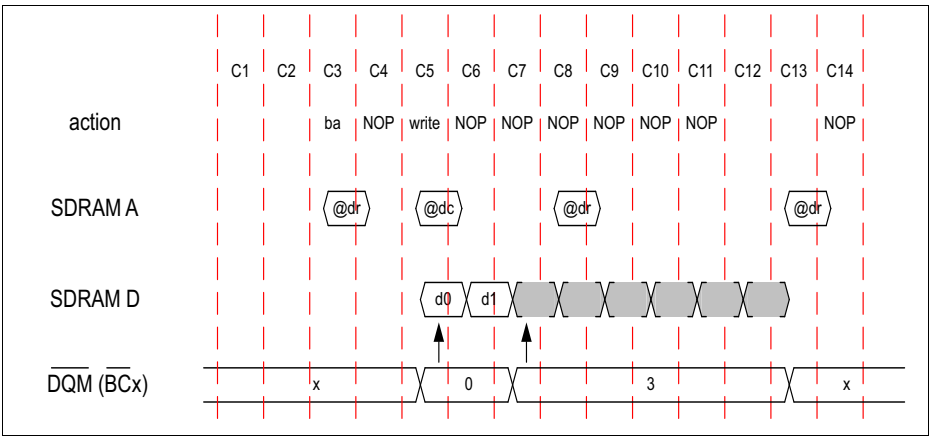

Figure 15-42 Short Burst Write Access through Data Masking

The figure shows how a two beat burst write is translated to an eight beat burst write with data masking. During the first two data cycles (C5 and C6) the $\overline{BC0}$ and $\overline{BC1}$ outputs are driven low to cause the SDRAM device to write the required data. In cycle C7 the $\overline{BC0}$ and $\overline{BC1}$ outputs are driven high to mask subsequent data writes.

When performing byte writes, the DQM signals on $\overline{BC[3:0]}$ signals are used to mask the byte lines not required for the write in progress.

15.18.13 SDRAM Addressing Scheme

SDRAM devices use a multiplexed address issued as “bank”, “row” and “column” addresses.

The bank address is used to qualify row and column addresses and is used to divide the addressed memory into physically indpendent regions. An SDRAM bank will have its own sense amplifiers and row buffer which operate independently of the sense amplifiers and row buffers of the other banks in the device.

The row address determines which row is being accessed within a bank and is placed on the bus during a “bank activate command”. The bank activate command loads to contents of the row into one of the row buffers of the SDRAM device. Once in the row buffer it can be modified by write commands or transferred to the memory controller by read commands. The row buffer used is determined by the bank address bits.

The column address determines which location is being accessed within a row. The column address is placed on the bus during read or write commands.

Since the number of rows per bank and the row sizes can differ from one SDRAM device to another it is necessary to provide a programmable address multiplexing scheme. Selection of the multiplexing scheme is via the **EBU_SDRMCON.AWIDTH** and **EBU_SDRMCON.BANKM** bit-fields.

The SRI address (A_{SRI}) is mapped to the SDRAM as follows:

- A_{SRI}(n:0) are used as the column address, where n is defined using the **AWIDTH** field. See **“Column Address Multiplexing” on Page 15-127**
- A_{SRI}(m-1:n+1) are used as the row address, where m is defined using the **BANKM** field. See **“Row Address Multiplexing” on Page 15-128**
- A_{SRI}(m+1:m) are used as the bank address. See **“Bank Address Multiplexing” on Page 15-126**

15.18.14 Bank Address Multiplexing

A bank address is always issued whenever either a row or column address is issued. As a result the Bank Address multiplexing must be the same regardless of whether a row or column address is being issued.

Note: The Memory Controller uses it’s address output pins to select the bank being accessed (rather than having dedicated Bank Select outputs).

The SDRAM Bank Select pin(s) (BA[1:0]) must be connected to the Memory Controller A[15:14] address pins. The **EBU_SDRMCON.BANKM** bit-field must be set correctly to ensure that they are driven by the appropriate SRI Address (according to the SDRAM geometry).

The "EBU_SDRMCON.**BANKM**" (bank mask) bit-field must be set to the appropriate value to set the SRI address bit range used to detect which bank is being accessed. The value to be written to this bit-field is determined by the device size setting (see **“SDRAM device size” on Page 15-120**) and the number of banks in the device.

- When the device has 2 banks then the "**BANKM**" value must be set to include the most significant address bit of the SRI address range occupied by the SDRAM device (i.e. region) - see **Table 15-45** and **Table 15-46**.
- When the device has 4 banks then the "bankm" value must be set to include the most significant two address bits of the SRI address range occupied by the SDRAM device (i.e. region) - see **Table 15-45** and **Table 15-46**.

The following settings must be used:

Table 15-41 “BANKM” Selection

“BANKM” setting	SRI Address Bits used for BA[1:0]	Comment
0	none	Reserved - do not use (default after reset).
1	A_{SRI}[21 to 20]	Bank Size = 8MBit
2	A_{SRI}[22 to 21]	Bank Size = 16MBit
3	A_{SRI}[23 to 22]	Bank Size = 32MBit
4	A_{SRI}[24 to 23]	Bank Size = 64MBit
5	A_{SRI}[25 to 24]	Bank Size = 128MBit
6	A_{SRI}[26 to 25]	Bank Size = 256MBit.
7	A_{SRI}[27 to 26]	not supported for SDRAM/DDRAM

15.18.15 Column Address Multiplexing

When a column address is issued:

- The most significant Memory Controller address outputs (A[27:16]) are driven with '0' (zero).
- The least significant ten address outputs (A[9:0]) are driven with the (correctly aligned) column address. This address alignment is a one bit right shift of the SRI address if the SDRAM is 16 bit or a two bit shift if the SDRAM is 32 bit. This address alignment is performed according to the device row size specified by the "AWIDTH" bit-field and the “PORTW” field (see **Table 15-42**). Note that all 10 possible column address lines are always driven regardless of the row size of the device. Superfluous address bits will be ignored by the attached memory
- Address output ten (A[10]) is driven with a “command” value (used by the SDRAM in conjunction with the other control signals to determine which command is to be executed.
- The address outputs (A[15:14]) are driven with the bank address signals, BA[1:0] (see **“Bank Address Multiplexing” on Page 15-126**).

The "EBU_SDRMCOM.**AWIDTH**" bit-field sets row size of the attached memory and therefore the number of address bits the memory device require for the column address. The value to be written to this bit-field is as follows:

Table 15-42 Selection of address multiplexing

AWIDTH	Row size	16 bit DRAM PORTW="01"	32 bit DRAM PORTW="11"
00_B	Reserved; do not use	-	-
01_B	256 words	A_{SRI}(8:0) (512 bytes)	A_{SRI}(9:0) (1024 bytes)
10_B	512 words	A_{SRI}(9:0) (1024 bytes)	A_{SRI}(10:0) (2048 bytes)
11_B	1024 words	A_{SRI}(10:0) (2048 bytes)	A_{SRI}(11:0) (4096 bytes)

Table 15-43 Column Address Generation for SDRAM/DDRAM

16 bit, PORTW="01" Address Generation (at Memory Controller pins)	32 bit, PORTW="11" Address Generation (at Memory Controller pins)
A[27:16] = '0' A[15:14] = BA[1:0] A[10] = Command A[9:0] = A_{SRI}[10:1]	A[26:16] = '0' A[15:14] = BA[1:0] A[10] = Command A[9:0] = A_{SRI}[11:2]

15.18.16 Row Address Multiplexing

When a row address is issued as follows:-

- The most significant Memory Controller address outputs not required by the SDRAM (A[27:16]) are driven with '0' (zero).
- A[15:14] are driven with the bank address signals, BA[1:0]
- The least significant fourteen address outputs (A[13:0]) are driven with the correctly aligned row address. This address alignment is performed according to the device row size specified by the "AWIDTH" bit-field and the "PORTW" field (see **Table 15-44**). Note that all 14 possible row address lines are always driven regardless of the number of rows in the device. Superfluous address bits will be ignored by the attached memory.

During the issue of a row address the following address multiplexing is used:-

Table 15-44 Row address generation for 16 bit SDRAM

AWIDTH	16 bit, PORTW="01" Address Generation (at Memory Controller pins)	32 bit, PORTW="11" Address Generation (at EBU pins)
01_B	A[13:0] = A_{SRI}[22:9]	A[13:0] = A_{SRI}[23:10]
10_B	A[13:0] = A_{SRI}[23:10]	A[13:0] = A_{SRI}[24:11]
11_B	A[13:0] = A_{SRI}[24:11]	A[13:0] = A_{SRI}[25:12]

15.18.17 Supported SDRAM Configurations

The following SDRAM types can be connected to Memory Controller:

Table 15-45 Example Supported Configurations for 16-bit wide data bus

15.18.18 SDRAM Bank Management

The EBU maintains a page tag register for each bank of the SDRAM device. This is updated with the row tag of the opened page when a “bank activate” occurs.

It is flagged as valid every time a row is opened in the bank and invalidated when the row is precharged (the bank is “closed”).

The EBU contains four page tag registers. This allows devices with up to four banks to be supported.

The "EBU_SDRMCON.**AWIDTH**" bit-field is used to set the lower bound of the SRI address range of the page tag. The upper end of the address range is determined by the **BANKM** setting.

The row tag is the address range between the most-significant column address width as determined by **AWIDTH** and the least significant bank address bit as determined by **BANKM**.

When a read or write transaction is addressed to the SDRAM, The bank address bits will decoded from the SRI address. This will be used to select the appropriate page tag. If the page tag is valid (bank hit) and the row tag of the current access matches the row tag stored in the page tag register, then a “row hit” will be flagged.

The other options, invalidated page tag register (bank miss) and unmatched page tag (row miss) are used to determine the necessary controller actions needed to complete the access.

15.18.18.1Decisions over “row hit”

When a row hit occurs, the memory controller can continue the access operation using data already in the SDRAM row buffer and without updating the stored page tag.

The absence of a “row hit” can result in several other activities.

- If the absence of a “row hit” is due to the bank being accessed not having an open row (“bank miss”), then the memory controller does not have to issue a precharge operation but can activate the bank, update the appropriate page tag to reflect the new bank status (i.e. to “open” with the specified row address) and continue the access operation.
- If a “row miss” occurs without a “bank miss”, then the memory controller has to close the open row in the bank being accessed, (i.e. do a precharge). This is then followed by re-activating the bank, updating the appropriate page tag to reflect the new bank status (i.e. “open” with the new page address) and continuing the access operation.

15.18.19 Banks Precharge

The system is required to precharge a bank under one of the following conditions:

1. When the next access to a bank is to a different row to the previous access within the bank, the affected bank will be selectively precharged to enable the new row to be opened. This is triggered as detailed in **“Bank Address Multiplexing” on Page 15-126**.
2. When an SRI request cannot be completed before the row active time $t_{RAS\ max}$ is due, then the bank must explicitly be closed and opened again for the current request. Since $t_{RAS\ max}$ (of the order of 100 µs) is usually much greater compared to the refresh

period (distributed refresh is in order of 15 µs for 4096 rows) this is generally fulfilled by systematically carrying out refresh to the SDRAMs (see '3' below).
3. All banks must also be pre-charged, when a refresh cycle is due as explained next. See **"Refresh Cycles" on Page 15-133**.
4. All banks must also be pre-charged, prior to issuing Self Refresh Entry command. See **"Self-Refresh Mode" on Page 15-133**.

15.18.20 Refresh Cycles

The refresh sequence is controlled by the EBU hardware and is periodically triggered by an internal refresh counter with programmable rate. The rate is set using the **ERFSHC** and **REFRESHC** fields in the EBU_SDRMREF register. These fields are combined to create an eight bit value (**ERFSHC** as MSBs). This value is then multiplied by 64 and used as the number of EBU_CLK cycles between refresh operations being requested.

All SDRAM banks will be pre-charged using a single "precharge all" command before any refresh commnads are issued. After the "precharge all" command, the EBU will insert NOP commands on the external bus to allow the precharge command to be completed by the memory device. The number of NOPs will be determined by the **EBU_SDRMCON.CRP** bitfield.

The specific refresh command issued is Auto Refresh (CBR) command, in which the device keeps track of the row addresses to be refreshed. The number of commands issued for each refresh sequence is programmable through **REFRESHR** in **EBU_SDRMREF**. After each refresh command, the EBU will issue NOP commands on the external bus to allow time for the device to complete the refresh operation before another command is issued. The number of NOPs will be determined by the **EBU_SDRMCON.CRC** bitfield.

A refresh request has precedence over an SRI access to SDRAM, i.e. if both occur at the same time the refresh sequence is entered and the SRI access is delayed.

A refresh error occurs when a previous refresh request has not been satisfied and another refresh request occurs. An error flag (**REFERR**) in the **EBU_SDRSTAT** status register will be set accordingly.

15.18.21 Self-Refresh Mode

SDRAM devices provide a Self-Refresh Mode. In this mode the SDRAM automatically performs internal refresh sequences in response to an on-chip timer. Self Refresh Mode is entry command is asserted with RAS, CAS, and CKE low and $\overline{WE}$ high. In Self-Refresh Mode all external control signals except CKE (but including the clock) are disabled). Returning CKE to high enables the clock and initiates the Self-Refresh Mode exit operation. After the exit command, at least one tRC delay is required prior to any access command. This delay can be configured using the **EBU_SDRMREF.SELFREX_DLY** bitfield.

Low Power SDRAMs provide additional power saving features such as:-

Programmable refresh period of the on-chip timer such that the refresh period can be optimised (maximised) by taking the device operating temperature in to account.

Partial array self-refresh mode such that only selected banks will be refreshed. Data written to the non-selected banks will be lost (due to lack of refresh to the bank) after a period defined by t_{REF}.

These additional features are programmed by issuing an Extended Mode Register write (see **"Mobile SDRAM Support" on Page 15-124**).

To activate Self-Refresh Mode, software must write '1' to bit **SELFREN** in **EBU_SDRMREF** register. Memory Controller will then:

1. precharge all the banks, and
2. issue a self refresh command (see **Table 15-39**) to the attached SDRAM device.

In completion of this command all SDRAM devices will ignore all inputs but CKE signal. The read-only bit **SELFRENST** reflects the status of issuing this command. When the command is completed, power-down can be safely entered. The devices would perform low-current self refresh during the power down. When exiting from power-down and before doing any accesses to SDRAM, software must write '1' to bit **SELFREX** in EBU_SDRMREF registers. Memory Controller will then assert the CKE signal for all the SDRAM devices to get out of the self-refresh mode. The read-only bit **SELFREXST** reflects the completion of this command, upon which an access to SDRAMs can be performed.

Two additional fields affect the method the memory controller uses to exit self refresh.

1. After CKE is taken high (self refresh exit command), a single NOP cycle is generated. The **EBU_SDRMREF.ARFSH** field is checked. If set to one a single auto refresh command is output to the memory.
2. After step 1, the **EBU_SDRMREF.SELFREX_DLY** field is checked. If the field is non-zero, the value in the field is used to generate a sequence of NOP instructions to the memory. This allows between 1 and 255 NOPs to be inserted before the device sees a non-null command.

For predictable operation of the device during warm start, both the **EBU_SDRMREF.ARFSH** and **EBU_SDRMREF.SELFREX_DLY** fields should be set to 0 before triggering the warm start.

15.18.22 Power Down Mode

In order to reduce standby power consumption SDRAM devices provide a Power Down Mode. All banks can optionally be precharged before the device enters Power Down mode. Once Power Down mode is initiated by holding CKE low, all receiver circuits except for CLK and CKE are gated off. Power Down mode does not perform any refresh operations in the way that self refresh mode does, therefore to prevent loss of data, the device must not remain in Power Down mode longer than the Refresh period (tREF) of

the device. Taking the device out of power down to perform autoreresh is handled automatically by the SDRAM controller. Exit from this mode is performed by taking CKE “high”. One clock cycle delay is required for power down mode entry and exit.

The Memory Controller provides automatic support for Power Down Mode via the EBU_SDRMCON.SDCMSEL (SDRAM clock mode select) bit. When this bit is ‘0’ Power Down mode will not be used and the SDRAM clock will always be present at the SDCLKO pin. When the bit is ‘1’ the device will automatically be placed into Power Down Mode when there are no SDRAM accesses pending. In this case the SDRAM clock will only be present during an Memory Controller-generated SDRAM access (data, refresh, bank/row open etc) and will be gated off at all other times.

When a refresh is required (at the programmed rate) Memory Controller will automatically take the device out of Power Down Mode, issue the required refresh and will then return the device to Power Down Mode (providing no other SDRAM accesses are pending following the refresh).

By default, the Memory Controller automatically issues the “Pre-Charge All” command sequence and closes all pages prior to entry into Power Down Mode (EBU_SDRMCON.PWR_MODE set to 00_B).

The memory controller can also be configured to use the auto-precharge option when running a command (EBU_SDRMCON.PWR_MODE set to 01_B) or not to precharge banks at all (active power down mode) with EBU_SDRMCON.PWR_MODE set to 10_B.

As a final option, "clock stop" power down mode is also supported. In this case, the clock is disabled between accesses with no preparatory command cycles (EBU_SDRMCON.PWR_MODE set to 11_B).

The default reset state of Memory Controller is Power Down Mode disabled (EBU_SDRMCON.SDCMSEL = ‘0’).

Note: The programmer should be very careful about the use of this feature as some external devices may require this clock to be running in some modes. There are restrictions within the PC-133 specification about when the clock can be disabled, especially if the SDRAMs are operated in self-refresh mode.

A separate field **EBU_SDRMREF.RES_DLY** is provided to allow a delay to be programmed after exiting the power down mode. This field is the delay, in external clock cycles (NOPs), after CKE is taken high on exiting power down mode before another command is permitted.

An additional bit EBU_SDRMCON.CLKDIS is provided to allow the clock output to be completely disabled. Setting this bit will allow a self refresh exit to be performed to enable CKE without starting the clock.

15.18.23 SDRAM Recovery Phases

15.18.23.1Recovery after SDRAM Command

A recovery phase can be programmed to increase the minimum gap between an SDRAM access and an access to another connected memory.

For write cycles, the minimum value for this gap is two periods of the internal clock between last command/data driven and the next access starting (for DDR the gap for data is one cycle). This can be increased by setting the BUSWAP.WRDTACS field to the required number of internal clock cycles.

For read accesses, the gap can also be increased using the BUSRAP.RDDTACS field in the same way. However, the counter is started when the last read command is issued by the controller and the controller does not permit another device to be accessed until two clock cycles after the last data has been read into the read buffers. As the read data is significantly delayed by the latency through the read synchronisation logic (minimum latency is 2 clock cycles CAS latency plus 2 clock cycles internal latency), setting this for read accesses is unlikely to make a significant difference unless very large values are used.

15.18.23.2Write Recovery Time (T_{WRC})

SDRAMs require a write recovery time after the last data is written before the next command can be processed. The usual value for this is one cycle of the SDRAM clock and this value is hard coded into the controlling state machine. Some devices require more delay and this can be programmed using the **WRRECOVC** field of the BUSWAPx register. Values of 0_H or 1_H (corresponding to zero or one cycle of recovery) have no effect because of the hardcoded lower limit of one clock cycle of recovery but programming larger values will set the number of clock cycles of write recovery time to the number programmed into the field.

The programmed value will set the number of SDRAM clock (SDCLKO) cycles of write recovery used rather than the number of EBU_CLK cycles.

15.18.24 Status Register Definition

The **EBU_SDRSTAT** register contains four bits which can be used to interrogate the status of EBU functions critical for SDRAM accesses. where these bits report an error condition, they will latch at 1_B until reset by writing 0_B to the register bit.

15.18.24.1Refresh Error (REFERR)

The SDRAM controller will schedule a refresh operation to an attached SDRAM memory at an interval set by the **EBU_SDRMREF**.**REFRESHR** bitfield. The **REFERR** bit is set if the scheduled refresh has not occurred by the time the next refresh becomes due. If this error condition occurs, then the refresh operations are not keeping up with the device reaquirements and data loss is likely. This bit latches and must be cleared by software.

15.18.24.2SDRAM Controller Busy (SDRMBUSY)

This bit is set while the controller is performing the initialisation sequence of an attached memory. It will clear once the initialisation is complete. This bit can be polled to ensure that other EBU functions (such as clock switching) are not performed while an initialisation is in progress.

15.18.24.3SDRAM Read Error (SDERR)

The **SDERR** bit is set when the control logic detects an error has occurred transferring data from an attached memory device using the SDRAM data path. This bit will latch. The bit will set under the following conditions:

- The addressed memory does not respond within sixteen clock cycles of the external bus clock
- The device returns more data than is expected by the controller.
- The device does not return enough data to complete the access.
- FIFO bypass mode is enabled and the controller detects that a DDR device is not returning data within half a clock period

15.18.24.4DLL Drift Detected (DRIFT_WARN)

See **“DLL Drift detector” on Page 15-23**.

15.18.25 Programmable Parameters

The following table lists programmable parameters for SDRAM accesses. These parameters are only effective when parameter **AGEN** (in BUSCONx registers) for a particular memory region is set to "8_D".

