

1.8V Serial Quad I/O (SQI) Flash Memory

SST26WF032

Advance Information

The SST26WF032 Serial Quad I/O™ (SQI™) flash device utilizes a 4-bit multiplexed I/O serial interface to boost performance while maintaining the compact form factor of standard serial flash devices. Operating at frequencies reaching 80 MHz, the SST26WF032 enables minimum latency execute-in-place (XIP) capability without the need for code shadowing on an SRAM. The device's high performance and small footprint make it the ideal choice for mobile handsets, Bluetooth headsets, optical disk drives, GPS applications and other portable electronic products. Further benefits are achieved with SST's proprietary, high-performance CMOS SuperFlash® technology, which significantly improves performance and reliability, and lowers power consumption for high bandwidth, compact designs.

Features:

- **Single Voltage Read and Write Operations**
 - 1.65-1.95V
- **Serial Interface Architecture**
 - Nibble-wide multiplexed I/O's with SPI-like serial command structure
 - Mode 0 and Mode 3
 - Single-bit, SPI backwards compatible
 - Read, High-Speed Read, and JEDEC ID Read
- **High Speed Clock Frequency**
 - 80 MHz
 - 320 Mbit/s sustained data rate
- **Burst Modes**
 - Continuous linear burst
 - 8/16/32/64 Byte linear burst with wrap-around
- **Superior Reliability**
 - Endurance: 100,000 Cycles
 - Greater than 100 years Data Retention
- **Low Power Consumption:**
 - Active Read current: 12 mA (typical @ 80 MHz)
 - Standby Current: 8 µA (typical)
- **Fast Erase and Byte-Program:**
 - Chip-Erase time: 35 ms (typical)
 - Sector-/Block-Erase time: 18 ms (typical)
- **Page-Program**
 - 256 Bytes per page
 - Fast Page Program time in 1 ms (typical)
- **End-of-Write Detection**
 - Software polling the BUSY bit in status register
- **Flexible Erase Capability**
 - Uniform 4 KByte sectors
 - Four 8 KByte top and bottom parameter overlay blocks
 - Two 32 KByte top and bottom overlay blocks
 - Uniform 64 KByte overlay blocks
 - SST26WF032 – 62 blocks
- **Write-Suspend**
 - Suspend Program or Erase operation to access another block/sector
- **Software Reset (RST) mode**
- **Software Write Protection**
 - Individual Block-Locking
 - 64 KByte blocks, two 32 KByte blocks, and eight 8 KByte parameter blocks
 - Write Lock, Read Lock, and Lockdown options
- **Security ID**
 - One-Time Programmable (OTP) 256 bit, Secure ID
 - 64 bit unique, factory pre-programmed identifier
 - 192 bit user-programmable
- **Temperature Range**
 - Industrial: -40°C to +85°C
- **Packages Available**
 - 8-contact WSON (6mm x 5mm)
 - 8-lead SOIC (200 mil)
- **All devices are RoHS compliant**

1.8V Serial Quad I/O (SQI) Flash Memory

SST26WF032

Advance Information

Product Description

The Serial Quad I/O™ (SQI™) family of flash-memory devices features a 4-bit, multiplexed I/O interface that allows for low-power, high-performance operation in a low pin-count package. System designs using SQI flash devices occupy less board space and ultimately lower system costs.

All members of the 26 Series, SQI family are manufactured with SST proprietary, high-performance CMOS SuperFlash® technology. The split-gate cell design and thick-oxide tunneling injector attain better reliability and manufacturability compared with alternate approaches.

The SST26WF032 significantly improves performance and reliability, while lowering power consumption. This device writes (Program or Erase) with a single power supply of 1.65-1.95V. The total energy consumed is a function of the applied voltage, current, and time of application. Since for any given voltage range, the SuperFlash technology uses less current to program and has a shorter erase time, the total energy consumed during any Erase or Program operation is less than alternative flash memory technologies.

SST26WF032 is offered in both 8-contact WSON (6 mm x 5 mm), and 8-lead SOIC (200 mil) packages. See Figure 2 for pin assignments.