Table 15-47 SDRAM Access Programmable Parameters

Parameter	Function	Register
Address Mapping		
BANKM	Map SRI address bits to the bank address bits.	EBU_SDRMCON
AWIDTH	Number of address bits to be used for column address	EBU_SDRMCON
Refresh Control Parameters		
REFRESHR	Number of refresh commands issued during each refresh operation.	EBU_SDRMREF

Table 15-47 SDRAM Access Programmable Parameters (cont'd)

Parameter	Function	Register
ERFSHC & **REFRESHC**	Number of cycles (multiplied by 64) between refresh operations: 0 : no refresh needed 1 - 255 : refresh period defined	EBU_SDRMREF
ARFSH	execute auto refresh on exit from self refresh when set to one	EBU_SDRMREF
CRFSH	Number of refresh commands during initialization	EBU_SDRMCON
SDRAM Timing Constraint Compliance Parameters		
CRC	Number of NOP cycles after a refresh comand before another command can be executed. (device t_{RFC})	EBU_SDRMCON
CRCD	Number of NOP cycles between a row and column address (device t_{RCD})	EBU_SDRMCON
CRP	Number of NOP cycles after a precharge command before another command can be executed. (device t_{RP})	EBU_SDRMCON
CRSC	Number of NOP cycles after a mode register set command before another command can be executed. (device t_{MRD})	EBU_SDRMCON
CRAS	Minimmum number of cycles between a row activate and a precharge command to the same row (device t_{RAS} minimum)	EBU_SDRMCON
RES_DLY	delay after exiting power down before permitting any command other than NOP (device t_{XP})	EBU_SDRMREF
SELFREX_DLY	delay after exiting self refresh before permitting any command other than NOP (device t_{XSR})	EBU_SDRMREF
WRRECOVC	recovery time after write command before starting another command, used to meet device T_{wr} parameter	EBU_BUSWAP
RDDTACS	recovery time after read command before accessing another region.	EBU_BUSRAP
WRDTACS	recovery time after write command before accessing another region.	EBU_BUSWAP

Table 15-47 SDRAM Access Programmable Parameters (cont'd)

Parameter	Function	Register
SDRAM Device Register Contents		
OPMODE	To specify write operation mode: only BURST_WRITE is recognized	EBU_SDRMOD
CASLAT	To specify $\overline{\text{CAS}}$ latency : 2 or 3 clocks	EBU_SDRMOD
BTYP	To specify burst operation mode: SEQUENTIAL only	EBU_SDRMOD
BURSTL	To specify burst length: 1,2,4, 8 or 16	EBU_SDRMOD
XOPM	Value to be written to the extended mode register	EBU_SDRMOD
XBA	Bank Address value to be used for extended mode register write	EBU_SDRMOD
SDRAM Status		
SDRMBUSY	Indicate the busy status of SDRAM	EBU_SDRSTAT
REFERR	Indicate a refresh error	EBU_SDRSTAT
SDERR	Indicates an error has occurred on an SDRAM read	EBU_SDRSTAT
DRIFT_WARN	Indicates an error has occurred on an SDRAM read	EBU_SDRSTAT
SDRAM Controller Mode Control		
PWR_MODE	SDRAM controller power savemode	EBU_SDRMCON
SELFREN	To kick-off a self refresh entry command	EBU_SDRMREF
SELFRENST	Status of self refresh entry command	EBU_SDRMREF
SELFREX	To kick-off a self refresh exit command	EBU_SDRMREF
SELFREXST	Status of self refresh exit command	EBU_SDRMREF
AUTOSELFR	To activate automatic self refresh entry/exit when arbitrating the external bus	EBU_SDRMREF
Clock Control		
EXTCLOCK	ratio between internal clock and external memory clock for SDRAM accesses.	EBU_BUSRAP
SDCMSEL	SDRAM Clocking Mode - continuous clock or power save enabled	EBU_SDRMCON
CLKDIS	Disable the SDRAM clock output	EBU_SDRMCON

15.19 DDRAM/Mobile DDRAM Support

Support for DDRAM is in most ways similar to support for SDRAM. Device command definitions are the same. The major differences are necessary to support the generation and latching of data on both clock edges. This section should therefore be read as an extension of **Chapter 15.18**, **SDRAM Interface**.

Additional waveform diagrams can be found in JESD209, Low Power Double Data Rate (LPDDR) SDRAM Standard.

The following functionality has been provided to support DDR memory:

- A DLL is used to retime the DQS signals for read and write accesses to enable successful data capture. See **"DLL Operation" on Page 15-20** for information on the DLL.
- A read data FIFO is used to enable data to be successfully transferred to the read buffers after being latched by the DDR generated DQS lines.

These functions, and the necessary remapping of interface pins to support the load requirements of the DDR interface, are enabled by configuring the **AGEN** field of any EBU_BUSRCON register to specify a DDR device.

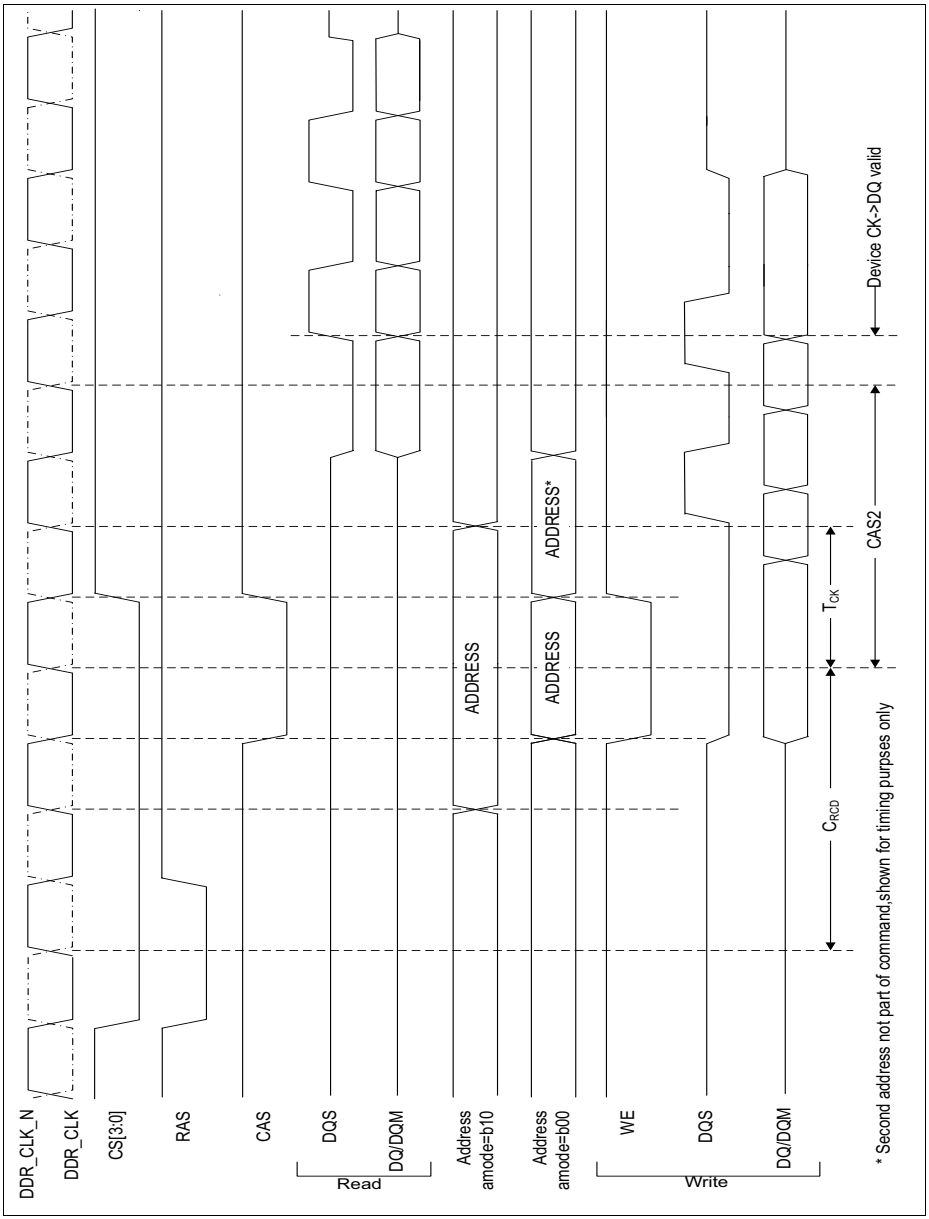

Figure 15-43 Example DDR Waveform

Notes on **Figure 15-43**

1. The DDR clock is a differential signal with the positive clock edge defined as the time when a rising edge of DDR_CLK crosses a falling edge on DDR_CLK_N
2. Two different modes for address generation are available. See **"SDRAM Addressing Scheme" on Page 15-125** for information.
3. CAS is shown for a burst length of 4. Address for amode=b00 and b01 is shown for burst length 2 to clarify differences in addressing modes.
4. The address will only change if necessary. The final address change shown on the waveforms will therefore only occur if a further access has been pipelined. If no access is pending, the last address will remain on the bus.

15.19.1 DDR Mode Address Outputs

There are two options for generating the address outputs to DDR memory.

Option one is for the address for a DDR memory access to be generated in phase with the rising edge of the DDR device clock. This allows a whole clock cycle of setup for the address but means that the address cannot be incremented every clock cycle without timing violations. This prevents burst lengths of two being used for DDRAM but is the simplest mode to configure. Set **EBU_DLLCON.AMODE** to 01_B for this mode.

As a second option, the DDR addresses can be generated with the same timing as the DDR control signals. This will work if the address line loading is closely matched to the clock signal loading. The exact amount of mismatch that can be tolerated will depend on the implementation and required operating frequency. Set **EBU_DLLCON.AMODE** to 00_B for this mode.

15.19.2 DDRAM Initialization sequence

DDRAMs must be initialised in the same way as SDRAMs before being used. Application of power must be followed by 200 µs pause (timed by software) with a stable clock. Then a Precharge All Banks command must be issued. Following this, the device must go through Auto Refresh Cycles (the number of refresh commands is programmable through **Crfsh** in SDRMCON registers and the number of NOP cycles in between is programmable through **Crc**). At the end of it, the Mode Register must be programmed through the address lines. Following that some number of NOP cycles programmable through **Crsc** in EBU_SDRMCON.

Note: This sequence will be referred to as a "cold start",and is necessary when both the memory and the memory controller have just had power applied. Conversely a "warm start" will be required when the memory controller has just been powered up but data has been retained in the external memory by the use of self refresh mode.

The SDRAM controller will, by default, power up with the DDRAM clock disabled and CKE high in compliance with the JEDEC specification JESD209 for mobile DDRAM. This

is not compatible with JESD79E, the specification for standard DDRAM, which requires CKE to be low.

15.19.2.1 Cold Start Initialisation

Care must be taken during software configuration of Memory Controller to ensure the correct DDRAM initialisation sequence is generated for both cold start and warm start.

The recomended sequence for Memory Controller register initialisation after a cold start when using mobile DDRAM devices requires a pull-up resistor to be attached to the CKE pin[1] and is as follows:-

1. If the EBU is in “nobus” arbitration mode, write to the MODCON register to set a valid arbitration mode which allows accesses to external memory.
2. Write to the appropriate BUSRCONx to define which region has DDRAM connected and the required divide ratio for the DDRAM clock output.[2]
3. For DDR mode, initialise the DLL if required[3].
4. Write to EBU_SDRMCON to configure the controller for the attached DDRAM device(s) and to enable the DDRAM clock. (**SDCMSEL**=0_B and **CLKDIS**=0_B.)
5. All other Memory Controller registers except SDRAM specific registers (i.e. other than those listed below).
6. Wait for 200ms (or the appropriate initialisation delay required by the attached device)
7. Write to EBU_SDRMOD with the "**COLDSTART**" bit set to write the mode register values to the DDRAM mode register.
8. Write to EBU_SDRMREF to configure refresh rate.

15.19.2.2 Warm Start Initialisation

The pull-up resistor needed on the CKE pin for correct cold start initialisation means that mobile DDRAM cannot be used with warm start as CKE will taken high by the pull up as soon as the EBU is disabled which will in turn take the attached device out of self-refresh mode.

The recomended sequence for Memory Controller register initialisation after a warm start when using DDRAM devices is as follows:-

1. If the EBU is in “nobus” arbitration mode, write to the MODCON register to set a valid arbitration mode which allows accesses to external memory.

1) The initialisation sequence for standard DDRAM requires a pull-down resistor on the CKE pin but is otherwise the same.

2) The AGEN field in the appropriate BUSWCONx register will be set automatically to the same value.

3) The DLL is required for DDR if either the internal to external clock ratio is 1:1 or the EBU input clock has an asymmetric duty cycle and the internal to external clock ratio is 1:2 or 1:3.

2. Write to BUSRCONx to define which region has DDRAM connected and the required divide ratio for the DDRAM clock.
3. For DDR mode, trigger a lock of the DLL if required.
4. Write to EBU_SDRMCON to configure the controller for the attached DDRAM device(s) and to enable the DDRAM clock. (**SDCMSEL**=0 and **CLKDIS**=0_B.)
5. Initialise all other Memory Controller registers except SDRAM specific registers.
6. Write to EBU_SDRMOD with the "**COLDSTART**" bit cleared to update the mode register values.

15.19.3 DDR External Bus Clock Generation

The frequency of the DDR Clock is controlled in the same way as SDRAM clock generation (See **“SDRAM External Bus Clock Generation” on Page 15-117**) except that the EBU_BUSRCONx.**AGEN** value of 12_D is used as well as 8_D when determining whether a region has a valid device attached. See **“External Bus Clock Generation” on Page 15-26** for more information on clocking DDR devices.

15.20 LPDDR NVM Flash Support (JEDEC 42.4 LPDDR-NVM Protocol)

This section should be read in conjucntion with **Chapter 15.19, “DDRAM/Mobile DDRAM Support” on Page 15-140**

15.20.1 Overview

The memory controller can be confgured to support NOR flash devices utilising an extended version of the interface protocol used for DDR SDRAM memories. The variations on the protocol can be summarised as follows:

- No refresh required
- No precharge required
- No pipelining of "Row Activate" during a running access possible (only one set of sense AMPS)
- Two clock cycles of RAS during "Row Activate" due to the smaller row size creating the need to load more row address bits
- Longer "Row to Column Delay" required because of longer flash read time
- Extra mode register command needed during initialisation. This maps the command registers of the flash into the memory space at an arbitrary address.
- Support for “status register reads” required.

Due to the complexity of the initialisation sequence, it is not be possible to boot directly from the LPDDR-NVM device. The device initialisation must be handled by code running from the internal flash before accesses are attempted.

Support for the LPDDR-NVM protocol is linked to the support for mobile DDRAM memory and will therefore enable the DDR mode of the SDRAM controller when any

AGEN field is set to 10_D. The memory controller can support one DDRAM memory and one LPDDR- NVM memory simultaneously.

A region is configured for accessing LPDDR-NVM flash by setting the BUSCON.agen field to 10_D.

Pin restrictions on the device do not allow DDR and non-DDR memories to be mixed in the same application unless either extreme care is taken to match the DQ/DQS/DQM loading or the maximum operating frequency is reduced to allow for the differential signal skew.

15.20.2 Implementation Requirements

As this LPDDR NVM flash protocol is based on the DDRAM protocol, implementation will be described as deltas to the DDR implementation described in **Section 15.19**.

For a description of options for address generation timing, see **Section 15.10.4 DLL Operation**.

15.20.3 Initialisation

As the NOR flash does not require precharge or refresh, the mandatory device initialisation sequence consists of the following operations under the control of the boot ROM firmware

- Once power has stabilised, drive CKE to logic ‘1’. This will happen as soon as the EBU is enabled by setting EBU_MODCON.ARBMODE to a value other than 00_B.
- Configure the DLL or set up the EBU_CLK to DDR_CLK ratio to allow DDR accesses without the DLL.
- Enable DDR clock. Clock frequency on the external bus should be 50 MHz maximum.
- The external bus must then remain in either the DESELECT or IDLE command states for 200us.
- Write to mode register 11_B to set the DAI bit in the internal control register of the memory device.
- Wait for $\mathbf{t}_{MRD}$.
- Poll the DAI bit (see **“Status Register Reads” on Page 15-148**)
  - Write to mode register 01_B with address 12_H
  - Wait for tSRR
  - Issue read command to mode register 01 with address 12
  - check state of DAI bit in returned data
- If the DAI bit is not cleared, repeat the mode register read
- Read the device characteristics from status register 0
  - Write to mode register 01_B with address 11_H
  - Wait for tSRR
  - Issue read command to mode register 01 with address 11
  - decode device boot characteristics from returned data

- Program initial values to to DDR flash configuration registers.
- Program initial values to the **EBU_DDRNMOD** register based on “Min CL” and “Max BL” values.

Control can now be code read from the external flash device. This code can optionally reconfigure the EBU parameters for optimally match the attached flash device if this has not been done as part of the initialisation.

15.20.4 Additional Supported Commands

The LPDDR-NVM specification requires two new commands to be implemented. These commands are signalled to the device by reusing two of the commands from the SDRAM/DDRAM protocol. Preactivate and Activate are linked commands used to load an RAB (Row Address Buffer) in the memory device. The Activate command will also load the memory page selected by the RAB into one of the RDBs (Row Data Buffers). The RAB and RDB to be used are selected by the Bank Address used for the Preactive and Active commands.

Table 15-48 Supported LPDDR-NVM Commands

Command	Event	CKE (n-1)	CKE (n)	CS	RAS	CAS	RD/ WR	See Section 15.20.5 for Memory Controller pins	
								A(13:0)	BA(1:0)
Preactivate	Load high address bits into RAB	H	-	L	L	H	L	Address MSBs[1)]	Bank Address
Activate	Load RDB	H	-	L	L	H	H	Address LSBs	

1) See **“Normal operating mode” on Page 15-146** for details of address bit mapping.

15.20.5 Normal operating mode

Normal operating mode is enabled when the **EBU_DDRNCON.MODE** field is set to 0_B. This defines the memory as being suitable for “execute in place” (XIP) operation.

During normal operation, the memory controller will issue PREACTIVE and ACTIVE commands to load a page of the attached memory into an internal buffer of the memory device from where it can be read. These commands are separated by sufficient clock cycles not to violate t_{RP} for the memory device. This delay is set by the **EBU_DDRNCON.CRP** field.

There is then a row to column delay (set with **EBU_DDRNCON.CRCD**) before the column address is issued. The number of address bits required for the column address

is set using the **EBU_DDRNCON.PAGESIZE** field. This is used to inform the memory controller of the page size of the attached memory device.

As the LPDDR NVM is only assumed to have one set of sense amplifiers a row activate cannot be queued before the row to column delay of a previous ACTIVE command has expired.

The **EBU_DDRNCON.MAXADD** field is used to set the size of the device. This performs a similar function to the **EBU_SDRMCON.BANKM** when mapping access addresses to pages in the memroy device.

The memory controller will maintain a set of “page tag” registers. This will allow the memory controller to track the addresses of the four, row data buffers (RDB) in the flash memory. Each page tag will be linked to a particular value of the bank address bits used when accessing the device and hence one particular RDB. The **EBU_DDRNCON.MAXADD** bitfield is used to determine the most significant address bit used for page comparisons and **EBU_DDRNCON.PAGESIZE** is used to determine the least significant address bit.

The memory controller will reuse an RDB under the following condition:

- If an access is to the page that has already been loaded into an RDB, the page tag will be reused, the row activate cycles will be skipped and only the column address will be issued.

If the reuse criterion above does not apply, the memory controller will apply a “least active” algorithm to determine which RDB to use for an access. Each page tag register in the memory controller has a counter and an “active flag”[1)] associated with it. This counter will be incremented when an access to the LPDDR-NVM occurs unless the access uses the page tag, in which case the counter will be set to zero and the active flag set. In the event of an access not matching an active page tags full address then

- As a first case, a inactive page tag will be used an its associated RDB opened
- otherwise, the page tag with the highest count will be reused

If, in either case, more than one page tag matches the condition, then the page tag with the lowest value for bank address will be used.

If the page tag to be used already has the correct value for the PREACTIVE address bits then the PREACTIVE command will be skipped

1) the active flag will only be cleared when an RDB invalidation occurs.

Table 15-49 A_{SRI} and CA to SDA bit Mapping(16 bit port width)

	Com-mand	SDA bit[1)]															
		15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
A_{SRI}	PRE-ACTIVE	BA (1:0)		-	-	-	28	27	26	25	24	23	22	21	20	19	18
	ACTIVE			-	17	16	15	14	13	12	11	10	9	8	7	6	5
CA(n)	READ/ WRITE	BA (1:0)		-	13	12	11	10	9	8	7	6	5	4	3	2	1

1) The JEDEC standard allows for memories of up to 16 GBytes. This implementation only supports memories up to 1 Gbyte requiring A(28:0) of the internal address

Table 15-50 A_{SRI} and CA to SDA bit Mapping(32 bit port width)

	Com-mand	SDA bit[1)]															
		15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
A_{SRI}	PRE-ACTIVE	BA (1:0)		-	-	-	-	28	27	26	25	24	23	22	21	20	19
	ACTIVE			-	18	17	16	15	14	13	12	11	10	9	8	7	6
CA(n)	READ/ WRITE	BA (1:0)		-	14	13	12	11	10	9	8	7	6	5	4	3	2

1) The JEDEC standard allows for memories of up to 16 GBytes. This implementation only supports memories up to 1 Gbyte requiring A(28:0) of the internal address

15.20.6 Status Register Reads

Status register reads are a variation on the mode register write commands used for DDRAM. A mode register write is performed to the device and the next read is then performed on an internal status register of the memory device instead of the memory array.

Status register reads are controlled by accessing the **EBU_DDRNMOD2** register. Writing to **EBU_DDRNMOD2** with a bank address value of 01_B (set by the **EBU_DDRNMOD2.XBA** field) and the **ACT** bit set will trigger the expected mode register write. The address of the status register to be read will be obtained from the **XOPM** field of the **EBU_DDRNMOD2** register. This defines A(11:0) of the external address bus. Bits (13:12) are always set to 00_B.

However as a write to mode register 01 is used as a command to prepare the device for a status register read, the write will be followed (after a delay set by the **CSRR** field in the **EBU_DDRNCON** register) by a read operation using the same value on the address bus as the write. The data returned by this read will be placed in the **EBU_DDRNSRR.SRRDATA0** field if a single device is connected or both **EBU_DDRNSRR.SRRDATA0** and **EBU_DDRNSRR.SRRDATA1** if two 16 bit devices are connected in parallel in a 32 bit configuration.

It is not normally permitted for other commands to be pipelined to the LPDDR NVM before the status register read command has completed. This delay is set by the **EBU_DDRNCON.CSRS** field.

While a status register operation is in progress, the **ACT** bit will remain set. Once the operation has completed, the bit will be cleared by hardware.

15.20.7 Discrete Mode Register Writes

when operating an LPDDR_NVM memory it is necessary to perform writes to mode registers which are not connected to device initialisation. These discrete mode register writes are using to configure the device programming interface.

Mode register 11_B is available for these functions and is accessed by writing to the **EBU_DDRNMOD2** register with the **ACT** bit set and the **XBA** field set to 11_B. The data to be written to the register is contained in the **XOPM** field of the **EBU_DDRNMOD2** register. This field contains twelve bits of data and will be output on A[11:0] of the external address bus. The unused bits of the external address bus will be set to 0_B.

15.20.8 Page Preload

This register has two uses. The first applies when **EBU_DDRNCON.MODE** is set to 1_B. In this case, the memory is defined as being unsuitable for “execute in place” XIP operation and therefore needs to be treated in the same way as a NAND flash memory.

If a value is written to the **EBU_DDRNPRLD** register, the contents will be treated as the MEMPORT address of a memory page to be preloaded into the device buffer. The memory controller will issue the PREACTIVE and ACTIVE command sequence as detailed in **“Normal operating mode” on Page 15-146**, but will not expect any data to be returned and so will not issue the final READ command. The page tags in the memory controller will be updated to show that the page is available.

This is intended to enable support for a NAND flash memory with the LPDDR NVM type interface. The proposed method of access would be to issue the page load and then wait for the device t_{RCD} to expire. Accesses to the preloaded page could then be issued. It would be the responsibility of software to ensure that a premature access to the page was not accidentally issued by either polling the device status register or using a dead reckoning timer to measure the page load time of the device.

Accesses to an unopened page will result in an error being returned on the internal bus.

If the CSA function is enabled for the LPDDR-NVM, then bit 28 of the register (corresponding to $A_{MEMPORT}(28)$ will be monitored and used to determine which of the two LPDDR-NVM memories is affected by the preload operation.

It is invalid for two RDBs to have overlapping addresses. The memory controller hardware will detect if the address to be preloaded overlaps another page tag other than that targetted by the page load operation and prevent the page load from taking place. This will not be flagged to the controlling software as the requested page is already available.

For the second use, see **"Overlay Window Control" on Page 15-150**.

15.20.9 Page Tag Control

Page tags are set active when first used. There are some circumstances in which the contents of the RDBs in the memory are no longer guaranteed to be an accurate copy of the device contents and in these cases the RDBs need to be invalidated. This is done by resetting the page tags to inactive. The next accesses to the memory will then force a reload of the RDBs from the memory contents. The following conditions will automatically invalidate the page tags:

- Writing to any of mode registers 00_B, 01_B or 11_B either by triggering an initialisation sequence (write to **EBU_DDRNMOD**) or by a mode register write (write to **EBU_DDRNMOD2**).

The page tags can be invalidated under software control by writing 0_B to the **EBU_DDRNTAGx (x=0-3).ACTIVE** bitfield of the appropriate register. Writing 1_B to this bit field has no effect and will not activate an inactive page tag. This operation does not invalidate the RDB in the memory device

15.20.10 Overlay Window Control

The overlay window is controlled using mode register 11_B in the memory device. Mode register 11_B can be accessed using the **EBU_DDRNMOD2** register to trigger discrete mode register writes (see **"Discrete Mode Register Writes" on Page 15-149**).

Once enabled, the overlay window occupies part of the memory device address space and can be written to. Note that writes to the overlay window are via the RDBs and that the RDB will therefore need to be flushed to transfer the data to the overlay window.

If the memory device supports the optional FLUSH bit in mode register 11, then the data can be flushed to the Overlay Window by using a discrete mode register write to write 1 to the FLUSH bit.

Otherwise, the flush operation can be triggered by sending an ACTIVE command to the appropriate RDB. To do this, use the **EBU_DDRNPRLD** register to trigger the command sequence using the **EBU_DDRNPRLD.BA** field to select the correct RDB. Which RDB (or RDBs) is currently allocated to the Overlay Window address space can be determined by polling the **EBU_DDRNTAGx (x=0-3)** registers.

15.20.11 Clearing The Read FIFO error flag

Writing to the **EBU_DDRNCON** will clear the read FIFO error flag in the SDRAM status register. This is in addition to a write to the **EBU_SDRMCON** register clearing the flag.

15.20.12 LPDDR-NVM Access Programmable Parameters

The following parameters can be used to configure accesses to LPDDR-NVM memories.

Table 15-51 LPDDR-NVM Access Programmable Parameters

Parameter	Function	Register
MAXADD	Highest order address bit used by the NVM memory	**EBU_DDRNCON**
PAGESIZE	Size of a page in the NVM memory	**EBU_DDRNCON**
CRSC	Number of NOP cycles after a mode register set command	**EBU_DDRNCON**
CRP	Number of NOP cycles between a PREACTIVE and ACTIVE command	**EBU_DDRNCON**
CSRS	Number of delay cycles between a status register read and the next command on the bus	**EBU_DDRNCON**
CSRR	Number of delay cycles between a mode register write to MR01 and the associated status register read	**EBU_DDRNCON**
CRCD	Number of NOP cycles between a row activate and a column address	**EBU_DDRNCON**
MODE	Operating mode for attached memory. Either XIP (execute in place) or software controlled page load (NAND mode)	**EBU_DDRNCON**
XBA	Bank address value to be used for an extended mode register access	**EBU_DDRNMOD**
OPMODE	To specify write operation mode: only BURST_WRITE is recognized	**EBU_DDRNMOD**
XOPM	Value to be written to the extended mode register	**EBU_DDRNMOD**
CASLAT	CAS latency setting to be used for device accesses	**EBU_DDRNMOD**
BTYP	To specify burst operation mode: SEQUENTIAL	**EBU_DDRNMOD**
BURSTL	To specify burst length: 4, 8 or 16	**EBU_DDRNMOD**
XBA	Bank address value to be used for an extended mode register access to the second extended mode register.	**EBU_DDRNMOD2**

Table 15-51 LPDDR-NVM Access Programmable Parameters (cont'd)

Parameter	Function	Register
XOPM	Value to be written to the second extended mode register	EBU_DDRNMOD2
BA	Bank address to be used for page preloaded	EBU_DDRNPRLD
PAGE	Internal, byte address of page to be preloaded	EBU_DDRNPRLD

15.21 EBU Registers

[cover refid=Register_map_24] This section describes the registers and programmable parameters of the EBU. All these registers can be read in User Mode, but can only be written in Supervisor Mode.

All registers are reset by the module reset.

1) The EXTBOOT register is only writable when the BOOT_ACTIVE flag from the SCU is set.

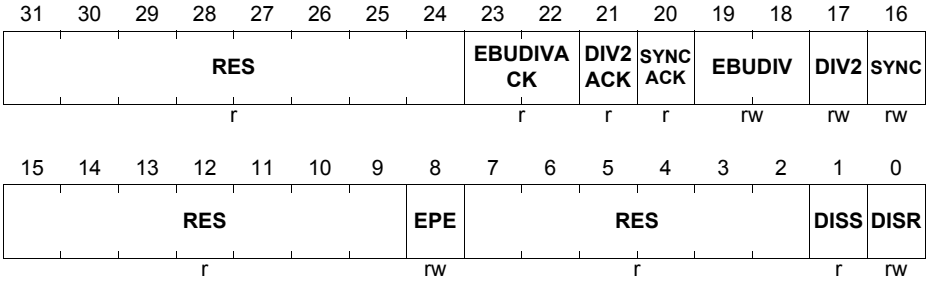
Access Restrictions

Note: The EBU registers are accessible only through word or double-word accesses. Half-word and byte accesses on EBU registers will generate a bus error. Accesses

to a 64bit word only partially populated with accessible registers will cause a bus error. Writes to unused address space, or writes to the endinit protected CLC register will also cause an error .

15.21.1 Clock Control Register, CLC

EBU_CLC
EBU Clock Control Register **(000_H)** **Reset Value: $0055\ 0000_H$**



Field	Bits	Type	Description
DISR	0	rw	**EBU Disable Request Bit**[1)] This bit is used for enable/disable control of the EBU. 0_B EBU disable is not requested 1_B EBU disable is requested
DISS	1	r	**EBU Disable Status Bit** DISS is always read as 0, as accessing the EBU will automatically enable it. 0_B EBU is enabled (default after reset) 1_B EBU is disabled
RES	7:2	r	**Reserved** Read as 0; should be written with 0.
EPE	8	rw	**Endinit Protection Enable**[2)] 0_B Disable Endinit protection of the CLC register (default after reset). 1_B Enable Endinit protection of the CLC register.
RES	15:9	r	**Reserved** Read as 0; should be written with 0.

Field	Bits	Type	Description
SYNC	16	rw	**EBU Clocking Mode** 0_B request EBU to run asynchronously to processor clock and use separate clock source 1_B request EBU to run synchronously to processor (default after reset)
DIV2	17	rw	**DIV2 Clocking Mode** 0_B standard clocking mode. clock input selected by SYNC bitfield (default after reset). 1_B request EBU to run off processor clock divided by 2.
EBUDIV	19:18	rw	**EBU Clock Divide Ratio** 00_B request EBU to run off input clock 01_B request EBU to run off input clock divided by 2 (default after reset) 10_B request EBU to run off input clock divided by 3 11_B request EBU to run off input clock divided by 4
SYNCACK	20	r	**EBU Clocking Mode Status** 0_B the EBU is asynchronous to the SRI bus clock and is using a separate clock source 1_B EBU is synchronous to the SRI bus clock (default after reset)
DIV2ACK	21	r	**DIV2 Clocking Mode Status** 0_B EBU is using standard clocking mode. clock input selected by SYNC bitfield (default after reset). 1_B EBU is running off processor clock divided by 2.
EBUDIVACK	23:22	r	**EBU Clock Divide Ratio Status** 00_B EBU is running off input clock (default after reset) 01_B EBU is running off input clock divided by 2 10_B EBU is running off input clock divided by 3 11_B EBU is running off input clock divided by 4
RES	31:24	r	**Reserved** Read as 0; should be written with 0.

1) *While the DISR bit is implemented in the EBU, it connects to the standby logic which will disable the clock tree. Standby mode will be exited automatically when an attempt is made to access the EBU.*

2) *This register can be Endinit-protected after initialization. Writing to this register in this state will cause the EBU to generate an SRI Error.*

15.21.2 Configuration Register, MODCON

EBU_MODCON
EBU Configuration Register **(004_H)**
Internal Boot Reset Value: $3000\ 0020_H$

EBU_MODCON
EBU Configuration Register **(004_H)**
External Boot Reset Value: $3000\ 0060_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ALE	BUSSTATE	ACCSINHACK	ACCSINH	RES	OCDS_SUSP_DIS	FAST_SRI	FIFO_BYPASS	LOCKTIMEOUT							
rw	rh	r	rw	r	rw	rw	rw	rw							

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TIMEOUTC								ARB MODE		ARB SYNC	EXTLOCK	CLK_COMB	SDTRI	LCKABRT	STS
				rw				rw		rw	rw	rw	rwh	rwh	r

Field	Bits	Type	Description
STS	0	r	**Memory Status Bit** Software access to the $\overline{WAIT}$ input pin to the EBU.
LCKABRT	1	rwh	**Lock Abort** This is a status bit which is set when a chip select lock has been cancelled by a program fetch. The flag is cleared by writing 1_B to the field. See **Section 15.9.1** 0_B Lock function is operating normally 1_B Lock function has been aborted by processor instruction read from locked device
SDTRI	2	rw	**SDRAM Tristate** 0_B SDRAM control signals are driven by the EBU when the EBU does not own the external bus. SDRAM cannot be shared. 1_B SDRAM control signals are tri-stated by the EBU when the EBU does not own the external bus. The SDRAM can be shared. *Note: The signals affected by this setting are CKE, SDCLKO, CAS and RAS*

Field	Bits	Type	Description
CLK_COMB	3	rw	**Combined External Bus Clock** Burst flash protocol and SDRAM protocol devices use the same external clock when set. 0_B The SDRAM and synchronous state machines use clocks on separate pins 1_B Both state machines use the clock on BFCLKO when accessing external memories
EXTLOCK	4	rw	**External Bus Lock Control** Allows the external bus arbitration to be locked with the EBU owning the bus. 0_B External bus is not locked after the EBU gains ownership 1_B External bus is locked after the EBU gains ownership
ARBSYNC	5	rw	**Arbitration Signal Synchronization Control** Assumed status of the arbitration control signals, $\overline{BREQ}$ and $\overline{HLDA}$ 0_B Arbitration inputs are synchronous 1_B Arbitration inputs are asynchronous, use two resynchronisation flip-flops.
ARBMODE	7:6	rw	**Arbitration Mode Selection** Operating mode of the external bus arbitration 00_B No Bus arbitration mode selected 01_B Arbiter Mode arbitration mode selected 10_B Participant arbitration mode selected 11_B Sole Master arbitration mode selected
TIMEOUTC	15:8	rw	**Bus Time-out Control** This bit field determines the number of inactive cycles after the EBU gains ownsership of the external bus before an arbitration time-out occurs and re-arbitration can occur. 00_H Time-out is disabled. 01_H Time-out is generated after 1×8 clock cycles. $\cdots_H$ … FF_H Time-out is generated after 255×8 clock cycles.

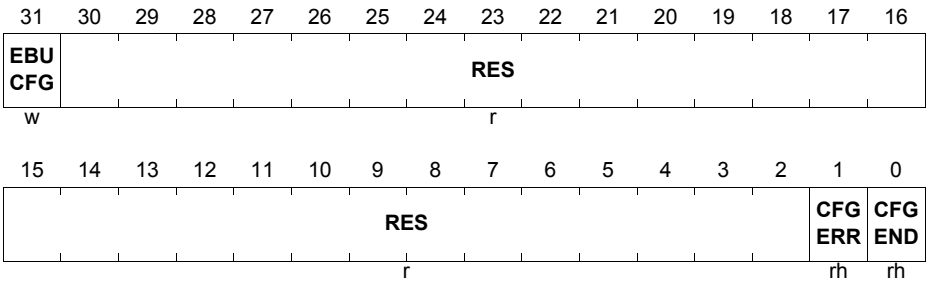
Field	Bits	Type	Description
LOCKTIMEOUT	23:16	rw	**Lock Timeout Counter Preload** Value to be preloaded into the timeout counter for the arbitration lock. *Note: (see **Section 15.9.1**)*
FIFO_BYPASS	24	rw	**Read Mode for SDRAM/DDR Memories** 0_B Use Data FIFO for read data (default) 1_B Bypass the FIFO. See **"FIFO Bypass Mode" on Page 15-25** for detailed description.
FAST_SRI	25	rw	**Clock Cycles used for SRI Address Decode** 0_B Use two clock cycles for address decode (default after reset) 1_B Use one clock cycle for address decode. See **"Address Comparison" on Page 15-48** for a detailed description.
OCDS_SUSP_DIS	26	rw	**OCDS SUSPEND Disable** The EBU external arbitration will normally be disabled with the EBU owning the external bus while OCDS is active. Setting this bit will allow external bus arbitration to continue operation. See **Section 15.11.7**
RES	27	r	**Reserved** write with 0_H
ACCSINH	28	rw	**Access Inhibit request** Prevent any transactions except for processor initiated transfers from accessing the memory regions 0_B Accesses enabled 1_B Accesses inhibited *Note: (see **Section 15.9**)*
ACCSINHACK	29	r	**Access inhibit acknowledge** 0_B Port normal operation possible 1_B Port accesses have been inhibited (except processor) *Note: (see **Section 15.9**)*

Field	Bits	Type	Description
BUSSTATE	30	rh	**External Bus State** Status bit controlled by the arbitration logic (See **"External Bus Arbitration" on Page 15-28**) reflecting the ownership of the external memory bus. 0_B The EBU does not own the external bus and attached memories cannot be accessed. 1_B The EBU owns the external bus.
ALE	31	rw	**ALE Mode** Switch the $\overline{ADV}$ output to be an active high ALE signal instead of active low $\overline{ADV}$. 0_B Output is $\overline{ADV}$ 1_B Output is ALE

15.21.3 External Boot Configuration Control Register, EXTBOOT

EBU_EXTBOOT

EBU External Boot Configuration Register(00010_H) **Reset Value: $0000\ 0001_H$**



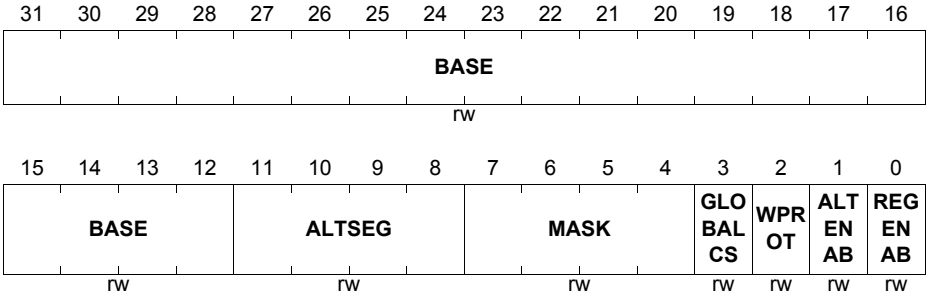
Field	Bits	Type	Description
CFGEND	0	rh	**Configuration End** 0_B Configuration fetch is running 1_B Configuration fetch has completed or not started
CFGERR	1	rh	**Configuration Fetch Error** 0_B No error 1_B The configuration fetch has returned a word with all bits set. This indicates an unprogrammed or missing flash

Field	Bits	Type	Description
EBUCFG	31	w	**Configuration Word Fetch** Write 1_B to trigger automatically set the EBU to arbiter arbitration mode and fetch a configuration word from external memory. Always reads 0_B
RES	30:2	r	**Reserved** Read as 0; must be written with 0.

15.21.4 Address Select Register, ADDRSELx

EBU_ADDRSELx (x = 1-3)
EBU Address Select Register 1-3 (018_H+x*4_H)
ADDRSEL[3:1] - Reset Value: 0000 0000$_H$

EBU_ADDRSEL0
EBU Address Select Register 0 (018_H)
ADDRSEL0 - Reset Value: A000 0001$_H$



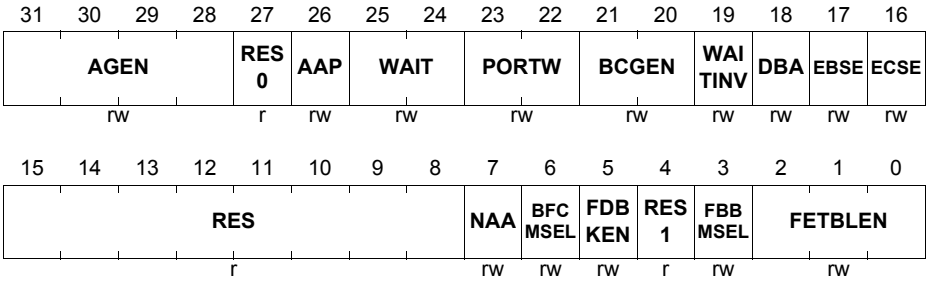
Field	Bits	Type	Description
REGENAB	0	rw	**Memory Region Enable** 0_B Memory region is disabled (default after reset[1)]). 1_B Memory region is enabled.
ALTENAB	1	rw	**Alternate Segment Comparison Enable** 0_B ALTSEG is never compared to SRI address (default after reset). 1_B ALTSEG is always compared to SRI address.
WPROT	2	rw	**Memory Region Write Protect** 0_B Region is enabled for write accesses 1_B Region is write protected.
GLOBALCS	3	rw	**Combined Chip Select Control** Controls whether the $\overline{\text{CSCOMB}}$ output should be asserted for valid accesses to this region. 0_B $\overline{\text{CSCOMB}}$ not asserted 1_B CSCOMB asserted

Field	Bits	Type	Description
MASK	7:4	rw	**Memory Region Address Mask** Specifies the number of right-most bits in the base address starting at bit 26, which should be included in the address comparison. Bits [31:27] will always be part of the comparison.
ALTSEG	11:8	rw	**Memory Region Alternate Segment** Alternate segment to be compared to SRI address bit [31:28].
BASE	31:12	rw	**Memory Region Base Address** Base address to be compared to SRI address in conjunction with the mask control.

1) except for ADDRSEL0, **REGENAB in register ADDRSEL0 is 1_B after reset.**

15.21.5 Bus Configuration Register, BUSRCONx

EBU_BUSRCONx (x = 0-3)
EBU Bus Configuration Register (028_H+x*10_H) **Reset Value: 00D3 0040_H**



Field	Bits	Type	Description
FETBLEN	2:0	rw	**Burst Length for Synchronous Burst** Defines maximum number of burst data cycles which are executed by Memory Controller during a burst access to a Synchronous Burst device. 000_B 1 data access (default after reset). 001_B 2 data accesses. 010_B 4 data accesses. 011_B 8 data accesses. $1xx_B$ reserved.
FBBMSEL	3	rw	**Synchronous burst buffer mode select** 0_B Burst buffer length defined by value in fetblen (default after reset). 1_B Continuous mode. All data required for transaction is transferred in a single burst.
RESERVED	4	r	**Reserved** 0_B Reserved bit always reads ‘0’.
FDBKEN	5	rw	**Burst FLASH Clock Feedback Enable** 0_B BFCLK feedback not used. 1_B Incoming data and control signals (from the Burst FLASH device) are re-synchronised to the BFCLKI input.