Block Diagram

Figure 1: Functional Block Diagram

Pin Description

Figure 2: Pin Description for 8-lead SOIC and 8-contact WSON

Table 1: Pin Description

Symbol	Pin Name	Functions
SCK	Serial Clock	To provide the timing of the serial interface. Commands, addresses, or input data are latched on the rising edge of the clock input, while output data is shifted out on the falling edge of the clock input.
SIO[3:0]	Serial Data Input/Output	To transfer commands, addresses, or data serially into the device or data out of the device. Inputs are latched on the rising edge of the serial clock. Data is shifted out on the falling edge of the serial clock. The EQIO command instruction configures these pins for Quad I/O mode.
SI	Serial Data Input for SPI mode	To transfer commands, addresses or data serially into the device. Inputs are latched on the rising edge of the serial clock. SI is the default state after a power on reset.
SO	Serial Data Output for SPI mode	To transfer data serially out of the device. Data is shifted out on the falling edge of the serial clock. SO is the default state after a power on reset.
CE#	Chip Enable	The device is enabled by a high to low transition on CE#. CE# must remain low for the duration of any command sequence; or in the case of Write operations, for the command/data input sequence.
V _{DD}	Power Supply	To provide power supply voltage: 1.65-1.95V
V _{SS}	Ground	

T1.0 1409

1.8V Serial Quad I/O (SQI) Flash Memory

SST26WF032

Advance Information

Memory Organization

The SST26WF032 SQI memory array is organized in uniform, 4 KByte erasable sectors with erasable overlay blocks: eight 8 KByte parameter blocks, two 32 KByte blocks, and sixty-two 64 KByte blocks. See Figure 3.

Figure 3: Memory Map

Device Operation

The SST26WF032 supports both Serial Peripheral Interface (SPI) bus protocol and the new 4-bit multiplexed Serial Quad I/O (SQI) bus protocol. To provide backward compatibility to traditional SPI Serial Flash devices, the device's initial state after a power-on reset is SPI bus protocol supporting only Read, High Speed Read, and JEDEC-ID Read instructions. A command instruction configures the device to Serial Quad I/O bus protocol. The dataflow in this bus protocol is controlled with four multiplexed I/O signals, a chip enable (CE#), and serial clock (SCK).

SQI Flash Memory protocol supports both Mode 0 (0,0) and Mode 3 (1,1) bus operations. The difference between the two modes, as shown in Figures 4 and 5, is the state of the SCK signal when the bus master is in Stand-by mode and no data is being transferred. The SCK signal is low for Mode 0 and SCK signal is high for Mode 3. For both modes, the Serial Data I/O (SIO[3:0]) is sampled at the rising edge of the SCK clock signal for input, and driven after the falling edge of the SCK clock signal for output. The traditional SPI protocol uses separate input (SI) and output (SO) data signals as shown in Figure 4. The SST26WF032 uses four multiplexed signals, SIO[3:0], for both data in and data out, as shown in Figure 5. This quadruples the traditional bus transfer speed at the same clock frequency, without the need for more pins on the package.

Figure 5: SQI Serial Quad I/O Protocol

1.8V Serial Quad I/O (SQI) Flash Memory

SST26WF032

Advance Information

Device Protection

The SST26WF032 has a Block-Protection register which provides a software mechanism to write-lock the array and write-lock, and/or read-lock, the parameter blocks. The Block-Protection Register is 80 bits wide per device: two bits each for the eight 8 KByte parameter blocks (write-lock and read-lock), and one bit each for the remaining 32 KByte and 64 KByte overlay blocks (write-lock). See Table 8 for address range protected per register bit.

Each bit in the Block-Protection Register can be written to a '1' (protected) or '0' (unprotected). For the parameter blocks, the most significant bit is for read-lock, and the least significant bit is for write-lock. Read-locking the parameter blocks provides additional security for sensitive data after retrieval (e.g., after initial boot). If a block is read-locked all reads to the block return data 00H. All blocks are write-locked and read-unlocked after power-up. The Write Block Locking Register command is a two cycle command requiring Write-Enable (WREN) to be executed prior to the Write Block-Protection Register command.

Figure 6: Block Locking Memory Map

1.8V Serial Quad I/O (SQI) Flash Memory

SST26WF032

Advance Information

Write-Protection Lock-Down

To prevent changes, the Block-Protection register can be set to Write-Protection Lock-Down using the Lock Down Block Protection Register (LPBR) command. Once the Write-Protection Lock-Down is enabled, the Block-Protection register can not be changed. To avoid inadvertent lock down, the WREN command must be executed prior to the LBPR command.

To reset Write-Protection Lock-Down, power cycle the device. The Write-Protection Lock-Down status may be read from the Status register.

Security ID

SST26WF032 offers a 256-bit Security ID (Sec ID) feature. The Security ID space is divided into two parts – one factory-programmed, 64-bit segment and one user-programmable 192-bit segment. The factory-programmed segment is programmed at SST with a unique number and cannot be changed. The user-programmable segment is left unprogrammed for the customer to program as desired.

Use the SecID Program command to program the Security ID using the address shown in Table 7. Once programmed, the Security ID can be locked using the Lockout Sec ID command. This prevents any future write to the Security ID.

The factory-programmed portion of the Security ID can't be programmed by the user; neither factory-programmed nor user-programmable areas can be erased.

1.8V Serial Quad I/O (SQI) Flash Memory

SST26WF032

Advance Information

Status Register

The Status register is a read-only register that provides status on whether the flash memory array is available for any Read or Write operation, whether the device is Write enabled, and whether an erase or program operation is suspended. During an internal Erase or Program operation, the Status register may be read to determine the completion of an operation in progress. Table 2 describes the function of each bit in the Status register.

Table 2: Status Register

Bit	Name	Function	Default at Power-up
0	RES	Reserved for future use	0
1	WEL	Write-Enable Latch status 1 = Device is memory Write enabled 0 = Device is not memory Write enabled	0
2	WSE	Write Suspend-Erase status 1 = Erase suspended 0 = Erase is not suspended	0
3	WSP	Write Suspend-Program status 1 = Program suspended 0 = Program is not suspended	0
4	WPLD	Write Protection Lock-Down status 1 = Write Protection Lock-Down enabled 0 = Write Protection Lock-Down disabled	0
5	SEC ¹	Security ID status 1 = Security ID space locked 0 = Security ID space not locked	0 ¹
6	RES	Reserved for future use	0
7	BUSY	Write operation status 1 = Internal Write operation is in progress 0 = No internal Write operation is in progress	0

T2.0 1409

1. The Security ID status will always be '1' at power-up after a successful execution of the Lockout Sec ID instruction, otherwise default at power-up is '0'.

Write-Enable Latch (WEL)

The Write-Enable Latch (WEL) bit indicates the status of the internal memory's Write-Enable Latch. If the WEL bit is set to '1', the device is write enabled. If the bit is set to '0' (reset), the device is not write enabled and does not accept any memory Program or Erase, Protection Register Write, or Lock-Down commands. The Write-Enable Latch bit is automatically reset under the following conditions:

- Power-up
- Reset
- Write-Disable (WRDI) instruction completion
- Page-Program instruction completion
- Sector-Erase instruction completion
- Block-Erase instruction completion
- Chip-Erase instruction completion
- Write-Block-Protection register instruction
- Lock-Down Block-Protection register instruction
- Program Security ID instruction completion
- Lockout Security ID instruction completion
- Write-Suspend instruction

Write Suspend Erase Status (WSE)

The Write Suspend-Erase Status (WSE) indicates when an Erase operation has been suspended. The WSE bit is '1' after the host issues a suspend command during an Erase operation. Once the suspended Erase resumes, the WSE bit is reset to '0.'

Write Suspend Program Status (WSP)

The Write Suspend-Program Status (WSP) bit indicates when a Program operation has been suspended. The WSP is '1' after the host issues a suspend command during the Program operation. Once the suspended Program resumes, the WSP bit is reset to '0.'

Write Protection Lockdown Status (WPLD)

The Write Protection-Lockdown Status (WPLD) bit indicates when the Block Protection register is locked-down to prevent changes to the protection settings. The WPLD is '1' after the host issues a Lock-Down Block Protection command. After a power cycle, the WPLD bit is reset to '0.'

Security ID Status (SEC)

The Security ID Status (SEC) bit indicates when the Security ID space is locked to prevent a Write command. The SEC is '1' after the host issues a Lockout SID command. Once the host issues a Lock-out SID command, the SEC bit can never be reset to '0.'

Busy

The Busy bit determines whether there is an internal Erase or Program operation in progress. If the BUSY bit is '1', the device is busy with an internal Erase or Program operation. If the bit is '0', no Erase or Program operation is in progress.

1.8V Serial Quad I/O (SQI) Flash Memory

SST26WF032

Advance Information

Instructions

Instructions are used to read, write (erase and program), and configure the SST26WF032. The instruction bus cycles are two nibbles each for commands (Op Code), data, and addresses. Prior to executing any write instructions, the Write-Enable (WREN) instruction must be executed. The complete list of the instructions is provided in Table 3.

All instructions are synchronized off a high to low transition of CE#. Inputs are accepted on the rising edge of SCK starting with the most significant nibble. CE# must be driven low before an instruction is entered and must be driven high after the last nibble of the instruction has been input (except for read instructions). Any low-to-high transition on CE# before receiving the last nibble of an instruction bus cycle, will terminate the instruction being entered and return the device to the standby mode.