Field	Bits	Type	Description
BFCMSEL	6	rw	**Burst Flash Clock Mode Select** 0_B Burst Flash Clock runs continously with values selected by this register 1_B Burst Flash Clock is disabled between accesses
NAA	7	rw	**Enable flash non-array access workaround** set to logic one to enable workaround when region is accessed with address bit 28 set. See **"Flash Non-Array Access Support" on Page 15-101**
RES1	15:8	r	**Reserved** 00_H Reserved Value
ECSE	16	rw	**Early Chip Select for Synchronous Burst** 0_B CS is delayed. 1_B CS is not delayed. *Note: (see **Control of ADV & Other Signal Delays During Asynchronous Accesses** and **Control of ADV & Control Signal Delays During Synchronous Accesses**)*
EBSE	17	rw	**Early Burst Signal Enable for Synchronous Burst** 0_B ADV is delayed. 1_B ADV is not delayed. *Note: (see **Control of ADV & Other Signal Delays During Asynchronous Accesses** and **Control of ADV & Control Signal Delays During Synchronous Accesses**)*

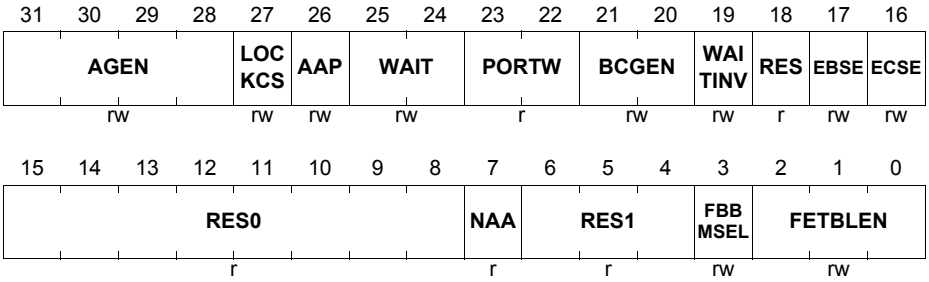
Field	Bits	Type	Description
DBA	18	rw	**Disable Burst Address Wrapping** 0_B Memory Controller automatically re-aligns any non-aligned synchronous burst access so that data can be fetched from the device in a single burst transaction. 1_B Memory Controller always starts any burst access to a synchronous burst device at the address specified by the SRI request. Any required address wrapping must be automatically provided by the Burst FLASH device. *Note: Care must be taken with the use of this feature. The Burst capable device must be programmed to wrap at the appropriate address boundary prior to selection of this mode.* ***"Critical Word First Read Accesses" on Page 15-96***
WAITINV	19	rw	**Reversed polarity at WAIT** 0_B **OFF**, input at WAIT pin is active low (default after reset). 1_B **Polarity reversed**, input at WAIT pin is active high.
BCGEN	21:20	rw	**Byte Control Signal Control** This bit field selects the timing mode of the byte control signals. 00_B Byte control signals follow chip select timing. 01_B Byte control signals follow control signal timing ($\overline{RD}$, RD/$\overline{WR}$) (default after reset). 10_B Byte control signals follow write enable signal timing (RD/$\overline{WR}$ only). 11_B SDRAM access type. Signals used for DQM.
PORTW	23:22	rw	**Device Addressing Mode** See **Table 15-16** and **Table 15-18**

Field	Bits	Type	Description
WAIT	25:24	rw	**External Wait Control** Function of the WAIT input. This is specific to the device type (i.e. the agen field). **For Asynchronous Devices, see "External Extension of the Command Phase by WAIT" on Page 15-76** **For Synchronous Burst Devices, see "External Cycle Control via the WAIT Input" on Page 15-99**
AAP	26	rw	**Asynchronous Address phase:** Enables an access mode for synchronous memories where the clock is not started until after the address hold phase. 0_B Clock is enabled at beginning of access. 1_B Clock is enabled at after address phase.
RES0	27	r	**Reserved, always 0**
AGEN	31:28	rw	**Device Type for Region** See **Section 15.14.1 Programmable Device Types**

*Note: When in external boot mode (see **Page 15-41**) the reset value of BUSCON0 is overwritten automatically (subsequent to the release of reset) as a result of the external Boot Configuration Value fetch.*

15.21.6 Bus Write Configuration Register, BUSWCONx

EBU_BUSWCONx (x = 0-3)
EBU Bus Write Configuration Register(030_H+x*10_H) **Reset Value: 00D3 0000_H**



Field	Bits	Type	Description
FETBLEN	2:0	rw	**Burst Length for Synchronous Burst** Defines maximum number of burst data cycles which are executed by Memory Controller during a burst access to a Synchronous Burst device. 000_B 1 data access (default after reset). 001_B 2 data accesses. 010_B 4 data accesses. 011_B 8 data accesses. $1xx_B$ reserved.
FBBMSEL	3	rw	**Synchronous burst buffer mode select** 0_B Burst buffer length defined by value in FETBLEN (default after reset). 1_B Continuous mode. All data required for transaction transferred in single burst
RES	6:4	r	**Reserved, always reads 0**
NAA	7	r	**Enable flash non-array access workaround** set to logic one to enable workaround when region is accessed with address bit 28 set. See **"Flash Non-Array Access Support" on Page 15-101**. Mirror of equivalent field in BUSRCON register.
RES0	15:8	r	**Reserved** 00_H Reserved Value

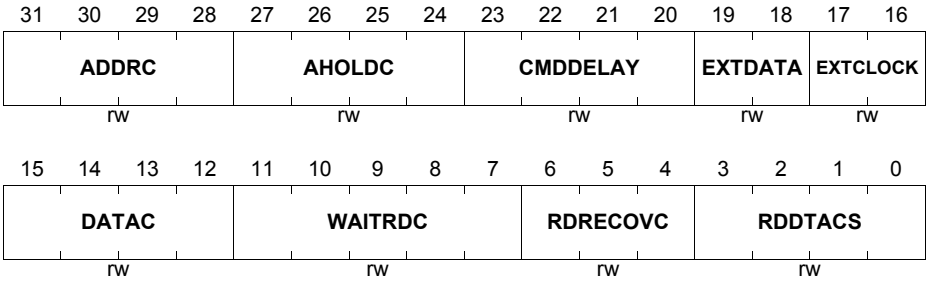
Field	Bits	Type	Description
ECSE	16	rw	**Early Chip Select for Synchronous Burst** 0_B CS is delayed. 1_B CS is not delayed. *Note: (see **Control of ADV & Other Signal Delays During Asynchronous Accesses** and **Control of ADV & Control Signal Delays During Synchronous Accesses**)*
EBSE	17	rw	**Early Burst Signal Enable for Synchronous Burst** 0_B ADV is delayed. 1_B ADV is not delayed. *Note: (see **Control of ADV & Other Signal Delays During Asynchronous Accesses** and **Control of ADV & Control Signal Delays During Synchronous Accesses**)*
RES1	18	r	**Reserved, always reads 0**
WAITINV	19	rw	**Reversed polarity at WAIT** 0_B **OFF**, input at WAIT pin is active low (default after reset). 1_B **Polarity reversed**, input at WAIT pin is active high.
BCGEN	21:20	rw	**Byte Control Signal Control** This bit field selects the timing mode of the byte control signals. 00_B Byte control signals follow chip select timing. 01_B Byte control signals follow control signal timing ($\overline{RD}$, RD/$\overline{WR}$) (default after reset). 10_B Byte control signals follow write enable signal timing (RD/$\overline{WR}$ only). 11_B Reserved.
PORTW	23:22	r	**Device Addressing Mode** See **Table 15-16** and **Table 15-17**

Field	Bits	Type	Description
WAIT	25:24	rw	**External Wait Control** Function of the WAIT input. This is specific to the device type (i.e. the agen field). **For Asynchronous Devices, see "External Extension of the Command Phase by WAIT" on Page 15-76** **For Synchronous Burst Devices, see "External Cycle Control via the WAIT Input" on Page 15-99**
AAP	26	rw	**Asynchronous Address phase:** Enables an access mode for synchronous memories where the clock is not started until after the address hold phase. 0_B Clock is enabled at beginning of access. 1_B Clock is enabled at after address phase.
LOCKCS	27	rw	**Lock Chip Select** Enable Chip Select for Automatic Locking in the event of a write access 0_B Chip Select cannot be locked (default after reset). 1_B Chip Select will be automatically locked when written to from the processor data port.
AGEN	31:28	rw	**Device Type for Region** See **Section 15.14.1 Programmable Device Types**

*Note: When in external boot mode (see **Page 15-41**) the reset value of BUSCON0 is overwritten automatically (subsequent to the release of reset) as a result of the external Boot Configuration Value fetch.*

15.21.7 Bus Read Access Parameter Register, BUSRAPx

EBU_BUSRAPx (x = 0-3)
EBU Bus Read Access Parameter Register
($02C_H$+x*10_H) **Reset Value: FFFF FFFF$_H$**



Field	Bits	Type	Description
RDDTACS	3:0	rw	**Recovery Cycles between Different Regions** This bit field determines the number of clock cycles of the Recovery Phase between consecutive accesses directed to different regions or different types of access. See **"Recovery Phase (RP)" on Page 15-67** and **"SDRAM Recovery Phases" on Page 15-135** 0000_B No Recovery Phase clock cycles available. 0001_B 1 clock cycle selected. …$_B$ … 1110_B 14 clock cycles selected. 1111_B 15 clock cycles selected.
RDRECOVC	6:4	rw	**Recovery Cycles after Read Accesses** This bit field determines the basic number of clock cycles of the Recovery Phase at the end of read accesses. 000_B No Recovery Phase clock cycles available. 001_B 1 clock cycle selected. …$_B$ … 110_B 6 clock cycles selected. 111_B 7 clock cycles selected.

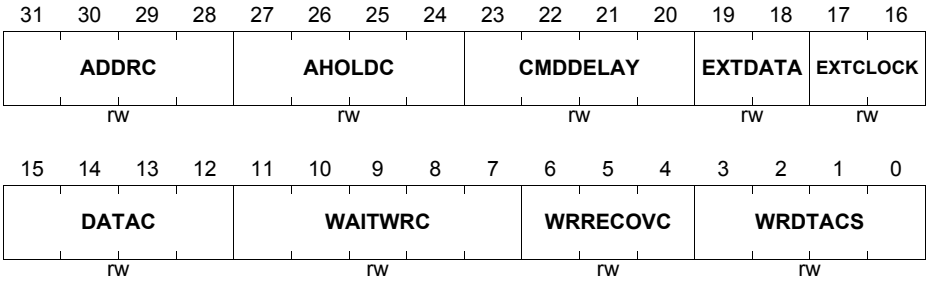
Field	Bits	Type	Description
WAITRDC	11:7	rw	**Programmed Wait States for read accesses** Number of programmed wait states for read accesses. For synchronous accesses, this will always be adjusted so that the phase exits on a rising edge of the external clock. 00000_B1 wait state. 00001_B1 wait states. 00010_B2 wait state. …$_B$ … 11110_B30 wait states. 11111_B31 wait states.
DATAC	15:12	rw	**Data Hold Cycles for Read Accesses** This bit field determines the basic number of Data Hold phase clock cycles during read accesses. This is used for a limited number of read cycle types. See **"Data Hold Phase (DH)" on Page 15-65**. Also controls the length of the Control Hold phase. See **"Control Hold (CH)" on Page 15-66**. 0000_B No Recovery Phase clock cycles available. 0001_B 1 clock cycle selected. …$_B$ … 1110_B 14 clock cycles selected. 1111_B 15 clock cycles selected.
EXTCLOCK	17:16	rw	**Frequency of external clock at pin BFCLKO or SDCLKO** See **"External Bus Clock Generation" on Page 15-26**
EXTDATA	19:18	rw	**Extended data** See **Burst Phase (BP)** 00_B external memory outputs data every BFCLK cycle 01_B external memory outputs data every two BFCLK cycles 10_B external memory outputs data every four BFCLK cycles 11_B external memory outputs data every eight BFCLK cycles

Field	Bits	Type	Description
CMDDELAY	23:20	rw	**Command Delay Cycles** This bit field determines the basic number of Command Delay phase clock cycles. 000_B 0 clock cycle selected. 001_B 1 clock cycle selected. …B … 110_B 6 clock cycles selected. 111_B 7 clock cycles selected.
AHOLDC	27:24	rw	**Address Hold Cycles** This bit field determines the number of clock cycles of the address hold phase.. 0000_B1 clock cycle selected 0001_B1 clock cycle selected …B … 1110_B14 clock cycles selected 1111_B15 clock cycles selected
ADDRC	31:28	rw	**Address Cycles** This bit field determines the number of clock cycles of the address phase. 000_B 1 clock cycle selected 001_B 1 clock cycle selected …B … 110_B 6 clock cycles selected 111_B 7 clock cycles selected

*Note: When in external boot mode (see **Page 15-41**), the reset value of BUSAP0 is overwritten automatically (subsequent to the release of reset) as a result of the external Boot Configuration Value fetch.*

15.21.8 Bus Write Access Parameter Register, BUSWAPx

EBU_BUSWAPx (x = 0-3)
EBU Bus Write Access Parameter Register
(034_H+x*10_H) **Reset Value: FFFF FFFF$_H$**



Field	Bits	Type	Description
WRDTACS	3:0	rw	**Recovery Cycles between Different Regions** This bit field determines the number of clock cycles of the Recovery Phase between consecutive accesses directed to different regions or different types of access. See **"Recovery Phase (RP)" on Page 15-67** and **"SDRAM Recovery Phases" on Page 15-135** 0000_B No Recovery Phase clock cycles available. 0001_B 1 clock cycle selected. …$_B$ … 1110_B 14 clock cycles selected. 1111_B 15 clock cycles selected.
WRRECOVC	6:4	rw	**Recovery Cycles after Write Accesses** This bit field determines the basic number of clock cycles of the Recovery Phase at the end of write accesses. See **"Recovery Phase (RP)" on Page 15-67** and **"SDRAM Recovery Phases" on Page 15-135** 000_B No Recovery Phase clock cycles available. 001_B 1 clock cycle selected. …$_B$ … 110_B 6 clock cycles selected. 111_B 7 clock cycles selected.

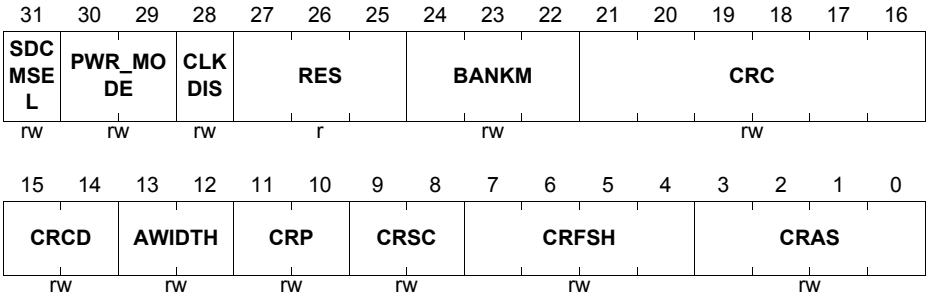
Field	Bits	Type	Description
WAITWRC	11:7	rw	**Programmed Wait States for write accesses** Number of programmed wait states for write accesses. For synchronous accesses, this will always be adjusted so that the phase exits on a rising edge of the external clock. 00000_B 1 wait state. 00001_B 1 wait states. 00010_B 2 wait state. …B … 11110_B 30 wait states. 11111_B 31 wait states.
DATAC	15:12	rw	**Data Hold Cycles for Write Accesses** This bit field determines the basic number of Data Hold phase clock cycles during write accesses. 0000_B No Recovery Phase clock cycles available. 0001_B 1 clock cycle selected. …B … 1110_B 14 clock cycles selected. 1111_B 15 clock cycles selected.
EXTCLOCK	17:16	rw	**Frequency of external clock at pin BFCLKO or SDCLKO** See **"External Bus Clock Generation" on Page 15-26**.
EXTDATA	19:18	rw	**Extended data** See **Burst Phase (BP)** 00_B external memory outputs data every BFCLK cycle 01_B external memory outputs data every two BFCLK cycles 10_B external memory outputs data every four BFCLK cycles 11_B external memory outputs data every eight BFCLK cycles

Field	Bits	Type	Description
CMDDELAY	23:20	rw	**Command Delay Cycles** This bit field determines the basic number of Command Delay phase clock cycles. 000_B 0 clock cycles selected. 001_B 1 clock cycles selected. …B … 110_B 6 clock cycles selected. 111_B 7 clock cycles selected.
AHOLDC	27:24	rw	**Address Hold Cycles** This bit field determines the number of clock cycles of the address hold phase.. 0000_B1 clock cycle selected 0001_B1 clock cycle selected …B … 1110_B14 clock cycles selected 1111_B15 clock cycles selected
ADDRC	31:28	rw	**Address Cycles** This bit field determines the number of clock cycles of the address phase. 0000_B1 clock cycle selected 0001_B1 clock cycle selected …B … 1110_B14 clock cycles selected 1111_B15 clock cycles selected

15.21.9 SDRAM Control Register, SDRMCON

MEMCTRL SDRAM Control Register

EBU_SDRMCON
EBU SDRAM Control Register (068$_H$) Reset Value: 1000 0000$_H$



Field	Bits	Type	Description
SDCMSEL	31	rw	**SDRAM clock mode select** 1_B clock disabled between accesses 0_B clock continuously runs *Note: (see **"Power Down Mode" on Page 15-134**)*
PWR_MODE	30:29	rw	**Power Save Mode used for gated clock mode** 0_H precharge before clock stop (default after reset) 1_H auto-precharge before clock stop 2_H active power down (stop clock without precharge) 3_H clock stop power down *Note: (see **"Power Down Mode" on Page 15-134**)*
CLKDIS	28	rw	**Disable SDRAM clock output** 0_B clock enabled 1_B clock disabled *Note: (see **"Power Down Mode" on Page 15-134**)*
RES	27:25	r	**Reserved**

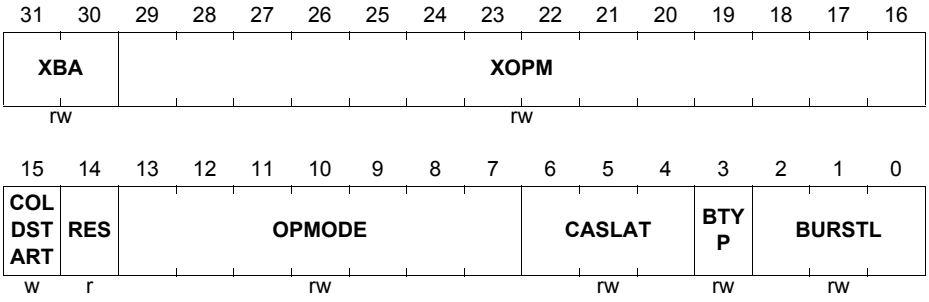
Field	Bits	Type	Description
BANKM	24:22	rw	**Mask for bank tag** SRI address bits to be used for determining bank number. 0_H Reserved; (default after reset) 1_H Address bit 21 to 20 2_H Address bit 22 to 21 3_H Address bit 23 to 22 4_H Address bit 24 to 23 5_H Address bit 25 to 24 6_H Address bit 26 to 25 7_H Address bit 26 *Note: See* ***"Bank Address Multiplexing" on Page 15-126****.*
CRC	21:16	rw	**Refresh cycle time counter** Number of NOP cycles following a refresh command before another command (other than a NOP) can be issued to the SDRAM. Combined with the Crce bit as follows:- 0-$3F_H$: Insert Crc + 1 NOP cycles.
CRCD	15:14	rw	**Row to column delay counter** Number of NOP cycles between a row address and a column address. 0-3_H: Insert Crcd + 1 NOP cycles (default after reset Crcd is 0).
AWIDTH	13:12	rw	**Width of column address** Number of address bits from bit 0 to be used for column address. See also **"SDRAM Addressing Scheme" on Page 15-125**. e.g. for 16 bit DRAMs 0_H **reserved**, do not use 1_H Address(8:0) 2_H Address(9:0) 3_H Address(10:0)
CRP	11:10	rw	**Row precharge time counter** Number of NOP cycles inserted after a precharge command. The actual number performed can be greater due to CAS latency and burst length. 0-3_H: Insert Crsc + 1 NOP cycles (default after reset Crp is 0)

Field	Bits	Type	Description
CRSC	9:8	rw	**Mode register set-up time** Number of NOP cycles after a mode register set command. $0\text{-}3_H$: Insert Crsc + 1 NOP cycles (default after reset Crsc is 0)
CRFSH	7:4	rw	**Initialization refresh commands counter** Number of refresh commands issued during power-up initialization sequence. $0\text{-}15_H$: Perform Crfsh + 1 refresh cycles (default after reset Crfsh is 0)
CRAS	3:0	rw	**Row to precharge delay counter** Number of clock cycles between row activate command and a precharge command. $0\text{-}15_H$: Minimum Cras + 1 clock cycles (default after reset Cras is 0)

15.21.10 SDRAM Mode Register, SDRMOD

SDRAM Mode Register

EBU_SDRMOD
EBU SDRAM Mode Register ($6C_H$) Reset Value: 0000 0020$_H$



Field	Bits	Type	Description
XBA	31:30	rw	**Extended Operation Bank Select** Value to be written to the bank select pins of a “Mobile” SDRAM device during an extended mode register write operation. Control of these bits is provided to allow support of future enhanced “Mobile” SDRAM devices. See **“Mobile SDRAM Support” on Page 15-124** *Note: Care must be taken when programming these bits to ensure that a valid extended mode register access occurs (e.g. it is possible to generate an extra unwanted standard mode register write by incorrect programming of these bits).* *3. Consult the appropriate SDRAM documentation for the function of these bits.*
XOPM	29:16	rw	**Extended Operation Mode** Value to be written to the extended mode register of a “Mobile” SDRAM device. This value is issued to the SDRAM via it’s address inputs during an extended mode register write. This field is wider than current extended mode registers to allow support of future enhanced “Mobile” SDRAM devices. *Note: Consult the appropriate SDRAM documentation for the function of these bits.*
COLDSTART	15	w	**SDRAM coldstart** This bit will always read 0. If a write to the **EBU_SDRMOD** register takes place with this bit set, the SDRAM device mode register will be updated to match the data written to the register. See **“Initialization sequence” on Page 15-121**
RES	14	r	**Reserved** 0_H Fixed Value

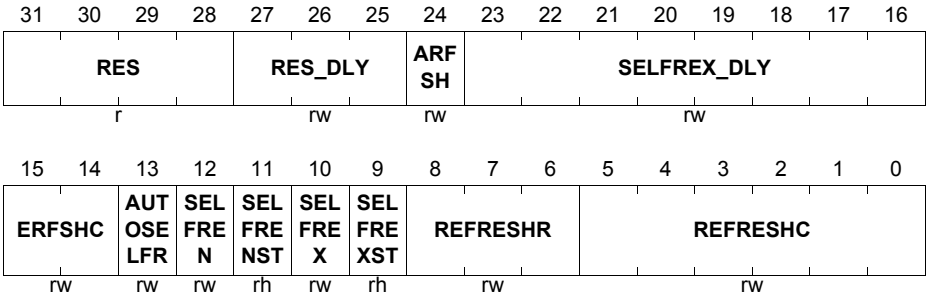
Field	Bits	Type	Description
OPMODE	13:7	rw	**Operation Mode** Memory Controller only supports burst write standard operation. 0_H Only this value should be written (default after reset) *Note: Other values reserved*
CASLAT	6:4	rw	**CAS latency** Number of clocks between a READ command and the availability of data. 2_H Two clocks (default after reset) 3_H Three clocks *Note: Other values reserved*
BTYP	3	rw	**Burst type** Memory Controller only supports sequential burst. 0_B Only this value should be written (default after reset) 1_B Reserved
BURSTL	2:0	rw	**Burst length** Number of locations can be accessed with a single command. 0_H 1 (default after reset) 1_H 2 2_H 4 3_H 8 4_H 16 *Note: Other values reserved*

15.21.11 SDRAM Refresh Control Register, SDRMREF

SDRAM Refresh Control Register

EBU_SDRMREF

EBU SDRAM Refresh Control Register(070_H) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
RES	31:28	r	**Reserved** 0_H Reserved Value
RES_DLY	27:25	rw	**Delay on Power Down Exit** Number of NOPs after the SDRAM controller exits power down before an active command is permitted. *Note: See **"Power Down Mode" on Page 15-134***
ARFSH	24	rw	**Auto Refresh on Self refresh Exit** If set to one, an auto refresh cycle will be performed on exiting self refresh before the self refresh exit delay. If set to zero, no refresh will be performed. *Note: See **"Self-Refresh Mode" on Page 15-133***
SELFREX_DLY	23:16	rw	**Self Refresh Exit Delay** Number of NOP cycles inserted after a self refresh exit before a command is permitted to the SDRAM/DDRAM. *Note: See **"Self-Refresh Mode" on Page 15-133***
ERFSHC	15:14	rw	**Extended Refresh Counter Period** This field is used to increase the range of the refreshc field from 6 bits to 8 bits with erfshc being used as bits 7 and 6 of the extended field and refreshc as bit 5 to 0.