Table 3: Device Operation Instructions for SST26WF032

Instruction	Description	Command Cycle ¹	Address Cycle(s) ²	Dummy Cycle(s)	Data Cycle(s)	Maximum Frequency
NOP	No Operation	00H	0	0	0	80 MHz
RSTEN	Reset Enable	66H	0	0	0	
RST ³	Reset Memory	99H	0	0	0	
EQIO	Enable Quad I/O	38H	0	0	0	
RSTQIO ⁴	Reset Quad I/O	FFH	0	0	0	
Read ⁵	Read Memory	03H	3	0	1 to ∞	25 MHz
High-Speed Read ⁵	Read Memory at Higher Speed	0BH	3	2	1 to ∞	80 MHz
Set Burst ⁶	Set Burst Length	C0H	0	0	1	
Read Burst	nB Burst with Wrap	0CH	3	2	n to ∞	
JEDEC-ID ^{5,7}	JEDEC-ID Read	9FH	0	0	3 to ∞	
Quad J-ID ⁷	Quad I/O J-ID Read	AFH	0	0	3 to ∞	
Sector Erase ⁸	Erase 4 KBytes of Memory Array	20H	3	0	0	
Block Erase ⁹	Erase 64, 32 or 8 KBytes of Memory Array	D8H	3	0	0	
Chip Erase	Erase Full Array	C7H	0	0	0	
Page Program	Program 1 to 256 Data Bytes	02H	3	0	1 to 256	
Write Suspend	Suspends Program/ Erase	B0H	0	0	0	
Write Resume	Resumes Program/ Erase	30H	0	0	0	
Read SID	Read Security ID	88H	1	2	1 to 32	
Program SID ¹⁰	Program User Security ID area	A5H	1	0	1 to 24	
Lockout SID ¹⁰	Lockout Security ID Programming	85H	0	0	0	
RDSR ¹¹	Read Status Register	05H	0	0	1 to ∞	
WREN	Write Enable	06H	0	0	0

Advance Information

Table 3: Device Operation Instructions for SST26WF032

Instruction	Description	Command Cycle ¹	Address Cycle(s) ²	Dummy Cycle(s)	Data Cycle(s)	Maximum Frequency
WRDI	Write Disable	04H	0	0	0	80 MHz
RBPR ¹²	Read Block Protection Register	72H	0	0	1 to m/4	
WBPR ^{10,12}	Write Block Protection Register	42H	0	0	1 to m/4	
LBPR ¹⁰	Lock Down Block Protection Register	8DH	0	0	0	

T3.0 1409

1. One BUS cycle is two clock periods (command, access, or data).
2. Address bits above the most significant bit of each density can be V_{IL} or V_{IH} .
3. RST command only executed if RSTEN command is executed first. Any intervening command will disable Reset.
4. Device accepts eight-clock command in SPI mode, or two-clock command in SQI mode.
5. After a power cycle, Read, High-Speed Read, and JEDEC-ID Read instructions input and output cycles are SPI bus protocol.
6. Burst length— n = 8 Bytes: Data(00H); n = 16 Bytes: Data(01H); n = 32 Bytes: Data(02H); n = 64 Bytes: Data(03H).
7. The Quad J-ID read wraps the three Quad J-ID Bytes of data until terminated by a low-to-high transition on CE#
8. Sector Addresses: Use $A_{MS} - A_{12}$, remaining address are don't care, but must be set to V_{IL} or V_{IH} .
9. Blocks are 64 KByte, 32 KByte, or 8KByte, depending on location. Block Erase Address: $A_{MS} - A_{16}$ for 64 KByte; $A_{MS} - A_{15}$ for 32 KByte; $A_{MS} - A_{13}$ for 8 KByte. Remaining addresses are don't care, but must be set to V_{IL} or V_{IH} .
10. Requires a prior WREN command.
11. The Read-Status register is continuous with ongoing clock cycles until terminated by a low-to-high transition on CE#.
12. Data is written/read from MSB to LSB. MSB = 79 for SST26WF032.

No Operation (NOP)

The No Operation command only cancels a Reset Enable command. NOP has no impact on any other command.

Reset-Enable (RSTEN) and Reset (RST)

The Reset operation is used as a system (software) reset that puts the device in normal operating Ready mode. This operation consists of two commands: Reset-Enable (RSTEN) and Reset (RST).

To reset the SST26WF032, the host drives CE# low, sends the Reset-Enable command (66H), and drives CE# high. Next, the host drives CE# low again, sends the Reset command (99H), and drives CE# high, see Figure 7.

The Reset operation requires the Reset-Enable command followed by the Reset command. Any command other than the Reset command after the Reset-Enable command will disable the Reset-Enable.

A successful command execution will reset the burst length to 8 Bytes and all the bits in the Status register to their default states, except for bit 4 (WPLD) and bit 5 (SEC). A device reset during an active Program or Erase operation aborts the operation, which can cause the data of the targeted address range to be corrupted or lost. Depending on the prior operation, the reset timing may vary. Recovery from a Write operation requires more latency time than recovery from other operations.

Figure 7: Reset sequence

1.8V Serial Quad I/O (SQI) Flash Memory

SST26WF032

Advance Information

Read (25 MHz)

The Read instruction, 03H, is supported in SPI bus protocol only with clock frequencies up to 25 MHz. This command is not supported in SQI bus protocol. The device outputs the data starting from the specified address location, then continuously streams the data output through all addresses until terminated by a low-to-high transition on CE#. The internal address pointer will automatically increment until the highest memory address is reached. Once the highest memory address is reached, the address pointer will automatically return to the beginning (wrap-around) of the address space.

Initiate the Read instruction by executing an 8-bit command, 03H, followed by address bits A23:A0. CE# must remain active low for the duration of the Read cycle. SIO2 and SIO3 must be driven V_{IH} for the duration of the Read cycle. See Figure 8 for Read Sequence.

Figure 8: Read Sequence (SPI)

Enable Quad I/O (EQIO)

The Enable Quad I/O (EQIO) instruction, 38H, enables the flash device for SQI bus operation. Upon completion of the instruction, all instructions thereafter will be 4-bit multiplexed input/output until a power cycle or a "Reset Quad I/O instruction" is executed. See Figure 9.

Figure 9: Enable Quad I/O Sequence

1.8V Serial Quad I/O (SQI) Flash Memory

SST26WF032

Advance Information

Reset Quad I/O (RSTQIO)

The Reset Quad I/O instruction, FFH, resets the device to 1-bit SPI protocol operation. To execute a Reset Quad I/O operation, the host drives CE# low, sends the Reset Quad I/O command cycle (FFH) then, drives CE# high. The device accepts either SPI (8 clocks) or SQI (2 clocks) command cycles. For SPI, SIO[3:1] are don't care for this command, but should be driven to V_{IH} or V_{IL} .

High-Speed Read (80 MHz)

The High-Speed Read instruction, 0BH, is supported in both SPI bus protocol and SQI protocol. On power-up, the device is set to use SPI.

Initiate High-Speed Read by executing an 8-bit command, 0BH, followed by address bits [A23-A0] and a dummy byte. CE# must remain active low for the duration of the High-Speed Read cycle. SIO2 and SIO3 must be driven V_{IH} for the duration of the Read cycle. See Figure 10 for the High-Speed Read sequence for SPI bus protocol.

Figure 10:High-Speed Read Sequence (SPI)

In SQI protocol, the host drives CE# low then send the Read command cycle command, 0BH, followed by three address cycles and two dummy cycles. Each cycle is two nibbles (clocks) long, most significant nibble first.

After the dummy cycles, the 1.8V Serial Quad I/O (SQI) Flash Memory outputs data on the falling edge of the SCK signal starting from the specified address location. The device continually streams data output through all addresses until terminated by a low-to-high transition on CE#. The internal address pointer automatically increments until the highest memory address is reached, at which point the address pointer returns to address location 000000H.

During this operation, blocks that are Read-locked will output data 00H.

Figure 11:High-Speed Read and Read Burst Sequence (SQI)

Set Burst

The Set Burst command specifies the number of bytes to be output during a Read Burst command before the device wraps around. To set the burst length the host drives CE# low, sends the Set Burst command cycle (C0H) and one data cycle, then drives CE# high. A cycle is two nibbles, or two clocks, long, most significant nibble first. After power-up or reset, the burst length is set to eight Bytes (00H). See Table 4 for burst length data and Figure 12 for the sequence.

Table 4: Burst Length Data

Burst Length	High Nibble (H0)	Low Nibble (L0)
8 Bytes	0h	0h
16 Bytes	0h	1h
32 Bytes	0h	2h
64 Bytes	0h	3h

T4.0 1409

Figure 12: Set Burst Length Sequence

Read Burst

To execute a Read Burst operation the host drives CE# low, then sends the Read Burst command cycle (0CH), followed by three address cycles, and then one dummy cycle. Each cycle is two nibbles (clocks) long, most significant nibble first.

After the dummy cycle, the device outputs data on the falling edge of the SCK signal starting from the specified address location. The data output stream is continuous through all addresses until terminated by a low-to-high transition on CE#.