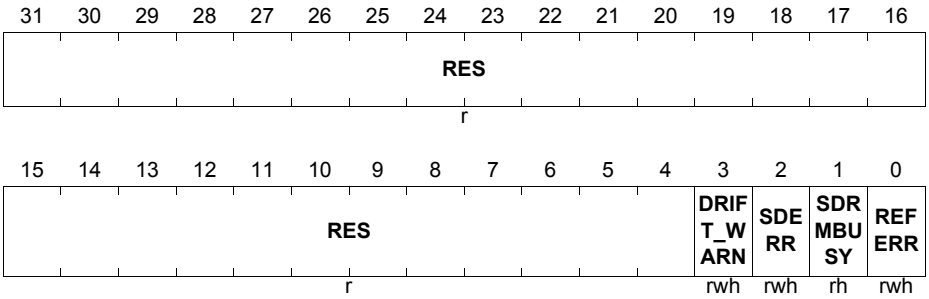
Field	Bits	Type	Description
AUTOSELFR	13	rw	**Automatic Self Refresh** When this bit is set to '1', Memory Controller will automatically issue the Self Refresh Entry command to all SDRAM devices when it gives up control of the external bus, and will automatically issue Self Refresh Exit when it regains control of the bus.
SELFREN	12	rw	**Self Refresh Entry** When this bit is written with '1' the Self Refresh Entry command is issued to all SDRAM devices, regardless whether they are attached to type 0 or type 1.
SELFRENST	11	rh	**Self Refresh Entry Status.** If this bit is set to '1', it means the Self Refresh Entry command has been successfully issued. This bit is reset when bit selfrex is set to '1' or a reset takes place.
SELFREX	10	rw	**Self Refresh Exit (Power Up).** When this bit is written with '1' the Self Refresh Exit command is issued to all SDRAM devices, regardless whether they are attached to type 0 or type 1. This is also used after power is applied to drive CKE high
SELFREXST	9	rh	**Self Refresh Exit Status.** If this bit is set to '1', it means the Self Refresh Exit command has been successfully issued. This bit is reset when bit selfren is set to '1' or a reset takes place.
REFRESHR	8:6	rw	**Number of refresh commands** The number of additional refresh commands issued to SDRAM each time a refresh is due. 00_H 1 refresh command is issued (default after reset). 01_H 1 additional refresh command is issued. $\ldots_H$ … 06_H 6 additional refresh commands are issued. 07_H 7 additional refresh commands are issued.

Field	Bits	Type	Description
REFRESHC	5:0	rw	**Refresh counter period** Number of clock cycles between refresh operations. Uses ((erfshc x 64) +refreshc) as a single counter value where 0_D means that no refresh is needed an the refresh generator is disable. This is the default setting after reset. For all other vales, the refresh period is ((erfshc x 64) + refreshc) x 64 clock cycles

15.21.12 SDRAM Status Register, SDRSTAT

SDRAM Status Register

EBU_SDRSTAT
EBU SDRAM Status Register (074_H) Reset Value: 0000 0000$_H$



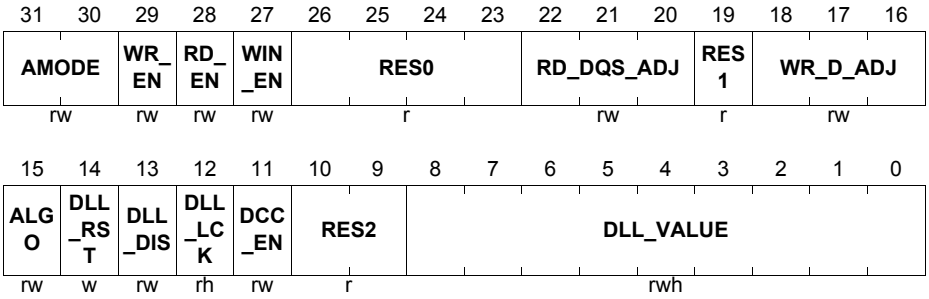
Field	Bits	Type	Description
RES	31:4	r	**Reserved** 0_H Reserved Value
DRIFT_WARN	3	rwh	**DLL Drift Warning** The Drift detector has detected that the DLL operating point drift has exceeded the tracking limit of the DLL. This bit latches at 1_B until cleared by writing a 0_B. See **"DLL Drift Detected (DRIFT_WARN)" on Page 15-137** 0_B DLL tracking successfully 1_B DLL tracking limit has been exceeded

Field	Bits	Type	Description
SDERR	2	rwh	**SDRAM read error** SDRAM controller has detected an error when returning read data. See **"SDRAM Read Error (SDERR)" on Page 15-137** 0_B Reads running successfully 1_B Read error condition has been detected *Note: This bit latches at 1_B and is reset by writing 0_B.*
SDRMBUSY	1	rh	**SDRAM Busy** The status of power-up initialization sequence. See **"SDRAM Controller Busy (SDRMBUSY)" on Page 15-137** 0_B Power-up initialization sequence is not running 1_B Power-up initialization sequence is running
REFERR	0	rwh	**SDRAM Refresh Error** Unsuccessful previous refresh request collides with a new request. See **"Refresh Error (REFERR)" on Page 15-136** This bit latches at 1_B and is reset by writing 0_B. 0_B No refresh error. 1_B Refresh error occurred.

15.21.13 DLL Control Register, EBU_DLLCON

DLL Control Register

EBU_DLLCON
EBU DLL Control Register **(078_H)** **Reset Value: 0000 2000$_H$**



Field	Bits	Type	Description
AMODE	31:30	rw	**Mode for generating address bits on DDR accesses.** 00_B DDR control timing 01_B early address generation) 10_B reserved 11_B reserved. *Note: See* ***"DDR Mode Address Outputs" on Page 15-142***
WR_EN	29	rw	**Write Delay Enable** 0_B The slave delay line used to phase shift the outgoing DQS signals is disabled. 1_B The slave delay line used to phase shift the outgoing DQS signals is enabled.
RD_EN	28	rw	**Read Delay Enable** 0_B The slave delay lines used to phase shift the incoming DQS signals are disabled. 1_B The slave delay lines used to phase shift the incoming DQS signals are enabled.

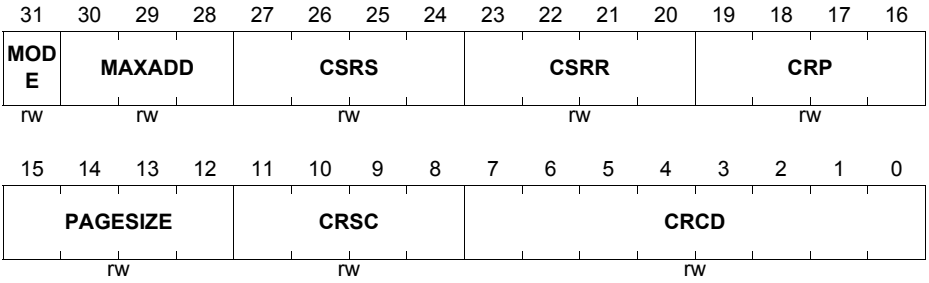
Field	Bits	Type	Description
WIN_EN	27	rw	**Drift Window Enable** See **"DLL Drift detector" on Page 15-23** for information on this field 0_B Warning Window is disabled 1_B Warning Window is Enabled
RES0	26:23	r	**Reserved**
RD_DQS_ADJ	22:20	rw	**Read DQS Adjust** signed binary number (in 64ths of a clock cycle) added to the shift value for the DQS inputs. The value will be sign extended. See **"DLL Operation" on Page 15-20**
RES1	19	r	**Reserved** 0_B Reserved Value
WR_D_ADJ	18:16	rw	**Write Data Adjust** signed binary number (in 64ths of a clock cycle) added to the shift value for the write data outputs. The value will be sign extended. See **"DLL Operation" on Page 15-20**
ALGO	15	rw	**Lock Algorithm Control** 0_B Fast Locking Algorithm 1_B Slow Locking Algorithm
DLL_RST	14	w	**Reset the DLL** Write '1' to reset the DLL control logic. If the DLL is enabled, this will trigger a full relock. Always reads '0'
DLL_DIS	13	rw	**Disable DLL Lock Function** 0_B DLL normal operation 1_B Lock DLL to value in DLL_value field *Note: This should be set to one when the DDR clock frequency is too low for the DLL to lock. It will force the DLL to use the preloaded value.*
DLL_LCK	12	rh	**DLL Lock Status** 0_B DLL is not locked 1_B DLL is locked
DCC_EN	11	r	**Duty Cycle Correction Enable** 0_B Disabled 1_B Enabled

Field	Bits	Type	Description
RES2	10:9	r	**Reserved** 0_B Reserved Value
DLL_VALUE	8:0	rwh	**DLL Lock Value** When read will return the current lock value of the DLL register. (i.e. the number of delay elements required to delay the clock by one clock period) When written will preload the DLL register if the DLL is not enabled. See **“DLL Operation” on Page 15-20**

15.21.14 LPDDR NVM Configuration Register, DDRNCON

EBU_DDRNCON
EBU LPDDR NVM Configuration Register

($07C_H$) **Reset Value: $0000\ 0000_H$**

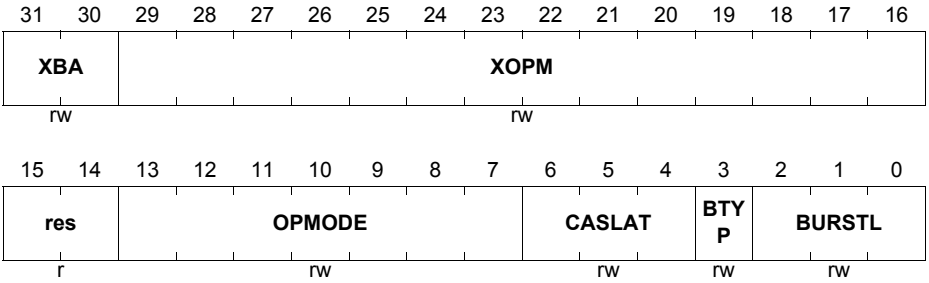


Field	Bits	Type	Description
MODE	31	rw	**Device Operating Mode** 0_B **XIP**, Attached memory is Execute in place technology. 1_B **NAND**, Attached memory is not capable of being used as XIP
MAXADD	30:28	rw	**NVM Device Size** SRI address bits to be used for accessing the attached device. 0_H SRI Address bits 21 to 0 1_H SRI Address bits 22 to 0 2_H SRI Address bits 23 to 0 3_H SRI Address bits 24 to 0 4_H SRI Address bits 25 to 0 5_H SRI Address bits 26 to 0 6_H SRI Address bits 27 to 0 7_H SRI Address bits 28 to 0 *Note: See "Bank Address Multiplexing" on Page 15-126.*
CSRS	27:24	rw	**SRR to next command delay** Number of memory clock cycles delay to insert after the SRR command of a status register read to satisfy the memory device t_{SRS} parameter. Delay inserted will be CSRS+1 NOP cycles.

Field	Bits	Type	Description
CSRR	23:20	rw	**MRS to SRR command delay** Number of memory clock cycles delay to insert between the MRS command and the SRR command during a status register read to satisfy the memory device t_{SRR} parameter.
CRP	19:16	rw	**PREACTIVE to ACTIVE command delay** Number of memory clock cycles delay to insert between PREACTIVE and ACTIVE commands to satisfy the memory device t_{RP} parameter.
PAGESIZE	15:12	rw	**Device Page Size** Page size of the memory device. This defines the number of internal address bits from bit 1 to be used for column address. See also **"Normal operating mode" on Page 15-146**. 3_H **32 bytes** , Address(3:1) 4_H **64 byte**, Address(4:1) 5_H **128 byte**, Address(5:1) 6_H **256 bytes**, Address(6:1) 7_H **512 bytes**, Address(7:1) 8H **1024 bytes**, Address(8:1) 9_H **2048 bytes**, Address(9:1) A_H **4096 bytes**, Address(10:1) B_H **8192 bytes**, Address(11:1) C_H **16384 bytes**, Address(12:1) *Note: All other values reserved and must not be used*
CRSC	11:8	rw	**Mode register set-up time** Number of NOP cycles after a mode register set command. 0-3_H: Insert Crsc + 1 NOP cycles (default after reset Crsc is 0)
CRCD	7:0	rw	**Row to column delay counter** Number of NOP cycles between a row address and a column address. 0-31_D: Insert Crcd + 1 NOP cycles of the device clock (default after reset Crcd is 0).

15.21.15 LPDDR NVM Mode Register, DDRNMOD

EBU_DDRNMOD
EBU DDR NVM Mode Register **(080_H)** **Reset Value: 0000 0024$_H$**



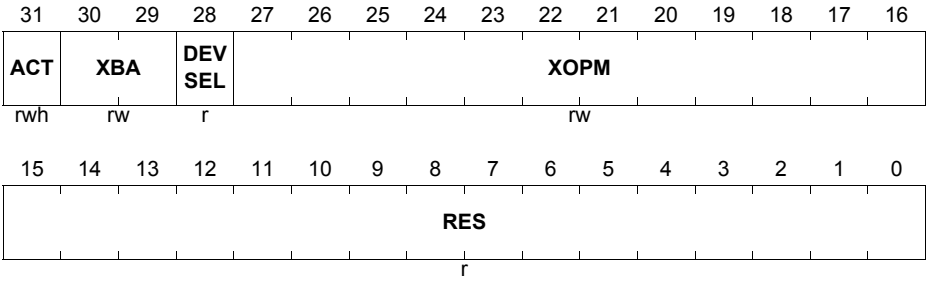
Field	Bits	Type	Description
XBA	31:30	rw	**Extended Operation Bank Select** Value to be written to the bank select pins of a LPDDR NVM device during an extended mode register write operation. Control of these bits is provided to allow support of future devices. *Note: Care must be taken when programming these bits to ensure that a valid extended mode register access occurs (e.g. it is possible to generate an extra unwanted standard mode register write by incorrect programming of these bits).*
XOPM	29:16	rw	**Extended Operation Mode** Value to be written to the extended mode register of a LPDDR NVM device. This value is issued to the device via it's address inputs during an extended mode register write. This field is wider than current extended mode registers to allow support of future devices. *Note: Consult the appropriate device documentation for the function of these bits.*
Res	15:14	r	**Reserved** reads 0_B. Must be written with 0_B.

Field	Bits	Type	Description
OPMODE	13:7	rw	**Operation Mode** Memory Controller only supports burst write standard operation. This field should always be programmed with 00_H. All other values are reserved for possible future device extensions. See the memory device data sheet for any further information.
CASLAT	6:4	rw	**CAS latency** Number of clocks between a READ command and the availability of data. 010_B **CAS2**, Two clocks (default after reset) 011_B **CAS3**, Three clocks *Note: All other values reserved for future expansion and are not supported by the memory controller*
BTYP	3	rw	**Burst type** Memory Controller only supports sequential burst. 0_B **Linear**, Only this value should be written (default after reset) 1_B **Interleave**, reserved. This value is not supported by the memory controller and is reserved in the JEDEC specification
BURSTL	2:0	rw	**Burst length** Number of locations can be accessed with a single command. 010_B **4**, word burst 011_B **8**, word burst 100_B **16**, word burst *Note: All other values reserved and not supported by the memory controller. Not all burst lengths are necessarily supported by all memory devices.*

15.21.16 LPDDR NVM Extended Mode Register, DDRNMOD2

EBU_DDRNMOD2
EBU DDR NVM Extended Mode Register

(084_H) **Reset Value: 0000 0000_H**

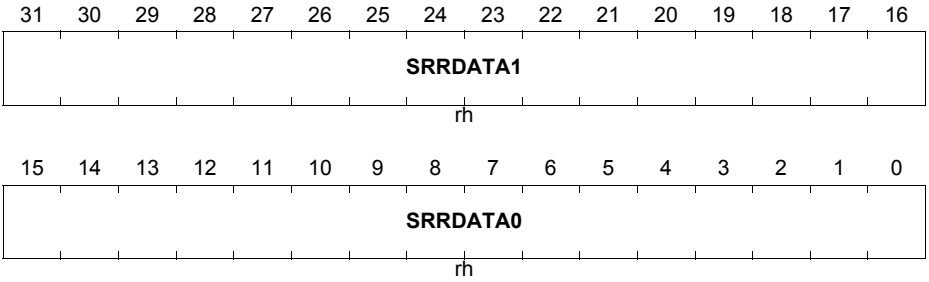


Field	Bits	Type	Description
ACT	31	rwh	**Status Register Operation Active** Write 1_B to this bitfield to trigger a mode/status register operation. When the operation is completed, the bit will be reset to 0_B by hardware. Writing 0_B will have no effect. Writing 1_B while an operation is in progress will not trigger a second status register operation but may overwrite the data to be written by the first.
XBA	30:29	rw	**Extended Operation Bank Select** Value to be written to the bank select pins of an LPDDR-NVM device during an mode register write operation. *Note: Care must be taken when programming these bits to ensure that a valid extended mode register access occurs (e.g. it is possible to generate an extra unwanted standard mode register write by incorrect programming of these bits).*
DEV_SEL	28	r	**Device Select** Must be written with 0_B.

Field	Bits	Type	Description
XOPM	27:16	rw	**Extended Operation Mode** Value to be written to the second extended mode register of a LPDDR-NVM device. This value is issued to the NVM via it's address inputs during an extended mode register write. This field is wider than current extended mode registers to allow support of future devices. *Note: Consult the appropriate device documentation for the function of these bits.* *4. Memory Controller provides a 12-bit wide bit-field for the extended mode register to cater for devices that could theoretically use additional control bits (in comparison to currently available devices).*
RES	15:0	r	**Reserved** Reads as all 0_B.

15.21.17 LPDDR NVM Status Register, DDRNSRR

EBU_DDRNSRR
EBU DDR NVM Status Register (088_H) Reset Value: 0000 0000$_H$

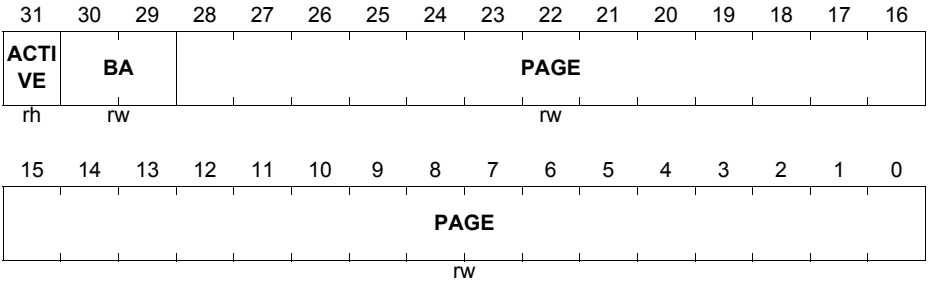


Field	Bits	Type	Description
SRRDATA1	31:16	rh	**Status Register Read Data** Returns the value of the last status register read operation. This field is only used when the LPDDR-NVM region is configured as twin 16 bit. ie. two 16 bit memories are connected.
SRRDATA0	15:0	rh	**Status Register Read Data** Returns the value of the last status register read operation. This field is used when a single 16 bit or 32 bit device is connected

15.21.18 DDR Preload Register, DDRNPRLD

EBU_DDRNPRLD
EBU DDR NVM Page Preload Register

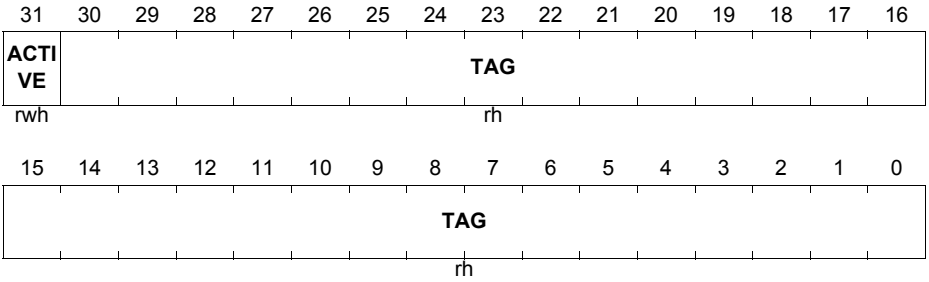
($08C_H$) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
PAGE	28:0	rw	**Preload Page** Byte Address of page to be preloaded. *Note: See* ***"Page Preload" on Page 15-149***
BA	30:29	rw	**Bank Address** Two bit field identifying the RDB to be used. This value will be used as the bank address bits for the access
ACTIVE	31	rh	**Preload Active** This bit will be set to 1_B while the preload command is in progress

15.21.19 DDR Tag Register, DDRNTAGx

EBU_DDRNTAGx (x=0-3)
EBU DDR Tag Registers **(090_H+x*4_H)** **Reset Value: 0000 0000_H**

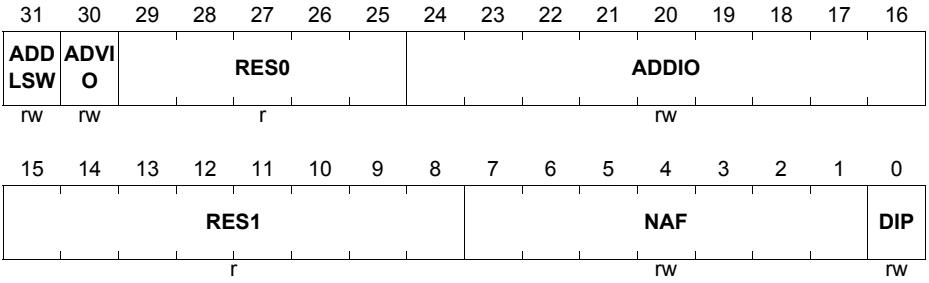


Field	Bits	Type	Description
TAG	30:0	rh	**Current Value for Page Tag** Byte Address (internal, processor address) of page tag. Significant bits will depend on hardware settings
ACTIVE	31	rwh	**Page Tag Active Status** 0_B **Inactive**, Tag Status is Idle. Address is invalid 1_B **active**, Tag Status is Idle. Address is valid

15.21.20 Test/Control Configuration Register, USERCON

EBU_USERCON
EBU Test/Control Configuration Register

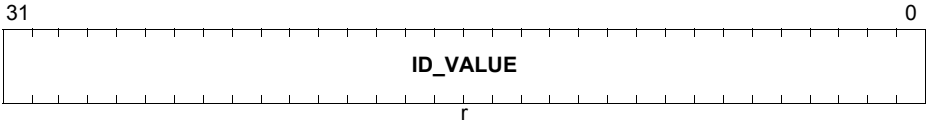
($00C_H$) **Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
DIP	0	rw	**Disable Internal Pipelining** Reserved, set to 0_B
NAF	7:1	rw	**No Assigned Function** Reserved for future requirements
RES1	15:8	r	**Reserved** Read as 0; should be written with 0.
ADDIO	24:16	rw	**Address Pins to GPIO Mode** Individual Control Bits for Address Bus Bits 27 downto 19 respectively. 0_B Address Bit is required for addressing memory 1_B Address Bit switched to GPIO function
RES	29:25	r	**Reserved**
ADVIO	30	rw	**ADV Pin to GPIO Mode** Control Bit for the $\overline{ADV}$/ALE output 0_B $\overline{ADV}$ pin is required for controlling memory 1_B $\overline{ADV}$ pin is switched to GPIO function
ADDLSW	31	rw	**Enable Address LSW, A(15:0) for GPIO** Switch the least significant 16 bits of the address bus to GPIO mode. 0_B A(15:0) in use by EBU 1_B A(15:0) used as GPIO.