During Read Burst, the internal address pointer automatically increments until the last byte of the burst is reached, then jumps to first byte of the burst. All bursts are aligned to addresses within the burst length, see Table 5. For example, if the burst length is eight Bytes, and the start address is 06h, the burst sequence would be: 06h, 07h, 00h, 01h, 02h, 03h, 04h, 05h, 06h, etc. The pattern would repeat until the command was terminated by a low-to-high transition on CE#.

During this operation, blocks that are Read-locked will output data 00H.

Table 5: Burst Address Ranges

Burst Length	Burst Address Ranges
8 Bytes	00-07H, 08-0FH, 10-17H, 18-1FH...
16 Bytes	00-0FH, 10-1FH, 20-2FH, 30-3FH...
32 Bytes	00-1FH, 20-3FH, 40-5FH, 60-7FH...
64 Bytes	00-3FH, 40-7FH, 80-BFH, C0-FFH

T5.0 1409

JEDEC-ID Read (SPI Protocol)

Using traditional SPI protocol, the JEDEC-ID Read instruction identifies the device as SST26WF032 and the manufacturer as SST. To execute a JEDEC-ID operation the host drives CE# low then sends the JEDEC-ID command cycle (9FH). For SPI modes, each cycle is eight bits (clocks) long, most significant bit first.

Immediately following the command cycle the device outputs data on the falling edge of the SCK signal. The data output stream is continuous until terminated by a low-to-high transition on CE#. The device outputs three bytes of data: manufacturer, device type, and device ID, see Table 6. See Figure 13 for instruction sequence.

Table 6: Device ID Data Output

Product	Manufacturer ID (Byte 1)	Device ID	
		Device Type (Byte 2)	Device ID (Byte 3)
SST26WF032	BFH	26H	22H

T6.1 1409

Figure 13: JEDEC-ID Sequence (SPI Mode)

Quad J-ID Read (SQI Protocol)

The Quad J-ID Read instruction identifies the device as SST26WF032 and manufacturer as SST. To execute a Quad J-ID operation the host drives CE# low and then sends the Quad J-ID command cycle (AFH). Each cycle is two nibbles (clocks) long, most significant nibble first.

Immediately following the command cycle the device outputs data on the falling edge of the SCK signal. The data output stream is continuous until terminated by a low-to-high transition of CE#. The device outputs three bytes of data: manufacturer, device type, and device ID, see Table 6. See Figure 14 for instruction sequence.

1.8V Serial Quad I/O (SQI) Flash Memory

SST26WF032

Advance Information

Figure 14:Quad J-ID Read Sequence

Sector-Erase

The Sector-Erase instruction clears all bits in the selected 4 KByte sector to '1,' but it does not change a protected memory area. Prior to any write operation, the Write-Enable (WREN) instruction must be executed.

To execute a Sector-Erase operation, the host drives CE# low, then sends the Sector Erase command cycle (20H) and three address cycles, and then drives CE# high. Each cycle is two nibbles, or clocks, long, most significant nibble first. Address bits [A_{MS}:A₁₂] (A_{MS} = Most Significant Address) determine the sector address (SA_X); the remaining address bits can be V_{IL} or V_{IH}. Poll the BUSY bit in the Status register or wait T_{SE} for the completion of the internal, self-timed, Sector-Erase operation. See Figure 15 for the Sector-Erase sequence.

Figure 15:4 KByte Sector-Erase Sequence

Block-Erase

The Block-Erase instruction clears all bits in the selected block to '1'. Block sizes can be 8 KByte, 32 KByte or 64 KByte depending on address, see Figure 3, Memory Map, for details. A Block-Erase instruction applied to a protected memory area will be ignored. Prior to any write operation, execute the WREN instruction. Keep CE# active low for the duration of any command sequence.

To execute a Block-Erase operation, the host drives CE# low then sends the Block-Erase command cycle (D8H), three address cycles, then drives CE# high. Each cycle is two nibbles, or clocks, long, most significant nibble first. Address bits A_{MS}-A₁₃ determine the block address; the remaining address bits can be V_{IL} or V_{IH}. For 32 KByte blocks, A₁₄:A₁₃ can be V_{IL} or V_{IH}; for 64 KByte blocks, A₁₅:A₁₃ can be V_{IL} or V_{IH}. Poll the BUSY bit in the Status register or wait T_{BE} for the completion of the internal, self-timed, Block-Erase operation See Figure 16 for the Block-Erase sequence.

Figure 16:Block-Erase Sequence

Chip-Erase

The Chip-Erase instruction clears all bits in the device to '1'. The Chip-Erase instruction is ignored if any of the memory area is protected. Prior to any write operation, execute the the WREN instruction.

To execute a Chip-Erase operation, the host drives CE# low, sends the Chip-Erase command cycle (C7H), then drives CE# high. A cycle is two nibbles, or clocks, long, most significant nibble first. Poll the BUSY bit in the Status register or wait T_{CE} for the completion of the internal, self-timed, Chip-Erase operation. See Figure 17 for the Chip Erase sequence.

Figure 17:Chip-Erase Sequence

Page-Program

The Page-Program instruction programs up to 256 Bytes of data in the memory. The data for the selected page address must be in the erased state (FFH) before initiating the Page-Program operation. A Page-Program applied to a protected memory area will be ignored. Prior to the program operation, execute the WREN instruction.

To execute a Page-Program operation, the host drives CE# low then sends the Page Program command cycle (02H), three address cycles followed by the data to be programmed, then drives CE# high. The programmed data must be between 1 to 256 Bytes and in whole Byte increments; sending an odd number of nibbles will cause the last nibble to be ignored. Each cycle is two nibbles (clocks) long, most significant bit first. Poll the BUSY bit in the Status register or wait T_{PP} for the completion of the internal, self-timed, Page-Program operation. See Figure 18 for the Page-Program sequence.

When executing Page-Program, the memory range for the SST26WF032 is divided into 256 Byte page boundaries. The device handles shifting of more than 256 Bytes of data by maintaining the last 256 Bytes of data as the correct data to be programmed. If the target address for the Page-Program instruction is not the beginning of the page boundary (A7:A0 are not all zero), and the number of data input exceeds or overlaps the end of the address of the page boundary, the excess data inputs wrap around and will be programmed at the start of that target page.

Figure 18: Page-Program Sequence

Write-Suspend and Write-Resume

Write-Suspend allows the interruption of Sector-Erase, Block-Erase or Page-Program operations in order to erase, program, or read data in another portion of memory. The original operation can be continued with the Write-Resume command.

Only one write operation can be suspended at a time; if an operation is already suspended, the device will ignore the Write-Suspend command. Write-Suspend during Chip-Erase is ignored; Chip-Erase is not a valid command while a write is suspended.

Write-Suspend During Sector-Erase or Block-Erase

Issuing a Write-Suspend instruction during Sector-Erase or Block-Erase allows the host to program or read any sector that was not being erased. The device will ignore any programming commands pointing to the suspended sector(s). Any attempt to read from the suspended sector(s) will output unknown data because the Sector- or Block-Erase will be incomplete.

To execute a Write-Suspend operation, the host drives CE# low, sends the Write Suspend command cycle (B0H), then drives CE# high. A cycle is two nibbles long, most significant nibble first. The Status register indicates that the erase has been suspended by changing the WSE bit from '0' to '1,' but the device will not accept another command until it is ready. To determine when the device will accept a new command, poll the BUSY bit in the Status register or wait T_{WS} .

Write Suspend During Page Programming

Issuing a Write-Suspend instruction during Page Programming allows the host to erase or read any sector that is not being programmed. Erase commands pointing to the suspended sector(s) will be ignored. Any attempt to read from the suspended page will output unknown data because the program will be incomplete.

To execute a Write Suspend operation, the host drives CE# low, sends the Write Suspend command cycle (B0H), then drives CE# high. A cycle is two nibbles long, most significant nibble first. The Status register indicates that the programming has been suspended by changing the WSP bit from '0' to '1,' but the device will not accept another command until it is ready. To determine when the device will accept a new command, poll the BUSY bit in the Status register or wait T_{WS} .

Write-Resume

Write-Resume restarts a Write command that was suspended, and changes the suspend status bit in the Status register (WSE or WSP) back to '0'.

To execute a Write-Resume operation, the host drives CE# low, sends the Write Resume command cycle (30H), then drives CE# high. A cycle is two nibbles long, most significant nibble first. To determine if the internal, self-timed Write operation completed, poll the BUSY bit in the Status register, or wait the specified time T_{SE} , T_{BE} or T_{PP} for Sector-Erase, Block-Erase, or Page-Programming, respectively. The total write time before suspend and after resume will not exceed the uninterrupted write times T_{SE} , T_{BE} or T_{PP} .

Read Security ID

To execute a Read Security ID (SID) operation, the host drives CE# low, sends the Read Security ID command cycle (88H), one address cycle, and then two dummy cycles. Each cycle is two nibbles long, most significant nibble first.

After the dummy cycles, the device outputs data on the falling edge of the SCK signal, starting from the specified address location. The data output stream is continuous through all SID addresses until terminated by a low-to-high transition on CE#. The internal address pointer automatically increments until the last SID address is reached, then outputs 00H until CE# goes high.