15.22 Registers for SFR Extraction

EBU_ID
EBU Module Identification Register (08_H) **Reset Value: 0014 C00A$_H$**



Field	Bits	Type	Description
ID_VALUE	[31:0]	r	**Module Identification Value**

16 Interrupt System

The TC1798 interrupt system provides a flexible and time-efficient means of processing interrupts. This chapter describes the interrupt system for the TC1798. Topics covered include the architecture of the interrupt system, interrupt system configuration, and the interrupt operations of the TC1798 peripherals and Central Processing Unit (CPU). General information is also given about the Peripheral Control Processor (PCP).

16.1 Overview

An interrupt request can be serviced either by the CPU or by the PCP. Interrupt requests are called “service requests” rather than “interrupt requests” in this document because they can be serviced by either one of the service providers.

Each peripheral in the TC1798 can generate service requests. Additionally, the Bus Control Units, the Debug Unit, the PCP, and even the CPU itself can generate service requests to either of the two service providers.

As shown in **Figure 16-1**, each TC1798 unit that can generate service requests is connected to one or more Service Request Nodes (SRNs). Each SRN contains a Service Request Control Register mod_SRCx, where “mod” is the identifier of the service requesting unit and “x” an optional index. Two arbitration buses connect the SRNs with two Interrupt Control Units (ICUs), which handle interrupt arbitration among competing interrupt service requests, as follows:

- The Interrupt Control Unit (ICU) arbitrates service requests for the CPU and administers the CPU interrupt arbitration bus.
- The Peripheral Interrupt Control Unit (PICU) arbitrates service requests for the PCP and administers the PCP interrupt arbitration bus.

The PCP can make service requests directly to itself (via the PICU), or it can make service requests to the CPU. The Debug Unit can generate service requests to the PCP or the CPU. The CPU can make service requests directly to itself (via the ICU), or it can make service requests to the PCP. The CPU Service Request Nodes are activated through software.

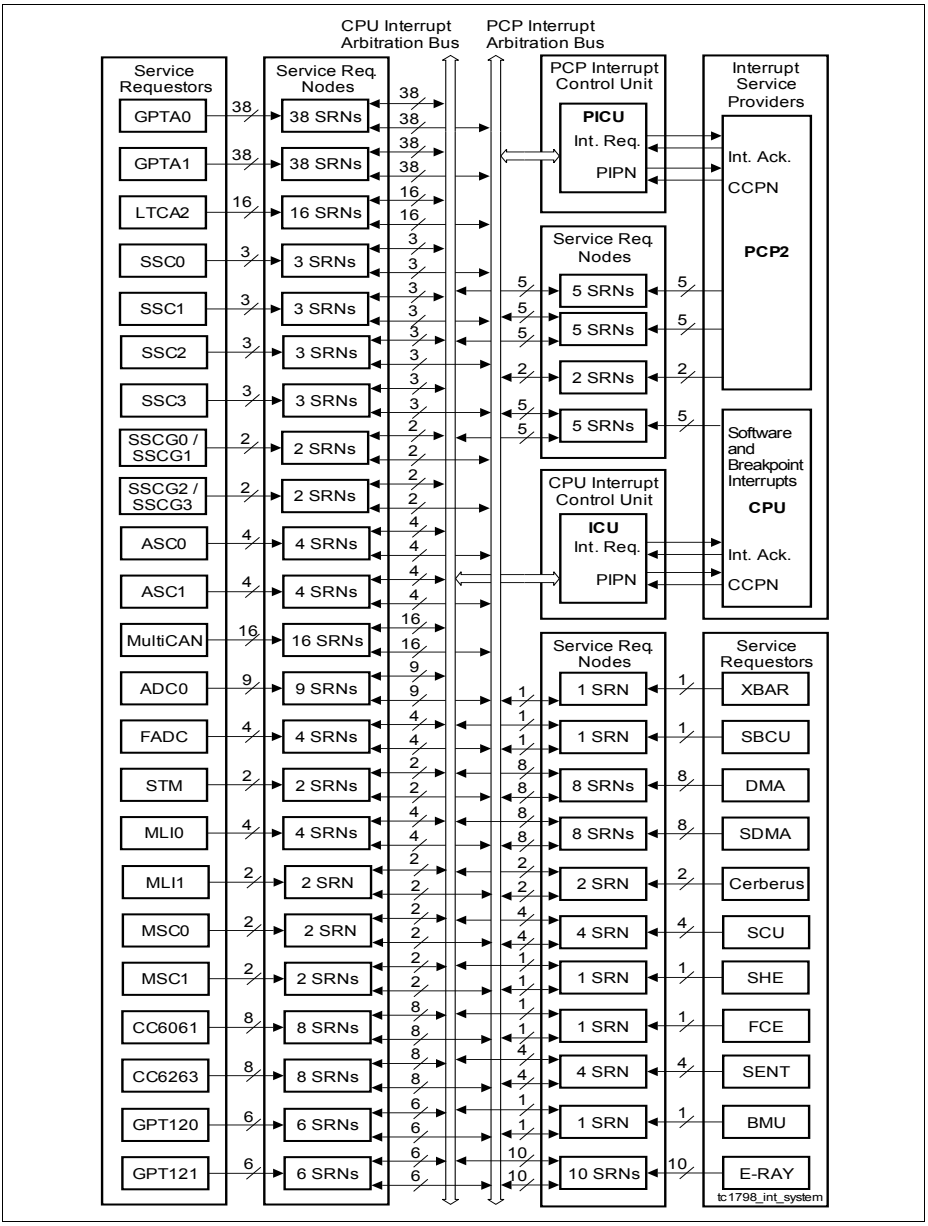


Figure 16-1 Block Diagram of the TC1798 Interrupt System

16.2 Service Request Nodes

Each SRN contains a Service Request Control Register and interface logic that connects it to the triggering unit and to the two interrupt arbitration buses. Some peripheral units of the TC1798 have multiple SRNs.

16.2.1 Service Request Control Registers

All Service Request Control Registers in the TC1798 have the same format. In general, these registers contain:

- Enable/disable information
- Priority information
- Service provider destination
- Service request status bit
- Software-initiated service request set and reset bits

Besides being activated by the associated triggering unit through hardware, each SRN can also be set or reset by software via two software-initiated service request control bits.

The description given in this chapter characterizes all Service Request Control Registers of the TC1798. Information on peripheral module interrupt functions such as enable or request flags is provided in the corresponding sections of the module chapters.

16.2.1.1 General Service Request Control Register Format

The description given in this chapter characterizes all Service Request Control Registers of the TC1798. Information on peripheral module interrupt functions such as enable or request flags is provided in the corresponding sections of the module chapters.

mod_SRC

TOS	10	rw	**Type of Service Control** 0 CPU service is initiated 1 PCP request is initiated
SRE	12	rw	**Service Request Enable** 0 Service request is disabled 1 Service request is enabled
SRR	13	rh	**Service Request Flag** 0 No service request is pending 1 A service request is pending
CLRR	14	w	**Request Clear Bit** CLRR is required to reset SRR. 0 No action 1 Clear SRR; bit value is not stored; read always returns 0; no action if SETR is set also.
SETR	15	w	**Request Set Bit** SETR is required to set SRR. 0 No action 1 Set SRR; bit value is not stored; read always returns 0; no action if CLRR is set also.
0	[9:8], 11, [31:16]	r	**Reserved** Read as 0; should be written with 0.

16.2.1.2 Request Set and Clear Bits (SETR, CLRR)

The SETR and CLRR bits allow software to set or clear the service request bit SRR. Writing a 1 to SETR causes bit SRR to be set to 1. Writing a 1 to CLRR causes bit SRR to be cleared to 0. If hardware attempts to modify SRR during a read-modify-write software operation (such as the bit-set or bit-clear instructions), the software operation will succeed and the hardware operation will have no effect.

The value written to SETR or CLRR is not stored. Writing a 0 to these bits has no effect. These bits always return 0 when read. If both, SETR and CLRR, are set to 1 at the same time, SRR is not changed.

16.2.1.3 Enable Bit (SRE)

The SRE bit enables an interrupt to take part in the arbitration for the selected service provider. It does not enable or disable the setting of the request flag SRR; the request flag can be set by hardware or by software (via SETR) independent of the state of the SRE bit. This allows service requests to be handled automatically by hardware or through software polling.

If SRE = 1, pending service requests are passed on to the designated service provider for interrupt arbitration. The SRR bit is automatically set to 0 by hardware when the service request is acknowledged and serviced. It is recommended that in this case, software should not modify the SRR bit to avoid unexpected behavior due to the hardware controlling this bit.

If SRE = 0, pending service requests are not passed on to service providers. Software can poll the SRR bit to check whether a service request is pending. To acknowledge the service request, the SRR bit must then be reset by software by writing a 1 to CLRR.

Note: In this document, ‘active source’ means an SRN whose Service Request Control Register has its request enable bit SRE set to 1 to allow its service requests to participate in interrupt arbitration.

16.2.1.4 Service Request Flag (SRR)

When set, the SRR flag indicates that a service request is pending. It can be set or reset directly by hardware or indirectly through software using the SETR and CLRR bits. Writing directly to this bit via software has no effect.

The SRR status bit can be directly set or reset by the associated hardware. For instance, in the General Purpose Array Unit, an associated timer event can cause this bit to be set to 1. The details of how hardware events can cause the SRR bit to be set are defined in the individual peripheral/module chapters.

The acknowledgment of the service request by either the Interrupt Control Unit (ICU) or the PCP Interrupt Control Unit (PICU) causes the SRR bit to be cleared.

SRR can be set or cleared either by hardware or by software regardless of the state of the enable bit SRE. However, the request is only forwarded for service if the enable bit is set. If SRE = 1, a pending service request takes part in the interrupt arbitration of the service provider selected by the device's TOS bit. If SRE = 0, a pending service request is excluded from interrupt arbitrations.

SRR is automatically reset by hardware when the service request is acknowledged and serviced. Software can poll SRR to check for a pending service request. SRR must be reset by software in this case by writing a 1 to CLRR.

It is not advisable to clear a pending service request flag SRR (writing CLRR = 1) and enable the corresponding service request node SRN (writing SRE = 1) simultaneously at the same write access to the Service Request Control Register. If this should happen, an unintended interrupt request may be generated. Instead of executing one write access, it is recommended to split the two actions into two consecutive write accesses to the corresponding Service Request Control Register, starting with the clearing of the pending interrupt flag and followed by the enabling of the service request node.

16.2.1.5 Type-Of-Service Control (TOS)

There are two service providers for service requests in the TC1798, the CPU and the PCP. The TOS bit is used to select whether a service request generates an interrupt to the CPU (TOS = 0) or to the PCP (TOS = 1). Bit 11 of the Service Request Control Register is read-only, returning 0 when read. Writing to this bit position has no effect. However, to ensure compatibility with future extensions, bit 11 should always be written with a 0.

Note that several Service Request Control Registers (e.g. in the PCP) have a hardwired TOS bit (0 or 1) that cannot be written. These registers can only generate an interrupt to one dedicated service provider (PCP or CPU).

Note: Before modifying the content of a TOS bit, the corresponding SRN must be disabled (SRE = 0).

16.2.1.6 Service Request Priority Number (SRPN)

The 8-bit Service Request Priority Number (SRPN) indicates the priority of a service request with respect to other sources requesting service from the same service provider, and with respect to the priority of the service provider itself.

Each active source selecting the same service provider must have a unique SRPN value to differentiate its priority. The special SRPN value of 00_H excludes an SRN from taking part in arbitration, regardless of the state of its SRE bit. The SRPN values for active sources selecting different service providers (CPU vs. PCP) may overlap. If a source is not active – meaning its SRE bit is 0 – no restrictions are applied to the service request priority number.

The SRPN is used by service providers to select an Interrupt Service Routine (ISR)) or Channel Program (in case of the PCP) to service the request. ISRs are associated with Service Request Priority Numbers by an Interrupt Vector Table located in each service provider. This means that the TC1798 Interrupt Vector Table is ordered by priority number. This is unlike traditional interrupt architectures in which their interrupt vector tables are ordered by the source of the interrupt. The TC1798 Interrupt Vector Table allows a single peripheral to have multiple priorities for different purposes.

The range of values for SRPNs used in a system depends on the number of possible active service requests and the user-definable organization of the Interrupt Vector Table. The 8-bit SRPNs permit up to 255 sources to be active at one time (remembering that the special SRPN value of 00_H excludes an SRN from taking part in arbitration).

Note: Before modifying the content of an SRPN bit field, the corresponding SRN must be disabled (SRE = 0).

SRPNs in the TC1798

In the TC1798, interrupt sources selecting the same Service Provider are also allowed to have identical SRPN values. In this case, the software (interrupt service routine) must check which of the interrupt sources with identical SRPN has become active.

Note that module-specific interrupt request flags must be available because the SRR flags cannot be used for this check. SRR flags (meaning all SRR flags of interrupts with identical SRPN values) are in general automatically reset by hardware when a service request is acknowledged and serviced.

Note: This practice with identical SRPN values is not recommended as it is not portable to other TriCore devices.

16.3 Interrupt Control Units

The Interrupt Control Units manage the interrupt system, arbitrate incoming service requests, and determine whether and when to interrupt the service provider. The TC1798 contains two interrupt control units, one for the CPU (called ICU), and one for the PCP (called PICU). Each one controls its associated interrupt arbitration bus and manages the communication with its service provider (see).

16.3.1 Interrupt Control Unit (ICU)

This section describes the interrupt control unit (ICU) for the CPU.

16.3.1.1 ICU Interrupt Control Register (ICR)

The ICU Interrupt Control Register ICR holds the current CPU priority number (CCPN), the global interrupt enable/disable bit (IE), the pending interrupt priority number (PIPN), and bit fields which control the interrupt arbitration process.

ICR

ICU Interrupt Control Register (F7E1FE2C$_H$) Reset Value: 0000 0000$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0					CONECYC	CARBCYC		PIPN

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0							IE	CCPN							
r							rwh	rwh							

Field	Bits	Type	Description
CCPN	[7:0]	rwh	**Current CPU Priority Number** The Current CPU Priority Number (CCPN) bit field indicates the current priority level of the CPU. It is automatically updated by hardware on entry and exit of interrupt service routines, and through the execution of a BISR instruction. CCPN can also be updated through an MTCR instruction.

Field	Bits	Type	Description
IE	8	rwh	**Global Interrupt Enable Bit** The interrupt enable bit globally enables the CPU service request system. Whether or not a service request is delivered to the CPU depends on the individual Service Request Enable Bits (SRE) in the SRNs, and the current state of the CPU. IE is automatically updated by hardware on entry and exit of an Interrupt Service Routine (ISR). IE is cleared to 0 when an interrupt is taken, and is restored to the previous value when the ISR executes an RFE instruction to terminate itself. IE can also be updated through the execution of the ENABLE, DISABLE, MTCR, and BISR instructions. 0 Interrupt system is globally disabled 1 Interrupt system is globally enabled
PIPN	[23:16]	rh	**Pending Interrupt Priority Number** PIPN is a read-only bit field that is updated by the ICU at the end of each interrupt arbitration process. It indicates the priority number of the pending service request. PIPN is set to 0 when no request is pending, and at the beginning of each new arbitration process. 00_H No valid pending request YY_H A request with priority YY_H is pending
CARBCYC	[25:24]	rw	**Number of Arbitration Cycles** CARBCYC controls the number of arbitration cycles used to determine the request with the highest priority. 00_B 4 arbitration cycles (default) 01_B 3 arbitration cycles 10_B 2 arbitration cycles 11_B 1 arbitration cycle
CONECYC	26	rw	**Number of Clocks per Arbitration Cycle Control** The CONECYC bit determines the number of system clocks per arbitration cycle. For the TC1798 this bit can be set to 1 (for SPB frequencies up to the max SPB frequency as defined in the Data Sheet). 0 2 clocks per arbitration cycle (default) 1 1 clock per arbitration cycle
0	[15:9], [31:27]	r	**Reserved** Read as 0; should be written with 0.

16.3.1.2 Operation of the Interrupt Control Unit (ICU)

Service-request arbitration is performed in the ICU in parallel with normal CPU operation. When a triggering event occurs in one or more interrupt sources, the associated SRNs, if enabled, send service requests to the CPU through the ICU. The ICU determines which service request has the highest priority. The ICU will then forward the service request to the CPU. The service request will be acknowledged by the CPU and serviced, depending upon the state of the CPU.

The ICU arbitration process takes place in one or more arbitration cycles over the CPU interrupt arbitration bus. The ICU begins a new arbitration process when a new service request is detected. At the end of the arbitration process, the ICU will have determined the service request with the highest priority number. This number is stored in the ICR.PIPN bit field and becomes the pending service request.

After the arbitration process, the ICU forwards the pending service request to the CPU by attempting to interrupt it. The CPU can be interrupted only if interrupts are enabled globally (that is, ICR.IE = 1) and if the priority of the service request is higher than the current processor priority (ICR.PIPN > ICR.CCPN). Also, the CPU may be temporarily blocked from taking interrupts, for example, if it is executing a multi-cycle instruction such as an atomic read-modify-write operation. The full list of conditions which could block the CPU from immediately responding to an interrupt request generated by the ICU is:

- Current CPU priority, ICR.CCPN, is equal to or higher than the pending interrupt priority, ICR.PIPN
- Interrupt system is globally disabled (ICR.IE = 0)
- CPU is in the process of entering an interrupt- or trap-service routine
- CPU is executing non-interruptible trap services
- CPU is executing a multi-cycle instruction
- CPU is executing an instruction which modifies the conditions of the global interrupt system, such as modifying the ICR
- CPU detects a trap condition (such as context depletion) when trying to enter a service routine

When the CPU is not otherwise prevented from taking an interrupt, the CPU's program counter will be directed to the Interrupt Service Routine entry point associated with the priority of the service request. Next, the CPU saves the value of ICR.PIPN internally, and acknowledges the ICU. The ICU then forwards the acknowledge signal back to the SRN that is requesting service in order to inform it that it will be serviced by the CPU. The SRR bit in this SRN is then reset to 0.

After sending the acknowledgement, the ICU resets ICR.PIPN to 0 and may start a new arbitration process if there is another pending interrupt request. If not, ICR.PIPN remains at 0 and the ICU enters an idle state, waiting for the next interrupt request to awaken it. If there is a new service request waiting, the priority number of the new request will be written to ICR.PIPN at the end of the new arbitration process and the ICU will deliver the pending interrupt to the CPU according to the rules described in this section.

If a new service request is received by the ICU before the CPU has acknowledged the pending interrupt request, the ICU deactivates the pending request and starts a new arbitration process. This reduces the latency of service requests posted before the current request is acknowledged. The ICU deactivates the current pending interrupt request by setting the ICR.PIPN bit field to 0, indicating that the ICU has not yet found a new valid pending request. It then executes its arbitration process again. If the new service request has a higher priority than the previous one, its priority will be written to ICR.PIPN. If the new interrupt has a lower priority, the priority of the previous interrupt request will again be written to ICR.PIPN. In any case, the ICU will deliver a new interrupt request to the CPU according to the rules described in this section.

Once the CPU has acknowledged the current pending interrupt request, any new service request generated by an SRN must wait at least until the end of the next service request arbitration process to be serviced.

Essentially, arbitration in the ICU is performed whenever a new service request is detected, regardless of whether or not the CPU is servicing interrupts. Because of this, the ICR.PIPN bit field always reflects the pending service request with the highest priority. This can, for example, be used by software polling techniques to determine high-priority requests while leaving the interrupt system disabled.

16.3.2 PCP Interrupt Control Unit (PICU)

The PCP Interrupt Control Unit (PICU) is closely coupled with the PCP and its Interrupt Control Register (PCP_PICR). The operation of the PICU is very similar to the ICU of the CPU with respect to the overall scheme.

Note: Details of the PICU and the PCP_ICR register are described in the chapter about the PCP.

16.4 Arbitration Process

The arbitration process implemented in the TC1798 uses a number of arbitration cycles to determine the pending interrupt request with the highest priority number, SRPN. In each of these cycles, two bits of the SRPNs of all pending service requests are compared against each other. The sequence starts with the high-order bits of the SRPNs and works downwards, such that in the last cycle, bits [1:0] of the SRPNs are compared. Thus, to perform an arbitration through all 8 bits of an SRPN, four arbitration cycles are required. There are two factors determining the duration of the arbitration process:

- Number of arbitration cycles, and
- Duration of arbitration cycles.

Both of these can be controlled by the user.

16.4.1 Controlling the Number of Arbitration Cycles

In a real-time system where responsiveness is critical, arbitration must be as fast as possible. However, to maintain flexibility, the TC1798 system is designed to have a large range of service priorities. If not all priorities are needed in a system, arbitration can be accelerated by not examining all the bits used to identify all 255 unique priorities.

For instance, if a 6-bit number is enough to identify all priority numbers used in a system (meaning that bits [7:6] of all SRPNs are always 0), it is not necessary to perform arbitration on these two bits. Three arbitration cycles will be enough to find the highest number in bits [5:0] of the SRPNs of all pending requests. Similarly, the number of arbitration cycles can be reduced to two if only bits [3:0] are used in all SRPNs, and the number of arbitration cycles can be reduced to one cycle if only bits [1:0] are used.

The ICR.CARBCYC bit field controls the number of cycles in the arbitration process. Its default value is 0, which selects four arbitration cycles. **Table 16-1** gives the options for arbitration cycle control.

Table 16-1 Arbitration Cycle Control

Number of Arbitration Cycles	4	3	2	1
ICR.CARBCYC	00_B	01_B	10_B	11_B
Relevant bits of the SRPNs	[7:0]	[5:0]	[3:0]	[1:0]
Range of priority numbers covered	1..255	1..63	1..15	1..3

Note: If less than four arbitration cycles are selected, the corresponding upper bits of the SRPNs are not examined, even if they do not contain zeros.

16.4.2 Controlling the Duration of Arbitration Cycles

During each arbitration cycle, the rate of information flow between the SRNs and the ICU can become limited by propagation delays within the TC1798 when it is executing at high system clock frequencies. At high frequencies, arbitration cycles may require two system clocks to execute properly. In order to optimize the arbitration scheme at lower system frequencies, an additional control bit, ICR.CONECYC, is implemented. The default value of 0 of this bit selects two clock cycles per arbitration cycle. Setting this bit to 1 selects one clock cycle per arbitration cycle. The maximum frequency for the ICR.CONECYC=´1´ setting is defined in the product data sheetSetting this bit for system frequencies above the specified limit leads to unpredictable behavior of the interrupt system. Correct operation is then not guaranteed.