Figure 19: Read SID Sequence

Program Security ID

The Program Security ID instruction programs one to 24 Bytes of data in the user-programmable, Security ID space. The device ignores a Program Security ID instruction pointing to an invalid or protected address, see Table 7. Prior to the program operation, execute WREN.

To execute a Program SID operation, the host drives CE# low, sends the Program Security ID command cycle (A5H), one address cycle, the data to be programmed, then drives CE# high. The programmed data must be between 1 to 24 Bytes and in whole Byte increments; sending an odd number of nibbles will cause the last nibble to be ignored. Each cycle is two nibbles long, most significant nibble first. To determine the completion of the internal, self-timed Program SID operation, poll the BUSY bit in the software status register, or wait T_{PSID} for the completion of the internal self-timed Program Security ID operation.

Table 7: Program Security ID

Program Security ID	Address Range
Pre-Programmed at factory	00H – 07H
User Programmable	08H – 1FH

T7.0 1409

Lockout Security ID

The Lockout Security ID instruction prevents any future changes to the Security ID. To execute a Lockout SID, the host drives CE# low, sends the Lockout Security ID command cycle (85H), then drives CE# high. A cycle is two nibbles long, most significant nibble first. The user map polls the BUSY bit in the software status register or waits T_{PSID} for the completion of the Lockout Security ID operation.

Read-Status Register (RDSR)

The Read-Status register (RDSR) command outputs the contents of the Status register. The Status register may be read at any time even during a Write operation. When a Write is in progress, check the BUSY bit before sending any new commands to assure that the new commands are properly received by the device.

To execute a Read-Status-Register operation the host drives CE# low, then sends the Read-Status-Register command cycle (05H). Each cycle is two nibbles long, most significant nibble first. Immediately after the command cycle, the device outputs data on the falling edge of the SCK signal. The data output stream continues until terminated by a low-to-high transition on CE#. See Figure 20 for the RDSR instruction sequence.

Figure 20: Read-Status-Register (RDSR) Sequence

Write-Enable (WREN)

The Write Enable (WREN) instruction sets the Write-Enable-Latch bit in the Status Register to '1,' allowing Write operations to occur. The WREN instruction must be executed prior to any of the following operations: Sector Erase, Block Erase, Chip Erase, Page Program, Program Security ID, Lockout Security ID, Write Block-Protection Register and Lockdown Block-Protection Register. To execute a Write Enable the host drives CE# low then sends the Write Enable command cycle (06H) then drives CE# high. A cycle is two nibbles (clocks) long, most significant nibble first. See Figure 21 for the WREN instruction sequence.

Figure 21: Write-Enable Sequence

Write-Disable (WRDI)

The Write-Disable (WRDI) instruction sets the Write-Enable-Latch bit in the Status Register to '0,' preventing Write execution without a prior WREN instruction. To execute a Write-Disable, the host drives CE# low, sends the Write Disable command cycle (04H), then drives CE# high. A cycle is two nibbles long, most significant nibble first.

Figure 22: Write-Disable (WRDI) Sequence

Read Block-Protection Register (RBPR)

The Read Block-Protection Register instruction outputs the Block-Protection Register data which determines the protection status. To execute a Read Block-Protection Register operation, the host drives CE# low, and then sends the Read Block-Protection Register command cycle (72H). Each cycle is two nibbles long, most significant nibble first.

After the command cycle, the device outputs data on the falling edge of the SCK signal starting with the most significant nibble, see Table 8 for definitions of each bit in the Block-Protection Register. The RBPR command does not wrap around. After all data has been output, the device will output 0H until terminated by a low-to-high transition on CE#.

Figure 23: Read Block Protection Register Sequence

Write Block-Protection Register (WBPR)

To execute a Write Block-Protection Register operation the host drives CE# low, sends the Write Block-Protection Register command cycle (42H), sends 10 cycles of data, and finally drives CE# high. Each cycle is two nibbles long, most significant nibble first. See Table 8 for definitions of each bit in the Block-Protection Register.

1. All blocks are write-locked and read-unlocked after power-up or reset.

T8.0 1409

Lockdown Block-Protection Register (LBPR)

The Lockdown Block-Protection Register instruction prevents changes to the Block-Protection Register. Lockdown resets after power cycling; this allows the Block-Protection Register to be changed.

To execute a Lockdown Block-Protection Register, the host drives CE# low, then sends the Lockdown Block-Protection Register command cycle (8DH), then drives CE# high. A cycle is two nibbles long, most significant nibble first.

Figure 25: Lockdown Block-Protection Register