16.5 Entering an Interrupt Service Routine

When an interrupt request from the ICU is pending and all conditions are met such that the CPU can now service the interrupt request, the CPU performs the following actions in preparation for entering the designated Interrupt Service Routine (ISR):

1. Upper context of the current task is saved[1]. The current CPU priority number, ICR.CCPN, and the state of the global interrupt enable bit, ICR.IE, are automatically saved with the PCXI register (bit field PCPN and bit PIE).
2. Interrupt system is globally disabled (ICR.IE is set to 0).
3. Current CPU priority number (ICR.CCPN) is set to the value of ICR.PIPN.
4. PSW is set to a default value:
   a) All permissions are enabled, that is, PSW.IO = 10_B.
   b) Memory protection is switched to PRS0, that is, PSW.PRS = 0.
   c) The stack pointer bit is set to the interrupt stack, that is, PSW.IS = 1.
   d) The call depth counter is cleared, the call depth limit is set to 63, that is, PSW.CDC = 0.
5. Stack pointer, A10, is reloaded with the contents of the Interrupt Stack Pointer, ISP, if the PSW.IS bit of the interrupted routine was set to 0 (using the user stack); otherwise it is left unaltered.
6. CPU program counter is assigned with an effective address consisting of the contents of the BIV register OR-ed with the ICR.PIPN number left-shifted by 5. This indexes the Interrupt Vector Table entry corresponding to the interrupt priority.
7. Contents at the effective address of the program counter in the Interrupt Vector Table are fetched as the first instruction of the Interrupt Service Routine (ISR). Execution continues linearly from there until the ISR branches or exits.

1) Note that, if a context-switch trap occurs while the CPU is in the process of saving the upper context of the current task, the pending ISR will not be entered, the interrupt request will be left pending, and the CPU will enter the appropriate trap handling routine instead.

As explained, receipt of further interrupts is disabled (ICR.IE = 0) when an Interrupt Service Routine is entered. At the same time, the current CPU priority ICR.CCPN is set by hardware to the priority of the interrupting source (ICR.PIPN).

Clearly, before the processor can receive any more interrupts, the ISR must eventually re-enable the interrupt system again by setting ICR.IE = 1. Furthermore, the ISR can also modify the priority number ICR.CCPN to allow effective interrupt priority levels. It is up to the user to enable the interrupt system again and optionally modify the priority number CCPN to implement interrupt priority levels or handle special cases.

To simply enable the interrupt system again, the ENABLE instruction can be used, which sets ICR.IE bit to 1. The BISR instruction offers a convenient way to re-enable the interrupt system, to set ICR.CCPN to a new value, and to save the lower context of the interrupted task. It is also possible to use an MTCR instruction to modify ICR.IE and ICR.CCPN. However, this should be performed together with an ISYNC instruction (which synchronizes the instruction stream) to ensure completion of this operation before the execution of following instructions.

Note: The lower context can also be saved through execution of an SVLCX (Save Lower Context) instruction.

16.6 Exiting an Interrupt Service Routine

When an ISR exits with an RFE (Return From Exception) instruction, the hardware automatically restores the upper context. Register PCXI, which holds the Previous CPU Priority Number (PCPN) and the Previous Global Interrupt Enable Bit (PIE), is a part of this upper context. The value saved in PCPN is written to ICR.CCPN to set the CPU priority number to the value before the interruption, and bit PIE is written to ICR.IE to restore the state of this bit. The interrupted routine then continues.

Note: There is no automatic restoring of the lower context on an exit from an Interrupt Service Routine. If the lower context was saved during the execution of the ISR, either through execution of the BISR instruction or an SVLCX instruction, the ISR must restore the lower context again via the RSLCX (Restore Lower Context) instruction before it exits through RFI execution.

16.7 Interrupt Vector Table

Interrupt Service Routines (ISRs) are associated with interrupts at a particular priority by way of the Interrupt Vector Table. The Interrupt Vector Table is an array of ISR entry points.

When the CPU takes an interrupt, it calculates an address in the Interrupt Vector Table that corresponds with the priority of the interrupt (the ICR.PIPN bit field). This address is loaded in the program counter. The CPU begins executing instructions at this address in the Interrupt Vector Table. The code at this address is the start of the selected ISR. Depending on the code size of the ISR, the Interrupt Vector Table may only store the initial portion of the ISR, such as a jump instruction that vectors the CPU to the rest of the ISR elsewhere in memory.

The Interrupt Vector Table is stored in code memory. The BIV register specifies the base address of the Interrupt Vector Table. Interrupt vectors are ordered in the table by increasing priority.

The Base of Interrupt Vector Table register (BIV) stores the base address of the Interrupt Vector Table. It can be assigned to any available code memory. Its default on power-up is fixed at $0000\ 0000_H$. However, the BIV register can be modified using the MTCR instruction during the initialization phase of the system, before interrupts are enabled. With this arrangement, it is possible to have multiple Interrupt Vector Tables and switch between them by changing the contents of the BIV register.

Note: The BIV register is protected by the ENDINIT bit (see chapter describing the watchdog timer). Modifications should only be done while the interrupt system is globally disabled (ICR.IE = 0). Also, an ISYNC instruction should be issued after modifying BIV to ensure completion of this operation before execution of following instructions.

When interrupted, the CPU calculates the entry point of the appropriate ISR from the PIPN and the contents of the BIV register. The PIPN is left-shifted by five bits and OR-ed with the address in the BIV register to generate a pointer into the Interrupt Vector Table. Execution of the ISR begins at this address. Due to this operation, it is recommended that bits [12:5] of register BIV are set to 0 (see **Figure 16-2**). Note that bit 0 of the BIV register is always 0 and cannot be written to (instructions have to be aligned on even byte boundaries).

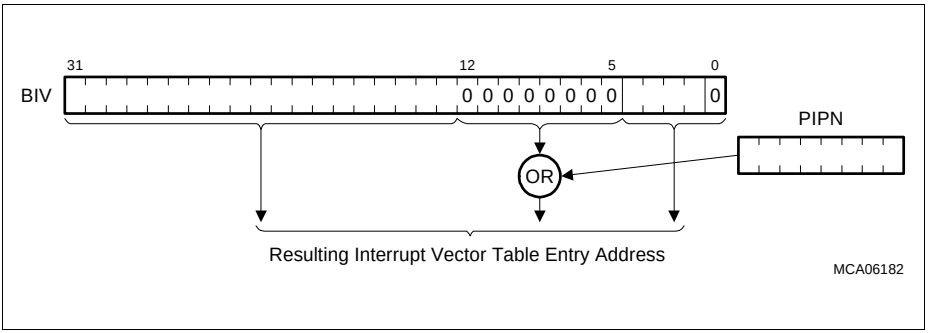

Figure 16-2 Interrupt Vector Table Entry Address Calculation

Left-shifting the PIPN by 5 bits creates entries into the Interrupt Vector Table which are evenly spaced 8 words apart. If an ISR is very short, it may fit entirely within the eight words available in the vector table entry. Otherwise, the code at the entry point must ultimately cause a jump to the rest of the ISR residing elsewhere in memory. Due to the way the vector table is organized according to the interrupt priorities, the TC1798 offers an additional option by allowing spanning several Interrupt Vector Table entries as long as those entries are otherwise unused. **Figure 16-3** illustrates this.

The required size of the Interrupt Vector Table depends only on the range of priority numbers actually used in a system. Of the 256 vector entries, 255 may be used. Vector entry 0 is never used, because if ICR.PIPN is 0, the CPU is not interrupted. Distinct interrupt handlers are supported, but systems requiring fewer entries need not dedicate the full memory area required by the largest configurations.

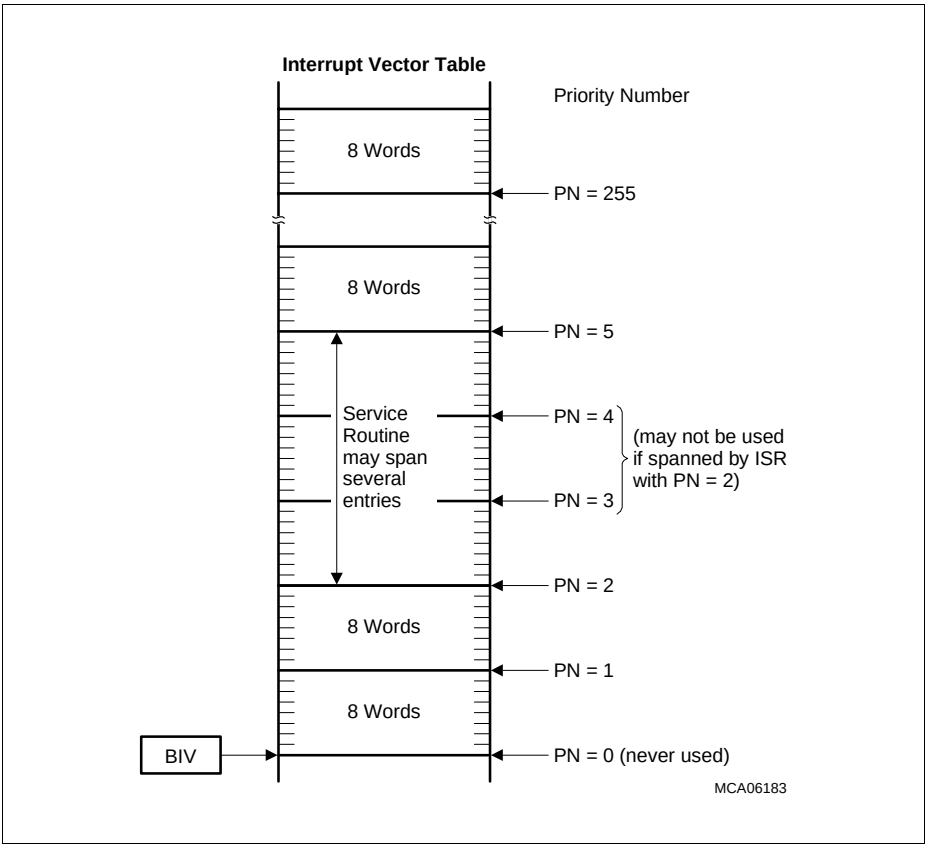

Figure 16-3 Interrupt Vector Table

16.8 Usage of the TC1798 Interrupt System

The following sections provide examples of using the TC1798 interrupt system to solve both typical and special application requirements.

16.8.1 Spanning Interrupt Service Routines Across Vector Entries

Each Interrupt Vector Table entry consists of eight words of memory. If an ISR can be made to fit directly in the Interrupt Vector Table there is no need for a jump instruction to vector to the rest of the interrupt handler elsewhere in memory. However, only the simplest ISRs can fit in the eight words available to a single entry in the table. But it is easy to arrange for ISRs to span across multiple entries, since the Interrupt Vector Table is ordered not by the interrupt source but by interrupt priority. This technique is explained in this section.

In the example of **Figure 16-3**, entry locations 3 and 4 are occupied by the ISR for entry 2. In **Figure 16-3**, the next available entry after entry 2 is entry 5. Of course, if this technique is used, it would be improper to allow any SRN to request service at any of the spanned vector priorities. Thus, priority levels 3 and 4 must not be assigned to SRNs requesting CPU service. They can, however, be used to request PCP service.

There is a performance trade-off that may arise when using this technique because the range of priority numbers used increases. This may have an impact on the number of arbitration cycles required to perform arbitration. Consider the case in which a system uses only three active interrupt sources, that is, where there are only three SRNs enabled to request service. If these three active sources are assigned to priority numbers 1, 2, and 3, it would be sufficient to perform the arbitration in just one cycle. However, if the ISR for interrupt priority 2 is spanned across three Interrupt Vector Table entries as shown in **Figure 16-3**, the priority numbers 1, 2 and 5 would have to be assigned. Thus, two arbitration cycles would have to be used to perform the full arbitration process.

The trade-off between the performance impact of the number of arbitration cycles and the performance gain through spanning service routines can be made by the system designer depending on system needs. Reducing the number of arbitration cycles reduces the service request arbitration latency - spanning service routines reduces the run time of service routines (and therefore also the latency for further interrupts at that priority level or below). For example, if there are multiple fleeting measurements to be made by a system, reducing arbitration latency may be most important. But if keeping total interrupt response time to a minimum is most urgent, spanning Interrupt Vector Table entries may be a solution.

16.8.2 Configuring Ordinary Interrupt Service Routines

When the CPU starts to service an interrupt, the interrupt system is globally disabled and the CPU priority ICR.CCPN is set to the priority of the interrupt now being serviced. This blocks all further interrupts from being serviced until the interrupt system is enabled again.

After an ordinary ISR begins execution, it is usually desirable for the ISR to re-enable global interrupts so that higher-priority interrupts (that is, interrupts that are greater than the current value of ICR.CCPN) can be serviced even during the current ISR's execution. Thus, such an ISR may set ICR.IE = 1 again with, for instance, the ENABLE instruction.

If the ISR enables the interrupt system again by setting ICR.IE = 1 but does not change ICR.CCPN, the effect is that from that point on the hardware can be interrupted by higher-priority interrupts but will be blocked from servicing interrupt requests with the same or lower priority than the current value of bit field ISR.CCPN. Since the current ISR is clearly also at this priority level, the hardware is also blocked from delivering further interrupts to it as well. (This condition is clearly necessary so that the ISR can service the interrupt request automatically.)

When the ISR is finished, it exits with an RFE instruction. Hardware then restores the values of ICR.CCPN and ICR.IE to the values of the interrupted program.

16.8.3 Interrupt Priority Groups

It is sometimes useful to create groups of interrupts at the same or different interrupt priorities that cannot interrupt each other's ISRs. For instance, devices that can generate multiple interrupts may need to have interrupts at different priorities interlocked in this way. The TC1798 interrupt architecture can be used to create such interrupt priority groups. It is effected by managing the current CPU priority level ICR.CCPN in a way described in this section.

For example, in order to make an interrupt priority group out of priority numbers 11 and 12, one would not want an ISR executing at priority 11 to be interrupted by a service request at priority 12, since this would be in the same priority group. Only interrupts above 12 should be allowed to interrupt the ISRs in this interrupt priority group. However, under ordinary ISR usage, the ISR at priority 11 would be interrupted by any request with a higher priority number, including priority 12.

If, however, all ISRs in the interrupt priority group set the value of ICR.CCPN to the highest priority level within their group before they re-enable interrupts, then the desired interlocking will occur.

Figure 16-4 shows an example for interrupt priority grouping. The interrupt requests with the priority numbers 11 and 12 form one group, while the requests with priority numbers 14 through 17 form another group. Each ISR in group 1 sets the value of ICR.CCPN to 12, the highest number in that group, before re-enabling the interrupt system. Each ISR in group 2 sets the value of ICR.CCPN to 17 before re-enabling the interrupt system. If,

for example, interrupt 14 is serviced, it can only be interrupted by requests with a priority number higher than 17; therefore it will not be interrupted by requests from its own priority group or requests with lower priority.

In **Figure 16-4**, the interrupt request with priority number 13 can be said to form an interrupt priority group with just itself as a member.

Setting ICR.CCPN to the maximum value 255 in each service routine has the same effect as not re-enabling the interrupt system; all interrupt requests can then be considered to be in the same group.

Interrupt priority groups demonstrate the power of the TC1798 priority-based interrupt-ordering system. Thus the flexibility of interrupt priority levels ranges from all interrupts in one group to each interrupt request building its own group, and to all possible combinations in between.

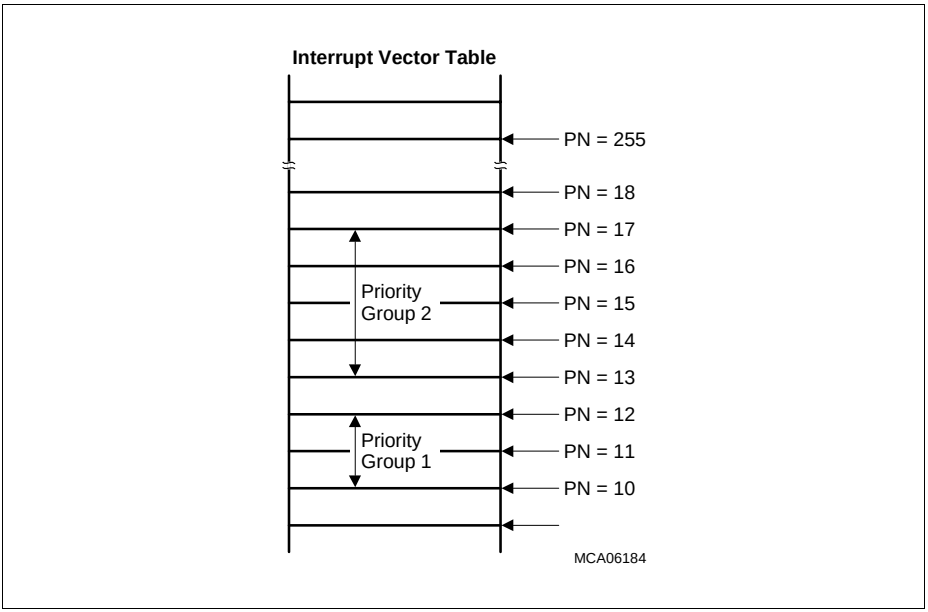

Figure 16-4 Interrupt Priority Groups

16.8.4 Splitting Interrupt Service Across Different Priority Levels

Interrupt service can be divided into multiple ISRs that execute at different priority levels. For example, the beginning stage of interrupt service may be very time-critical, such as reading a data value within a limited time window after the interrupt request activation. However, once the time-critical phase is past, there may still be more to do – for instance,

to process the observation. During this second phase, it may be acceptable for this ISR to be interrupted by lower-level interrupts. This can be performed as follows.

For example, the initial interrupt priority is fixed very high because response time is critical. The necessary actions are carried out immediately by the ISR at that high-priority level. Then the ISR prepares to invoke another ISR at a lower priority level through software to perform the lower-priority actions.

To invoke an ISR through software, the high-priority ISR directly sets an interrupt request bit in an SRN that will invoke the appropriate low-priority ISR. Then the high-priority ISR exits.

When the high-priority ISR exits, the pending low-priority interrupt will eventually be serviced (depending on the priority of other pending interrupts). When the low-priority ISR eventually executes, the low-priority actions of the interrupt will be performed.

The inverse of this method can also be employed, wherein a low-priority ISR raises its own priority level, or leaves interrupts turned off while it executes. For instance, the priority of a service request might be low because the time to respond to the event is not critical, but once it has been granted service, this service should not be interrupted. In this case, the ISR could raise the value of ICR.CCPN to a priority that would exclude some or all other interrupts, or simply leave interrupts disabled.

16.8.5 Using different Priorities for the same Interrupt Source

For some applications, the urgency of a service request may vary, depending on the current state of the system. To handle this, different priority numbers (SRPNs) can be assigned at different times to a service request depending on the application needs.

Of course, Interrupt Service Routines must be placed in the Interrupt Vector Table at all addresses corresponding to the range of priorities used. If service remains the same at different priorities, copies of the ISR can be placed at the possible different entries, or the entries can all vector to a common ISR. If the ISR should execute different code depending on its priority, one need merely put the appropriate ISR in the appropriate entry of the Interrupt Vector Table.

This flexibility is another advantage of the TC1798 interrupt architecture. In traditional interrupt systems where the interrupt vectors are ordered by interrupting source, the ISR would have to check the current priority of the interrupt request and perform a branch to the appropriate code section, causing a delay in the response to the request. In the TC1798, however, the extra check and branch in the ISR are not necessary, hence reduces the interrupt latency.

Because this approach may necessitate an increase in the range of interrupt priorities, the system designer must trade off this advantage against any possible increase in the number of arbitration cycles.

16.8.6 Interrupt Priority 1

Interrupt Priority 1 is the first and lowest-priority entry in the Interrupt Vector Table. It is generally reserved for ISRs which perform task management. ISRs whose actions cause software-managed tasks to be created post a software interrupt request at priority level 1 to signal the event.

The ISR that triggers this event can then execute a normal return from interrupt. There is no need for it to check whether the ISR is returning to the background-task priority level (priority 0) or is returning to a lower-priority ISR that it interrupted. When there is a pending interrupt at a priority higher than the return context for the current interrupt, this interrupt will then be serviced. When a return to the background-task priority level (level 0) is performed, the software-posted interrupt at priority level 1 will be serviced automatically.

16.8.7 Software-Initiated Interrupts

Software can set the service request bit (SRR) in a SRN by writing to its Service Request Control Register. Thus, software can initiate interrupts that are handled by the same mechanism as hardware interrupts.

After the SRR bit is set in an active SRN, there is no way to distinguish between a software-initiated interrupt request and a hardware interrupt request. For this reason, software should only use SRNs and interrupt priority numbers that are not being used for hardware interrupts.

The TC1798 contains four SRNs that support software-initiated interrupts. These SRNs are not connected to peripheral modules and can only cause interrupts when software sets its SRR bit. These SRNs are called the CPU Service Request Nodes (CPU_SRC[3:0]). The PCP can also cause these four SRNs to generate service requests. See also the TriCore chapter for TC1798-specific implementation details of the four CPU Service Request Control Registers.

Additionally, any otherwise unused SRN can be employed to generate software interrupts.

16.8.8 External Interrupts

Four SRNs (SCU_SRC[3:0]) are reserved to handle external interrupts. The setup for external GPIO port input signals (edge/level triggering, gating etc.) that are able to generate an interrupt request is controlled in the External Request Unit (ERU). The ERU functionality is described in detail in the SCU chapter.

16.9 Service Request Node Table

Table 16-2 shows all TC1798 Service Request Nodes.

Table 16-2 Service Request Nodes in the TC1798

Module	No. of Nodes	Description	SRC Register

1) These service request registers are not bit-addressable because its register address is outside the first 16 Kbyte of a segment.

17 System Timer (STM)

This chapter describes the System Timer (STM). The TC1798's STM is designed for global system timing applications requiring both high precision and long period.

17.1 Overview

The STM has the following features:

- Free-running 56-bit counter
- All 56 bits can be read synchronously
- Different 32-bit portions of the 56-bit counter can be read synchronously
- Flexible service request generation based on compare match with partial STM content
- Counting starts automatically after a reset operation
- STM registers are reset by an application reset if bit ARSTDIS.STMDIS is cleared. If bit ARSTDIS.STMDIS is set, the STM registers are not reset.[1)]
- STM can be halted in debug/suspend mode (via STM_CLC register)

Special STM register semantics provide synchronous views of the entire 56-bit counter, or 32-bit subsets at different levels of resolution.

The maximum timer period is $2^{56} \times f_{STM}$. At f_{STM} = 50 MHz, for example, the STM counts 46.85 years before overflowing. Thus, it is capable of continuously timing the entire expected product life time of a system without overflowing.

17.2 Operation

The STM is an upward counter, running either at the FPI-Bus frequency f_{FPI} or at a fraction of it. The STM clock frequency is $f_{STM} = f_{FPI}$/RMC with RMC = 0-7 (default after reset is $f_{STM} = f_{FPI}/2$, selected by RMC = 010_B). RMC is a bit field in register STM_CLC. In case of an application reset, the STM is reset if bit SCU_ARSTDIS.DIS0 is set. After reset, the STM is enabled and immediately starts counting up. It is not possible to affect the content of the timer during normal operation of the TC1798. The timer registers can only be read but not written to.

The STM can be optionally disabled for power-saving purposes, or suspended for debugging purposes via its clock control register. In suspend mode of the TC1798 (initiated by writing an appropriate value to STM_CLC register), the STM clock is stopped but all registers are still readable.

Due to the 56-bit width of the STM, it is not possible to read its entire content with one instruction. It needs to be read with two load instructions. Since the timer would continue to count between the two load operations, there is a chance that the two values read are not consistent (due to possible overflow from the low part of the timer to the high part

1) "STM registers" means all registers except STM_CLC, STM_SRC0, and STM_SRC1.

between the two read operations). To enable a synchronous and consistent reading of the STM content, a capture register (STM_CAP) is implemented. It latches the content of the high part of the STM each time when one of the registers STM_TIM0 to STM_TIM5 is read. Thus, STM_CAP holds the upper value of the timer at exactly the same time when the lower part is read. The second read operation would then read the content of the STM_CAP to get the complete timer value.

The STM can also be read in sections from seven registers, STM_TIM0 through STM_TIM6, that select increasingly higher-order 32-bit ranges of the STM. These can be viewed as individual 32-bit timers, each with a different resolution and timing range.

The content of the 56-bit System Timer can be compared against the content of two compare values stored in the STM_CMP0 and STM_CMP1 registers. Service requests can be generated on a compare match of the STM with the STM_CMP0 or STM_CMP1 registers.

Figure 17-1 provides an overview on the STM module. It shows the options for reading parts of the STM content.

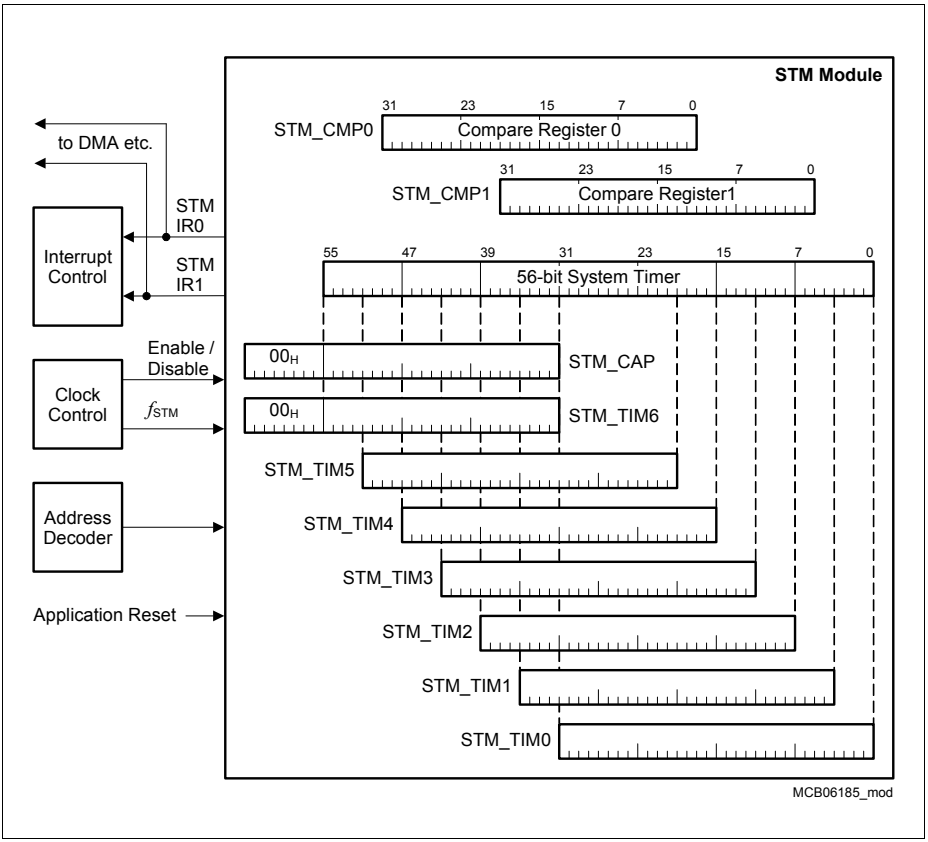

Figure 17-1 General Block Diagram of the STM Module Registers

17.2.1 Resolution and Ranges

Table 17-1 is an overview on the individual timer registers with their resolutions and timing ranges. As an example, the values for 75 MHz STM input clock frequency f_{STM} are given.

Table 17-1 System Timer Resolutions and Ranges

Register	STM Bits	Resolution [s]	Range [s]	Resolution	Range	f_{STM} [MHz]
STM_TIM0	[31:0]	1 / f_{STM}	2^{32} / f_{STM}	13.3 ns	57.3 s	75
STM_TIM1	[35:4]	16 / f_{STM}	2^{36} / f_{STM}	213 ns	916.2 s	
STM_TIM2	[39:8]	256 / f_{STM}	2^{40} / f_{STM}	3.41 µs	244.3 min	
STM_TIM3	[43:12]	4096 / f_{STM}	2^{44} / f_{STM}	54.6 µs	65.1 h	
STM_TIM4	[47:16]	65536 / f_{STM}	2^{48} / f_{STM}	0.874 ms	43.44 days	
STM_TIM5	[51:20]	2^{20} / f_{STM}	2^{52} / f_{STM}	13.98 ms	1.90 yr	
STM_TIM6	[55:32]	2^{32} / f_{STM}	2^{56} / f_{STM}	57.3 s	30.47 yr	
STM_CAP	[55:32]	2^{32} / f_{STM}	2^{56} / f_{STM}	57.3 s	30.47 yr	

17.2.2 Compare Register Operation

The content of the 56-bit STM can be compared against the content of two compare values stored in the STM_CMP0 and STM_CMP1 registers. Service requests can be generated on a compare match of the STM with the STM_CMP0 or STM_CMP1 registers.

Two parameters are programmable for the compare operation:

1. The width of the relevant bits in registers STM_CMP0/STM_CMP1 (compare width MSIZEx) that is taken for the compare operation can be programmed from 1 to 32.
2. The first bit location in the 56-bit STM that is taken for the compare operation can be programmed from 0 to 24.

These programming capabilities make compare functionality very flexible. It even makes it possible to detect bit transitions of a single bit n (n = 0 to 24) within the 56-bit STM by setting MSIZE = 0 and MSTART = n.

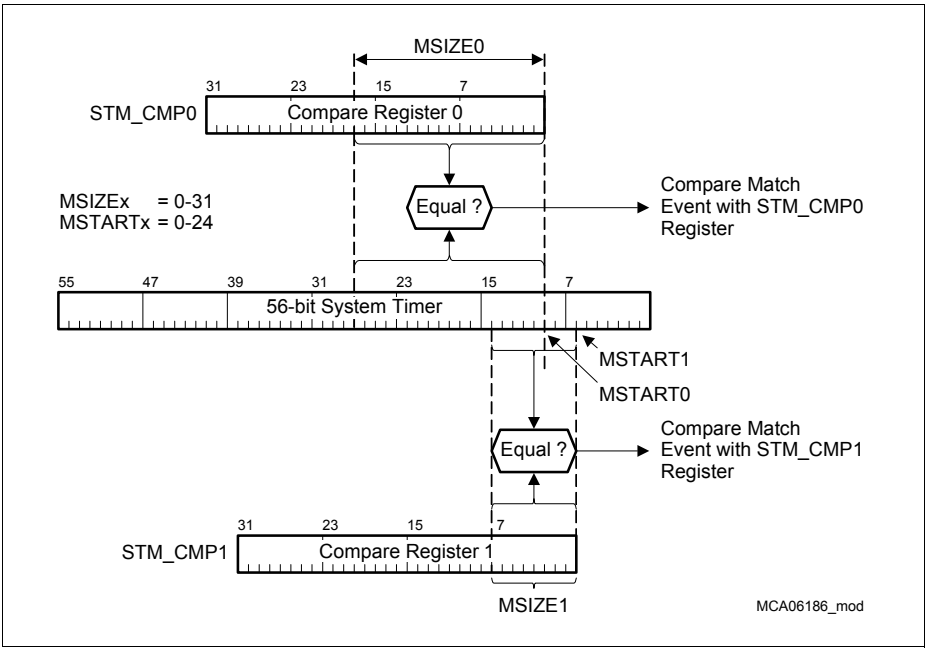

Figure 17-2 Compare Mode Operation

Figure 17-2 shows an example of the compare operation. In this example the following parameters are programmed:

- MSIZE0 = $10001_B = 17_D$; MSTART0 = $01010_B = 9_D$
- MSIZE1 = $00111_B = 7_D$; MSTART1 = $00111_B = 6_D$

A compare operation with MSIZE not equal 0 always implies that the compared value as stored in the CMP register is right-extended with zeros. This means that in the example of **Figure 17-2**, the compare register content STM_CMP0[17:0] plus nine zero bits right-extended is compared with STM[27:0] with STM[8:0] = 000_H. In case of register STM_CMP1, STM[14:0] with STM[5:0] = 00_H are compared with STM_CMP1[8:0] plus six zero bits right-extended.

17.2.3 Compare Match Interrupt Control

The compare match interrupt control logic is shown in **Figure 17-3**. Each STM_CMPx register has its compare match interrupt request flag (STM_ICR.CMPxIR) that is set by hardware on a compare match event. The interrupt request flags can be set (STM_ISSR.CMPxIRS) or cleared (STM_ISSR.CMPxIRR) by software. Note that setting STM_ICR.CMPxIR by writing a 1 into STM_ISSR.CMPxIRS does not generate an interrupt at STMIRx. The compare match interrupts from CMP0 and CMP1 can be further directed by STM_ICR.CMPxOS to either output signal STMIR0 or STMIR1. The STMIR0 and STMIR1 outputs are each connected to interrupt service request control registers, STM_SRC0 and STM_SCR1, respectively.

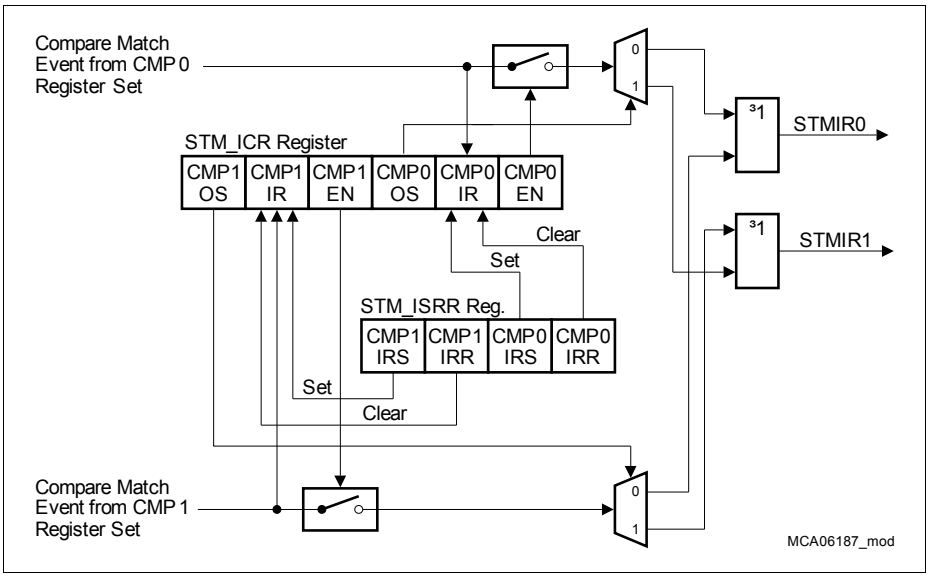

Figure 17-3 STM Interrupt Control

The compare match interrupt flags STM_ICR.CMPxIR are immediately set after an STM reset operation, caused by a compare match event with the reset values of the STM and the compare registers STM_CMPx. This setting of the CMPxIR flags does not directly

generate compare match interrupts because the compare match interrupts are automatically disabled after a STM reset operation (CMPxEN = 0). Therefore, before enabling a compare match interrupt after a STM reset operation, the CMPxIR flags should be cleared by software (writing register STM_ISSR with CMPxIRR set). Otherwise, undesired compare match interrupt events are triggered. Details about DMA connections of STMIR0 and STMIR1 are given in **Table 17-4** on **Page 17-21**.

17.3 STM Registers

This section describes the STM registers of the STM. The STM registers can be divided into four types, as shown in **Figure 17-4**.

STM Registers Overview

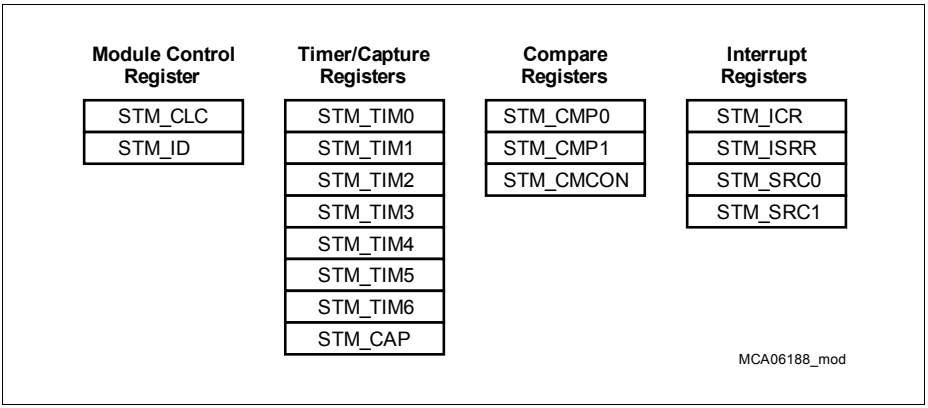

Figure 17-4 STM Registers

In TC1798 all registers are readable is suspend mode. The complete and detailed address map of the STM module with its registers is shown in **Table 17-5** on **Page 17-22**.

Table 17-2 Registers Address Space

Module	Base Address	End Address	Note
STM	$F000\ 0200_H$	$F000\ 02FF_H$	-

Table 17-3 Registers Overview - STM Registers

Register Short Name	Register Long Name	Offset Address	Description see
STM_CLC[1)]	STM Clock Control Register	00_H	Page 17-9
STM_ID	STM Module Identification Register	08_H	Page 17-10
STM_TIM0	STM Timer Register 0	10_H	Page 17-11
STM_TIM1	STM Timer Register 1	14_H	Page 17-11
STM_TIM2	STM Timer Register 2	18_H	Page 17-12
STM_TIM3	STM Timer Register 3	$1C_H$	Page 17-12
STM_TIM4	STM Timer Register 4	20_H	Page 17-12
STM_TIM5	STM Timer Register 5	24_H	Page 17-13
STM_TIM6	STM Timer Register 6	28_H	Page 17-13
STM_CAP	STM Timer Capture Register	$2C_H$	Page 17-14

STM_SRC0[1)]	STM Service Request Control Register 0	FC_H	Page 17-20

1) These registers are reset by an application reset if bit ARSTDIS.STMDIS is set.

17.3.1 Clock Control Register

The STM clock control register is used to switch the STM on or off and to control its input clock rate. After a power-on reset, the STM is always enabled and starts counting. The STM can be disabled by setting bit DISR to 1.

STM_CLC
STM Clock Control Register **(00_H)** **Reset Value: $0000\ 0200_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

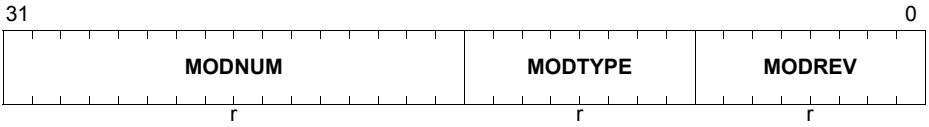
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0					RMC			0		FSOE	SBWE	EDIS	SPEN	DISS	DISR
r					rw			r		rw	w	rw	rw	r	rw

Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the STM module. 0_B No disable requested 1_B Disable requested
DISS	1	r	**Module Disable Status Bit** Bit indicates the current status of the STM module. 0_B STM module is enabled 1_B STM module is disabled
SPEN	2	rw	**Module Suspend Enable for OCDS** Used for enabling the suspend mode.
EDIS	3	rw	**Sleep Mode Enable Control** Used for module sleep mode control.
SBWE	4	w	**Module Suspend Bit Write Enable for OCDS** Determines whether SPEN and FSOE are write-protected.
FSOE	5	rw	**Fast Switch Off Enable** Used for fast clock switch off in OCDS suspend mode.

Field	Bits	Type	Description
RMC	[10:8]	rw	**Clock Divider in Run Mode** 000_B No clock signal f_{STM} generated 001_B Clock signal $f_{STM} = f_{FPI}$ selected 010_B Clock signal f_{STM} / 2 selected (default after reset) 011_B Clock signal f_{STM} / 3 selected ... 111_B Clock signal f_{STM} / 7 selected
0	[7:6], [31:11]	r	**Reserved** Read as 0; should be written with 0.

The STM Module Identification Register ID contains read-only information about the module version.

STM_ID
STM Module Identification Register (08_H) **Reset Value: 0000 C0XX$_H$**

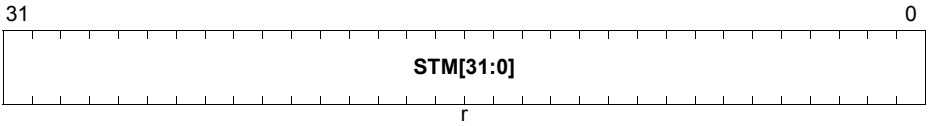


Field	Bits	Type	Description
MODREV	[7:0]	r	**Module Revision Number** MODREV defines the module revision number. The value of a module revision starts with 01_H (first revision).
MODTYPE	[15:8]	r	**Module Type** This bit field defines the module as a 32-bit module: $C0_H$
MODNUM	[31:16]	r	**Module Number Value** This bit field defines the module identification number for the STM: 0000_H

17.3.2 Timer/Capture Registers

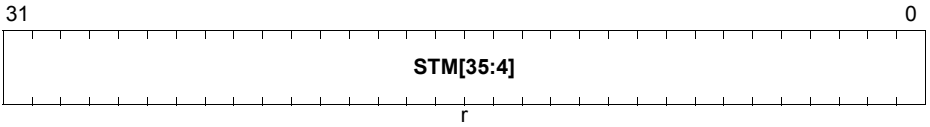
Registers STM_TIM1 to STM_TIM6 provide 32-bit views at varying resolutions of the underlying STM counter.

STM_TIM0
STM Timer Register 0 **(10_H)** **Reset Value: 0000 0000$_H$**



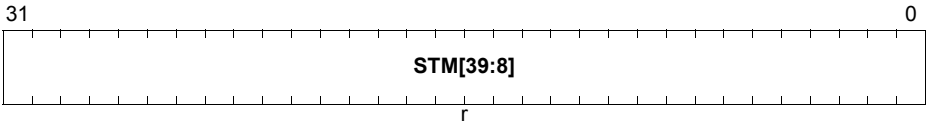
Field	Bits	Type	Description
STM[31:0]	[31:0]	r	**System Timer Bits [31:0]** This bit field contains bits [31:0] of the 56-bit STM.

STM_TIM1
STM Timer Register 1 **(14_H)** **Reset Value: 0000 0000$_H$**



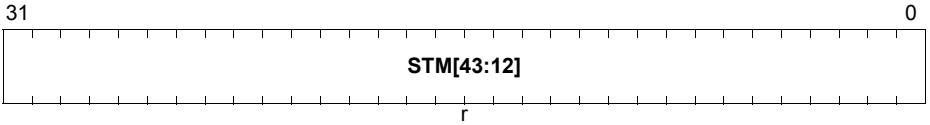
Field	Bits	Type	Description
STM[35:4]	[31:0]	r	**System Timer Bits [35:4]** This bit field contains bits [35:4] of the 56-bit STM.

STM_TIM2
STM Timer Register 2 **(18_H)** **Reset Value: 0000 0000$_H$**



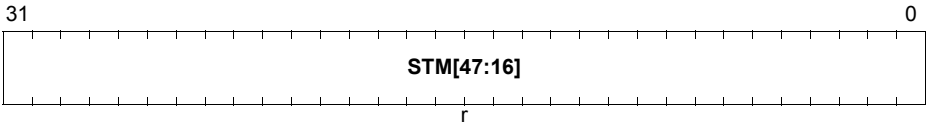
Field	Bits	Type	Description
STM[39:8]	[31:0]	r	**System Timer Bits [39:8]** This bit field contains bits [39:8] of the 56-bit STM.

STM_TIM3
STM Timer Register 3 **($1C_H$)** **Reset Value: 0000 0000$_H$**



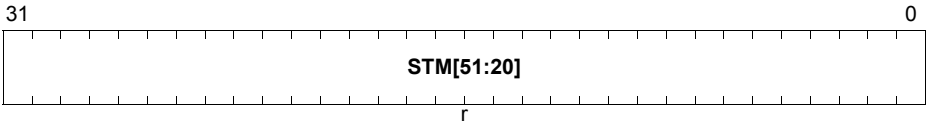
Field	Bits	Type	Description
STM[43:12]	[31:0]	r	**System Timer Bits [43:12]** This bit field contains bits [43:12] of the 56-bit STM.

STM_TIM4
STM Timer Register 4 **(20_H)** **Reset Value: 0000 0000$_H$**



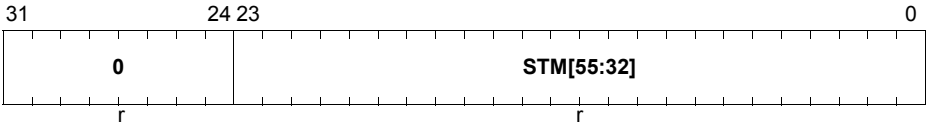
Field	Bits	Type	Description
STM[47:16]	[31:0]	r	**System Timer Bits [47:16]** This bit field contains bits [47:16] of the 56-bit STM.

STM_TIM5
STM Timer Register 5 **(24_H)** **Reset Value: 0000 0000$_H$**



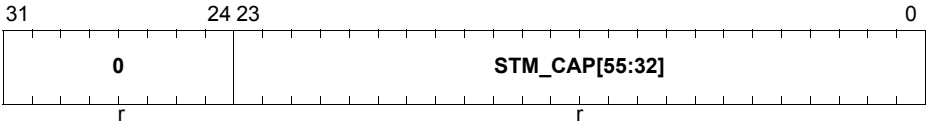
Field	Bits	Type	Description
STM[51:20]	[31:0]	r	**System Timer Bits [51:20]** This bit field contains bits [51:20] of the 56-bit STM.

STM_TIM6
STM Timer Register 6 **(28_H)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
STM[55:32]	[23:0]	r	**System Timer Bits [55:32]** This bit field contains bits [55:32] of the 56-bit STM.
0	[31:24]	r	**Reserved** Read as 0.

STM_CAP
STM Timer Capture Register **($2C_H$)** **Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
